[resp,rnggrid] = step(response,x,xref)
[resp,rnggrid] = step(response,x,coeff)
```

## Description

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

[resp,rnggrid] = step(response,x) computes the range response, resp, for the input signal, x, and the range values, rnggrid, corresponding to the response. This syntax applies when you set RangeMethod to 'FFT' and DechirpInput to false. This syntax assumes that the input signal has already been dechirped. This syntax is most commonly used with FMCW signals.

[resp,rnggrid] = step(response,x,xref) computes the range response of the input signal, x using the reference signal, xref. This syntax applies when you set RangeMethod to 'FFT' and DechirpInput to true. Often, the reference signal is the transmitted signal. This syntax assumes that the input signal has not been dechirped. This syntax is most commonly used with FMCW signals.

[resp,rnggrid] = step(response,x,coeff) computes the range response of x using the matched filter coeff. This syntax applies when you set RangeMethod to 'Matched filter'. This syntax is most commonly used with pulsed signals.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `response` — Range response

`phased.RangeResponse` System object

Range response, specified as a `phased.RangeResponse` System object.

Example: `phased.RangeResponse`

### `x` — Input radar data cube

complex-valued *K*-element column vector | complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N*-by-*L* array

Input radar data cube, specified as a complex-valued *K*-by-1 column vector, a *K*-by-*L* matrix, or *K*-by-*N*-by-*L* array.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or directions.
- *L* is the slow-time dimension that corresponds to the number of pulses or sweeps in the input signal.

See “Radar Data Cube”.

Each *K*-element fast-time dimension is processed independently.

For FMCW waveforms with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.

- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`

### `xref` — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the fast-time dimension of `x`.

#### Dependencies

To enable this input argument, set the value of `RangeMethod` to `'FFT'` and `DechirpInput` to `true`.

Data Types: `single` | `double`

### `coeff` — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*. *K* is the number of fast-time or range sample.

#### Dependencies

To enable this input argument, set the value of `RangeMethod` to `'Matched filter'`.

Data Types: `double`

## Output Arguments

### `resp` — Range response data cube

complex-valued *M*-element column vector | complex-valued *M*-by-*L* matrix | complex-valued *M*-by-*N* by-*L* array

Range response data cube, returned as one of the following:

- Complex-valued *M*-element column vector
- Complex-valued *M*-by-*L* matrix
- Complex-valued *M*-by-*N* by-*L* array

The value of *M* depends on the type of processing

| RangeMethod Property | DechirpInput Property | Value of *M* |
|---|---|---|
| `'FFT'` | `false` | If you set the `RangeFFTLength` property to `'Auto'`, $M = K$, the length of the fast-time dimension of `x`. Otherwise, *M* equals the value of the `RangeFFTLength` property. |
| | `true` | *M* equals the quotient of the number of rows, *K*, of the input signal by the value of the decimation factor, *D*, specified in `DecimationFactor`. |
| `'Matched filter'` | n/a | $M = K$, the length of the fast-time dimension of `x`. |

Data Types: `single` | `double`

**`rnggrid` — Range values along range dimension**
real-valued *M*-by-1 column vector

Range values along range dimension, returned as a real-valued *M*-by-1 column vector. `rnggrid` defines the ranges corresponding to the fast-time dimension of the `resp` output data cube. *M* is the length of the fast-time dimension of `resp`. Range values are monotonically increasing and equally spaced. Units are in meters.

Example: `[0,0.1,0.2,0.3]`

Data Types: `single` | `double`

## Examples

### Range Response of Three Targets

Compute the radar range response of three targets by using the `phased.RangeResponse` System object™. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system. The transmitted signal is a linear FM waveform with a pulse repetition interval of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The radar transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radars on the *x*-axis. The targets move along the *x*-axis at speeds of −60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB.

Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of half the sample rate. Find the length of the pri in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
```

Create a free-space propagation channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. The receiver gain is 42 dB and noise figure is 10.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 10;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over 128 pulses to build a data cube. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions, where last dimension corresponds to antennas or beams. Because only one sensor is used in this example, the cube has only two dimensions.

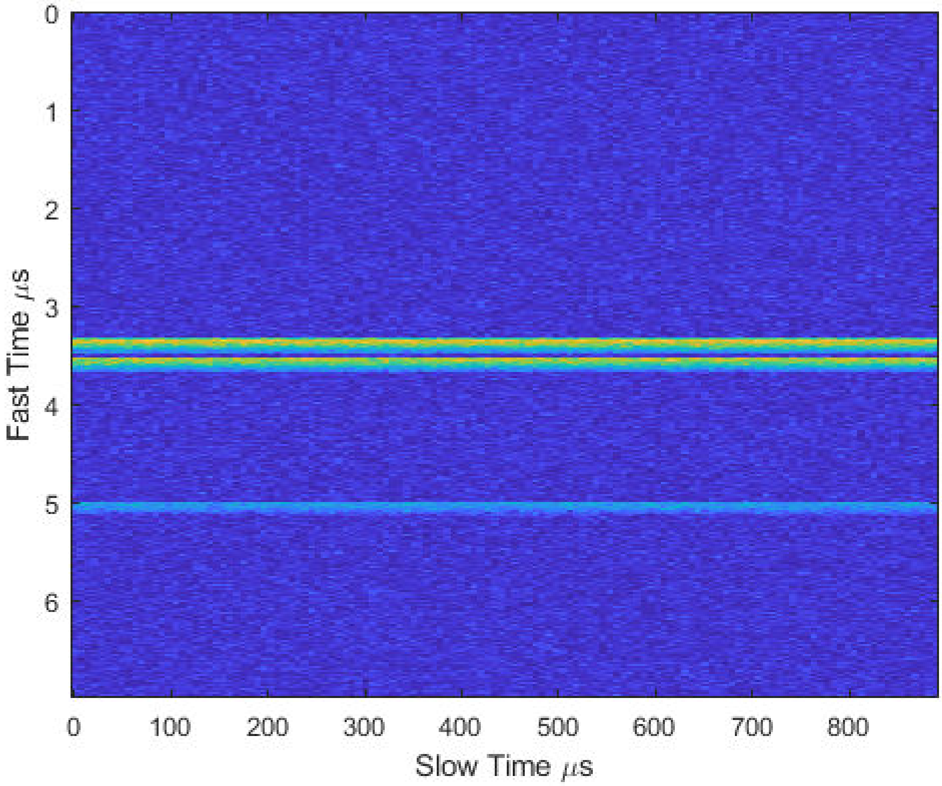
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation mode enables you to combine the returned propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(pri);
    [tgtpos,tgtvel] = tgtmotion(pri);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

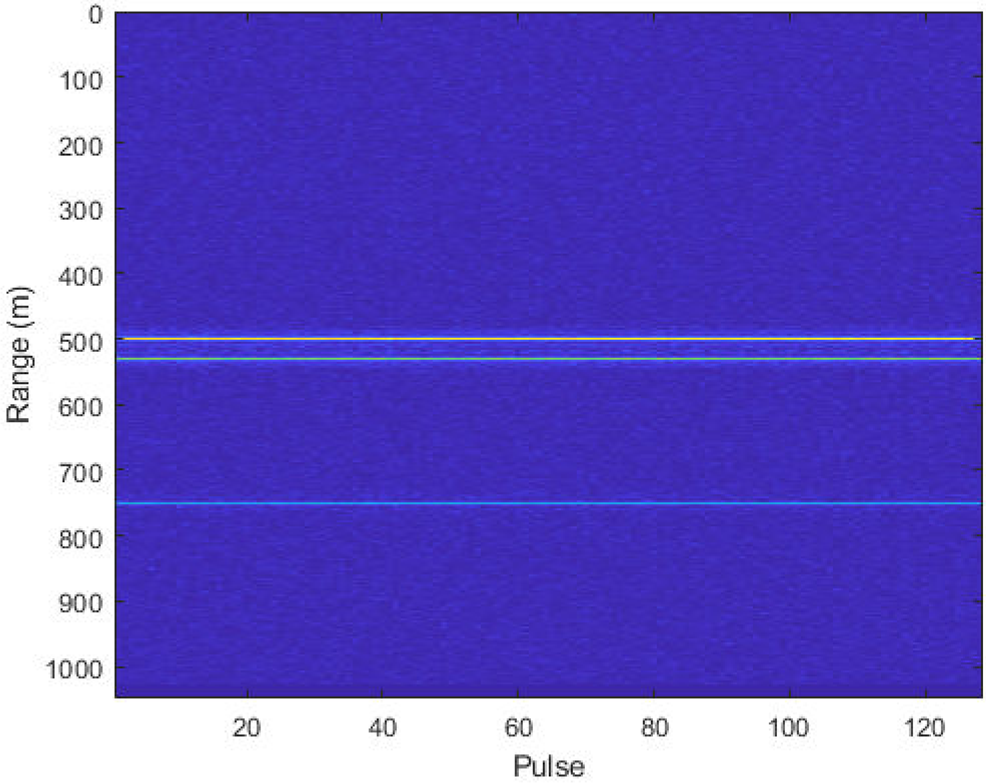
Display the image of the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
```



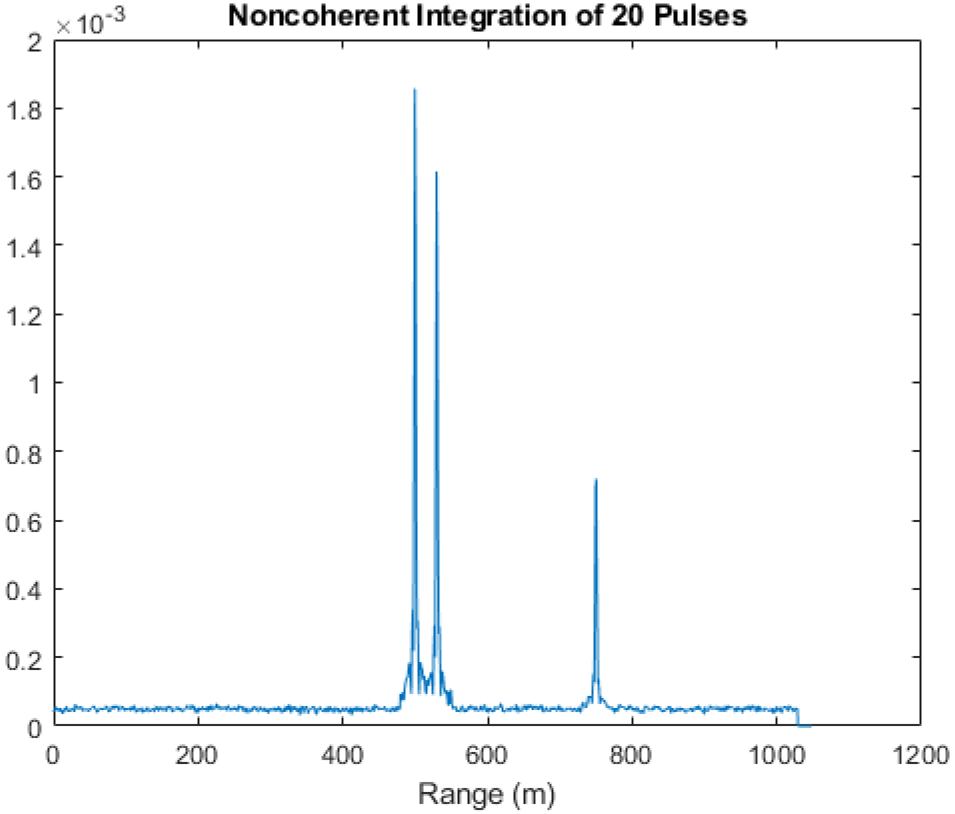
Create a `phased.RangeResponse` System object in matched filter mode. Then, display the range response image for the 128 pulses. The image shows range vertically and pulse number horizontally.

```
matchingcoeff = getMatchedFilter(waveform);
ndop = 128;
rangeresp = phased.RangeResponse('SampleRate',fs,'PropagationSpeed',c);
[resp,rnggrid] = rangeresp(cube,matchingcoeff);
imagesc([1:Np],rnggrid,abs(resp))
xlabel('Pulse')
ylabel('Range (m)')
```



Integrate 20 pulses noncoherently.

```
intpulse = pulsint(resp(:,1:20),'noncoherent');
plot(rnggrid,abs(intpulse))
xlabel('Range (m)')
title('Noncoherent Integration of 20 Pulses')
```



**Introduced in R2017a**

# phased.ReceiverPreamp

**Package:** `phased`

Receiver preamp

## Description

The `ReceiverPreamp` System object implements a model of a receiver preamplifier. The object receives incoming signals, multiplies them by the amplifier gain and divides by system losses. Finally, Gaussian white noise is added to the signal.

To model a receiver preamp:

1. Define and set up your receiver preamp. See "Construction" on page 1-1891.
2. Call `step` to amplify the input signal according to the properties of `phased.ReceiverPreamp`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ReceiverPreamp` creates a receiver preamp System object, `H`.

`H = phased.ReceiverPreamp(Name,Value)` creates a receiver preamp object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### Gain

Gain of receiver

A scalar containing the gain (in decibels) of the receiver preamp.

**Default:** 20

### LossFactor

Loss factor of receiver

A scalar containing the loss factor (in decibels) of the receiver preamp.

**Default:** 0

### NoiseMethod

Noise specification method

Specify how to compute noise power using one of 'Noise power' | 'Noise temperature'. If you set this property to 'Noise temperature', complex baseband noise is added to the input signal with noise power computed from the ReferenceTemperature, NoiseFigure, and SampleRate properties. If you set this property to 'Noise power', noise is added to the signal with power specified in the NoisePower property.

**Default:** 'Noise temperature'

### NoiseFigure

Noise figure of receiver

A scalar containing the noise figure (in decibels) of the receiver preamp. If the receiver has multiple channels/sensors, the noise figure applies to each channel/sensor. This property is only applicable when you set the NoiseMethod property to 'Noise temperature'.

**Default:** 0

### ReferenceTemperature

Reference temperature of receiver

A scalar containing the reference temperature of the receiver (in kelvin). If the receiver has multiple channels/sensors, the reference temperature applies to each channel/sensor. This property is only applicable when you set the `NoiseMethod` property to `'Noise temperature'`.

**Default:** `290`

### SampleRate

Sample rate

Specify the sample rate, in hertz, as a positive scalar. This property is only applicable when you set the `NoiseMethod` property to `'Noise temperature'`. The `SampleRate` property also specifies the noise bandwidth.

**Default:** `1e6`

### NoisePower

Noise power

Specify the noise power (in Watts) as a positive scalar. This property is only applicable when you set the `NoiseMethod` property to `'Noise power'`.

**Default:** `1.0`

### NoiseComplexity

Noise complexity

Specify the noise complexity as one of `'Complex'` | `'Real'`. When you set this property to `'Complex'`, the noise power is evenly divided between real and imaginary channels. Usually, complex-valued baseband signals require the addition of complex-valued noise. On occasion, when the signal is real-valued, you can use this option to specify that the noise is real-valued as well.

**Default:** `'Complex'`

**EnableInputPort**

Add input to specify enabling signal

To specify a receiver enabling signal, set this property to `true` and use the corresponding input argument when you invoke `step`. If you do not want to specify a receiver enabling signal, set this property to `false`.

**Default:** `false`

**PhaseNoiseInputPort**

Add input to specify phase noise

To specify the phase noise for each incoming sample, set this property to `true` and use the corresponding input argument when you invoke `step`. You can use this information to emulate coherent-on-receive systems. If you do not want to specify phase noise, set this property to `false`.

**Default:** `false`

**SeedSource**

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

| | |
|---|---|
| `'Auto'` | The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software. |
| `'Property'` | The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software. |

**Default:** `'Auto'`

**Seed**

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}$–1. This property applies when you set the `SeedSource` property to `'Property'`.

**Default:** `0`

## Methods

| | |
|---|---|
| reset | Reset random number generator for noise generation |
| step | Receive incoming signal |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Preamplify Signal

This example shows how to use the `phased.ReceiverPreamp` System object™ to amplify a sine wave.

Create a `phased.ReceiverPreamp` System object with a sample rate of 100 Hz. Assume a receiver noise figure of 60 dB.

```
fs = 100;
receiver = phased.ReceiverPreamp('NoiseFigure',60, ...
    'SampleRate',fs,'NoiseComplexity','Real');
```

Create the input signal.

```
t = linspace(0,1-1/fs,100);
x = 1e-6*sin(2*pi*5*t);
```

Amplify the signal and compare it with the input signal.

```
y = receiver(x);
plot(t,x,t,real(y))
xlabel('Time (s)')
```

```
ylabel('Amplitude')
legend('Input signal','Amplified signal')
```

“Receiver Preamp”

**Introduced in R2012a**

# reset

**System object:** phased.ReceiverPreamp
**Package:** phased

Reset random number generator for noise generation

## Syntax

```
reset(H)
```

## Description

reset(H) resets the states of the ReceiverPreamp object, H. This method resets the random number generator state if the SeedSource property is set to 'Property'.

# step

**System object:** `phased.ReceiverPreamp`
**Package:** `phased`

Receive incoming signal

## Syntax

```
Y = step(H,X)
Y = step(H,X,EN_RX)
Y = step(H,X,PHNOISE)
Y = step(H,X,EN_RX,PHNOISE)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies the receiver gain and the receiver noise to the input signal, `X`, and returns the resulting output signal, `Y`.

`Y = step(H,X,EN_RX)` uses input `EN_RX` as the enabling signal when the `EnableInputPort` property is set to `true`.

`Y = step(H,X,PHNOISE)` uses input `PHNOISE` as the phase noise for each sample in `X` when the `PhaseNoiseInputPort` is set to `true`. The phase noise is the same for all channels in `X`. The elements in `PHNOISE` represent the random phases the transmitter adds to the transmitted pulses. The receiver preamp object removes these random phases from all received samples returned within corresponding pulse intervals. Such setup is often referred to as *coherent on receive*.

`Y = step(H,X,EN_RX,PHNOISE)` combines all input arguments. This syntax is available when you configure `H` so that `H.EnableInputPort` is `true` and `H.PhaseNoiseInputPort` is `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Receiver object.

**`X`**

Input signal

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**`EN_RX`**

Enabling signal, specified as a column vector whose length equals the number of rows in `X`. The data type of `EN_RN` is `double` or `logical`. Every element of `EN_RX` that equals `0` or `false` indicates that the receiver is turned off, and no input signal passes through the receiver. Every element of `EN_RX` that is nonzero or `true` indicates that the receiver is turned on, and the input passes through.

**`PHNOISE`**

Phase noise for each sample in `X`, specified as a column vector whose length equals the number of rows in `X`. You can obtain `PHNOISE` as an optional output argument from the `step` method of `phased.Transmitter`.

# Output Arguments

### Y

Output signal. Y has the same dimensions as X.

# Examples

### Preamplify Cosine Signal

This example shows how to construct a phased.ReceiverPreamp System object™ with a noise figure of 5 dB and a bandwidth of 1 MHz. Then use the object to amplify the signal.

Construct the Receiver Preamp system object.

```
receiver = phased.ReceiverPreamp('NoiseFigure',5,'SampleRate',1e6);
```

Create the signal.

```
Fs = 1e3;
t = linspace(0,1,1e3);
x = cos(2*pi*200*t)';
```

Use the step method to amplify the signal and then plot the first 100 samples.

```
y = receiver(x);
idx = [1:100];
plot(t(idx),x(idx),t(idx),real(y(idx)))
xlabel('Time (s)')
ylabel('Amplitude')
legend('Original signal','Received signal')

# phased.RectangularWaveform

**Package:** phased

Rectangular pulse waveform

## Description

The RectangularWaveform object creates a rectangular pulse waveform.

To obtain waveform samples:

1. Define and set up your rectangular pulse waveform. See "Construction" on page 1-1903.
2. Call step to generate the rectangular pulse waveform samples according to the properties of phased.RectangularWaveform. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations. When the only argument to the step method is the System object itself, replace y = step(obj) by y = obj().

## Construction

H = phased.RectangularWaveform creates a rectangular pulse waveform System object, H. The object generates samples of a rectangular pulse.

H = phased.RectangularWaveform(Name,Value) creates a rectangular pulse waveform object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

**Default:** `1e6`

### `DurationSpecification`

Method to set pulse duration

Method to set pulse duration (pulse width), specified as `'Pulse width'` or `'Duty cycle'`. This property determines how you set the pulse duration. When you set this property to `'Pulse width'`, then you set the pulse duration directly using the `PulseWidth` property. When you set this property to `'Duty cycle'`, you set the pulse duration from the values of the `PRF` and `DutyCycle` properties. The pulse width is equal to the duty cycle divided by the *PRF*.

**Default:** `'Pulse width'`

### `PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

**Default:** `50e-6`

### `DutyCycle`

Waveform duty cycle

Waveform duty cycle, specified as a scalar from 0 through 1, inclusive. This property applies when you set the `DurationSpecification` property to `'Duty cycle'`. The pulse width is the value of the `DutyCycle` property divided by the value of the `PRF` property.

**Default:** `0.5`

### PRF

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The*PRF* must satisfy these restrictions:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of `PRF` must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* using property settings alone or using property settings in conjunction with the `prfidx` input argument of the `step` method.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties only. You can
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an argument specifying an index into the *PRF* vector.

In all cases, the number of output samples is fixed when you set the `OutputFormat` property to `'Samples'`. When you use a varying *PRF* and set the `OutputFormat` property to `'Pulses'`, the number of samples can vary.

**Default:** `10e3`

### PRFSelectionInputPort

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property. When you set this property to `true`, you pass an index argument into the `step` method to select a value from the PRF vector.

**Default:** `false`

### OutputFormat

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

**Default:** `'Pulses'`

### NumSamples

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

### NumPulses

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

**Default:** `1`

### PRFOutputPort

Set this property to `true` to output the PRF for the current pulse using a `step` method argument.

#### Dependencies

This property can be used only when the `OutputFormat` property is set to `'Pulses'`.

**Default:** `false`

## Methods

| | |
|---|---|
| bandwidth | Bandwidth of rectangular pulse waveform |
| getMatchedFilter | Matched filter coefficients for waveform |

## Examples

### Plot Rectangular Waveform and Spectrum

Create and plot a rectangular pulse waveform object and then plot its spectrum.

#### Plot the waveform

Create and plot a pulse waveform. The sample rate is 500 kHz, the pulse width is 0.1 millisecond. The pulse repetition interval is twice the pulse duration.

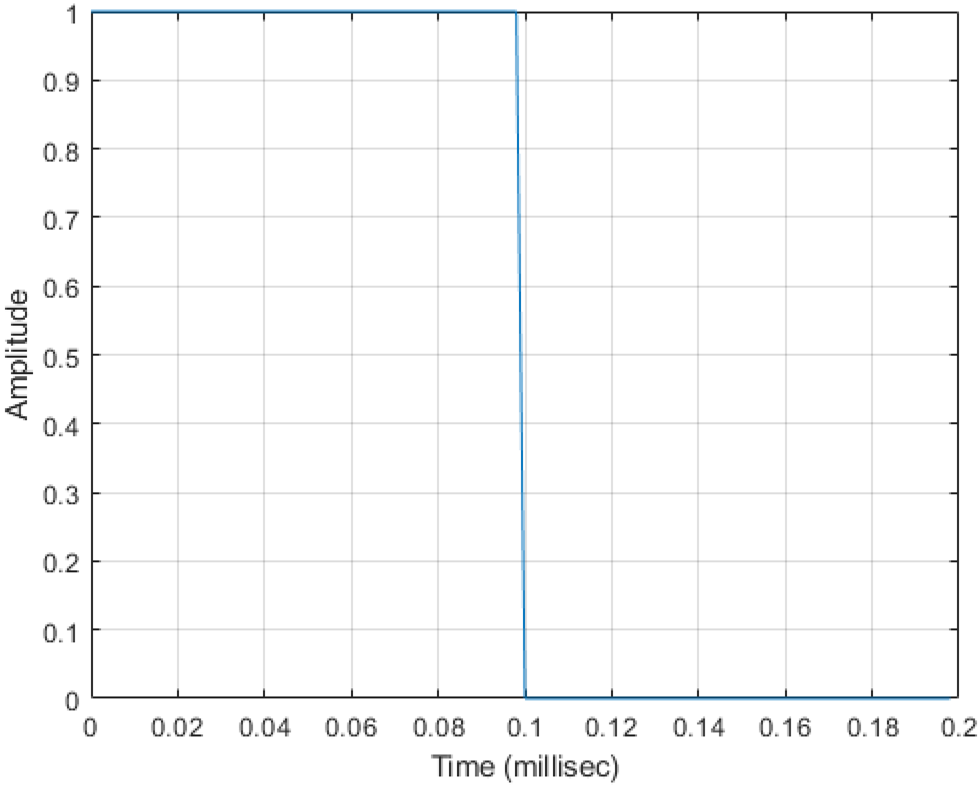
```
fs = 500e3;
```

Create the rectangular waveform System object™.

```
sWF = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-4,'PRF',5000.0);
```

Use the step method to obtain the waveform. Then, plot the waveform.

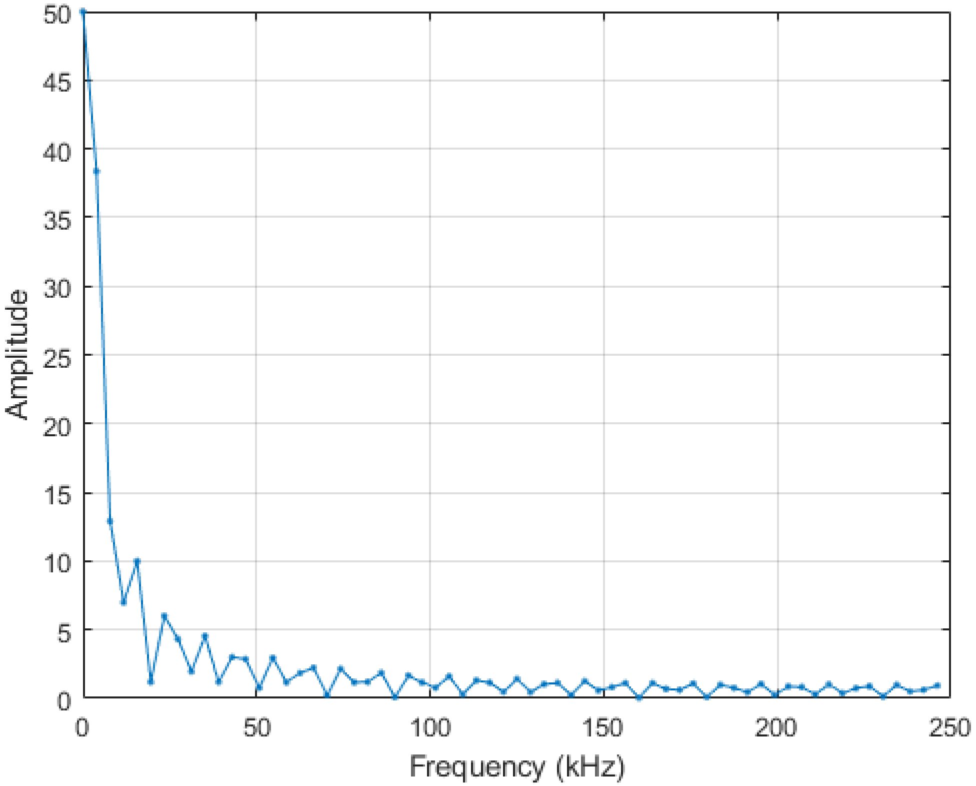
```
rectwav = step(sWF);
nsamp = size(rectwav,1);
t = [0:(nsamp-1)]/fs;
plot(t*1000,real(rectwav))
xlabel('Time (millisec)')
ylabel('Amplitude')
grid
```



### Plot the spectrum

Compute the Fourier transform of the complex signal. Then show the spectrum.

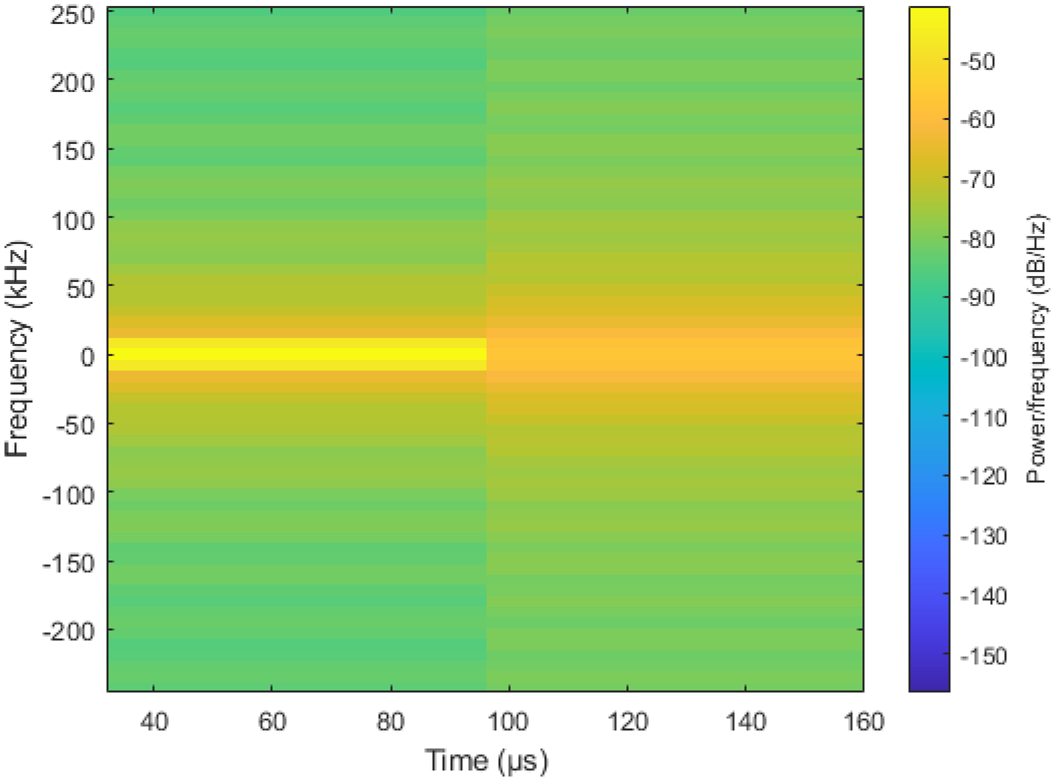
```
nfft = 2^nextpow2(nsamp);
Z = fft(real(rectwav),nfft);
fr = [0:(nfft/2-1)]/nfft*fs;
plot(fr/1000,abs(Z(1:nfft/2)),'.-')
xlabel('Frequency (kHz)')
ylabel('Amplitude')
grid
```



### Plot the spectrogram

Plot a spectrogram of the function with a window size of 64 samples and 50% overlap. Window the signal with a Hamming function.

```
nfft1 = 64;
nov = floor(0.5*nfft1);
spectrogram(rectwav,hamming(nfft1),nov,nfft1,fs,'centered','yaxis')
```



This plot shows the constant frequency of the signal.

### Topics

Waveform Analysis Using the Ambiguity Function

**Introduced in R2012a**

# bandwidth

**System object:** `phased.RectangularWaveform`
**Package:** `phased`

Bandwidth of rectangular pulse waveform

## Syntax

```
BW = bandwidth(H)
```

## Description

`BW = bandwidth(H)` returns the bandwidth (in hertz) of the pulses for the rectangular pulse waveform, `H`. The bandwidth equals the reciprocal of the pulse width.

## Input Arguments

**`H`**

Rectangular pulse waveform object.

## Output Arguments

**`BW`**

Bandwidth of the pulses, in hertz.

## Examples

### Find Bandwidth of Rectangular Pulse

Determine the bandwidth of a rectangular pulse waveform.

```
waveform = phased.RectangularWaveform;
bw = bandwidth(waveform)
```

```
bw = 20000
```

# getMatchedFilter

**System object:** phased.RectangularWaveform
**Package:** phased

Matched filter coefficients for waveform

## Syntax

```
Coeff = getMatchedFilter(H)
```

## Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the rectangular waveform object `H`. `Coeff` is a column vector.

## Examples

### Matched Filter Coefficients for Rectangular Pulse

Get the matched filter coefficients for a rectangular pulse waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',1e-5,...
    'OutputFormat','Pulses','NumPulses',1);
coeff = getMatchedFilter(waveform)
```

```
coeff = 10×1

# plot

**System object:** phased.RectangularWaveform
**Package:** phased

Plot rectangular pulse waveform

## Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

## Description

plot(Hwav) plots the real part of the waveform specified by Hwav.

plot(Hwav,Name,Value) plots the waveform with additional options specified by one or more Name,Value pair arguments.

plot(Hwav,Name,Value,LineSpec) specifies the same line color, line style, or marker options as are available in the MATLAB plot function.

h = plot( ___ ) returns the line handle in the figure.

## Input Arguments

### Hwav

Waveform object. This variable must be a scalar that represents a single waveform object.

**LineSpec**

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

**Default:** `'b'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**PlotType**

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

**Default:** `'real'`

**PulseIdx**

Index of the pulse to plot. This value must be a scalar.

**Default:** `1`

# Output Arguments

**h**

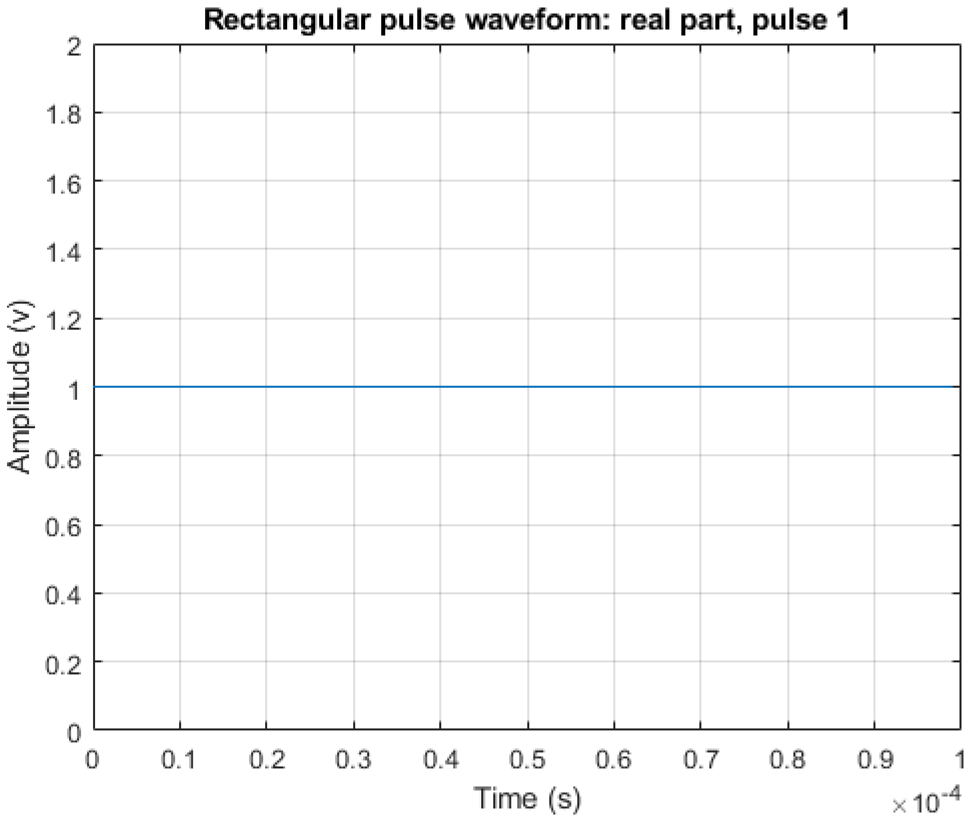
Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

# Examples

### Plot Rectangular Waveform

Create and plot a 100 μs rectangular pulse waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',100e-6);
plot(waveform);
```



# reset

**System object:** `phased.RectangularWaveform`
**Package:** `phased`

Reset states of rectangular waveform object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `RectangularWaveform` object, `H`. Afterward, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

# step

**System object:** `phased.RectangularWaveform`
**Package:** `phased`

Samples of rectangular pulse waveform

## Syntax

```
Y = step(sRFM)
Y = step(sRFM,prfidx)
[Y,PRF] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sRFM)` returns samples of a rectangular pulse in the column vector `Y`.

`Y = step(sRFM,prfidx)`, uses the `prfidx` index to select the PRF from the predefined vector of values specified by the `PRF` property. This syntax applies when you set the `PRFSelectionInputPort` property to `true`.

`[Y,PRF] = step( ___ )` also returns the current pulse repetition frequency, `PRF`. To enable this syntax, set the `PRFOutputPort` property to `true` and set the `OutputFormat` property to `'Pulses'`.

.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

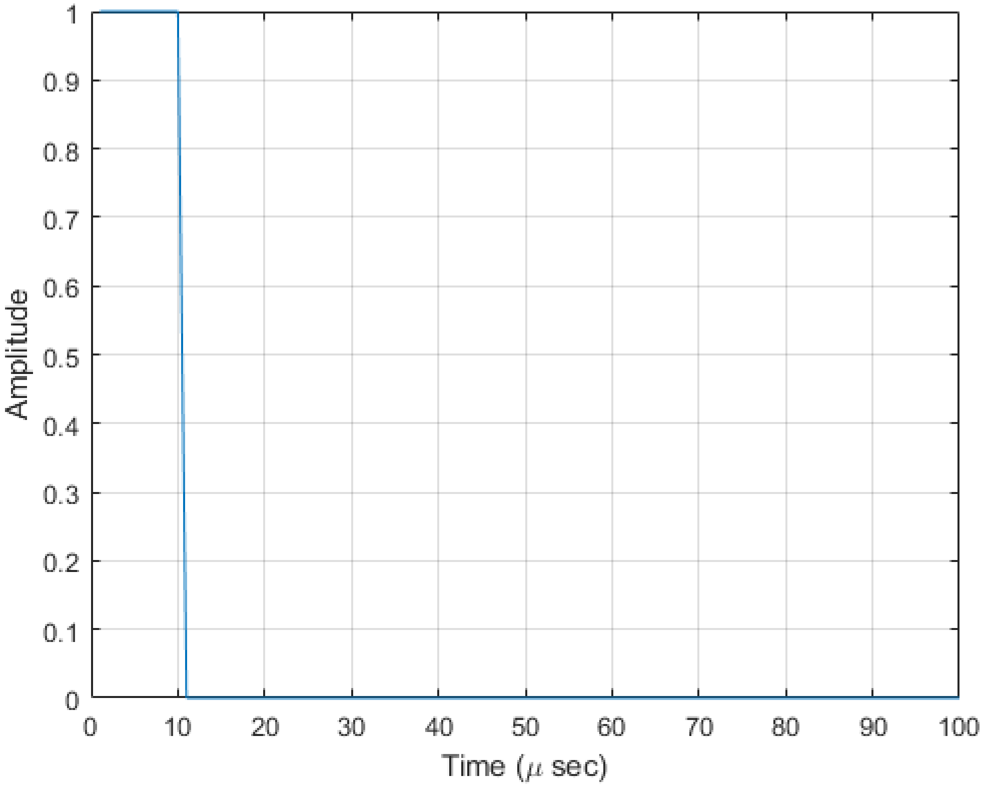
dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

### Create Rectangular Waveform Pulse

Construct a 10 microseconds rectangular pulse with a pulse repetition interval of 100 microseconds.

```
Pulsewidth = 10e-6;
PRI = 100e-6;
sRFM = phased.RectangularWaveform('PulseWidth',Pulsewidth,...
    'OutputFormat','Pulses','NumPulses',1,...
    'SampleRate',1e6,'PRF',1/PRI);
wav = step(sRFM);
plot(wav)
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



### Create Rectangular Pulses with Variable PRF

Construct rectangular waveforms with two pulses each. Set the sample rate to 1 MHz, a pulse width of 50 microseconds, and a duty cycle of 20%. Vary the pulse repetition frequency.

Set the sample rate and PRF. The ratio of sample rate to PRF must be an integer.

```
fs = 1e6;
PRF = [10000,25000];
waveform = phased.RectangularWaveform('OutputFormat','Pulses','SampleRate',fs,...
    'DurationSpecification','Duty Cycle','DutyCycle',.2,...
    'PRF',PRF,'NumPulses',2,'PRFSelectionInputPort',true);
```

Obtain and plot the rectangular waveforms. For the first call to the `step` method, set the PRF to 10kHz using the PRF index. For the next call, set the PRF to 25 kHz. For the final call, set the PRF to 10kHz.

```
wav = [];
wav1 = waveform(1);
wav = [wav; wav1];
wav1 = waveform(2);
wav = [wav; wav1];
wav1 = waveform(1);
wav = [wav; wav1];
nsamps = size(wav,1);
t = [0:(nsamps-1)]/waveform.SampleRate;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```

# phased.ReplicatedSubarray

**Package:** `phased`

Phased array formed by replicated subarrays

## Description

The `ReplicatedSubarray` object represents a phased array that contains copies of a subarray created by replicating a single specified array.

To obtain the response of the subarrays:

1. Define and set up your phased array containing replicated subarrays. See "Construction" on page 1-1925.
2. Call `step` to compute the response of the subarrays according to the properties of `phased.ReplicatedSubarray`. The behavior of `step` is specific to each object in the toolbox.

You can also use a `ReplicatedSubarray` object as the value of the `SensorArray` or `Sensor` property of objects that perform beamforming, steering, and other operations.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ReplicatedSubarray` creates a replicated subarray System object, `H`. This object represents an array that contains copies of a subarray.

`H = phased.ReplicatedSubarray(Name,Value)` creates a replicated subarray object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `Subarray`

Subarray to replicate

Specify the subarray you use to form the array. The subarray must be a `phased.ULA`, `phased.URA`, or `phased.ConformalArray` object.

**Default:** `phased.ULA` with default property values

### `Layout`

Layout of subarrays

Specify the layout of the replicated subarrays as `'Rectangular'` or `'Custom'`.

**Default:** `'Rectangular'`

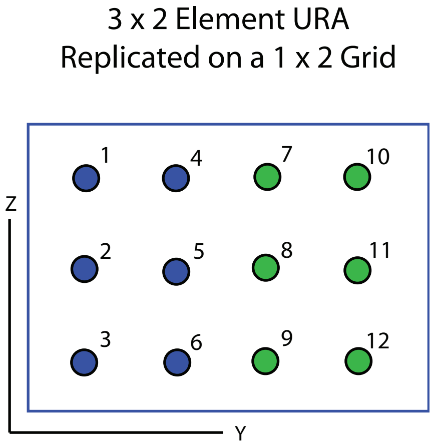
### `GridSize`

Size of rectangular grid

Specify the size of the rectangular grid as a single positive integer or 1-by-2 positive integer row vector. This property applies only when you set the `Layout` property to `'Rectangular'`.

If `GridSize` is a scalar, the array has the same number of subarrays in each row and column.

If `GridSize` is a 1-by-2 vector, the vector has the form `[NumberOfRows, NumberOfColumns]`. The first entry is the number of subarrays along each column, while the second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. This figure shows how a 3-by-2 URA subarray is replicated using a `GridSize` value of `[1,2]`.



**Default:** `[1 2]`

**`GridSpacing`**

Spacing of rectangular grid

Specify the rectangular grid spacing of subarrays as a positive real-valued scalar, a 1-by-2 row vector, or `'Auto'`. This property applies only when you set the `Layout` property to `'Rectangular'`. Grid spacing units are expressed in meters.

If `GridSpacing` is a scalar, the spacing along the row and the spacing along the column is the same.

If `GridSpacing` is a length-2 row vector, it has the form `[SpacingBetweenRows, SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

If `GridSpacing` is `'Auto'`, the replication preserves the element spacing in both row and column. This option is available only if you use a `phased.ULA` or `phased.URA` object as the subarray.

**Default:** `'Auto'`

**`SubarrayPosition`**

Subarray positions in custom grid

Specify the positions of the subarrays in the custom grid. This property value is a 3-by-N matrix, where N indicates the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array’s local coordinate system, in meters, using the form [x; y; z].

This property applies when you set the `Layout` property to `'Custom'`.

**Default:** `[0 0; -0.5 0.5; 0 0]`

### SubarrayNormal

Subarray normal directions in custom grid

Specify the normal directions of the subarrays in the array. This property value is a 2-by-N matrix, where N is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form [azimuth; elevation]. Each angle is in degrees and is defined in the local coordinate system.

You can use the `SubarrayPosition` and `SubarrayNormal` properties to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

This property applies when you set the `Layout` property to `'Custom'`.

**Default:** `[0 0; 0 0]`

### SubarraySteering

Subarray steering method

Specify the method of subarray steering as either `'None'` | `'Phase'` | `'Time'` | `'Custom'`.

- When you set this property to `'Phase'`, a phase shifter is used to steer the subarray. Use the `STEERANG` argument of the `step` method to define the steering direction.
- When you set this property to `'Time'`, subarrays are steered using time delays. Use the `STEERANG` argument of the `step` method to define the steering direction.
- When you set this property to `'Custom'`, subarrays are steered by setting independent weights for all elements in each subarray. Use the `WS` argument of the `step` method to define the weights for all subarrays.

**Default:** `'None'`

**`PhaseShifterFrequency`**

Subarray phase shifter frequency

Specify the operating frequency of phase shifters that perform subarray steering. The property value is a positive scalar in hertz. This property applies when you set the `SubarraySteering` property to `'Phase'`.

**Default:** `3e8`

**`NumPhaseShifterBits`**

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Default:** `0`

## Methods

| | |
|---|---|
| directivity | Directivity of replicated subarray |
| collectPlaneWave | Simulate received plane waves |
| getElementPosition | Positions of array elements |
| getNumElements | Number of elements in array |
| getNumSubarrays | Number of subarrays in array |
| getSubarrayPosition | Positions of subarrays in array |
| isPolarizationCapable | Polarization capability |
| pattern | Plot replicated subarray directivity and patterns |
| patternAzimuth | Plot replicated subarray directivity or pattern versus azimuth |
| patternElevation | Plot replicated subarray directivity or pattern versus elevation |
| plotResponse | Plot response pattern of array |
| step | Output responses of subarrays |
| viewArray | View array geometry |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

## Examples

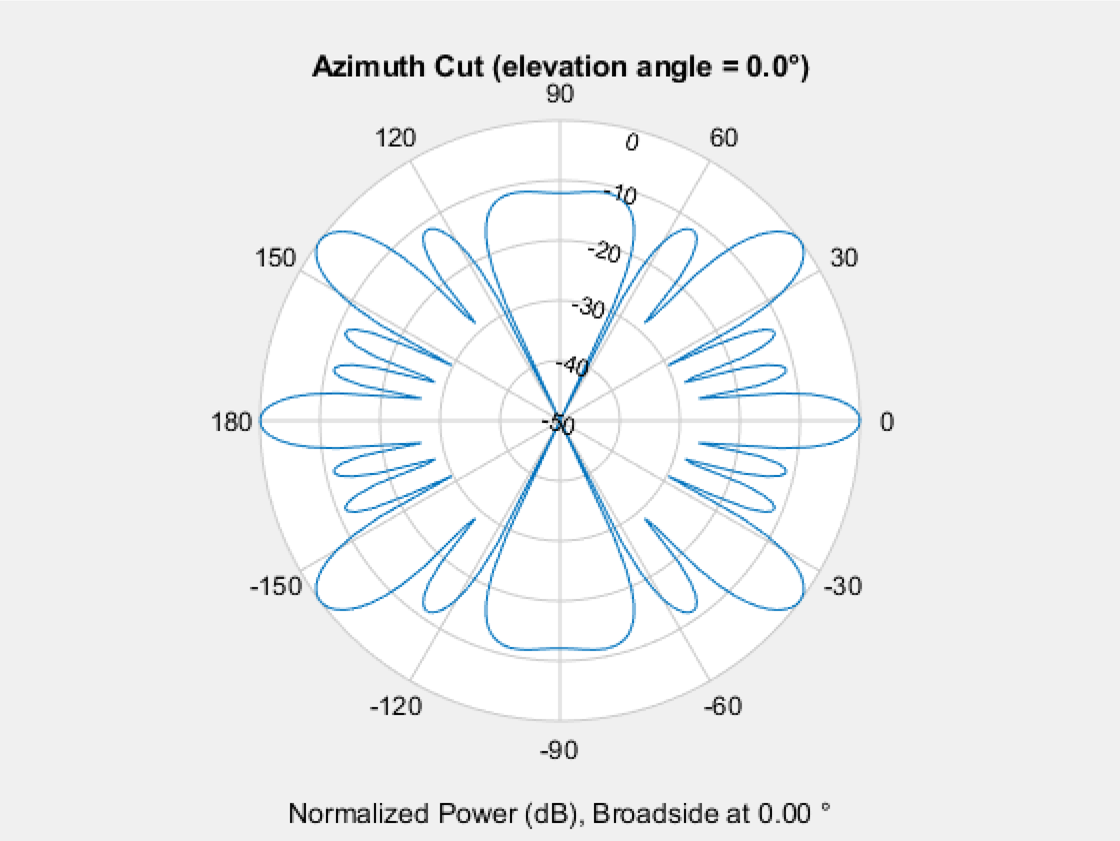
### Azimuth Response of Array with Subarrays

Plot the azimuth response of a 4-element ULA composed of two 2-element ULAs. By default, the antenna elements are isotropic.

```
sArray = phased.ULA('NumElements',2,'ElementSpacing',0.5);
sRSA = phased.ReplicatedSubarray('Subarray',sArray,...
   'Layout','Rectangular','GridSize',[1 2],...
   'GridSpacing','Auto');
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
fc = 1.0e9;
pattern(sRSA,fc,[-180:180],0,...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Type','powerdb',...
    'Normalize',true,...
    'CoordinateSystem','polar')
```



### Response of Subarrays with Polarized Antenna Elements

Create a 4-element ULA from two 2-element ULA subarrays consisting of short-dipole antenna elements. Then, calculate the response at boresight. Because the array elements support polarization, the response consists of horizontal and vertical components.

Create the arrays from subarrays.

```
sSD = phased.ShortDipoleAntennaElement;
sULA = phased.ULA('Element',sSD,...
    'NumElements',2,...
    'ElementSpacing',0.5);
sRSA = phased.ReplicatedSubarray('Subarray',sULA,...
    'Layout','Rectangular',...
    'GridSize',[1 2],...
    'GridSpacing','Auto');
```

Show the vertical polarization response for the subarrays.

```
fc = 1.0e9;
ang = [0;0];
resp = step(sRSA,fc,ang,physconst('LightSpeed'));
disp(resp.V)
```

```
   -2.4495
   -2.4495
```

### Independently Steered Replicated Subarrays

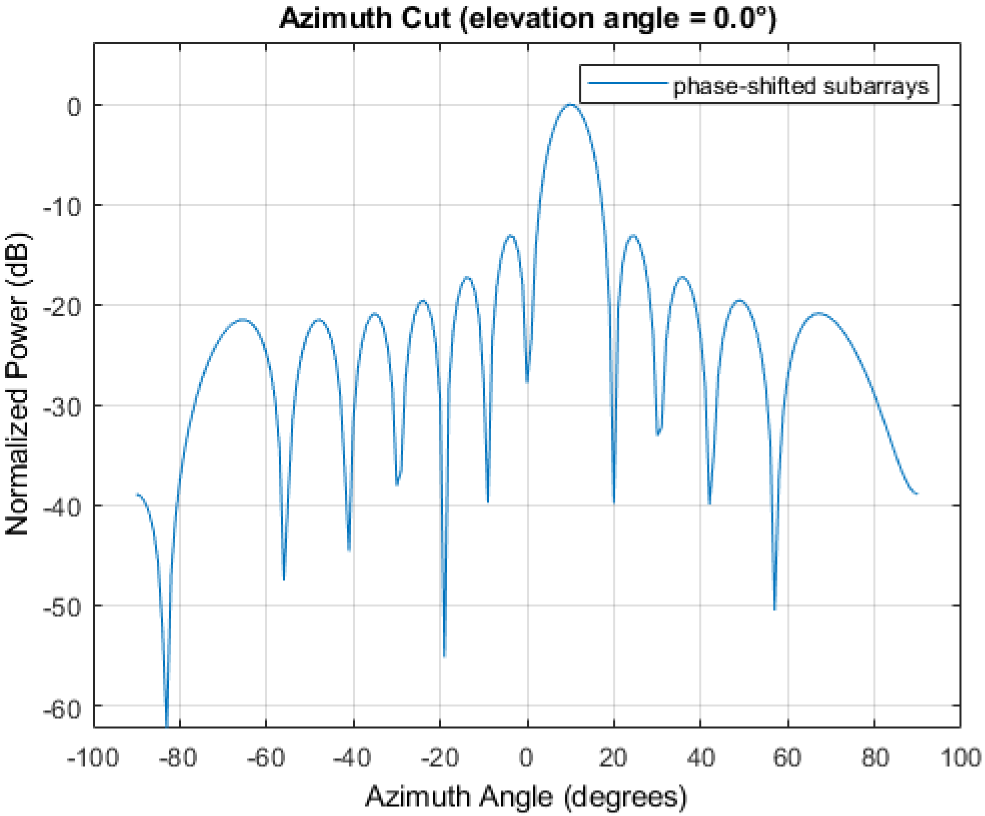
Create a array consisting of three copies of a 4-element ULA having elements spaced 1/2 wavelength apart. The array operates at 300 MHz.

```
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
subarray = phased.ULA(4,0.5*lambda);
```

Steer all subarrays by a common phase shift to 10 degrees azimuth.

```
array = phased.ReplicatedSubarray('Subarray',subarray,'GridSize',[1 3], ...
    'SubarraySteering','Phase','PhaseShifterFrequency',fc);
steer_ang = [10;0];
```

```
sv_array = phased.SteeringVector('SensorArray',array,...
    'PropagationSpeed',c);
wts_array = sv_array(fc,steer_ang);
pattern(array,fc,-90:90,0,'CoordinateSystem','Rectangular',...
    'Type','powerdb','PropagationSpeed',c,'Weights',wts_array,...
    'SteerAngle',steer_ang);
legend('phase-shifted subarrays')
```



Compute independent subarray weights from subarray steering vectors. The weights point to 5, 15, and 30 degrees azimuth. Set the `SubarraySteering` property to `'Custom'` .

```
steer_ang_subarrays = [5 15 30;0 0 0];
sv_subarray = phased.SteeringVector('SensorArray',subarray,...
    'PropagationSpeed',c);
wc = sv_subarray(fc,steer_ang_subarrays);
array.SubarraySteering = 'Custom';
pattern(array,fc,-90:90,0,'CoordinateSystem','Rectangular',...
    'Type','powerdb','PropagationSpeed',c,'Weights',wts_array,...
    'ElementWeight',conj(wc));
legend('independent subarrays')
hold off
```

# directivity

**System object:** phased.ReplicatedSubarray
**Package:** phased

Directivity of replicated subarray

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-1941 of a replicated array of antenna or microphone element, `H`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### H — Replicated subarray

System object

Replicated subarray, specified as a `phased.ReplicatedSubarray` System object.

Example: `H = phased.ReplicatedSubarray;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

| Weights dimension | FREQ dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `‘Weights’` for the corresponding frequency in the `FREQ` argument. |

Example: `'Weights',ones(N,M)`

Data Types: `double`

### SteerAngle — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

### `ElementWeights` — Weights applied to elements within subarray

`1` (default) | complex-valued $N_{SE}$-by-$N$ matrix

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix. Weights are applied to the individual elements within a subarray. All subarrays have the same dimensions and sizes. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray.

#### Dependencies

To enable this name-value pair, set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `D` — Directivity

$M$-by-$L$ matrix

Directivity, returned as an $M$-by-$L$ matrix. Each row corresponds to one of the $M$ angles specified by `ANGLE`. Each column corresponds to one of the $L$ frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Replicated Subarray

Compute the directivity of an array built up from ULA subarrays. Determine the directivity of the replicated subarray when the array is steered to towards 30 degrees azimuth.

Set the signal propagation speed to the speed of light. Set the signal frequency to 300 MHz.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
```

Create a 4-element ULA of isotropic antenna elements spaced 0.4-wavelength apart.

```
myArray = phased.ULA;
myArray.NumElements = 4;
myArray.ElementSpacing = 0.4*lambda;
```

Construct a 2-by-1 replicated subarray.

```
myRepArray = phased.ReplicatedSubarray;
myRepArray.Subarray = myArray;
myRepArray.Layout = 'Rectangular';
myRepArray.GridSize = [2 1];
myRepArray.GridSpacing = 'Auto';
myRepArray.SubarraySteering = 'Time';
```

Steer the array to 30 degrees azimuth and zero degrees elevation.

```
ang = [30;0];
mySV = phased.SteeringVector;
mySV.SensorArray = myRepArray;
mySV.PropagationSpeed = c;
```

Find the directivity at 30 degrees azimuth.

```
d = directivity(myRepArray,fc,ang,...
    'PropagationSpeed',c,...
    'Weights',step(mySV,fc,ang),...
    'SteerAngle',ang)
```

```
d = 7.4776
```

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Package:** `phased`

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in `X`. Each column of `ANG` is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `ANG` is a row vector of length M, each entry in `ANG` specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. `FREQ` must be a scalar.

**Default:** `3e8`

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

## Output Arguments

**Y**

Received signals. `Y` is an N-column matrix, where N is the number of subarrays in the array `H`. Each column of `Y` is the received signal at the corresponding subarray, with all incoming signals combined.

## Examples

### Plane Waves Received at Array of Subarrays

Simulate the received signal at a 16-element ULA composed of four 4-element ULAs.

```
array = phased.ULA('NumElements',4);
subarrays = phased.ReplicatedSubarray('Subarray',array,'GridSize',[4 1]);
```

Simulate two signals received from 10° azimuth and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
y = collectPlaneWave(subarrays,randn(4,2),[10 30],100.0e6,...
    physconst('LightSpeed'));
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array and only models the array factor among subarrays. Therefore, the result does not depend on whether the subarray is steered.

# getElementPosition

**System object:** phased.ReplicatedSubarray
**Package:** phased

Positions of array elements

## Syntax

```
POS = getElementPosition(H)
```

## Description

`POS = getElementPosition(H)` returns the element positions in the array `H`.

## Input Arguments

**H**

Array object consisting of replicated subarrays.

## Output Arguments

**POS**

Element positions in array. `POS` is a 3-by-N matrix, where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

## Examples

### Positions of Elements in Array with Replicated Subarrays

Create an array with two copies of a 3-element ULA, and obtain the positions of the elements.

```
subarrays = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[1 2]);
pos = getElementPosition(subarrays)
```

```
pos = 3×6

         0         0         0         0         0         0
   -1.2500   -0.7500   -0.2500    0.2500    0.7500    1.2500
         0         0         0         0         0         0
```

# getNumElements

**System object:** phased.ReplicatedSubarray
**Package:** phased

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

`N = getNumElements(H)` returns the number of elements in the array object `H`. This number includes the elements in all subarrays of the array.

## Input Arguments

**H**

Array object consisting of replicated subarrays.

## Examples

### Number of Elements in Array with Replicated Subarrays

Create an array with two copies of a 3-element ULA, and obtain the total number of elements.

```
subarray = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[1 2]);
N = getNumElements(subarray)
```

```
N = 6
```

## See Also

`getNumSubarrays`

# getNumSubarrays

**System object:** `phased.ReplicatedSubarray`
**Package:** `phased`

Number of subarrays in array

## Syntax

```
N = getNumSubarrays(H)
```

## Description

`N = getNumSubarrays(H)` returns the number of subarrays in the array object `H`.

## Input Arguments

**`H`**

Array object consisting of replicated subarrays.

## Examples

### Number of Subarrays in Array

Create an array by tiling copies of a ULA in a 2-by-5 grid. Then, obtain the number of subarrays.

```
subarrays = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[2 5]);
N = getNumSubarrays(subarrays)
```

```
N = 10
```

# getSubarrayPosition

**System object:** `phased.ReplicatedSubarray`
**Package:** `phased`

Positions of subarrays in array

## Syntax

```
POS = getSubarrayPosition(H)
```

## Description

`POS = getSubarrayPosition(H)` returns the subarray positions in the array `H`.

## Input Arguments

**`H`**

Partitioned array object.

## Output Arguments

**`POS`**

Subarrays positions in array. `POS` is a 3-by-N matrix, where N is the number of subarrays in `H`. Each column of `POS` defines the position of a subarray in the local coordinate system, in meters, using the form [x; y; z].

## Examples

### Replicated Subarray Positions

Create an array with two copies of a 3-element ULA, and obtain the positions of the subarrays.

```
subarray = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[1 2]);
pos = getSubarrayPosition(subarray)
```

```
pos = 3×2

# isPolarizationCapable

**System object:** `phased.ReplicatedSubarray`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

### h — Replicated subarray

Replicated subarray specified as a `phased.ReplicatedSubarray` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

## Examples

### Replicated Array of Short Dipoles Supports Polarization

Verify that a replicated subarray of short-dipole antenna elements supports polarization.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
array = phased.URA([3,2],'Element',antenna);
reparray = phased.ReplicatedSubarray('Subarray',array, ...
    'Layout','Rectangular','GridSize',[1,2],'GridSpacing','Auto');
isPolarizationCapable(reparray)
```

```
ans = logical
   1
```

# pattern

**System object:** `phased.ReplicatedSubarray`
**Package:** `phased`

Plot replicated subarray directivity and patterns

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern(___,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern(___)
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern(___,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern(___)` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-1965 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sArray` — Replicated subarray

System object

Replicated subarray, specified as a `phased.ReplicatedSubarray` System object.

Example: `sArray= phased.ReplicatedSubarray;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

| Weights dimension | FREQ dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `‘Weights’` for the corresponding frequency in the `FREQ` argument. |

Example: `'Weights',ones(N,M)`

Data Types: double

**SteerAngle — Subarray steering angle**
[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of 'SteerAngle' and a scalar or a 2-by-1 column vector.

If 'SteerAngle' is a 2-by-1 column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If 'SteerAngle' is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the 'SubarraySteering' property of the System object is set to 'Phase' or 'Time'.

Example: 'SteerAngle',[20;30]

Data Types: double

**ElementWeights — Weights applied to elements within subarray**
1 (default) | complex-valued $N_{SE}$-by-$N$ matrix

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix. Weights are applied to the individual elements within a subarray. All subarrays have the same dimensions and sizes. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray.

**Dependencies**

To enable this name-value pair, set the SubarraySteering property of the array to 'Custom'.

Data Types: double
Complex Number Support: Yes

## Output Arguments

**PAT — Array pattern**
*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

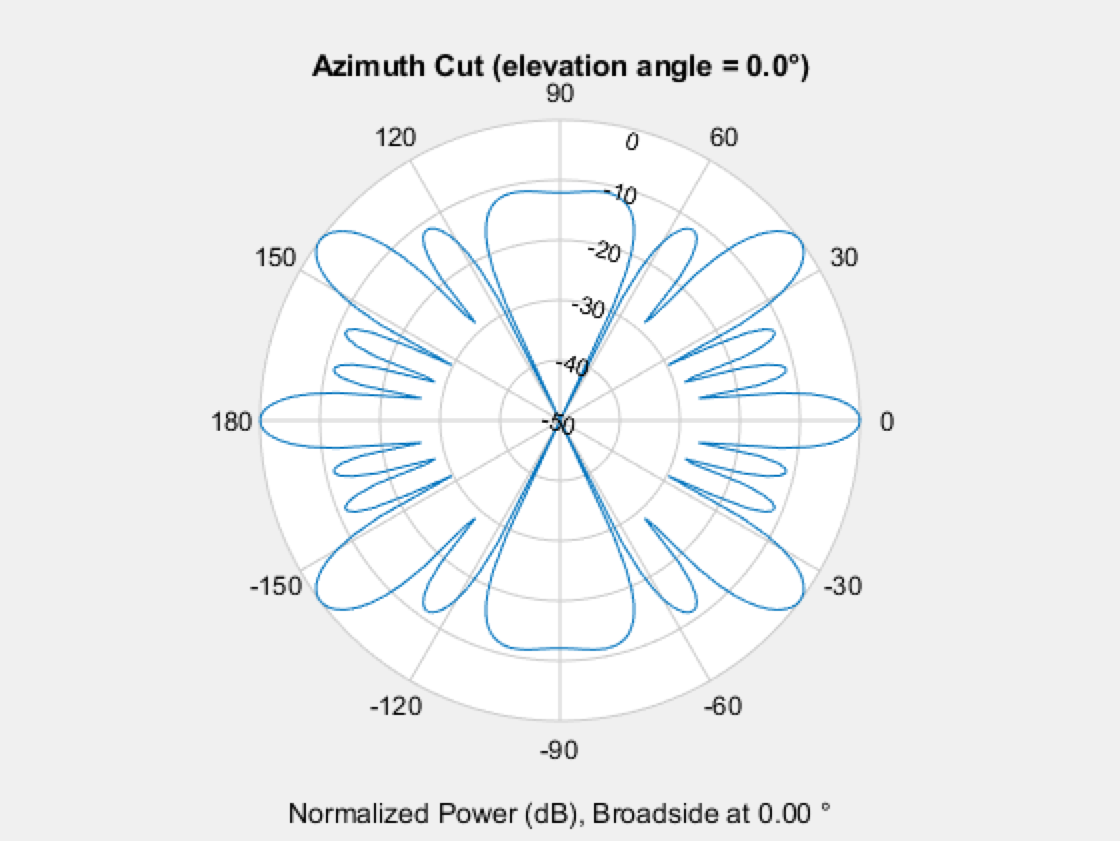
### Azimuth Response of Array with Subarrays

Plot the azimuth response of a 4-element ULA composed of two 2-element ULAs. By default, the antenna elements are isotropic.

```
sArray = phased.ULA('NumElements',2,'ElementSpacing',0.5);
sRSA = phased.ReplicatedSubarray('Subarray',sArray,...
   'Layout','Rectangular','GridSize',[1 2],...
   'GridSpacing','Auto');
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
fc = 1.0e9;
pattern(sRSA,fc,[-180:180],0,...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Type','powerdb',...
    'Normalize',true,...
    'CoordinateSystem','polar')
```



### Directivity of Array with Subarrays

Create a 2-by-2-element URA of isotropic antenna elements, and arrange four copies to form a 16-element URA. Plot the 3-D directivity pattern.

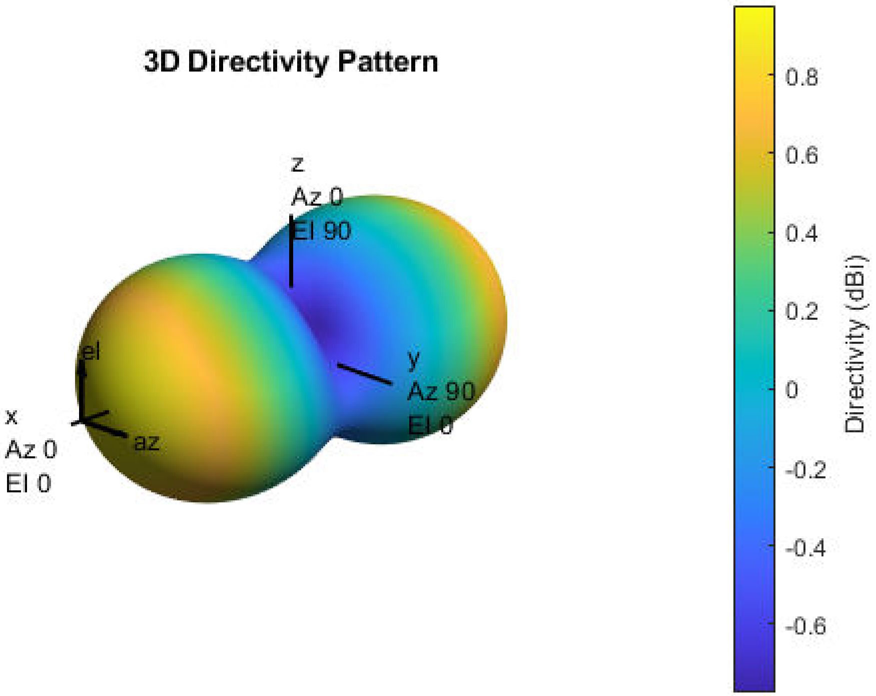
#### Create the array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
```

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,...
    'Size',[2 2],...
    'ElementSpacing',lam/2);
sRS = phased.ReplicatedSubarray('Subarray',sURA,...
    'Layout','Rectangular','GridSize',[2 2],...
    'GridSpacing','Auto');
```

**Plot 3-D directivity pattern**

```
fc = 1e9;
wts = [0.862,1.23,1.23,0.862]';
pattern(sRS,fc,[-180:180],[-90:90],...
    'PropagationSpeed',physconst('LightSpeed'),....
    'Type','directivity',...
    'Weights',wts);
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.ReplicatedSubarray
**Package:** phased

Plot replicated subarray directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth(___)
```

## Description

patternAzimuth(sArray,FREQ) plots the 2-D array directivity pattern versus azimuth (in dBi) for the array sArray at zero degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(sArray,FREQ,EL), in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array sArray at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(sArray,FREQ,EL,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth(___) returns the array pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

**sArray — Replicated subarray**
System object

Replicated subarray, specified as a `phased.ReplicatedSubarray` System object.

Example: `sArray= phased.ReplicatedSubarray;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **Type — Displayed pattern type**

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### **PropagationSpeed — Signal propagation speed**

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### **Weights — Subarray weights**

*M*-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### SteerAngle — Subarray steering angle

[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of 'SteerAngle' and a scalar or a 2-by-1 column vector.

If 'SteerAngle' is a 2-by-1 column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If 'SteerAngle' is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the 'SubarraySteering' property of the System object is set to 'Phase' or 'Time'.

Example: 'SteerAngle',[20;30]

Data Types: double

### ElementWeights — Weights applied to elements within subarray

1 (default) | complex-valued $N_{SE}$-by-$N$ matrix

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix. Weights are applied to the individual elements within a subarray. All subarrays have the same dimensions and sizes. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray.

#### Dependencies

To enable this name-value pair, set the SubarraySteering property of the array to 'Custom'.

Data Types: double
Complex Number Support: Yes

### Azimuth — Azimuth angles

[-180:180] (default) | 1-by-$P$ real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of 'Azimuth' and a 1-by-$P$ real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: 'Azimuth',[-90:2:90]

Data Types: `double`

## Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Azimuth Pattern of Array with Subarrays

Create a 2-element ULA of isotropic antenna elements, and arrange three copies to form a 6-element ULA. Plot the directivity azimuth pattern within a restricted range of azimuth angles from -30 to 30 degrees in 0.1 degree increments. Plot directivity for 0 degrees and 45 degrees elevation.

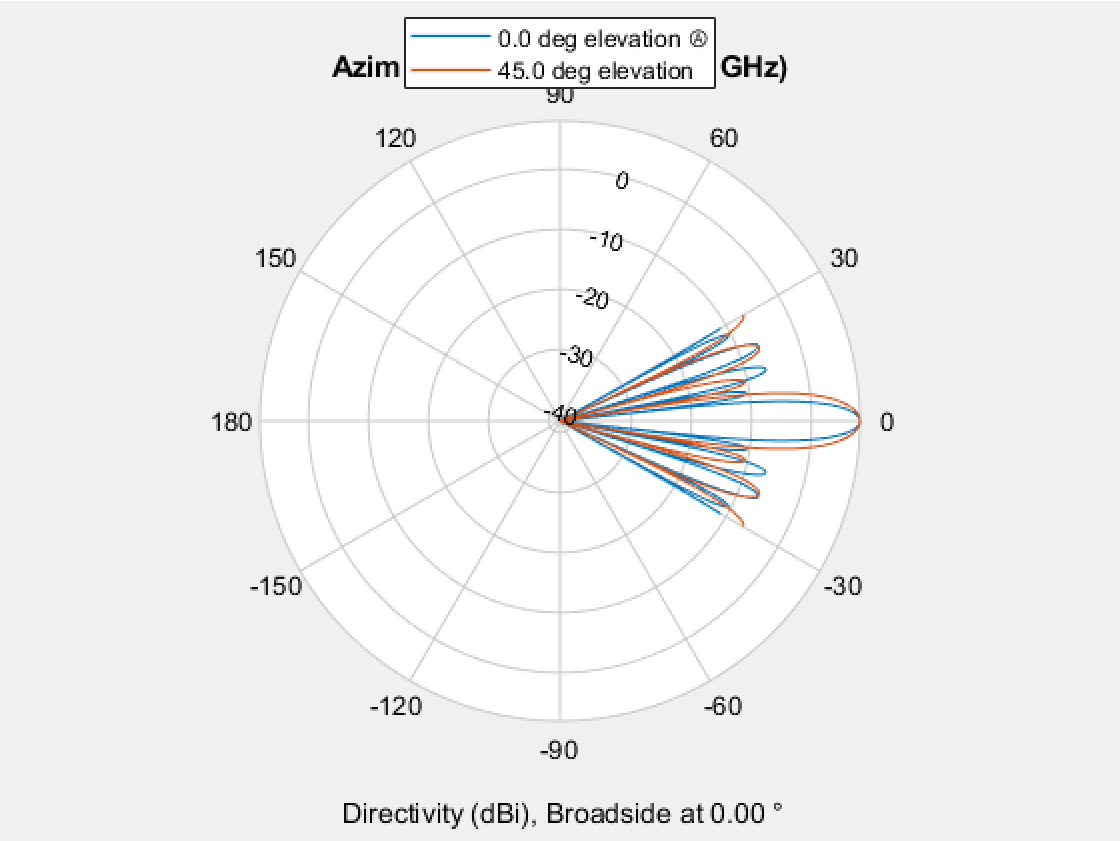
#### Create the array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sULA = phased.ULA('Element',sIso,...
    'NumElements',2,'ElementSpacing',0.5);
sRS = phased.ReplicatedSubarray('Subarray',sULA,...
    'Layout','Rectangular','GridSize',[1 3],...
    'GridSpacing','Auto');
```

#### Plot azimuth directivity pattern

```
fc = 1e9;
wts = [0.862,1.23,0.862]';
```

```
patternAzimuth(sRS,fc,[0,45],'PropagationSpeed',physconst('LightSpeed'),...
    'Azimuth',[-30:0.1:30],...
    'Type','directivity',...
    'Weights',wts);
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## See Also

`pattern` | `patternElevation`

**Introduced in R2015a**

# patternElevation

**System object:** phased.ReplicatedSubarray
**Package:** phased

Plot replicated subarray directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(sArray,FREQ) plots the 2-D array directivity pattern versus elevation (in dBi) for the array sArray at zero degrees azimuth angle. When AZ is a vector, multiple overlaid plots are created. The argument FREQ specifies the operating frequency.

patternElevation(sArray,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(sArray,FREQ,AZ,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the array pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**sArray — Replicated subarray**
System object

Replicated subarray, specified as a `phased.ReplicatedSubarray` System object.

Example: `sArray= phased.ReplicatedSubarray;`

### FREQ — Frequency for computing directivity and pattern
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Subarray weights

*M*-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### SteerAngle — Subarray steering angle

[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of 'SteerAngle' and a scalar or a 2-by-1 column vector.

If 'SteerAngle' is a 2-by-1 column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If 'SteerAngle' is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the 'SubarraySteering' property of the System object is set to 'Phase' or 'Time'.

Example: 'SteerAngle',[20;30]

Data Types: double

### ElementWeights — Weights applied to elements within subarray

1 (default) | complex-valued $N_{SE}$-by-$N$ matrix

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix. Weights are applied to the individual elements within a subarray. All subarrays have the same dimensions and sizes. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray.

#### Dependencies

To enable this name-value pair, set the SubarraySteering property of the array to 'Custom'.

Data Types: double
Complex Number Support: Yes

### Elevation — Elevation angles

[-90:90] (default) | 1-by-$P$ real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of 'Elevation' and a 1-by-$P$ real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: 'Elevation',[-90:2:90]

Data Types: double

# Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the 'Elevation' name-value pair argument. The dimension *N* is the number of azimuth angles determined by the AZ argument.

# Examples

### Elevation Pattern of Array with Subarrays

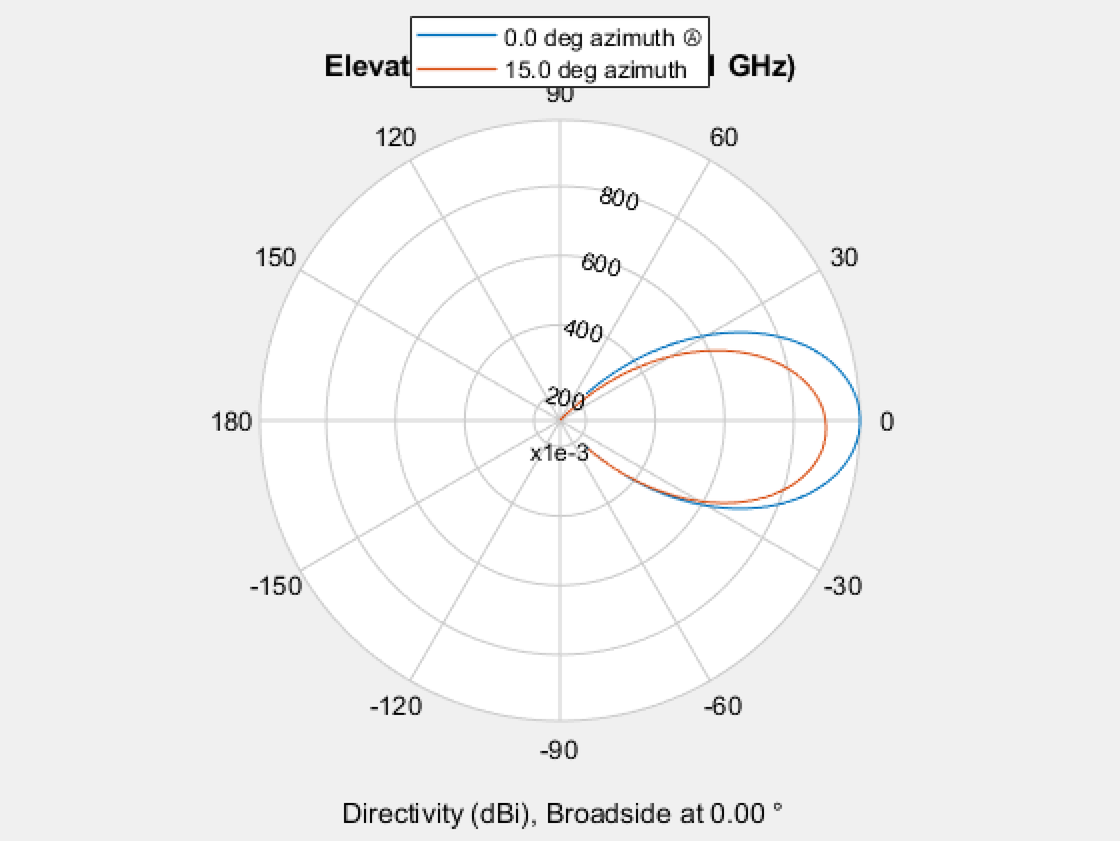
Create a 2-by-2-element URA of isotropic antenna elements, and arrange four copies to form a 16-element URA. Plot the elevation directivity pattern within a restricted range of elevation angles from -45 to 45 degrees in 0.1 degree increments. Plot directivity for 0 degrees and 15 degrees azimuth.

**Create the array**

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,...
    'Size',[2 2],...
    'ElementSpacing',lam/2);
sRS = phased.ReplicatedSubarray('Subarray',sURA,...
    'Layout','Rectangular','GridSize',[2 2],...
    'GridSpacing','Auto');
```

### Plot elevation directivity pattern

```
fc = 1e9;
wts = [0.862,1.23,1.23,0.862]';
patternElevation(sRS,fc,[0,15],...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Elevation',[-45:0.1:45],...
    'Type','directivity',...
    'Weights',wts);
```



## More About

### Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# plotResponse

**System object:** phased.ReplicatedSubarray
**Package:** phased

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

plotResponse(H,FREQ,V) plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in FREQ. The propagation speed is specified in V.

plotResponse(H,FREQ,V,Name,Value) plots the array response with additional options specified by one or more Name,Value pair arguments.

hPlot = plotResponse( ___ ) returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**H**

Array object.

**FREQ**

Operating frequency, in hertz. Typical values are within the range specified by a property of H.Subarray.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range. If FREQ is a nonscalar row vector, the plot shows multiple frequency responses on the same axes.

**V**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CutAngle**

Cut angle specified as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

**Default:** 0

**Format**

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

**Default:** 'Line'

**NormalizeResponse**

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** true

**OverlayFreq**

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, then FREQ must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and `RespCut` is not `'3D'`.

**Default:** `true`

**`Polarization`**

Specify the polarization options for plotting the array response pattern. The allowable values are |`'None'` | `'Combined'` | `'H'` | `'V'` | where:

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `'None'`

**`RespCut`**

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

**`SteerAng`**

Subarray steering angle. `SteerAng` can be either a 2-element column vector or a scalar.

If `SteerAng` is a 2-element column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `SteerAng` is a scalar, it specifies the azimuth angle. In this case, the elevation angle is assumed to be 0.

This option is applicable only if the `SubarraySteering` property of `H` is `'Phase'` or `'Time'`.

**Default:** `[0;0]`

### `Unit`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of subarrays in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting subarray response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'Az' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the AzimuthAngles and ElevationAngles parameters simultaneously.

**Default:** [-180:180]

**ElevationAngles**

Elevation angles for plotting subarray response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

**UGrid**

*U* coordinate values for plotting subarray response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

**VGrid**

*V* coordinate values for plotting subarray response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the VGrid and UGrid parameters simultaneously.

**Default:** [-1:0.01:1]

# Examples

### Azimuth Response and Directivity of ULA with Subarrays

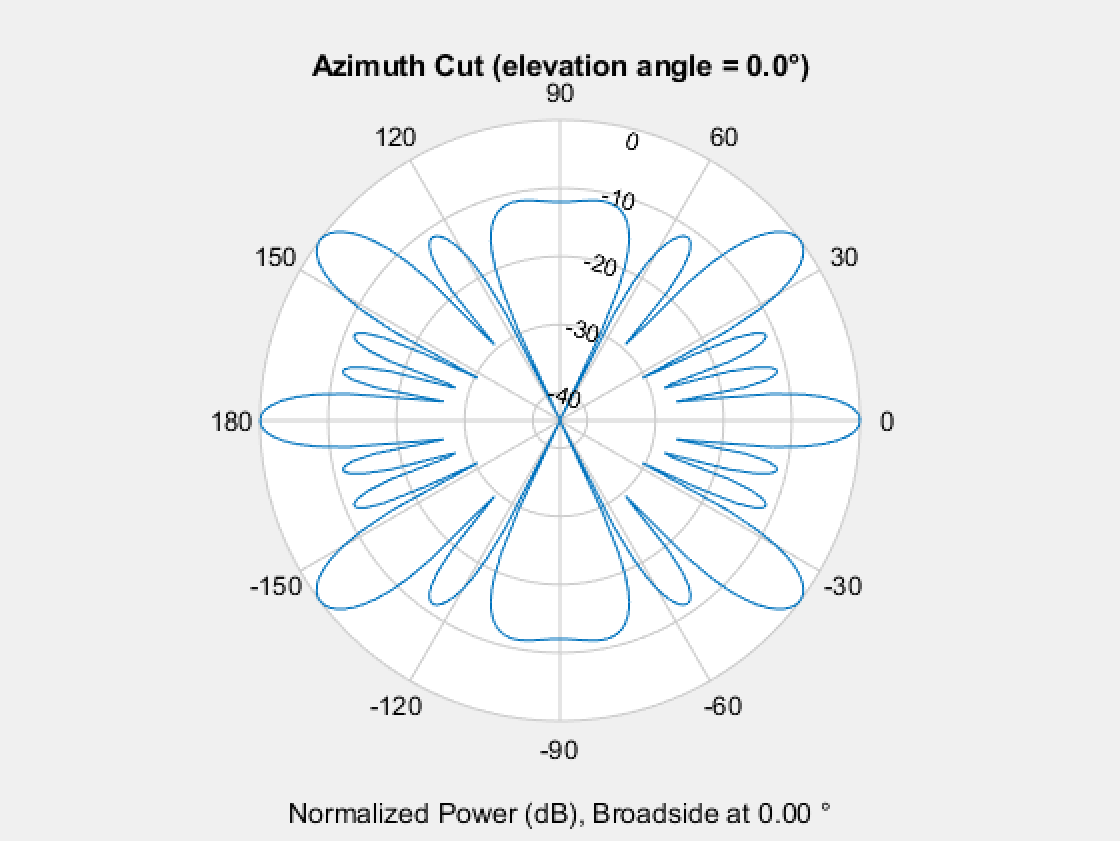
Plot the azimuth response of a 4-element ULA composed of two 2-element ULAs.

Create a 2-element ULA, and arrange two copies to form a 4-element ULA.

```
h = phased.ULA('NumElements',2,'ElementSpacing',0.5);
ha = phased.ReplicatedSubarray('Subarray',h,...
    'Layout','Rectangular','GridSize',[1 2],...
    'GridSpacing','Auto');
```

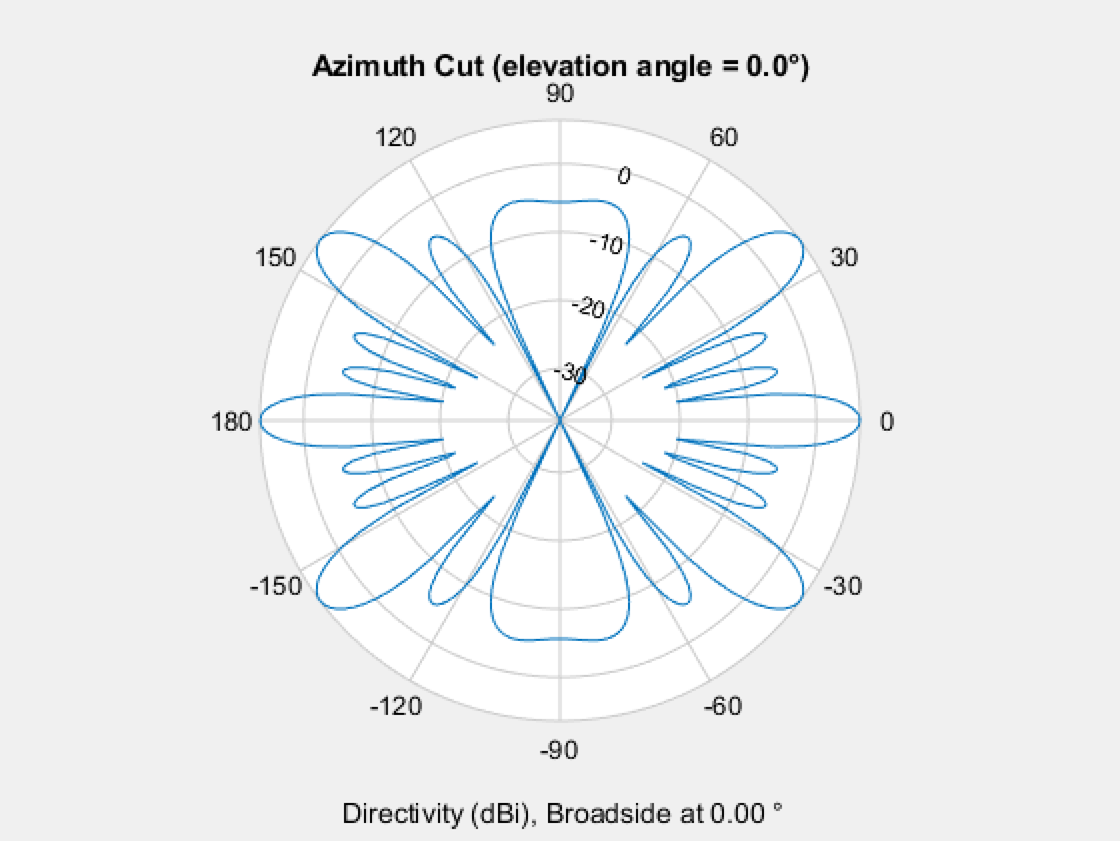
Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the wave propagation speed is 3e8 m/s.

```
plotResponse(ha,1e9,3e8,'RespCut','Az','Format','Polar');
```



Plot the azimuth directivity of the array.

```
plotResponse(ha,1e9,3e8,'RespCut','Az','Format','Polar','Unit','dbi');
```

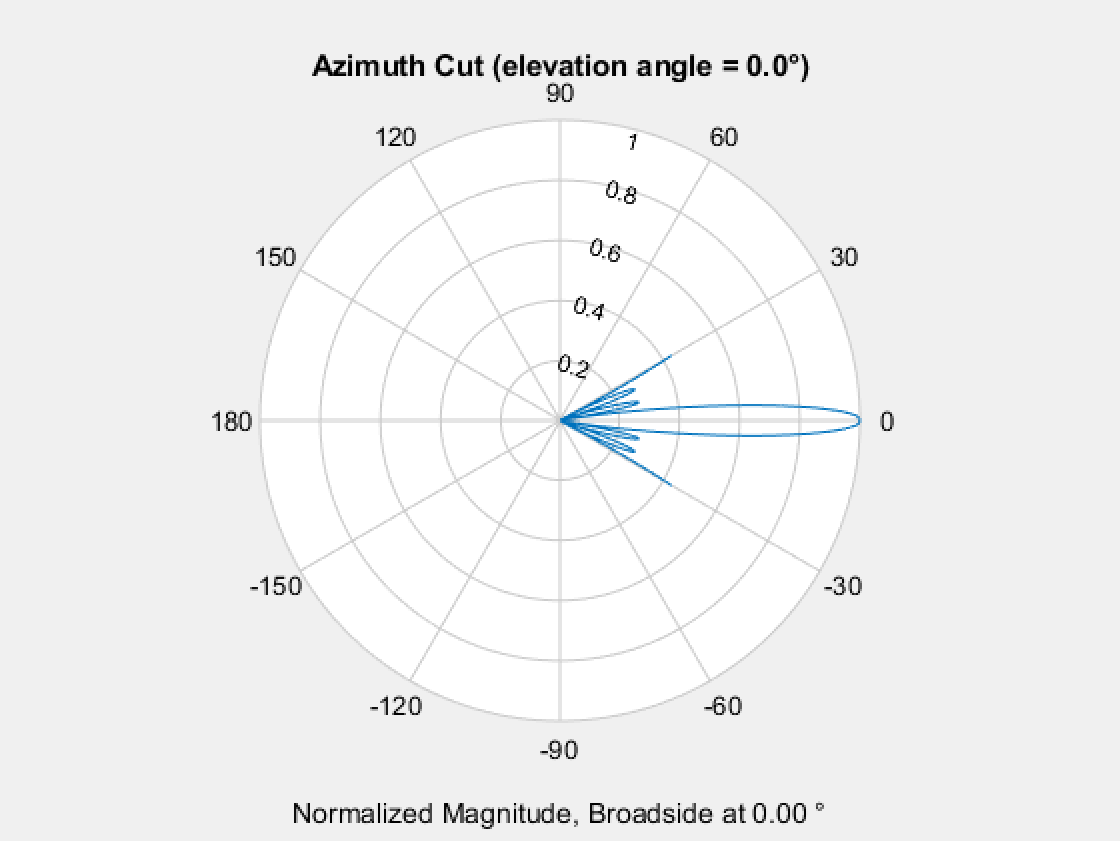


### Display Azimuth Response of Array with Subarrays Between -30 and 30 Degrees

Create a 2-element ULA, and arrange two copies to form a 4-element ULA. Using the `AzimuthAngles` parameter, plot the response within a restricted range of azimuth angles from -30 to 30 degrees in 0.1 degree increments.

```
h = phased.ULA('NumElements',2,'ElementSpacing',0.5);
ha = phased.ReplicatedSubarray('Subarray',h,...
    'Layout','Rectangular','GridSize',[1 2],...
    'GridSpacing','Auto');
```

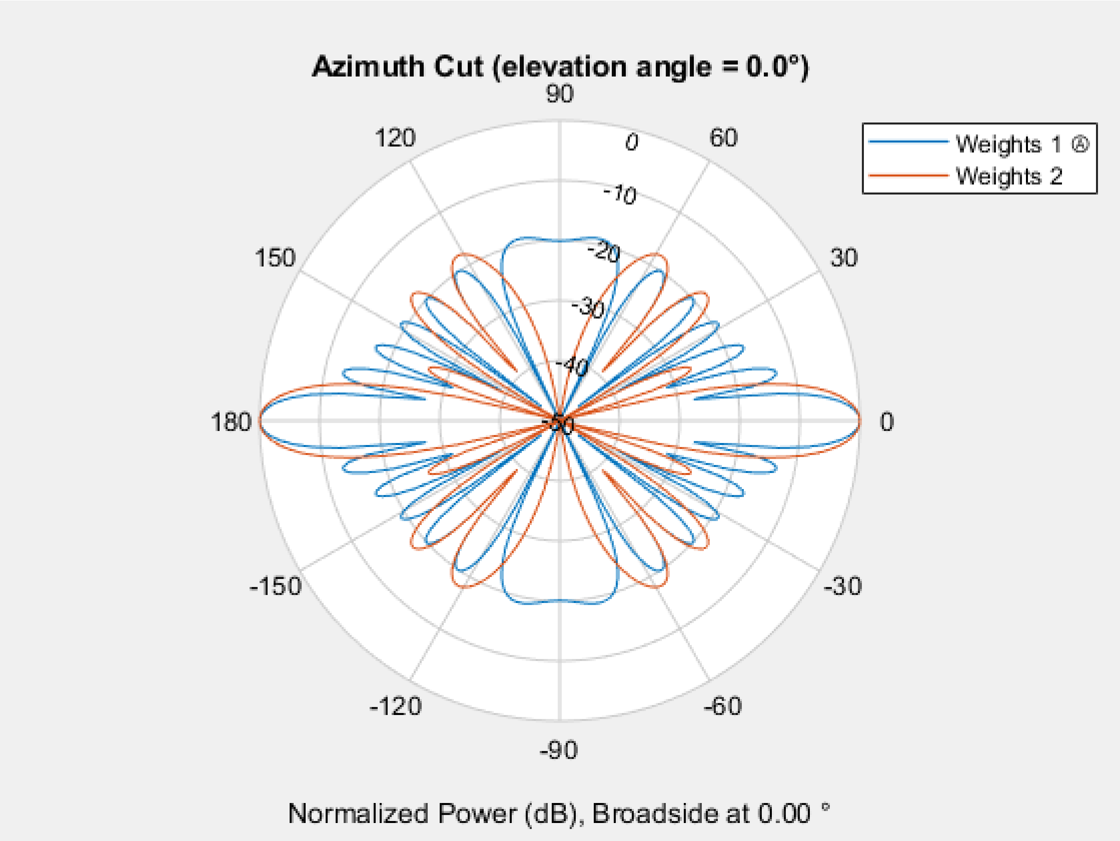
```
plotResponse(ha,1e9,3e8,'RespCut','Az','Format','Polar',...
    'AzimuthAngles',[-30:0.1:30],'Unit','mag');
```



### Apply Two Sets of Weights at a Single Frequency

Construct an array of replicated subarrays. Start with a 2-element uniform line array (ULA), and duplicate it 5 times to create a 10-element ULA. Apply both uniform weights and tapered weights. Then, use `plotResponse` to show that the tapered set of weights reduces the adjacent sidelobes while broadening the main lobe.

```
h = phased.ULA('NumElements',2,'ElementSpacing',0.2);
ha = phased.ReplicatedSubarray('Subarray',h,...
    'Layout','Rectangular','GridSize',[1 5],...
    'GridSpacing',0.4);
c = physconst('LightSpeed');
fc = 1e9;
wts1 = [0.2,0.2,0.2,0.2,0.2]';
wts2 = [0.1,0.23333,.33333,0.23333,0.1]';
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar',...
    'Weights',[wts1,wts2]);
```



## See Also

azel2uv | uv2azel

# step

**System object:** `phased.ReplicatedSubarray`
**Package:** `phased`

Output responses of subarrays

## Syntax

```
RESP = step(H,FREQ,ANG,V)
RESP = step(H,FREQ,ANG,V,STEERANGLE)
RESP = step(H,FREQ,ANG,V,WS)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG,V)` returns the responses, `RESP`, of the subarrays in the array, at operating frequencies specified in `FREQ` and directions specified in `ANG`. `V` is the propagation speed. The elements within each subarray are connected to the subarray phase center using an equal-path feed.

`RESP = step(H,FREQ,ANG,V,STEERANGLE)` uses `STEERANGLE` as the subarray's steering direction. This syntax is available when you set the `SubarraySteering` property to either `'Phase'` or `'Time'`.

`RESP = step(H,FREQ,ANG,V,WS)` uses `WS` as the subarray element weights. This syntax is available when you set the `SubarraySteering` property to `'Custom'`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# Input Arguments

**H**

Phased array formed by replicated subarrays.

**FREQ**

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of `H.Subarray.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

**ANG**

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

**V**

Propagation speed in meters per second. This value must be a scalar.

**STEERANGLE**

Subarray steering direction. `STEERANGLE` can be either a 2-element column vector or a scalar.

If this argument is a 2-element column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If STEERANGLE is a scalar, it specifies the direction's azimuth angle. In this case, the elevation angle is assumed to be 0°.

**Dependencies**

To enable this argument, set the SubarraySteering to 'Phase' or 'Time'.

### WS

Subarray element weights

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix. Weights are applied to the individual elements within a subarray. All subarrays have the same dimensions and sizes. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray.

**Dependencies**

To enable this argument, set the SubarraySteering to 'Custom'.

## Output Arguments

### RESP

Voltage responses of the subarrays of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions $N$-by-$M$-by-$L$. The first dimension, $N$ , represents the number of subarrays in the phased array, the second dimension, $M$, represents the number of angles specified in ANG, while $L$ represents the number of frequencies specified in FREQ. Each column of RESP contains the responses of the subarrays for the corresponding direction specified in ANG. Each of the $L$ pages of RESP contains the responses of the subarrays for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V, each having dimensions $N$-by-$M$-by-$L$. The field, RESP.H, represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. The first dimension, $N$ , represents the number of subarrays in the phased array, the second dimension, $M$, represents the number of angles specified in ANG, while $L$ represents

the number of frequencies specified in FREQ. Each of the *M* columns contains the responses of the subarrays for the corresponding direction specified in ANG. Each of the *L* pages contains the responses of the subarrays for the corresponding frequency specified in FREQ.

## Examples

### Subarray Response

Calculate the response at boresight for two 2-element ULA arrays that form subarrays of a 4-element ULA array of short-dipole antenna elements.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

Create a two-element ULA of short-dipole antenna elements. Then, arrange two copies to form a 4-element ULA.

```
antenna = phased.ShortDipoleAntennaElement;
array = phased.ULA('Element',antenna,'NumElements',2,'ElementSpacing',0.5);
replicatedarray = phased.ReplicatedSubarray('Subarray',array,...
    'Layout','Rectangular','GridSize',[1 2],...
    'GridSpacing','Auto');
```

Find the response of each subarray at boresight. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
resp = replicatedarray(1.0e9,[0;0],c)
```

```
resp = struct with fields:
    H: [2x1 double]
    V: [2x1 double]
```

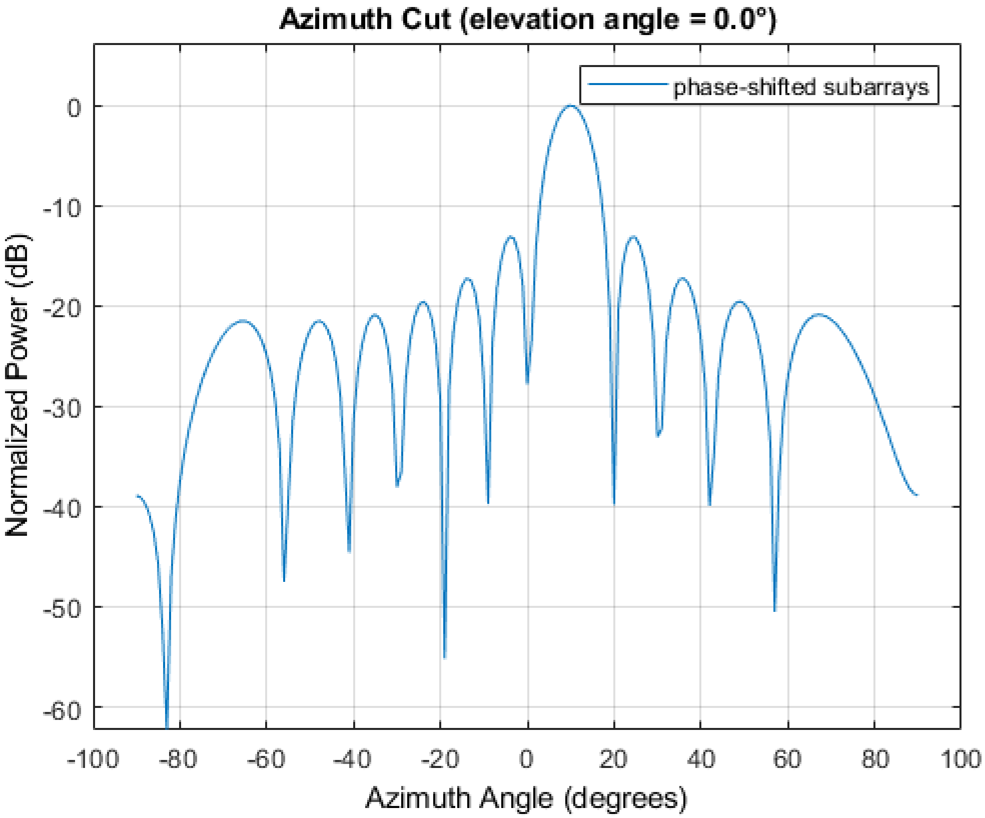
### Independently Steered Replicated Subarrays

Create a array consisting of three copies of a 4-element ULA having elements spaced 1/2 wavelength apart. The array operates at 300 MHz.

```
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
subarray = phased.ULA(4,0.5*lambda);
```

Steer all subarrays by a common phase shift to 10 degrees azimuth.

```
array = phased.ReplicatedSubarray('Subarray',subarray,'GridSize',[1 3], ...
    'SubarraySteering','Phase','PhaseShifterFrequency',fc);
steer_ang = [10;0];
sv_array = phased.SteeringVector('SensorArray',array,...
    'PropagationSpeed',c);
wts_array = sv_array(fc,steer_ang);
pattern(array,fc,-90:90,0,'CoordinateSystem','Rectangular',...
    'Type','powerdb','PropagationSpeed',c,'Weights',wts_array,...
    'SteerAngle',steer_ang);
legend('phase-shifted subarrays')
```



Compute independent subarray weights from subarray steering vectors. The weights point to 5, 15, and 30 degrees azimuth. Set the `SubarraySteering` property to `'Custom'` .

```
steer_ang_subarrays = [5 15 30;0 0 0];
sv_subarray = phased.SteeringVector('SensorArray',subarray,...
    'PropagationSpeed',c);
wc = sv_subarray(fc,steer_ang_subarrays);
array.SubarraySteering = 'Custom';
pattern(array,fc,-90:90,0,'CoordinateSystem','Rectangular',...
    'Type','powerdb','PropagationSpeed',c,'Weights',wts_array,...
    'ElementWeight',conj(wc));
legend('independent subarrays')
hold off
```

# viewArray

**System object:** `phased.ReplicatedSubarray`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handles of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`ShowIndex`**

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value as `'All'` to show indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

**`ShowNormals`**

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

**`ShowTaper`**

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

**`ShowSubarray`**

Vector specifying the indices of subarrays to highlight in the figure. Each number in the vector must be an integer between 1 and the number of subarrays. You can also specify the value as `'All'` to highlight all subarrays of the array or `'None'` to suppress subarray highlighting. Highlighting uses different colors for different subarrays.

**Default:** `'All'`

**`Title`**

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

**hPlot**

Handles of array elements in figure window.

## Examples

### Array of Replicated Hexagonal Arrays on a Sphere

This example shows how to construct a full array by replicating subarrays.

Create a hexagonal array to use as a subarray.

```
Nmin = 9;
Nmax = 17;
dy = 0.5;
dz = 0.5*sin(pi/3);
rowlengths = [Nmin:Nmax Nmax-1:-1:Nmin];
numels_hex = sum(rowlengths);
stopvals = cumsum(rowlengths);
startvals = stopvals-rowlengths+1;
pos = zeros(3,numels_hex);
rowidx = 0;
for m = Nmin-Nmax:Nmax-Nmin
    rowidx = rowidx+1;
    idx = startvals(rowidx):stopvals(rowidx);
    pos(2,idx) = (-(rowlengths(rowidx)-1)/2:...
        (rowlengths(rowidx)-1)/2) * dy;
    pos(3,idx) = m*dz;
end
hexa = phased.ConformalArray('ElementPosition',pos,...
    'ElementNormal',zeros(2,numels_hex));
```

Arrange copies of the hexagonal array on a sphere.

```
radius = 9;
az = [-180 -180 -180 -120 -120 -60 -60   0  0  60 60 120 120 180];
el = [-90   -30   30  -30   30 -30  30 -30 30 -30 30 -30  30  90];
numsubarrays = size(az,2);
[x,y,z] = sph2cart(deg2rad(az),deg2rad(el),...
    radius*ones(1,numsubarrays));
ha = phased.ReplicatedSubarray('Subarray',hexa,...
    'Layout','Custom',...
    'SubarrayPosition',[x; y; z], ...
    'SubarrayNormal',[az; el]);
```

Display the geometry of the array, highlighting selected subarrays with different colors.

```
viewArray(ha,'ShowSubarray',3:2:13,...
    'Title','Hexagonal Subarrays on a Sphere');
view(0,90)
```

# phased.RootMUSICEstimator

**Package:** `phased`

Root MUSIC direction of arrival (DOA) estimator for ULA and UCA

## Description

The `RootMUSICEstimator` object implements the root multiple signal classification (root-MUSIC) direction of arrival estimator for uniform linear arrays (ULA) and uniform circular arrays (UCA). When a uniform circular array is used, the algorithm transforms the input to a ULA-like structure using the phase mode excitation technique [2].

To estimate the direction of arrival (DOA):

1. Define and set up your DOA estimator. See “Construction” on page 1-2008.
2. Call `step` to estimate the DOA according to the properties of `phased.RootMUSICEstimator`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.RootMUSICEstimator` creates a root MUSIC DOA estimator System object, `H`. The object estimates the signal's direction of arrival using the root MUSIC algorithm with a uniform linear array (ULA).

`H = phased.RootMUSICEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Sensor array System object

Sensor array specified as a System object. The sensor array must be a `phased.ULA` object or a `phased.UCA` object.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

**Default:** `false`

### `SpatialSmoothing`

Spatial smoothing

The averaging number used by spatial smoothing to estimate the covariance matrix, specified as a strictly positive integer. Each additional smoothing value handles one additional coherent source, but reduces the effective number of elements by one. The maximum value of this property is *M-2*. For a ULA, *M* is the number of sensors. For a UCA, *M* is the size of the internal ULA-like array structure defined by the phase mode excitation technique. The default value of zero indicates that no spatial smoothing is employed. You can specify this property as single or double precision.

**Default:** `0`

**`NumSignalsSource`**

Source of number of signals

Specify the source of the number of signals as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of signals is estimated by the method specified by the `NumSignalsMethod` property.

When spatial smoothing is employed on a UCA, you cannot set the `NumSignalsSource` property to`'Auto'` to estimate the number of signals. You can use the functions `aictest` or `mdltest` independently to determine the number of signals.

**Default:** `'Auto'`

**`NumSignalsMethod`**

Method to estimate number of signals

Specify the method to estimate the number of signals as one of `'AIC'` or `'MDL'`. `'AIC'` uses the Akaike Information Criterion and `'MDL'` uses Minimum Description Length Criterion. This property applies when you set the `NumSignalsSource` property to `'Auto'`.

**Default:** `'AIC'`

**`NumSignals`**

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the `NumSignalsSource` property to `'Property'`. The number of signals must be smaller than the number of elements in the array specified in the `SensorArray` property. You can specify this property as single or double precision.

**Default:** 1

## Examples

### Root-MUSIC Estimation of DOA for ULA

Estimate the DOA's of two signals received by a standard 10-element uniform linear array (ULA) having an element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10 degrees in azimuth and 20 degrees in elevation. The direction of the second signal is 45 degrees in azimuth and 60 degrees in elevation.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
sULA = phased.ULA('NumElements',10,...
    'ElementSpacing',1);
sULA.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(sULA,[x1 x2],[10 20;45 60]',fc);
rng default;
noise = 0.1/sqrt(2)*(randn(size(x))+1i*randn(size(x)));
sDOA = phased.RootMUSICEstimator('SensorArray',sULA,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'NumSignals',2);
doas = step(sDOA,x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az = 1×2
```

```
   10.0001   45.0107
```

# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2012a**

# step

**System object:** `phased.RootMUSICEstimator`
**Package:** `phased`

Perform DOA estimation

## Syntax

```
ANG = step(H,X)
ANG = step(H,X,ElAng)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ANG = step(H,X)` estimates the direction of arrivals (DOA's) from a signal `X` using the DOA estimator `H`. `X` is a matrix whose columns correspond to the signal channels. `ANG` is a row vector of the estimated broadside angles (in degrees). You can specify the argument `X` as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`ANG = step(H,X,ElAng)` specifies, in addition, the assumed elevation angles of the signals. This syntax is only applicable when the `SensorArray` property of the object specifies a uniform circular array (UCA). `ElAng` is a scalar between -90° and 90° and is applied to all signals. The elevation angles for all signals must be the same as required by the phase mode excitation algorithm. You can specify the argument `ElAng` as single or double precision.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

### Root-MUSIC Estimation of DOA for ULA

Estimate the DOA's of two signals received by a standard 10-element uniform linear array (ULA) having an element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10 degrees in azimuth and 20 degrees in elevation. The direction of the second signal is 45 degrees in azimuth and 60 degrees in elevation.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
sULA = phased.ULA('NumElements',10,...
    'ElementSpacing',1);
sULA.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(sULA,[x1 x2],[10 20;45 60]',fc);
rng default;
noise = 0.1/sqrt(2)*(randn(size(x))+1i*randn(size(x)));
sDOA = phased.RootMUSICEstimator('SensorArray',sULA,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'NumSignals',2);
doas = step(sDOA,x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az = 1×2

   10.0001   45.0107
```

### Root-MUSIC Estimation of DOA for UCA

Using the root-MUSIC algorithm, estimate the azimuth angle of arrival of two signals received by a 15-element UCA having a 1.5 meter radius. The antenna operating frequency is 150 MHz. The actual direction of arrival of the first signal is 10 degrees in azimuth and 4 degrees in elevation. The direction of arrival of the second signal is 45 degrees in azimuth and -2 degrees in elevation. In estimating the directions of arrival, assume the signals arrive from 0 degrees elevation.

Set the frequencies of the signals to 500 and 600 Hz. Set the sample rate to 8 kHz and the operating frequency to 150 MHz. Then, create the baseband signals, the UCA array and the plane wave signals.

```
fs = 8000;
fc = 150e6;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*500);
x2 = cos(2*pi*t*600);
sUCA = phased.UCA('NumElements',15,...
    'Radius',1.5);
x = collectPlaneWave(sUCA,[x1 x2],[10 4; 45 -2]',fc);
```

Add random complex gaussian white noise to the signals.

```
rs = RandStream('mt19937ar','Seed',0);
noise = 0.1/sqrt(2)*(randn(rs,size(x))+1i*randn(rs,size(x)));
```

Create the phased.RootMUSICEstimator System object

```
sDOA = phased.RootMUSICEstimator('SensorArray',sUCA,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'NumSignals',2);
```

Solve for the azimuth angles for zero degrees elevation.

```
elang = 0;
doas = step(sDOA, x + noise, elang);
az = sort(doas)
```

```
az = 1×2
```

```
    9.9815   44.9986
```

# phased.RootWSFEstimator

**Package:** `phased`

Root WSF direction of arrival (DOA) estimator for ULA

## Description

The `RootWSFEstimator` object implements a root weighted subspace fitting direction of arrival algorithm.

To estimate the direction of arrival (DOA):

1. Define and set up your root WSF DOA estimator. See “Construction” on page 1-2018.
2. Call `step` to estimate the DOA according to the properties of `phased.RootWSFEstimator`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.RootWSFEstimator` creates a root WSF DOA estimator System object, `H`. The object estimates the signal's direction of arrival using the root weighted subspace fitting (WSF) algorithm with a uniform linear array (ULA).

`H = phased.RootWSFEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `NumSignalsSource`

Source of number of signals

Specify the source of the number of signals as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of signals is estimated by the method specified by the `NumSignalsMethod` property.

**Default:** `'Auto'`

### `NumSignalsMethod`

Method to estimate number of signals

Specify the method to estimate the number of signals as one of `'AIC'` or `'MDL'`. `'AIC'` uses the Akaike Information Criterion and `'MDL'` uses the Minimum Description Length Criterion. This property applies when you set the `NumSignalsSource` property to `'Auto'`.

**Default:** `'AIC'`

**`NumSignals`**

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the `NumSignalsSource` property to `'Property'`. You can specify this property as single or double precision.

**Default:** `1`

**`Method`**

Iterative method

Specify the iterative method as one of `'IMODE'` or `'IQML'`.

**Default:** `'IMODE'`

**`MaximumIterationCount`**

Maximum number of iterations

Specify the maximum number of iterations as a positive integer scalar or `'Inf'`. This property is tunable. You can specify this property as single or double precision.

**Default:** `'Inf'`

# Examples

### Estimate DOA of Two Signals Using WSF

First, estimate the DOAs of two signals received by a standard 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and −5° in elevation.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the signals with added noise. Then, create the ULA System object™.

Construct WSF estimator System object.

Estimate the DOAs.

```
doas =

   10.0002   20.7934
```

# phased.ScenarioViewer

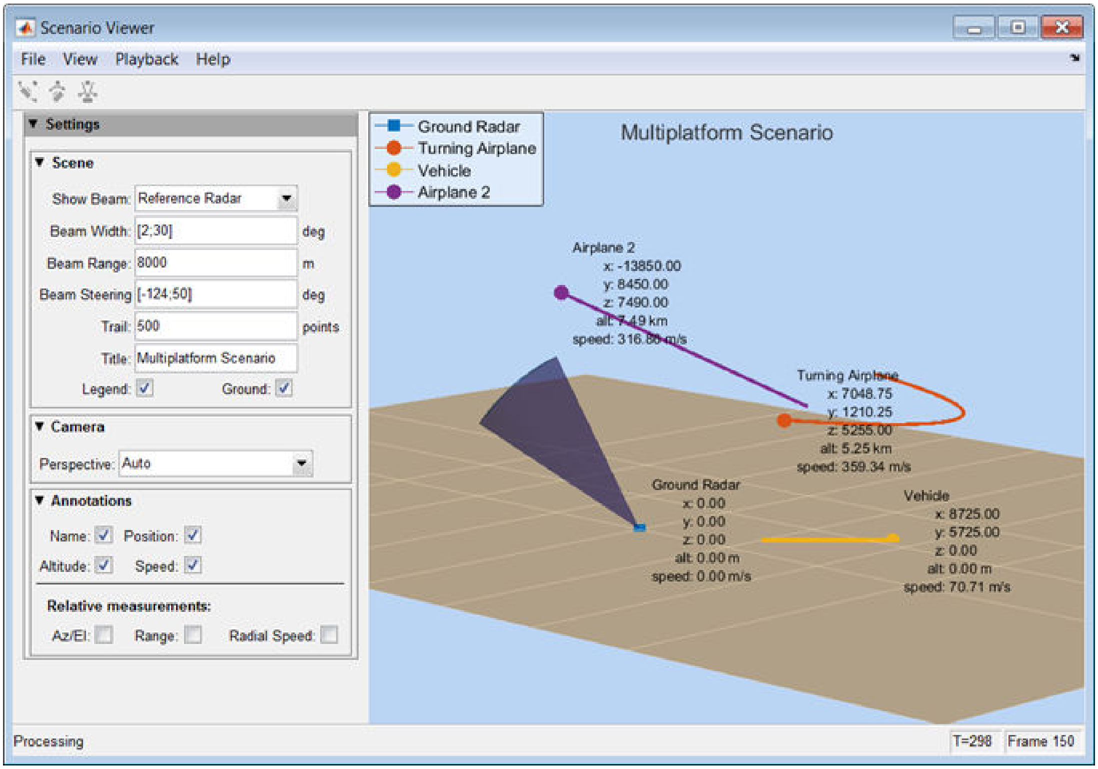
**Package:** `phased`

Display motion of radars and targets

## Description

The `phased.ScenarioViewer` System object creates a 3-D viewer to display the motion of radars and targets that you model in your radar simulation. You can display current positions and velocities, object tracks, position and speed annotations, radar beam directions, and other object parameters. You can change radar features such as beam range and beam width during the simulation. You can use the `phased.Platform` System object to model moving objects or you can supply your own dynamic models.

This figure shows a four-object scenario consisting of a ground radar, two airplanes, and a ground vehicle. You can view the code that generated this figure in the "Visualize Multiplatform Scenario" on page 1-2039 example.



Settings

Az/El: □ Range: □ Radial Speed: □

To create a scenario viewer:

1. Define and set up the `phased.ScenarioViewer` System object. See “Construction” on page 1-2027. You can set System object properties at construction time or leave them to their default values. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. Call the `step` method to update radar and target displayed positions according to the properties of the `phased.ScenarioViewer` System object. You can change tunable properties at any time.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

sIS = phased.ScenarioViewer creates a scenario viewer System object, sIS having default property values.

sIS = phased.ScenarioViewer(Name,Value) returns a scenario viewer System object, sIS, with any specified property Name set to a specified Value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## Properties

### Name — Window caption name

'Scenario Viewer' (default) | character vector

Window caption name, specified as a character vector. The Name property and the Title property are different.

Example: 'Multitarget Viewer'

Data Types: char

### ReferenceRadar — Reference radar index

1 (default) | positive integer

Reference radar index, specified as a positive integer. This property selects one of the radars as the reference radar. Its value must be less than or equal to the number of radars that you specify in the radar_pos argument of the step method. This property is tunable. Target range, radial speed, azimuth, and elevation are defined with respect to this radar.

Example: 2

Data Types: double

### ShowBeam — Show radar beams

'ReferenceRadar' (default) | 'None' | 'All'

Enable the display of radar beams, specified as 'ReferenceRadar', 'None', or 'All'. This option determines which radar beams to show.

| Option | Beams to show |
|---|---|
| `'ReferenceRadar'` | Show the beam of the radar specified in the `ReferenceRadar` property. |
| `'None'` | Do not show any radar beams. |
| `'All'` | Show the beams for all radars. |

This property is tunable.

Example: `'All'`

Data Types: `char`

**`BeamWidth` — Vertical and horizontal radar beam widths**
15 (default) | positive, real-valued scalar | positive, real-valued 2-element column vector | positive, real-valued *N*-element row vector | positive, real-valued 2-by-*N* matrix

Vertical and horizontal radar beam widths, specified as a positive real-valued scalar, a 2-element column vector, an *N*-element row vector, or a 2-by-*N* matrix. *N* is the number of radars. All scalar, vector, and matrix entries are positive, real-valued numbers between 0–360°. Units are in degrees.

| Value Specification | Interpretation |
|---|---|
| Scalar | The horizontal and vertical radar beam widths are equal and identical for all radars. |
| 2-element column vector | The first row specifies the horizontal beam width. The second row specifies the vertical beam width. These values are identical for all radars. |
| *N*-element row vector | Each element applies to one radar. Vertical and horizontal beam widths for each radar are equal. |
| 2-by-*N* matrix | Each column applies to one radar. The first row specifies the horizontal beam width and the second row specifies the vertical beam width for each radar. |

When `CameraPerspective` is set to `'Radar'`, the System object uses this property to calculate the value of `CameraViewAngle`. This property is tunable.

Example: `[20 10; 18 9]`

Data Types: `double`

### `BeamRange` — Radar beam range

1000 (default) | positive scalar | real-valued *N*- element row vector of positive values

Radar beam range, specified as a positive scalar or an *N*-element row vector, where *N* is the number of radars. Units are in meters. When specified as a scalar, all radars have the same beam range. When specified as a vector, each element corresponds to one radar. This property is tunable.

Example: `[1000 1500 850]`

Data Types: `double`

### `BeamSteering` — Beam steering direction

`[0;0]` (default) | positive real-valued 2-element column vector | positive real-valued *N*-element row vector

Beam steering directions of radars, specified as a real-valued 2-element column vector of positive values or 2-by-*N* real-valued matrix of positive values. *N* is the number of radars. Beam steering angles are relative to the local coordinate axes of each radar. Units are in degrees. Each column takes the form `[azimuthangle;elevationangle]`. When only one column is specified, the beam steering directions of all radars are the same. Azimuth angles are from –180° to 180°, and the elevation angles are from –90° to 90°. This property is tunable.

Example: `[20 60 35; 5 0 10]`

Data Types: `double`

### `VelocityInputPort` — Enable velocity input

`true` (default) | `false`

Enable the velocity input arguments, `radar_velocity` and `tgt_velocity`, of the `step` method, specified as `true` or `false`. Setting this property to `true` enables the input arguments. When this property is `false`, velocity vectors are estimated from the position change between consecutive updates divided by the update interval. The update interval is the inverse of the `UpdateRate` value.

Example: `false`

Data Types: `logical`

### OrientationInputPort — Enable orientation input

false (default) | true

Enable the input of local coordinate system orientation axes, radar_laxes and tgt_laxes, to the step method, specified as false or true. Setting this property to true enables the input arguments. When this property is false, the orientation axes are aligned with the global coordinate axes.

Example: true

Data Types: logical

### UpdateRate — Update rate of scenario viewer

1 (default) | positive scalar

Update rate of scenario viewer, specified as a positive scalar. Units are in hertz.

Example: 2.5

Data Types: double

### Title — Display title

'' (default) | character vector

Display title, specified as a character vector. The Title property and the Name property are different. The display title appears within the figure at the top. The name appears at the top of the figure window. This property is tunable.

Example: 'Radar and Target Display'

Data Types: char

### PlatformNames — Names of radars and targets

'Auto' (default) | 1-by-*(N+M)* cell array of character vectors

Names assigned to radars and targets, specified as a 1-by-*(N+M)* cell array of character vectors. *N* is the number of radars and *M* is the number of targets. Order the cell entries by radar names, followed by target names. Names appear in the legend and annotations. When you set PlatformNames to 'Auto', names are created sequentially starting from 'Radar 1' for radars and 'Target 1' for targets.

Example: {'Stationary Radar','Mobile Radar','Airplane'}

Data Types: cell

### `TrailLength` — Length of visible tracks

`500` (default) | positive integer | *(N+M)*-length vector of positive integers

Length of the visibility of object tracks, specified as a positive integer or *(N+M)*-length vector of positive integers. *N* is the number of radars and *M* is the number of targets. When `TrailLength` is a scalar, all tracks have the same length. When `TrailLength` is a vector, each element of the vector specifies the length of the corresponding radar or target trajectory. Order the entries by radars, followed by targets. Each call to the `step` method generates a new visible point. This property is tunable.

Example: `[100,150,100]`

Data Types: `double`

### `CameraPerspective` — Camera perspective

`'Auto'` (default) | `'Custom'` | `'Radar'`

Camera perspective, specified as `'Auto'`, `'Custom'`, or `'Radar'`. When you set this property to `'Auto'`, the System object estimates appropriate values for the camera position, orientation, and view angle to show all tracks. When you set this property to `'Custom'`, you can set the camera position, orientation, and angles using camera properties or the camera toolbar. When you set this property to `'Radar'`, the System object determines the camera position, orientation, and angles from the radar position and the radar beam steering direction. This property is tunable.

Example: `'Radar'`

Data Types: `char`

### `CameraPosition` — Camera position

`[x,y,z]` vector of real-values

Camera position, specified as an `[x,y,z]` vector of real values. Units are in meters. This property applies when you set `CameraPerspective` to `'Custom'`. When you do not specify this property, the System object chooses values based on your display configuration. This property is tunable.

Example: `[100,50,40]`

Data Types: `double`

### `CameraOrientation` — Camera orientation

`[pan,tilt,roll]` vector of positive, real values

Camera orientation, specified as a `[pan,tilt,roll]` vector of positive, real values. Units are in degrees. Pan and roll angles take values from *–180°* to *180°*. The tilt angle takes values from *–90°* to *90°*. Camera rotations are performed in the order: pan, tilt, and roll. This property applies when you set `CameraPerspective` to `'Custom'`. When you do not specify this property, the System object chooses values based on your display configuration. This property is tunable.

Example: `[180,45,30]`

Data Types: `double`

**`CameraViewAngle` — Camera view angle**
real-valued scalar from 0° to 360°

Camera view angle, specified as a real-valued scalar. Units are in degrees. View angle values are in the range 0° to 360°. This property applies when you set `CameraPerspective` to `'Custom'`. When you do not specify this property, the System object chooses values based on your display configuration. This property is tunable.

Example: `75`

Data Types: `double`

**ShowLegend — Show viewer legend**
`false` (default) | `true`

Option to show the viewer legend, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

**ShowGround — Show ground plane of scenario**
`true` (default) | `false`

Option to show the ground plane of the viewer scenario, specified as `true` or `false`. This property is tunable.

Example: `false`

Data Types: `logical`

**ShowName — Option to annotate radar and target tracks with names**
`true` (default) | `false`

Annotate radar and target tracks with names, specified as `true` or `false`. You can define custom platform names using `PlatformNames`. This property is tunable.

Example: `false`

Data Types: `logical`

**`ShowPosition` — Annotate radar and target tracks with positions**
`false` (default) | `true`

Option to annotate radar and target tracks with positions, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

**`ShowRange` — Annotate radar and target tracks with ranges**
`false` (default) | `true`

Option to annotate radar and target tracks with the range from the reference radar, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

**`ShowAltitude` — Annotate radar and target tracks with altitude**
`false` (default) | `true`

Option to annotate radar and target tracks with altitude, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

**`ShowSpeed` — Annotate radar and target tracks with speed**
`false` (default) | `true`

Option to annotate radar and target tracks with speed, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

### ShowRadialSpeed — Annotate radar and target tracks with radial speed

false (default) | true

Option to annotate radar and target tracks with radial speed, specified as false or true. Radial speed is relative to the reference radar. This property is tunable.

Example: true

Data Types: logical

### ShowAzEl — Annotate radar and target tracks with azimuth and elevation

false (default) | true

Option to annotate radar and target tracks with azimuth and elevation angles relative to the reference radar, specified as false or true. This property is tunable.

Example: true

Data Types: logical

### Position — Viewer window size and position

[left bottom width height] vector of positive, real values

Scenario viewer window size and position, specified as a [left bottom width height] vector of positive, real values. Units are in pixels.

- left sets the position of the left edge of the window.
- bottom sets the position of the bottom edge of the window.
- width sets the width of the window.
- height sets the height of the window.

When you do not specify this property, the window is positioned at the center of the screen, with width and height taking the values 410 and 300 pixels, respectively. This property is tunable.

Example: [100,200,800,500]

Data Types: double

### ReducePlotRate — Enable reduced plot rate

true (default) | false

Option to reduce the plot rate to improve performance, specified as true or false. Set this property to true to update the viewer at a reduced rate. Set this property to false to update the viewer with each call to the step method. This mode adversely affects viewer performance. This property is tunable.

Example: false

Data Types: logical

# Methods

| | |
|---|---|
| hide | Hide scenario viewer window |
| reset | Reset state of the System object |
| show | Show scenario viewer window |
| step | Update scenario viewer display |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

# Examples

### View Tracks of Stationary Radar and One Target

Visualize the tracks of a radar and a single airplane target. The radar is stationary and the airplane is moving in a straight line. Maintain the radar beam pointing at the airplane.

Create the radar and airplane platform System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
radarPlatform = phased.Platform(...
    'InitialPosition',[0;0;10], ...
    'Velocity',[0;0;0]);
airplanePlatforms = phased.Platform(...
    'InitialPosition',[5000.0;3500.0;6000.0],...
    'Velocity',[-300;0;0]);
```

Create the phased.ScenarioViewer System object. Show the radar beam and annotate the tracks with position, speed, and altitude.

```
sSV = phased.ScenarioViewer('BeamRange',5000.0,'UpdateRate',updateRate,...
    'PlatformNames',{'Ground Radar','Airplane'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true);
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(radarPlatform,updateRate);
    [tgt_pos,tgt_vel] = step(airplanePlatforms,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    sSV.BeamSteering = ang;
    step(sSV,radar_pos,radar_vel,tgt_pos,tgt_vel);
    pause(0.1);
end
```

### View Tracks of Airborne Radar and Ground Target

Visualize the tracks of an airborne radar and a ground vehicle target. The airborne radar is carried by a drone flying at 5 km altitude.

Create the drone radar and ground vehicle using `phased.Platform` System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
drone = phased.Platform(...
    'InitialPosition',[100;1000;5000], ...
    'Velocity',[400;0;0]);
vehicle = phased.Platform('MotionModel','Acceleration',...
    'InitialPosition',[5000.0;3500.0;0.0],...
    'InitialVelocity',[40;5;0],'Acceleration',[0.1;0.1;0]);
```

Create the `phased.ScenarioViewer` System object?. Show the radar beam and annotate the tracks with position, speed, and, altitude.

```
viewer = phased.ScenarioViewer('BeamRange',8000.0,'BeamWidth',2,'UpdateRate',updateRate
    'PlatformNames',{'Drone Radar','Vehicle'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'Title','Vehicle Tracking Ra
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(drone,updateRate);
    [tgt_pos,tgt_vel] = step(vehicle,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    viewer.BeamSteering = ang;
    viewer(radar_pos,radar_vel,tgt_pos,tgt_vel)
    pause(.1)
end
```

### Visualize Multiplatform Scenario

This example shows how to create and display a multiplatform scenario containing a ground-based stationary radar, a turning airplane, a constant-velocity airplane, and a moving ground vehicle. The turning airplane follows a parabolic flight path while descending at a rate of 20 m/s.

Specify the scenario refresh rate at 0.5 Hz. For 150 steps, the time duration of the scenario is 300 s.

```
updateRate = 0.5;
N = 150;
```

Set up the turning airplane using the `Acceleration` model of the `phased.Platform` System object?. Specify the initial position of the airplane by range and azimuth from the ground-based radar and its elevation. The airplane is 10 km from the radar at 60? azimuth and has an altitude of 6 km. The airplane is accelerating at 10 $m/s^2$ in the negative *x*-direction.

```
airplane1range = 10.0e3;
airplane1Azimuth = 60.0;
airplane1alt = 6.0e3;
airplane1Pos0 = [cosd(airplane1Azimuth)*airplane1range;...
    sind(airplane1Azimuth)*airplane1range;airplane1alt];
airplane1Vel0 = [400.0;-100.0;-20];
airplane1Accel = [-10.0;0.0;0.0];
airplane1platform = phased.Platform('MotionModel','Acceleration',...
    'AccelerationSource','Input port','InitialPosition',airplane1Pos0,...
    'InitialVelocity',airplane1Vel0,'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',eye(3));
```

Set up the stationary ground radar at the origin of the global coordinate system. To simulate a rotating radar, change the ground radar beam steering angle in the processing loop.

```
groundRadarPos = [0,0,0]';
groundRadarVel = [0,0,0]';
groundradarplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundRadarPos,'Velocity',groundRadarVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the ground vehicle to move at a constant velocity.

```
groundVehiclePos = [5e3,2e3,0]';
groundVehicleVel = [50,50,0]';
groundvehicleplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundVehiclePos,'Velocity',groundVehicleVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the second airplane to also move at constant velocity.

```
airplane2Pos = [8.5e3,1e3,6000]';
airplane2Vel = [-300,100,20]';
airplane2platform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',airplane2Pos,'Velocity',airplane2Vel,...
    'InitialOrientationAxes',eye(3));
```

Set up the scenario viewer. Specify the radar as having a beam range of 8 km, a vertical beam width of 30?, and a horizontal beam width of 2?. Annotate the tracks with position, speed, altitude, and range.

```
BeamSteering = [0;50];
viewer = phased.ScenarioViewer('BeamRange',8.0e3,'BeamWidth',[2;30],'UpdateRate',update
    'PlatformNames',{'Ground Radar','Turning Airplane','Vehicle','Airplane 2'},'ShowPos
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'ShowRange',true,...
    'Title','Multiplatform Scenario','BeamSteering',BeamSteering);
```

Step through the display processing loop, updating radar and target positions. Rotate the ground-based radar steering angle by four degrees at each step.

```
for n = 1:N
    [groundRadarPos,groundRadarVel] = groundradarplatform(updateRate);
    [airplane1Pos,airplane1Vel,airplane1Axes] = airplane1platform(updateRate,airplane1A
    [vehiclePos,vehicleVel] = groundvehicleplatform(updateRate);
    [airplane2Pos,airplane2Vel] = airplane2platform(updateRate);
    viewer(groundRadarPos,groundRadarVel,[airplane1Pos,vehiclePos,airplane2Pos],...
        [airplane1Vel,vehicleVel,airplane2Vel]);
    BeamSteering = viewer.BeamSteering(1);
    BeamSteering = mod(BeamSteering + 4,360.0);
    if BeamSteering > 180.0
        BeamSteering = BeamSteering - 360.0;
    end
    viewer.BeamSteering(1) = BeamSteering;
    pause(0.2);
end
```

### Topics

“Visualizing Radar and Target Trajectories in System Simulation”

**Introduced in R2016a**

# hide

**System object:** phased.ScenarioViewer
**Package:** phased

Hide scenario viewer window

## Syntax

```
hide(sSV)
```

## Description

hide(sSV) hides the display window of the phased.ScenarioViewer System object, sSV.

## Input Arguments

### sSV — Scenario viewer

phased.ScenarioViewer System object

Scenario viewer, specified as a phased.ScenarioViewer System object.

Example: phased.ScenarioViewer

**Introduced in R2016a**

# reset

**System object:** `phased.ScenarioViewer`
**Package:** `phased`

Reset state of the System object

## Syntax

`reset(sSV)`

## Description

`reset(sSV)` resets the internal state of the `phased.ScenarioViewer` System object, `sSV`, to its initial value.

## Input Arguments

### sSV — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a `phased.ScenarioViewer` System object.

Example: `phased.ScenarioViewer`

**Introduced in R2016a**

# show

**System object:** `phased.ScenarioViewer`
**Package:** `phased`

Show scenario viewer window

## Syntax

`show(sSV)`

## Description

`show(sSV)` shows the display window of the `phased.ScenarioViewer` System object, `sSV`.

## Input Arguments

### sSV — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a `phased.ScenarioViewer` System object.

Example: `phased.ScenarioViewer`

**Introduced in R2016a**

# step

**System object:** `phased.ScenarioViewer`
**Package:** `phased`

Update scenario viewer display

## Syntax

```
step(sSV,radar_pos,tgt_pos)
step(sSV,radar_pos,tgt_pos,radar_velocity,tgt_velocity)
step(sSV,radar_pos,radar_laxes,tgt_pos,tgt_laxes)
step(sSV,radar_pos,radar_velocity,radar_laxes,tgt_pos,tgt_velocity,
tgt_laxes)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(sSV,radar_pos,tgt_pos)` updates the scenario viewer display with new radar positions, `radar_pos`, and target positions, `tgt_pos`. This syntax applies when `VelocityInputPort` and `OrientationInputPort` are set to `false`.

`step(sSV,radar_pos,tgt_pos,radar_velocity,tgt_velocity)` also specifies the radar velocity, `radar_velocity`, and target velocity, `tgt_velocity`. This syntax applies when `VelocityInputPort` is set to `true` and `OrientationInputPort` is set to `false`.

`step(sSV,radar_pos,radar_laxes,tgt_pos,tgt_laxes)` also specifies the radar orientation axes, `radar_laxes`, and the target orientation axes, `tgt_laxes`. This syntax applies when `VelocityInputPort` is set to `false` and `OrientationInputPort` is set to `true`.

`step(sSV,radar_pos,radar_velocity,radar_laxes,tgt_pos,tgt_velocity, tgt_laxes)` also specifies velocity and orientation axes when `VelocityInputPort` and `OrientationInputPort` are set to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### sSV — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a `phased.ScenarioViewer` System object.

Example: `phased.ScenarioViewer`

### radar_pos — Radar positions

real-valued 3-by-*N* matrix

Radar positions, specified as a real-valued 3-by-*N* matrix. *N* is the number of radar tracks and must be equal to or greater than one. Each column has the form `[x;y;z]`. Position units are in meters.

Example: `[100,250,75;0,20,49;300,5,120]`

Data Types: `double`

### tgt_pos — Target positions

real-valued 3-by-*M* matrix

Target positions, specified as a real-valued 3-by-*N* matrix. *M* is the number of target tracks and must be equal to or greater than one. Each column has the form `[x;y;z]`. Position units are in meters.

Example: `[200,40;10,40;305,15]`

Data Types: `double`

### `radar_velocity` — Radar velocities

real-valued 3-by-*N* matrix

Radar velocities, specified as a real-valued 3-by-*N* matrix. *N* is the number of radar tracks and must be equal to or greater than one. Each column has the form `[vx;vy;vz]`. The dimensions of `radar_velocity` must match the dimensions of `radar_pos`. Velocity units are in meters per second.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

### `tgt_velocity` — Target velocities

real-valued 3-by-*M* matrix

Target velocities, specified as a real-valued 3-by-*M* matrix. *M* is the number of target tracks and must be equal to or greater than one. Each column has the form `[vx;vy;vz]`. The dimensions of `tgt_velocity` must match the dimensions of `target_position`. Velocity units are in meters per second.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

### `radar_laxes` — Radar local coordinate axes

real-valued 3-by-3-by-*N* array

Local coordinate axes of radar, specified as a real-valued 3-by-3-by-*N* array. *N* is the number of radar tracks. Each page (third index) represents a 3-by-3 orthogonal matrix that specifies the local coordinate axes of one radar. The columns are the unit vectors that form the *x*, *y*, and *z* axes of the local coordinate system. Array units are dimensionless.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

### `tgt_laxes` — Target local coordinate axes

real-valued 3-by-3-by-*M* array

Local coordinate axes of target, specified as a real-valued 3-by-3-by-*M* array. *M* is the number of target tracks. Each page (third index) represents a 3-by-3 orthogonal matrix that specifies the local coordinate axes of one radar. The columns are the unit vectors that form the *x*, *y*, and *z* axes of the local coordinate system. Array units are dimensionless.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: double

## Examples

### View Tracks of Stationary Radar and One Target

Visualize the tracks of a radar and a single airplane target. The radar is stationary and the airplane is moving in a straight line. Maintain the radar beam pointing at the airplane.

Create the radar and airplane platform System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
radarPlatform = phased.Platform(...
    'InitialPosition',[0;0;10], ...
    'Velocity',[0;0;0]);
airplanePlatforms = phased.Platform(...
    'InitialPosition',[5000.0;3500.0;6000.0],...
    'Velocity',[-300;0;0]);
```

Create the phased.ScenarioViewer System object. Show the radar beam and annotate the tracks with position, speed, and altitude.

```
sSV = phased.ScenarioViewer('BeamRange',5000.0,'UpdateRate',updateRate,...
    'PlatformNames',{'Ground Radar','Airplane'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true);
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(radarPlatform,updateRate);
    [tgt_pos,tgt_vel] = step(airplanePlatforms,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    sSV.BeamSteering = ang;
    step(sSV,radar_pos,radar_vel,tgt_pos,tgt_vel);
    pause(0.1);
end
```

## View Tracks of Airborne Radar and Ground Target

Visualize the tracks of an airborne radar and a ground vehicle target. The airborne radar is carried by a drone flying at 5 km altitude.

Create the drone radar and ground vehicle using `phased.Platform` System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
drone = phased.Platform(...
    'InitialPosition',[100;1000;5000], ...
    'Velocity',[400;0;0]);
vehicle = phased.Platform('MotionModel','Acceleration',...
    'InitialPosition',[5000.0;3500.0;0.0],...
    'InitialVelocity',[40;5;0],'Acceleration',[0.1;0.1;0]);
```

Create the `phased.ScenarioViewer` System object?. Show the radar beam and annotate the tracks with position, speed, and, altitude.

```
viewer = phased.ScenarioViewer('BeamRange',8000.0,'BeamWidth',2,'UpdateRate',updateRate
    'PlatformNames',{'Drone Radar','Vehicle'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'Title','Vehicle Tracking Ra
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(drone,updateRate);
    [tgt_pos,tgt_vel] = step(vehicle,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    viewer.BeamSteering = ang;
    viewer(radar_pos,radar_vel,tgt_pos,tgt_vel)
    pause(.1)
end
```

### Visualize Multiplatform Scenario

This example shows how to create and display a multiplatform scenario containing a ground-based stationary radar, a turning airplane, a constant-velocity airplane, and a moving ground vehicle. The turning airplane follows a parabolic flight path while descending at a rate of 20 m/s.

Specify the scenario refresh rate at 0.5 Hz. For 150 steps, the time duration of the scenario is 300 s.

```
updateRate = 0.5;
N = 150;
```

Set up the turning airplane using the `Acceleration` model of the `phased.Platform` System object?. Specify the initial position of the airplane by range and azimuth from the ground-based radar and its elevation. The airplane is 10 km from the radar at 60? azimuth and has an altitude of 6 km. The airplane is accelerating at 10 $m/s^2$ in the negative *x*-direction.

```
airplane1range = 10.0e3;
airplane1Azimuth = 60.0;
airplane1alt = 6.0e3;
airplane1Pos0 = [cosd(airplane1Azimuth)*airplane1range;...
    sind(airplane1Azimuth)*airplane1range;airplane1alt];
airplane1Vel0 = [400.0;-100.0;-20];
airplane1Accel = [-10.0;0.0;0.0];
airplane1platform = phased.Platform('MotionModel','Acceleration',...
    'AccelerationSource','Input port','InitialPosition',airplane1Pos0,...
    'InitialVelocity',airplane1Vel0,'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',eye(3));
```

Set up the stationary ground radar at the origin of the global coordinate system. To simulate a rotating radar, change the ground radar beam steering angle in the processing loop.

```
groundRadarPos = [0,0,0]';
groundRadarVel = [0,0,0]';
groundradarplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundRadarPos,'Velocity',groundRadarVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the ground vehicle to move at a constant velocity.

```
groundVehiclePos = [5e3,2e3,0]';
groundVehicleVel = [50,50,0]';
groundvehicleplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundVehiclePos,'Velocity',groundVehicleVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the second airplane to also move at constant velocity.

```
airplane2Pos = [8.5e3,1e3,6000]';
airplane2Vel = [-300,100,20]';
airplane2platform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',airplane2Pos,'Velocity',airplane2Vel,...
    'InitialOrientationAxes',eye(3));
```

Set up the scenario viewer. Specify the radar as having a beam range of 8 km, a vertical beam width of 30?, and a horizontal beam width of 2?. Annotate the tracks with position, speed, altitude, and range.

```
BeamSteering = [0;50];
viewer = phased.ScenarioViewer('BeamRange',8.0e3,'BeamWidth',[2;30],'UpdateRate',update
    'PlatformNames',{'Ground Radar','Turning Airplane','Vehicle','Airplane 2'},'ShowPos
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'ShowRange',true,...
    'Title','Multiplatform Scenario','BeamSteering',BeamSteering);
```

Step through the display processing loop, updating radar and target positions. Rotate the ground-based radar steering angle by four degrees at each step.

```
for n = 1:N
    [groundRadarPos,groundRadarVel] = groundradarplatform(updateRate);
    [airplane1Pos,airplane1Vel,airplane1Axes] = airplane1platform(updateRate,airplane1A
    [vehiclePos,vehicleVel] = groundvehicleplatform(updateRate);
    [airplane2Pos,airplane2Vel] = airplane2platform(updateRate);
    viewer(groundRadarPos,groundRadarVel,[airplane1Pos,vehiclePos,airplane2Pos],...
        [airplane1Vel,vehicleVel,airplane2Vel]);
    BeamSteering = viewer.BeamSteering(1);
    BeamSteering = mod(BeamSteering + 4,360.0);
    if BeamSteering > 180.0
        BeamSteering = BeamSteering - 360.0;
    end
    viewer.BeamSteering(1) = BeamSteering;
    pause(0.2);
end
```

**Introduced in R2016a**

# phased.STAPSMIBeamformer

**Package:** `phased`

Sample matrix inversion (SMI) beamformer

## Description

The `SMIBeamformer` object implements a sample matrix inversion space-time adaptive beamformer. The beamformer works on the space-time covariance matrix.

To compute the space-time beamformed signal:

1. Define and set up your SMI beamformer. See “Construction” on page 1-2056.
2. Call `step` to execute the SMI beamformer algorithm according to the properties of `phased.STAPSMIBeamformer`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.STAPSMIBeamformer` creates a sample matrix inversion (SMI) beamformer System object, `H`. The object performs the SMI space-time adaptive processing (STAP) on the input data.

`H = phased.STAPSMIBeamformer(Name,Value)` creates an SMI object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `PRFSource`

Source of pulse repetition frequency

Source of the PRF values for the STAP processor, specified as `'Property'` or `'Input port'`. When you set this property to `'Property'`, the PRF is determined by the value of the `PRF` property. When you set this property to `'Input port'`, the PRF is determined by an input argument to the `step` method at execution time.

**Default:** `'Property'`

### PRF

Pulse repetition frequency

Pulse repetition frequency (PRF) of the received signal, specified as a positive scalar. Units are in Hertz. This property can be specified as single or double precision.

#### Dependencies

To enable this property, set the `PRFSource` property to `'Property'`.

**Default:** `1`

### DirectionSource

Source of targeting direction

Specify whether the targeting direction for the STAP processor comes from the `Direction` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Direction` property of this object specifies the targeting direction. |
| `'Input port'` | An input argument in each invocation of `step` specifies the targeting direction. |

**Default:** `'Property'`

### Direction

Targeting direction

Specify the targeting direction of the SMI processor as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). Azimuth angle should be between –180 and 180. Elevation angle should be between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`. You can specify this property as single or double precision.

**Default:** `[0; 0]`

### NumPhaseShifterBits

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed. You can specify this property as single or double precision.

**Default:** `0`

**`DopplerSource`**

Source of targeting Doppler

Specify whether the targeting Doppler for the STAP processor comes from the `Doppler` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Doppler` property of this object specifies the Doppler. |
| `'Input port'` | An input argument in each invocation of `step` specifies the Doppler. |

**Default:** `'Property'`

**`Doppler`**

Targeting Doppler frequency

Specify the targeting Doppler of the STAP processor as a scalar. This property applies when you set the `DopplerSource` property to `'Property'`. You can specify this property as single or double precision.

**Default:** `0`

**`NumGuardCells`**

Number of guarding cells

Specify the number of guard cells used in the training as an even integer. This property specifies the total number of cells on both sides of the cell under test. You can specify this property as single or double precision.

**Default:** `2`, indicating that there is one guard cell at both the front and back of the cell under test

### `NumTrainingCells`

Number of training cells

Specify the number of training cells used in the training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test. You can specify this property as single or double precision.

**Default:** `2`, indicating that there is one training cell at both the front and back of the cell under test

### `WeightsOutputPort`

Output processing weights

To obtain the weights used in the STAP processor, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the weights, set this property to `false`.

**Default:** `false`

## Methods

| | |
|---|---|
| step | Perform SMI STAP processing on input data |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Process Data Cube Using SMI

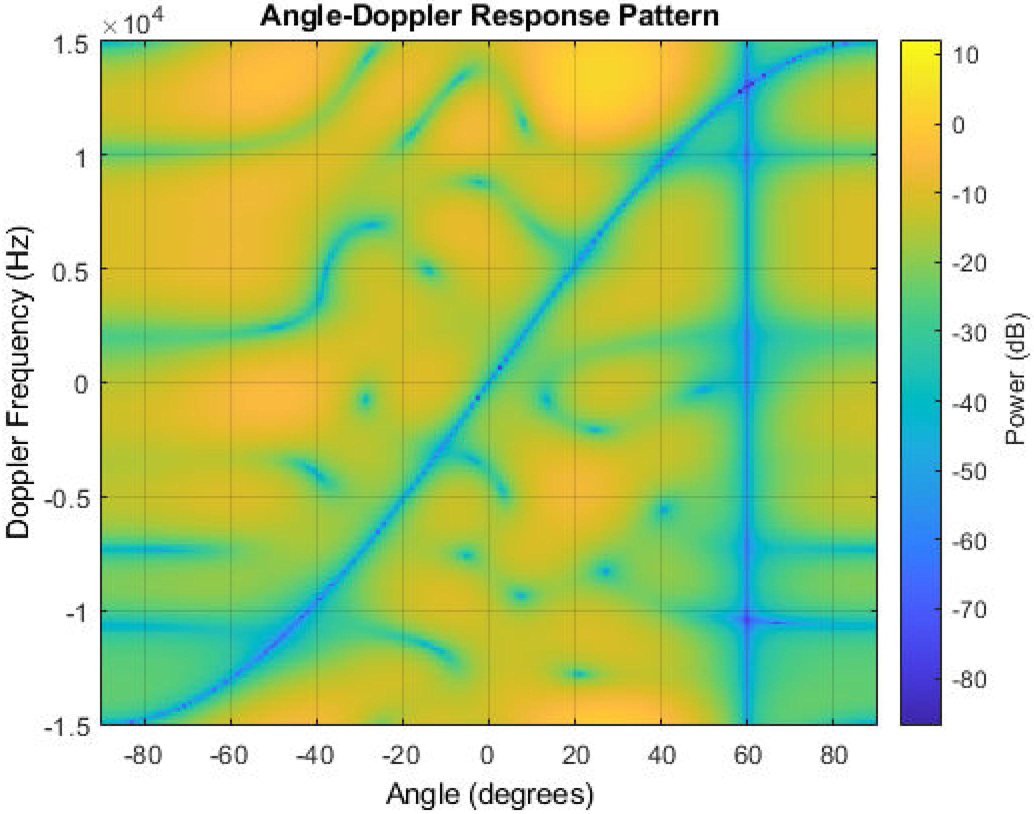
Process a data cube using an SMI beamformer. The weights are calculated for the 71st cell of a collected data cube pointing in the azimuth and elevation direction *(45°,-35°)* and with a Doppler of 12.980 kHz.

Load the cube data and create the SMI beamformer.

```
load STAPExampleData;
beamformer = phased.STAPSMIBeamformer('SensorArray',STAPEx_HArray, ...
    'PRF',STAPEx_PRF,'PropagationSpeed',STAPEx_PropagationSpeed, ...
    'OperatingFrequency',STAPEx_OperatingFrequency, ...
    'NumTrainingCells',100,'WeightsOutputPort',true, ...
    'DirectionSource','Input port','DopplerSource','Input port');
[y,w] = beamformer(STAPEx_ReceivePulse,71,[45;-35],12.980e3);
```

Plot the angle-doppler response.

```
response = phased.AngleDopplerResponse( ...
    'SensorArray',beamformer.SensorArray, ...
    'OperatingFrequency',beamformer.OperatingFrequency, ...
    'PRF',beamformer.PRF,'PropagationSpeed',beamformer.PropagationSpeed);
plotResponse(response,w)
```



## Algorithms

### Weight Computation

The optimum beamformer weights are

$$w = kR^{-1}v$$

where:

- $k$ is a scalar
- $R$ represents the space-time covariance matrix
- $v$ indicates the space-time steering vector

Because the space-time covariance matrix is unknown, you must estimate that matrix from the data. The sample matrix inversion (SMI) algorithm estimates the covariance matrix by designating a number of range gates to be training cells. Because you use the training cells to estimate the interference covariance, these cells should not contain target returns. To prevent target returns from contaminating the estimate of the interference covariance, you can specify insertion of a number of guard cells before and after the designated target cell.

To use the general algorithm for estimating the space-time covariance matrix:

1. Assume you have a M-by-N-by-K matrix. M represents the number of slow-time samples, and N is the number of array sensors. K is the number of training cells (range gates for training). Also assume that the number of training cells is an even integer and that you can designate K/2 training cells before and after the target range gate excluding the guard cells. Reshape the M-by-N-by-K matrix into a MN-by-K matrix by letting X denote the MN-by-K matrix.
2. Estimate the space-time covariance matrix as

   $$\frac{1}{K}XX^H$$
3. Invert the space-time covariance matrix estimate.
4. Obtain the beamforming weights by multiplying the sample space-time covariance matrix inverse by the space-time steering vector.

## Single Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

# step

**System object:** `phased.STAPSMIBeamformer`
**Package:** `phased`

Perform SMI STAP processing on input data

## Syntax

```
Y = step(H,X,CUTIDX)
Y = step(H,X,CUTIDX,PRF)
Y = step(H,X,CUTIDX,ANG)
Y = step(H,X,CUTIDX,DOP)
[Y,W] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,CUTIDX)` applies SMI processing to the input data, `X`. `X` must be a 3-dimensional *M*-by-*N*-by-*P* numeric array whose dimensions are (range, channels, pulses). The processing weights are calculated according to the range cell specified by `CUTIDX`. The targeting direction and the targeting Doppler are specified by `Direction` and `Doppler` properties, respectively. `Y` is a column vector of length *M*. This syntax is available when the `DirectionSource` property is `'Property'` and the `DopplerSource` property is `'Property'`.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Y = step(H,X,CUTIDX,PRF) uses PRF as the pulse repetition frequency. This syntax is available when the PRFSource property is 'Input port'.

Y = step(H,X,CUTIDX,ANG) uses ANG as the targeting direction. This syntax is available when the DirectionSource property is 'Input port'. ANG must be a 2-by-1 vector in the form of [AzimuthAngle; ElevationAngle] (in degrees). The azimuth angle must be between –180 and 180. The elevation angle must be between –90 and 90.

Y = step(H,X,CUTIDX,DOP) uses DOP as the targeting Doppler frequency (in hertz). This syntax is available when the DopplerSource property is 'Input port'. DOP must be a scalar.

You can combine optional input arguments when their enabling properties are set: Y = step(H,X,CUTIDX,ANG,DOP)

[Y,W] = step( ___ ) returns the additional output, W, as the processing weights. This syntax is available when the WeightsOutputPort property is true. W is a column vector of length *N*P*.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Examples

### Process Data Cube Using SMI

Process a data cube using an SMI beamformer. The weights are calculated for the 71st cell of a collected data cube pointing in the azimuth and elevation direction *(45°,-35°)* and with a Doppler of 12.980 kHz.

Load the cube data and create the SMI beamformer.

```
load STAPExampleData;
beamformer = phased.STAPSMIBeamformer('SensorArray',STAPEx_HArray, ...
    'PRF',STAPEx_PRF,'PropagationSpeed',STAPEx_PropagationSpeed, ...
    'OperatingFrequency',STAPEx_OperatingFrequency, ...
    'NumTrainingCells',100,'WeightsOutputPort',true, ...
    'DirectionSource','Input port','DopplerSource','Input port');
[y,w] = beamformer(STAPEx_ReceivePulse,71,[45;-35],12.980e3);
```

# phased.ShortDipoleAntennaElement

**Package:** `phased`

Short-dipole antenna element

## Description

The `phased.ShortDipoleAntennaElement` object models a short-dipole antenna element. A short-dipole antenna is a center-fed wire whose length is much shorter than one wavelength. This antenna object only supports polarized fields.

To compute the response of the antenna element for specified directions:

1. Define and set up your short-dipole antenna element. See “Construction” on page 1-2069 .
2. Call `step` to compute the antenna response according to the properties of `phased.ShortDipoleAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`h = phased.ShortDipoleAntennaElement` creates the system object, `h`, to model a short-dipole antenna element.

`h = phased.ShortDipoleAntennaElement(Name,Value)` creates the system object, `h`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `FrequencyRange`

Antenna operating frequency range

Antenna operating frequency range specified as a 1-by-2 row vector in the form of `[LowerBound HigherBound]`. This vector defines the frequency range over which the antenna has a response. The antenna element has zero response outside this specified frequency range.

**Default:** `[0 1e20]`

### `AxisDirection`

Dipole axis direction

Dipole axis direction, specified as one of `'X'`, `'Y'`, `'Z'`, or `'Custom'`. The dipole axis defines the direction of the dipole current with respect to the local coordinate system. `'X'` specifies a dipole along the *x*-axis, `'Y'` specifies a dipole along the *y*-axis, and `'Z'` specifies a dipole along the *z*-axis. An *x*-axis or *y*-axis direction is equivalent to a horizontal dipole and a *z*-axis direction is equivalent to a vertical dipole. When you set the `AxisDirection` property to `'Custom'`, you can specify the dipole axis using the `CustomAxisDirection` property.

**Default:** `'Z'`

### `CustomAxisDirection`

Custom dipole axis direction

Custom axis direction of the dipole antenna, specified as a real-valued 3-element column vector. Each entry in the vector represents the component of the dipole axis along the *x*, *y*, and *z* axes in the local coordinate system. To enable this property, set the `AxisDirection` property to `'Custom'`.

**Default:** `[0;0;1]`

## Methods

| | |

## Examples

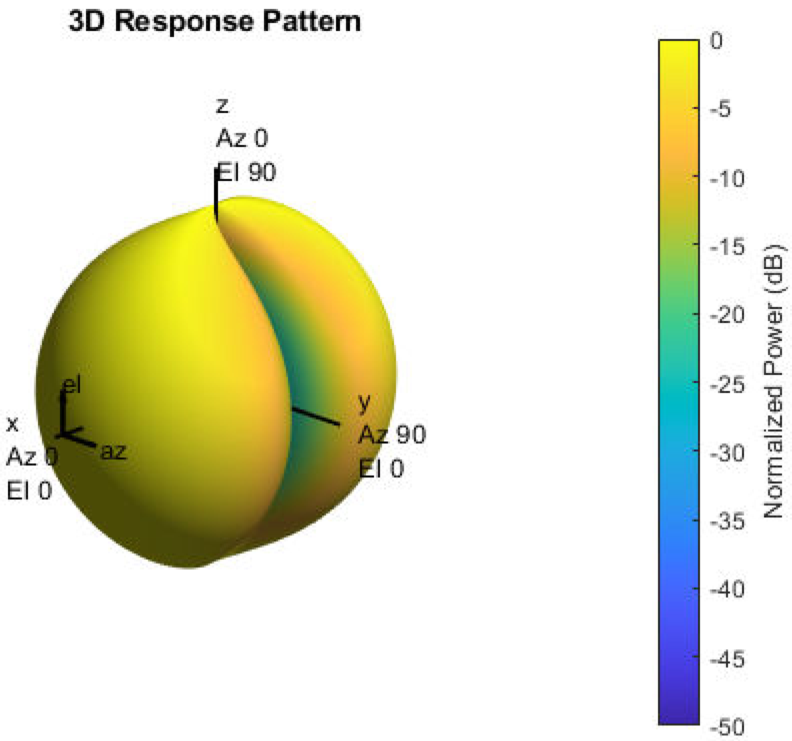
### Short-Dipole Antenna Aligned Along the Y-Axis

Specify a short-dipole antenna with the dipole oriented along the *y*-axis and operating at 250 MHz. Then, plot the 3-D responses for both the horizontal and vertical polarizations.

```
antenna = phased.ShortDipoleAntennaElement( ...
    'FrequencyRange',[100e6,600e6],'AxisDirection','Y');
fc = 250.0e6;
```

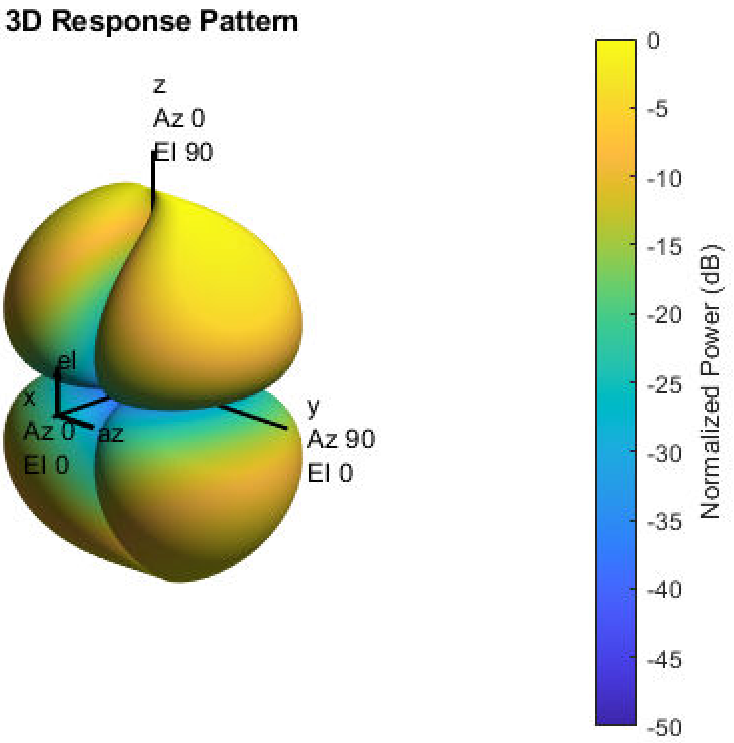
Plot the horizontal polarization response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Polarization','H');
```



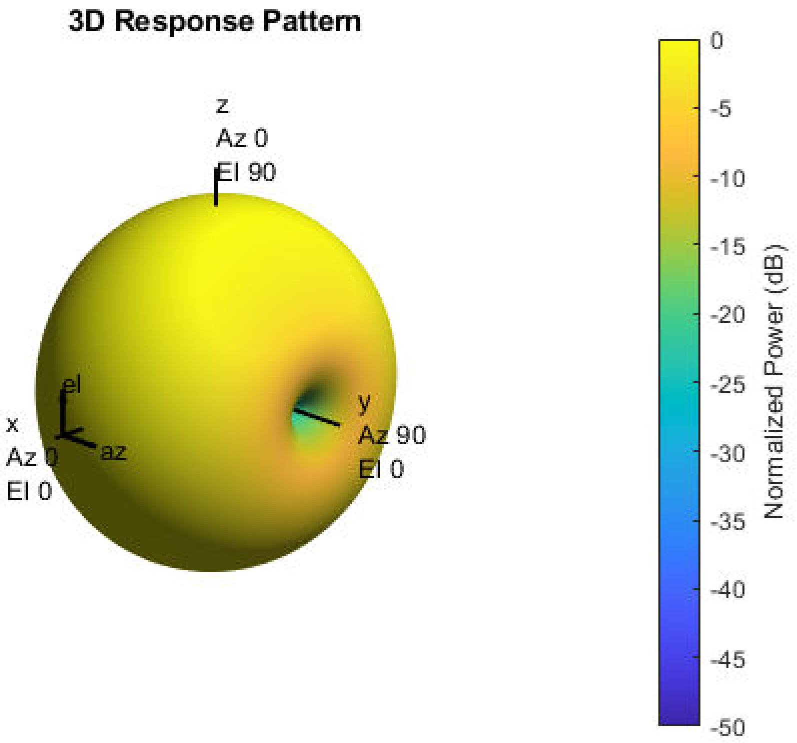
Plot the vertical polarization response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Polarization','V');
```



Plot the combined response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar',...
    'Type','powerdb','Polarization','C');
```



### Short-Dipole Antenna Aligned Along Arbitrary Axis

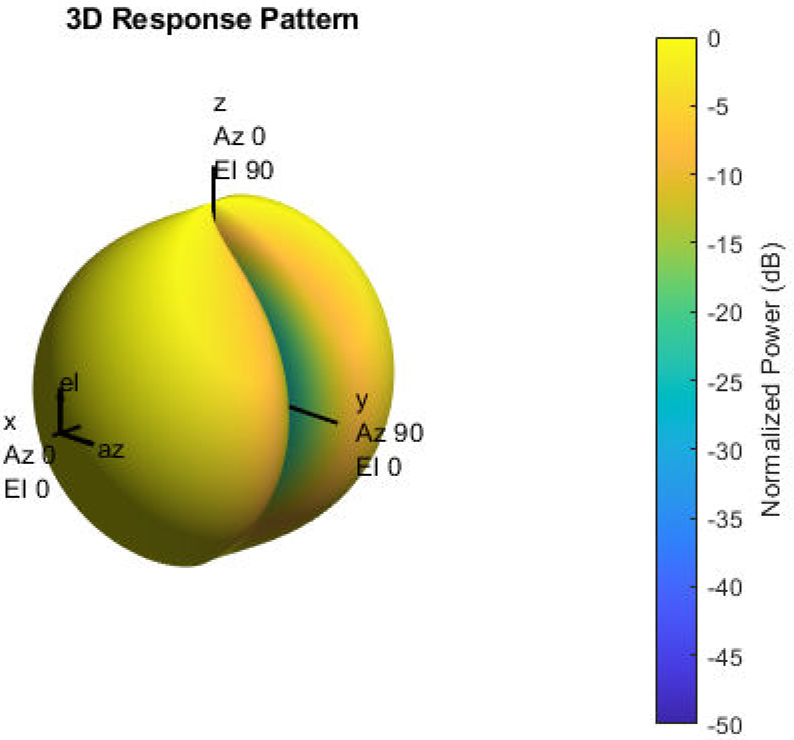
Specify a short-dipole antenna with the dipole oriented along a custom axis and operating at 250 MHz. Then, plot the 3-D responses for both the horizontal and vertical polarizations.

Create the short-dipole antenna element System object™. An easy way to create a custom axis is to rotate a unit vector using rotation functions.

```
v = rotx(30)*rotz(45)*[0;0;1];
antenna = phased.ShortDipoleAntennaElement( ...
    'FrequencyRange',[100e6,600e6],'AxisDirection','Custom', ...
    'CustomAxisDirection',v);
```

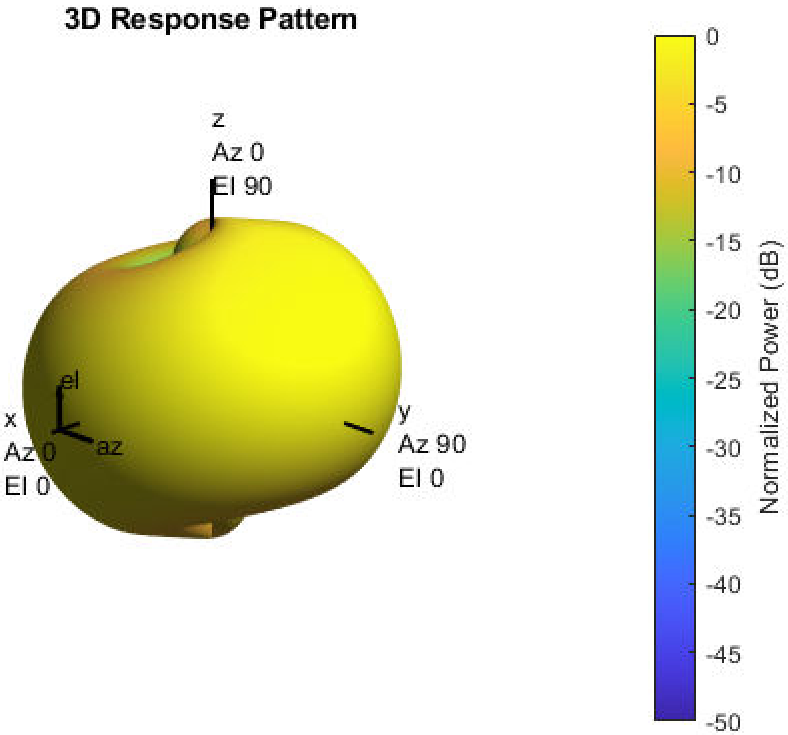
Plot the horizontal polarization response.

```
fc = 250.0e6;
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Polarization','H');
```



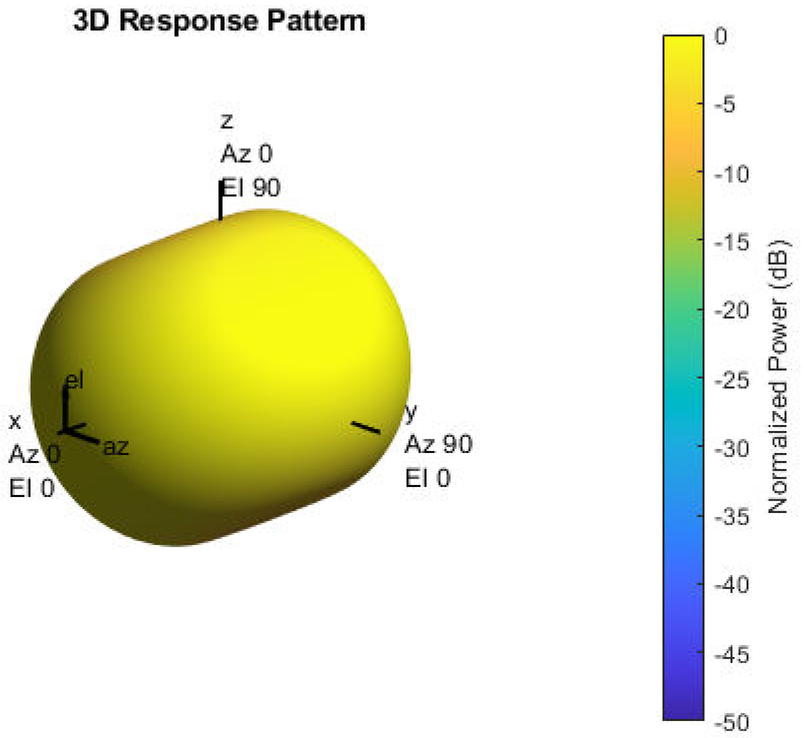
Plot the vertical polarization response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Polarization','V');
```



Plot the combined response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Polarization','C');
```



# Algorithms

The total response of a short-dipole antenna element is a combination of its frequency response and spatial response. This System object calculates both responses using nearest neighbor interpolation and then multiplies the responses to form the total response.

# directivity

**System object:** `phased.ShortDipoleAntennaElement`
**Package:** `phased`

Directivity of short-dipole antenna element

## Syntax

```
D = directivity(H,FREQ,ANGLE)
```

## Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-2082 of a short-dipole antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

## Input Arguments

### `H` — Short-dipole antenna element

System object

Short-dipole antenna element specified as a `phased.ShortDipoleAntennaElement` System object.

Example: `H = phased.ShortDipoleAntennaElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

### `D` — Directivity

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Short-Dipole Antenna Element

Compute the directivity of a z-directed short-dipole antenna element as a function of elevation.

Create the crossed-dipole antenna element system object.

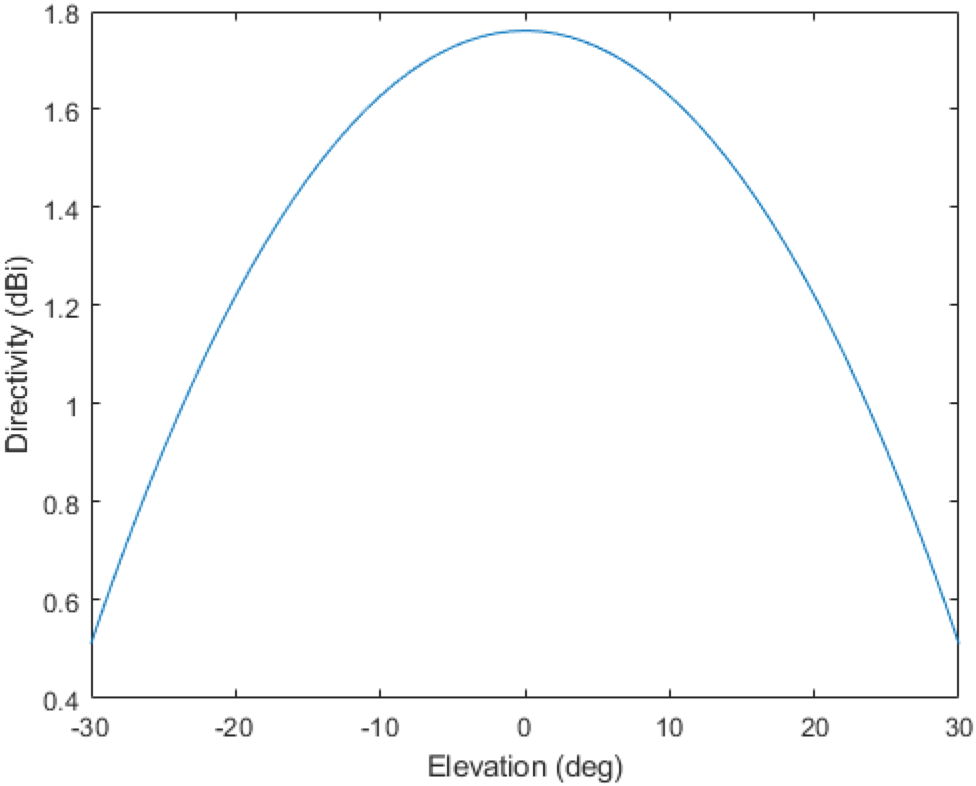
```
myAnt = phased.ShortDipoleAntennaElement;
myAnt.AxisDirection = 'Z';
myAnt.FrequencyRange = [0,10e9];
```

Select the desired angles of interest to be at constant azimuth angle at zero degrees. Set the elevation angles to center around boresight (zero degrees azimuth and zero degrees elevation). Set the frequency to 1 GHz.

```
elev = [-30:30];
azm = zeros(size(elev));
ang = [azm;elev];
freq = 1e9;
```

Plot the directivity along the constant azimuth cut.

```
d = directivity(myAnt,freq,ang);
plot(elev,d)
xlabel('Elevation (deg)');
ylabel('Directivity (dBi)');
```



# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** `phased.ShortDipoleAntennaElement`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the `phased.ShortDipoleAntennaElement` antenna element supports polarization or not. An antenna element supports polarization if it can create or respond to polarized fields. The `phased.ShortDipoleAntennaElement` object always supports polarization.

## Input Arguments

### h — Short-dipole antenna element

Short-dipole antenna element specified as a `phased.ShortDipoleAntennaElement` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. Because the short-dipole antenna element supports polarization, the returned value is always `true`.

# Examples

### Short-Dipole Antenna Supports Polarization

Show that a `phased.ShortDipoleAntennaElement` antenna supports polarization.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
isPolarizationCapable(antenna)
```

```
ans = logical
   1
```

The returned value of 1 shows that this antenna supports polarization.

# pattern

**System object:** `phased.ShortDipoleAntennaElement`
**Package:** `phased`

Plot short-dipole antenna element directivity and patterns

## Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-2095 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sElem` — Short-dipole antenna element

System object

Short-dipole antenna element, specified as a `phased.ShortDipoleAntennaElement` System object.

Example: `sElem = phased.ShortDipoleAntennaElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Normalize` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize`' and a Boolean. Set this parameter to `true` to display a normalized pattern. This parameter does not apply when you set `'Type'` to `'directivity'`. Directivity patterns are already normalized.

Data Types: `logical`

### `PlotStyle` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Data Types: `char`

### `Polarization` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the

sensors are polarization-capable and when the 'Type' parameter is not set to 'directivity'. This table shows the meaning of the display options.

| 'Polarization' | Display |
|---|---|
| 'combined' | Combined *H* and *V* polarization components |
| 'H' | *H* polarization component |
| 'V' | *V* polarization component |

Example: 'V'

Data Types: char

## Output Arguments

**PAT — Element pattern**
*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

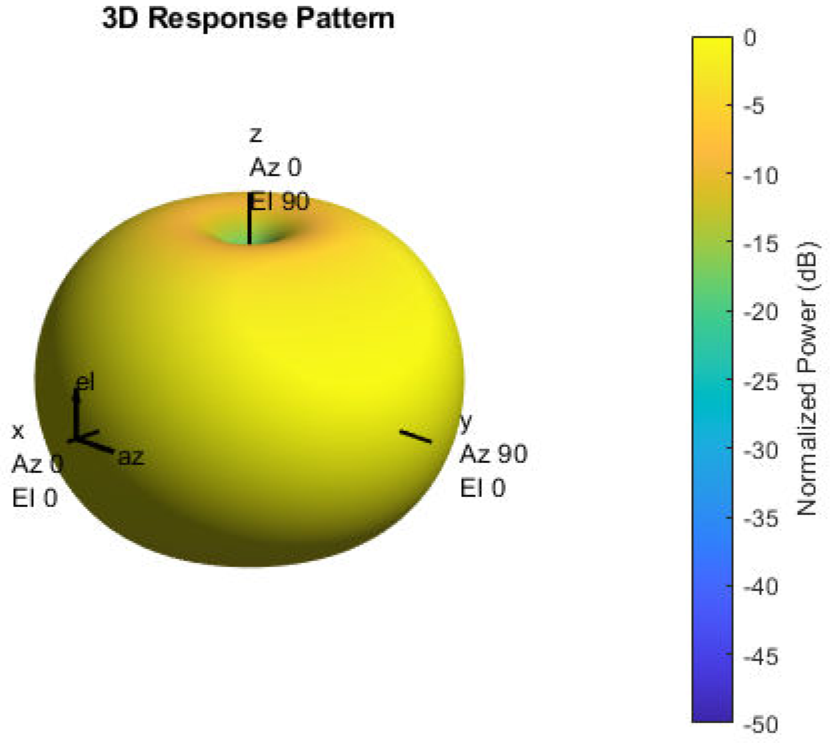
### Pattern of Short-Dipole Antenna Oriented Along the Z-Axis

Specify a short-dipole antenna element with its dipole axis pointing along the z-axis. To do so, set the 'AxisDirection' value to 'Z'.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Z');
```

Plot the antenna's vertical polarization power pattern at 200 MHz as a 3-D polar plot.

```
fc = 200e6;
pattern(sSD,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','V')
```



As the above figure shows, the antenna pattern is that of a vertically-oriented dipole and has its maximum at the equator and nulls at the poles.

### Short-Dipole Antenna Element Pattern Over Selected Range

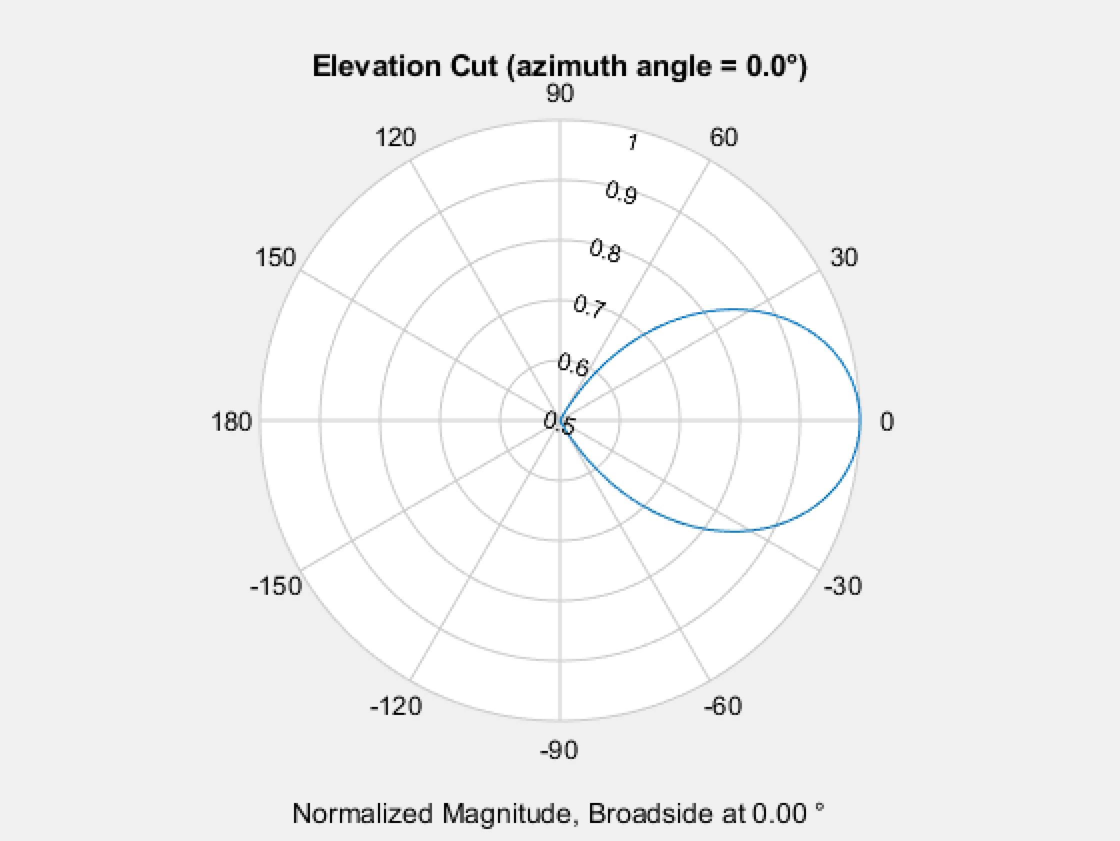
Specify a short-dipole antenna element with its dipole axis pointing along the z-axis. Then, plot the magnitude pattern over a selected range of angles. The antenna operating frequency spans the range 100 to 900 MHz.

To construct a z-directed short-dipole antenna, set the `'AxisDirection'` value to `'Z'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,...
    'AxisDirection','Z');
```

Plot the antenna's vertical polarization response at 200 MHz as an elevation cut at zero degrees azimuth angle. Restrict the plot from -60 to 60 degrees elevation in 0.1 degree increments.

```
fc = 200e6;
pattern(sSD,fc,0,[-60:0.1:60],...
    'CoordinateSystem','polar',...
    'Type','efield',...
    'Polarization','V')
```



### Short-Dipole Antenna Element Directivity

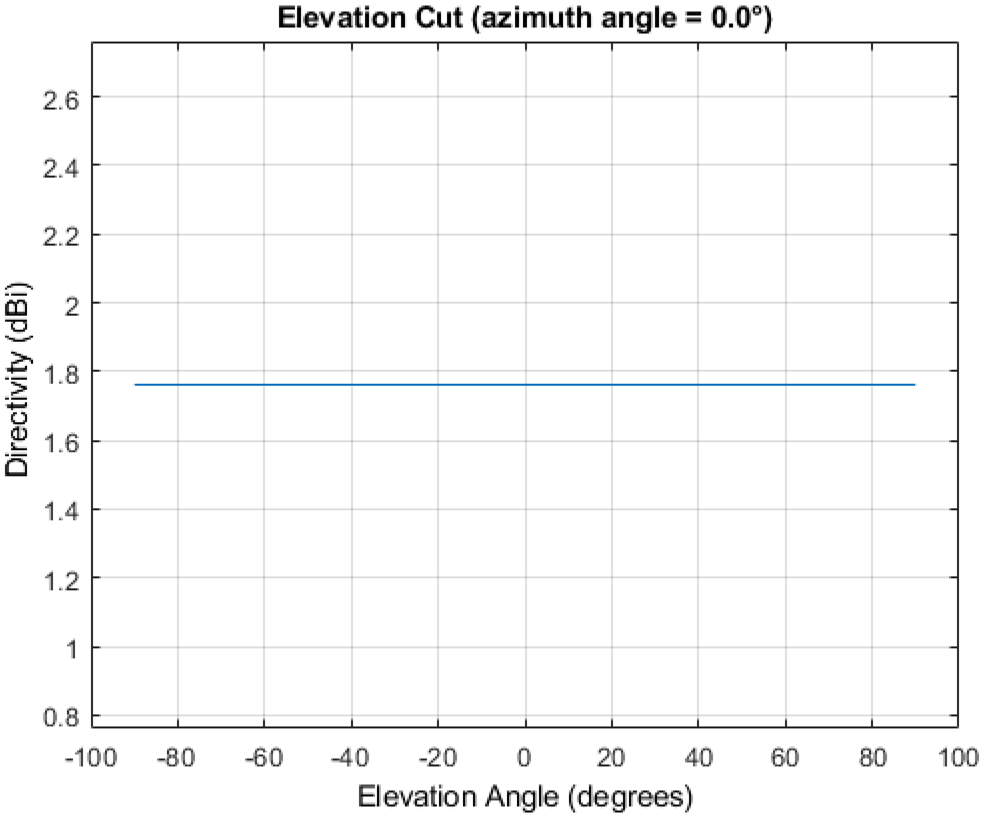
Specify a short-dipole antenna element with its dipole axis pointing along the y-axis. Then, plot the directivity. The antenna operating frequency spans the range 100 to 900 MHz.

Construct a y-directed short-dipole antenna by setting the `'AxisDirection'` value to `'Y'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,...
    'AxisDirection','Y');
```

Plot the antenna's directivity at 500 MHz as an elevation cut at zero degrees azimuth angle.

```
fc = 500e6;
pattern(sSD,fc,0,[-90:90],...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

## See Also

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** `phased.ShortDipoleAntennaElement`
**Package:** `phased`

Plot short-dipole antenna element directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

### `sElem` — Short-dipole antenna element

System object

Short-dipole antenna element, specified as a `phased.ShortDipoleAntennaElement` System object.

Example: `sElem = phased.ShortDipoleAntennaElement;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Azimuth` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

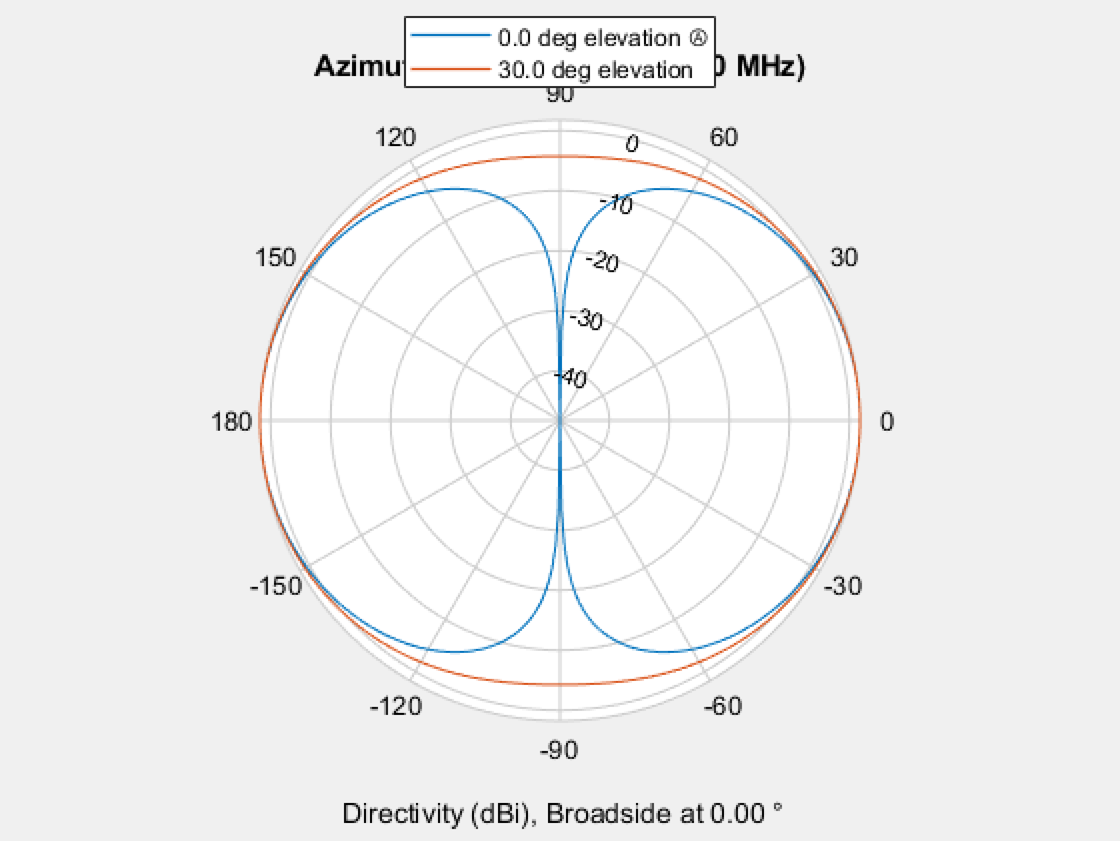
## Examples

### Azimuth Directivity of Short-Dipole Antenna Element at Two Elevations

Specify a short-dipole antenna element having a direction along the y-axis. Then, plot an azimuth cut of the directivity at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

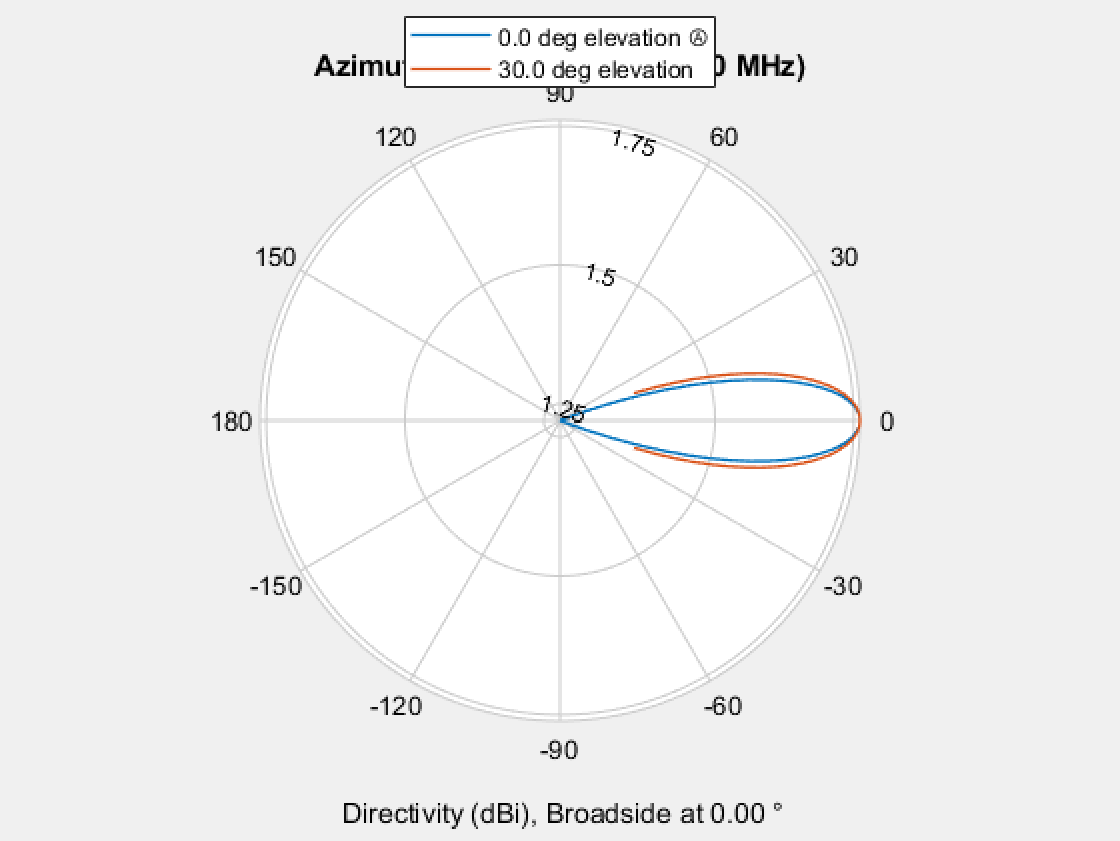
Create the antenna element.

```
fc = 500e6;
sSD = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6,...
    'AxisDirection','y');
patternAzimuth(sSD,fc,[0 30])
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
patternAzimuth(sSD,fc,[0 30],'Azimuth',[-20:20])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternElevation`

**Introduced in R2015a**

# patternElevation

**System object:** phased.ShortDipoleAntennaElement
**Package:** phased

Plot short-dipole antenna element directivity or pattern versus elevation

## Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(sElem,FREQ) plots the 2-D element directivity pattern versus elevation (in dBi) for the element sElem at zero degrees azimuth angle. The argument FREQ specifies the operating frequency.

patternElevation(sElem,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(sElem,FREQ,AZ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**sElem — Short-dipole antenna element**
System object

Short-dipole antenna element, specified as a `phased.ShortDipoleAntennaElement` System object.

Example: `sElem = phased.ShortDipoleAntennaElement;`

**`FREQ` — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**`AZ` — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

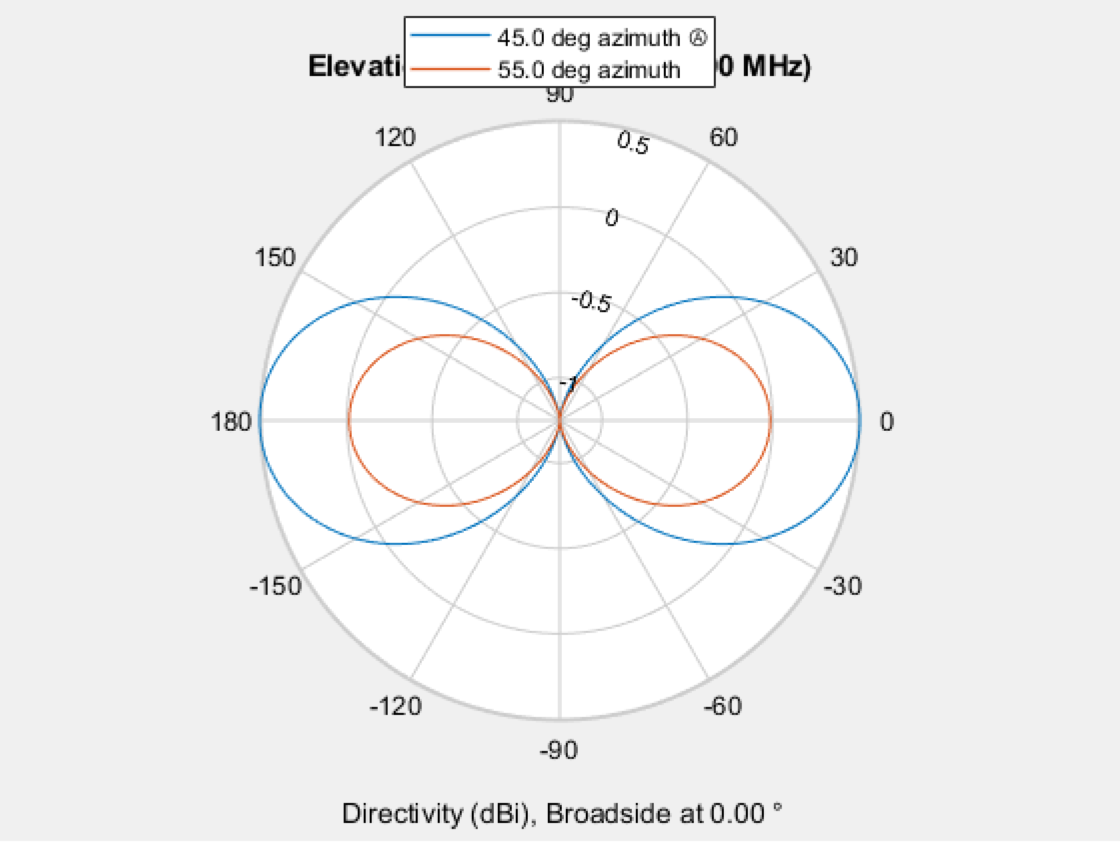
Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Plot Elevation Pattern of Crossed-Dipole Antenna Element

Plot the elevation directivity pattern of a crossed-dipole antenna at two different azimuths: 45° and 55°. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
patternElevation(sCD,fc,[45 55])
```



Plot a reduced range of elevation angles using the `Elevation` parameter. Notice the change in scale.

```
patternElevation(sCD,fc,[45 55],'Elevation',-20:20)
```

# plotResponse

**System object:** `phased.ShortDipoleAntennaElement`
**Package:** `phased`

Plot response pattern of antenna

## Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Element System object

**`FREQ`**

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CutAngle`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

### `Format`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

### `NormalizeResponse`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### `OverlayFreq`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the antenna response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| db | power pattern in dB scale |
| mag | field pattern |
| pow | power pattern |
| dbi | directivity |

**Default:** 'db'

### AzimuthAngles

Azimuth angles for plotting element response, specified as a row vector. The AzimuthAngles parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'Az' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the AzimuthAngles and ElevationAngles parameters simultaneously.

**Default:** [-180:180]

### ElevationAngles

Elevation angles for plotting element response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

### UGrid

*U* coordinate values for plotting element response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

### VGrid

*V* coordinate values for plotting element response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid

should be between –1 and 1 and should be specified in nondecreasing order. You can set the VGrid and UGrid parameters simultaneously.

**Default:** [-1:0.01:1]

## Examples

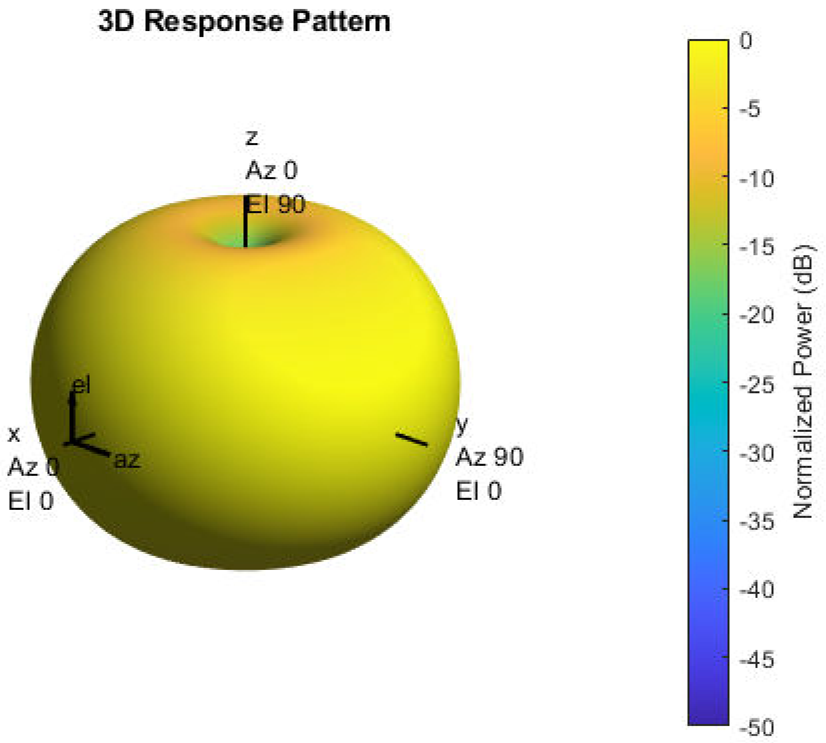
### Response of Short-Dipole Antenna Oriented Along the Z-Axis

Specify a short-dipole antenna element with its dipole axis pointing along the z-axis. To do so, set the 'AxisDirection' value to 'Z'.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Z');
```

Plot the antenna's vertical polarization response at 200 MHz as a 3-D polar plot.

```
fc = 200e6;
plotResponse(sSD,fc,'Format','Polar',...
    'RespCut','3D','Polarization','V');
```



As the above figure shows, the antenna pattern is that of a vertically-oriented dipole and has its maximum at the equator and nulls at the poles.

### Plot Short-Dipole Antenna Element Response Over Selected Range

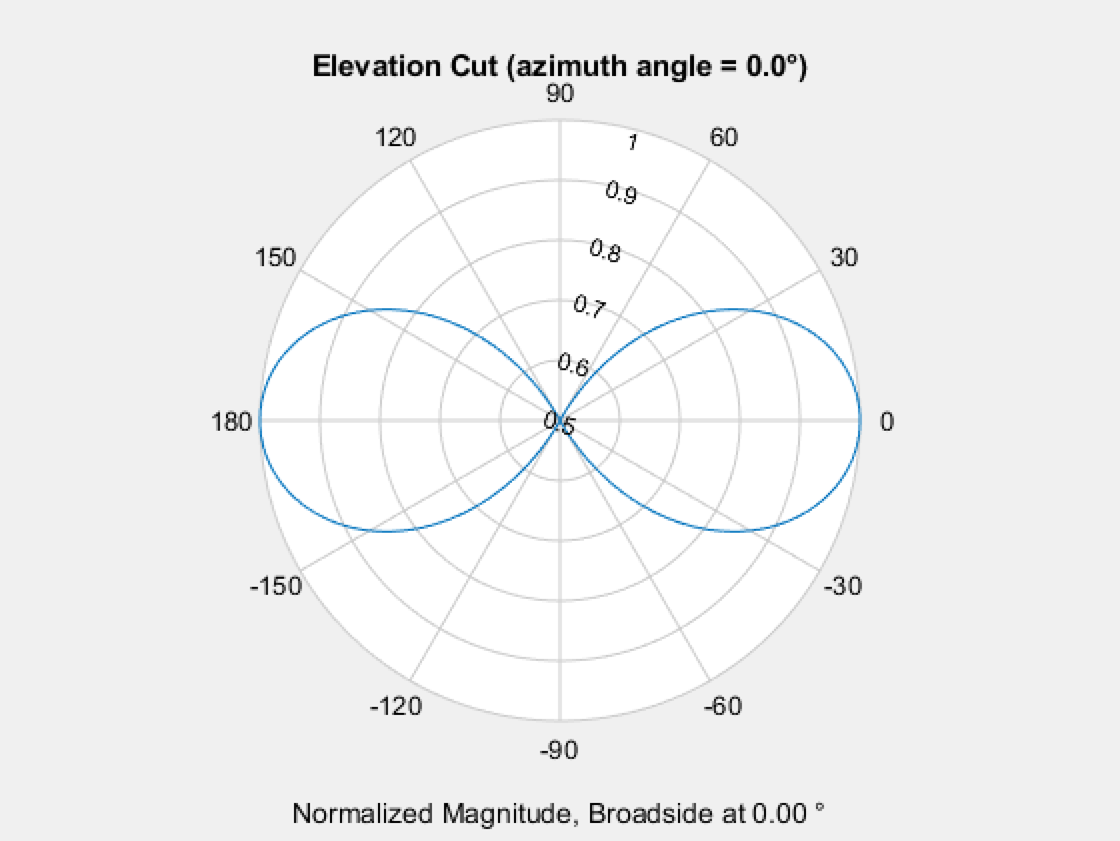
This example shows how to construct a short-dipole antenna element with its dipole axis pointing along the z-axis and how to plot the response over a selected range of angles. The antenna operating frequency spans the range 100 to 900 MHz.

To construct a z-directed short-dipole antenna, set the `'AxisDirection'` value to `'Z'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Z');
```

Plot the antenna's vertical polarization response at 200 MHz as an elevation cut at a fixed azimuth angle. Use the 'ElevationAngles' property to restrict the plot from -60 to 60 degrees elevation in 0.1 degree increments.

```
plotResponse(sSD,200e6,'Format','Polar',...
    'RespCut','El','Polarization','V',...
    'ElevationAngles',[-60:0.1:60],'Unit','mag');
```



### Plot Short-Dipole Antenna Element Directivity

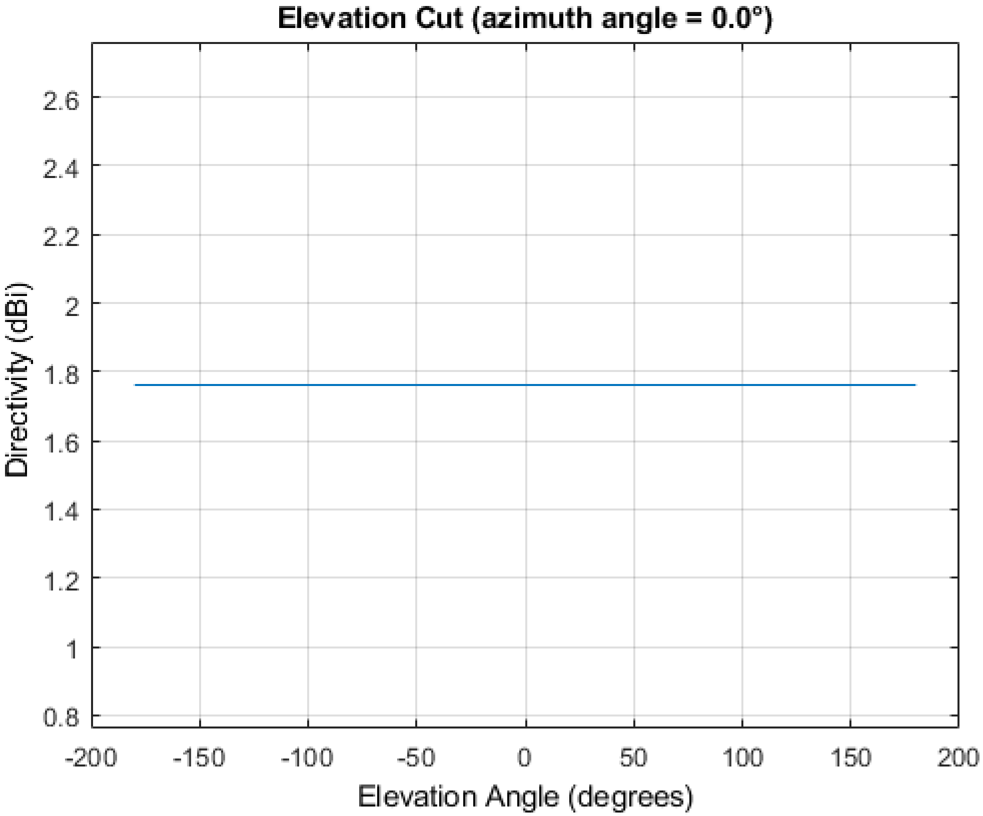
This example shows how to construct a short-dipole antenna element with its dipole axis pointing along the y-axis and how to plot the directivity. The antenna operating frequency spans the range 100 to 900 MHz.

To construct a y-directed short-dipole antenna, set the `'AxisDirection'` value to `'Y'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Y');
```

Plot the antenna's directivity at 500 MHz as an elevation cut at a fixed azimuth angle.

```
plotResponse(sSD,500e6,'Format','Line',...
    'RespCut','El','Unit','dbi');
```



## See Also

# step

**System object:** `phased.ShortDipoleAntennaElement`
**Package:** `phased`

Output response of antenna element

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna’s voltage response, `RESP`, at the operating frequencies specified in `FREQ` and in the directions specified in `ANG`. For the short-dipole antenna element object, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`, representing the horizontal and vertical polarization components of the antenna's response. Each field is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# Input Arguments

### H

Antenna element object.

### FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

### ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

# Output Arguments

### RESP

Voltage response of antenna element returned as a MATLAB struct with fields RESP.H and RESP.V. Both RESP.H and RESP.V contain responses for the horizontal and vertical polarization components of the antenna radiation pattern. Both RESP.H and RESP.V are *M*-by-*L* matrices. In these matrices, *M* represents the number of angles specified in ANG, and *L* represents the number of frequencies specified in FREQ.

# Examples

### Response of Short-Dipole Antenna

Find the response of a short-dipole antenna element at boresight, (0°,0°), and off boresight, (30°,0°). The antenna operates at 256 MHz.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Y');
ang = [0 30;0 0];
fc = 250e6;
resp = antenna(fc,ang)
```

```
resp = struct with fields:
    H: [2x1 double]
    V: [2x1 double]
```

Horizontal response.

```
disp(resp.H)
```

```
   -1.2247
   -1.0607
```

Vertical response.

```
disp(resp.V)
```

```
     0
     0
```

## Algorithms

The total response of a short-dipole antenna element is a combination of its frequency response and spatial response. This System object calculates both responses using nearest neighbor interpolation and then multiplies the responses to form the total response.

# phased.ScatteringMIMOChannel

**Package:** `phased`

Scattering MIMO channel

## Description

The `phased.ScatteringMIMOChannel` System object models a multipath propagation channel in which radiated signals from a transmitting array are reflected from multiple scatterers back toward a receiving array. In this channel, propagation paths are line of sight from point to point. The object models range-dependent time delay, gain, Doppler shift, phase change, and atmospheric loss due to gases, rain, fog, and clouds.

The attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range from 1 through 1000 GHz. The attenuation model for fog and clouds is valid from 10 through 1000 GHz. Outside of these frequency ranges, the object uses the nearest valid value.

To compute the multipath propagation for specified source and receiver points:

1. Define and set up your scattering MIMO channel using the "Construction" on page 1-2126 procedure. You can set the System object properties during construction or leave them at their default values.
2. Call the `step` method to compute the propagated signals using the properties of the `phased.ScatteringMIMOChannel` System object. You can change tunable properties before or after any call to the `step` method.

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`channel = phased.ScatteringMIMOChannel` creates a scattering MIMO propagation channel System object, `channel`.

`channel = phased.ScatteringMIMOChannel(Name,Value)` creates a System object, `channel`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `TransmitArray` — Transmitting array

`phased.ULA` (default) | Phased Array System Toolbox antenna array System object

Transmitting array, specified as a Phased Array System Toolbox antenna array System object. The default value for this property is a `phased.ULA` array with its default property values.

Example: `phased.URA`

### `ReceiveArray` — Receiving array

`phased.ULA` (default) | Phased Array System Toolbox antenna array System object

Receiving array, specified as a Phased Array System Toolbox antenna array System object. The default value for this property is a `phased.ULA` array with its default property values.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `CarrierFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `100e6`

Data Types: `double`

### `Polarization` — Polarization configuration

`'None'` (default) | `'Combined'` | `'Dual'`

Polarization configuration, specified as `'None'`, `'Combined'`, or `'Dual'`. When you set this property to `'None'`, the output field is considered a scalar field. When you set this property to `'Combined'`, the radiated fields are polarized and are interpreted as a single signal in the sensor's inherent polarization. When you set this property to `'Dual'`, the *H* and *V* polarization components of the radiated field are independent signals.

Example: `'Dual'`

Data Types: `char`

### `SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

### `Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

Example: `7.4`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

#### `SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

#### `SimulateDirectPath` — Enable propagation along direct path

`false` (default) | `true`

Option to enable signal propagation along the direct path, specified as `false` or `true`. The direct path is a line-of-sight path from the transmitting array to the receiving array with no scattering.

Data Types: `logical`

#### `ChannelResponseOutputPort` — Enable output of channel response

`false` (default) | `true`

Option to enable output of channel response, specified as `false` or `true`. Set this property to `true`to output the channel response and time delay by using the `chmatrix` and `tau` output arguments of the `step` method.

Data Types: `logical`

#### `MaximumDelaySource` — Source of maximum delay

`'Auto'` (default) | `'Property'`

Source of the maximum delay value, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the channel automatically allocates enough memory to simulate the propagation delay. When you set this property to `'Property'`, you can specify the maximum delay by using the `MaximumDelay` property. Signals arriving after the maximum delay are ignored.

#### `MaximumDelay` — Maximum signal delay

`10e-6` (default) | positive scalar

Maximum signal delay, specified as a positive scalar. Delays greater than this value are ignored. Units are in seconds.

**Dependencies**

To enable this property, set the `MaximumDelaySource` property to `'Property'`.

Data Types: `double`

### `TransmitArrayMotionSource` — Source of transmitting array motion parameters

`'Property'` (default) | `'Input port'`

Source of the transmitting array motion parameters, specified as `'Property'` or `'Input port'`.

- When you set this property to `'Property'`, the transmitting array is stationary. Then, you can specify the location and orientation of the array using the `TransmitArrayPosition` and `TransmitArrayOrientationAxes` properties.
- When you set this property to `'Input port'`, specify the transmitting array location, velocity, and orientation by using the `txpos`, `txvel`, and `txaxes` input arguments of the `step` method.

Data Types: `char`

### `TransmitArrayPosition` — Position of transmitting array phase center

`[0;0;0]` (default) | real-valued three-element vector

Position of the transmitting array phase center, specified as a real-valued three-element vector in Cartesian form, `[x;y;z]`, with respect to the global coordinate system. Units are in meters.

Example: `[1000;-200;55]`

**Dependencies**

To enable this property, set the `TransmitArrayMotionSource` property to `'Property'`.

Data Types: `double`

### `TransmitArrayOrientationAxes` — Orientation of transmitting array

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

Orientation of transmitting array, specified as a real-valued 3-by-3 orthonormal matrix. The matrix specifies the three axes, *(x,y,z)*, that define the local coordinate system of the array with respect to the global coordinate system. Matrix columns correspond to the axes of the local array coordinate system.

Example: `rotz(45)`

**Dependencies**

To enable this property, set the `TransmitArrayMotionSource` property to `'Property'`.

Data Types: `double`

### `ReceiveArrayMotionSource` — Source of receiving array motion parameters

`'Property'` (default) | `'Input port'`

Source of the receiving array motion parameters, specified as `'Property'` or `'Input port'`.

- When you set this property to `'Property'`, the receiving array is stationary. Then, you can specify the location and orientation of the array by using the `ReceiveArrayPosition` and `ReceiveArrayOrientationAxes` properties.
- When you set this property to `'Input port'`, you can specify the receiving array location, velocity, and orientation by using the `rxpos`, `rxvel`, and `rxaxes` input arguments of the `step` method.

Data Types: `char`

### `ReceiveArrayPosition` — Position of receiving array

`[0;0;0]` (default) | real-valued three-element vector

Position of the receiving array phase center, specified as a real-valued three-element vector in Cartesian form,`[x;y;z]`, with respect to the global coordinate system. Units are in meters.

Example: `[1000;-200;55]`

**Dependencies**

To enable this property, set the `ReceiveArrayMotionSource` property to `'Property'`.

Data Types: `double`

### `ReceiveArrayOrientationAxes` — Orientation of receiving array

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

Orientation of receiving array, specified as a real-valued 3-by-3 orthonormal matrix. The matrix specifies the three axes, *(x,y,z)*, that define the local coordinate system of the array with respect to the global coordinate system. Matrix columns correspond to the axes of the local array coordinate system.

Example: `roty(60)`

**Dependencies**

To enable this property, set the `ReceiveArrayMotionSource` property to `'Property'`.

Data Types: `double`

### `ScattererSpecificationSource` — Source of scatterer parameters

`'Auto'` (default) | `'Property'` | `'Input port'`

Source of scatterer parameters, specified as `'Auto'`, `'Property'`, `'Input port'`.

- When you set this property to `'Auto'`, all scatterer positions and coefficients are randomly generated. Scatterer velocities are zero. The generated positions are contained within the region defined by the `ScattererPositionBoundary`. To set the number of scatterers, use the `NumScatterers` property.
- When you set this property to `'Property'`, you can set the scatterer positions by using the `ScattererPosition` property and the scattering coefficients by using the `ScattererCoefficient` property. All scatterer velocities are zero.
- When you set this property to `'Input port'`, you can specify the scatterer positions, velocities, and scattering coefficients using the `scatpos`, `scatvel`, and `scatcoef` input arguments of the `step` method.

Example: `'Input port'`

Data Types: `char`

### `NumScatterers` — Number of scatterers

`1` (default) | nonnegative integer

Number of scatterers, specified as a nonnegative integer.

Example: `9`

**Dependencies**

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'`.

Data Types: `double`

### ScattererPositionBoundary — Boundary of scatterer positions

[0,1000] (default) | 1-by-2 real-valued vector | 3-by-2 real-valued matrix

Boundary of the scatterer positions, specified as a 1-by-2 real-valued row vector or a 3-by-2 real-valued matrix. The vector specifies the minimum and maximum, [minbdry maxbdry], for all three dimensions. The matrix specifies boundaries in all three dimensions in the form [x_minbdry x_maxbdry;y_minbdry y_maxbdry; z_minbdry z_maxbdry].

Example: [-1000 500;-100 100;-200 0]

#### Dependencies

To enable this property, set the ScattererSpecificationSource property to 'Auto'.

Data Types: double

### ScattererPosition — Positions of scatterers

[0;0;0] (default) | real-valued 3-by-*K* matrix

Positions of the scatterers, specified as real-valued 3-by-*K* matrix. *K* is the number of scatterers. Each column represents a different scatterer and has the Cartesian form [x;y;z] with respect to the global coordinate system. Units are in meters.

Example: [1050 -100;-300 55;0 -75]

#### Dependencies

To enable this property, set the ScattererSpecificationSource property to 'Property'.

Data Types: double

### ScattererCoefficient — Scattering coefficients

1 (default) | complex-valued 1-by-*K* vector

Scattering coefficients, specified as a complex-valued 1-by-*K* vector. *K* is the number of scatterers. Units are dimensionless.

Example: 2+1i

#### Dependencies

To enable this property, set the ScattererSpecificationSource property to 'Property'.

Data Types: `double`

### `ScatteringMatrix` — Scattering matrices

`[1 0;0 1]` | complex–valued 2-by-2-by-$N_s$ array

Scattering matrices of the scatterers, specified as a complex–valued 2-by-2-by-$N_s$ array where $N_s$ is the number of scatterers. Each page of this array represents the scattering matrix of a scatterer. Each scattering matrix has the form `[s_hh s_hv;s_vh s_vv]`. For example, the component `s_hv` specifies the complex scattering response when the input signal is vertically polarized and the reflected signal is horizontally polarized. The other components are defined similarly. Units are in square meters.

**Dependencies**

To enable this property, set the `ScatteringMatrixSource` property to `'Property'` and the `Polarization` property to `'Combined'` or `'Dual'`.

Data Types: `double`

### `ScattererOrientationAxes` — Orientation of scatterers

`[1 0 0;0 1 0;0 0 1]` (default) | real–valued 3-by-3-by-$N_s$ array

Orientation of the scatterers, specified as a real–valued 3-by-3-by-$N_s$ array where $N_s$ is the number of scatterers. Each page of this array is an orthonormal matrix. Matrix columns represent the axis of the local coordinates $(x,y,z)$ of the scatterer with respect to the global coordinate system.

Example: `roty(45)`

**Dependencies**

To enable this property, set the `ScatteringMatrixSource` property to `'Property'` and the `Polarization` property to `'Combined'` or `'Dual'`.

Data Types: `double`

### `SeedSource` — Source of random number generator seed

`'Auto'` (default) | `'Property'`

Source of random number generator seed, specified as `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, random numbers are generated using the default MATLAB random number generator.

- When you set this property to `'Property'`, the object uses a private random number generator with the seed specified by the value of the `Seed` property.

To use this object with Parallel Computing Toolbox software, set this property to `'Auto'`.

**Dependencies**

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'`.

**Seed — Random number generator seed**
`0` (default) | nonnegative integer

Random number generator seed, specified as a nonnegative integer less than $2^{32}$.

Example: `5005`

**Dependencies**

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'` and the `SeedSource` property to `'Property'`.

Data Types: `double`

## Methods

|---|---|
| reset | Reset state of the System object |
| step | Propagate signals in scattering MIMO channel |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Propagate Signals in MIMO Channel

Create a 30 GHz MIMO channel with random scatterers. The scenario contains a stationary 21-element transmitting ULA array and a stationary 15-element receiving ULA array. The transmitting antennas have cosine responses and the receiving antennas are isotropic. Element spacing for both arrays is less than one-half wavelength. The channel has 50 randomly generated static scatterers within a specified bounding box. The transmit array is located at [0;20;50] meters and the receive array is located at [200;10;10] meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 30e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.CosineAntennaElement,...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement,...
    'NumElements',15,'ElementSpacing',0.45*lambda);

channel = phased.ScatteringMIMOChannel('TransmitArray',txarray,...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayPosition',[0;20;50],...
    'ReceiveArrayPosition',[200;10;10],'NumScatterers',50,...
    'ScattererPositionBoundary',[10 180; -30 30; -30 30]);
```

Create a random data signal of ones and zeros for each transmitter.

```
x = randi(2,[100 21]) - 1;
```

Compute the received signals after propagating through the channel.

```
y = channel(x);
```

### Propagate Signals in MIMO Channel from Moving Transmitter

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array operating at 72 GHz, and a 15-element receiving ULA array. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the transmitting antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array starts at (0,20,50) meters and moves towards the receiver at 2 m/s. The receiving array is located at (200,10,10) meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
```

```
lambda = c/fc;
fs = 10e6;
txplatform = phased.Platform('MotionModel','Velocity','InitialPosition', ...
    [0;20;50],'Velocity',[2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayMotionSource','Input port', ...
    'ReceiveArrayMotionSource','Property','ReceiveArrayPosition',[200;10;10],...
    'ReceiveArrayOrientationAxes',rotz(180),...
    'ScattererSpecificationSource','Property','ScattererPosition', ...
    [75 100 120; -10 20 12; 5 -5 8],'ScattererCoefficient',[1i,2+3i,-1+1i]);
```

Move the platforms for two time steps at one second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. The orientations are fixed.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [txpos,txvel] = txplatform(1);
    txaxes = eye(3);
    y = channel(x,txpos,txvel,txaxes);
end
```

### Propagate Signals Through MIMO Channel to Moving Receiver

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array and a 15-element receiving ULA array. Both arrays operating at 72 GHz. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the receiving antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array is located at (0,20,50) meters. The receiving array starts at (200,10,10) meters and moves toward the transmitter at 2 m/s. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
rxplatform = phased.Platform('MotionModel','Velocity','InitialPosition',...
    [200;10;10],'Velocity',[-2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc, ...
    'SampleRate',fs,'TransmitArrayMotionSource','Property',...
    'TransmitArrayPosition',[0;20;50],'TransmitArrayOrientationAxes',eye(3,3), ...
    'ReceiveArrayMotionSource','Input port','ScattererSpecificationSource', ...
    'Property','ScattererPosition',[75 100 120; -10 20 12; 5 -5 8], ...
    'ScattererCoefficient',[1i,2+3i,-1+1i],'SpecifyAtmosphere',false);
```

Move the platforms for two time steps at one-second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. Fix the array orientations.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [rxpos,rxvel] = rxplatform(1);
    rxaxes = rotz(45);
    y = channel(x,rxpos,rxvel,rxaxes);
end
```

### Propagate Polarized Signals in MIMO Channel

Create a MIMO channel at 30 GHz with an 16-element transmit array and a 64-element receive array. Assume the elements are short-dipole antennas and the arrays are uniform linear arrays. The transmit array is located at [0;0;50] meters.

The receive array has an initial position at [200;0;0] meters and is moving at a speed of [10;0;0] meters/second. There are 200 static scatterers randomly located on the *xy* plane within a square centered at [200;0;0] and with a side length of 100 meters.

Use the channel to compute the propagated polarized signal. Assume the sample rate for the signal is 10 MHz and the frame length is 1000 samples. Collect 5 frames of received signal.

```
fc = 30e9;
c = 3e8;
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.ShortDipoleAntennaElement,...
    'NumElements',16,'ElementSpacing',lambda/2);
rxarray = phased.ULA('Element',phased.ShortDipoleAntennaElement,...
    'NumElements',64,'ElementSpacing',lambda/2);

Ns = 200;
scatpos = [100*rand(1,Ns) + 150; 100*rand(1,Ns) + 150; zeros(1,Ns)];
temp = randn(1,Ns) + 1i*randn(1,Ns);
scatcoef = repmat(eye(2),1,1,Ns).*permute(temp,[1 3 2]);
scatax = repmat(eye(3),1,1,Ns);

Nframesamp = 1000;
Tframe = Nframesamp/fs;
rxmobile = phased.Platform('InitialPosition',[200;0;0],...
    'Velocity',[10;0;0],'OrientationAxesOutputPort',true);

chan = phased.ScatteringMIMOChannel(...
    'TransmitArray',txarray,...
    'ReceiveArray',rxarray,...
    'PropagationSpeed',c,...
    'CarrierFrequency',fc,...
    'SampleRate',fs,...
    'Polarization','Dual',...
    'TransmitArrayPosition',[0;0;50],...
    'ReceiveArrayMotionSource','Input port',...
    'ScattererSpecificationSource','Property',...
    'ScattererPosition',scatpos,...
    'ScatteringMatrix',scatcoef,...
    'ScattererOrientationAxes',scatax);

xh = randi(2,[Nframesamp 16])-1;
xv = randi(2,[Nframesamp 16])-1;

for m = 1:5
    [rxpos,rxvel,rxax] = rxmobile(Tframe);
    [yh,yv] = chan(xh,xv,rxpos,rxvel,rxax);
end
```

# More About

## Attenuation and Loss Factors

Attenuation or path loss in the scattering MIMO channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where:

- $L_{fsp}$ is the free-space path attenuation.
- $L_g$ is the atmospheric path attenuation.
- $L_c$ is the fog and cloud path attenuation.
- $L_r$ is the rain path attenuation.

Each component is in magnitude units, not in dB.

## Free-Space Time Delay and Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity *v* is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [8]

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_i$, multiplied by a spectral line strength, *S*$_i$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1-\left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1-\left(\frac{300}{T}\right)\right]W\,.$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}.$$

The total atmospheric pressure is *P* + *W*.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, *R*. Then, the total attenuation is $L_g= R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

For a complete description of this model, see [4].

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where *M* is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

For a complete description of this model, see [5]

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Propagate signals in scattering MIMO channel

## Syntax

```
Y = step(channel,X)
[YH,YV] = step(channel,[XH,XV])
[ ___ ] = step( ___ ,txpos,txvel,txaxes)
[ ___ ] = step( ___ ,rxpos,rxvel,rxaxes)
[ ___ ] = step( ___ ,scatpos,scatvel,scatcoef)
[ ___ ] = step( ___ ,scatpos,scatvel,scatmat,scataxes)
[ ___ ,CR,TAU] = step(channel, ___ )
[ ___ ,CR_HH,CR_HV,CR_VH,CR_V,TAU] = step(channel, ___ )
[Y,CR,TAU] = step(channel,X,txpos,txvel,txaxesrxpos,rxvel,rxaxes,
scatpos,scatvel,scatcoef)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `Y = step(obj,X)` and `Y = obj(X)` perform equivalent operations.

`Y = step(channel,X)` uses the scattering MIMO channel, `channel`, to propagate a signal, `X`, from a transmitting array towards multiple scatterers, and returns the scattered signals, `Y`, to a receiving array.

To enable this syntax, set the `TransmitArrayMotionSource`, `ReceiveArrayMotionSource`, and `ScattererSpecificationSource` properties to `'Property'`.

`[YH,YV] = step(channel,[XH,XV])`propagates the polarized signals, `XH` and `XV`, through the *H*-port and *V*-port of the transmit array. The object returns the received signals, `YH` and `YV` to the *H*-port and *V*-port of the receive array.

To enable this syntax, set the `Polarization` property to `'Dual'`.

`[ ___ ] = step( ___ ,txpos,txvel,txaxes)` also specifies the transmitting array position, velocity, and axes orientation.

To enable this syntax, set the `ReceiveArrayMotionSource` and `ScattererSpecificationSource` properties to `'Property'` and set `TransmitArrayMotionSource` to `'Input port'`.

`[ ___ ] = step( ___ ,rxpos,rxvel,rxaxes)` specifies the receiving array position, velocity, and axes orientation.

To enable this syntax, set the `TransmitArrayMotionSource` and `ScattererSpecificationSource` properties to `'Property'` and set `ReceiveArrayMotionSource` to `'Input port'`.

`[ ___ ] = step( ___ ,scatpos,scatvel,scatcoef)` specifies the scatterer positions and velocities, and the scattering coefficients.

To enable this syntax, set the `TransmitArrayMotionSource` and `ReceiveArrayMotionSource` properties to `'Property'`, set `ScattererSpecificationSource` to `'Input port'`, and set the `Polarization` property to `'None'`.

`[ ___ ] = step( ___ ,scatpos,scatvel,scatmat,scataxes)` specifies the scatterer positions, `scatpos`, and velocities, `scatvel`, the scattering matrix, `scatmat`, and the scatterer orientation axes, `scataxes`.

To enable this syntax, set the `TransmitArrayMotionSource` and `ReceiveArrayMotionSource` properties to `'Property'`, set `ScattererSpecificationSource` to `'Input port'`, and set the `Polarization` property to `'Combined'` or `'Dual'`.

`[ ___ ,CR,TAU] = step(channel, ___ )` also returns the channel response matrix, `CR`, and the channel path delays, `TAU`, using any of the previous input argument combinations.

To enable this syntax, set the `ChannelResponseOutputPort` property to `true` and set the `Polarization` property to `'None'` or `'Combined'`.

`[ ___ ,CR_HH,CR_HV,CR_VH,CR_V,TAU] = step(channel, ___ )` also returns the channel response matrices, `CR_HH`, `CR_HV`, `CR_VH`, and `CR_V`, using any of the previous input argument combinations.

To enable this syntax, set the `ChannelResponseOutputPort` property to `true` and set the `Polarization` property to `'Dual'`.

You can combine optional input arguments when their enabling properties are set. For example, `[Y,CR,TAU] = step(channel,X,txpos,txvel,txaxesrxpos,rxvel, rxaxes,scatpos,scatvel,scatcoef)`.

**Note** The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `channel` — Scattering MIMO channel

`phased.ScatteringMIMOChannel` System object

Scattering MIMO channel, specified as a `phased.ScatteringMIMOChannel` System object.

Example: `phased.ScatteringMIMOChannel`

### X — Transmitted narrowband signal

$M$-by-$N_t$ complex-valued matrix

Transmitted narrowband signal, specified as an $M$-by-$N_t$ complex-valued matrix. The quantity $M$ is the number of samples in the signal, and $N_t$ is the number of transmitting array elements. Each column represents the signal transmitted by the corresponding array element.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

#### Dependencies

To enable this argument, set the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### XH — Transmitted narrowband H-polarization signal

*M*-by-$N_t$ complex-valued matrix

Transmitted narrowband *H*-polarization signal, specified as an *M*-by-$N_t$ complex-valued matrix. The quantity *M* is the number of samples in the signal, and $N_t$ is the number of transmitting array elements. Each column represents the signal transmitted by the corresponding array element.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### XV — Transmitted narrowband V-polarization signal

*M*-by-$N_t$ complex-valued matrix

Transmitted narrowband *V*-polarization signal, specified as an *M*-by-$N_t$ complex-valued matrix. The quantity *M* is the number of samples in the signal, and $N_t$ is the number of transmitting array elements. Each column represents the signal transmitted by the corresponding array element.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### `txpos` — Position of transmitting antenna array

real-valued three-element column vector

Position of transmitting antenna array, specified as real-valued three-element column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

Example: `[1000;100;500]`

#### Dependencies

To enable this argument, set the `TransmitArrayMotionSource` property to `'Input port'`.

Data Types: `double`

### `txvel` — Velocity of transmitting antenna array

real-valued three-element column vector

Velocity of transmitting antenna array, specified as a real-valued three-element column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

Example: `[10;0;5]`

#### Dependencies

To enable this argument, set the `TransmitArrayMotionSource` property to `'Input port'`.

Data Types: `double`

### `txaxes` — Axes orientation of transmitting antenna array

real-valued 3-by-3 real orthonormal matrix

Axes orientation of transmitting antenna array, specified as a real-valued 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

Example: `rotx(35)`

**Dependencies**

To enable this argument, set the `TransmitArrayMotionSource` property to `'Input port'`.

Data Types: `double`

### `rxpos` — Position of receiving antenna array

real-valued three-element column vector

Position of receiving antenna array, specified as a real-valued three-element column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

Example: `[1000;100;500]`

**Dependencies**

To enable this argument, set the `ReceiveArrayMotionSource` property to `'Input port'`.

Data Types: `double`

### `rxvel` — Velocity of receiving antenna array

real-valued three-element column vector

Velocity of receiving antenna array, specified as a real-valued three-element column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

Example: `[10;0;5]`

**Dependencies**

To enable this argument, set the `ReceiveArrayMotionSource` property to `'Input port'`.

Data Types: `double`

### `rxaxes` — Axes orientation of receiving antenna array

real-valued 3-by-3 real orthonormal matrix

Axes orientation of receiving antenna array, specified as a real-valued 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

Example: `rotx(35)`

**Dependencies**

To enable this argument, set the `ReceiveArrayMotionSource` property to `'Input port'`.

Data Types: `double`

### `scatpos` — Positions of scatterers

real-valued 3-by-$N_s$ matrix

Positions of scatterers, specified as a real-valued 3-by-$N_s$ matrix. The matrix contains the *(x,y,z)* positions of scatterers. Each column of the matrix specifies a different scatterer and takes the form `[x;y;z]`. Units are in meters.

Example: `[1000;100;500]`

**Dependencies**

To enable this argument, set the `ScattererSpecificationSource` property to `'Input port'`.

Data Types: `double`

### `scatvel` — Velocities of scatterers

real-valued 3-by-$N_s$ matrix

Velocities of scatterers, specified as a real-valued 3-by-$N_s$ matrix. The matrix contains the $(v_x,v_y,v_z)$ positions of scatterers. Each column of the matrix specifies a different scatterer and takes the form `[vx;vy;vz]` Units are in meters per second.

Example: `[1000;100;500]`

**Dependencies**

To enable this argument, set the `ScattererSpecificationSource` property to `'Input port'`.

Data Types: `double`

### `scatcoef` — Scattering coefficients

complex-valued 1-by-$N_s$row vector

Scattering coefficients, specified as a complex-valued 1-by-$N_s$row vector. Each vector element specifies the scattering coefficient of the corresponding scatterer. Units are dimensionless.

Example: [5+3*1i;4+1i;2]

**Dependencies**

To enable this argument, set the ScattererSpecificationSource property to 'Input port' and the Polarization property to 'None'.

Data Types: double

### scatmat — Scattering matrices

[1 0;0 1] | complex–valued 2-by-2-by-$N_\mathrm{s}$ array

Scattering matrices of the scatterers, specified as a complex–valued 2-by-2-by-$N_\mathrm{s}$ array where $N_\mathrm{s}$ is the number of scatterers. Each page of this array represents the scattering matrix of a scatterer. Each scattering matrix has the form [s_hh s_hv;s_vh s_vv]. For example, the component s_hv specifies the complex scattering response when the input signal is vertically polarized and the reflected signal is horizontally polarized. The other components are defined similarly. Units are in square meters.

**Dependencies**

To enable this property, set the ScattererSpecificationSource property to 'Input port' and the Polarization property to 'Combined' or 'Dual'.

Data Types: double

### scataxes — Scatterer orientation axes

real-valued 3-by-3-by-$N_\mathrm{s}$ array

Scatterer orientation axes, specified as a real-valued 3-by-3-by-$N_\mathrm{s}$ array where $N_\mathrm{s}$ is the number of scatterers. Each page of this array represents the orientation axes matrix of a scatterer. The columns of the matrix represent the *x*- ,*y*-, and *z*-axes of the scatterer. Units are dimensionless.

**Dependencies**

To enable this property, set the ScattererSpecificationSource property to 'Input port' and the Polarization property to 'Combined' or 'Dual'.

Data Types: double

## Output Arguments

### Y — Received narrowband signal

complex-valued $M$-by-$N_r$ matrix

Received narrowband signal, returned as an $M$-by-$\mathrm{N_r}$ complex-valued matrix. $M$ is the number of samples in the signal, and $N_r$ is the number of receiving array elements. Each column represents the signal received by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

#### Dependencies

To enable this argument, set the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### YH — Received narrowband H-polarization signal

complex-valued $M$-by-$N_r$ matrix

Received narrowband $H$-polarization signal, returned as a complex-valued $M$-by-$N_r$ matrix. $M$ is the number of samples in the signal, and $N_r$ is the number of receiving array elements. Each column represents the signal received by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### YV — Received narrowband V-polarization signal

complex-valued $M$-by-$N_r$ matrix

Received narrowband $V$-polarization signal, returned as a complex-valued $M$-by-$N_r$ matrix. $M$ is the number of samples in the signal, and $N_r$ is the number of receiving array elements. Each column represents the signal received by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### CR — Channel response

complex-valued $N_t$-by-$N_r$-by-$N_c$ array

Channel response, returned as an $N_t$-by-$N_r$-by-$N_c$ complex-valued array.

- $N_t$ is the number of transmitting array elements.
- $N_r$ is the number of receiving array elements.
- - When you specify `SimulateDirectPath` as `false`, $N_c = N_s$, the number of scatterers.
  - When you specify `SimulateDirectPath` as `true`, $N_c = N_s + 1$ to account for the direct path.

Each page of the array corresponds to the channel response matrix for a specific scatterer.

#### Dependencies

To enable this argument, set the `ChannelResponseOutputPort` property to `true` and the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### CR_HH — Channel response for H-input to H-output

complex-valued $N_t$-by-$N_r$-by-$N_c$ array

Channel response from H-polarization input to H-polarization output returned as a complex-valued $N_t$-by-$N_r$-by-$N_c$ array.

- $N_t$ is the number of transmitting array elements.
- $N_r$ is the number of receiving array elements.
- - When you specify `SimulateDirectPath` as `false`, $N_c = N_s$, the number of scatterers.
  - When you specify `SimulateDirectPath` as `true`, $N_c = N_s + 1$ to account for the direct path.

Each page of the array corresponds to the channel response matrix for a specific scatterer.

#### Dependencies

To enable this argument, set the `ChannelResponseOutputPort` property to `true` and the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### `CR_HV` — Channel response for H-input to V-output

complex-valued $N_t$-by-$N_r$-by-$N_c$ array

Channel response from H-polarization input to V-polarization output returned as a complex-valued $N_t$-by-$N_r$-by-$N_c$ array.

- $N_t$ is the number of transmitting array elements.
- $N_r$ is the number of receiving array elements.
- - When you specify `SimulateDirectPath` as `false`, $N_c = N_s$, the number of scatterers.
  - When you specify `SimulateDirectPath` as `true`, $N_c = N_s + 1$ to account for the direct path.

Each page of the array corresponds to the channel response matrix for a specific scatterer.

#### Dependencies

To enable this argument, set the `ChannelResponseOutputPort` property to `true` and the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### `CR_VH` — Channel response for V-input to H-output

complex-valued $N_t$-by-$N_r$-by-$N_c$ array

Channel response from V-polarization input to H-polarization output returned as a complex-valued $N_t$-by-$N_r$-by-$N_c$ array.

- $N_t$ is the number of transmitting array elements.

- $N_r$ is the number of receiving array elements.
- - When you specify `SimulateDirectPath` as `false`, $N_c = N_s$, the number of scatterers.
  - When you specify `SimulateDirectPath` as `true`, $N_c = N_s + 1$ to account for the direct path.

Each page of the array corresponds to the channel response matrix for a specific scatterer.

**Dependencies**

To enable this argument, set the `ChannelResponseOutputPort` property to `true` and the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### CR_VV — Channel response for V-input to V-output

complex-valued $N_t$-by-$N_r$-by-$N_c$ array

Channel response from V-polarization input to V-polarization output returned as a complex-valued $N_t$-by-$N_r$-by-$N_c$ array.

- $N_t$ is the number of transmitting array elements.
- $N_r$ is the number of receiving array elements.
- - When you specify `SimulateDirectPath` as `false`, $N_c = N_s$, the number of scatterers.
  - When you specify `SimulateDirectPath` as `true`, $N_c = N_s + 1$ to account for the direct path.

Each page of the array corresponds to the channel response matrix for a specific scatterer.

**Dependencies**

To enable this argument, set the `ChannelResponseOutputPort` property to `true` and the `Polarization` property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### TAU — Path delays

1-by-$N_s$ real-valued vector

Path delays, returned as a 1-by-$N_C$ real-valued vector. Each element corresponds to the path time delay from the transmitting array phase center to a scatterer and then to the receiving array phase center.

- When you specify `SimulateDirectPath` as `false`, $N_c = N_s$, the number of scatterers.
- When you specify `SimulateDirectPath` as `true`, $N_c = N_s + 1$ to account for the direct path.

#### Dependencies

To enable this argument, set the `ChannelResponseOutputPort` property to `true`.

Data Types: `double`

## Examples

### Propagate Signals in MIMO Channel

Create a 30 GHz MIMO channel with random scatterers. The scenario contains a stationary 21-element transmitting ULA array and a stationary 15-element receiving ULA array. The transmitting antennas have cosine responses and the receiving antennas are isotropic. Element spacing for both arrays is less than one-half wavelength. The channel has 50 randomly generated static scatterers within a specified bounding box. The transmit array is located at [0;20;50] meters and the receive array is located at [200;10;10] meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 30e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.CosineAntennaElement,...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement,...
    'NumElements',15,'ElementSpacing',0.45*lambda);

channel = phased.ScatteringMIMOChannel('TransmitArray',txarray,...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayPosition',[0;20;50],...
    'ReceiveArrayPosition',[200;10;10],'NumScatterers',50,...
    'ScattererPositionBoundary',[10 180; -30 30; -30 30]);
```

Create a random data signal of ones and zeros for each transmitter.

```
x = randi(2,[100 21]) - 1;
```

Compute the received signals after propagating through the channel.

```
y = channel(x);
```

### Propagate Signals in MIMO Channel from Moving Transmitter

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array operating at 72 GHz, and a 15-element receiving ULA array. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the transmitting antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array starts at (0,20,50) meters and moves towards the receiver at 2 m/s. The receiving array is located at (200,10,10) meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txplatform = phased.Platform('MotionModel','Velocity','InitialPosition', ...
    [0;20;50],'Velocity',[2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayMotionSource','Input port', ...
    'ReceiveArrayMotionSource','Property','ReceiveArrayPosition',[200;10;10],...
    'ReceiveArrayOrientationAxes',rotz(180),...
    'ScattererSpecificationSource','Property','ScattererPosition', ...
    [75 100 120; -10 20 12; 5 -5 8],'ScattererCoefficient',[1i,2+3i,-1+1i]);
```

Move the platforms for two time steps at one second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. The orientations are fixed.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [txpos,txvel] = txplatform(1);
    txaxes = eye(3);
    y = channel(x,txpos,txvel,txaxes);
end
```

### Propagate Signals Through MIMO Channel to Moving Receiver

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array and a 15-element receiving ULA array. Both arrays operating at 72 GHz. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the receiving antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array is located at (0,20,50) meters. The receiving array starts at (200,10,10) meters and moves toward the transmitter at 2 m/s. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
rxplatform = phased.Platform('MotionModel','Velocity','InitialPosition',...
    [200;10;10],'Velocity',[-2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc, ...
    'SampleRate',fs,'TransmitArrayMotionSource','Property',...
    'TransmitArrayPosition',[0;20;50],'TransmitArrayOrientationAxes',eye(3,3), ...
    'ReceiveArrayMotionSource','Input port','ScattererSpecificationSource', ...
    'Property','ScattererPosition',[75 100 120; -10 20 12; 5 -5 8], ...
    'ScattererCoefficient',[1i,2+3i,-1+1i],'SpecifyAtmosphere',false);
```

Move the platforms for two time steps at one-second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. Fix the array orientations.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [rxpos,rxvel] = rxplatform(1);
    rxaxes = rotz(45);
    y = channel(x,rxpos,rxvel,rxaxes);
end
```

### Compute Propagated Signals Through MIMO Channel with Moving Scatterers

Create a MIMO channel containing 3 moving scatterers. The scenario contains a 21-element transmitting ULA array and a 15-element receiving ULA array. Both arrays operate at 72 GHz. The transmitting elements have cosine responses and the receiving antennas are isotropic. Element spacing for both arrays is less than one-half wavelength. The transmitting array is located at (0,20,50) meters. The receiving array is located at (200,10,10) meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz. Obtain the channel response matrix and time delays.

```
fc = 30e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc, ...
    'SampleRate',fs,'TransmitArrayPosition',[0;20;50], ...
    'ReceiveArrayPosition',[200;10;10],'ScattererSpecificationSource','Input port', ..
    'ChannelResponseOutputPort',true);
```

Create a random data signal of ones and zeros for each transmitter.

```
x = randi(2,[100 21]) - 1;
```

Compute the received signals after propagating through the channel. Also return the channel matrix and delays.

```
scatpos = [75 100 120; -10 20 12; 5 -5 8];
scatvel = [0 0.5 0; -0.1 1.2 0.04; .05 -0.45 0.8];
scatcoef = [1i,2+3i,-1+1i];
[y,chmat,delays] = channel(x,scatpos,scatvel,scatcoef);
```

Display the dimensions of the channel matrix.

```
size(chmat)
```

```
ans = 1×3

    21    15     3
```

Display the time delays in microseconds.

```
delays*1e6
```

```
ans = 1×3

    0.7310    0.7196    0.6919
```

### Propagate Polarized Signals in MIMO Channel

Create a MIMO channel at 30 GHz with an 16-element transmit array and a 64-element receive array. Assume the elements are short-dipole antennas and the arrays are uniform linear arrays. The transmit array is located at [0;0;50] meters.

The receive array has an initial position at [200;0;0] meters and is moving at a speed of [10;0;0] meters/second. There are 200 static scatterers randomly located on the *xy* plane within a square centered at [200;0;0] and with a side length of 100 meters.

Use the channel to compute the propagated polarized signal. Assume the sample rate for the signal is 10 MHz and the frame length is 1000 samples. Collect 5 frames of received signal.

```
fc = 30e9;
c = 3e8;
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.ShortDipoleAntennaElement,...
    'NumElements',16,'ElementSpacing',lambda/2);
rxarray = phased.ULA('Element',phased.ShortDipoleAntennaElement,...
    'NumElements',64,'ElementSpacing',lambda/2);

Ns = 200;
scatpos = [100*rand(1,Ns) + 150; 100*rand(1,Ns) + 150; zeros(1,Ns)];
temp = randn(1,Ns) + 1i*randn(1,Ns);
scatcoef = repmat(eye(2),1,1,Ns).*permute(temp,[1 3 2]);
scatax = repmat(eye(3),1,1,Ns);

Nframesamp = 1000;
Tframe = Nframesamp/fs;
rxmobile = phased.Platform('InitialPosition',[200;0;0],...
    'Velocity',[10;0;0],'OrientationAxesOutputPort',true);

chan = phased.ScatteringMIMOChannel(...

**Introduced in R2017a**

# phased.SteeringVector

**Package:** `phased`

Sensor array steering vector

## Description

The `SteeringVector` System object creates steering vectors for a sensor array for multiple directions and frequencies.

To compute the steering vector for an array for specified directions and frequency

1. Create the `phased.SteeringVector` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
steervec = phased.SteeringVector
steervec = phased.SteeringVector(Name,Value)
```

### Description

`steervec = phased.SteeringVector` creates a steering vector System object, `steervec`, with default property values.

`steervec = phased.SteeringVector(Name,Value)` creates a steering vector with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `steervec = phased.SteeringVector('SensorArray',phased.URA,'PropagationSpeed',physconst('LightSpeed'))` creates a steering vector object for a uniform rectangular array (URA) with default URA property values and sets the propagation speed to the speed of light.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `SensorArray` — Sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox array

Sensor array, specified as an array System object belonging to Phased Array System Toolbox. The sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `IncludeElementResponse` — Include individual element responses in the steering vector

`false` (default) | `true`

Option to include the individual element responses in the steering vector, specified as `false` or `true`. If this property is set to `true`, the steering vector includes individual array element responses. If this property is set to `false`, the steering vector is computed assuming that the elements are isotropic, regardless of how the elements are specified. Set this property to `true` to model polarized signals.

When the array specified in the SensorArray property contains subarrays, the steering vector applies to the subarrays. If SensorArray does not contain subarrays, the steering vector is applied to the array elements.

Data Types: `logical`

**`NumPhaseShifterBits` — Number of phase shifter quantization bits**
`0` (default) | nonnegative integer

Number of phase shifter quantization bits, specified as a nonnegative integer. This number of bits is used to quantize the phase shift component of the beamformer or steering vector weights. A value of zero indicates that no quantization is performed.

Data Types: `double`

**`EnablePolarization` — Enable polarized fields**
`false` (default) | `true`

Option to enable polarized fields, specified as `false` or `true`. Set this property to `true` to enable polarization. Set this property to `false` to ignore polarization. Enabling polarization requires that the sensor array specified in the SensorArray property can simulate polarization.

If you set this property to `false` for an array that actually supports polarization, then all polarization information is discarded. A combined pattern from the *H* and *V* polarization components is used at each element to compute the steering vector.

Data Types: `logical`

# Usage

# Syntax

```
SV = steervec(FREQ,ANG)
SV = steervec(FREQ,ANG,STEERANG)
SV = steervec(FREQ,ANG,STEERANG,WS)
```

## Description

`SV = steervec(FREQ,ANG)` returns the steering vector, `SV`, pointing in the directions specified by `ANG` and for the operating frequencies specified in `FREQ`. The meaning of `SV` depends on the IncludeElementResponse property, as follows:

- If IncludeElementResponse is `true`, the components of `SV` include individual element responses.
- If IncludeElementResponse is `false`, the computation assumes that the elements are isotropic and `SV` does not include the individual element responses. If the array contains subarrays, `SV` is the array factor among the subarrays. The phase center of each subarray is at its geometric center. If SensorArray does not contain subarrays, `SV` is the array factor among the elements.

`SV = steervec(FREQ,ANG,STEERANG)` also specifies the subarray steering angle, `STEERANG`. To use this syntax, set the SensorArray property to an array type that contains subarrays and set the IncludeElementResponse to `true`. Arrays that contain subarrays are the `phased.PartitionedArray` and the `phased.ReplicatedSubarray`. In this case, set the `SubarraySteering` property of these arrays to either `'Phase'` or `'Time'`.

`SV = steervec(FREQ,ANG,STEERANG,WS)` also specifies `WS` as weights applied to each element within each subarray. To use this syntax, set the SensorArray property to an array that supports subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

## Input Arguments

### ANG — Steering vector direction

`[0;0]` (default) | real-valued length-*M* vector | real-valued 2-by-*M* matrix

Steering vector directions, specified as a real-valued, length-*M* vector, or a real-valued 2-by-*M* matrix. *M* is the number of steering directions. When `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in space in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, and the elevation angle must be between –90° and 90°. When `ANG` is a length-*M* vector, its values correspond to the azimuth angles of the steering vector direction with elevation angles set to zero. Angle units are in degrees.

Example: `[50.0,17.0,-24.5;0.4,4.0,23.9]`

Data Types: `single` | `double`

### FREQ — Operating frequencies

1-by-$L$ vector of positive values

Operating frequencies, specified as a 1-by-$L$ vector of positive values. Units are in Hz.

Example: `[4100.0,4200.0]`

Data Types: `single` | `double`

### STEERANG — Subarray steering direction

scalar | real-valued 2-by-1 vector

Subarray steering direction, specified as a scalar or a real-valued 2-by-1 vector. When `STEERANG` is a 2-by-1 vector, it specifies the subarray steering direction in the form `[azimuth;elevation]`. The azimuth angle must be between –180° and 180°, and the elevation angle must be between –90° and 90°. When `STEERANG` is a scalar, its value corresponds to the azimuth angle of the subarray steering direction with elevation angles set to zero. Angle units are in degrees.

Example: `[50.0;10.0]`

Data Types: `single` | `double`

### WS — Subarray element weights

complex-valued $N_{SE}$-by-$N$ matrix | 1-by-$N$ cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

#### Dependencies

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### SV — Steering vector

complex-valued $N$-by-$M$-by-$L$ array | structures

Steering vector, returned as a complex-valued *N*-by-*M*-by-*L* array or a structure containing arrays.

The form of the steering vector depends upon whether the EnablePolarization property is set to `true` or `false`.

- If EnablePolarization is set to `false`, the steering vector, `SV`, is an *N*-by-*M*-by-*L* array. The length of the first dimension, *N*, is the number of elements of the phased array. If SensorArray contains subarrays, *N* is the number of subarrays. The length of the second dimension, *M*, corresponding to the number of steering directions specified in the `ANG` argument. The length of the third dimension, *L*, is the number of frequencies specified in the `FREQ` argument.
- If EnablePolarization is set to `true`, `SV` is a MATLAB `struct` containing two fields, `SV.H` and `SV.V`. These two fields represent the horizontal (*H*) and vertical (*V*) polarization components of the steering vector. Each field is an *N*-by-*M*-by-*L* array. The length of the first dimension, *N*, is the number of elements of the phased array. If SensorArray contains subarrays, *N* is the number of subarrays. The length of the second dimension, *M*, corresponds to the number of steering directions specified in the `ANG` argument. The length of the third dimension, *L*, is the number of frequencies specified in the `FREQ` argument.

  Simulating polarization also requires that the sensor array specified in the SensorArray property can simulate polarization, and that the IncludeElementResponse property is set to `true`.

Data Types: `single` | `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Steering Vector for Uniform Linear Array

Calculate and display the steering vector for a 4-element uniform linear array in the direction of 30 degrees azimuth and 20 degrees elevation. Assume the array's operating frequency is 300 MHz.

```
array = phased.ULA('NumElements',4);
steervec = phased.SteeringVector('SensorArray',array);
fc = 3e8;
ang = [30; 20];
sv = steervec(fc,ang)
```

```
sv = 4×1 complex

  -0.6011 - 0.7992i
   0.7394 - 0.6732i
   0.7394 + 0.6732i
  -0.6011 + 0.7992i
```

### Beam Pattern With and Without Steering

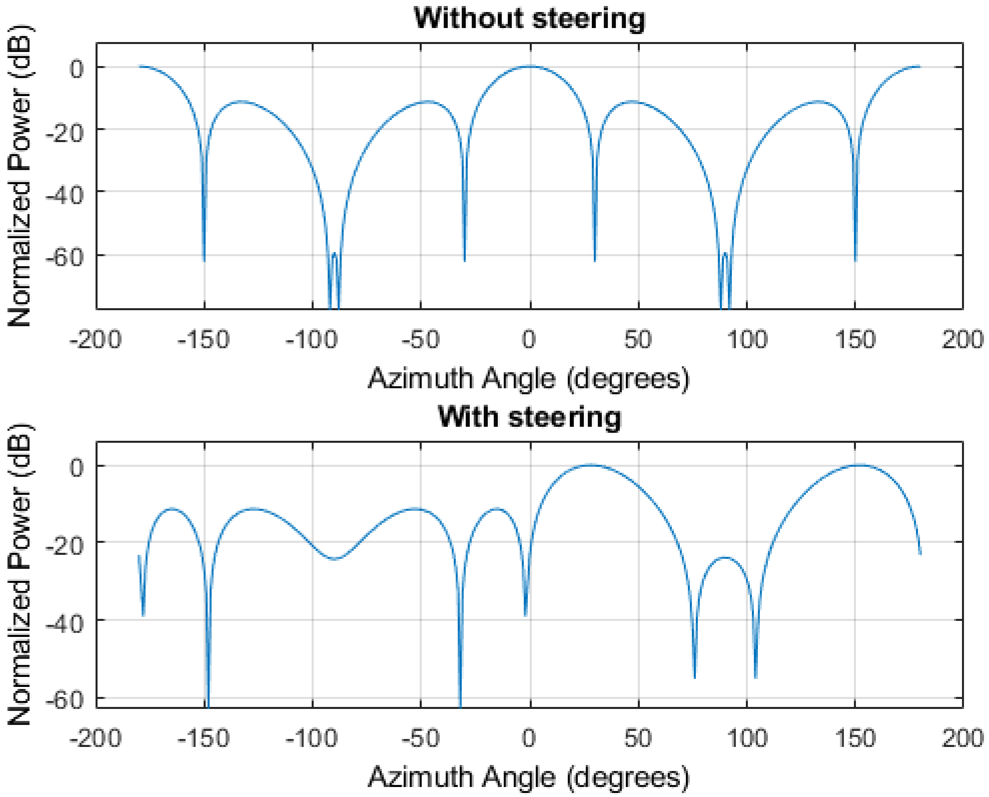
Calculate the steering vector for a 4-element uniform linear array (ULA) in the direction of 30 degrees azimuth and 20 degrees elevation. Assume the array operating frequency is 300 MHz.

```
fc = 300e6;
c = physconst('LightSpeed');
array = phased.ULA('NumElements',4);
steervec = phased.SteeringVector('SensorArray',array);
sv = steervec(fc,[30;20]);
```

Plot the beam patterns for the uniform linear array when no steering vector is applied (steered broadside) and when a steering vector is applied.

```
subplot(211)
pattern(array,fc,-180:180,0,'CoordinateSystem','rectangular', ...
    'PropagationSpeed',c,'Type','powerdb')
```

```
title('Without steering')
subplot(212)
pattern(array,fc,-180:180,0,'CoordinateSystem','rectangular', ...
    'PropagationSpeed',c,'Type','powerdb','Weights',sv)
title('With steering')
```



### Steering Vector for Uniform Linear Array

Calculate the steering vector for a uniform linear array in the direction of 30° azimuth and 20° elevation. Assume the array’ operates at 300 MHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
array = phased.ULA('NumElements',2);
steeringvector = phased.SteeringVector('SensorArray',array);
fc = 300.0e6;
ang = [30;20];
sv = steeringvector(fc,ang);
```

**Package:** `phased`

Calculate steering vector

## Syntax

```
SV = step(H,FREQ,ANG)
SV = step(H,FREQ,ANG,STEERANGLE)
SV = step(H,FREQ,ANG,WS)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`SV = step(H,FREQ,ANG)` returns the steering vector `SV` of the array for the directions specified in `ANG`. The operating frequencies are specified in `FREQ`. The meaning of `SV` depends on the `IncludeElementResponse` property of `H`, as follows:

- If `IncludeElementResponse` is `true`, `SV` includes the individual element responses.
- If `IncludeElementResponse` is `false`, the computation assumes the elements are isotropic and `SV` does not include the individual element responses. Furthermore, if the `SensorArray` property of `H` contains subarrays, `SV` is the array factor among the subarrays and the phase center of each subarray is at its geometric center. If `SensorArray` does not contain subarrays, `SV` is the array factor among the elements.

`SV = step(H,FREQ,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays, `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`, and `H.IncludeElementResponse` is `true`.

`SV = step(H,FREQ,ANG,WS)` uses `WS` as weights applied to each element within each subarray. To use this syntax, set the `SensorArray` property to an array that supports subarrays and set the `SubarraySteering` property of the array to `'Custom'`, and `H.IncludeElementResponse` is `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Steering vector object.

### FREQ

Operating frequencies in hertz. `FREQ` is a row vector of length L.

### ANG

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in space in the form `[azimuth; elevation]`. The azimuth angle must be between –180 degrees and 180 degrees, and the elevation angle must be between –90 degrees and 90 degrees.

If `ANG` is a row vector of length M, each element specifies the direction azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

### STEERANGLE

Subarray steering angle in degrees. `STEERANGLE` can be a length-2 column vector or a scalar.

If `STEERANGLE` is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 degrees and 180 degrees, and the elevation angle must be between –90 degrees and 90 degrees.

If `STEERANGLE` is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

**`WS`**

Subarray element weights

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

### Subarray Element Weights

| Sensor Array | Subarray Weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays cannot have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

#### Dependencies

To enable this argument, set the `SensorArray` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`, and `H.IncludeElementResponse` is `true`.

## Output Arguments

### SV

Steering vector. The form of the steering vector depends upon whether the `EnablePolarization` property is set to `true` or `false`.

- If EnablePolarization is set to false, the steering vector, SV, has the dimensions *N*-by-*M*-by-*L*. The first dimension, *N*, is the number of elements of the phased array. If H.SensorArray contains subarrays, *N* is the number of subarrays. Each column of SV contains the steering vector of the array for the corresponding direction specified in ANG. Each of the *L* pages of SV contains the steering vectors of the array for the corresponding frequency specified in FREQ.

  If you set the H.IncludeElementResponse property to true, the steering vector includes the individual element responses. If you set the H.IncludeElementResponse property to false, the elements are assumed to be isotropic. Then, the steering vector does not include individual element responses.
- If EnablePolarization is set to true, SV is a MATLAB struct containing two fields, SV.H and SV.V. These fields represent the steering vector horizontal and vertical polarization components. Each field has the dimensions *N*-by-*M*-by-*L*. The first dimension, *N*, is the number of elements of the phased array. If H.SensorArray contains subarrays, *N* is the number of subarrays. Each column of SV contains the steering vector of the array for the corresponding direction specified in ANG. Each of the *L* pages of SV contains the steering vectors of the array for the corresponding frequency specified in FREQ.

  If you set EnablePolarization to false for an array that supports polarization, then all polarization information is discarded. The combined pattern from both H and V polarizations is used at each element to compute the steering vector.

  Simulating polarization also requires that the sensor array specified in the SensorArray property can simulate polarization, and the IncludeElementResponse property is set to true.

## Examples

### Steering Vector for Uniform Linear Array

Calculate the steering vector for a uniform linear array in the direction of 30° azimuth and 20° elevation. Assume the array' operates at 300 MHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

```
array = phased.ULA('NumElements',2);
steeringvector = phased.SteeringVector('SensorArray',array);
fc = 300.0e6;
ang = [30;20];
sv = steeringvector(fc,ang);
```

# phased.SteppedFMWaveform

**Package:** `phased`

Stepped FM pulse waveform

## Description

The `SteppedFMWaveform` object creates a stepped FM pulse waveform.

To obtain waveform samples:

1. Define and set up your stepped FM pulse waveform. See “Construction” on page 1-2182.
2. Call `step` to generate the stepped FM pulse waveform samples according to the properties of `phased.SteppedFMWaveform`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

## Construction

`sSFM = phased.SteppedFMWaveform` creates a stepped FM pulse waveform System object, `sSFM`. The object generates samples of a linearly stepped FM pulse waveform.

`sSFM = phased.SteppedFMWaveform(Name,Value)` creates a stepped FM pulse waveform object, `sSFM`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

**Default:** `1e6`

### `DurationSpecification`

Method to set pulse duration

Method to set pulse duration (pulse width), specified as `'Pulse width'` or `'Duty cycle'`. This property determines how you set the pulse duration. When you set this property to `'Pulse width'`, then you set the pulse duration directly using the `PulseWidth` property. When you set this property to `'Duty cycle'`, you set the pulse duration from the values of the `PRF` and `DutyCycle` properties. The pulse width is equal to the duty cycle divided by the *PRF*.

**Default:** `'Pulse width'`

### `PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

**Default:** `50e-6`

### `DutyCycle`

Waveform duty cycle

Waveform duty cycle, specified as a scalar from 0 through 1, inclusive. This property applies when you set the `DurationSpecification` property to `'Duty cycle'`. The pulse width is the value of the `DutyCycle` property divided by the value of the `PRF` property.

**Default:** `0.5`

**PRF**

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The*PRF* must satisfy these restrictions:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of `PRF` must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* using property settings alone or using property settings in conjunction with the `prfidx` input argument of the `step` method.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties only. You can
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an argument specifying an index into the *PRF* vector.

In all cases, the number of output samples is fixed when you set the `OutputFormat` property to `'Samples'`. When you use a varying *PRF* and set the `OutputFormat` property to `'Pulses'`, the number of samples can vary.

**Default:** `10e3`

### PRFSelectionInputPort

Enable PRF selection input

Enable the PRF selection input, specified as true or false. When you set this property to false, the step method uses the values set in the PRF property. When you set this property to true, you pass an index argument into the step method to select a value from the PRF vector.

**Default:** false

### FrequencyStep

Linear frequency step size

Specify the linear frequency step size (in hertz) as a positive scalar. The default value of this property corresponds to 20 kHz.

**Default:** 20e3

### NumSteps

Specify the number of frequency steps as a positive integer. When NumSteps is 1, the stepped FM waveform reduces to a rectangular waveform.

**Default:** 5

### OutputFormat

Output signal format

Specify the format of the output signal as 'Pulses' or 'Samples'. When you set the OutputFormat property to 'Pulses', the output of the step method takes the form of multiple pulses specified by the value of the NumPulses property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the OutputFormat property to 'Samples', the output of the step method is in the form of multiple samples. In this case, the number of output signal samples is the value of the NumSamples property and is fixed.

**Default:** 'Pulses'

### NumSamples

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

### NumPulses

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

**Default:** `1`

### PRFOutputPort

Set this property to `true` to output the PRF for the current pulse using a `step` method argument.

#### Dependencies

This property can be used only when the `OutputFormat` property is set to `'Pulses'`.

**Default:** `false`

## Methods

# Examples

### Plot Stepped-FM Waveform and Spectrum

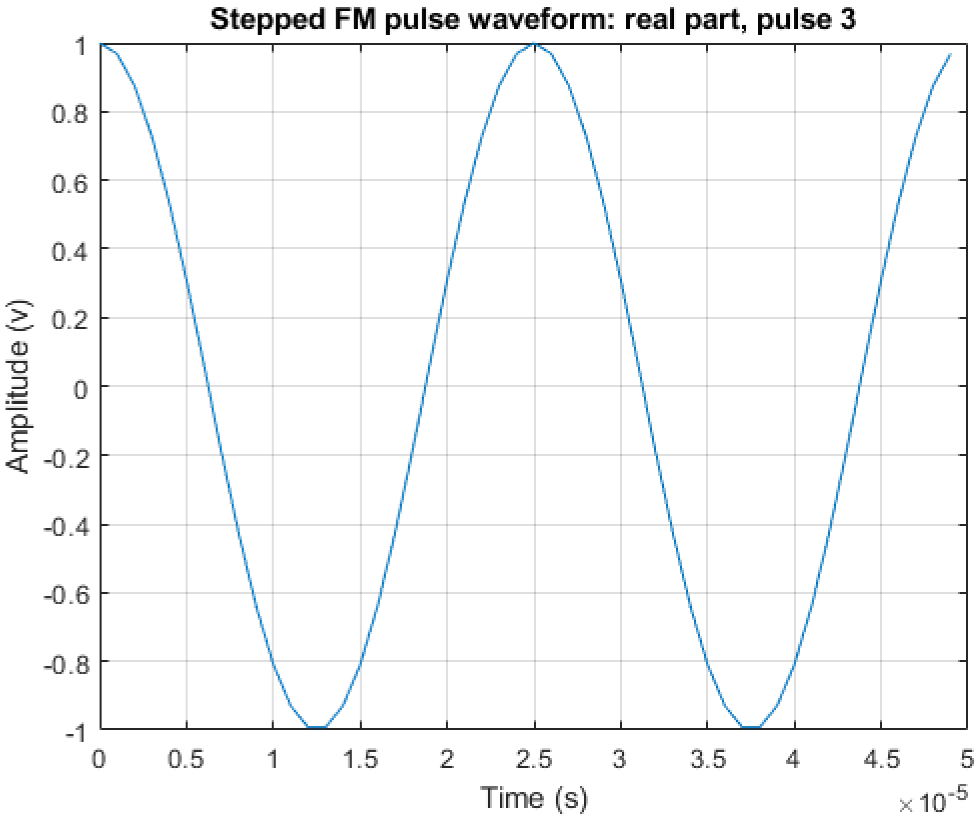
Create a stepped frequency pulse waveform object. Assume the default value, 1 MHz, for the sample rate. Then, plot the waveform.

Create the SteppedFMWaveform System object™ with 20 kHz frequency step size.

```
sSFM = phased.SteppedFMWaveform('NumSteps',3,'FrequencyStep',20e3);
fs = sSFM.SampleRate;
```

Plot the third pulse of the wave using the `phased.SteppedFMWaveform.plot` method. Pass in the pulse number using the `'PulseIdx'` name-value pair.

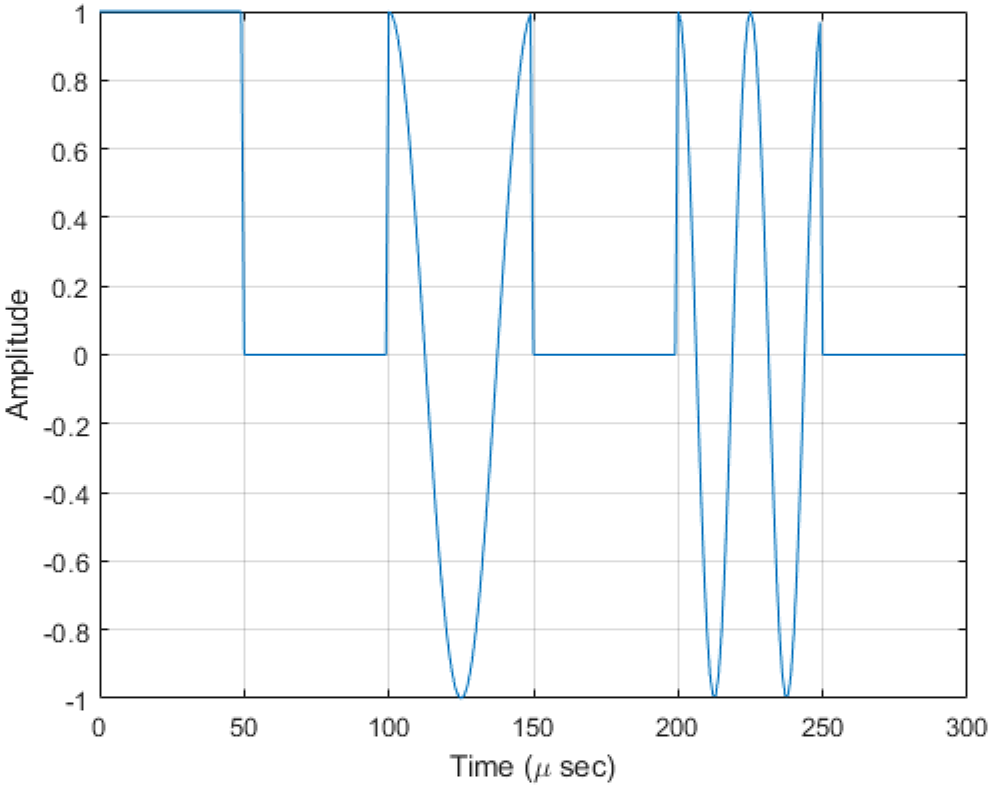
```
plot(sSFM,'PulseIdx',3);
```



Alternatively, call the `step` method three times to obtain three pulses. Collect the three pulses in a single time series. Then plot the waveform using the `plot` function. You can see the full duty cycles of the pulses.

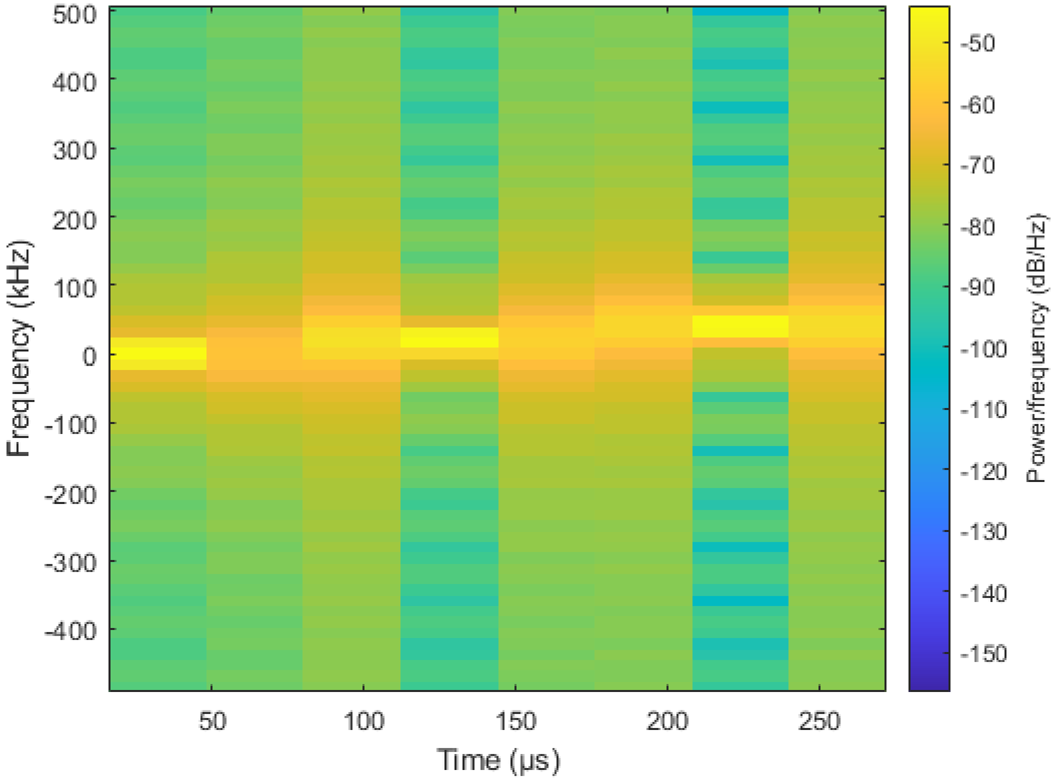
```
wavfull = [];
wav = step(sSFM);
wavfull = [wavfull;wav];
wav = step(sSFM);
wavfull = [wavfull;wav];
wav = step(sSFM);
wavfull = [wavfull;wav];
nsamps = size(wavfull,1);
t = [0:(nsamps-1)]/fs*1e6;
plot(t,real(wavfull))
```

```
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



Plot the spectrum using the `spectrogram` function. Assume an fft of 64 samples and a 50% overlap. Window the signal with a hamming function.

```
nfft1 = 64;
nov = floor(0.5*nfft1);
spectrogram(wavfull,hamming(nfft1),nov,nfft1,fs,'centered','yaxis')
```



# More About

## Stepped FM Waveform

In a stepped FM waveform, a group of pulses together sweep a certain bandwidth. Each pulse in this group occupies a given center frequency and these center frequencies are uniformly located within the total bandwidth.

### Topics

Waveform Analysis Using the Ambiguity Function

**Introduced in R2012a**

# bandwidth

**System object:** `phased.SteppedFMWaveform`
**Package:** `phased`

Bandwidth of stepped FM pulse waveform

## Syntax

```
BW = bandwidth(H)
```

## Description

`BW = bandwidth(H)` returns the bandwidth (in hertz) of the pulses for the stepped FM pulse waveform `H`. If there are N frequency steps, the bandwidth equals N times the value of the `FrequencyStep` property. If there is no frequency stepping, the bandwidth equals the reciprocal of the pulse width.

## Input Arguments

**`H`**

Stepped FM pulse waveform object.

## Output Arguments

**`BW`**

Bandwidth of the pulses, in hertz.

## Examples

### Bandwidth of Stepped FM Waveform.

Determine the bandwidth of a stepped FM waveform.

```
waveform = phased.SteppedFMWaveform;
bw = bandwidth(waveform)
```

```
bw = 100000
```

# getMatchedFilter

**System object:** `phased.SteppedFMWaveform`
**Package:** `phased`

Matched filter coefficients for waveform

## Syntax

```
Coeff = getMatchedFilter(H)
```

## Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the stepped FM waveform object `H`. `Coeff` is a matrix whose columns correspond to the different frequency pulses in the stepped FM waveform.

## Examples

### Matched Filter Coefficients for Stepped FM Pulse

Get the matched filter coefficients for a stepped FM pulse waveform.

```
waveform = phased.SteppedFMWaveform(...
    'NumSteps',3,'FrequencyStep',2e4,...
    'OutputFormat','Pulses','NumPulses',3);
coeff = getMatchedFilter(waveform);
```

Show the first four coefficients for each step.

```
coeff(1:4,:)
```

```
ans = 4×3 complex

   1.0000 + 0.0000i   0.9921 + 0.1253i   0.9686 + 0.2487i
   1.0000 + 0.0000i   0.9686 + 0.2487i   0.8763 + 0.4818i
```

```
    1.0000 + 0.0000i   0.9298 + 0.3681i   0.7290 + 0.6845i
    1.0000 + 0.0000i   0.8763 + 0.4818i   0.5358 + 0.8443i
```

# plot

**System object:** `phased.SteppedFMWaveform`
**Package:** `phased`

Plot stepped FM pulse waveform

## Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

## Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

## Input Arguments

### Hwav

Waveform object. This variable must be a scalar that represents a single waveform object.

### LineSpec

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

**Default:** `'b'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### PlotType

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

**Default:** `'real'`

### PulseIdx

Index of the pulse to plot. This value must be a scalar.

**Default:** `1`

# Output Arguments

### h

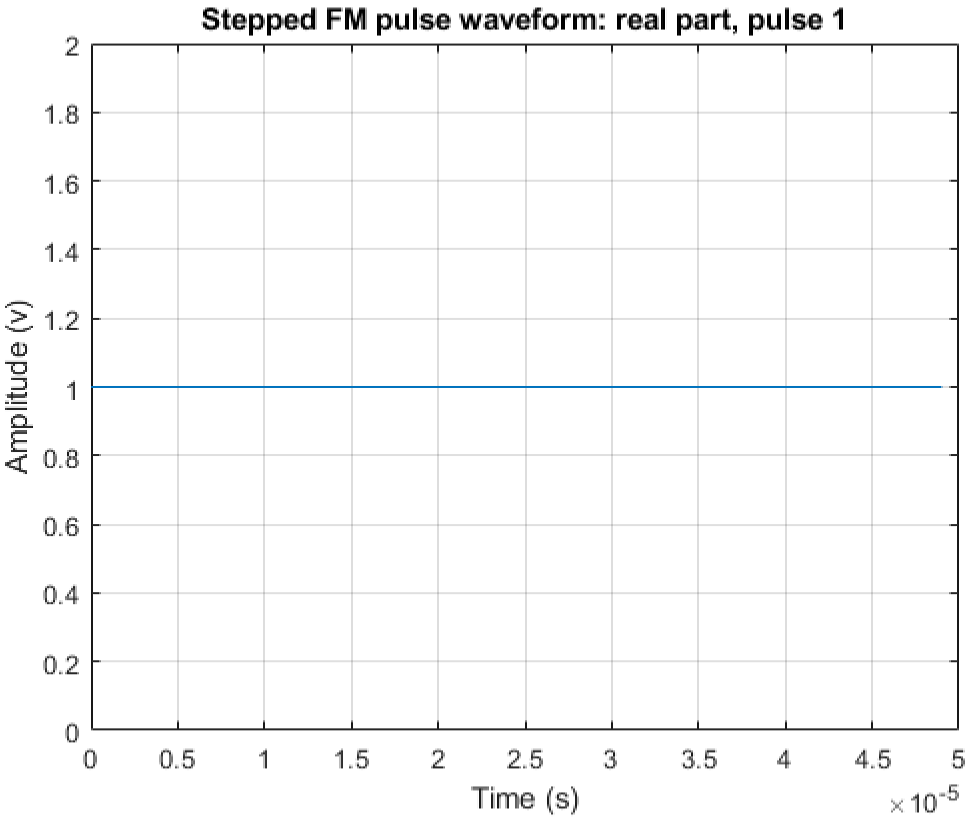
Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

# Examples

### Plot Stepped FM Waveform

Create and plot a stepped frequency pulse waveform.

```
waveform = phased.SteppedFMWaveform('NumSteps',3);
plot(waveform);
```



# reset

**System object:** `phased.SteppedFMWaveform`
**Package:** `phased`

Reset state of stepped FM pulse waveform object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `SteppedFMWaveform` object, `H`. Afterward, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

# step

**System object:** `phased.SteppedFMWaveform`
**Package:** `phased`

Samples of stepped FM pulse waveform

## Syntax

```
Y = step(sSFM)
Y = step(sSFM,prfidx)
[Y,PRF] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sSFM)` returns samples of the stepped FM pulses in a column vector, `Y`. The output, `Y`, results from increasing the frequency of the preceding output by an amount specified by the `FrequencyStep` property. If the total frequency increase is larger than the value specified by the `SweepBandwidth` property, the samples of a rectangular pulse are returned.

`Y = step(sSFM,prfidx)`, uses the `prfidx` index to select the PRF from the predefined vector of values specified by in the `PRF` property. This syntax applies when you set the `PRFSelectionInputPort` property to `true`.

`[Y,PRF] = step( ___ )` also returns the current pulse repetition frequency, `PRF`. To enable this syntax, set the `PRFOutputPort` property to `true` and set the `OutputFormat` property to `'Pulses'`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

### Create Stepped Frequency Pulse Waveform

Create a stepped frequency pulse waveform object with a frequency step of 40 kHz and four frequency steps.

```
waveform = phased.SteppedFMWaveform(...
    'NumSteps',4,'FrequencyStep',40e3,...
    'OutputFormat','Pulses','NumPulses',1);
fs = waveform.SampleRate;
```

Use the `waveform` method to obtain the pulses.

First, generate pulse 1.

```
pulse1 = waveform();
```

Then, generate pulse 2, incremented by the frequency step 40 kHz

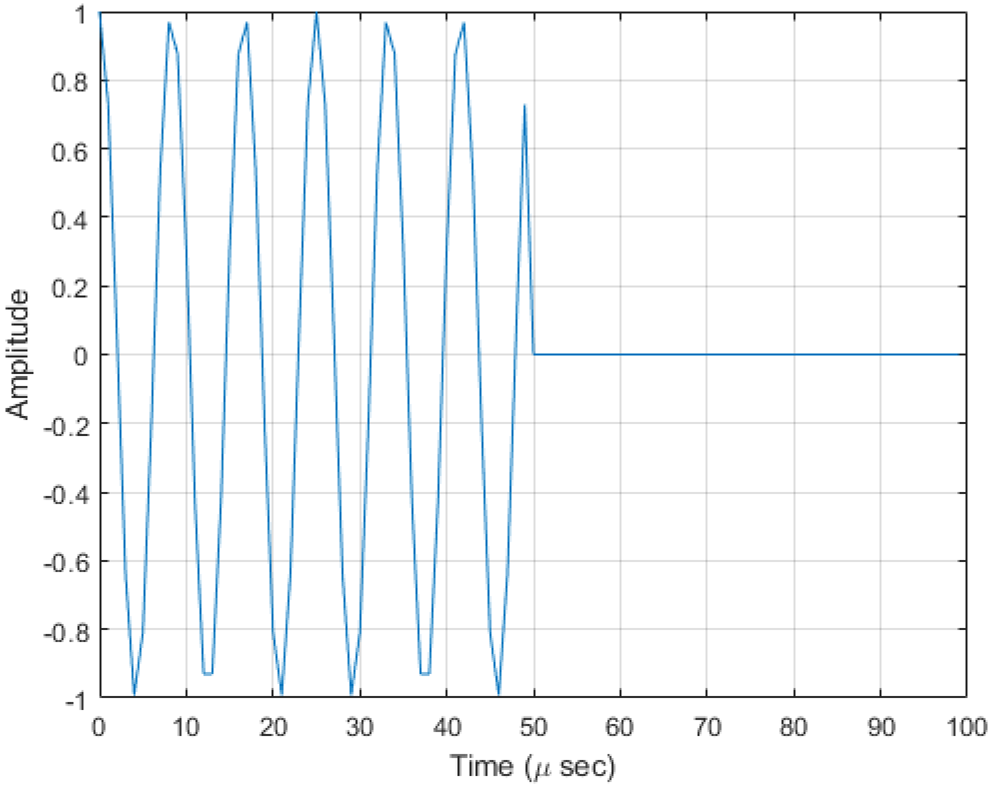
```
pulse2 = waveform();
```

Next, generate pulse 3, incremented by the frequency step 40 kHz

```
pulse3 = waveform();
```

Finally, generate pulse 4, incremented by the frequency step 40 kHz

```
pulse4 = waveform();
nsamps = size(pulse4,1);
t = [0:(nsamps-1)]/fs*1e6;
plot(t,real(pulse4))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



# More About

## Stepped FM Waveform

In a stepped FM waveform, a group of pulses together sweep a certain bandwidth. Each pulse in this group occupies a given center frequency and these center frequencies are uniformly located within the total bandwidth.

# phased.StretchProcessor

**Package:** phased

Stretch processor for linear FM waveform

## Description

The StretchProcessor object performs stretch processing on data from a linear FM waveform.

To perform stretch processing:

1. Define and set up your stretch processor. See “Construction” on page 1-2203.
2. Call step to perform stretch processing on input data according to the properties of phased.StretchProcessor. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.StretchProcessor creates a stretch processor System object, H. The object performs stretch processing on data from a linear FM waveform.

H = phased.StretchProcessor(Name,Value) creates a stretch processor object, H, with additional options specified by one or more Name,Value pair arguments. Name is a property name on page 1-2204, and Value is the corresponding value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1,…,NameN,ValueN.

## Properties

### `SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples. This property can be specified as single or double precision.

**Default:** `1e6`

### `PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`. This property can be specified as single or double precision.

**Default:** `50e-6`

### `PRFSource`

Source of pulse repetition values

Source of the PRF values for the stretch processor, specified as `'Property'`, `'Auto'`, or `'Input port'`. When you set this property to `'Property'`, the PRF is determined by the value of the `PRF` property. When you set this property to `'Input port'`, the PRF is determined by an input argument to the `step` method at execution time. When you set this property to `'Auto'`, the PRF is computed from the number of rows in the input signal.

**Default:** `'Property'`

### `PRF`

Pulse repetition frequency

Pulse repetition frequency (PRF) of the received signal, specified as a positive scalar. Units are in Hertz. This property can be specified as single or double precision.

**Dependencies**

To enable this property, set the `PRFSource` property to `'Property'`.

**Default:** `1`

### `SweepSlope`

FM sweep slope

Specify the slope of the linear FM sweeping, in hertz per second, as a scalar.

**Default:** `2e9`

### `SweepInterval`

Location of FM sweep interval

Specify the linear FM sweeping interval using the value `'Positive'` or `'Symmetric'`. If `SweepInterval` is `'Positive'`, the waveform sweeps in the interval between 0 and B, where B is the sweep bandwidth. If `SweepInterval` is `'Symmetric'`, the waveform sweeps in the interval between –B/2 and B/2. This property can be specified as single or double precision.

**Default:** `'Positive'`

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `ReferenceRange`

Reference range of stretch processing

Specify the center of ranges of interest, in meters, as a positive scalar. The reference range must be within the unambiguous range of one pulse. This property can be specified as single or double precision. This property is tunable.

**Default:** `5000`

#### RangeSpan

Span of ranges of interest

Specify the length of the interval for ranges of interest, in meters, as a positive scalar. The range span is centered at the range value specified in the `ReferenceRange` property. This property can be specified as single or double precision.

**Default:** `500`

## Methods

| | |
|---|---|
| step | Perform stretch processing for linear FM waveform |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Detect a Target Using Stretch Processing

Use stretch processing to locate a target at a range of 4950 m.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Simulate the signal.

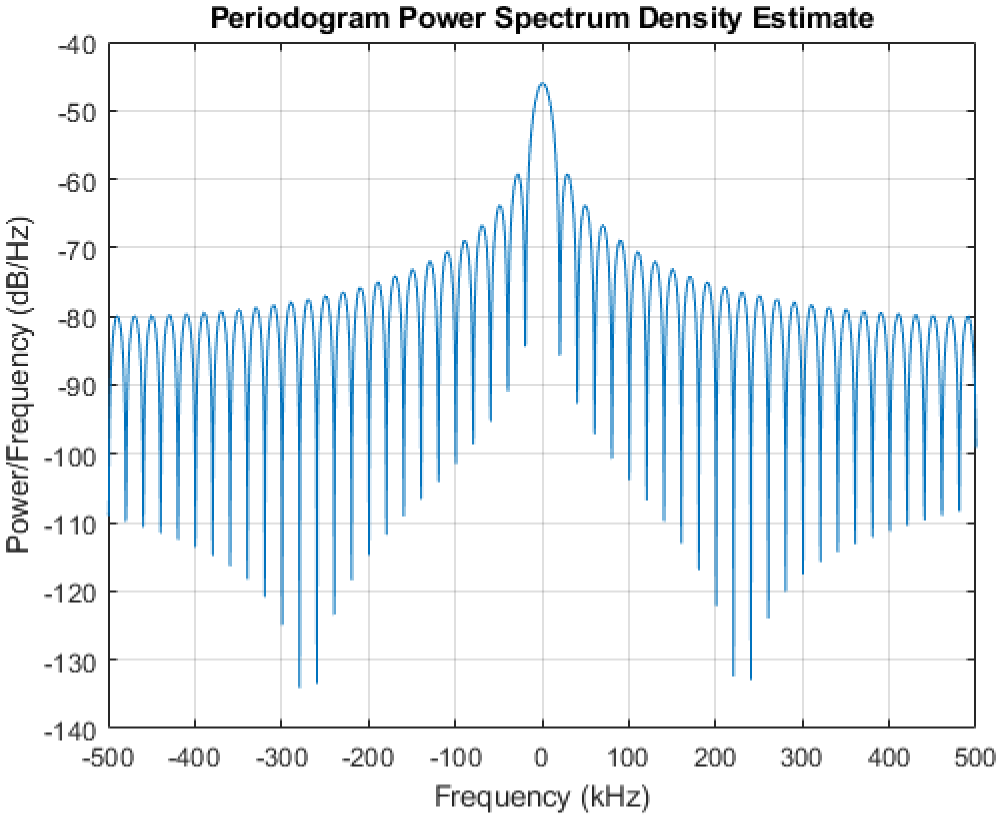
```
waveform = phased.LinearFMWaveform;
x = waveform();
c = physconst('LightSpeed');
rng = 4950.0;
num_samples = round(rng/(c/(2*waveform.SampleRate)));
x = circshift(x,num_samples);
```

Perform stretch processing.

```
stretchproc = getStretchProcessor(waveform,5000,200,c);
y = stretchproc(x);
```

Plot the spectrum of the resulting signal.

```
[Pxx,F] = periodogram(y,[],2048,stretchproc.SampleRate,'centered');
plot(F/1000,10*log10(Pxx))
grid
xlabel('Frequency (kHz)')
ylabel('Power/Frequency (dB/Hz)')
title('Periodogram Power Spectrum Density Estimate')
```



Detect the range.

```
[~,rngidx] = findpeaks(pow2db(Pxx/max(Pxx)),'MinPeakHeight',-5);
rngfreq = F(rngidx);
rng = stretchfreq2rng(rngfreq,stretchproc.SweepSlope,stretchproc.ReferenceRange,c)

rng = 4.9634e+03
```

## Algorithms

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# step

**System object:** `phased.StretchProcessor`
**Package:** `phased`

Perform stretch processing for linear FM waveform

## Syntax

```
Y = step(H,X)
Y = step(H,X,PRF)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies stretch processing along the first dimension of `X`. Each column of `X` represents one receiving pulse.

`Y = step(H,X,PRF)` uses `PRF` as the pulse repetition frequency. This syntax is available when the `PRFSource` property is `'Input port'`.

## Input Arguments

### H

Stretch processor object.

### X

Input signal matrix. Each column represents one received pulse.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**PRF**

Pulse repetition frequency specified as a positive scalar. To enable this argument, set the `PRFSource` property to `'Input port'`. Units are in Hertz.

# Output Arguments

**Y**

Result of stretch processing. The dimensions of `Y` match the dimensions of `X`.

# Examples

### Detect a Target Using Stretch Processing

Use stretch processing to locate a target at a range of 4950 m.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Simulate the signal.

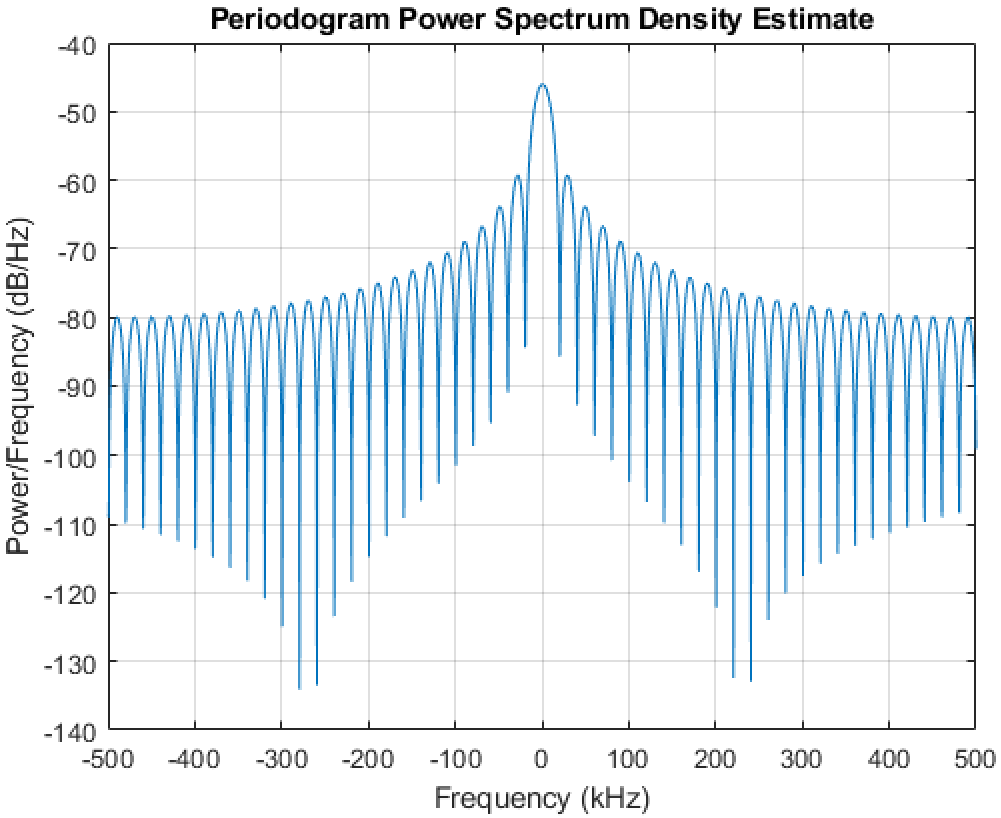
```
waveform = phased.LinearFMWaveform;
x = waveform();
c = physconst('LightSpeed');
rng = 4950.0;
num_samples = round(rng/(c/(2*waveform.SampleRate)));
x = circshift(x,num_samples);
```

Perform stretch processing.

```
stretchproc = getStretchProcessor(waveform,5000,200,c);
y = stretchproc(x);
```

Plot the spectrum of the resulting signal.

```
[Pxx,F] = periodogram(y,[],2048,stretchproc.SampleRate,'centered');
plot(F/1000,10*log10(Pxx))
grid
xlabel('Frequency (kHz)')
ylabel('Power/Frequency (dB/Hz)')
title('Periodogram Power Spectrum Density Estimate')
```



Detect the range.

```
[~,rngidx] = findpeaks(pow2db(Pxx/max(Pxx)),'MinPeakHeight',-5);
rngfreq = F(rngidx);
rng = stretchfreq2rng(rngfreq,stretchproc.SweepSlope,stretchproc.ReferenceRange,c)
```

```
rng = 4.9634e+03
```

# phased.SubbandMVDRBeamformer

**Package:** phased

Wideband minimum-variance distortionless-response beamformer

## Description

The phased.SubbandMVDRBeamformer System object implements a wideband minimum variance distortionless response beamformer (MVDR) based on the subband processing technique. This type of beamformer is also called a Capon beamformer.

To beamform signals arriving at an array:

1. Create the phased.SubbandMVDRBeamformer object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
beamformer = phased.SubbandMVDRBeamformer
beamformer = phased.SubbandMVDRBeamformer(Name,Value)
```

### Description

beamformer = phased.SubbandMVDRBeamformer creates a subband MVDR beamformer System object, beamformer. The object performs subband MVDR beamforming on the received signal.

beamformer = phased.SubbandMVDRBeamformer(Name,Value) creates a subband MVDR beamformer System object, beamformer, with each specified property Name set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1`,`Value1`,...,`NameN`,`ValueN`.

Example: `beamformer = phased.SubbandMVDRBeamformer('SensorArray',phased.URA('Size',[5 5]),'OperatingFrequency',500e6)` sets the sensor array to a 5-by-5 uniform rectangular array (URA) with all other default URA property values. The beamformer has an operating frequency of 500 MHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `SensorArray` — Sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox array

Sensor array, specified as an array System object belonging to Phased Array System Toolbox. The sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `single` | `double`

### `SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `single` | `double`

### `NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

### `DirectionSource` — Source of beamforming direction

`'Property'` (default) | `'Input port'`

Source of beamforming direction, specified as `'Property'` or `'Input port'`. Specify whether the beamforming direction comes from the `Direction` property of this object or from the input argument, `ANG`. Values of this property are:

| | |
|---|---|
| `'Property'` | Specify the beamforming direction using the `Direction` property. |
| `'Input port'` | Specify the beamforming direction using the input argument, `ANG`. |

Data Types: `char`

### `Direction` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 vector or a real-valued 2-by-*L* matrix. For a matrix, each column specifies a different beamforming direction. Each column has the form [AzimuthAngle;ElevationAngle]. Azimuth angles must lie between –180° and 180° and elevation angles must lie between –90° and 90°. All angles are defined with respect to the local coordinate system of the array. Units are in degrees.

Example: [40;30]

#### Dependencies

To enable this property, set the DirectionSource property to 'Property'.

Data Types: single | double

### DiagonalLoadingFactor — Diagonal loading factor

0 (default) | nonnegative scalar

Diagonal loading factor, specified as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample size is small. A small sample size can lead to an inaccurate estimate of the covariance matrix. Diagonal loading also provides robustness due to steering vector errors. The diagonal loading technique adds a positive scalar multiple of the identity matrix to the sample covariance matrix.

**Tunable:** Yes

Data Types: single | double

### TrainingInputPort — Enable training data input

false (default) | true

Enable training data input, specified as false or true. When you set this property to true, use the training data input argument, XT, when running the object. Set this property to false to use the input data, X, as the training data.

Data Types: logical

### WeightsOutputPort — Enable beamforming weights output

false (default) | true

Enable the output of beamforming weights, specified as false or true. To obtain the beamforming weights, set this property to true and use the corresponding output argument, W. If you do not want to obtain the weights, set this property to false.

Data Types: logical

**SubbandsOutputPort — Option to enable output of subband center frequencies**
false (default) | true

Option to enable output of subband center frequencies, specified as either true or false. To obtain the subband center frequencies, set this property to true and use the corresponding output argument FREQS when calling the object.

Data Types: logical

# Usage

# Syntax

```
Y = beamformer(X)
Y = beamformer(X,XT)
Y = beamformer(X,ANG)
[Y,W] = beamformer( ___ )
[Y,FREQS] = beamformer( ___ )
[Y,W,FREQS] = beamformer(X,XT,ANG)
```

## Description

Y = beamformer(X) performs wideband MVDR beamforming on the input, X, and returns the beamformed output in Y. This syntax uses X for training samples to calculate the beamforming weights. Use the Direction property to specify the beamforming direction.

Y = beamformer(X,XT) uses XT for training samples to calculate the beamforming weights.

Y = beamformer(X,ANG) uses ANG as the beamforming direction. This syntax applies when you set the DirectionSource property to 'Input port'.

[Y,W] = beamformer( ___ ) returns the beamforming weights, W. This syntax applies when you set the WeightsOutputPort property to true.

[Y,FREQS] = beamformer( ___ ) returns the center frequencies of the subbands, FREQS. This syntax applies when you set the SubbandsOutputPort property to true.

You can combine optional input arguments when you set their enabling properties. Optional input arguments must be listed in the same order as their enabling properties. For example, `[Y,W,FREQS] = beamformer(X,XT,ANG)` is valid when you specify TrainingInputPort as `true` and set DirectionSource to `'Input port'`.

## Input Arguments

### X — Wideband input signal

*M*-by-*N* complex-valued matrix

Wideband input signal, specified as an *M*-by-*N* matrix, where *N* is the number of array elements. *M* is the number of samples in the data. If the sensor array consists of subarrays, *N* is then the number of subarrays.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

If you set the TrainingInputPort to `false`, then the object uses `X` as training data. In this case, the dimension *M* must be greater than *N*×*NB*. where *NB* is the number of subbands specified in the NumSubbands.

If you set TrainingInputPort to `true`, use the `XT` argument to supply training data. In this case, the dimension *M* can be any positive integer.

Example: `[1,1;j,1;0.5,0]`

Data Types: `single` | `double`
Complex Number Support: Yes

### XT — Wideband training samples

*P*-by-*N* complex-valued matrix

Wideband training samples, specified as a *P*-by-*N* matrix where *N* is the number of elements. If the sensor array consists of subarrays, then *N* represents the number of subarrays.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

This argument applies when you set TrainingInputPort to `true`. The dimension *P* is the number of samples in the training data. *P* must be larger than *N*×*NB*, where *NB* is the number of subbands specified in the NumSubbands property.

Example: `FT = [1,1;j,1;0.5,0]`

Data Types: `single` | `double`
Complex Number Support: Yes

**`ANG` — Beamforming direction**
*2*-by-*L* real-valued matrix

Beamforming direction, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. This argument applies only when you set the DirectionSource property to `'Input port'`. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Example: `[40 30;0 10]`

Data Types: `single` | `double`

## Output Arguments

**`Y` — Beamformed output**
*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of beamforming directions specified in the `ANG` argument.

**`W` — Beamforming weights**
*N*-by-*K*-by-*L* complex-valued matrix

Beamforming weights, returned as an *N*-by-*K*-by-*L* complex-valued matrix. The quantity *N* is the number of sensor elements or subarrays and *K* is the number of subbands specified by the NumSubbands property. The quantity *L* is the number of beamforming directions. Each column of `W` contains the narrowband beamforming weights used in the corresponding subband for the corresponding directions.

**Dependencies**

To return this output, set the WeightsOutputPort property to `true`.

Data Types: single | double

**FREQS — Center frequencies of subbands**
*K*-by-1 real-valued column vector

Center frequencies of subbands, returned as a *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the NumSubbands property.

**Dependencies**

To return this output, set the SubbandsOutputPort property to `true`.

Data Types: single | double

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Subband MVDR Beamforming of ULA

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. The incident angle of the signal is 10° azimuth and 30° elevation. The signal is an FM chirp having a bandwidth of 1 kHz. The speed of sound is 1500 m/s.

### Simulate signal

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2e3;
```

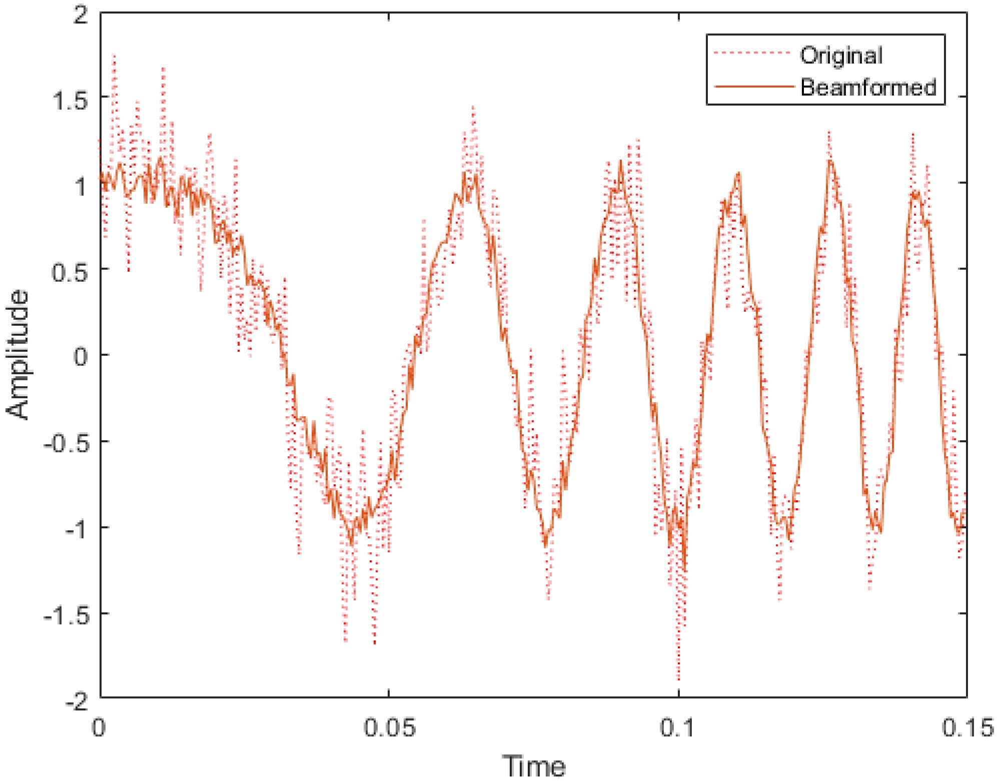
```
carrierFreq = 2000;
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
    'CarrierFrequency',carrierFreq);
incidentAngle = [10;0];
sig1 = collector(sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
rx = sig1 + noise;
```

### Apply MVDR beamforming

```
beamformer = phased.SubbandMVDRBeamformer('SensorArray',array,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true, ...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx, noise);
```

Plot the signal that is input to the middle sensor (channel 6) vs the beamformer output.

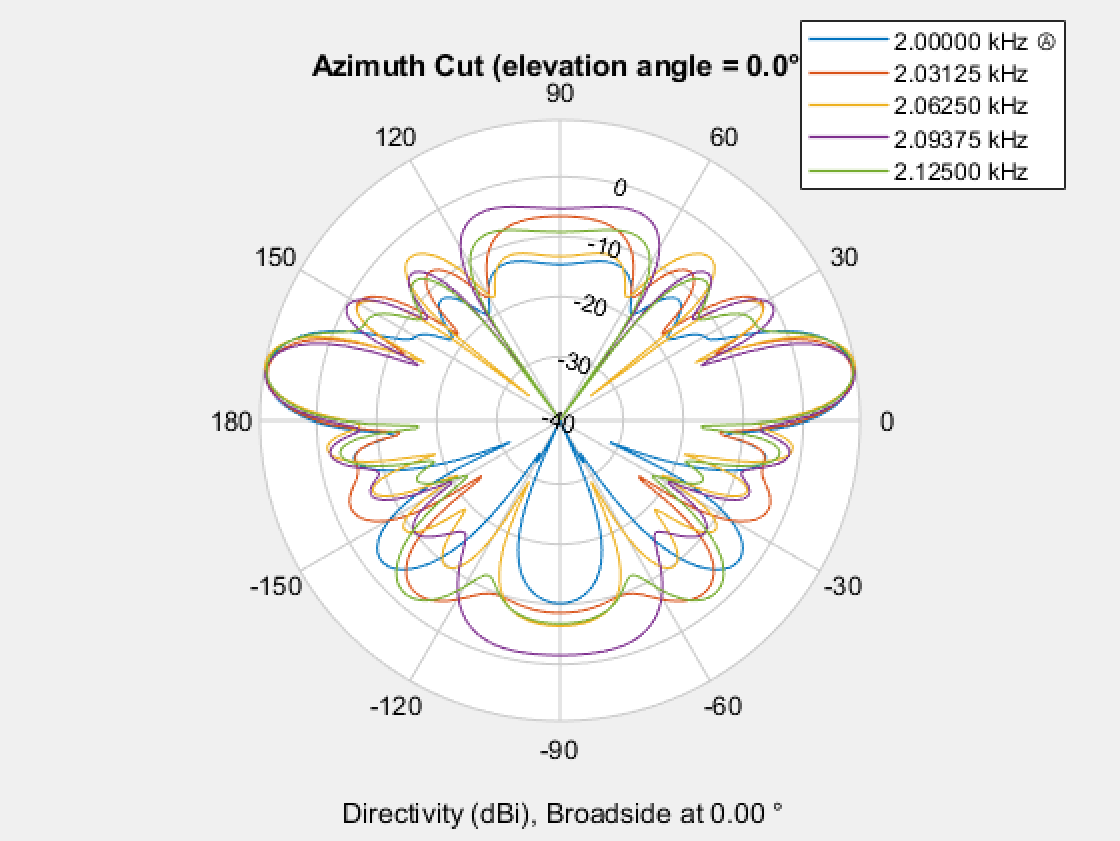
```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed');
```



### Plot array response

Plot the response pattern for five bands

```
pattern(array,subbandfreq(1:5).',-180:180,0,...
    'PropagationSpeed',c,'Weights',w(:,1:5));
```



### Subband MVDR Beamforming of Array with Interference

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. Beamform the arriving signals to optimize the gain of a linear FM chirp signal arriving from 0 degrees azimuth and 0 degrees elevation. The signal has a bandwidth of 2.0 kHz. In addition, there unit amplitude 2.250 kHz interfering sine wave arriving from 28 degrees azimuth and 0 degrees elevation. Show how the MVDR beamformer nulls the interfering signal. Display the array pattern for several frequencies in the neighborhood of 2.250 kHz. The speed of sound is 1500 meters/sec.

### Simulate Arriving Signal and Noise

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2000;
carrierFreq = 2000;
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
    'CarrierFrequency',carrierFreq);
incidentAngle = [0;0];
sig1 = collector(sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
```

### Simulate Interfering Signal

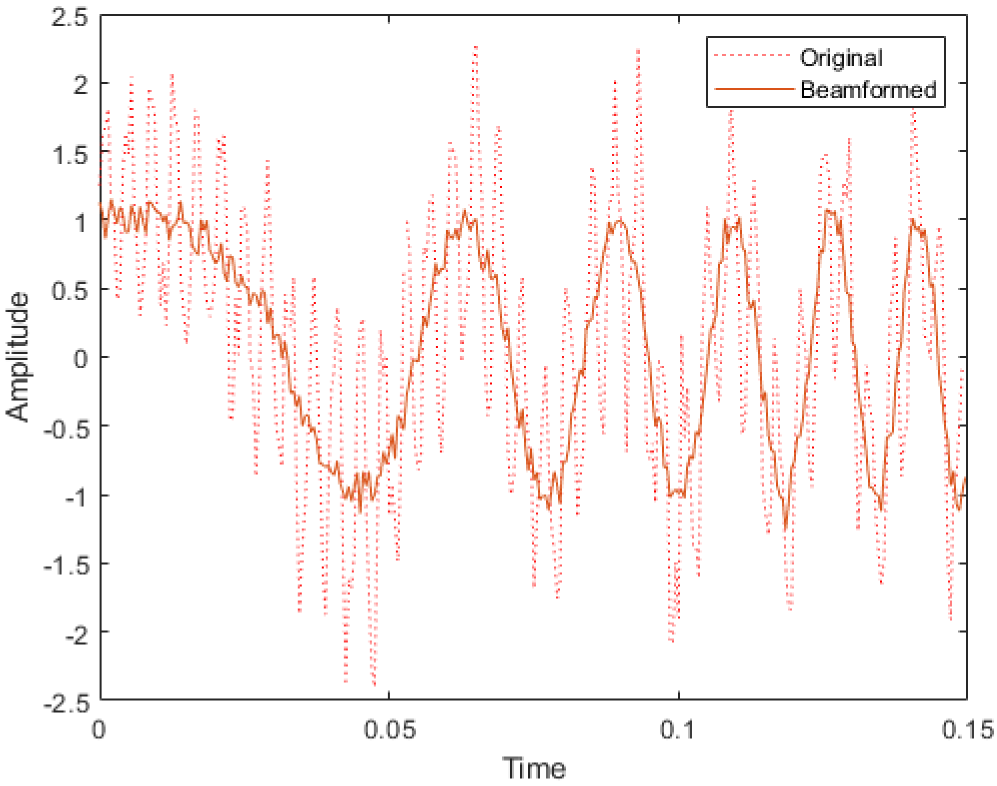
Combine both the desired and interfering signals.

```
fint = 250;
sigint = sin(2*pi*fint*t);
interfangle = [28;0];
sigint1 = collector(sigint,interfangle);
rx = sig1 + sigint1 + noise;
```

### Apply MVDR beamforming

Use the combined noise and interfering signal as training data.

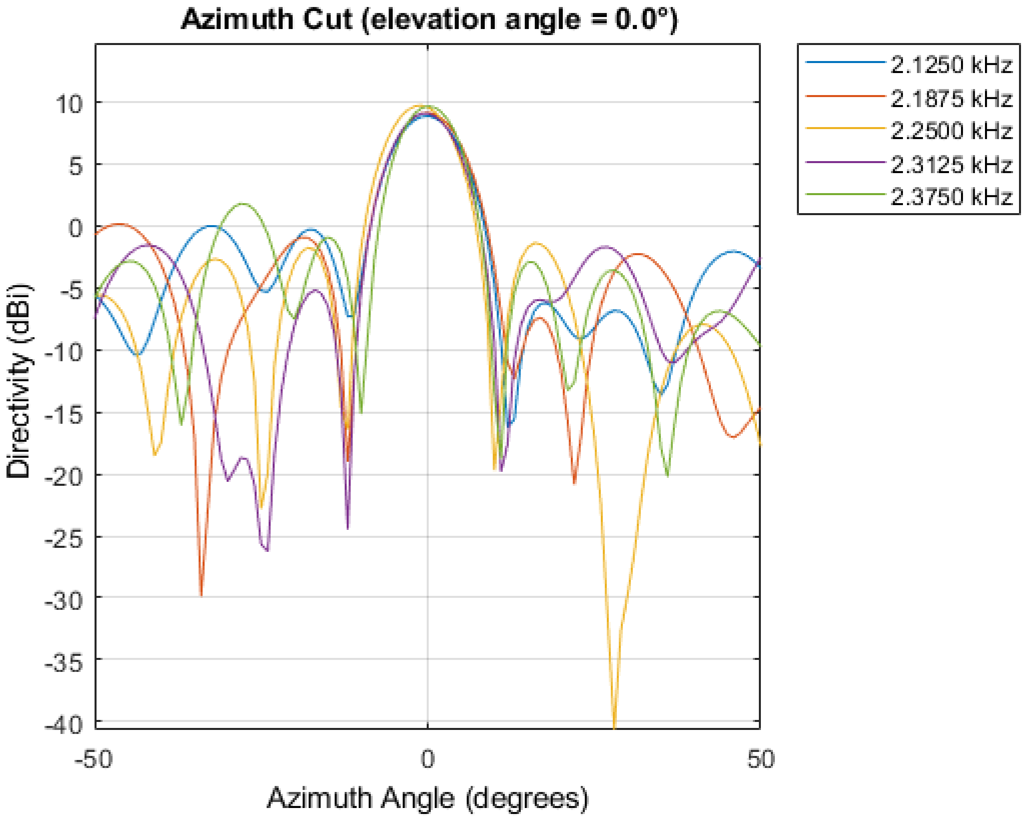
```
beamformer = phased.SubbandMVDRBeamformer('SensorArray',array,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true,...
    'NumSubbands',64,...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx,sigint1 + noise);
tidx = [1:300];
plot(t(tidx),real(rx(tidx,6)),'r:',t(tidx),real(y(tidx)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



### Plot Array Response Showing Beampattern Null

Plot the response pattern for five bands near 2.250 kHz.

```
fdx = [5,7,9,11,13];
pattern(array,subbandfreq(fdx).',-50:50,0,...
    'PropagationSpeed',c,'Weights',w(:,fdx),...
    'CoordinateSystem','rectangular');
```



The beamformer places a null at 28 degrees for the subband containing 2.250 kHz.

# More About

## Diagonal Loading

Diagonal loading is a technique to improve beamformer robustness when stability issues arise from steering vector errors or finite sample size effects. This technique adds a positive real-valued multiple of the identity matrix to the correlation matrix of the received array data vector. You can apply diagonal loading using the DiagonalLoadingFactor property.

# Algorithms

## Date Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_B$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N_B-1)f_s}{2N_B} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

**Introduced in R2015b**

# reset

**System object:** `phased.SubbandMVDRBeamformer`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(sMVDR)
```

## Description

`reset(sMVDR)` resets the internal state of the `phased.SubbandMVDRBeamformer` object, `sWBFS`. If the `SeedSource` property applies and has the value `'Property'`, then this method resets the state of the random number generator.

## Input Arguments

### `sMVDR` — Subband MVDR beamformer

System object

Subband MVDR beamformer, specified as a System object.

Example: `phased.SubbandMVDRBeamformer`

**Introduced in R2015b**

# step

**System object:** phased.SubbandMVDRBeamformer
**Package:** phased

Wideband MVDR beamforming

## Syntax

```
Y = step(sMVDR,X)
Y = step(sMVDR,X,XT)
Y = step(sMVDR,X,ang)
[Y,Wts] = step(sMVDR,___)
[Y,Freq] = step(sMVDR,___)
[Y,Wts,Freq] = step(sMVDR,X,XT,ang)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(sMVDR,X) performs wideband MVDR beamforming on the input, X, and returns the beamformed output in Y. This syntax uses X for training samples to calculate the beamforming weights. Use the Direction property to specify the beamforming direction.

Y = step(sMVDR,X,XT) uses XT as the training samples to calculate the beamforming weights. This syntax applies only when you set the TrainingInputPort property to true. Use the Direction property to specify the beamforming direction.

Y = step(sMVDR,X,ang) uses ang as the beamforming direction. This syntax applies only when you set the DirectionSource property to 'Input port'.

[Y,Wts] = step(sMVDR,___) returns the beamforming weights, Wts, when you set the WeightsOutputPort property to true.

[Y,Freq] = step(sMVDR,___) returns the center frequencies of the subbands, Freq, when you set the SubbandsOutputPort property to true. Freq is a length-*K* column vector where, *K* is the number of subbands specified in the NumSubbands property.

You can combine optional input arguments when you set their enabling properties. Optional input arguments must be listed in the same order as their enabling properties. For example, [Y,Wts,Freq] = step(sMVDR,X,XT,ang) is valid when you specify TrainingInputPort to true and specify DirectionSource to 'Input port'.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### sMVDR — Subband MVDR beamformer

System object

Subband MVDR beamformer, specified as a System object.

Example: phased.SubbandMVDRBeamformer

### X — Wideband input field

*M*-by-*N* complex-valued matrix

Wideband input field, specified as an *M*-by-*N* matrix, where *N* is the number of array elements. If the sensor array consists of subarrays, *N* is then the number of subarrays. *M* is the number of samples in the data.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

If you set the `TrainingInputPort` to `false`, then `step` uses `X` as training data. In this case, the dimension *M* must be greater than *N*×*NB*. where *NB* is the number of subbands specified in the `NumSubbands` property.

If you set `TrainingInputPort` to `true`, use the `XT` argument to supply training data. In this case, the dimension *M* can be any positive integer.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

**XT — Wideband training samples**
*P*-by-*N* complex-valued matrix

Wideband training samples, specified as a *P*-by-*N* matrix where *N* is the number of elements. If the sensor array consists of subarrays, then *N* represents the number of subarrays.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

This argument applies when you set `TrainingInputPort` to `true`. The dimension *P* is the number of samples in the training data. *P* must be larger than *N*×*NB*, where *NB* is the number of subbands specified in the `NumSubbands` property.

Example: `FT = [1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

**ang — Beamforming direction**
*2*-by-*L* real-valued matrix

Beamforming direction, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. This argument applies only when you set the `DirectionSource` property to `'Input port'`. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Example: `F = [40 30; 0 10]`

Data Types: `double`

## Output Arguments

### Y — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of beamforming directions specified in the `ang` argument.

### `Wts` — Beamforming weights

*N*-by-*K*-by-*L* complex-valued matrix

Beamforming weights, returned as an *N*-by-*K*-by-*L* complex-valued matrix. The quantity *N* is the number of sensor elements or subarrays and *K* is the number of subbands specified by the `NumSubbands` property. The quantity *L* is the number of beamforming directions. Each column of `Wts` contains the narrowband beamforming weights used in the corresponding subband for the corresponding directions. This output applies only when you set the `WeightsOutputPort` property to `true`.

### `Freq` — Center frequencies of subbands

*K*-by-1 real-valued column vector

Center frequencies of subbands, returned as a *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the `NumSubbands` property. To return this output, set the `SubbandsOutputPort` property to `true`.

## Examples

### Subband MVDR Beamforming of ULA

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. The incident angle of the signal is 10° azimuth and 30° elevation. The signal is an FM chirp having a bandwidth of 1 kHz. The speed of sound is 1500 m/s.

#### Simulate signal

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2e3;
carrierFreq = 2000;
```

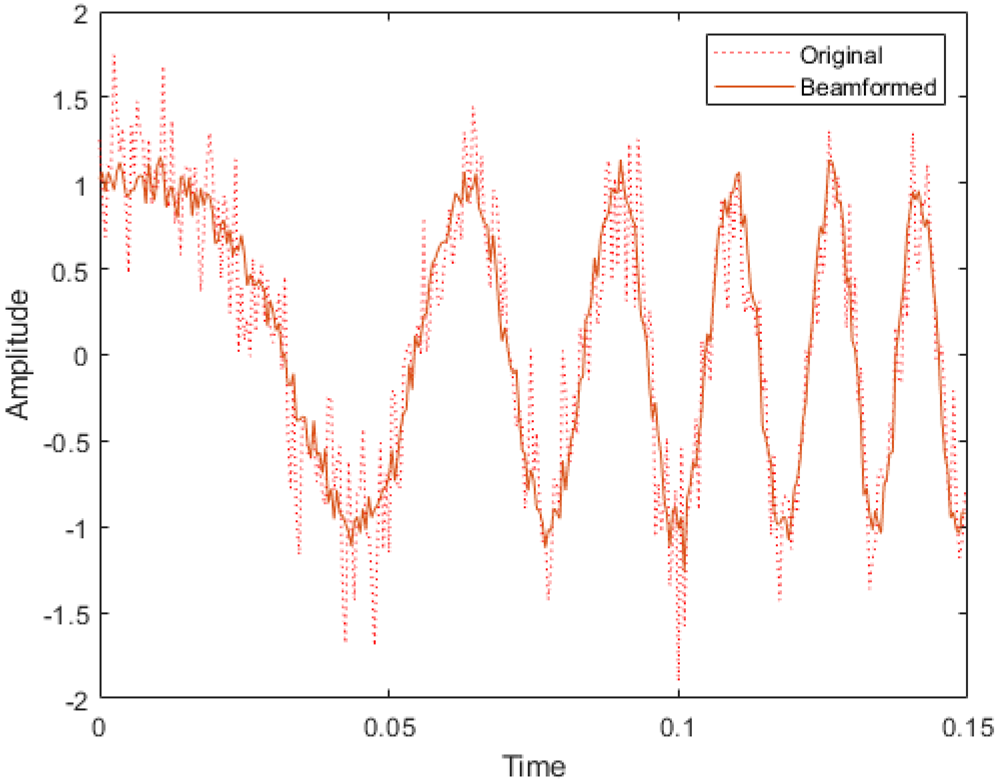
```
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
    'CarrierFrequency',carrierFreq);
incidentAngle = [10;0];
sig1 = collector(sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
rx = sig1 + noise;
```

### Apply MVDR beamforming

```
beamformer = phased.SubbandMVDRBeamformer('SensorArray',array,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true, ...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx, noise);
```

Plot the signal that is input to the middle sensor (channel 6) vs the beamformer output.

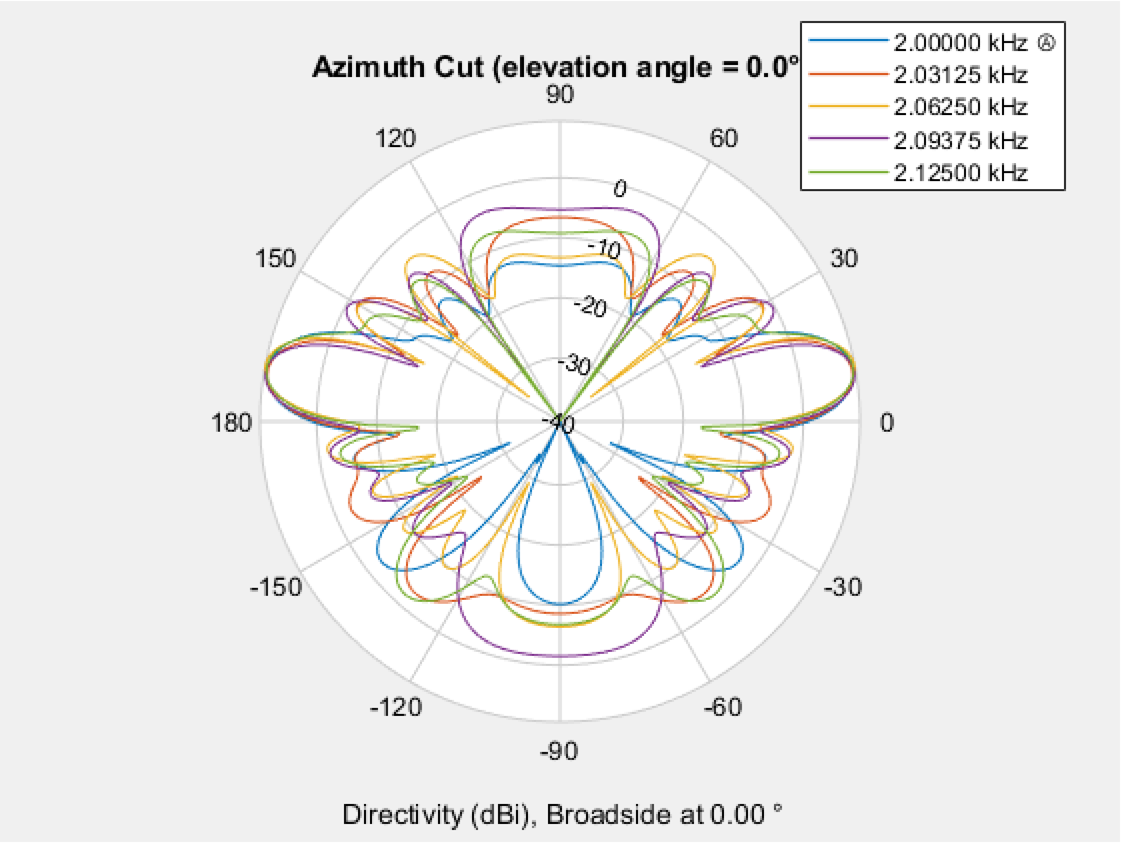
```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed');
```



### Plot array response

Plot the response pattern for five bands

```
pattern(array,subbandfreq(1:5).',-180:180,0,...
    'PropagationSpeed',c,'Weights',w(:,1:5));
```



### Subband MVDR Beamforming of Array with Interference

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. Beamform the arriving signals to optimize the gain of a linear FM chirp signal arriving from 0 degrees azimuth and 0 degrees elevation. The signal has a bandwidth of 2.0 kHz. In addition, there unit amplitude 2.250 kHz interfering sine wave arriving from 28 degrees azimuth and 0 degrees elevation. Show how the MVDR beamformer nulls the interfering signal. Display the array pattern for several frequencies in the neighborhood of 2.250 kHz. The speed of sound is 1500 meters/sec.

### Simulate Arriving Signal and Noise

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2000;
carrierFreq = 2000;
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
    'CarrierFrequency',carrierFreq);
incidentAngle = [0;0];
sig1 = collector(sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
```

### Simulate Interfering Signal

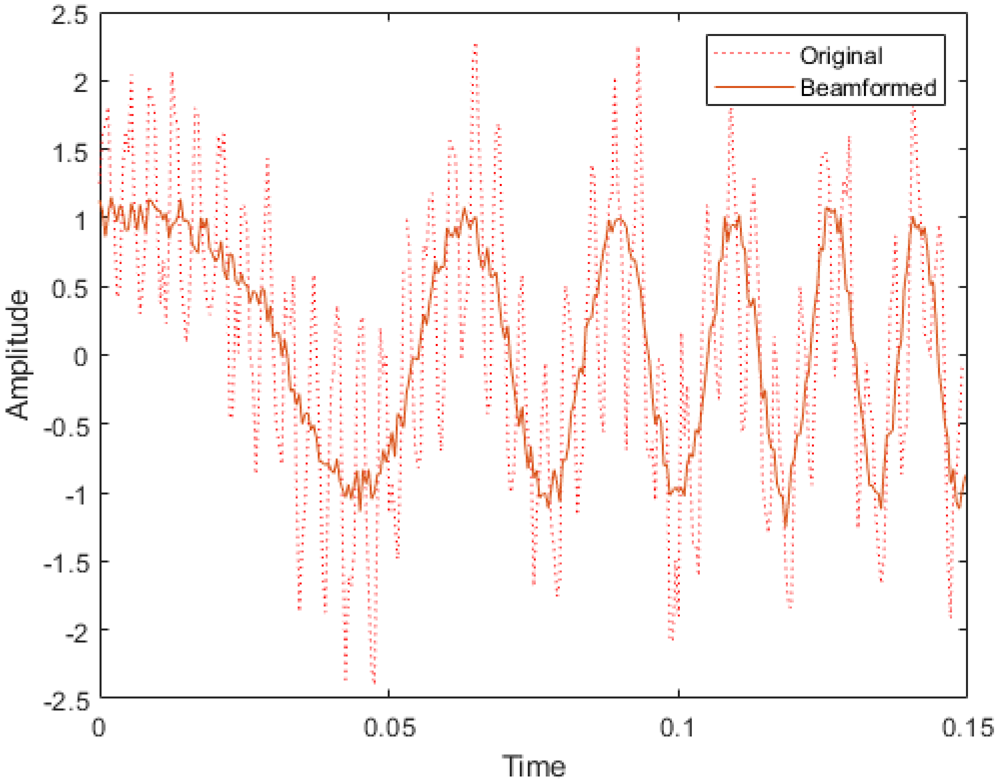
Combine both the desired and interfering signals.

```
fint = 250;
sigint = sin(2*pi*fint*t);
interfangle = [28;0];
sigint1 = collector(sigint,interfangle);
rx = sig1 + sigint1 + noise;
```

### Apply MVDR beamforming

Use the combined noise and interfering signal as training data.

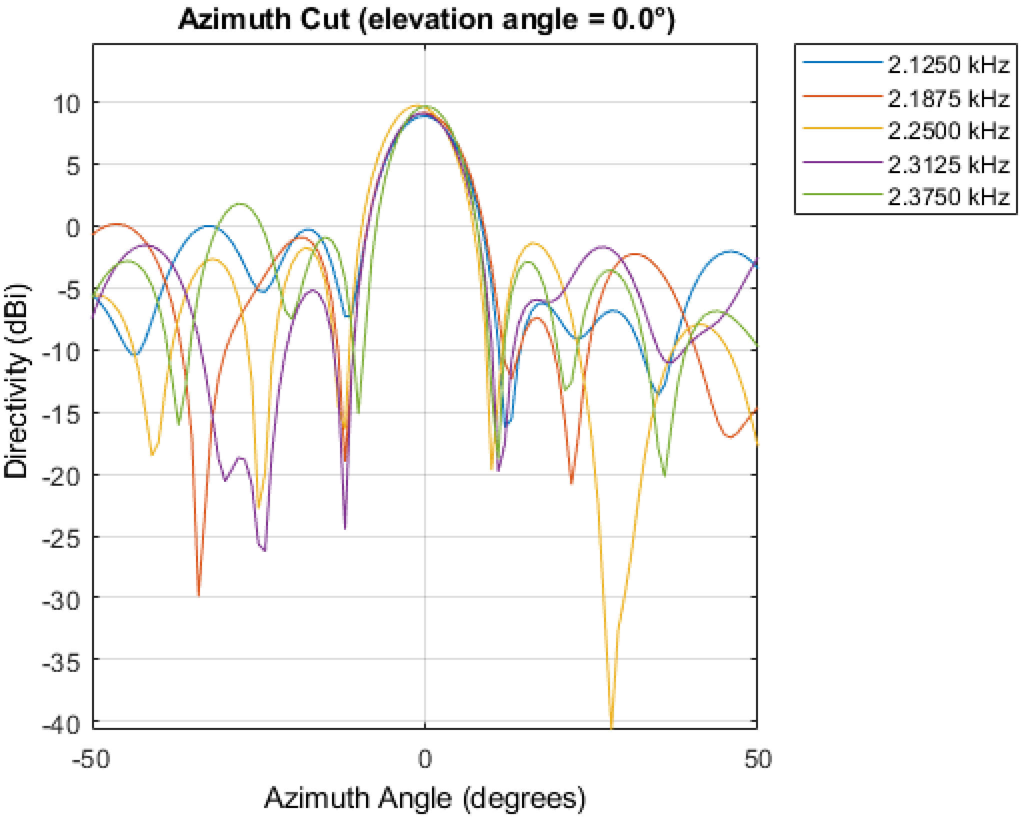
```
beamformer = phased.SubbandMVDRBeamformer('SensorArray',array,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true,...
    'NumSubbands',64,...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx,sigint1 + noise);
tidx = [1:300];
plot(t(tidx),real(rx(tidx,6)),'r:',t(tidx),real(y(tidx)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



### Plot Array Response Showing Beampattern Null

Plot the response pattern for five bands near 2.250 kHz.

```
fdx = [5,7,9,11,13];
pattern(array,subbandfreq(fdx).',-50:50,0,...
    'PropagationSpeed',c,'Weights',w(:,fdx),...
    'CoordinateSystem','rectangular');
```



The beamformer places a null at 28 degrees for the subband containing 2.250 kHz.

**Introduced in R2015b**

# phased.SubbandPhaseShiftBeamformer

**Package:** phased

Subband phase shift beamformer

## Description

The SubbandPhaseShiftBeamformer object implements a subband phase shift beamformer.

To compute the beamformed signal:

1. Define and set up your subband phase shift beamformer. See “Construction” on page 1-2242.
2. Call step to perform the beamforming operation according to the properties of phased.SubbandPhaseShiftBeamformer. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.SubbandPhaseShiftBeamformer creates a subband phase shift beamformer System object, H. The object performs subband phase shift beamforming on the received signal.

H = phased.SubbandPhaseShiftBeamformer(Name,Value) creates a subband phase shift beamformer object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the beamformer in hertz as a scalar. The default value of this property corresponds to 300 MHz. This property can be specified as single or double precision.

**Default:** `3e8`

### `SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar. This property can be specified as single or double precision.

**Default:** `1e6`

### `NumSubbands`

Number of subbands

Specify the number of subbands used in the subband processing as a positive integer. This property can be specified as single or double precision.

**Default:** `64`

### DirectionSource

Source of beamforming direction

Specify whether the beamforming direction for the beamformer comes from the `Direction` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Direction` property of this object specifies the beamforming direction. |
| `'Input port'` | An input argument in each invocation of `step` specifies the beamforming direction. |

**Default:** `'Property'`

### Direction

Beamforming directions

Specify the beamforming directions of the beamformer as a two-row matrix. Each column of the matrix has the form [AzimuthAngle; ElevationAngle] (in degrees). Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees. This property applies when you set the `DirectionSource` property to `'Property'`. This property can be specified as single or double precision.

**Default:** `[0; 0]`

### WeightsOutputPort

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the weights, set this property to `false`.

**Default:** `false`

### SubbandsOutputPort

Output subband center frequencies

To obtain the center frequencies of each subband, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the center frequencies, set this property to `false`.

**Default:** `false`

## Methods

| | |
|---|---|
| step | Beamforming using subband phase shifting |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Subband Phase-Shift Beamformer for Underwater ULA

Apply subband phase-shift beamforming to an 11-element underwater ULA. The incident angle of a wideband signal is 10° in azimuth and 30° in elevation. The carrier frequency is 2 kHz.

Create the ULA.

```
antenna = phased.ULA('NumElements',11,'ElementSpacing',0.3);
antenna.Element.FrequencyRange = [20 20000];
```

Create a chirp signal with noise.

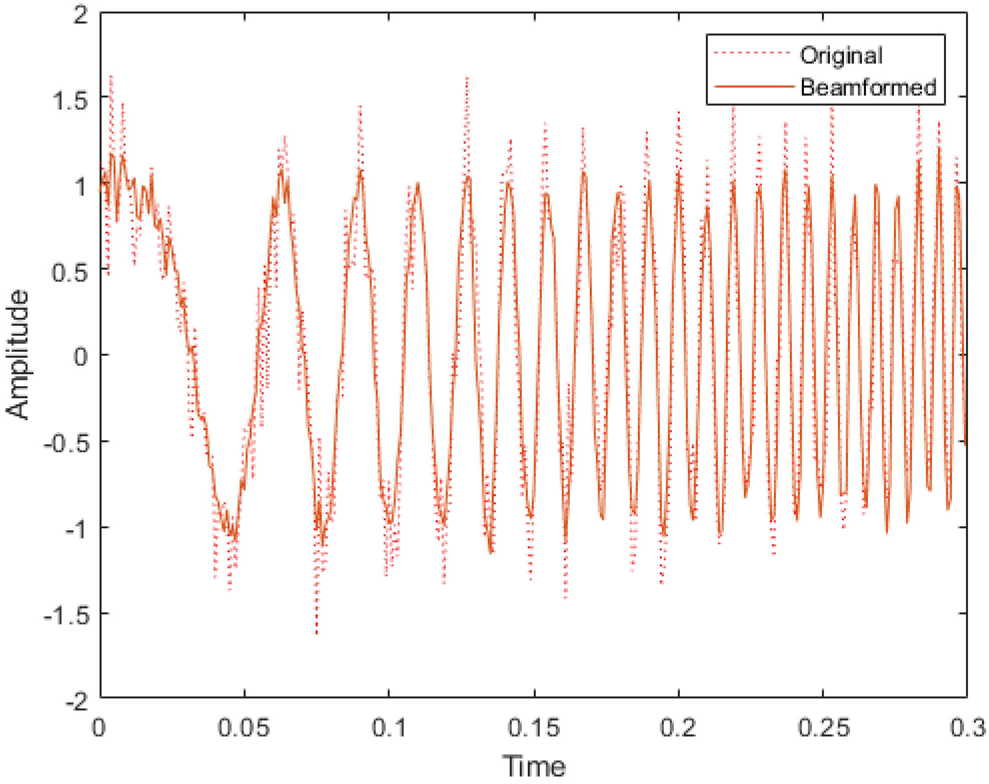
```
fs = 1e3;
carrierFreq = 2e3;
t = (0:1/fs:2)';
x = chirp(t,0,2,fs);
c = 1500;
collector = phased.WidebandCollector('Sensor',antenna, ...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',true,'CarrierFrequency',carrierFreq);
incidentAngle = [10;30];
x = collector(x,incidentAngle);
noise = 0.3*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Beamform in the direction of the incident angle.

```
beamformer = phased.SubbandPhaseShiftBeamformer('SensorArray',antenna, ...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq, ...
    'PropagationSpeed',c,'SampleRate',fs,'SubbandsOutputPort',true, ...
    'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx);
```

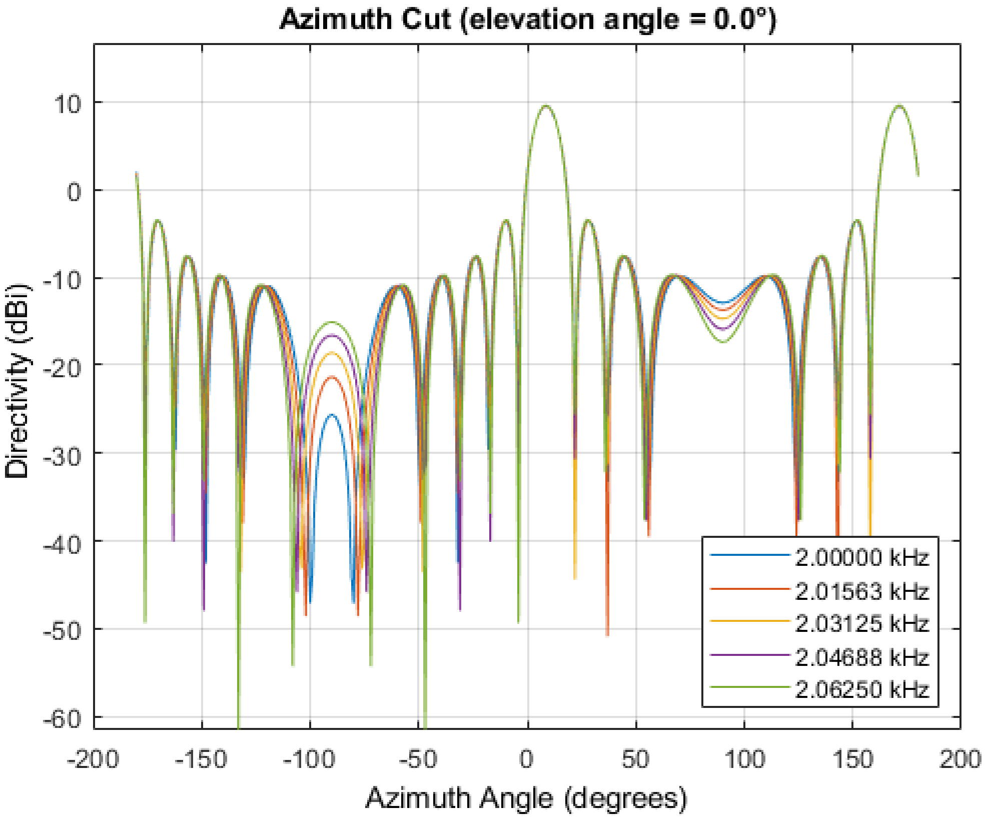
Plot the real part of the original and beamformed signals.

```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the response pattern for five frequency bands.

```
pattern(antenna,subbandfreq(1:5).',[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','rectangular','Weights',w(:,1:5))
legend('location','SouthEast')
```



# Algorithms

## Beamforming Algorithm

The subband phase shift beamformer separates the signal into several subbands and applies narrowband phase shift beamforming to the signal in each subband. The beamformed signals in all the subbands are regrouped to form the output signal.

For further details, see [1].

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

### Topics

“Wideband Beamforming”

### Introduced in R2012a

# step

**System object:** `phased.SubbandPhaseShiftBeamformer`
**Package:** `phased`

Beamforming using subband phase shifting

## Syntax

```
Y = step(H,X)
Y = step(H,X,ANG)
[Y,W] = step(___)
[Y,FREQ] = step(___)
[Y,W,FREQ] = step(___)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs subband phase shift beamforming on the input, `X`, and returns the beamformed output in `Y`.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`.

`[Y,W] = step(___)` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

`[Y,FREQ] = step(___)` returns the center frequencies of subbands, `FREQ`. This syntax is available when you set the `SubbandsOutputPort` property to `true`.

`[Y,W,FREQ] = step( ___ )` returns beamforming weights and center frequencies of subbands. This syntax is available when you set the `WeightsOutputPort` property to `true` and set the `SubbandsOutputPort` property to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**H**

Beamformer object.

**X**

Input signal, specified as an *M*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. This argument can be specified as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**ANG**

Beamforming directions, specified as a two-row matrix. Each column has the form [AzimuthAngle; ElevationAngle], in degrees. Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees. This argument can be specified as single or double precision.

## Output Arguments

### Y

Beamformed output. Y is an *M*-by-*L* matrix, where *M* is the number of rows of X and *L* is the number of beamforming directions. This argument can be returned as single or double precision.

### W

Beamforming weights. W has dimensions *N*-by-*K*-by-*L*. *K* is the number of subbands in the NumSubbands property. *L* is the number of beamforming directions. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. Each column of W specifies the narrowband beamforming weights used in the corresponding subband for the corresponding direction. This argument can be returned as single or double precision.

### FREQ

Center frequencies of subbands. FREQ is a column vector of length *K*, where *K* is the number of subbands in the NumSubbands property. This argument can be returned as single or double precision.

## Examples

### Subband Phase-Shift Beamformer for Underwater ULA

Apply subband phase-shift beamforming to an 11-element underwater ULA. The incident angle of a wideband signal is 10° in azimuth and 30° in elevation. The carrier frequency is 2 kHz.

Create the ULA.

```
antenna = phased.ULA('NumElements',11,'ElementSpacing',0.3);
antenna.Element.FrequencyRange = [20 20000];
```

Create a chirp signal with noise.

```
fs = 1e3;
carrierFreq = 2e3;
```

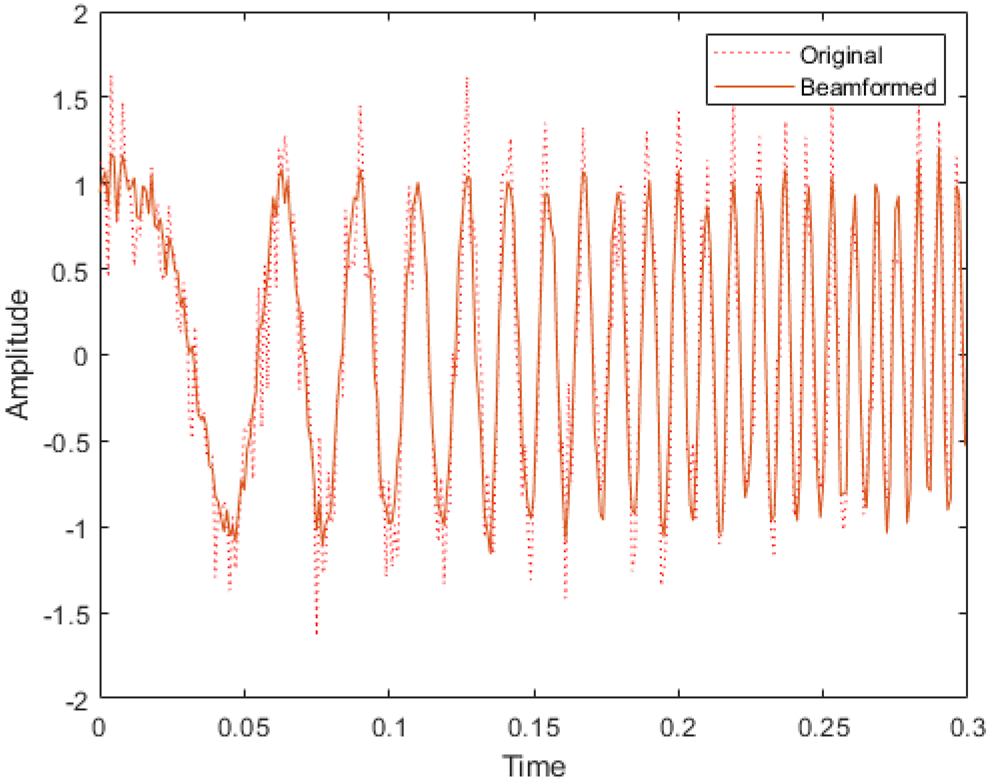
```
t = (0:1/fs:2)';
x = chirp(t,0,2,fs);
c = 1500;
collector = phased.WidebandCollector('Sensor',antenna, ...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',true,'CarrierFrequency',carrierFreq);
incidentAngle = [10;30];
x = collector(x,incidentAngle);
noise = 0.3*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Beamform in the direction of the incident angle.

```
beamformer = phased.SubbandPhaseShiftBeamformer('SensorArray',antenna, ...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq, ...
    'PropagationSpeed',c,'SampleRate',fs,'SubbandsOutputPort',true, ...
    'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx);
```

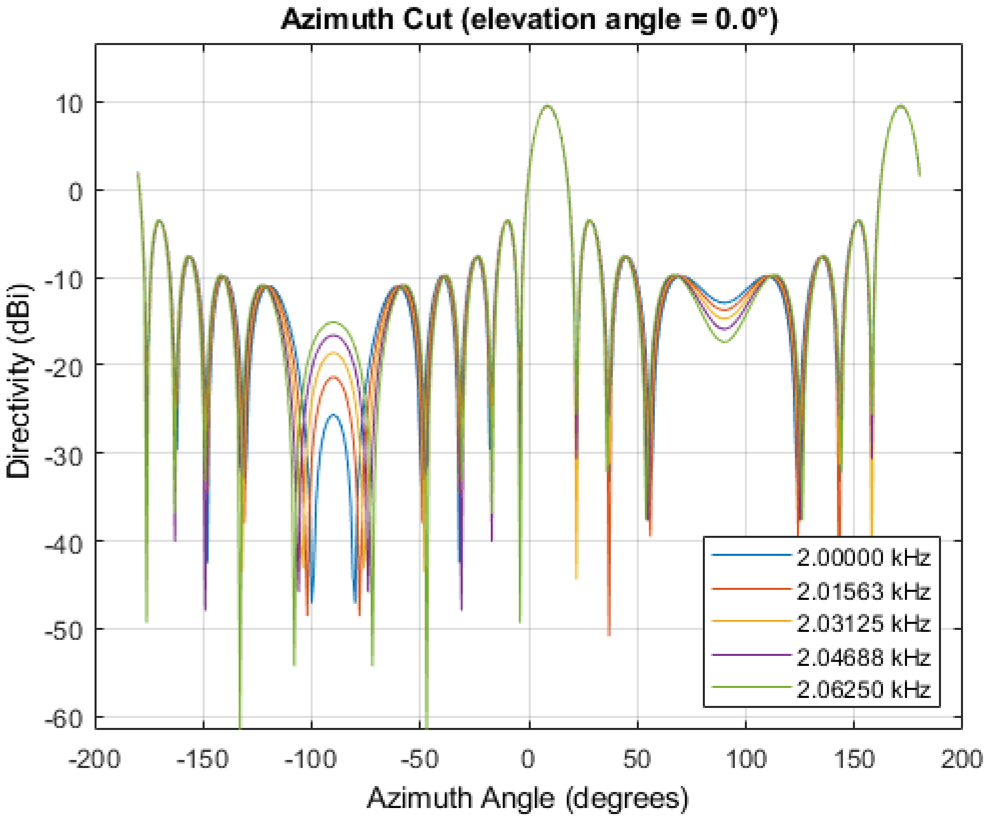
Plot the real part of the original and beamformed signals.

```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the response pattern for five frequency bands.

```
pattern(antenna,subbandfreq(1:5).',[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','rectangular','Weights',w(:,1:5))
legend('location','SouthEast')
```



## Algorithms

The subband phase shift beamformer separates the signal into several subbands and applies narrowband phase shift beamforming to the signal in each subband. The beamformed signals in all the subbands are regrouped to form the output signal.

For further details, see [1].

# phased.SumDifferenceMonopulseTracker

**Package:** `phased`

Sum and difference monopulse for ULA

## Description

The `SumDifferenceMonopulseTracker` object implements a sum and difference monopulse algorithm on a uniform linear array.

To estimate the direction of arrival (DOA):

1. Define and set up your sum and difference monopulse DOA estimator. See "Construction" on page 1-2258.
2. Call `step` to estimate the DOA according to the properties of `phased.SumDifferenceMonopulseTracker`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.SumDifferenceMonopulseTracker` creates a tracker System object, `H`. The object uses sum and difference monopulse algorithms on a uniform linear array (ULA).

`H = phased.SumDifferenceMonopulseTracker(Name,Value)` creates a ULA monopulse tracker object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed. You can specify this property as single or double precision.

**Default:** `0`

## Methods

## Examples

### Find Target Direction Using Monopulse Tracker

Determine the direction of a target at a 60.1° broadside angle to a ULA starting with an approximate direction of 60°

```
array = phased.ULA('NumElements',4);
steervec = phased.SteeringVector('SensorArray',array);
tracker = phased.SumDifferenceMonopulseTracker('SensorArray',array);
x = steervec(tracker.OperatingFrequency,60.1).';
est_dir = tracker(x,60)
```

```
est_dir = 60.1000
```

## Algorithms

### Monopulse Algorithm

The sum-and-difference monopulse algorithm is used to the estimate the arrival direction of a narrowband signal impinging upon a uniform linear array (ULA). First, compute the conventional response of an array steered to an arrival direction $\varphi_0$. For a ULA, the arrival direction is specified by the broadside angle. To specify that the maximum response axis (MRA) point towards the $\varphi_0$ direction, set the weights to be

$$\mathbf{w}_s = \left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ik(N-1)d\sin\phi_0}\right)$$

where $d$ is the element spacing and $k = 2\pi/\lambda$ is the wavenumber. An incoming plane wave, coming from any arbitrary direction $\varphi$, is represented by

$$\mathbf{v} = \left(1, e^{ikd\sin\phi}, e^{ik2d\sin\phi}, \ldots, e^{ik(N-1)d\sin\phi}\right)$$

The conventional response of this array to any incoming plane wave is given by $\mathbf{w}_s^H\mathbf{v}(\varphi)$ and is shown in the polar plot below as the *Sum Pattern*. The array is designed to steer towards $\varphi_0 = 30°$.

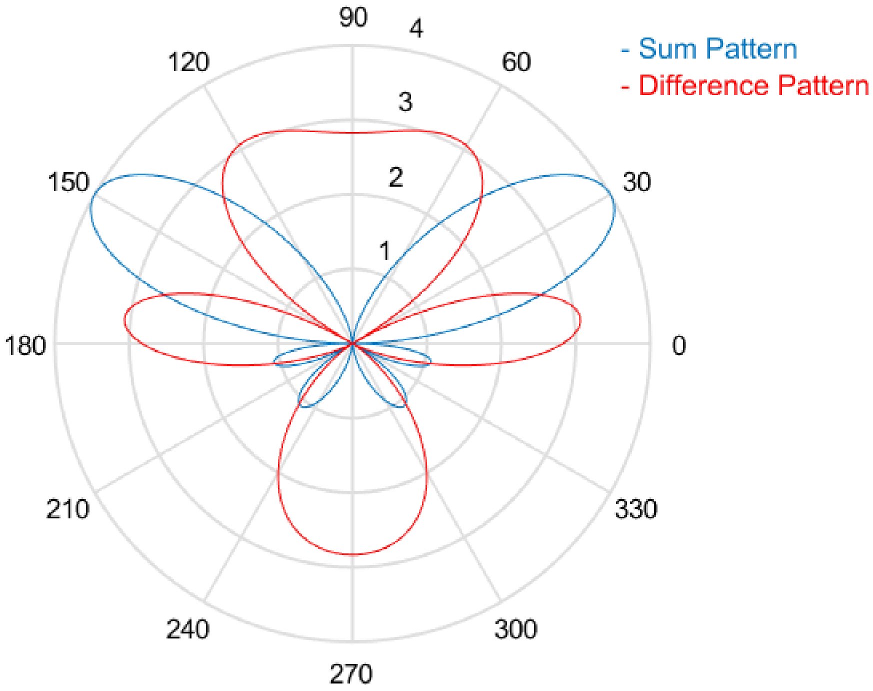
The second pattern, called the *Difference Pattern*, is obtained by using phased-reversed weights. The weights are determined by phase-reversing the latter half of the conventional steering vector. For an array with an even number of elements, the phase-reversed weights are

$$\mathbf{w}_d = -i\left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ikN/2d\sin\phi_0}, -e^{ik(N/2+1)d\sin\phi_0}, \ldots, -e^{ik(N-1)d\sin\phi_0}\right)$$

(For an array with an odd number of elements, the middle weight is set to zero). The multiplicative factor –*i* is used for convenience. The response of the difference array to the incoming vector is

$$\mathbf{w}_d^H\mathbf{v}(\varphi)$$

This figure shows the sum and difference beam patterns of a four-element uniform linear array (ULA) steered 30° from broadside. The array elements are spaced at one-half wavelength. The sum pattern shows that the array has its maximum response at 30° and the difference pattern has a null at 30°.



The monopulse response curve is obtained by dividing the difference pattern by the sum pattern and taking the real part.

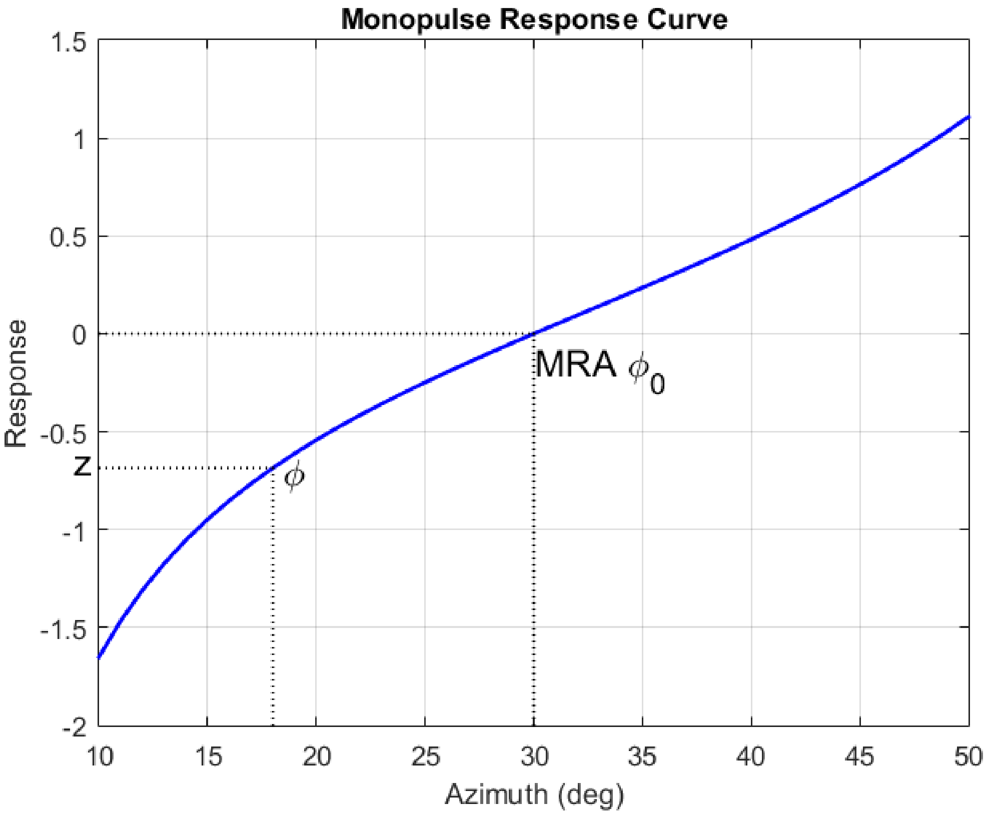
$$R(\varphi) = Re\left(\frac{\mathbf{w}_d^H \mathbf{v}(\varphi)}{\mathbf{w}_s^H \mathbf{v}(\varphi)}\right)$$

To use the monopulse response curve to obtain the arrival angle, $\varphi$, of a narrowband signal, **x**, compute

$$z = Re\left(\frac{\mathbf{w}_d^H \mathbf{x}}{\mathbf{w}_s^H \mathbf{x}}\right)$$

and invert the response curve, $\varphi = R^{-1}(z)$, to obtain $\varphi$.

The response curve is not generally single valued and can only be inverted when arrival angles lie within the main lobe where it is single valued This figure shows the monopulse response curve within the main lobe of the four-element ULA array.



There are two desirable properties of the monopulse response curve. The first is that it have a steep slope. A steep slope insures robustness against noise. The second property is that the mainlobe be as wide as possible. A steep slope is ensure by a larger array but leads to a smaller mainlobe. You will need to trade off one property with the other.

For further details, see [1].

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

Perform monopulse tracking using ULA

## Syntax

```
ESTANG = step(H,X,STANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ESTANG = step(H,X,STANG)` estimates the incoming direction `ESTANG` of the input signal, `X`, based on an initial guess of the direction.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `H`

Tracker object of type `phased.SumDifferenceMonopulseTracker`.

**X**

Input signal, specified as a row vector whose number of columns corresponds to number of channels. You can specify this argument as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**STANG**

Initial guess of the direction, specified as a scalar that represents the broadside angle in degrees. A typical initial guess is the current steering angle. The value of `STANG` is between –90 and 90. The angle is defined in the array's local coordinate system. For details regarding the local coordinate system of the ULA, type `phased.ULA.coordinateSystemInfo`. You can specify this argument as single or double precision.

# Output Arguments

**ESTANG**

Estimate of incoming direction, returned as a scalar that represents the broadside angle in degrees. The value is between –90 and 90. The angle is defined in the array's local coordinate system.

# phased.SumDifferenceMonopulseTracker2D

**Package:** phased

Sum and difference monopulse for URA

## Description

The SumDifferenceMonopulseTracker2D object implements a sum and difference monopulse algorithm for a uniform rectangular array.

To estimate the direction of arrival (DOA):

1. Define and set up your sum and difference monopulse DOA estimator. See "Construction" on page 1-2272.
2. Call step to estimate the DOA according to the properties of phased.SumDifferenceMonopulseTracker2D. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.SumDifferenceMonopulseTracker2D creates a tracker System object, H. The object uses sum and difference monopulse algorithms on a uniform rectangular array (URA).

H = phased.SumDifferenceMonopulseTracker2D(Name,Value) creates a URA monopulse tracker object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.URA` object.

**Default:** `phased.URA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed. You can specify this property as single or double precision.

**Default:** `0`

# phased.TimeDelayBeamformer

**Package:** `phased`

Time delay beamformer

## Description

The `TimeDelayBeamformer` object implements a time delay beamformer.

To compute the beamformed signal:

1. Define and set up your time delay beamformer. See "Construction" on page 1-2285.
2. Call `step` to perform the beamforming operation according to the properties of `phased.TimeDelayBeamformer`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.TimeDelayBeamformer` creates a time delay beamformer System object, `H`. The object performs delay and sum beamforming on the received signal using time delays.

`H = phased.TimeDelayBeamformer(Name,Value)` creates a time delay beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar. This property can be specified as single or double precision.

**Default:** `1e6`

### `DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction comes from the `Direction` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Direction` property of this object specifies the beamforming direction. |
| `'Input port'` | An input argument in each invocation of `step` specifies the beamforming direction. |

**Default:** `'Property'`

**Direction**

Beamforming direction

Specify the beamforming direction of the beamformer as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle is between –180 and 180. The elevation angle is between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`. This property can be specified as single or double precision.

**Default:** `[0; 0]`

**WeightsOutputPort**

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the weights, set this property to `false`.

**Default:** `false`

# Methods

| `release` | Allow System object property value changes |

# Examples

### Time-Delay Beamformer Applied to ULA

Apply a time-delay beamformer to an 11-element uniform linear acoustic array. The arrival angle of the signal is -50 degrees in azimuth and 30 degrees in elevation. The arriving signal is a 0.3 second segment of a linear FM chirp having a 500 Hz bandwidth. Assume the speed of sound in air is 340.0 m/s.

Simulate the arriving signal at the wideband collector.

```
microphone = phased.CustomMicrophoneElement('FrequencyVector',[20,20000],'FrequencyResp
array = phased.ULA('Element',microphone,'NumElements',11,'ElementSpacing',0.04);
fs = 8000;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,'ModulatedInput',false);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
```

Add white gaussian random noise to the signal.

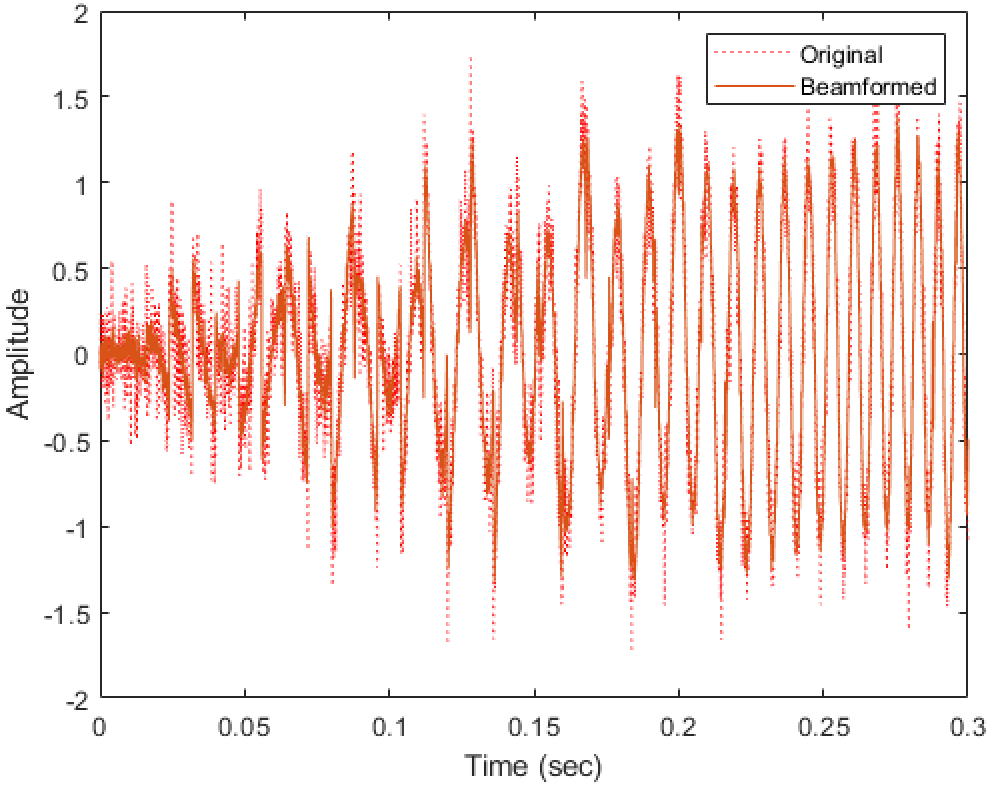
```
sigma = 0.2;
noise = sigma*randn(size(x));
rx = x + noise;
```

Beamform the incident signals using a time-delay beamformer.

```
beamformer = phased.TimeDelayBeamformer('SensorArray',array,...
    'SampleRate',fs,'PropagationSpeed',c,...
    'Direction',incidentAngle);
y = beamformer(rx);
```

Plot the beamformed signal against the incident signal at the middle sensor of the array.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time (sec)')
ylabel('Amplitude')
legend('Original','Beamformed')
```



# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

### Topics

“Wideband Beamforming”

**Introduced in R2012a**

# step

**System object:** `phased.TimeDelayBeamformer`
**Package:** `phased`

Perform time delay beamforming

## Syntax

```
Y = step(H,X)
Y = step(H,X,ANG)
[Y,W] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs time delay beamforming on the input, `X`, and returns the beamformed output in `Y`. `X` is an M-by-N matrix where N is the number of elements of the sensor array. `Y` is a column vector of length M.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to`'Input port'`. `ANG` is a column vector of length 2 in the form of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

`[Y,W] = step( ___ )` returns additional output, `W`, as the beamforming weights. This syntax is available when you set the `WeightsOutputPort` property to `true`. `W` is a column vector of length N. For a time delay beamformer, the weights are constant because the beamformer simply adds all the channels together and scales the result to preserve the signal power.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

All input and output arguments can be single or double precision.

# phased.TimeDelayLCMVBeamformer

**Package:** `phased`

Time delay LCMV beamformer

## Description

The `TimeDelayLCMVBeamformer` object implements a time-delay linear constraint minimum variance beamformer.

To compute the beamformed signal:

1. Define and set up your time-delay LCMV beamformer. See “Construction” on page 1-2295.
2. Call `step` to perform the beamforming operation according to the properties of `phased.TimeDelayLCMVBeamformer`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.TimeDelayLCMVBeamformer` creates a time-delay linear constraint minimum variance (LCMV) beamformer System object, `H`. The object performs time delay LCMV beamforming on the received signal.

`H = phased.TimeDelayLCMVBeamformer(Name,Value)` creates a time-delay LCMV beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar. This property can be specified as single or double precision.

**Default:** `1e6`

### `FilterLength`

FIR filter length

Specify the length of the FIR filter behind each sensor element in the array as a positive integer. This property can be specified as single or double precision.

**Default:** `2`

### `Constraint`

Constraint matrix

Specify the constraint matrix used for time-delay LCMV beamformer as an *M*-by-*K* matrix. Each column of the matrix is a constraint and *M* is the number of degrees of freedom of the beamformer. For a time-delay LCMV beamformer, the number of degrees of freedom is the product of the number of elements of the array and the filter length specified by the value of the `FilterLength` property. This property can be specified as single or double precision.

**Default:** `[1;1]`

### `DesiredResponse`

Desired response vector

Specify the desired response used for time-delay LCMV beamformer as a column vector of length *K*, where *K* is the number of constraints in the `Constraint` property. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the `Constraint` property. This property can be specified as single or double precision.

**Default:** `1`, which is equivalent to a distortionless response

### `DiagonalLoadingFactor`

Diagonal loading factor

Specify the diagonal loading factor as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small. This property is tunable. This property can be specified as single or double precision.

**Default:** `0`

### `TrainingInputPort`

Add input to specify training data

To specify additional training data, set this property to `true` and use the corresponding input argument when you invoke `step`. To use the input signal as the training data, set this property to `false`.

**Default:** `false`

### `DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction comes from the `Direction` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Direction` property of this object specifies the beamforming direction. |
| `'Input port'` | An input argument in each invocation of `step` specifies the beamforming direction. |

**Default:** `'Property'`

**`Direction`**

Beamforming direction

Specify the beamforming direction of the beamformer as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle is between –180° and 180°. The elevation angle is between –90° and 90°. This property applies when you set the `DirectionSource` property to `'Property'`. This property can be specified as single or double precision.

**Default:** `[0; 0]`

**`WeightsOutputPort`**

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the weights, set this property to `false`.

**Default:** `false`

## Methods

|---|---|
| step | Perform time-delay LCMV beamforming |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Time-Delay LCMV Beamformer

Apply a time delay LCMV beamformer to an 11-element acoustic ULA array. The elements are omnidirectional microphones. The incident angle of the signal is -50 degrees in azimuth and 30 degrees in elevation. The incident signal is an FM chirp with 500 Hz bandwidth. The propagation speed is a typical speed of sound in air, 340 m/s.

Simulate the signal and add noise.

```
nElem = 11;
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
array = phased.ULA('Element',microphone,'NumElements',nElem,'ElementSpacing',0.04);
fs = 8000;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

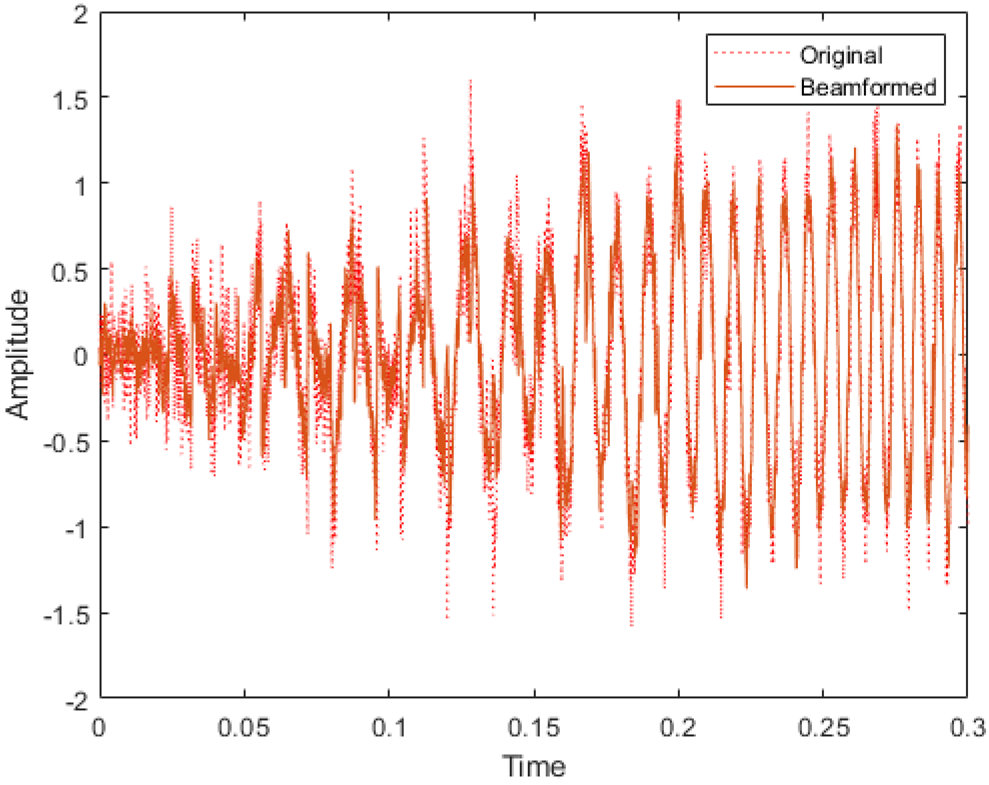
Create and apply the time-delay LCMV beamformer. Specify a filterlength of 5.

```
filterLength = 5;
constraintMatrix = kron(eye(filterLength),ones(nElem,1));
desiredResponseVector = eye(filterLength,1);
beamformer = phased.TimeDelayLCMVBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,'FilterLength',filterLength,...
    'Direction',incidentAngle,'Constraint',constraintMatrix,...
    'DesiredResponse',desiredResponseVector);
y = beamformer(rx);
```

Compare the beamformer output to the input to the middle sensor.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
```

```
ylabel('Amplitude')
legend('Original','Beamformed')
```



# Algorithms

## Beamforming Algorithms

The beamforming algorithm is the time-domain counterpart of the narrowband linear constraint minimum variance (LCMV) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the specified constraints. The filter is specific to each sensor.

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# step

**System object:** `phased.TimeDelayLCMVBeamformer`
**Package:** `phased`

Perform time-delay LCMV beamforming

## Syntax

```
Y = step(H,X)
Y = step(H,X,XT)
Y = step(H,X,ANG)
[Y,W] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs time-delay LCMV beamforming on the input, `X`, and returns the beamformed output in `Y`. `X` is an *M*-by-*N* matrix where *N* is the number of elements of the sensor array. *M* must be larger than the FIR filter length specified in the `FilterLength` property. `Y` is a column vector of length *M*.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,XT)` uses `XT` as the training samples to calculate the beamforming weights when you set the `TrainingInputPort` property to `true`. `XT` is an *M*-by-*N* matrix where *N* is the number of elements of the sensor array. *M* must be larger than the FIR filter length specified in the `FilterLength` property.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction, when you set the `DirectionSource` property to `'Input port'`. `ANG` is a column vector of length 2 in the form of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle must be between –180° and 180°, and the elevation angle must be between –90° and 90°.

You can combine optional input arguments when their enabling properties are set: `Y = step(H,X,XT,ANG)`

`[Y,W] = step(____)` returns additional output, `W`, as the beamforming weights when you set the `WeightsOutputPort` property to `true`. `W` is a column vector of length *L*, where *L* is the number of degrees of freedom of the beamformer. For a time-delay LCMV beamformer, the number of degrees of freedom is given by the product of the number of elements of the array and the filter length specified by the value of the `FilterLength` property.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

All input and output arguments can be single or double precision.

# phased.TimeVaryingGain

**Package:** `phased`

Time varying gain control

## Description

The `TimeVaryingGain` object applies a time varying gain to input signals. Time varying gain (TVG) is sometimes called automatic gain control (AGC).

To apply the time varying gain to the signal:

1. Define and set up your time varying gain controller. See “Construction” on page 1-2308.
2. Call `step` to apply the time varying gain according to the properties of `phased.TimeVaryingGain`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.TimeVaryingGain` creates a time varying gain control System object, `H`. The object applies a time varying gain to the input signal to compensate for the signal power loss due to the range.

`H = phased.TimeVaryingGain(Name,Value)` creates an object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `RangeLossSource`

Source of range losses

Specify the source of range losses as either `'Property'` or `'Input port'`. When you specify `RangeLossSource` as `'Property'`, the range loss for each sample is set in the `RangeLoss` property. When you specify the `RangeLossSource` as `'Input port'`, the range losses are specified using an input argument to the `step` method.

**Default:** `'Property'`

### `RangeLoss`

Loss at each input sample range

Specify the loss due to range as a vector — elements correspond to the samples in the input signal. Units are in dB. This property can have single or double precision.

**Default:** `0`

### `ReferenceLoss`

Loss at reference range

Specify the loss at a given reference range as a scalar. Units are in dB. This property can have single or double precision.

**Default:** `0`

## Methods

| | |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

# Examples

### Apply Time Varying Gain to Adjust for Range Loss

Apply time varying gain to a signal to compensate for signal power loss due to range.

First, create a signal with range loss. Set the reference loss to 16 dB.

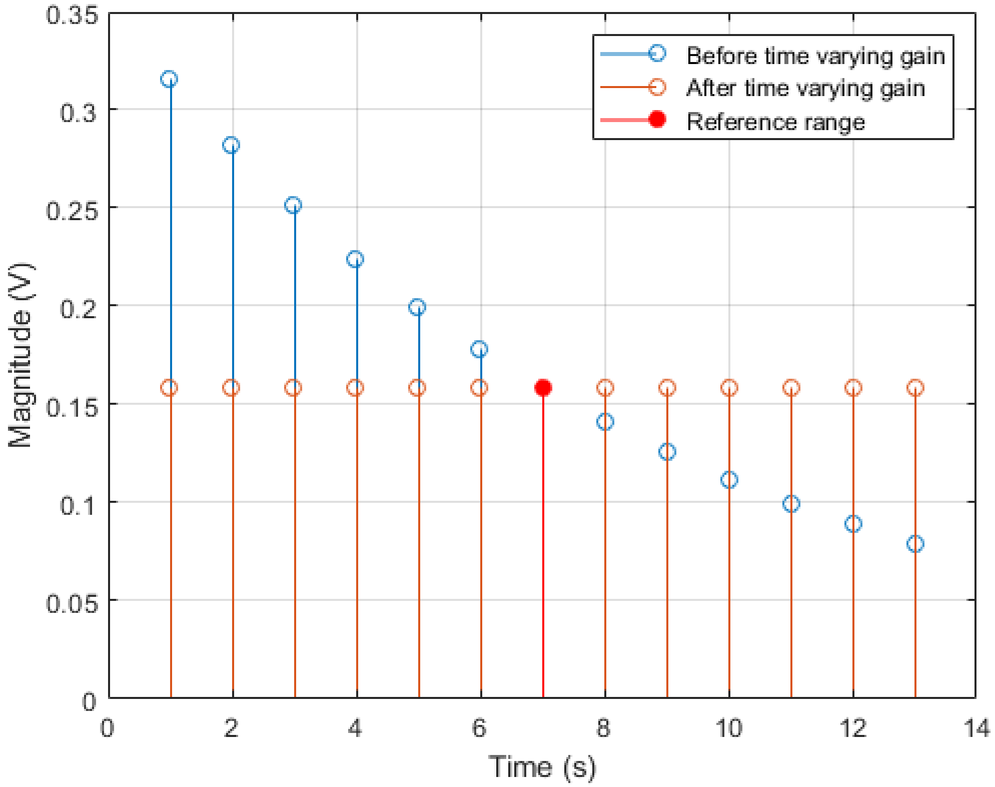
```
rngloss = 10:22;
refloss = 16;
t = (1:length(rngloss))';
x = 1./db2mag(rngloss(:));
```

Then add gain to compensate for range loss.

```
gain = phased.TimeVaryingGain('RangeLoss',rngloss,'ReferenceLoss',refloss);
y = gain(x);
```

Plot the signal with loss and the compensated signal.

```
tref = find(rngloss==refloss);
stem([t t],[abs(x) abs(y)])
hold on
stem(tref,x(tref),'filled','r')
xlabel('Time (s)'); ylabel('Magnitude (V)')
grid on
legend('Before time varying gain','After time varying gain',...
    'Reference range')
```



# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

## See Also

`phased.MatchedFilter` | `pulsint`

**Introduced in R2012a**

# step

**System object:** `phased.TimeVaryingGain`
**Package:** `phased`

Apply time varying gains to input signal

## Syntax

```
Y = step(H,X)
Y = step(H,X,L)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies time varying gains to the input signal matrix `X`. The process equalizes power levels across all samples to match a given reference range. The compensated signal is returned in `Y`. `X` can be a column vector, a matrix, or a cube. The gain is applied to each column in `X` independently. The number of rows in `X` cannot exceed the length of the loss vector specified in the `RangeLoss` property. `Y` has the same dimensionality as `X`. `X` can be single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,L)` in addition, specifies the range loss, `L` as a columns vector. Use this argument only when you set the `RangeLossSource` property to `'Input port'`. The length of `L` must be equal to or greater than the number of rows of `X`. `L` can be single or double precision.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

### Apply Time Varying Gain to Adjust for Range Loss

Apply time varying gain to a signal to compensate for signal power loss due to range.

First, create a signal with range loss. Set the reference loss to 16 dB.

```
rngloss = 10:22;
refloss = 16;
t = (1:length(rngloss))';
x = 1./db2mag(rngloss(:));
```

Then add gain to compensate for range loss.

```
gain = phased.TimeVaryingGain('RangeLoss',rngloss,'ReferenceLoss',refloss);
y = gain(x);
```

Plot the signal with loss and the compensated signal.

```
tref = find(rngloss==refloss);
stem([t t],[abs(x) abs(y)])
hold on
stem(tref,x(tref),'filled','r')
xlabel('Time (s)'); ylabel('Magnitude (V)')
grid on
legend('Before time varying gain','After time varying gain',...
    'Reference range')
```

# phased.Transmitter

**Package:** `phased`

Transmitter

## Description

The `Transmitter` object implements a waveform transmitter.

To compute the transmitted signal:

1. Define and set up your waveform transmitter. See “Construction” on page 1-2316.
2. Call `step` to compute the transmitted signal according to the properties of `phased.Transmitter`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.Transmitter` creates a transmitter System object, `H`. This object transmits the input waveform samples with specified peak power.

`H = phased.Transmitter(Name,Value)` creates a transmitter object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

**`PeakPower`**

Peak power

Specify the transmit peak power (in watts) as a positive scalar.

**Default:** `5000`

**`Gain`**

Transmit gain

Specify the transmit gain (in decibels) as a real scalar.

**Default:** `20`

**`LossFactor`**

Loss factor

Specify the transmit loss factor (in decibels) as a nonnegative scalar.

**Default:** `0`

**`InUseOutputPort`**

Enable transmitter status output

To obtain the transmitter in-use status for each output sample, set this property to `true` and use the corresponding output argument when invoking `step`. In this case, 1's indicate the transmitter is on, and 0's indicate the transmitter is off. If you do not want to obtain the transmitter in-use status, set this property to `false`.

**Default:** `false`

**`CoherentOnTransmit`**

Preserve coherence among pulses

Specify whether to preserve coherence among transmitted pulses. When you set this property to `true`, the transmitter does not introduce any random phase to the output pulses. When you set this property to `false`, the transmitter adds a random phase noise to each transmitted pulse. The random phase noise is introduced by multiplication of the pulse by $e^{j\phi}$where ϕ is a uniform random variable on the interval [0,2π].

**Default:** `true`

**`PhaseNoiseOutputPort`**

Enable pulse phase noise output

To obtain the introduced transmitter random phase noise for each output sample, set this property to `true` and use the corresponding output argument when invoking `step`. You can use in the receiver to simulate coherent on receive systems. If you do not want to obtain the random phase noise, set this property to `false`. This property applies when you set the `CoherentOnTransmit` property to `false`.

**Default:** `false`

**`SeedSource`**

Source of seed for random number generator

| | |
|---|---|
| `'Auto'` | The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software. |
| `'Property'` | The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software. |

This property applies when you set the `CoherentOnTransmit` property to `false`.

**Default:** `'Auto'`

**`Seed`**

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}$–1. This property applies when you set the `CoherentOnTransmit` property to `false` and the `SeedSource` property to `'Property'`.

**Default:** `0`

## Methods

| | |
|---|---|
| reset | Reset states of transmitter object |
| step | Transmit pulses |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Transmit LFM Pulse

Transmit a pulse containing a linear FM waveform with a bandwidth of 5 MHz. The sample rate is 10 MHz and the pulse repetition frequency is 10 kHz.

```
fs = 1e7;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PulseWidth',1e-5,'SweepBandwidth',5e6);
x = waveform();
transmitter = phased.Transmitter('PeakPower',5e3);
y = transmitter(x);
```

# reset

**System object:** `phased.Transmitter`
**Package:** `phased`

Reset states of transmitter object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `Transmitter` object, `H`. This method resets the random number generator state if the `SeedSource` property is applicable and has the value `'Property'`.

# step

**System object:** phased.Transmitter
**Package:** phased

Transmit pulses

## Syntax

```
Y = step(H,X)
[Y,STATUS] = step(H,X)
[Y,PHNOISE] = step(H,X)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) returns the transmitted signal Y, based on the input waveform X. Y is the amplified X where the amplification is based on the characteristics of the transmitter, such as the peak power and the gain.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

[Y,STATUS] = step(H,X) returns additional output STATUS as the on/off status of the transmitter when the InUseOutputPort property is true. STATUS is a logical vector where true indicates the transmitter is on for the corresponding sample time, and false indicates the transmitter is off.

[Y,PHNOISE] = step(H,X) returns the additional output PHNOISE as the random phase noise added to each transmitted sample when the CoherentOnTransmit property is false and the PhaseNoiseOutputPort property is true. PHNOISE is a vector which has the same dimension as Y. Each element in PHNOISE contains the random phase between 0 and 2*pi, added to the corresponding sample in Y by the transmitter.

You can combine optional output arguments when their enabling properties are set. Optional outputs must be listed in the same order as the order of the enabling properties. For example:

```
[Y,STATUS,PHNOISE] = step(H,X)
```

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Examples

### Transmit LFM Pulse

Transmit a pulse containing a linear FM waveform with a bandwidth of 5 MHz. The sample rate is 10 MHz and the pulse repetition frequency is 10 kHz.

```
fs = 1e7;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PulseWidth',1e-5,'SweepBandwidth',5e6);
x = waveform();
transmitter = phased.Transmitter('PeakPower',5e3);
y = transmitter(x);
```

# phased.TwoRayChannel

**Package:** `phased`

Two-ray propagation channel

## Description

The `phased.TwoRayChannel` models a narrowband two-ray propagation channel. A two-ray propagation channel is the simplest type of multipath channel. You can use a two-ray channel to simulate propagation of signals in a homogeneous, isotropic medium with a single reflecting boundary. This type of medium has two propagation paths: a line-of-sight (direct) propagation path from one point to another and a ray path reflected from the boundary. You can use this System object for short-range radar and mobile communications applications where the signals propagate along straight paths and the earth is assumed to be flat. You can also use this object for sonar and microphone applications. For acoustic applications, you can choose the fields to be non-polarized and adjust the propagation speed to be the speed of sound in air or water. You can use `phased.TwoRayChannel` to model propagation from several points simultaneously.

While the System object works for all frequencies, the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only. The attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.TwoRayChannel` System object applies range-dependent time delays to the signals, and as well as gains or losses, phase shifts, and boundary reflection loss. The System object applies Doppler shift when either the source or destination is moving.

Signals at the channel output can be kept *separate* or be *combined* — controlled by the `CombinedRaysOutput` property. In the *separate* option, both fields arrive at the destination separately and are not combined. For the *combined* option, the two signals at the source propagate separately but are coherently summed at the destination into a single quantity. This option is convenient when the difference between the sensor or array gains in the directions of the two paths is not significant and need not be taken into account.

Unlike the `phased.FreeSpace` System object, the `phased.TwoRayChannel` System object does not support two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your two-ray channel using the "Construction" on page 1-2325 procedure that follows.
2. Call the `step` method to compute the propagated signal using the properties of the `phased.TwoRayChannel` System object.

   The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`s2Ray = phased.TwoRayChannel` creates a two-ray propagation channel System object, `s2Ray`.

`s2Ray = phased.TwoRayChannel(Name,Value)` creates a System object, `s2Ray`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### OperatingFrequency — Operating frequency

300e6 (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: 1e9

Data Types: double

### SpecifyAtmosphere — Enable atmospheric attenuation model

false (default) | true

Option to enable the atmospheric attenuation model, specified as a false or true. Set this property to true to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to false to ignore atmospheric effects in propagation.

Setting SpecifyAtmosphere to true, enables the Temperature, DryAirPressure, WaterVapourDensity, LiquidWaterDensity, and RainRate properties.

Data Types: logical

### Temperature — Ambient temperature

15 (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: 20.0

#### Dependencies

To enable this property, set SpecifyAtmosphere to true.

Data Types: double

### DryAirPressure — Atmospheric dry air pressure

101.325e3 (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: 101.0e3

#### Dependencies

To enable this property, set SpecifyAtmosphere to true.

Data Types: double

### `WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

Example: `7.4`

**Dependencies**

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

**Dependencies**

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

**Dependencies**

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

### `EnablePolarization` — Enable polarized fields

`false` (default) | `true`

Option to enable polarized fields, specified as `false` or `true`. Set this property to `true` to enable polarization. Set this property to `false` to ignore polarization.

Data Types: `logical`

### `GroundReflectionCoefficient` — Ground reflection coefficient

`-1` (default) | complex-valued scalar | complex-valued 1-by-*N* row vector

Ground reflection coefficient for the field at the reflection point, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. Each coefficient has an absolute value less than or equal to one. The quantity *N* is the number of two-ray channels. Units are dimensionless. Use this property to model nonpolarized signals. To model polarized signals, use the `GroundRelativePermittivity` property.

Example: `-0.5`

#### Dependencies

To enable this property, set `EnablePolarization` to `false`.

Data Types: `double`
Complex Number Support: Yes

### `GroundRelativePermittivity` — Ground relative permittivity

`15` (default) | positive real-valued scalar | real-valued 1-by-*N*row vector of positive values

Relative permittivity of the ground at the reflection point, specified as a positive real-valued scalar or a 1-by-*N* real-valued row vector of positive values. The dimension *N* is the number of two-ray channels. Permittivity units are dimensionless. Relative permittivity is defined as the ratio of actual ground permittivity to the permittivity of free space. This property applies when you set the `EnablePolarization` property to `true`. Use this property to model polarized signals. To model nonpolarized signals, use the `GroundReflectionCoefficient` property.

Example: `5`

#### Dependencies

To enable this property, set `EnablePolarization` to `true`.

Data Types: `double`

### `CombinedRaysOutput` — Option to combine two rays at output

`true` (default) | `false`

Option to combine the two rays at channel output, specified as `true` or `false`. When this property is `true`, the object coherently adds the line-of-sight propagated signal and the reflected path signal when forming the output signal. Use this mode when you do not need to include the directional gain of an antenna or array in your simulation.

Data Types: `logical`

### `MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

### `MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

**Dependencies**

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

### `MaximumNumInputSamplesSource` — Source of maximum number of samples

`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

To use this object with variable-size signals in a MATLAB Function Block in Simulink, set the `MaximumNumInputSamplesSource` property to `'Property'` and set a value for the `MaximumNumInputSamples` property.

Example: `'Property'`

#### Dependencies

To enable this property, set `MaximumDistanceSource` to `'Property'`.

Data Types: `char`

### `MaximumNumInputSamples` — Maximum number of input signal samples

`100` (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the `step` method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform `OutputFormat` property is set to `'Samples'`, the maximum signal length is the value specified in the `NumSamples` property.
- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: `2048`

#### Dependencies

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

# Methods

# Examples

### Scalar Field Propagating in Two-Ray Channel

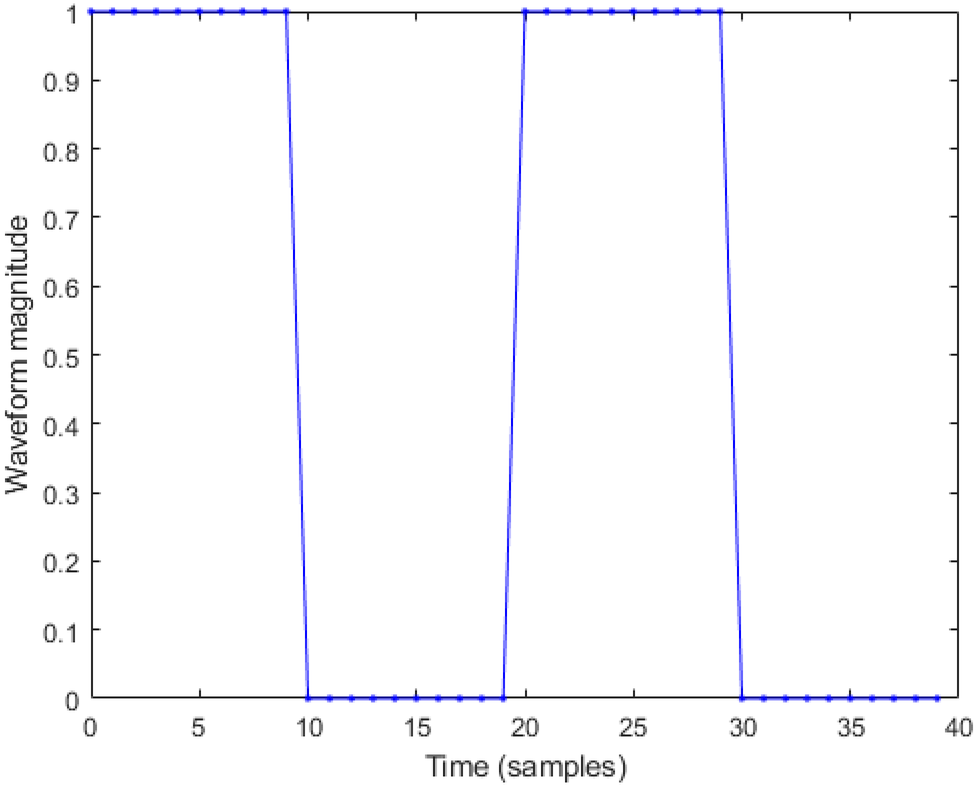
This example illustrates the two-ray propagation of a signal, showing how the signals from the line-of-sight and reflected path arrive at the receiver at different times.

### Create and Plot Propagating Signal

Create a nonpolarized electromagnetic field consisting of two rectangular waveform pulses at a carrier frequency of 100 MHz. Assume the pulse width is 10 ms and the sampling rate is 1 MHz. The bandwidth of the pulse is 0.1 MHz. Assume a 50% duty cycle in so that the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Set the `GroundReflectionCoefficient` to 0.9 to model strong ground reflectivity. Propagate the field from a stationary source to a stationary receiver. The vertical separation of the source and receiver is approximately 10 km.

```
c = physconst('LightSpeed');
fs = 1e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
lambda = c/fc;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2);
wav = waveform();
n = size(wav,1);
figure;
plot([0:(n-1)],real(wav),'b.-');
```

```
xlabel('Time (samples)')
ylabel('Waveform magnitude')
```



### Specify the Location of Source and Receiver

Place the source and receiver about 1000 meters apart horizontally and approximately 10 km apart vertically.

```
pos1 = [1000;0;10000];
pos2 = [0;100;100];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Compute the predicted signal delays in units of samples.

```
[rng,ang] = rangeangle(pos2,pos1,'two-ray');
delay = rng/c*fs
```

```
delay = 1×2

   33.1926   33.8563
```

### Create a Two-Ray Channel System Object™

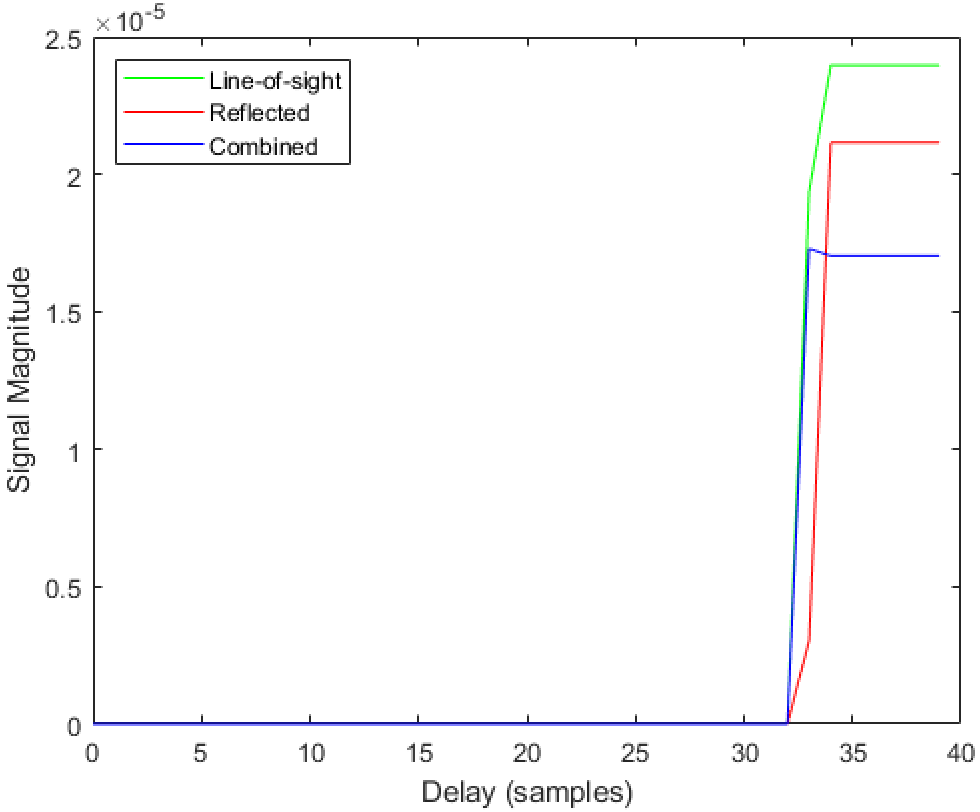
Create a two-ray propagation channel System object™ and propagate the signal along both the line-of-sight and reflected ray paths.

```
channel = phased.TwoRayChannel('SampleRate',fs,...
    'GroundReflectionCoefficient',.9,'OperatingFrequency',fc,...
    'CombinedRaysOutput',false);
prop_signal = channel([wav,wav],pos1,pos2,vel1,vel2);
```

### Plot the Propagated Signals

- Plot the signal propagated along the line-of-sight.
- Then, overlay a plot of the signal propagated along the reflected path.
- Finally, overlay a plot of the coherent sum of the two signals.

```
n = size(prop_signal,1);
delay = [0:(n-1)];
plot(delay,abs([prop_signal(:,1)]),'g')
hold on
plot(delay,abs([prop_signal(:,2)]),'r')
plot(delay,abs([prop_signal(:,1) + prop_signal(:,2)]),'b')
hold off
legend('Line-of-sight','Reflected','Combined','Location','NorthWest')
xlabel('Delay (samples)')
ylabel('Signal Magnitude')
```



The plot shows that the delay of the reflected path signal agrees with the predicted delay. The magnitude of the coherently combined signal is less than either of the propagated signals indicating that there is some interference between the two signals.

### Polarized Field Propagation in Two-Ray Channel

Create a polarized electromagnetic field consisting of linear FM waveform pulses. Propagate the field from a stationary source with a crossed-dipole antenna element to a stationary receiver approximately 10 km away. The transmitting antenna is 100 meters above the ground. The receiving antenna is 150 m above the ground. The receiving antenna is also a crossed-dipole. Plot the received signal.

### Set Radar Waveform Parameters

Assume the pulse width is $10\mu s$ and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle in which the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Assume a carrier frequency of 100 MHz.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
bw = 1e6;
lambda = c/fc;
```

### Set Up Required System Objects

Use a `GroundRelativePermittivity` of 10.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Up','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[50,200]*1e6);
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc,...
    'Polarization','Combined');
channel = phased.TwoRayChannel('SampleRate',fs,...
    'OperatingFrequency',fc,'CombinedRaysOutput',false,...
    'EnablePolarization',true,'GroundRelativePermittivity',10);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc,...
    'Polarization','Combined');
```

### Set Up Scene Geometry

Specify transmitter and receiver positions, velocities, and orientations. Place the source and receiver about 1000 m apart horizontally and approximately 50 m apart vertically.

```
posTx = [0;100;100];
posRx = [1000;0;150];
velTx = [0;0;0];
velRx = [0;0;0];
laxRx = rotz(180);
laxTx = rotx(1)*eye(3);
```

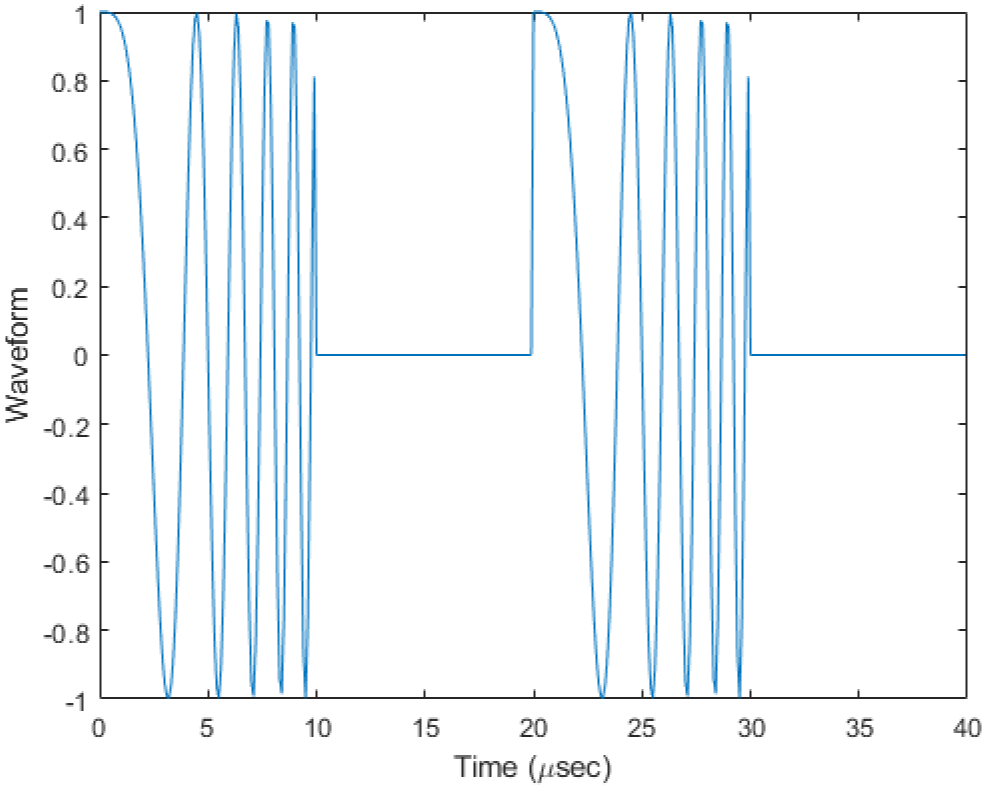
### Create and Radiate Signals from Transmitter

Compute the transmission angles for the two rays traveling toward the receiver. These angles are defined with respect to the transmitter local coordinate system. The `phased.Radiator` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[rng,angsTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
wav = waveform();
```

Plot the transmitted Waveform

```
n = size(wav,1);
plot([0:(n-1)]/fs*1000000,real(wav))
xlabel('Time ({\mu}sec)')
ylabel('Waveform')
```



```
sig = radiator(wav,angsTx,laxTx);
```

Propagate signals to receiver via two-ray channel

```
prop_sig = channel(sig,posTx,posRx,velTx,velRx);
```

### Receive Propagated Signal

Compute the reception angles for the two rays arriving at the receiver. These angles are defined with respect to the receiver local coordinate system. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

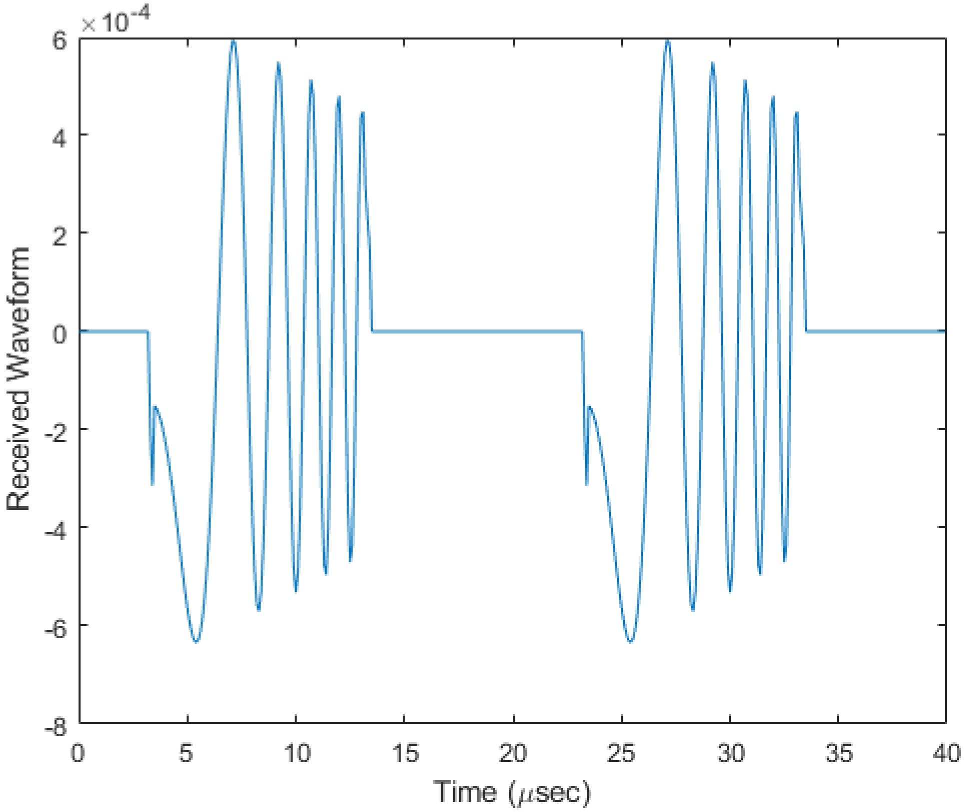
```
[~,angsRx] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine received rays.

```
y = collector(prop_sig,angsRx,laxRx);
```

### Plot received waveform

```
plot([0:(n-1)]/fs*1000000,real(y))
xlabel('Time ({\mu}sec)')
ylabel('Received Waveform')
```



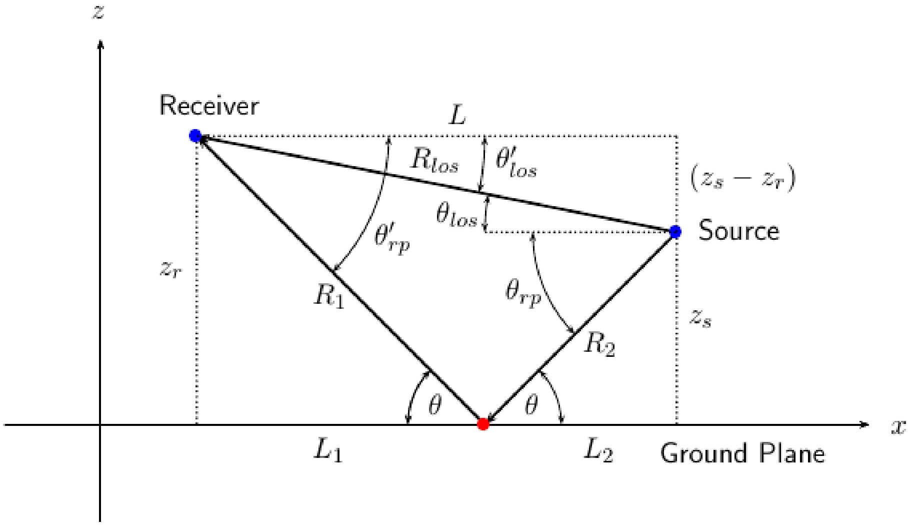
## More About

### Two-Ray Propagation Paths

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at *z = 0*. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel (see the `phased.FreeSpace` System object). The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The `phased.TwoRayChannel` and `phased.WidebandTwoRayChannel` System objects model propagation time delay, phase shift, Doppler shift, and loss effects for both paths. For the reflected path, loss effects include reflection loss at the boundary.

The figure illustrates two propagation paths. From the source position, $s_s$, and the receiver position, $s_r$, you can compute the arrival angles of both paths, $\theta'_{los}$ and $\theta'_{rp}$. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, $\theta_{los}$ and $\theta_{rp}$. In the global coordinates, the angle of reflection at the boundary is the same as the angles $\theta_{rp}$ and $\theta'_{rp}$. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by $R_{los}$ which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp}= R_1 + R_2$. The quantity $L$ is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{(z_r - z_s)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{(z_r + z_s)^2 + L^2}$$

$$\tan\theta_{los} = \frac{(z_s - z_r)}{L}$$

$$\tan\theta_{rp} = -\frac{(z_s + z_r)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

## Two-Ray Attenuation

Attenuation or path loss in the two-ray channel is the product of five components, $L = L_{tworay}\, L_G\, L_g\, L_c\, L_r$, where

- $L_{tworay}$ is the two-ray geometric path attenuation
- $L_G$ is the ground reflection attenuation
- $L_g$ is the atmospheric path attenuation
- $L_c$ is the fog and cloud path attenuation
- $L_r$ is the rain path attenuation

Each component is in magnitude units, not in dB.

## Ground Reflection and Propagation Loss

Losses occurs when a signal is reflected from a boundary. You can obtain a simple model of ground reflection loss by representing the electromagnetic field as a scalar field. This approach also works for acoustic and sonar systems. Let $E$ be a scalar free-space electromagnetic field having amplitude $E_0$ at a reference distance $R_0$ from a transmitter (for example, one meter). The propagating free-space field at distance $R_{los}$ from the transmitter is

$$E_{los} = E_0\left(\frac{R_0}{R_{los}}\right)e^{i\omega(t - R_{los}/c)}$$

for the line-of-sight path. You can express the ground-reflected $E$-field as

$$E_{rp} = L_G E_0\left(\frac{R_0}{R_{rp}}\right)e^{i\omega\left(t - R_{rp}/c\right)}$$

where $R_{rp}$ is the reflected path distance. The quantity $L_G$ represents the loss due to reflection at the ground plane. To specify $L_G$, use the `GroundReflectionCoefficient` property. In general, $L_G$ depends on the incidence angle of the field. If you have empirical information about the angular dependence of $L_G$, you can use `rangeangle` to compute the incidence angle of the reflected path. The total field at the destination is the sum of the line-of-sight and reflected-path fields.

For electromagnetic waves, a more complicated but more realistic model uses a vector representation of the polarized field. You can decompose the incident electric field into two components. One component, $E_p$, is parallel to the plane of incidence. The other component, $E_s$, is perpendicular to the plane of incidence. The ground reflection coefficients for these components differ and can be written in terms of the ground permittivity and incidence angle.

$$G_p = \frac{Z_1\cos\theta_1 - Z_2\cos\theta_2}{Z_1\cos\theta_1 + Z_2\cos\theta_2} = \frac{\cos\theta_1 - \frac{Z_2}{Z_1}\cos\theta_2}{\cos\theta_1 + \frac{Z_2}{Z_1}\cos\theta_2}$$

$$G_s = \frac{Z_2\cos\theta_1 - Z_1\cos\theta_2}{Z_2\cos\theta_1 + Z_1\cos\theta_2} = \frac{\cos\theta_2 - \frac{Z_2}{Z_1}\cos\theta_1}{\cos\theta_2 + \frac{Z_2}{Z_1}\cos\theta_1}$$

$$Z_1 = \sqrt{\frac{\mu_1}{\varepsilon_1}}$$

$$Z_2 = \sqrt{\frac{\mu_2}{\varepsilon_2}}$$

where *Z* is the impedance of the medium. Because the magnetic permeability of the ground is almost identical to that of air or free space, the ratio of impedances depends primarily on the ratio of electric permittivities

$$G_p = \frac{\sqrt{\rho}\cos\theta_1 - \cos\theta_2}{\sqrt{\rho}\cos\theta_1 + \cos\theta_2}$$

$$G_s = \frac{\sqrt{\rho}\cos\theta_2 - \cos\theta_1}{\sqrt{\rho}\cos\theta_2 + \cos\theta_1}$$

where the quantity $\rho = \varepsilon_2/\varepsilon_1$ is the *ground relative permittivity* set by the `GroundRelativePermittivity` property. The angle $\theta_1$ is the incidence angle and the angle $\theta_2$ is the refraction angle at the boundary. You can determine $\theta_2$ using Snell's law of refraction.

After reflection, the full field is reconstructed from the parallel and perpendicular components. The total ground plane attenuation, $L_G$, is a combination of $G_s$ and $G_p$.

When the origin and destination are stationary relative to each other, you can write the output `Y` of `step` as $Y(t) = F(t\text{-}\tau)/L$. The quantity $\tau$ is the signal delay and *L* is the free-space path loss. The delay $\tau$ is given by *R/c*. *R* is either the line-of-sight propagation path distance or the reflected path distance, and *c* is the propagation speed. The path loss

$$L_{tworay} = \frac{(4\pi R)^2}{\lambda^2},$$

where $\lambda$ is the signal wavelength.

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_i$, multiplied by a spectral line strength, *S*$_i$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right]W\,.$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is *P* + *W*.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, *R*. Then, the total attenuation is $L_g$= $R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^\alpha,$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

# reset

**System object:** `phased.TwoRayChannel`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(s2Ray)
```

## Description

`reset(s2Ray)` resets the internal state of the `phased.TwoRayChannel` object, `S`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

## Input Arguments

### s2Ray — Two-ray channel

System object

Two-ray channel, specified as a System object.

Example: `phased.TwoRayChannel`

**Introduced in R2015b**

# step

**System object:** `phased.TwoRayChannel`
**Package:** `phased`

Propagate signal from point to point using two-ray channel model

## Syntax

```
prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a narrowband signal, `sig`, propagates through a two-ray channel from the `origin_pos` position to the `dest_pos` position. Either the `origin_pos` or `dest_pos` arguments can have multiple points but you cannot specify both as having multiple points. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagated through a two-ray channel can be polarized or nonpolarized. For, nonpolarized fields, such as an acoustic field, the propagating signal field, `sig`, is a vector or matrix. When the fields are polarized, `sig` is an array of structures. Every structure element represents an electric field vector in Cartesian form.

In the two-ray environment, there are two signal paths connecting every signal origin and destination pair. For *N* signal origins (or *N* signal destinations), there are *2N* number of paths. The signals for each origin-destination pair do not have to be related. The signals along the two paths for any single source-destination pair can also differ due to phase or amplitude differences.

You can keep the two signals at the destination *separate* or *combined* — controlled by the `CombinedRaysOutput` property. *Combined* means that the signals at the source propagate separately along the two paths but are coherently summed at the destination into a single quantity. To use the *separate* option, set `CombinedRaysOutput` to `false`. To use the *combined* option, set `CombinedRaysOutput` to `true`. This option is convenient when the difference between the sensor or array gains in the directions of the two paths is not significant and need not be taken into account.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `channel` — Two-ray channel

System object

Two-ray channel, specified as a System object.

Example: `phased.TwoRayChannel`

### `sig` — Narrowband signal

*M*-by-*N* complex-valued matrix | *M*-by-2*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-2*N* `struct` array containing complex-valued fields

- Narrowband nonpolarized scalar signal, specified as an
    - *M*-by-*N* complex-valued matrix. Each column contains a common signal propagated along both the line-of-sight path and the reflected path. You can use this form when both path signals are the same.
    - *M*-by-2*N* complex-valued matrix. Each adjacent pair of columns represents a different channel. Within each pair, the first column represents the signal propagated along the line-of-sight path and the second column represents the signal propagated along the reflected path.

- Narrowband polarized signal, specified as a
  - 1-by-*N* `struct` array containing complex-valued fields. Each `struct` contains a common polarized signal propagated along both the line-of-sight path and the reflected path. Each structure element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`. You can use this form when both path signals are the same.
  - 1-by-*2N* `struct` array containing complex-valued fields. Each adjacent pair of array columns represents a different channel. Within each pair, the first column represents the signal along the line-of-sight path and the second column represents the signal along the reflected path. Each structure element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`.

For nonpolarized fields, the quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

For polarized fields, the `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

### `origin_pos` — Origin of the signal or signals

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are meters.

`origin_pos` and `dest_pos` cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

### `dest_pos` — Destination position of the signal or signals

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

### `origin_vel` — Velocity of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

### `dest_vel` — Velocity of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3–by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

## Output Arguments

**`prop_sig` — Propagated signal**

*M*-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-*2N* `struct` array containing complex-valued fields

- Narrowband nonpolarized scalar signal, returned as an:

  - *M*-by-*N* complex-valued matrix. To return this format, set the `CombinedRaysOutput` property to `true`. Each matrix column contains the coherently combined signals from the line-of-sight path and the reflected path.
  - *M*-by-*2N* complex-valued matrix. To return this format set the `CombinedRaysOutput` property to `false`. Alternate columns of the matrix contain the signals from the line-of-sight path and the reflected path.
- Narrowband polarized scalar signal, returned as:

  - 1-by-*N* `struct` array containing complex-valued fields. To return this format, set the `CombinedRaysOutput` property to `true`. Each column of the array contains the coherently combined signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector (`prop_sig.X`,`prop_sig.Y`,`prop_sig.Z`).
  - 1-by-*2N* `struct` array containing complex-valued fields. To return this format, set the `CombinedRaysOutput` property to `false`. Alternate columns contains the signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector (`prop_sig.X`,`prop_sig.Y`,`prop_sig.Z`).

The output `prop_sig` contains signal samples arriving at the signal destination within the current input time frame. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contributions from the input of the current time frame. The remaining output will appear in the next call to `step`.

## Examples

### Compare Two-Ray with Free Space Propagation

Propagate a signal in a two-ray channel environment from a radar at (0,0,10) meters to a target at (300,200,30) meters. Assume that the radar and target are stationary and that the transmitting antenna has a cosine pattern. Compare the combined signals from the two paths with the single signal resulting from free space propagation. Set the `CombinedRaysOutput` to `true` to produce a combined propagated signal.

#### Create a Rectangular Waveform

Set the sample rate to 2 MHz.

```
fs = 2e6;
waveform = phased.RectangularWaveform('SampleRate',fs);
wavfrm = waveform();
```

#### Create the Transmitting Antenna and Radiator

Set up a `phased.Radiator` System object™ to transmit from a cosine antenna

```
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
```

#### Specify Transmitter and Target Coordinates

```
posTx = [0;0;10];
posTgt = [300;200;30];
velTx = [0;0;0];
velTgt = [0;0;0];
```

#### Free Space Propagation

Compute the transmitting direction toward the target for the free-space model. Then, radiate the signal.

```
[~,angFS] = rangeangle(posTgt,posTx);
wavTx = radiator(wavfrm,angFS);
```

Propagate the signal to the target.

```
fschannel = phased.FreeSpace('SampleRate',waveform.SampleRate);
yfs = fschannel(wavTx,posTx,posTgt,velTx,velTgt);
release(radiator);
```

### Two-Ray Propagation

Compute the two transmit angles toward the target for line-of-sight (LOS) path and reflected paths. Compute the transmitting directions toward the target for the two rays. Then, radiate the signals.

```
[~,angTwoRay] = rangeangle(posTgt,posTx,'two-ray');
wavTwoRay = radiator(wavfrm,angTwoRay);
```

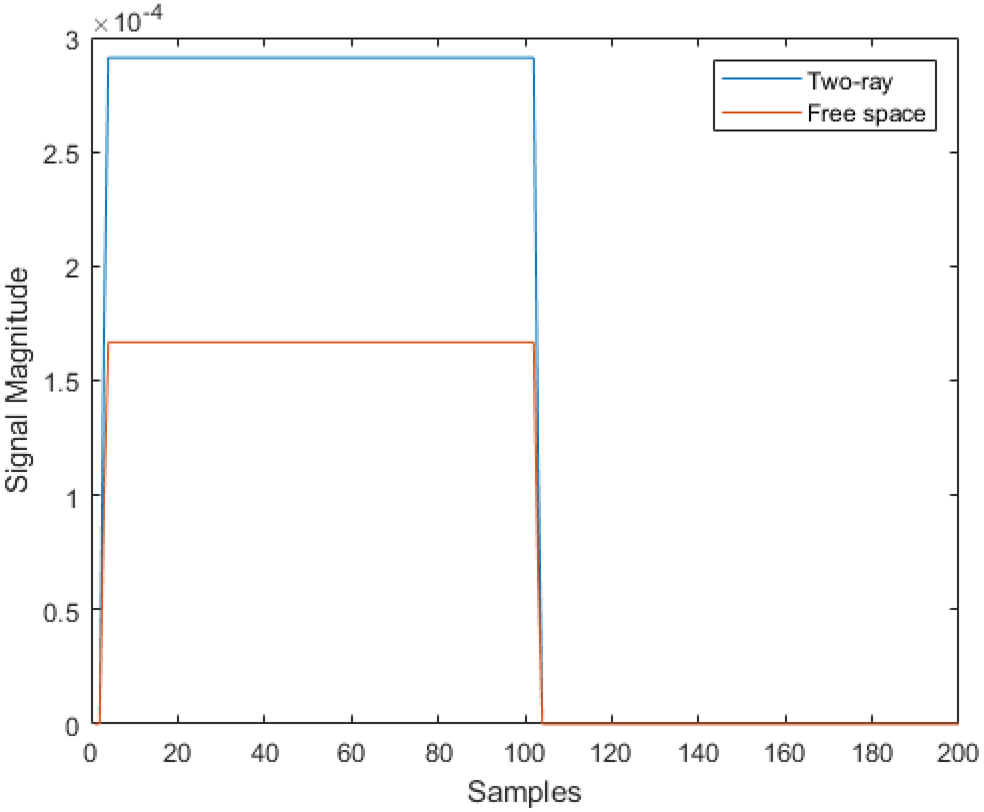
Propagate the signals to the target.

```
tworaychannel = phased.TwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',true);
y2ray = tworaychannel(wavTwoRay,posTx,posTgt,velTx,velTgt);
```

### Plot the Propagated Signals

Plot the combined signal against the free-space signal

```
plot(abs([y2ray yfs]))
legend('Two-ray','Free space')
xlabel('Samples')
ylabel('Signal Magnitude')
```



### Polarized Field Propagation in Two-Ray Channel

Create a polarized electromagnetic field consisting of linear FM waveform pulses. Propagate the field from a stationary source with a crossed-dipole antenna element to a stationary receiver approximately 10 km away. The transmitting antenna is 100 meters above the ground. The receiving antenna is 150 m above the ground. The receiving antenna is also a crossed-dipole. Plot the received signal.

#### Set Radar Waveform Parameters

Assume the pulse width is 10$\mu s$ and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle in which the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Assume a carrier frequency of 100 MHz.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
bw = 1e6;
lambda = c/fc;
```

### Set Up Required System Objects

Use a `GroundRelativePermittivity` of 10.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Up','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[50,200]*1e6);
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc,...
    'Polarization','Combined');
channel = phased.TwoRayChannel('SampleRate',fs,...
    'OperatingFrequency',fc,'CombinedRaysOutput',false,...
    'EnablePolarization',true,'GroundRelativePermittivity',10);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc,...
    'Polarization','Combined');
```

### Set Up Scene Geometry

Specify transmitter and receiver positions, velocities, and orientations. Place the source and receiver about 1000 m apart horizontally and approximately 50 m apart vertically.

```
posTx = [0;100;100];
posRx = [1000;0;150];
velTx = [0;0;0];
velRx = [0;0;0];
laxRx = rotz(180);
laxTx = rotx(1)*eye(3);
```

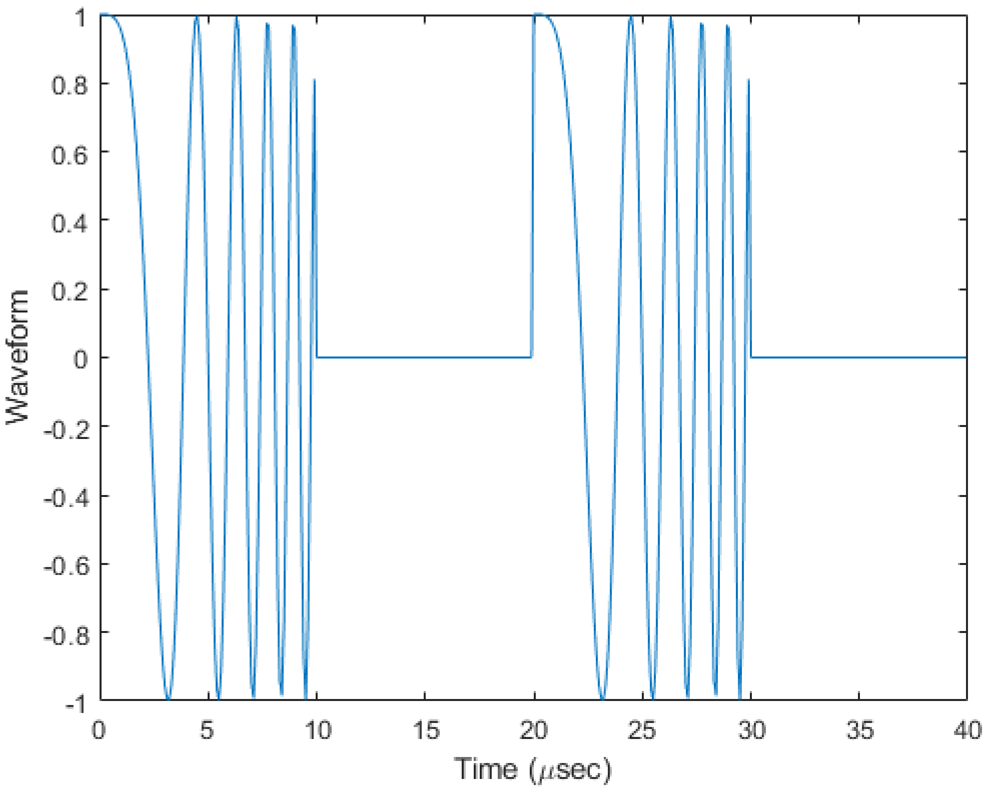
### Create and Radiate Signals from Transmitter

Compute the transmission angles for the two rays traveling toward the receiver. These angles are defined with respect to the transmitter local coordinate system. The phased.Radiator System object™ uses these angles to apply separate antenna gains to the two signals.

```
[rng,angsTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
wav = waveform();
```

Plot the transmitted Waveform

```
n = size(wav,1);
plot([0:(n-1)]/fs*1000000,real(wav))
xlabel('Time ({\mu}sec)')
ylabel('Waveform')
```



```
sig = radiator(wav,angsTx,laxTx);
```

Propagate signals to receiver via two-ray channel

```
prop_sig = channel(sig,posTx,posRx,velTx,velRx);
```

### Receive Propagated Signal

Compute the reception angles for the two rays arriving at the receiver. These angles are defined with respect to the receiver local coordinate system. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

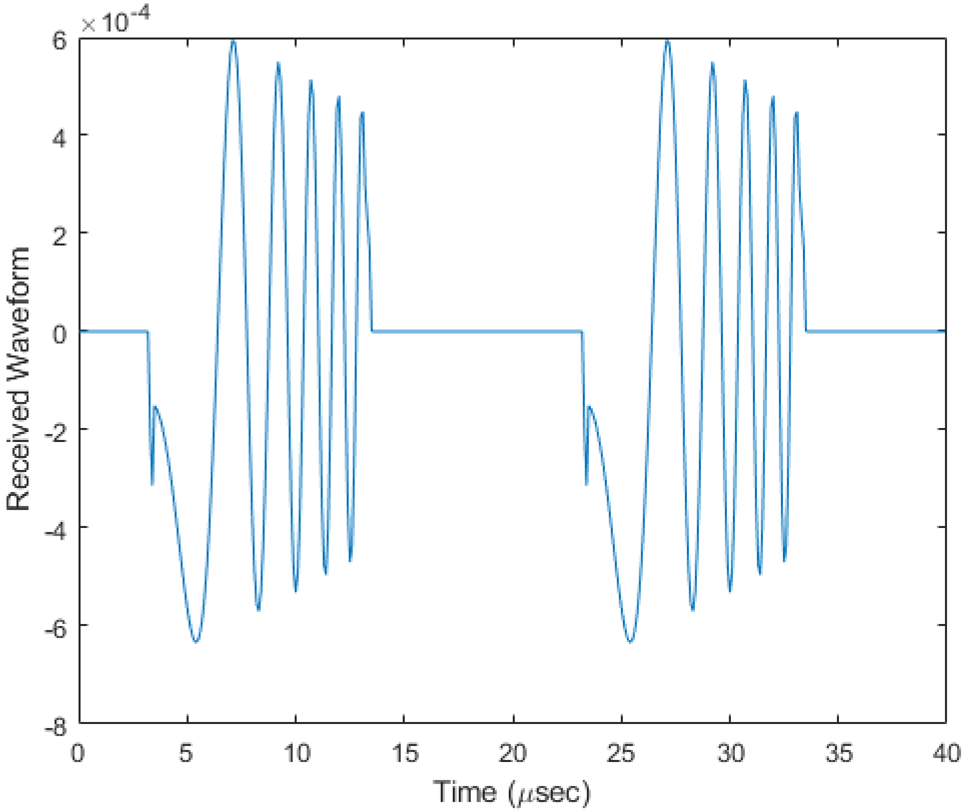
```
[~,angsRx] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine received rays.

```
y = collector(prop_sig,angsRx,laxRx);
```

### Plot received waveform

```
plot([0:(n-1)]/fs*1000000,real(y))
xlabel('Time ({\mu}sec)')
ylabel('Received Waveform')
```



### Two-Ray Propagation of LFM Waveform

Propagate a linear FM signal in a two-ray channel. The signal propagates from a transmitter located at (1000,10,10) meters in the global coordinate system to a receiver at (10000,200,30) meters. Assume that the transmitter and the receiver are stationary and that they both have cosine antenna patterns. Plot the received signal.

Set up the radar scenario. First, create the required System objects.

```
waveform = phased.LinearFMWaveform('SampleRate',1000000,...
    'OutputFormat','Pulses','NumPulses',2);
fs = waveform.SampleRate;
```

```
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
collector = phased.Collector('Sensor',antenna);
channel = phased.TwoRayChannel('SampleRate',fs,...
    'CombinedRaysOutput',false,'GroundReflectionCoefficient',0.95);
```

Set up the scene geometry. Specify transmitter and receiver positions and velocities. The transmitter and receiver are stationary.

```
posTx = [1000;10;10];
posRx = [10000;200;30];
velTx = [0;0;0];
velRx = [0;0;0];
```

Specify the transmitting and receiving radar antenna orientations with respect to the global coordinates. The transmitting antenna points along the +*x* direction and the receiving antenna points near but not directly in the -*x* direction.

```
laxTx = eye(3);
laxRx = rotx(5)*rotz(170);
```

Compute the transmission angles which are the angles that the two rays traveling toward the receiver leave the transmitter. The phased.Radiator System object™ uses these angles to apply separate antenna gains to the two signals. Because the antenna gains depend on path direction, you must transmit and receive the two rays separately.

```
[~,angTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
```

Create and radiate signals from transmitter along the transmission directions.

```
wavfrm = waveform();
wavtrans = radiator(wavfrm,angTx);
```

Propagate signals to receiver via two-ray channel.

```
wavrcv = channel(wavtrans,posTx,posRx,velTx,velRx);
```

Collect signals at the receiver. Compute the angle at which the two rays traveling from the transmitter arrive at the receiver. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

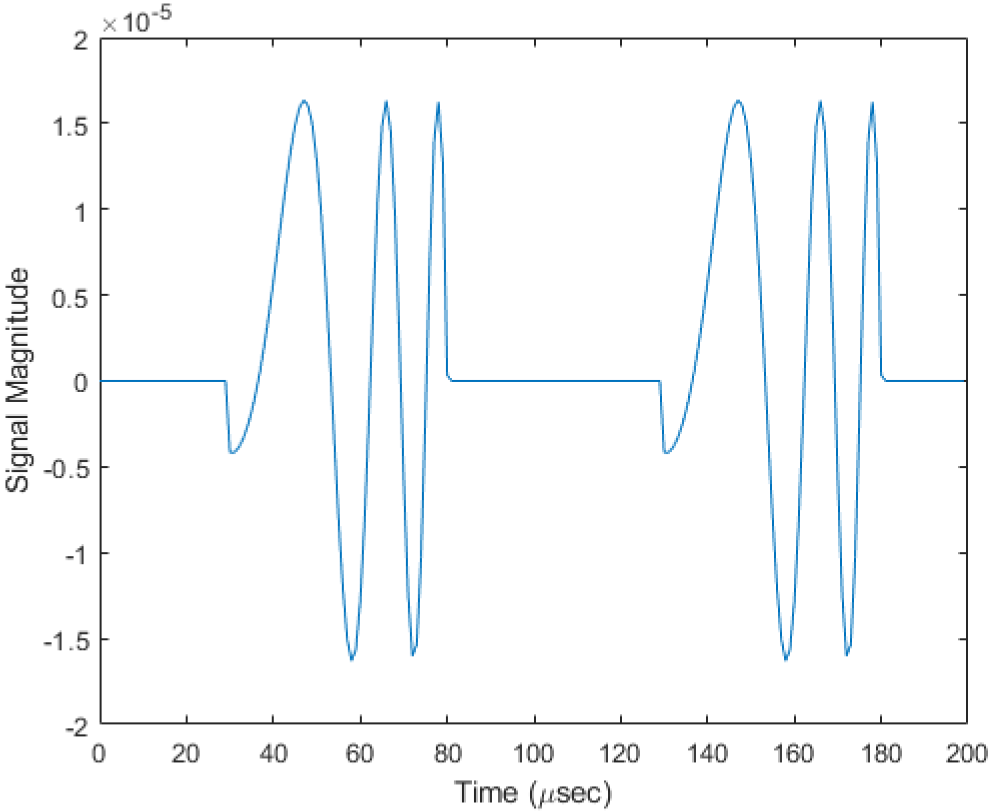
```
[~,angRcv] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine the two received rays.

```
yR = collector(wavrcv,angRcv);
```

Plot the received signals.

```
dt = 1/fs;
n = size(yR,1);
plot([0:(n-1)]*dt*1000000,real(yR))
xlabel('Time ({\mu}sec)')
ylabel('Signal Magnitude')
```



### Two-Ray Propagation of LFM Waveform with Atmospheric Losses

Propagate a linear FM signal in a two-ray channel. Assume there is signal loss caused by atmospheric gases and rain. The signal propagates from a transmitter located at `(0,0,0)` meters in the global coordinate system to a receiver at `(10000,200,30)` meters. Assume that the transmitter and the receiver are stationary and that they both have cosine antenna patterns. Plot the received signal. Set the dry air pressure to 102.0 Pa and the rain rate to 5 mm/hr.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

#### Set Up Radar Scenario

Create the required System objects.

```
waveform = phased.LinearFMWaveform('SampleRate',1000000,...
    'OutputFormat','Pulses','NumPulses',2);
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
collector = phased.Collector('Sensor',antenna);
tworaychannel = phased.TwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',false,'GroundReflectionCoefficient',0.95,...
    'SpecifyAtmosphere',true,'Temperature',20,...
    'DryAirPressure',102.5,'RainRate',5.0);
```

Set up the scene geometry. Specify transmitter and receiver positions and velocities. The transmitter and receiver are stationary.

```
posTx = [0;0;0];
posRx = [10000;200;30];
velTx = [0;0;0];
velRx = [0;0;0];
```

Specify the transmitting and receiving radar antenna orientations with respect to the global coordinates. The transmitting antenna points along the +*x*-direction and the receiving antenna points close to the -*x*-direction.

```
laxTx = eye(3);
laxRx = rotx(5)*rotz(170);
```

Compute the transmission angles which are the angles that the two rays traveling toward the receiver leave the transmitter. The phased.Radiator System object™ uses these angles to apply separate antenna gains to the two signals. Because the antenna gains depend on path direction, you must transmit and receive the two rays separately.

```
[~,angTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
```

### Create and Radiate Signals from Transmitter

Radiate the signals along the transmission directions.

```
wavfrm = waveform();
wavtrans = radiator(wavfrm,angTx);
```

Propagate signals to receiver via two-ray channel.

```
wavrcv = tworaychannel(wavtrans,posTx,posRx,velTx,velRx);
```

### Collect Signal at Receiver

Compute the angle at which the two rays traveling from the transmitter arrive at the receiver. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[~,angRcv] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine the two received rays.

```
yR = collector(wavrcv,angRcv);
```

### Plot Received Signal

```
dt = 1/waveform.SampleRate;
n = size(yR,1);
plot([0:(n-1)]*dt*1000000,real(yR))
xlabel('Time ({\mu}sec)')
ylabel('Signal Magnitude')
```

# phased.UCA

**Package:** phased

Uniform circular array

## Description

The phased.UCA System object creates a uniform circular array (UCA). A UCA is formed from identical sensor elements equally spaced around a circle.

To compute the response for the array for specified directions:

1. Define and set up your uniform circular array. See “Construction” on page 1-2368.
2. Call step to compute the response according to the properties of phased.UCA. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

sUCA = phased.UCA creates a uniform circular array (UCA) System object, sUCA, consisting of five identical isotropic antenna elements,phased.IsotropicAntennaElement. The elements are equally spaced around a circle of radius 0.5 meters.

sUCA = phased.UCA(Name,Value) creates a System object, sUCA, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

sUCA = phased.UCA(N,R) creates a UCA System object, sUCA, with the NumElements property set to N and the Radius property set to R. This syntax creates a UCA consisting of isotropic antenna elements, phased.IsotropicAntennaElement.

`sUCA = phased.UCA(N,R,Name,Value)` creates a UCA System object, `sUCA`, with the `NumElements` property set to `N`, the `Radius` property set to `R`, and other specified property Names set to the specified Values.

## Properties

### `Element` — Sensor array element

phased.IsotropicAntennaElement (default) | Phased Array System Toolbox antenna element | Phased Array System Toolbox microphone element

Sensor array element, specified as a Phased Array System Toolbox antenna or microphone element System object. You can specify antenna elements which do or do not support polarization.

Example: `phased.ShortDipoleAntennaElement()`

### `NumElements` — Number of array elements

5 (default) | integer greater than one

Number of array elements, specified as an integer greater than one.

Example: `3`

### `Radius` — Array radius

0.5 (default) | positive scalar

Array radius, specified as a positive scalar in meters.

Example: `2.5`

### `ArrayNormal` — Array normal direction

`'z'` (default) | `'x'` | `'y'`

Array normal direction, specified as one of `'x'`, `'y'`, or `'z'`. UCA elements lie in a plane orthogonal to the array normal direction. Element boresight vectors lie in the same plane and point radially outward from the origin.

| ArrayNormal Property Value | Element Positions and Boresight Directions |
|---|---|
| `'x'` | Array elements lie on the *yz*-plane. All element boresight vectors lie in the *yz*-plane and point outward from the array center. |
| `'y'` | Array elements lie on the *zx*-plane. All element boresight vectors lie in the *zx*-plane and point outward from the array center. |
| `'z'` | Array elements lie on the *xy*-plane. All element boresight vectors lie in the *xy*-plane and point outward from the array center. |

Example: `'y'`

### `Taper` — Element tapering

1 (default) | complex-valued scalar | complex-valued 1-by-*N* row vector | complex-valued *N*-by-1 column vector

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. The quantity *N* represents the number of elements of the array. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all element. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

Example: `[1 2 3 2 1]`

## Methods

| | |
|---|---|
| directivity | Directivity of uniform circular array |
| collectPlaneWave | Simulate received plane waves |
| getElementNormal | Normal vectors for array elements |
| getElementPosition | Positions of array elements |
| getElementSpacing | Spacing between array elements |
| getNumElements | Number of elements in array |
| getTaper | Array element tapers |
| isPolarizationCapable | Polarization capability |
| pattern | Plot UCA array pattern |
| patternAzimuth | Plot UCA array directivity or pattern versus azimuth |
| patternElevation | Plot UCA array directivity or pattern versus elevation |
| step | Output responses of array elements |
| viewArray | View array geometry |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Pattern of 11-Element UCA Antenna Array

Create an 11-element uniform circular array (UCA) having a 1.5 m radius and operating at 500 MHz. The array consist of short-dipole antenna elements. First, display the vertical component of the response at 45 degrees azimuth and 0 degrees elevation. Then plot the azimuth and elevation directivities.

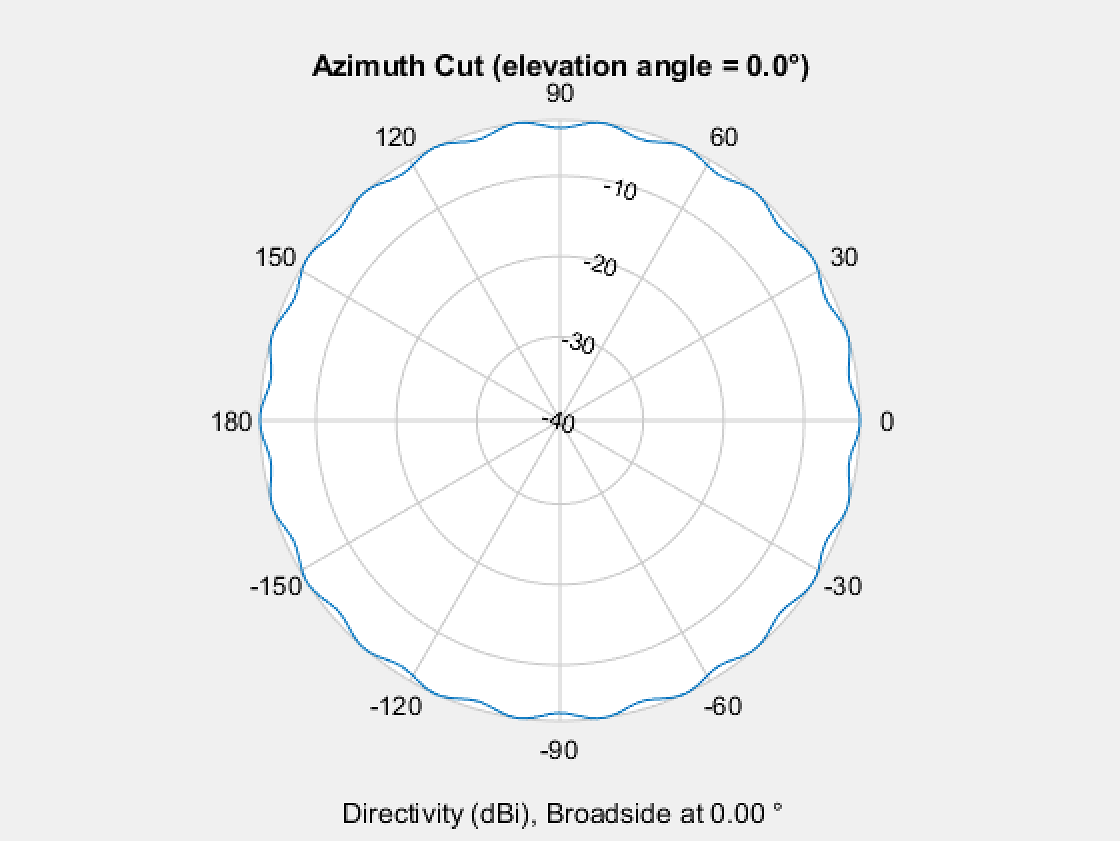
```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
array = phased.UCA('NumElements',11,'Radius',1.5,'Element',antenna);
fc = 500e6;
```

```
ang = [45;0];
resp = array(fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

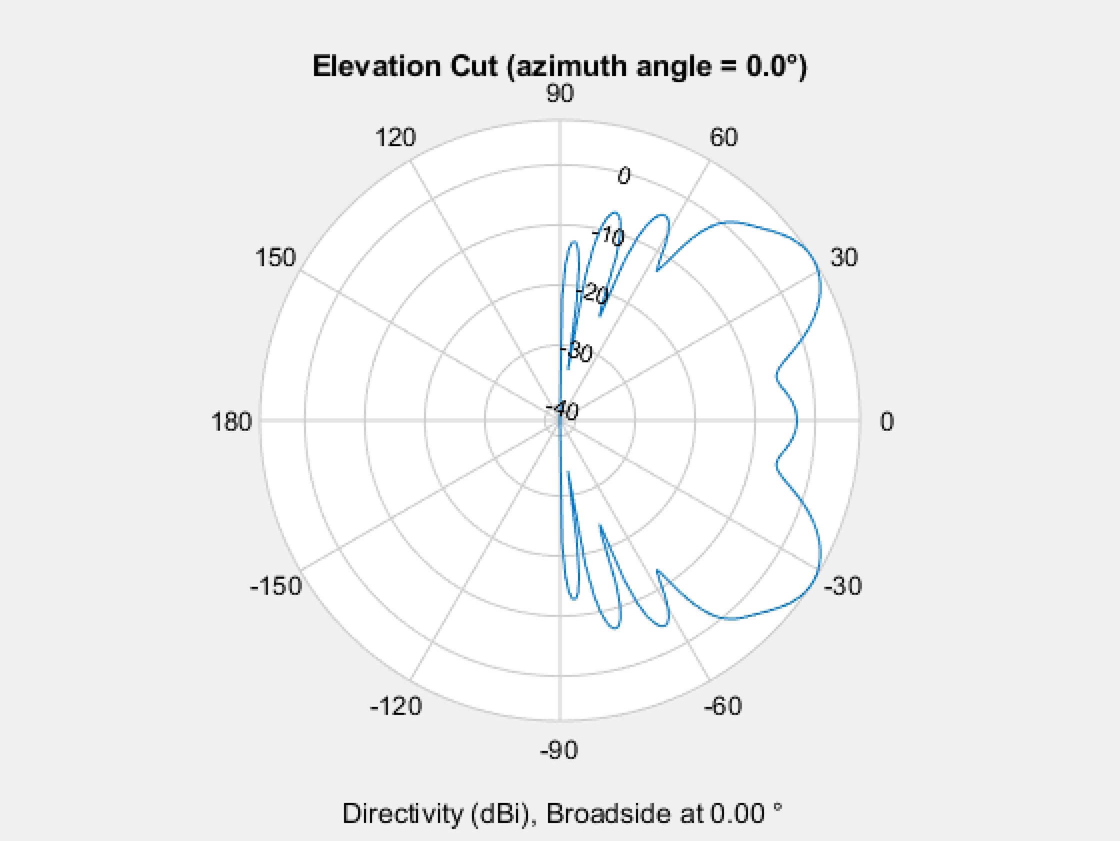
Display the azimuth directivity pattern at 500 MHz for azimuth angles between -180 and 180 degrees.

```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,'Type','directivity','PropagationSpeed',c)
```



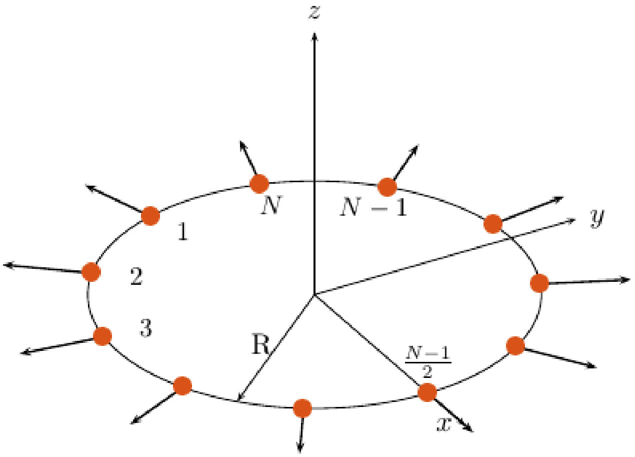
Display the elevation directivity pattern at 500 MHz for elevation angles between -90 and 90 degrees.

```
pattern(array,fc,[0],[-90:90],'Type','directivity','PropagationSpeed',c)
```



## Algorithms

A UCA is formed from *N* identical sensor elements equally spaced around a circle of radius *R*. The circle lies in the *xy*-plane of the local coordinate system whose origin lies at the center of the circle. The positions of the elements are defined with respect to the local array coordinate system. The circular array lies in the *xy*-plane of the coordinate system. The normal to the UCA plane lies along the positive *z*-axis. The elements are oriented so that their main response directions (normals) point radially outward in the *xy*-plane.



If the number of elements of the array is odd, the middle element lies on the *x*-axis. If the number of elements is even, the midpoint between the two middle elements lies on the *x*-axis. For an array of *N* elements, the azimuth angle of the position of the *nth* element is given by

$$\varphi_n = (-(N-1)/2 + n - 1) \cdot 360/N \quad n = 1, \ldots, N$$

The azimuth angle is defined as the angle, in the *xy*-plane, from the *x*-axis toward the *y*-axis. The elevation angle is defined as the angle from the *xy*-plane toward the *z*-axis. The angular distance between any two adjacent elements is *360/N* degrees. Azimuth angle values are in degrees. Elevation angles for all array elements are zero.

# directivity

**System object:** `phased.UCA`
**Package:** `phased`

Directivity of uniform circular array

## Syntax

```
D = directivity(sArray,FREQ,ANGLE)
D = directivity(sArray,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(sArray,FREQ,ANGLE)` returns the “Directivity (dBi)” on page 1-2381 of a uniform circular array (UCA) of antenna or microphone elements, `sArray`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(sArray,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `sArray` — Uniform circular array

System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `sArray= phased.UCA;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

**ANGLE — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**D — Directivity**
*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of a UCA

Compute the directivity of two uniform circular arrays (UCA) at zero degrees azimuth and elevation. The first array consists of isotropic antenna elements. The second array consists of cosine antenna elements. In addition, compute the directivity of the cosine element array steered to a 45 degrees elevation.

#### Array of isotropic antenna elements

First, create a 10-element UCA with a radius of one-half meter consisting of isotropic antenna elements. Set the signal frequency to 300 MHz.

```
c = physconst('LightSpeed');
fc = 300e6;
sIso = phased.IsotropicAntennaElement;
sArray = phased.UCA('Element',sIso,'NumElements',10,'Radius',0.5);
ang = [0;0];
d = directivity(sArray,fc,ang,'PropagationSpeed',c)
```

```
d = -1.1423
```

#### Array of cosine antenna elements

Next, create a 10-element UCA of cosine antenna elements also with a 0.5 meter radius.

```
sCos = phased.CosineAntennaElement('CosinePower',[3,3]);
sArray1 = phased.UCA('Element',sCos,'NumElements',10,'Radius',0.5);
ang = [0;0];
d = directivity(sArray1,fc,ang,'PropagationSpeed',c)
```

```
d = 3.2550
```

The directivity is increased due to the added directivity of the cosine antenna elements

**Steered array of cosine antenna elements**

Finally, steer the cosine antenna array toward 45 degrees elevation, and then examine the directivity at 45 degrees.

```
ang = [0;45];
lambda = c/fc;
w = steervec(getElementPosition(sArray1)/lambda,ang);
d = directivity(sArray1,fc,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d = -3.1410
```

The directivity is decreased because of the combined reduction of directivity of the elements and the array.

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2015a**

# collectPlaneWave

**System object:** `phased.UCA`
**Package:** `phased`

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

## Input Arguments

### H — Uniform circular array

System object

Uniform circular array specified as a `phased.UCA` System object.

Example: `H = phased.UCA();`

### X — Incoming signals

*M*-column matrix

Incoming signals, specified as an *M*-column matrix. Each column of X represents an individual incoming signal.

Example: `[1,5;2,10;3,10]`

Data Types: `double`
Complex Number Support: Yes

### ANG — Arrival directions of incoming signals

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Arrival directions of incoming signals, specified as a 1-by-*M* vector or a 2-by-*M* matrix, where *M* is the number of incoming signals. Each column specifies the direction of arrival of the corresponding signal in X. If ANG is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the incoming signal `[az;el]`. Angular units are in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°.

If ANG is a 1-by-*M* vector, then each entry represents a set of azimuth angles, with the elevation angles assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the arrival direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, the azimuth angle is positive.

The elevation angle is the angle between the arrival direction vector and the *xy*-plane. When measured toward the *z* axis, the elevation angle is positive.

Example: `[20,30;15,25]`

Data Types: `double`

### FREQ — Signal carrier frequency

3e8 (default) | positive scalar

Signal carrier frequency, specified as a positive scalar in hertz.

Data Types: `double`

### C — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Example: `physconst('LightSpeed')`

Data Types: `double`

## Output Arguments

**Y — Received signals**

*N*-column complex-valued row vector

Received signals, returned as an *N*-column complex-valued row vector. The quantity *N* is the number of elements in the array. Each column of `Y` contains the combined received signals at the corresponding array element.

## Examples

### Simulate Received Signal at 5-element UCA

Create a random signal arriving at a 5-element UCA from 10 degrees azimuth and 30 degrees azimuth. Both signals have an elevation angle of 0 degrees. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz. The signals are two random noise signals of three samples each.

```
sUCA = phased.UCA('NumElements',5,'Radius',2.0);
y = collectPlaneWave(sUCA,randn(3,2),[10 30],100e6,...
    physconst('LightSpeed'));
disp(y)
```

```
  Columns 1 through 4

  -0.8817 + 1.0528i   1.0037 - 0.3636i  -1.0579 - 0.8531i  -1.0698 + 0.5187i
  -1.6512 + 1.3471i   1.7358 + 0.7662i  -1.2932 - 1.6792i  -1.0279 + 1.6997i
   2.5071 - 2.4424i  -2.7270 - 0.2435i   2.4009 + 2.4977i   2.1808 - 2.1178i

  Column 5

  -0.6388 - 0.9769i
  -1.8283 - 0.7336i
   2.3743 + 1.8105i
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

# getElementNormal

**System object:** phased.UCA
**Package:** phased

Normal vectors for array elements

## Syntax

```
normvec = getElementNormal(sArray)
normvec = getElementNormal(sArray,elemidx)
```

## Description

normvec = getElementNormal(sArray) returns the element normals of the phased.UCA System object, sArray. normv is a 2-by-*N* matrix, where *N* is the number of elements in sArray. Each column of normv specifies the normal direction of the corresponding element in the local coordinate system in the form [azimuth;elevation]. Units are degrees. For details regarding the local coordinate system of a UCA, type

```
phased.UCA.coordinateSystemInfo;
```

at the command line.

normvec = getElementNormal(sArray,elemidx) returns only the normals of the elements that are specified in the element index vector elemidx.

## Input Arguments

### sArray — Uniform circular array

phased.UCA System object

Uniform circular array, specified as a phased.UCA System object.

Example: phased.UCA

**elemidx — Element index vector**
all elements (default) | vector of positive integers

Element index vector, specified as a vector of positive integers each of which takes a value from 1 to *N*. The dimension *N* is the number of elements of the array.

Example: [1,2,3]

## Output Arguments

**normvec — Normal vector**
2-by-*M* real-valued matrix

Normal vector of array elements, returned as a 2-by-*M* real matrix. Each column of `normvec` specifies the normal direction of the corresponding element in the local coordinate system in the form `[azimuth;elevation]`. Units are degrees. If the input argument `elemidx` is not specified, *M* is the number of elements of the array, *N*. If `elemidx` is specified, *M* is the dimension of `elemidx`.

## Examples

### UCA Element Normal Vectors

Construct three different 7-element UCA with a radius of 0.5 meters, and obtain the normal vectors of the middle three elements. Choose the array normal vectors to point along the *x*-, *y*-, and *z*-axes.

First, choose the array normal along the *x*-axis.

```
sUCA1 = phased.UCA('NumElements',7,'Radius',0.5,'ArrayNormal','x');
pos = getElementPosition(sUCA1,[3,4,5])
```

```
pos = 3×3

         0         0         0
    0.3117    0.5000    0.3117
   -0.3909         0    0.3909
```

```
normvec = getElementNormal(sUCA1,[3,4,5])
normvec = 2×3

   90.0000   90.0000   90.0000
  -51.4286         0   51.4286
```

These outputs show that the array elements lie in the *yz*-plane. The normal vectors of the array elements also lie in the *yz*-plane and point outward like spokes on a wheel.

Next, choose the array normal along the *y*-axis.

```
sUCA2 = phased.UCA('NumElements',7,'Radius',0.5,'ArrayNormal','y');
pos = getElementPosition(sUCA2,[3,4,5])
```

```
pos = 3×3

    0.3117    0.5000    0.3117
         0         0         0
   -0.3909         0    0.3909
```

```
normvec = getElementNormal(sUCA2,[3,4,5])
```

```
normvec = 2×3

         0         0         0
  -51.4286         0   51.4286
```

These outputs show that the array elements lie in the *zx*-plane. The normal vectors of the array elements also lie in the *zx*-plane and also point outward.

Finally, set the array normal along the *z*-axis. This is the default value of array normal.

```
sUCA3 = phased.UCA('NumElements',7,'Radius',0.5,'ArrayNormal','z');
pos = getElementPosition(sUCA3,[3,4,5])
```

```
pos = 3×3

    0.3117    0.5000    0.3117
   -0.3909         0    0.3909
         0         0         0
```

```
normvec = getElementNormal(sUCA3,[3,4,5])
normvec = 2×3

  -51.4286         0   51.4286
         0         0         0
```

These outputs show that the array elements lie in the *xy*-plane. The normal vectors of the array elements also lie in the *xy*-plane and also point outward.

**Introduced in R2015a**

# getElementPosition

**System object:** phased.UCA
**Package:** phased

Positions of array elements

## Syntax

```
pos = getElementPosition(sUCA)
pos = getElementPosition(sUCA,elemidx)
```

## Description

pos = getElementPosition(sUCA) returns the element positions of the phased.UCA System object, sUCA. pos is a 3-by-*N* matrix, where *N* is the number of elements in sUCA. Each column of pos defines the position of an element in the local coordinate system, in meters, using the form [x;y;z]. The origin of the local coordinate system is the center of the circular array.

pos = getElementPosition(sUCA,elemidx) returns only the positions of the elements that are specified in the element index vector elemidx.

## Input Arguments

### sUCA — Uniform circular array

phased.UCA System object

Uniform circular array, specified as a phased.UCA System object.

Example: phased.UCA

### elemidx — Element index vector

all elements (default) | vector of positive integers

Element index vector, specified as a vector of positive integers each of which takes a value from 1 to *N*. The quantity *N* is the number of elements of the array.

Example: [1,2,3]

## Output Arguments

**pos — Positions of array elements**
3-by-*M* real matrix

Positions of array elements, returned as a 3-by-*M* real matrix. If the input argument `elemidx` is not specified, *M* is the number of elements of the array, *N*. If `elemidx` is specified, *M* is the dimension of `elemidx`.

## Examples

### Positions of UCA Elements

Construct a 7-element UCA with a radius of 0.5 meters, and obtain the positions of the middle three elements.

```
sArray = phased.UCA('NumElements',7,'Radius',0.5);
pos = getElementPosition(sArray,[3,4,5])
```

```
pos = 3×3

    0.3117    0.5000    0.3117
   -0.3909         0    0.3909
         0         0         0
```

The output verifies that the position of the middle element of an array with an odd number of elements lies on the x-axis.

**Introduced in R2015a**

# getElementSpacing

**System object:** `phased.UCA`
**Package:** `phased`

Spacing between array elements

## Syntax

```
dist = getElementSpacing(sArray)
dist = getElementSpacing(sArray,disttype)
```

## Description

`dist = getElementSpacing(sArray)` returns the arc length between adjacent elements of the `phased.UCA` System object, `sArray`.

`dist = getElementSpacing(sArray,disttype)` returns either the arc length or chord length between adjacent elements depending on the specification of `disttype`.

## Input Arguments

### `sArray` — Uniform circular array

`phased.UCA` System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `phased.UCA()`

### `disttype` — Distance type

`'arc'` (default) | `'chord'`

Distance type to define path between adjacent array elements, specified as a either `'arc'` or `'chord'`. If `disttype` is specified as `'arc'`, the returned distance is the arc length between adjacent elements. If `disttype` is specified as `'chord'`, the returned distance is the chord length between adjacent elements.

Example: 'chord'

## Output Arguments

### spacing — Spacing between elements

scalar

Spacing between elements, returned as a scalar. A uniform circular array has a unique distance between all pairs of adjacent elements. The distance depends only upon the radius of the array, *R*, and the angle between two adjacent elements, $\Delta\varphi$ . The angle between two adjacent elements is computed from the number of elements, $\Delta\varphi = 2\pi/N$. If `disttype` is specified as `'arc'`, the method returns

$R\Delta\varphi$.

If `disttype` is specified as `'chord'`, the method returns

$2R\sin(\Delta\varphi/2)$.

The chord distance is always less than the arc distance.

## Examples

### Spacing Between UCA Elements

Construct a 10-element UCA with a radius of 1.5 meters, and obtain the arc distance between any two adjacent elements. Then, obtain the chord distance.

```
sArray = phased.UCA('NumElements',10,'Radius',1.5);
dist = getElementSpacing(sArray,'arc')
```

```
dist = 0.9425
```

```
dist = getElementSpacing(sArray,'chord')
```

```
dist = 0.9271
```

**Introduced in R2015a**

# getNumElements

**System object:** `phased.UCA`
**Package:** `phased`

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

`N = getNumElements(H)` returns the number of elements, *N*, in the UCA object `H`.

## Input Arguments

### `H` — Uniform circular array

`phased.UCA` System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `H = phased.UCA();`

## Output Arguments

### `N` — Number of elements

positive integer

Number of elements of array, returned as a positive integer.

## Examples

### Number of Elements of UCA

Create a UCA with the default number of elements. Verify that there are five elements.

```
sArray = phased.UCA();
N = getNumElements(sArray)
```

```
N = 5
```

**Introduced in R2015a**

# getTaper

**System object:** `phased.UCA`
**Package:** `phased`

Array element tapers

## Syntax

```
WTS = getTaper(H)
```

## Description

`WTS = getTaper(H)` returns the tapers, `WTS`, applied to each element of the phased uniform circular array (UCA), `H`. Tapers are often referred to as weights.

## Input Arguments

### `H` — Uniform circular array

System object

Uniform circular array, specified as a `phased.ULA` System object.

Example: `H = phased.UCA();`

## Output Arguments

### `WTS` — Array element tapers

*N*-by-1 complex-valued vector

Array element tapers, returned as an *N*-by-1 complex-valued vector, where *N* is the number of elements in the array.

## Examples

### Show UCA Element Tapers

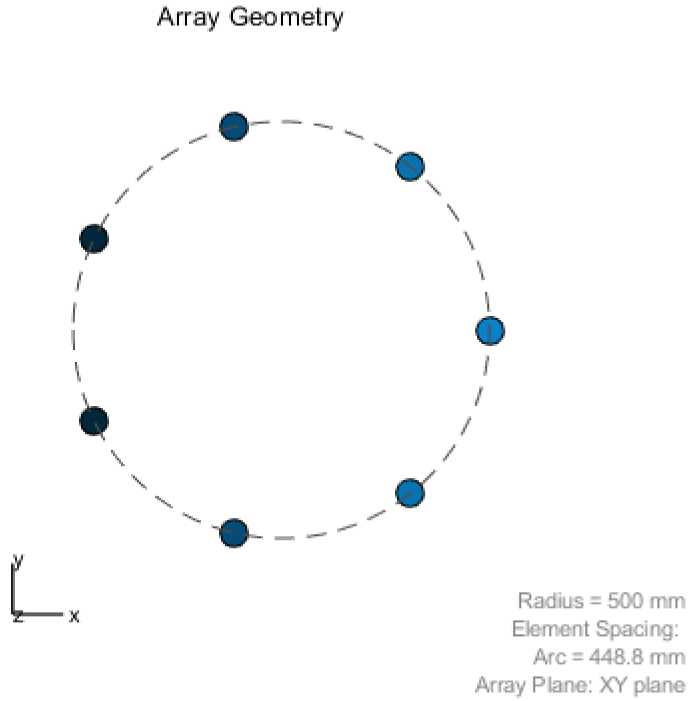
Construct a 7-element UCA array of isotropic antenna elements with a Taylor window taper. Design the array to have a radius of 0.5 meters. Then, draw the array showing the element taper shading.

```
Nelem = 7;
R = 0.5;
taper = taylorwin(Nelem);
sArray = phased.UCA(Nelem,R,'Taper',taper.');
w = getTaper(sArray)
```

```
w = 7×1

    0.4520
    0.9009
    1.3680
    1.5581
    1.3680
    0.9009
    0.4520
```

```
viewArray(sArray,'ShowTaper',true);
```



Both the output and figure above shows that the taper magnitudes are largest near the middle element.

**Introduced in R2015a**

# isPolarizationCapable

**System object:** `phased.UCA`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(H)
```

## Description

`flag = isPolarizationCapable(H)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization when all of its constituent sensor elements support polarization.

## Input Arguments

### `H` — Uniform line array

System object

Uniform line array specified as a `phased.UCA` System object.

## Output Arguments

### `flag` — Polarization-capability flag

boolean

Polarization-capability flag returned as a boolean value `true` when the array supports polarization or `false` when it does not.

# Examples

### Show UCA is Polarization Capable

Determine whether a UCA array of 7 short-dipole antenna elements supports polarization. The array radius is one-half meter.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
array = phased.UCA('NumElements',7,'Radius',0.5,'Element',antenna);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

The returned value 1 from `isPolarizationCapable` shows that a UCA of short-dipole antenna elements supports polarization.

**Introduced in R2015a**

# pattern

**System object:** `phased.UCA`
**Package:** `phased`

Plot UCA array pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

## Input Arguments

**`sArray` — Uniform circular array**
System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `sArray= phased.UCA;`

**`FREQ` — Frequency for computing directivity and patterns**
positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

**`AZ` — Azimuth angles**
`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

[-90:90] (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: [-75:1:70]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### CoordinateSystem — Plotting coordinate system

'polar' (default) | 'rectangular' | 'uv'

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of 'CoordinateSystem' and one of 'polar', 'rectangular', or 'uv'. When 'CoordinateSystem' is set to 'polar' or 'rectangular', the AZ and EL arguments specify the pattern azimuth and elevation, respectively. AZ values must lie between –180° and 180°. EL values must lie between –90° and 90°. If 'CoordinateSystem' is set to 'uv', AZ and EL then specify *U* and *V* coordinates, respectively. AZ and EL must lie between -1 and 1.

Example: 'uv'

Data Types: char

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.

- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Normalize` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize`' and a Boolean. Set this parameter to `true` to display a normalized pattern. This parameter does not apply when you set `'Type'` to `'directivity'`. Directivity patterns are already normalized.

Data Types: `logical`

### `PlotStyle` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Data Types: `char`

### `Polarization` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |

| 'Polarization' | Display |
|---|---|
| 'V' | *V* polarization component |

Example: 'V'

Data Types: char

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

### Weights — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by FREQ.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of 'Weights' for the corresponding frequency in FREQ. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**PAT — Array pattern**
*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Pattern of 11-Element UCA Antenna Array

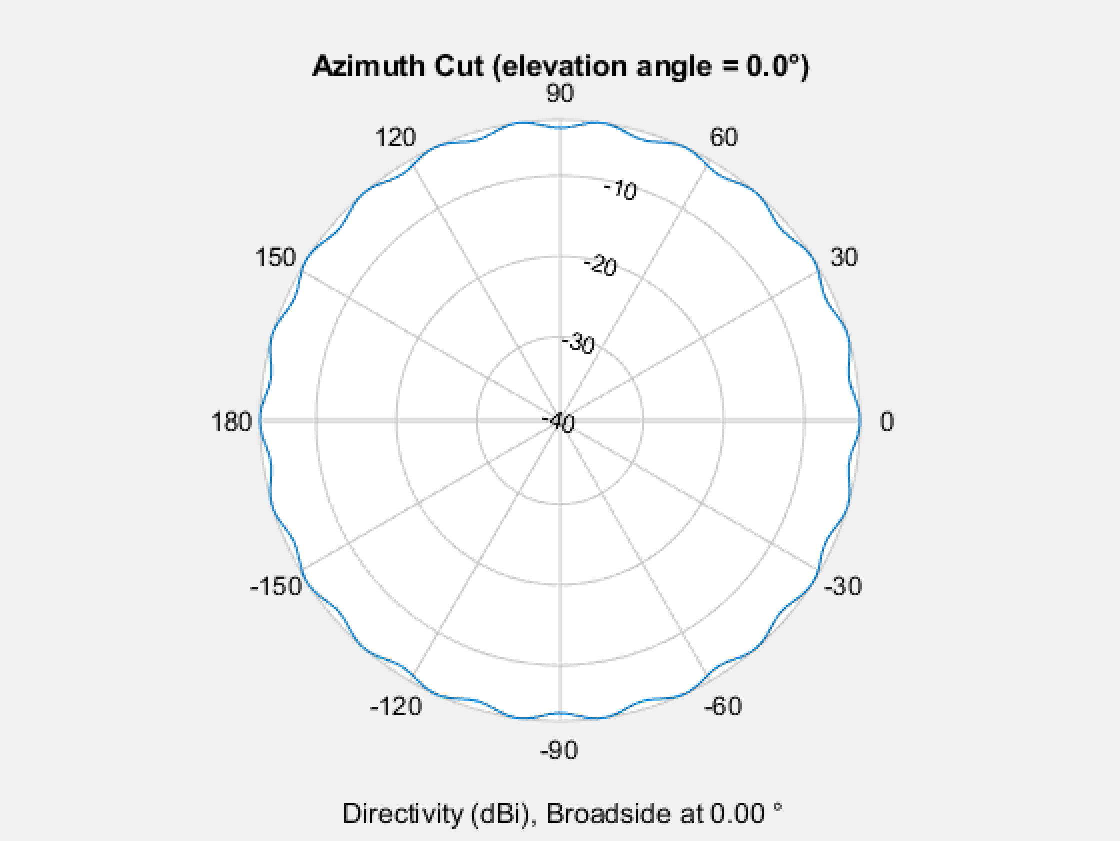
Create an 11-element uniform circular array (UCA) having a 1.5 m radius and operating at 500 MHz. The array consist of short-dipole antenna elements. First, display the vertical component of the response at 45 degrees azimuth and 0 degrees elevation. Then plot the azimuth and elevation directivities.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
array = phased.UCA('NumElements',11,'Radius',1.5,'Element',antenna);
fc = 500e6;
ang = [45;0];
resp = array(fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

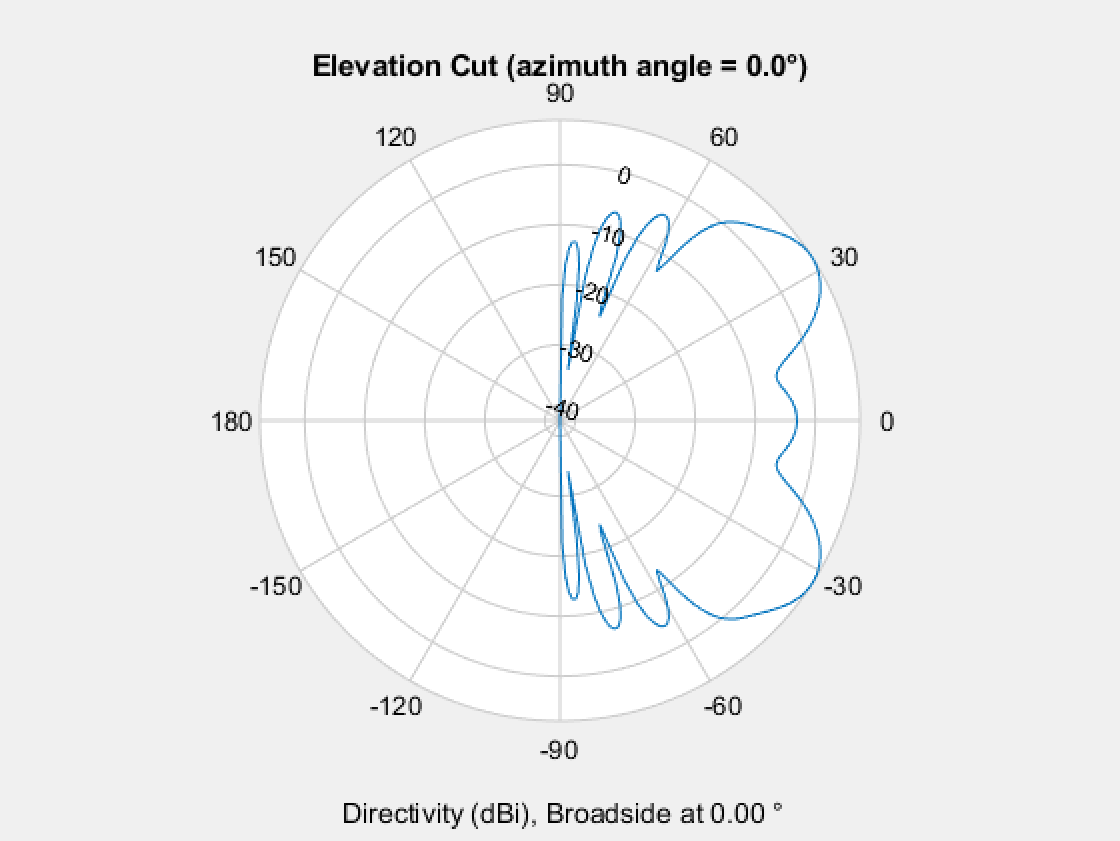
Display the azimuth directivity pattern at 500 MHz for azimuth angles between -180 and 180 degrees.

```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,'Type','directivity','PropagationSpeed',c)
```



Display the elevation directivity pattern at 500 MHz for elevation angles between -90 and 90 degrees.

```
pattern(array,fc,[0],[-90:90],'Type','directivity','PropagationSpeed',c)
```

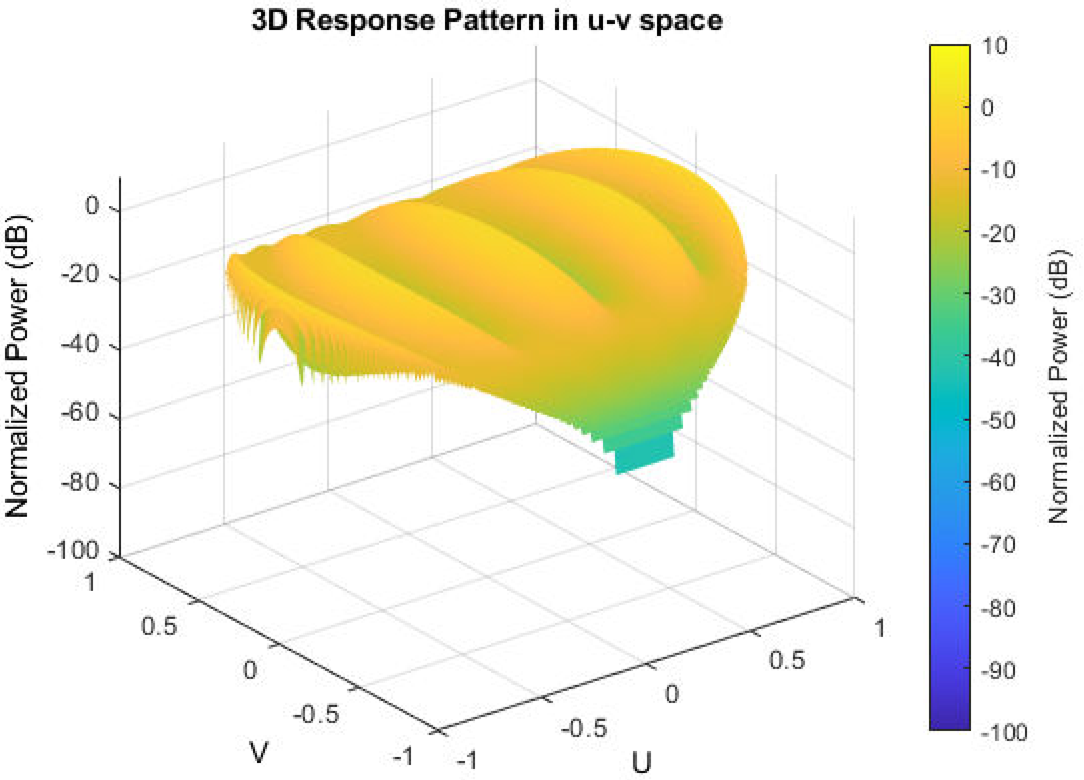


### Pattern of 10-Element UCA Antenna Array in UV Space

Create a 10-element UCA antenna array consisting of cosine antenna elements. Display the 3-D power pattern in UV space.

```
sCos = phased.CosineAntennaElement('FrequencyRange',[100e6 1e9],...
    'CosinePower',[2.5,2.5]);
sUCA = phased.UCA('NumElements',10,...
    'Radius',1.5,...
    'Element',sCos);
c = physconst('LightSpeed');
```

```
fc = 500e6;
pattern(sUCA,fc,[-1:.01:1],[-1:.01:1],...
    'CoordinateSystem','uv',...
    'Type','powerdb',...
    'PropagationSpeed',c)
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# See Also

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.UCA
**Package:** phased

Plot UCA array directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

patternAzimuth(sArray,FREQ) plots the 2-D array directivity pattern versus azimuth (in dBi) for the array sArray at zero degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(sArray,FREQ,EL), in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array sArray at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(sArray,FREQ,EL,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth( ___ ) returns the array pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

**sArray — Uniform circular array**
System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `sArray= phased.UCA;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Type` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Azimuth` — Azimuth angles**
`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

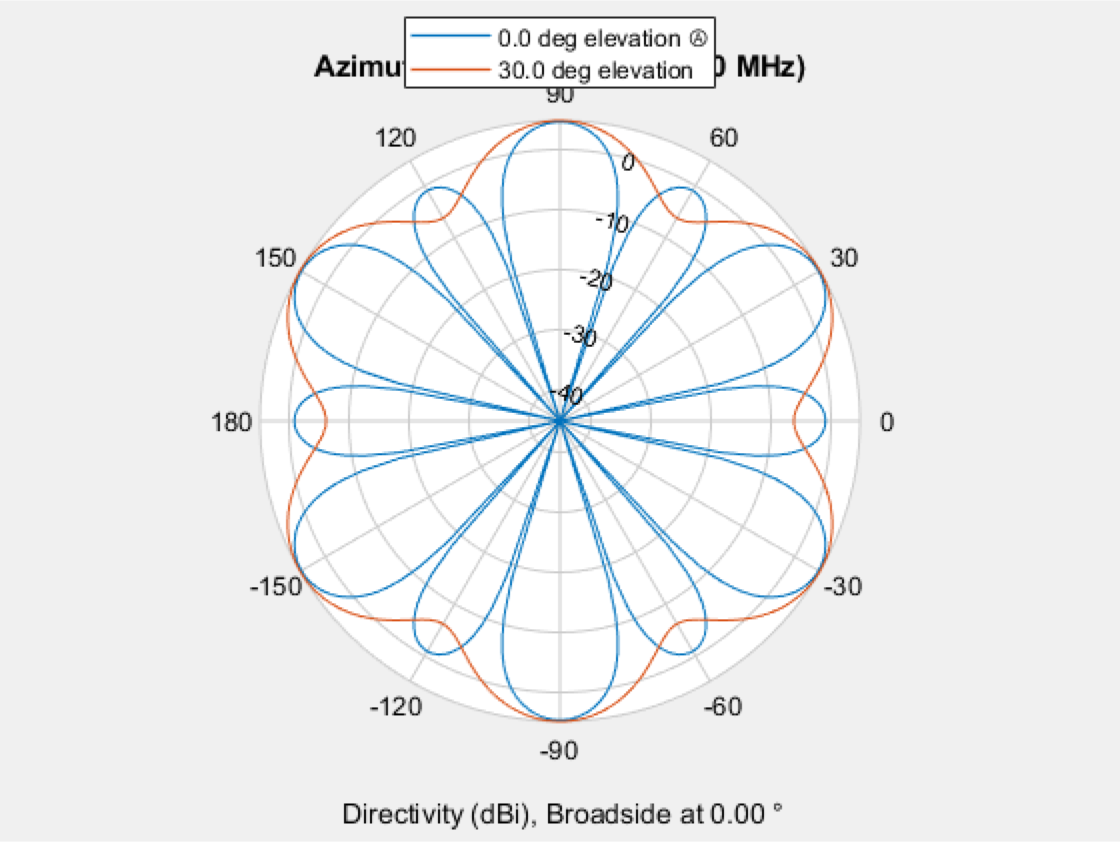
Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Plot Azimuth Pattern of UCA

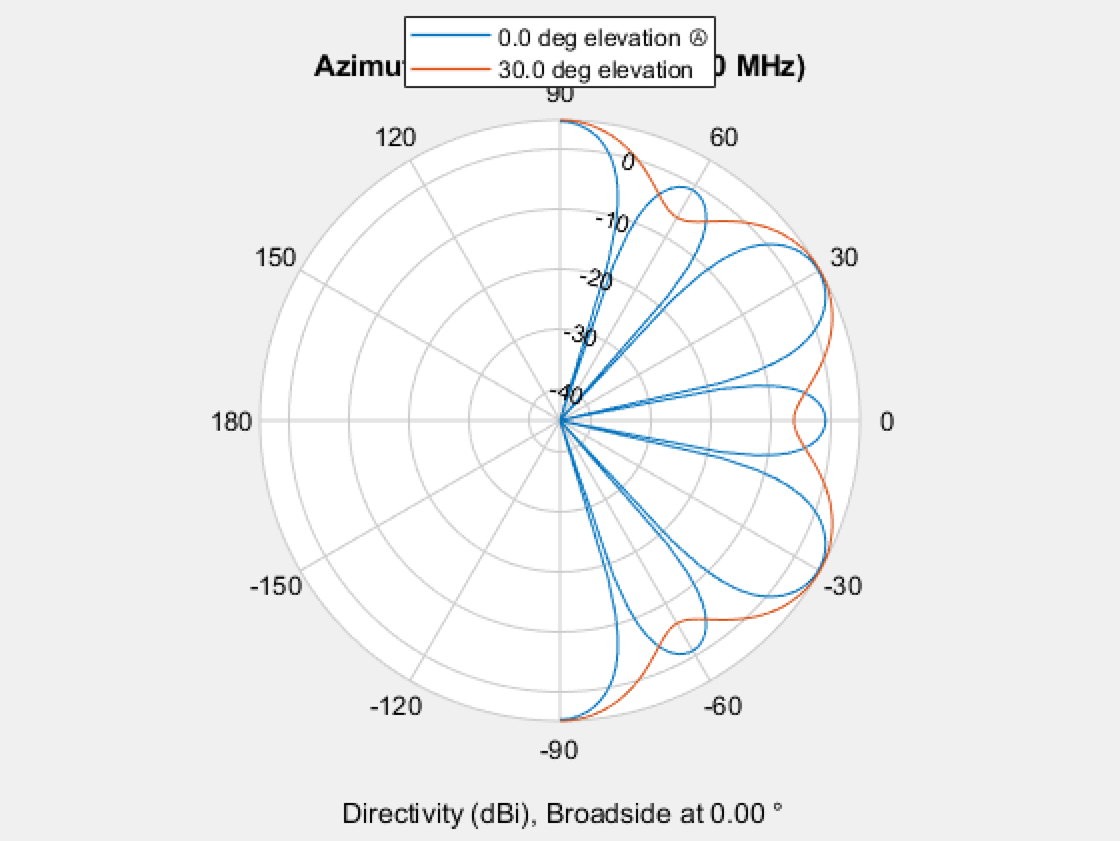
Create a 6-element UCA of short-dipole antenna elements. Design the array to have a radius of 0.5 meters. Plot an azimuth cut of directivity at 0 and 10 degrees elevation. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCDant = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sUCA = phased.UCA('NumElements',6,'Radius',0.5,'Element',sCDant);
patternAzimuth(sUCA,fc,[0 30])
```



You can plot a smaller range of azimuth angles by setting the `Azimuth` property.

```
patternAzimuth(sUCA,fc,[0 30],'Azimuth',[-90:90])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternElevation`

**Introduced in R2015a**

# patternElevation

**System object:** `phased.UCA`
**Package:** `phased`

Plot UCA array directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

### sArray — Uniform circular array

System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `sArray= phased.UCA;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Type` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

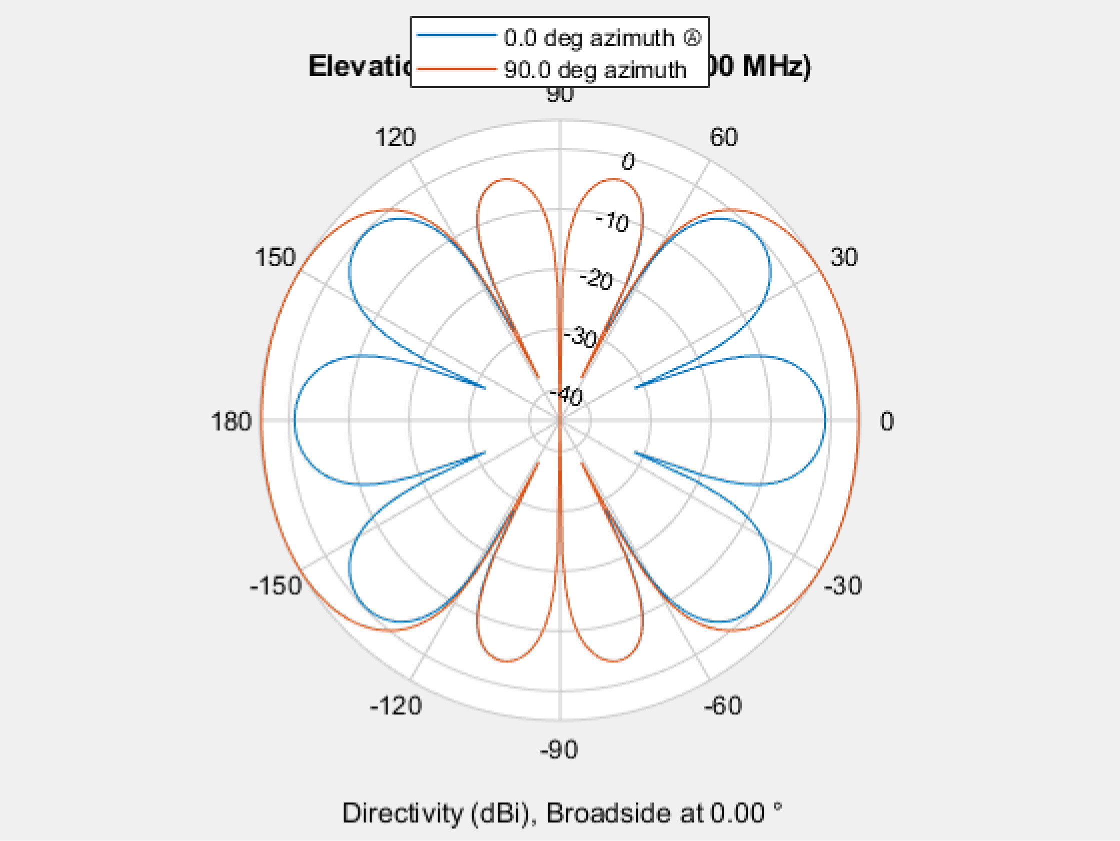
Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Plot Elevation Pattern of UCA

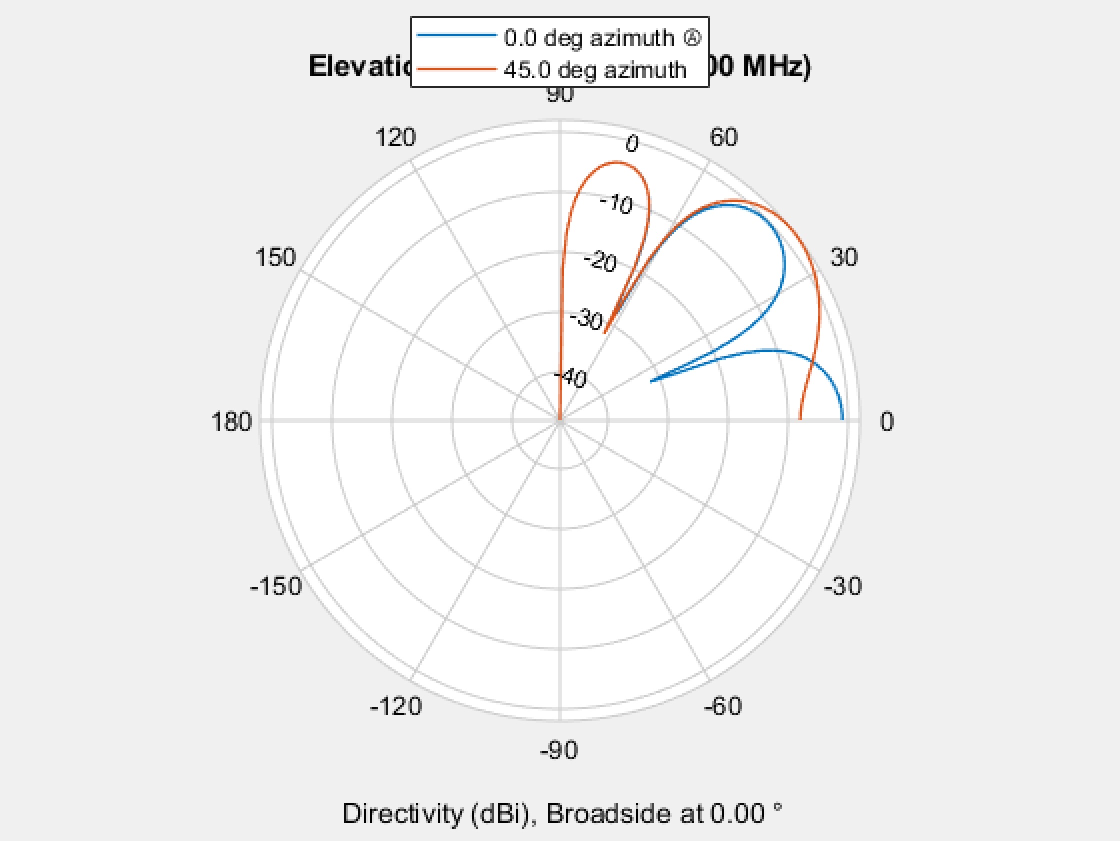
Create a 6-element UCA of short-dipole antenna elements. Design the array to have a radius of 0.5 meters. Plot an elevation cut of directivity at 0 and 90 degrees azimuth. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCDant = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sUCA = phased.UCA('NumElements',6,'Radius',0.5,'Element',sCDant);
patternElevation(sUCA,fc,[0 90])
```



You can plot a smaller range of elevation angles by setting the `Elevation` property.

```
patternElevation(sUCA,fc,[0 45],'Elevation',[0:90])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternAzimuth`

**Introduced in R2015a**

# step

**System object:** `phased.UCA`
**Package:** `phased`

Output responses of array elements

## Syntax

```
RESP = step(sArray,FREQ,ANG)
```

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`RESP = step(sArray,FREQ,ANG)` returns the responses, `RESP`, of the array elements, at operating frequencies specified in `FREQ` and directions specified in `ANG`.

---

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## Input Arguments

### `sArray` — Uniform circular array

System object

Uniform circular array, specified as a `phased.UCA` System object.

Example: `sArray= phased.UCA;`

### FREQ — Operating frequency

positive scalar | 1-by-*L* real-valued row vector

Operating frequency of array specified, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For antenna or microphone elements, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the array response is returned as zero. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as zero.

Example: `[1e8 2e8]`

Data Types: `double`

### ANG — Response directions

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Response directions, specified as either a 2-by-*M* real-valued matrix or a real-valued row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive. Angle units are in degrees.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Example: `[20;15]`

Data Types: `double`

## Output Arguments

### RESP — Voltage responses of phased array

complex-valued *N*-by-*M*-by-*L* matrix | complex-valued structure

Voltage responses of a phased array, specified as a complex-valued matrix or a `struct` with complex-valued fields. The output depends on whether the array supports polarization or not.

- If the array elements do not support polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*.

  - *N* (rows) is the number of elements in the array
  - *M* (columns) is the number of angles specified in `ANG`
  - *L* (pages) is the number of frequencies specified in `FREQ`

  For each array element, the columns of `RESP` contain the array element responses for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the array element responses for the corresponding frequency specified in `FREQ`.
- If the array supports polarization, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*.

  - *N* (rows) is the number of elements in the array
  - *M* (columns) is the number of angles specified in `ANG`
  - *L* (pages) is the number of frequencies specified in `FREQ`

  For each array element, the columns of `RESP.H` or `RESP.V` contain the array element responses for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP.H` or `RESP.V` contains the array element responses for the corresponding frequency specified in `FREQ`.

## Examples

### Response of UCA Array

Create a 5-element uniform circular array (UCA) of cosine antenna elements having a 0.5 meter radius. Find the element responses at the 0 degrees azimuth and elevation at a 300 MHz operating frequency.

```
c = physconst('LightSpeed');
fc = 300e6;
sCos = phased.CosineAntennaElement('CosinePower',[1,1]);
sArray = phased.UCA('Element',sCos,'NumElements',5,'Radius',0.5);
ang = [0;0];
resp = step(sArray,fc,ang)
```

```
resp = 5×1

         0
    0.3090
    1.0000
    0.3090
         0
```

**Introduced in R2015a**

# viewArray

**System object:** phased.UCA
**Package:** phased

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

viewArray(H) plots the geometry of the array specified in H.

viewArray(H,Name,Value) plots the geometry of the array, with additional options specified by one or more Name,Value pair arguments.

hPlot = viewArray( ___ ) returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

### H — Uniform circular array

System object

Uniform circular array specified as a phased.UCA System object.

Example: phased.UCA()

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `ShowIndex` — Element indices to show

`'None'` (default) | vector of positive integers | `'All'`

Element indices to show in the figure, specified as the comma-separated pair consisting of `'ShowIndex'` and a vector of positive integers. Each number in the vector must be an integer between 1 and the number of elements. To show all of indices of the array, specify `'All'`. To suppress all indices, specify `'None'`.

Example: `[1,2,3]`

Data Types: `double`

### `ShowNormals` — Option to show normal vectors

`false` (default) | `true`

Option to show normal directions, specified as the comma-separated pair consisting of `'ShowNormals'` and a Boolean value.

- `true` — show the normal directions of all elements in the array
- `false` — plot the elements without showing normal directions

Example: `false`

Data Types: `logical`

### `ShowTaper` — Option to show taper magnitude

`false` (default) | `true`

Option to show taper magnitude, specified as the comma-separated pair consisting of `'ShowTaper'` and a Boolean value.

- `true` — change the element color brightness in proportion to the element taper magnitude
- `false` — plot all elements using the same color

Example: `true`

Data Types: `logical`

### `Title` — Plot title

`'Array Geometry'` (default) | character vector

Plot title, specified as a character vector.

Example: `'My array plot'`

## Output Arguments

**`hPlot` — Handle of array elements**
scalar

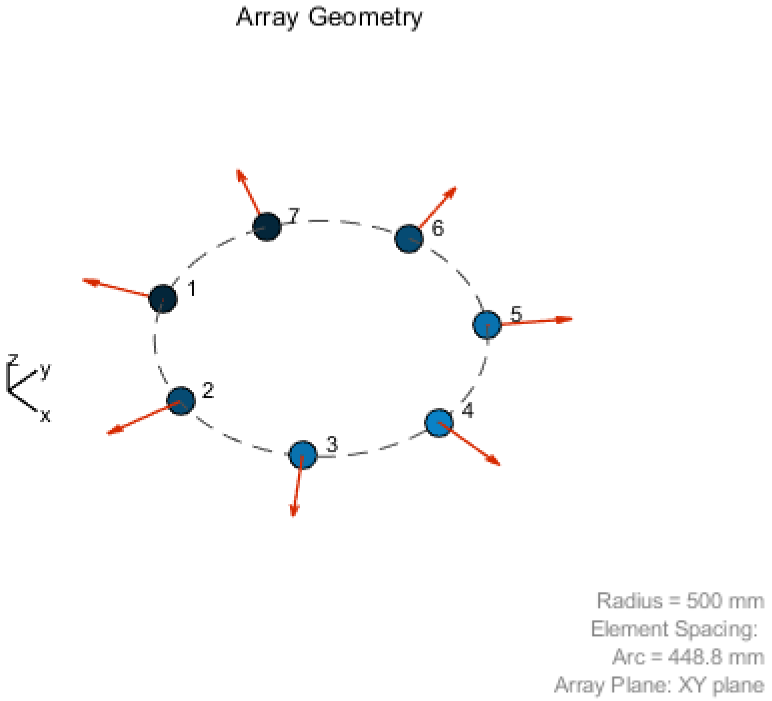
Handle of array elements in the figure window, specified as a scalar.

## Examples

### View UCA Array

Construct an 7-element UCA of isotropic antenna elements with a Taylor window taper. Design the array to have a radius of 0.5 meters. Then, draw the array showing the element normals, element indices, and element taper shading.

```
Nelem = 7;
R = 0.5;
taper = taylorwin(Nelem);
sArray = phased.UCA(Nelem,R,'Taper',taper.');
w = getTaper(sArray);
viewArray(sArray,'ShowNormals',true,'ShowIndex','All','ShowTaper',true);
```



## See Also

`phased.ArrayResponse`

Phased Array Gallery

**Introduced in R2015a**

# phased.ULA

**Package:** `phased`

Uniform linear array

## Description

The `phased.ULA` System object creates a uniform linear array (ULA).

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform linear array. See “Construction” on page 1-2435.
2. Call `step` to compute the response according to the properties of `phased.ULA`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ULA` creates a uniform linear array (ULA) System object, `H`. The object models a ULA formed with identical sensor elements. The origin of the local coordinate system is the phase center of the array. The positive *x*-axis is the direction normal to the array, and the elements of the array are located along the *y*-axis.

`H = phased.ULA(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = phased.ULA(N,D,Name,Value)` creates a ULA object, `H`, with the `NumElements` property set to `N`, the `ElementSpacing` property set to `D`, and other specified property Names set to the specified Values. `N` and `D` are value-only arguments. When specifying a value-only argument, specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

### `Element`

Element of array

Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

**Default:** Isotropic antenna element with default array properties

### `NumElements`

Number of elements

An integer containing the number of elements in the array.

**Default:** `2`

### `ElementSpacing`

Element spacing

A scalar containing the spacing (in meters) between two adjacent elements in the array.

**Default:** `0.5`

### `ArrayAxis`

Array axis

Array axis, specified as one of `'x'`, `'y'`, or `'z'`. ULA array elements are located along the selected coordinate system axis.

Element normal vectors are determined by the selected array axis

| ArrayAxis Property Value | Element Normal Direction |
|---|---|
| `'x'` | azimuth = 90°, elevation = 0° (*y*-axis) |
| `'y'` | azimuth = 0°, elevation = 0° (*x*-axis) |
| `'z'` | azimuth = 0°, elevation = 0° (*x*-axis) |

**Default:** `'y'`

### `Taper`

Element tapering

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. In this vector, *N* represents the number of elements of the array. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all elements. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

**Default:** `1`

## Methods

| | |
|---|---|
| directivity | Directivity of uniform linear array |
| collectPlaneWave | Simulate received plane waves |
| getElementPosition | Positions of array elements |
| getElementNormal | Normal vector to array elements |
| getNumElements | Number of elements in array |
| getTaper | Array element tapers |
| isPolarizationCapable | Polarization capability |
| plotResponse | Plot response pattern of array |
| pattern | Plot array pattern |
| patternAzimuth | Plot ULA array directivity or pattern versus azimuth |
| patternElevation | Plot ULA array directivity or pattern versus elevation |
| plotGratingLobeDiagram | Plot grating lobe diagram of array |
| step | Output responses of array elements |
| viewArray | View array geometry |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

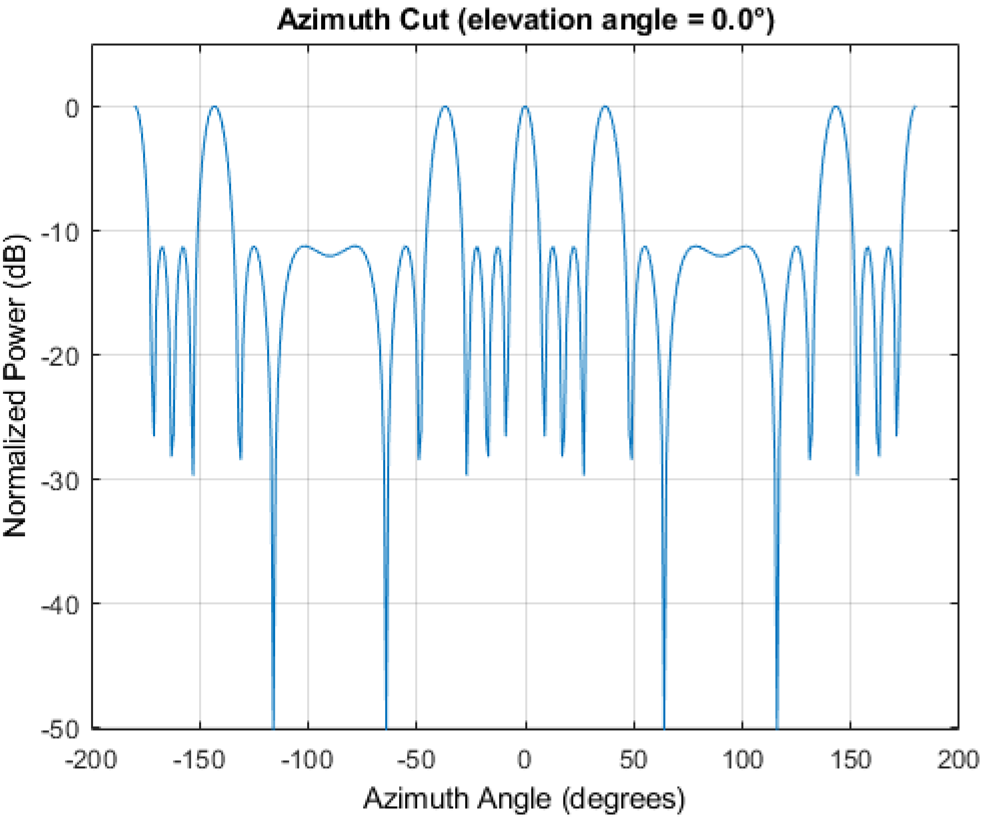
### Plot Pattern of 4-Element Antenna Array

Create a 4-element undersampled ULA and find the response of each element at boresight. Plot the array pattern at 1 GHz for azimuth angles between -180 and 180 degrees. The default element spacing is 0.5 meters.

```
array = phased.ULA('NumElements',4);
fc = 1e9;
ang = [0;0];
resp = array(fc,ang)
resp = 4×1

     1
     1
     1
     1
```

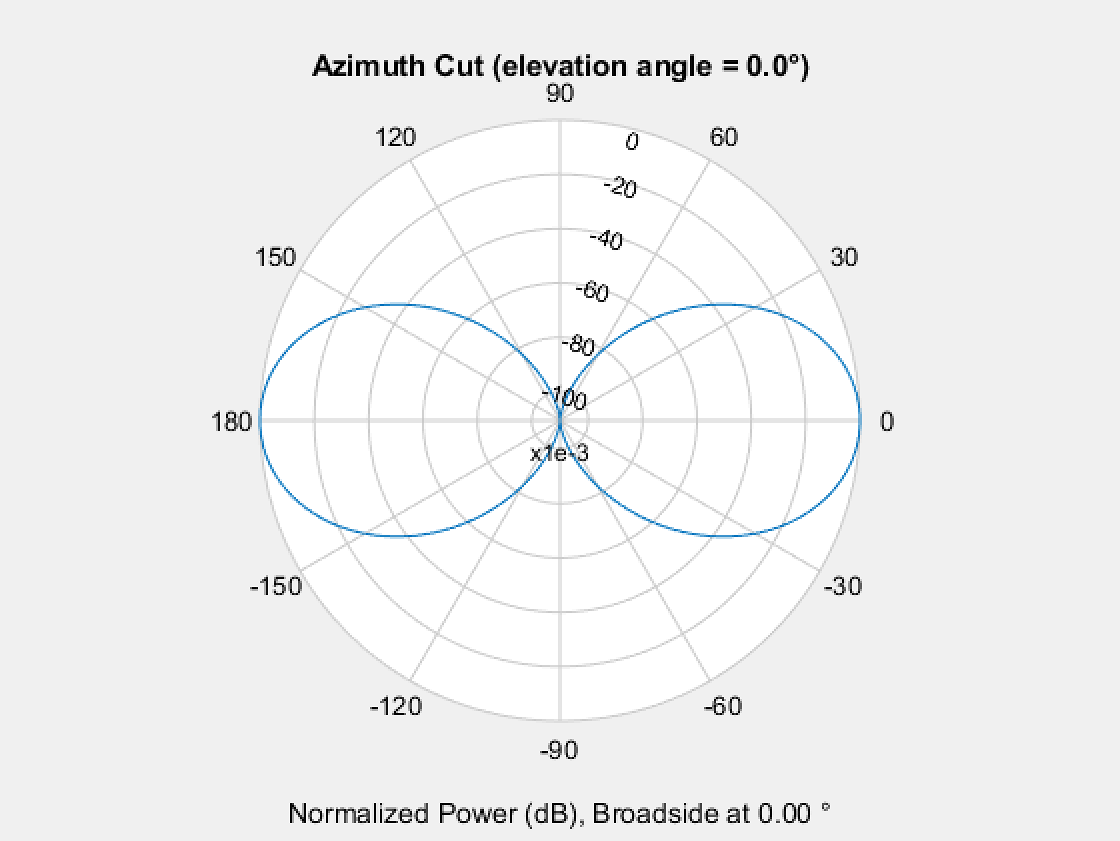
```
c = physconst('LightSpeed');
pattern(array,fc,-180:180,0,'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','powerdb','Normalize',true)
```



### Plot Pattern of 10-Element Microphone ULA

Construct a 10-element uniform linear array of omnidirectional microphones spaced 3 cm apart. Then, plot the array pattern at 100 Hz.

```
mic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
Nele = 10;
array = phased.ULA('NumElements',Nele,...
    'ElementSpacing',3e-2,...
    'Element',mic);
fc = 100;
ang = [0; 0];
resp = array(fc,ang);
c = 340;
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Normalize',true);
```



### Plot Pattern of Array of Polarized Short-Dipole Antennas

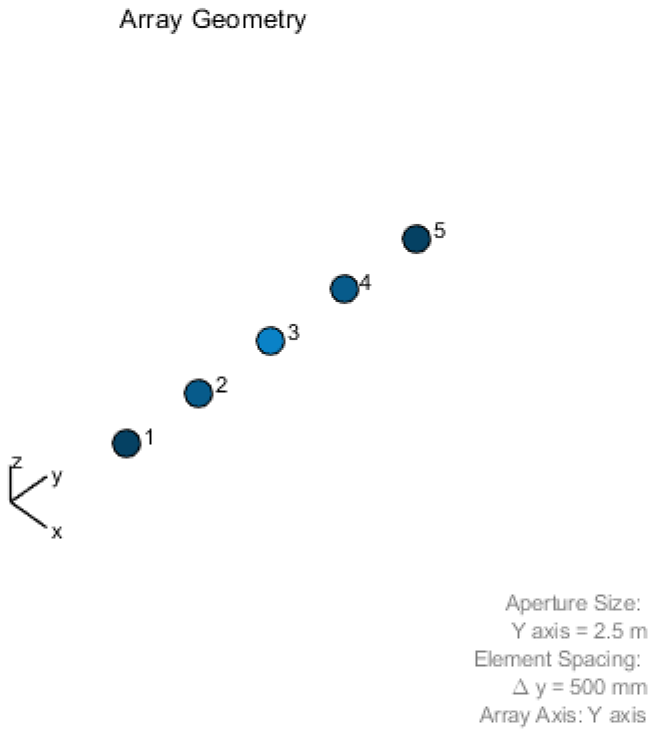
Build a tapered uniform line array of 5 short-dipole sensor elements. Because short dipoles support polarization, the array should as well. Verify that it supports polarization by looking at the output of the `isPolarizationCapable` method.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],'AxisDirection','Z');
array = phased.ULA('NumElements',5,'Element',antenna,...
    'Taper',[.5,.7,1,.7,.5]);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

Then, draw the array using the `viewArray` method.

```
viewArray(array,'ShowTaper',true,'ShowIndex','All')
```



Compute the horizontal and vertical responses.

```
fc = 150e6;
ang = [10];
resp = array(fc,ang);
```

Display the horizontal polarization response.

```
resp.H
```

```
ans = 5×1

     0
     0
     0
     0
     0
```

Display the vertical polarization response.

```
resp.V
```

```
ans = 5×1

   -0.6124
   -0.8573
   -1.2247
   -0.8573
   -0.6124
```

Plot an azimuth cut of the vertical polarization response.

```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Polarization','V',...
    'Type','powerdb',...
    'Normalize',true)
```

Directivity of uniform linear array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity (dBi)" on page 1-2451 of a uniform linear array (ULA) of antenna or microphone elements, `H`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### H — Uniform linear array

System object

Uniform linear array specified as a `phased.ULA` System object.

Example: `H = phased.ULA;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

### ANGLE — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**D — Directivity**
*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Uniform Linear Array

Compute the directivities of two different uniform linear arrays (ULA). One array consists of isotropic antenna elements and the second array consists of cosine antenna elements. In addition, compute the directivity when the first array is steered in a specified direction. For each case, calculated the directivities for a set of seven different azimuth directions all at zero degrees elevation. Set the frequency to 800 MHz.

**Array of isotropic antenna elements**

First, create a 10-element ULA of isotropic antenna elements spaced 1/2-wavelength apart.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
myAnt1 = phased.IsotropicAntennaElement;
myArray1 = phased.ULA(10,lambda/2,'Element',myAnt1);
```

Compute the directivity

```
d = directivity(myArray1,fc,ang,'PropagationSpeed',c)
```

```
d = 7×1

   -6.9886
   -6.2283
   -6.5176
   10.0011
   -6.5176
   -6.2283
   -6.9886
```

### Array of cosine antenna elements

Next, create a 10-element ULA of cosine antenna elements spaced 1/2-wavelength apart.

```
myAnt2 = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
myArray2 = phased.ULA(10,lambda/2,'Element',myAnt2);
```

Compute the directivity

```
d = directivity(myArray2,fc,ang,'PropagationSpeed',c)
```

```
d = 7×1

   -1.9838
    0.0529
    0.4968
   17.2548
    0.4968
    0.0529
   -1.9838
```

The directivity of the cosine ULA is greater than the directivity of the isotropic ULA because of the larger directivity of the cosine antenna element.

### Steered array of isotropic antenna elements

Finally, steer the isotropic antenna array to 30 degrees in azimuth and compute the directivity.

```
w = steervec(getElementPosition(myArray1)/lambda,[30;0]);
d = directivity(myArray1,fc,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d = 7×1

 -297.2705
  -13.9783
```

```
   -9.5713
   -6.9897
   -4.5787
   -2.0536
   10.0000
```

The directivity is greatest in the steered direction.

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1°

apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# collectPlaneWave

**System object:** `phased.ULA`
**Package:** `phased`

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

### ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

### FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

### C

Propagation speed of signal in meters per second.

**Default:** Speed of light

## Output Arguments

### Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

## Examples

### Simulate Received Signals at ULA

Simulate two received random signals at a 4-element ULA. The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
array = phased.ULA(4);
y = collectPlaneWave(array,randn(4,2),[10 30],100e6,physconst('LightSpeed'))
```

```
y = 4×4 complex

   0.7430 - 0.3705i   0.8433 - 0.1314i   0.8433 + 0.1314i   0.7430 + 0.3705i
   0.8418 + 0.4308i   0.5632 + 0.1721i   0.5632 - 0.1721i   0.8418 - 0.4308i
  -2.4817 + 0.9157i  -2.6683 + 0.3175i  -2.6683 - 0.3175i  -2.4817 - 0.9157i
   1.0724 - 0.4748i   1.1895 - 0.1671i   1.1895 + 0.1671i   1.0724 + 0.4748i
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

# getElementPosition

**System object:** phased.ULA
**Package:** phased

Positions of array elements

## Syntax

```
pos = getElementPosition(sULA)
pos = getElementPosition(sULA,elemidx)
```

## Description

pos = getElementPosition(sULA) returns the element positions of the phased.ULA System object, sULA. pos is a 3-by-*N* matrix, where *N* is the number of elements in sULA. Each column of pos defines the position of an element in the local coordinate system taking the form[x;y;z]. Units are meters. The origin of the local coordinate system is the phase center of the array.

pos = getElementPosition(sULA,elemidx) returns only the positions of the elements that are specified in the element index vector elemidx. This syntax can use any of the input arguments in the previous syntax.

## Examples

### ULA Element Positions

Construct a ULA with 5 elements along the z-axis. Obtain the element positions.

```
sULA = phased.ULA('NumElements',5,'ArrayAxis','z');
pos = getElementPosition(sULA)
```

```
pos = 3×5
```

```
         0         0         0         0         0
         0         0         0         0         0
   -1.0000   -0.5000         0    0.5000    1.0000
```

# getElementNormal

**System object:** `phased.ULA`
**Package:** `phased`

Normal vector to array elements

## Syntax

```
normvec = getElementNormal(sULA)
normvec = getElementNormal(sULA,elemidx)
```

## Description

`normvec = getElementNormal(sULA)` returns the normal vectors of the array elements of the `phased.ULA` System object, `sULA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sULA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form`[az;el]`. Units are degrees. Array elements are located along the axis selected in the `ArrayAxis` property. Element normal vectors are parallel to the array normal. The normal to a ULA array depends upon the selected `ArrayAxis` property.

| ArrayAxis Property Value | Array Normal Direction |
|---|---|
| `'x'` | azimuth = 90°, elevation = 0° (*y*-axis) |
| `'y'` | azimuth = 0°, elevation = 0° (*x*-axis) |
| `'z'` | azimuth = 0°, elevation = 0° (*x*-axis) |

The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sULA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Input Arguments

**sULA — Uniform line array**
phased.ULA System object

Uniform line array, specified as a phased.ULA System object.

Example: sULA = phased.ULA

**elemidx — Element indices**
all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When elemidx is specified, getElementNormal returns the normal vectors of the elements contained in elemidx.

Example: [1,5,4]

## Output Arguments

**normvec — Element normal vectors**
2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of normvec takes the form [az,el]. When elemidx is not specified, *P* equals the array dimension. When elemidx is specified, *P* equals the length of elemidx, *M*.

## Examples

### ULA Element Normals

Construct three ULA's with elements along the *x*-, *y*-, and *z*-axes. Obtain the element normals.

First, choose the array axis along the *x*-axis.

```
sULA1 = phased.ULA('NumElements',5,'ArrayAxis','x');
norm = getElementNormal(sULA1)
norm = 2×5

    90    90    90    90    90
     0     0     0     0     0
```

The element normal vectors point along the *y*-axis.

Next, choose the array axis along the *y*-axis.

```
sULA2 = phased.ULA('NumElements',5,'ArrayAxis','y');
norm = getElementNormal(sULA2)
```

```
norm = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

The element normal vectors point along the *x*-axis.

Finally, set the array axis along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sULA3 = phased.ULA('NumElements',5,'ArrayAxis','z');
norm = getElementNormal(sULA3,[1,3,5])
```

```
norm = 2×3

     0     0     0
     0     0     0
```

The element normal vectors also point along the *x*-axis.

**Introduced in R2016a**

# getNumElements

**System object:** `phased.ULA`
**Package:** `phased`

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

`N = getNumElements(H)` returns the number of elements, N, in the ULA object `H`.

## Examples

### Get Number of ULA Elements

Construct a default ULA and obtain the number of elements in that array.

```
array = phased.ULA;
N = getNumElements(array)
```

```
N = 2
```

# getTaper

**System object:** phased.ULA
**Package:** phased

Array element tapers

## Syntax

```
wts = getTaper(h)
```

## Description

`wts = getTaper(h)` returns the tapers, `wts`, applied to each element of the phased uniform line array (ULA), `h`. Tapers are often referred to as weights.

## Input Arguments

### h — Uniform line array

`phased.ULA` System object

Uniform line array specified as a `phased.ULA` System object.

## Output Arguments

### `wts` — Array element tapers

*N*-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1 complex-valued vector, where *N* is the number of elements in the array.

## Examples

### Construct ULA with Taylor Window

Construct a 5-element ULA with a Taylor window taper. Then, obtain the element taper values.

```
taper = taylorwin(5)';
array = phased.ULA(5,'Taper',taper);
w = getTaper(array)
```

```
w = 5×1

# isPolarizationCapable

**System object:** `phased.ULA`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

### h — Uniform line array

Uniform line array specified as a `phased.ULA` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

## Examples

### Short-Dipole Antenna ULA Supports Polarization

Show that an array of `phased.ShortDipoleAntennaElement` antenna elements supports polarization.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[1e9 10e9]);
array = phased.ULA('NumElements',3,'Element',antenna);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

The returned value of `1` shows that this array supports polarization.

# plotResponse

**System object:** `phased.ULA`
**Package:** `phased`

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Array object

**`FREQ`**

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no

response at frequencies outside that range. If you set the 'RespCut' property of H to '3D', FREQ must be a scalar. When FREQ is a row vector, plotResponse draws multiple frequency responses on the same axes.

**V**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CutAngle**

Cut angle as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

**Default:** 0

**Format**

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

**Default:** 'Line'

**NormalizeResponse**

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** true

### OverlayFreq

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, FREQ must be a vector with at least two entries.

This parameter applies only when Format is not 'Polar' and RespCut is not '3D'.

**Default:** true

### Polarization

Specify the polarization options for plotting the array response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimensions | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

### `ElevationAngles`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

**Default:** `[-90:90]`

### `UGrid`

*U* coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

### `VGrid`

*V* coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

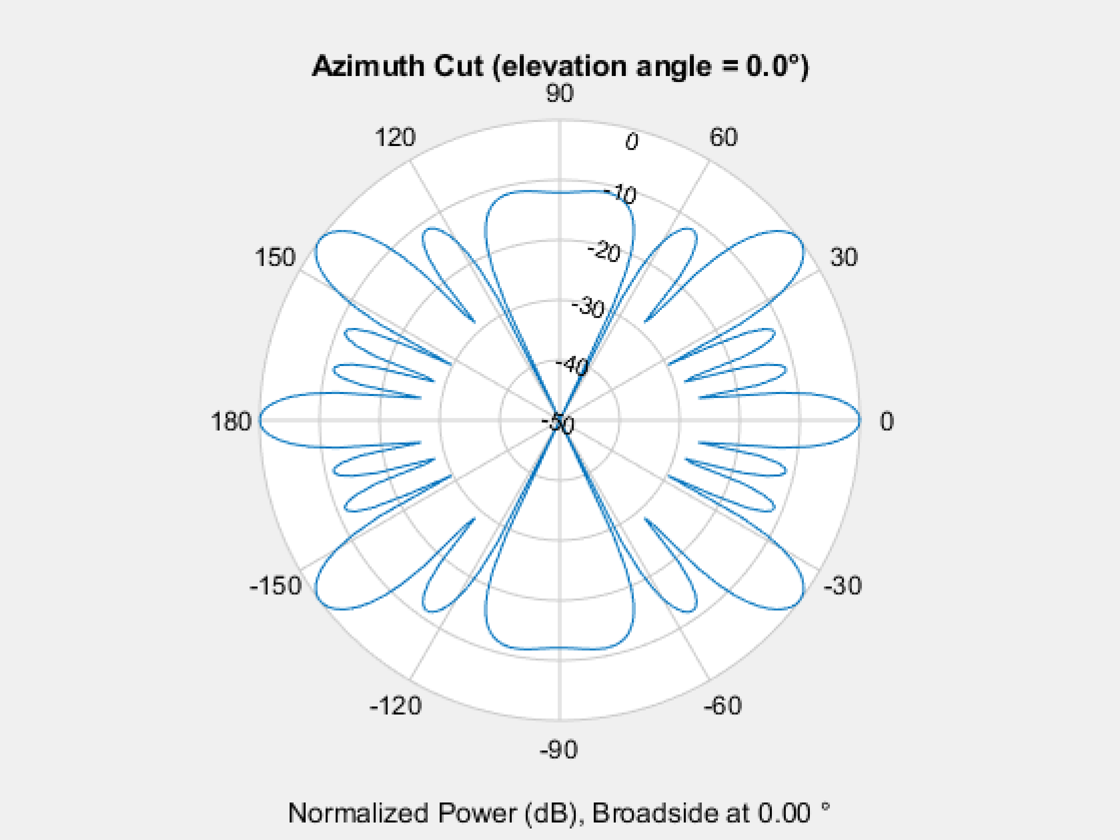
**Default:** `[-1:0.01:1]`

## Examples

### Plot Azimuth Response of 4-Element ULA

Construct a 4-element ULA of isotropic elements (the default) and plot its azimuth response in polar form. By default, the azimuth cut is at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light. The nominal element spacing is 1/2 meter which means that the array is undersampled at this frequency.

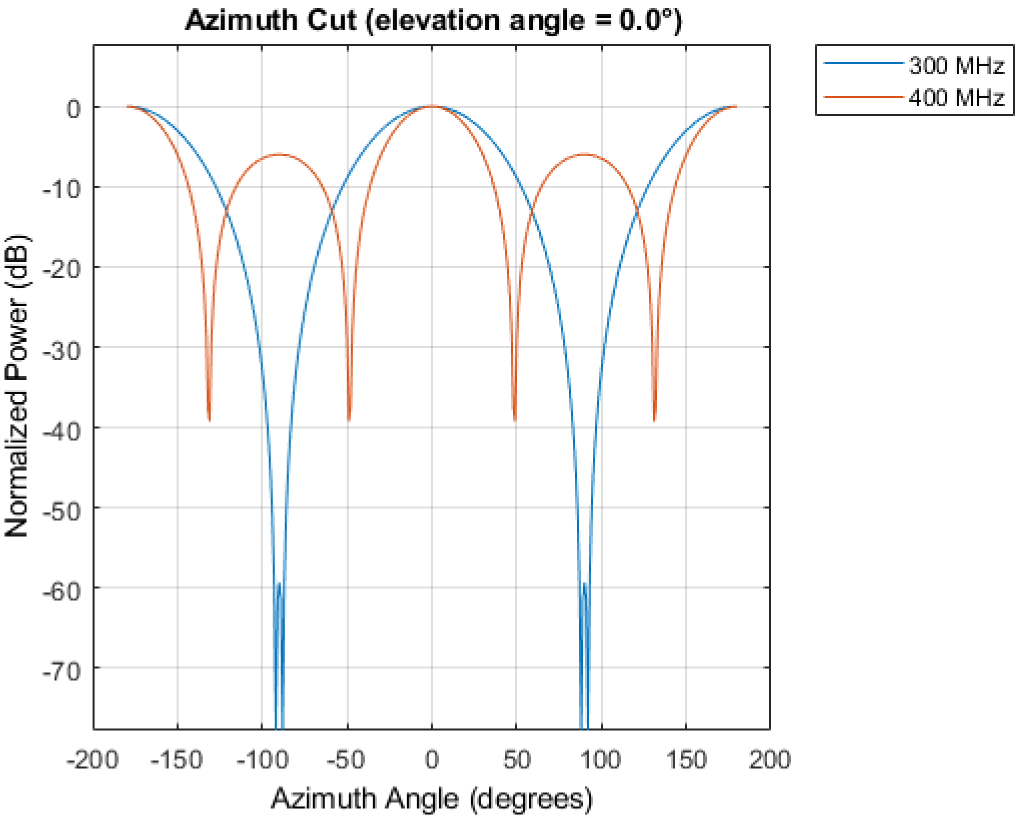
```
ha = phased.ULA(4);
fc = 1e9;
c = physconst('LightSpeed');
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar');
```



### Plot Response of ULA at Two Frequencies

This example shows how to plot an azimuth cut of the response of a uniform linear array at 0 degrees elevation using a line plot. The plot shows the responses at operating frequencies of 300 MHz and 400 MHz.

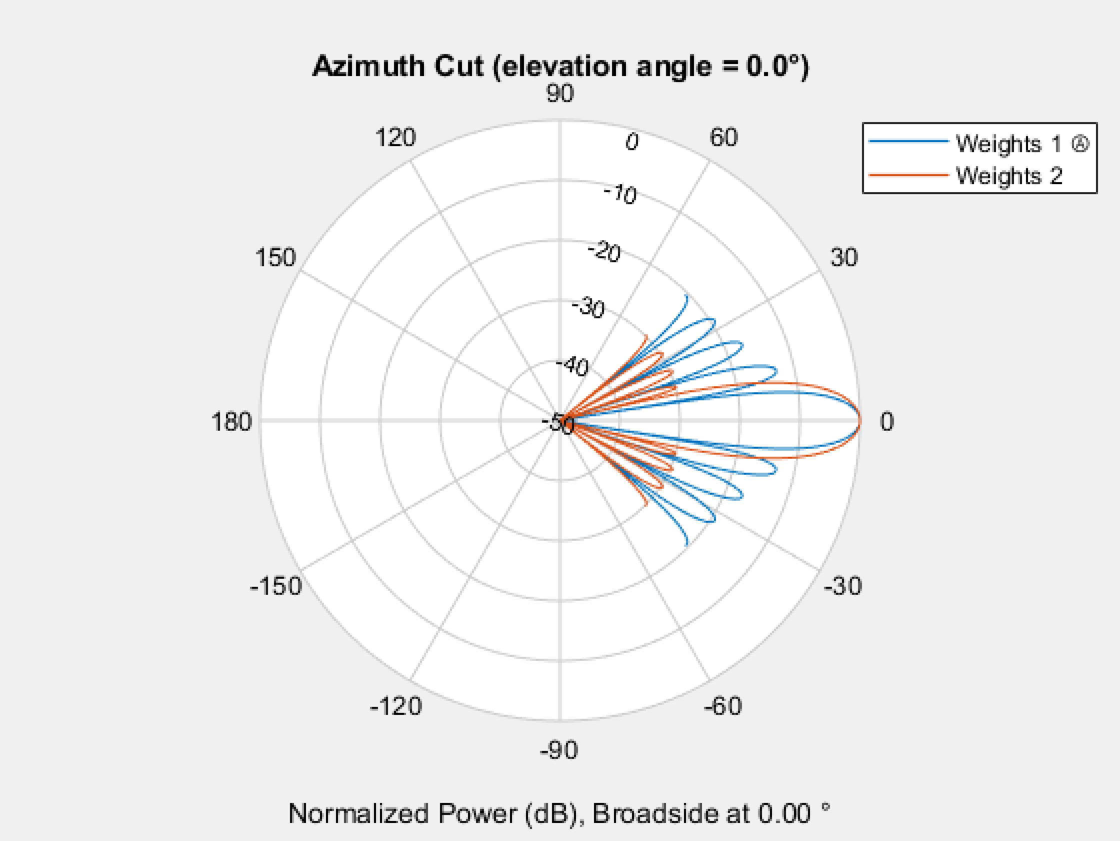
```
h = phased.ULA;
fc = [3e8 4e8];
c = physconst('LightSpeed');
plotResponse(h,fc,c);
```



### Plot Azimuth Response of Tapered 11-Element ULA

This example shows how to construct an 11-element ULA array of backbaffled omnidirectional microphones for beamforming the direction of arrival of sound in air. The elements are spaced four centimeters apart and have a frequency response lying in the 2000-8000 Hz frequency range. Use the `plotResponse` method to display an azimuth cut of the array's response at 5000 Hz. Use the `'Weights'` parameter to apply both uniform tapering and Taylor window tapering to the array at the same frequency. Finally, use the `'AzimuthAngles'` parameter to limit the display from -45 to 45 degrees in 0.1 degree increments. A typical value for the speed of sound in air is 343 meters/second.

```
s_omni = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[2000,8000],...
    'BackBaffled',true);
s_ula = phased.ULA(11,'Element',s_omni,...
    'ElementSpacing',0.04);
c = 343.0;
fc = 5000;
wts = taylorwin(11);
plotResponse(s_ula,fc,c,'RespCut','Az',...
    'Format','Polar',...
    'Weights',[ones(11,1),wts],...
    'AzimuthAngles',[-45:.1:45]);
```



The plot shows that the Taylor tapered set of weights reduces the adjacent sidelobes while broadening the main lobe compared to a uniformly tapered array.

### Plot Directivity of 11-Element ULA of Cosine Pattern Antennas

This example shows how to construct an 11-element ULA of cosine antenna elements that are spaced one-half wavelength apart. Then, using the `plotResponse` method, plot an azimuth cut of the array's directivity by setting the `'Unit'` parameter to `'dbi'`. Assume the operating frequency is 1.5 GHz and the wave propagation speed is the speed of light.

```
fc = 1.5e9;
c = physconst('Lightspeed');
lambda = c/fc;
sCos = phased.CosineAntennaElement('FrequencyRange',...
    [1e9 2e9],'CosinePower',[2.5,3.5]);
sULA = phased.ULA(11,0.5*lambda,'Element',sCos);
plotResponse(sULA,fc,c,'RespCut','Az','Unit','dbi');
```

# pattern

**System object:** phased.ULA
**Package:** phased

Plot array pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern(___,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern(___)
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern(___,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern(___)` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-2486 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sArray` — Uniform linear array

System object

Uniform linear array, specified as a `phased.ULA` System object.

Example: `sArray= phased.ULA;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

**EL — Elevation angles**
`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`CoordinateSystem` — Plotting coordinate system**
`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### PAT — Array pattern

*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

### AZ_ANG — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

### EL_ANG — Elevation angles

scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Plot Pattern of 9-Element ULA Antenna Array of Short Dipoles

Create an 9-element ULA of short dipole antenna elements spaced 0.2 meters apart. Display the azimuth and elevation directivities. The operating frequency is 500 MHz. Plot the directivities in polar coordinates.

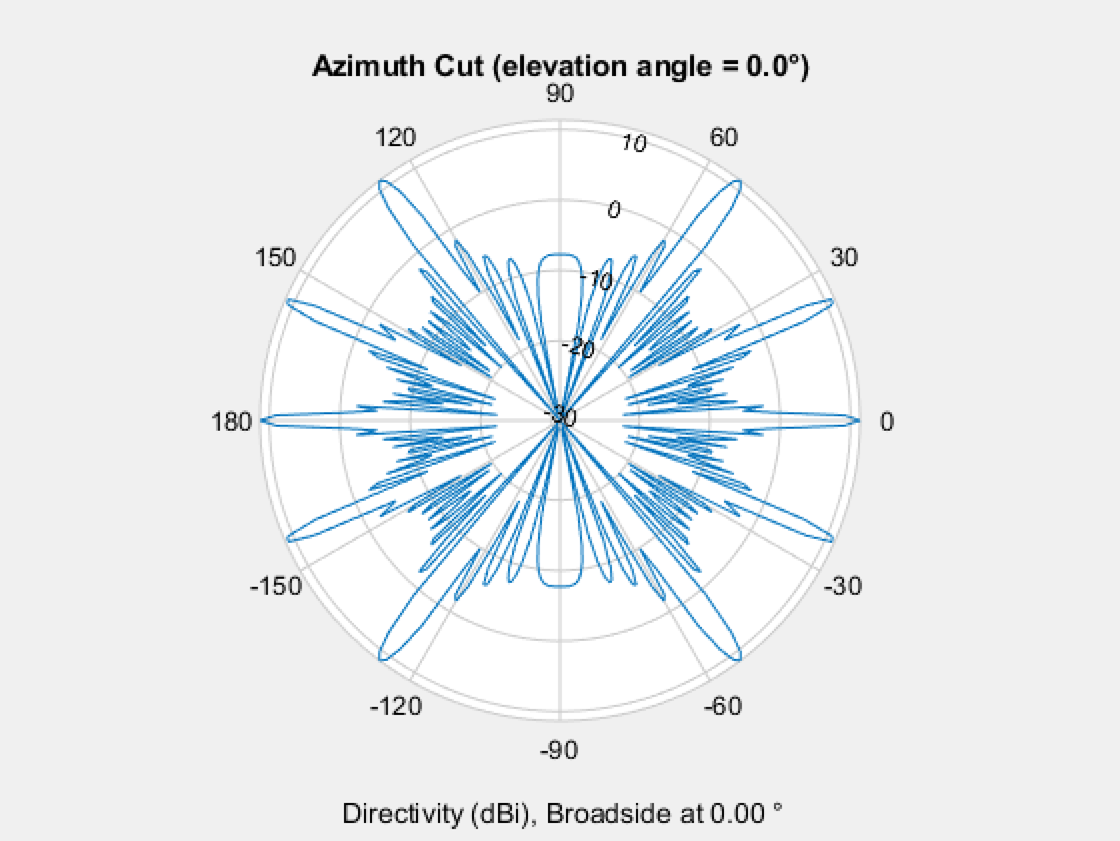
Evaluate the fields at 45 degrees azimuth and 0 degrees elevation.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
sULA = phased.ULA('NumElements',9,'ElementSpacing',1.5,'Element',sSD);
fc = 500e6;
ang = [45;0];
resp = step(sULA,fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

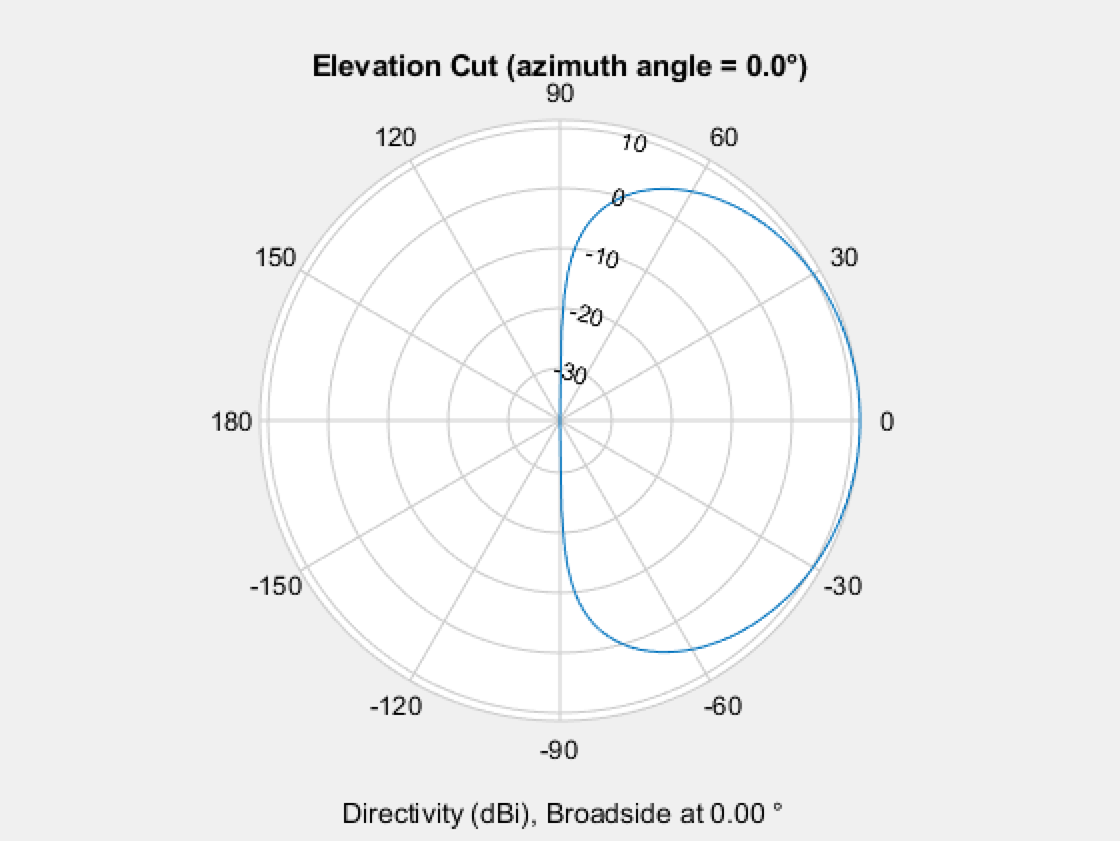
Display the azimuth directivity pattern at 500 MHz for azimuth angles between -180 and 180 degrees.

```
c = physconst('LightSpeed');
pattern(sULA,fc,[-180:180],0,...
    'Type','directivity',...
    'PropagationSpeed',c)
```



Display the elevation directivity pattern at 500 MHz for elevation angles between -90 and 90 degrees.

```
pattern(sULA,fc,[0],[-90:90],...
    'Type','directivity',...
    'PropagationSpeed',c)
```

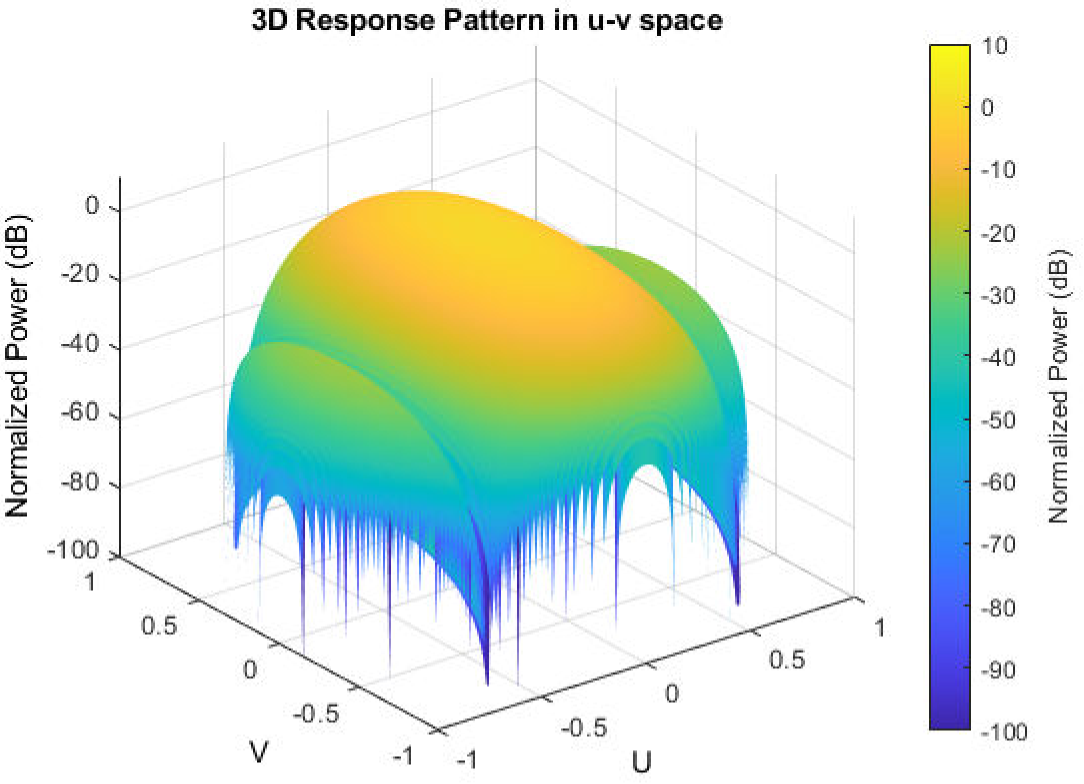


### Plot Pattern of 10-Element ULA Antenna Array in UV Space

Create a 10-element ULA antenna array consisting of cosine antenna elements spaced 10 cm apart. Display the 3-D power pattern in UV space. The operating frequency is 500 MHz.

```
sCos = phased.CosineAntennaElement('FrequencyRange',[100e6 1e9],...
    'CosinePower',[2.5,2.5]);
sULA = phased.ULA('NumElements',10,...
    'ElementSpacing',.1,...
    'Element',sCos);
```

```
c = physconst('LightSpeed');
fc = 500e6;
pattern(sULA,fc,[-1:.01:1],[-1:.01:1],...
    'CoordinateSystem','uv',...
    'Type','powerdb',...
    'PropagationSpeed',c)
```



# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These are the `azimuthPattern` and `elevationPattern` methods.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. You should notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and vice versa. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or <i>UV</i> space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.<br>Set the display axis using either the 'AzimuthAngles' or 'ElevationAngles' name-value pairs.</td></tr>

**Introduced in R2015a**

# patternAzimuth

**System object:** `phased.ULA`
**Package:** `phased`

Plot ULA array directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

### sArray — Uniform linear array

System object

Uniform linear array, specified as a `phased.ULA` System object.

Example: `sArray= phased.ULA;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

#### `Azimuth` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

#### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

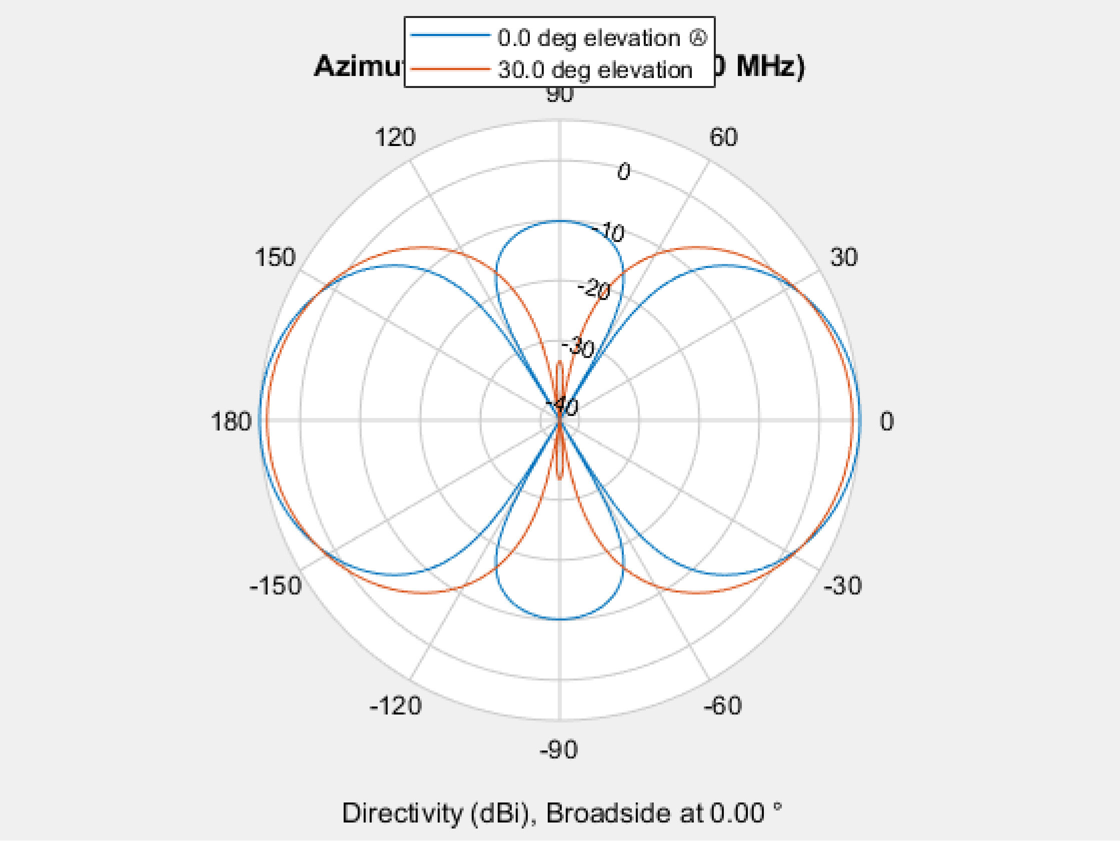
Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Plot Azimuth Pattern of ULA

Create a 7-element ULA of short-dipole antenna elements spaced 10 cm apart. Plot an azimuth cut of directivity at 0 and 10 degrees elevation. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCDant = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sULA = phased.ULA('NumElements',7,'ElementSpacing',0.1,'Element',sCDant);
patternAzimuth(sULA,fc,[0 30])
```



You can plot a smaller range of azimuth angles by setting the `Azimuth` property.

```
patternAzimuth(sULA,fc,[0 30],'Azimuth',[-90:90])
```

Plot ULA array directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

**`sArray` — Uniform linear array**
System object

Uniform linear array, specified as a `phased.ULA` System object.

Example: `sArray= phased.ULA;`

### `FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

### `AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Type — Displayed pattern type**
`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

**`PropagationSpeed` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**`Weights` — Array weights**
*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

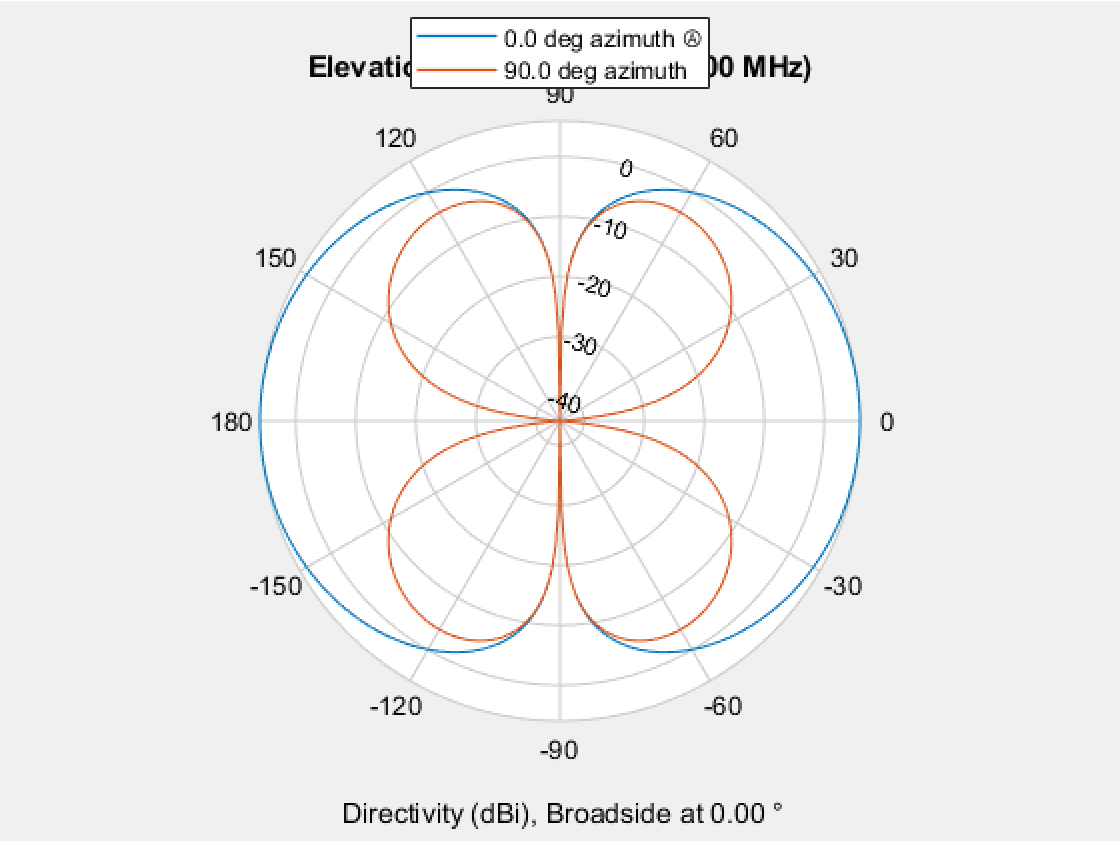
Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Plot Elevation Pattern of ULA

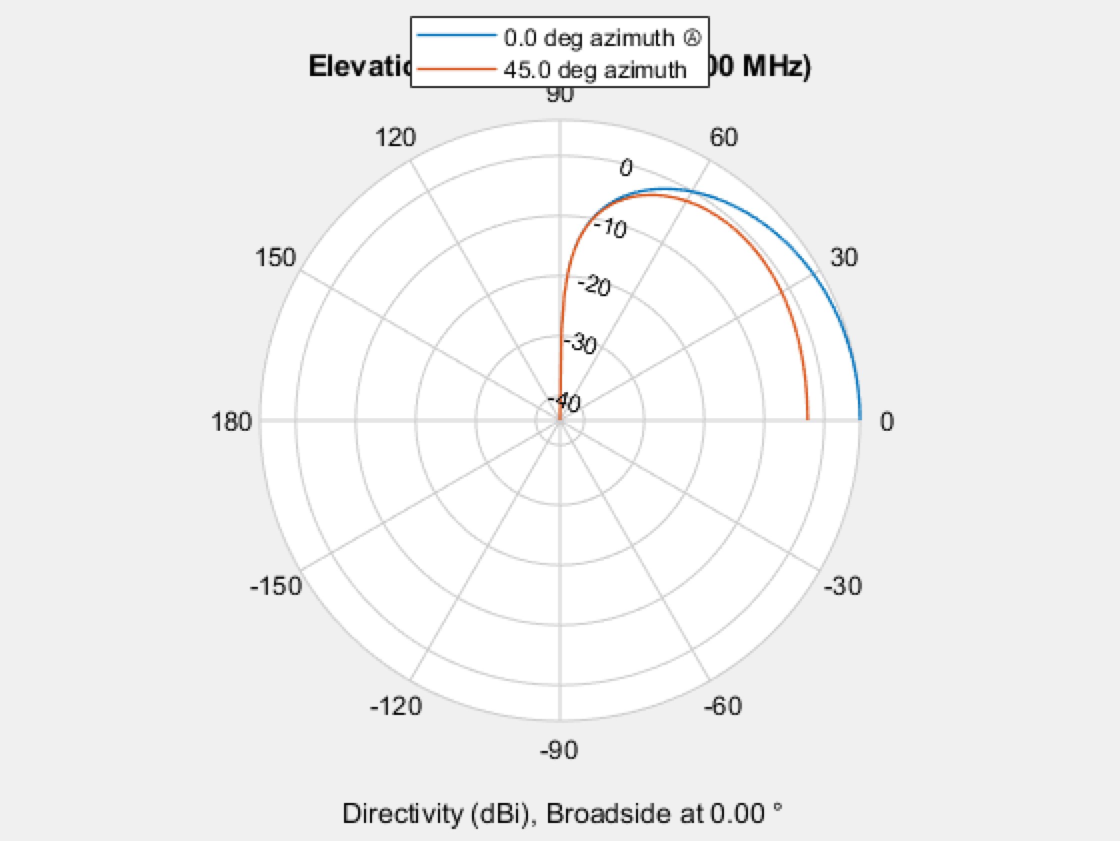
Create a 6-element ULA of short-dipole antenna elements with element spacing of 10 cm. Plot an elevation cut of directivity at 0 and 90 degrees azimuth. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
c = physconst('LightSpeed');
sSD = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sULA = phased.ULA('NumElements',6,'ElementSpacing',0.1,'Element',sSD);
patternElevation(sULA,fc,[0 90],'PropagationSpeed',c)
```



You can plot a smaller range of elevation angles by setting the `Elevation` property.

```
patternElevation(sULA,fc,[0 45],'Elevation',[0:90],'PropagationSpeed',c)
```



# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2015a**

# plotGratingLobeDiagram

**System object:** `phased.ULA`
**Package:** `phased`

Plot grating lobe diagram of array

## Syntax

```
plotGratingLobeDiagram(H,FREQ)
plotGratingLobeDiagram(H,FREQ,ANGLE)
plotGratingLobeDiagram(H,FREQ,ANGLE,C)
plotGratingLobeDiagram(H,FREQ,ANGLE,C,F0)
hPlot = plotGratingLobeDiagram( ___ )
```

## Description

`plotGratingLobeDiagram(H,FREQ)` plots the grating lobe diagram of an array in the *u-v* coordinate system. The System object `H` specifies the array. The argument `FREQ` specifies the signal frequency and phase-shifter frequency. The array, by default, is steered to 0° azimuth and 0° elevation.

A grating lobe diagram displays the positions of the peaks of the narrowband array pattern. The array pattern depends only upon the geometry of the array and not upon the types of elements which make up the array. Visible and nonvisible grating lobes are displayed as open circles. Only grating lobe peaks near the location of the mainlobe are shown. The mainlobe itself is displayed as a filled circle.

`plotGratingLobeDiagram(H,FREQ,ANGLE)`, in addition, specifies the array steering angle, `ANGLE`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C)`, in addition, specifies the propagation speed by `C`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C,F0)`, in addition, specifies an array phase-shifter frequency, `F0`, that differs from the signal frequency, `FREQ`. This argument is useful when the signal no longer satisfies the narrowband assumption and, allows you to estimate the size of beam squint.

`hPlot = plotGratingLobeDiagram( ___ )` returns the handle to the plot for any of the input syntax forms.

## Input Arguments

**`H`**

Antenna or microphone array, specified as a System object.

**`FREQ`**

Signal frequency, specified as a scalar. Frequency units are hertz. Values must lie within a range specified by the frequency property of the array elements contained in `H.Element`. The frequency property is named `FrequencyRange` or `FrequencyVector`, depending on the element type.

**`ANGLE`**

Array steering angle, specified as either a 2-by-1 vector or a scalar. If `ANGLE` is a vector, it takes the form `[azimuth;elevation]`. The azimuth angle must lie in the range `[-180°,180°]`. The elevation angle must lie in the range `[-90°,90°]`. All angle values are specified in degrees. If the argument `ANGLE` is a scalar, it specifies only the azimuth angle where the corresponding elevation angle is `0°`.

**Default:** `[0;0]`

**`C`**

Signal propagation speed, specified as a scalar. Units are meters per second.

**Default:** Speed of light in vacuum

**`F0`**

Phase-shifter frequency of the array, specified as a scalar. Frequency units are hertz When this argument is omitted, the phase-shifter frequency is assumed to be the signal frequency, `FREQ`.

**Default:** `FREQ`

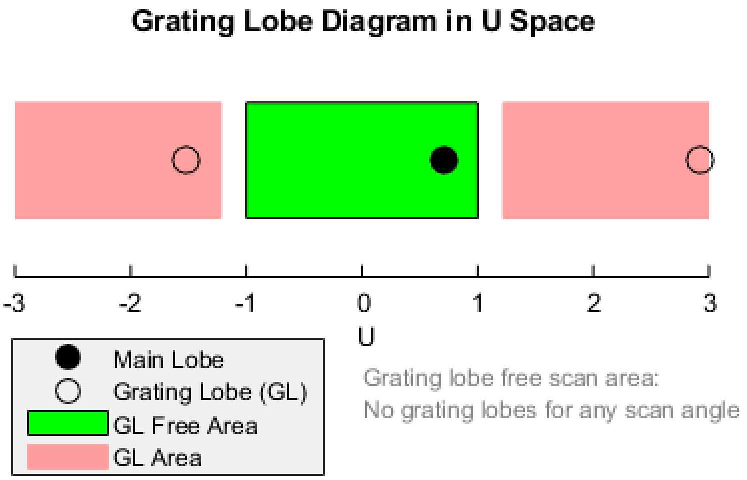
## Examples

### Create Grating Lobe Diagram for ULA

Plot the grating lobe diagram for a 4-element uniform linear array having element spacing less than one-half wavelength. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 3 GHz and the spacing between elements is 0.45 of the wavelength. All elements are isotropic antenna elements. Steer the array in the direction 45 degrees in azimuth and 0 degrees in elevation.

```
c = physconst('LightSpeed');
f = 3e9;
lambda = c/f;
sIso = phased.IsotropicAntennaElement;
sULA = phased.ULA('Element',sIso,'NumElements',4,...
    'ElementSpacing',0.45*lambda);
plotGratingLobeDiagram(sULA,f,[45;0],c);
```



The main lobe of the array is indicated by a filled black circle. The grating lobes in the visible and nonvisible regions are indicated by empty black circles. The visible region is defined by the direction cosine limits between [-1,1] and is marked by the two vertical black lines. Because the array spacing is less than one-half wavelength, there are no grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it coincides with the visible region.

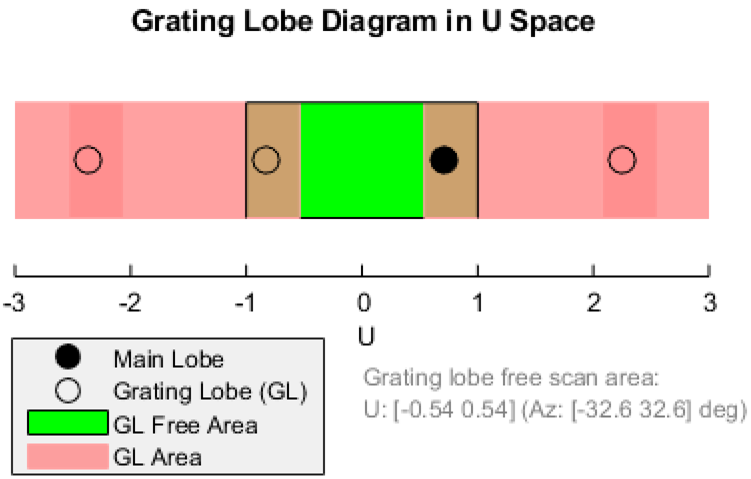
The white area of the diagram indicates a region where no grating lobes are possible.

### Create Grating Lobe Diagram for Undersampled ULA

Plot the grating lobe diagram for a 4-element uniform linear array having element spacing greater than one-half wavelength. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 3 GHz and the spacing between elements is 0.65 of a wavelength. All elements are isotropic antenna elements. Steer the array in the direction 45 degrees in azimuth and 0 degrees in elevation.

```
c = physconst('LightSpeed');
f = 3e9;
lambda = c/f;
sIso = phased.IsotropicAntennaElement;
sULA = phased.ULA('Element',sIso,'NumElements',4,'ElementSpacing',0.65*lambda);
plotGratingLobeDiagram(sULA,f,[45;0],c);
```



The main lobe of the array is indicated by a filled black circle. The grating lobes in the visible and nonvisible regions are indicated by empty black circles. The visible region, marked by the two black vertical lines, corresponds to arrival angles between -90 and 90 degrees. The visible region is defined by the direction cosine limits $-1 \leq u \leq 1$. Because the array spacing is greater than one-half wavelength, there is now a grating lobe in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those for which $-3 \leq u \leq 3$ are shown.

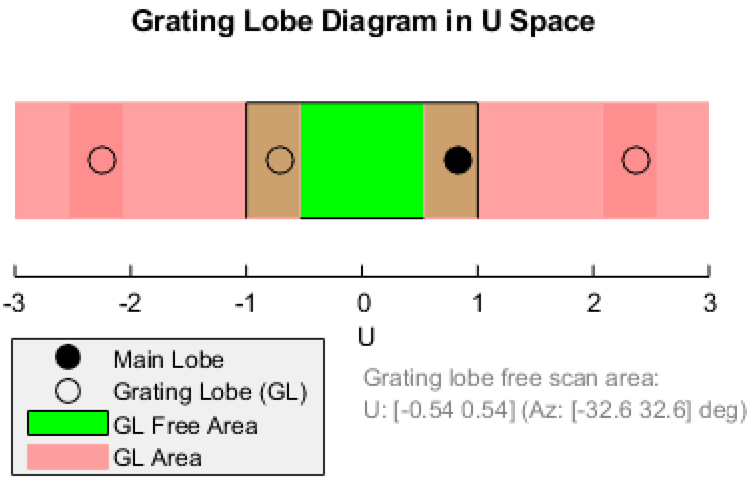
The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the visible region.

### Create Grating Lobe Diagram for ULA With Different Phase-Shifter Frequency

Plot the grating lobe diagram for a 4-element uniform linear array having element spacing greater than one-half wavelength. Apply a phase-shifter frequency that differs from the signal frequency. Grating lobes are plotted in u-v coordinates.

Assume the signal frequency is 3 GHz and the spacing between elements is 0.65 $\lambda$. All elements are isotropic antenna elements. The phase-shifter frequency is set to 3.5 GHz. Steer the array in the direction 45° azimuth, 0° elevation.

```
c = physconst('LightSpeed');
f = 3e9;
f0 = 3.5e9;
lambda = c/f;
sIso = phased.IsotropicAntennaElement;
sULA = phased.ULA('Element',sIso,'NumElements',4,...
    'ElementSpacing',0.65*lambda );
plotGratingLobeDiagram(sULA,f,[45;0],c,f0);
```



As a result of adding the shifted frequency, the mainlobe shifts right towards larger *u* values. The beam no longer points toward the actual source arrival angle.

The mainlobe of the array is indicated by a filled black circle. The grating lobes in the visible and nonvisible regions are indicated by empty black circles. The visible region, marked by the two black vertical lines, corresponds to arrival angles between -90° and 90°. The visible region is defined by the direction cosine limits $-1 \leq u \leq 1$. Because the array spacing is greater than one-half wavelength, there is now a grating lobe in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those for which $-3 \leq u \leq 3$ are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the visible region.

# Concepts

## Grating Lobes

Spatial undersampling of a wavefield by an array gives rise to visible grating lobes. If you think of the wavenumber, $k$, as analogous to angular frequency, then you must sample the signal at spatial intervals smaller than $\pi/k_{max}$ (or $\lambda_{min}/2$) in order to remove aliasing. The appearance of visible grating lobes is also known as spatial aliasing. The variable $k_{max}$ is the largest wavenumber value present in the signal.

The directions of maximum spatial response of a ULA are determined by the peaks of the array's array pattern (alternatively called the beam pattern or array factor). Peaks other than the mainlobe peak are called grating lobes. For a ULA, the array pattern depends only on the wavenumber component of the wavefield along the array axis (the $y$-direction for the `phased.ULA` System object). The wavenumber component is related to the look-direction of an arriving wavefield by $k_y = –2\pi \sin \varphi/\lambda$. The angle $\varphi$ is the broadside angle—the angle that the look-direction makes with a plane perpendicular to the array. The look-direction points away from the array to the wavefield source.

The array pattern possesses an infinite number of periodically-spaced peaks that are equal in strength to the mainlobe peak. If you steer the array to the $\varphi_0$ direction, the array pattern for a ULA has its mainlobe peak at the wavenumber value of $k_{y0} = –2\pi \sin \varphi_0/\lambda$. The array pattern has strong grating lobe peaks at $k_{ym} = k_{y0} + 2\pi m/d$, for any integer value $m$. Expressed in terms of direction cosines, the grating lobes occur at $u_m = u_0 + m\lambda/d$, where $u_0 = \sin \varphi_0$. The direction cosine, $u_0$, is the cosine of the angle that the look-direction makes with the $y$-axis and is equal to $\sin \varphi_0$ when expressed in terms of the look-direction.

In order to correspond to a physical look-direction, $u_m$ must satisfy, $–1 \leq u_m \leq 1$. You can compute a physical look-direction angle $\varphi_m$ from $\sin \varphi_m = u_m$ as long as $–1 \leq u_m \leq 1$. The spacing of grating lobes depends upon $\lambda/d$. When $\lambda/d$ is small enough, multiple grating lobe peaks can correspond to physical look-directions.

The presence or absence of visible grating lobes for the ULA is summarized in this table.

| Element Spacing | Grating Lobes |
|---|---|
| *$\lambda/d \geq 2$* | No visible grating lobes for any mainlobe direction. |
| *$1 \leq \lambda/d < 2$* | Visible grating lobes can exist for some range of mainlobe directions. |
| *$\lambda/d < 1$* | Visible grating lobes exist for every mainlobe direction. |

# step

**System object:** `phased.ULA`
**Package:** `phased`

Output responses of array elements

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array element responses, `RESP`, at the operating frequencies specified in `FREQ` and in directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Array object

### FREQ

Operating frequencies of array in hertz. FREQ is a row vector of length *L*. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

### ANG

Directions in degrees. ANG is either a 2-by-*M* matrix or a row vector of length *M*.

If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

## Output Arguments

### RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array’s horizontal polarization response, while RESP.V represents the array’s vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each

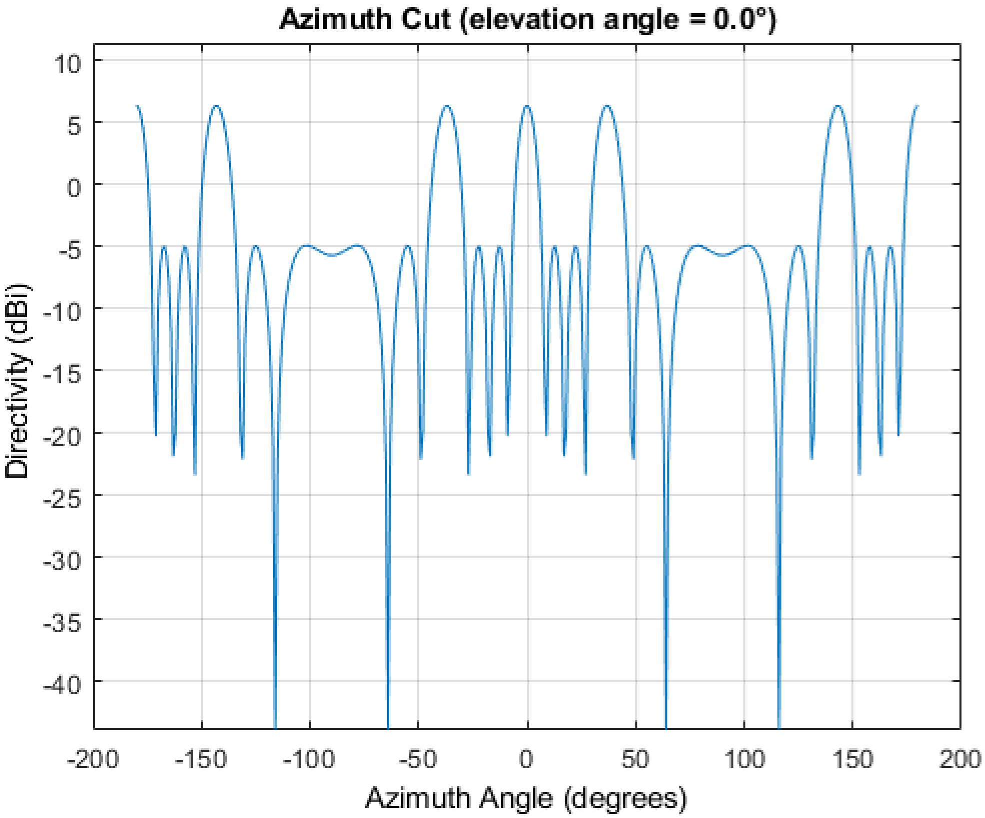
of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.

## Examples

### Response of Antenna ULA

Create a 4-element ULA of isotropic antenna elements and find the response of each element at boresight. Plot the array response at 1 GHz for azimuth angles between -180 and 180 degrees.

```
ha = phased.ULA('NumElements',4);
fc = 1e9;
ang = [0;0];
resp = step(ha,fc,ang);
c = physconst('LightSpeed');
pattern(ha,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular')
```



### Step Response of Microphone ULA Array

Find the response of a ULA array of 10 omnidirectional microphones spaced 1.5 meters apart. Set the frequency response of the microphone to the range 20 Hz to 20 kHz and choose the signal frequency to be 100 Hz. Using the `step` method, determine the response of each element at boresight: 0 degrees azimuth and 0 degrees elevation.

```
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
Nelem = 10;
sULA = phased.ULA('NumElements',Nelem,...
    'ElementSpacing',1.5,...
    'Element',sMic);
fc = 100;
ang = [0;0];
resp = step(sULA,fc,ang)
```

```
resp = 10×1

     1
     1
     1
     1
     1
     1
     1
     1
     1
     1
```

Plot the array directivity. Assume the speed of sound in air to be 340 m/s.

```
c = 340;
pattern(sULA,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','polar')
```

# viewArray

**System object:** `phased.ULA`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `ShowIndex`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

### `ShowNormals`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

### `ShowTaper`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

### `Title`

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

### `hPlot`

Handle of array elements in figure window.

## Examples

### Geometry and Indices of ULA Elements

This example shows how to draw a 6-element ULA. Use the 'ShowIndex' parameter to show the indices of the first and third elements.

```
sULA = phased.ULA(6);
viewArray(sULA,'ShowIndex',[1 3]);
```

# phased.UnderwaterRadiatedNoise

**Package:** `phased`

Radiate acoustic noise from underwater or surface sound source

## Description

The phased.UnderwaterRadiatedNoise System object creates a source of underwater radiated acoustic noise. The noise source can either be on the sea surface or underwater. The radiated noise consists of two components: broadband noise and tonal noise. Broadband noise fills the entire operating system bandwidth while tonal noise occurs at discrete frequencies within the bandwidth. In general, the intensity of the radiated noise depends on the noise spectrum and the source radiation pattern. The object lets you specify

- The spectral shape and levels of the broadband noise.
- The frequencies and levels of the tones.
- The noise source radiation pattern.

To propagate noise from a source to a receiver, use this object with the `phased.IsoSpeedUnderwaterPaths` and the `phased.MultipathChannel` objects.

To generate radiated underwater noise:

1. Create the `phased.UnderwaterRadiatedNoise` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
noiseradiator = phased.UnderwaterRadiatedNoise
noiseradiator = phased.UnderwaterRadiatedNoise(Name,Value)
```

## Description

`noiseradiator = phased.UnderwaterRadiatedNoise` creates an underwater radiated noise source with default property values.

`noiseradiator = phased.UnderwaterRadiatedNoise(Name,Value)` creates an underwater radiated noise source with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `noiseradiator = phased.UnderwaterRadiatedNoise('TonalLevels',[4700 4900 5150],'SampleRate',500,'OperatingFrequency',5000)` creates a noise source with tones at 4.7, 4.9, and 5.15 kHz. The sample rate is set to 0.5 kHz and the operating frequency is 5 kHz. The broadband noise levels are set to default values.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `NumSamples` — Number of output noise samples

`100` (default) | positive integer

Number of output noise samples, specified as a positive integer.

Example: `500`

Data Types: `double`

### `SampleRate` — Sample rate

`1.0e3` (default) | positive scalar

Sample rate, specified as a positive scalar. The sample rate together with the operating frequency determines the operating frequency band. See “Input and Output Frequency

Bands” on page 1-2540 for the definition of the operating frequency band. Units are in Hz.

Example: 2.0e3

Data Types: double

### OperatingFrequency — Signal operating frequency

20.0e3 (default) | positive scalar

Signal operating frequency, specified as a positive scalar. The operating frequency determines the center of the operating frequency band. See “Input and Output Frequency Bands” on page 1-2540 for the definition of the operating frequency band. Units are in Hz.

Example: 15.0e3

Data Types: double

### TonalFrequencies — Radiated tonal noise frequencies

[19700 20100 20300] (default) | real-valued vector of nonnegative values

Radiated tonal frequencies, specified as a vector of nonnegative values. Tonal frequencies must lie in the operating frequency band. Tonal frequencies outside this band are ignored. The length of the TonalFrequencies vector must match the length of the TonalLevels vector. Units are in Hz. See “Input and Output Frequency Bands” on page 1-2540 for the definition of the operating frequency band.

Example: [14900 15010 15200]

Data Types: double

### TonalLevels — Radiated tonal noise levels

[150 150 150] (default) | real-valued vector

Radiated tonal noise levels, specified as a vector of positive values. Units are in dB//1µPa. The length of the TonalLevels vector must match the length of the TonalFrequencies vector.

Example: [50 20 170]

Data Types: double

### BroadbandLevel — Broadband noise spectrum level

130 (default) | vector of real values

Broadband noise spectrum level, specified as a vector of real-values. This vector specifies the noise spectrum at uniformly spaced frequencies in the operating system band. Units are in dB/Hz//1μPa.

Example: `[140 145 145 130]`

Data Types: `double`

**`AzimuthAngles` — Elevation angles of source radiation pattern entries**
`-180:180` (default) | vector of real values

Azimuth angles of source radiation pattern entries, specified as a length-*P* vector. This property specifies the azimuth angles of the columns of the source radiation pattern, DirectionalPattern property. *P* must be greater than 2. Units are in degrees.

Example: `[140 145 145 130]`

Data Types: `double`

**`ElevationAngles` — Elevation angles of directional radiation pattern**
`-90:90` (default) | length-*Q* vector of real values

Elevation angles of the source radiation pattern entries, specified as a length-*Q* vector. This property specifies the elevation angles of the rows of the source radiation pattern, DirectionalPattern . *Q* must be greater than 2. Units are in degrees.

Example: `[-45 -30 0 45 30]`

Data Types: `double`

**`DirectionalPattern` — Source radiation pattern**
`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*K* array | 1-by-*P*-by-*K* array | real-valued *K*-by-*P* matrix

Source radiation pattern, specified as a real-valued matrix or array. Units are in dB. The allowable pattern dimensions are:

**Radiation Pattern Dimensions**

| Dimensions | Application |
|---|---|
| *Q*-by-*P* matrix | Specifies a directional pattern as a function of *Q* elevation angles and *P* azimuth angles. The same pattern is used for all frequencies. |
| *Q*-by-*P*-by-*K* array | Specifies a directional pattern as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If *K* = *1*, the directional pattern is equivalent to a *Q*-by-*P* matrix. |
| 1-by-*P*-by-*K* array | Specifies a directional pattern as a function of *P* azimuth angles and *K* frequencies. These dimensions apply when there is only one elevation angle. |
| *K*-by-*P* matrix | |

- *Q* is the length of the vector specified by the ElevationAngles property.
- *P* is the length of the vector specified by the AzimuthAngles property.
- *K* is the number of frequencies specified by the FrequencyVector property.

**Matrix and Array Specifications**

| Application | Radiation Pattern Dimensions |
|---|---|
| One source and *M* radiation directions specified in the `ang` argument of the object function. | Specify one radiation pattern matrix or array for all radiating angles. |
| *M* sources with the same pattern and *M* radiation directions specified in the `ang` argument of the object function. | Specify one radiation pattern matrix or array for all radiating angles. |
| *M* sources with individual radiation patterns and *M* radiation directions specified in the `ang` argument of the object function. | *M* radiation patterns in a cell array. All patterns must have the same sizes and types. The number of patterns must match the number of radiating angles. |

Example: `[1,3;5,-10]`

Data Types: `double`

### `FrequencyVector` — Radiation pattern frequencies

`[0 100e6]` (default) | positive, real-valued 1-by-*K* vector

Radiation pattern frequencies, specified as a positive, real-valued 1-by-*K* vector. The vector defines the frequencies at which the DirectionalPattern property values are specified. The elements of the vector must be in strictly increasing order and frequencies must lie in the operating frequency band. See “Input and Output Frequency Bands” on page 1-2540 for the definition of the operating frequency band. Units are in Hz.

Example: `1e6`

Data Types: `double`

### `SeedSource` — Random number generator seed source

`'Auto'` (default) | `'Property'`

Random number generator seed source, specified as `'Auto'` or `'Property'`. The random numbers are used to generate the noise. When you set this property to `'Auto'`, random numbers are generated using the default MATLAB random number generator. When you set this property to `'Property'`, the object uses a private random number generator with a seed specified by the `Seed` property.

To use this object with Parallel Computing Toolbox software, set this property to `'Auto'`.

Data Types: `char`

### Seed — Random number generator seed

0 (default) | nonnegative integer less than $2^{32}$.

Random number generator seed, specified as a nonnegative integer less than $2^{32}$.

Example: `10223`

#### Dependencies

To enable this property, set the SeedSource property to `'Property'`.

Data Types: `double`

# Usage

# Syntax

```
y = radiatednoise(ang)
```

## Description

`y = radiatednoise(ang)` returns the noise,`y`, radiated in the direction, `ang`.

## Input Arguments

### ang — Noise radiation directions

real-valued 2-by-*M* matrix

Noise radiation directions, specified as a real-valued 2-by-*M* matrix. Each column of `ang` specifies the direction of radiation of the corresponding noise signal in the form `[AzimuthAngle;ElevationAngle]`. When `ang` represents multiple angles, the DirectionalPattern property can contain one pattern or *M* patterns. In that case, each column of `ang` corresponds to one of the patterns. If there is only one pattern, then the multiple noise signals are generated using the same source pattern. Units are in degrees.

Example: `[0 20; 35 -10]`

Data Types: `double`

## Output Arguments

### y — Radiated noise

complex-valued *M*-by-*N* matrix

Radiated noise, specified as a complex-valued *M*-by-*N* matrix. *M* is the number of angles specified in the `ang` argument. *N* is the number of samples specified by the `NumSamples` property. Radiated noise lies in the baseband range *[-fs/2 fs/2]*. $f_s$ represents the sample rate set by the SampleRate property. Noise units are in Pa.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

The `reset` object function resets the random number generator state when the SeedSource property is set to `'Property'`.

# Examples

### Radiate Underwater Noise from Surface Ship

Generate radiated noise from a surface ship. The sonar operating frequency is 5.0 kHz and the sampling rate is 1.0 kHz. By definition, broadband noise band lies in the band 4.5 kHz to 5.5 kHz. In addition, there are tonal noises at 4.6, 5.2, and 5.4 kHz.

```
shippos = [0;0;0];
rcvpos = [100;0;-50];
```

Compute the noise transmission angle from the ship to the receiver.

```
[~,ang] = rangeangle(rcvpos,shippos)
```

```
ang = 2×1

         0
  -26.5651
```

Construct a `phased.UnderwaterRadiatedNoise` System object™ having a radiation pattern that depends only on elevation angle. Compute the noise radiated in the direction of the receiver. Create 10000 samples of the noise radiated towards the target.

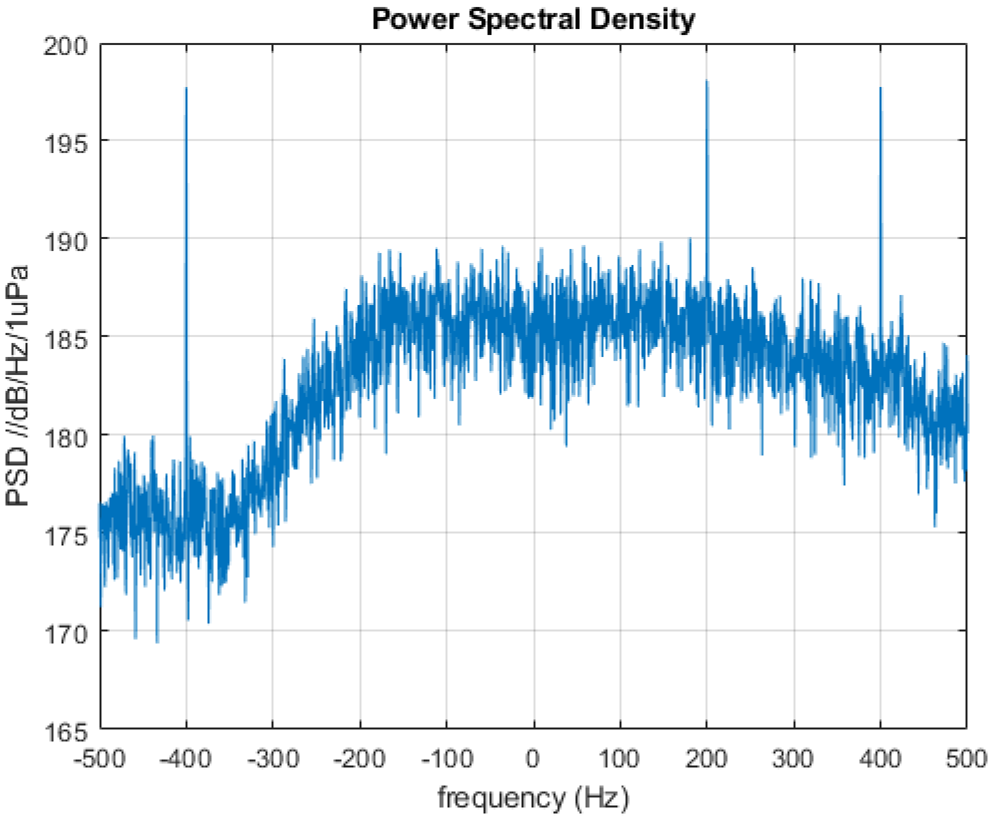
```
azang = [-180:180];
elang = [-80:80];
pattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
fs = 1000;
noiseradiator = phased.UnderwaterRadiatedNoise('NumSamples',10000, ...
    'SampleRate',fs,'TonalFrequencies',[4600 5200 5400],'TonalLevels',[200,200,200], .
    'BroadbandLevels',[180 180 190 190 190 188 185],'AzimuthAngles',azang, ...
    'ElevationAngles',elang,'DirectionalPattern',pattern, ...
    'OperatingFrequency',5e3,'SeedSource','Property','Seed',2781);
```

Generate 10000 samples of noise.

```
y = noiseradiator(ang);
```

Plot the noise power spectral density (psd). Convert the psd to intensity referenced to 1uPa.

```
[psd,fr] = pwelch(y,[],[],[],noiseradiator.SampleRate,'psd','centered');
plot(fr,10*log10(psd*1e12));
title('Power Spectral Density')
xlabel('frequency (Hz)')
ylabel('PSD //dB/Hz/1uPa')
grid
```



The three tones appear over the broadband spectrum.

### Radiate Underwater Noise with Frequency-Dependent Pattern

Generate radiated noise from an underwater vehicle. Assume that the noise radiation pattern depends on frequency. The sonar operating frequency is 5.0 kHz and the sampling rate is 1.0 kHz. By definition, the broadband noise band is from 4.5 kHz to 5.5 kHz. In addition, there are tonal noises at 4.6, 5.2, and 5.3 kHz. Define the radiation pattern at three frequencies within this band. All three patterns are multiples of the basic pattern. The frequencies of the radiation patterns are 4.6 kHz, 5.0 kHz, and 5.3 kHz.

First, specify the source and receiver positions.

```
srcpos = [0;50;-20];
rcvpos = [100;0;-50];
```

Compute the noise transmission angle from vehicle to receiver.

```
[~,ang] = rangeangle(rcvpos,srcpos)
```

```
ang = 2×1

  -26.5651
  -15.0203
```

Construct a `phased.UnderwaterRadiatedNoise` System object™ with a radiation pattern that depends only the azimuth angle and frequency. Compute the noise radiated in the direction of the receiver. Create 10000 samples of noise radiated from the vehicle.

```
azang = [-180:180];
elang = [-90:90];
fc = 5000.0;
```

Put the radiation pattern in a three-dimensional array.

```
basepattern = repmat(10*cosd(azang).^2,numel(elang),1);
pattern(:,:,1) = 0.5*basepattern;
pattern(:,:,2) = basepattern;
pattern(:,:,3) = 0.6*basepattern;
patterndb = mag2db(pattern);
noiseradiator = phased.UnderwaterRadiatedNoise('NumSamples',10000, ...
    'SampleRate',1e3,'TonalFrequencies',[4600,5200 5300], ...
    'TonalLevels',[200,210,200],'BroadbandLevels',[180 180 190 190 190 180 170], ...
    'AzimuthAngles',azang,'ElevationAngles',elang, ...
    'FrequencyVector',[4600,5000,5300],'DirectionalPattern',pattern, ...
    'OperatingFrequency',5e3,'SeedSource','Property','Seed',2081);
```

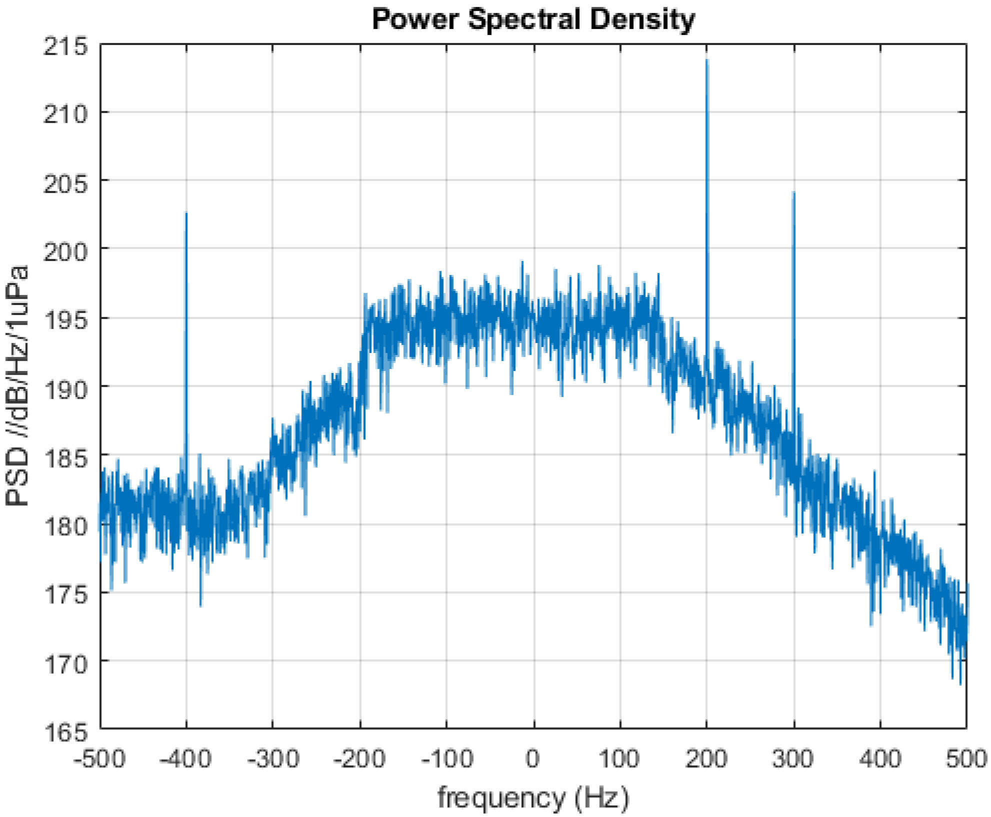
Generate 10000 samples of noise.

```
y = noiseradiator(ang);
```

Plot the noise power spectral density (psd). Convert the psd to intensity referenced to 1uPa.

```
[psd,fr] = pwelch(y,[],[],[],noiseradiator.SampleRate,'psd','centered');
plot(fr,10*log10(psd*1e12));
```

```
title('Power Spectral Density')
xlabel('frequency (Hz)')
ylabel('PSD //dB/Hz/1uPa')
grid
```



The three tones appear over the broadband spectrum.

### Radiate Underwater Noise from Two Sources

Generate radiated noise from a two underwater vehicles. Assume that the noise radiation pattern is different for each. The sonar operating frequency is 5.0 kHz and the sampling rate is 1.0 kHz. By definition, the broadband noise band is from 4.5 kHz to 5.5 kHz. In addition, there are tonal noises at 4.6, 5.2, and 5.3 kHz. The frequencies of the radiation patterns are 4.6 kHz, 5.0 kHz, and 5.3 kHz.

First, specify the source and receiver positions.

```
srcpos1 = [0;50;-20];
srcpos2 = [200;50;-80];
rcvpos = [100;0;-50];
```

Compute the noise transmission angle from vehicle to receiver.

```
[~,ang1] = rangeangle(rcvpos,srcpos1);
[~,ang2] = rangeangle(rcvpos,srcpos2);
```

Construct a `phased.UnderwaterRadiatedNoise` System object™ with a radiation pattern that depends only the azimuth angle and frequency. Compute the noise radiated in the direction of the receiver. Create 10000 samples of noise radiated from the vehicle.

```
azang = [-180:180];
elang = [-90:90];
fc = 5000.0;
```

Put the radiation pattern in a three-dimensional array.

```
pattern1 = repmat(10*cosd(azang).^2,numel(elang),1);
pattern2 = ones(181,361);
pattern1db = mag2db(pattern1);
pattern2db = mag2db(pattern2);
noiseradiator = phased.UnderwaterRadiatedNoise('NumSamples',10000, ...
    'SampleRate',1e3,'TonalFrequencies',[4600,5200 5300], ...
    'TonalLevels',[200,210,200],'BroadbandLevels',[180 180 190 190 190 180 170], ...
    'AzimuthAngles',azang,'ElevationAngles',elang, ...
    'FrequencyVector',[4600,5000,5300],'DirectionalPattern',{pattern1,pattern2}, ...
    'OperatingFrequency',5e3,'SeedSource','Property','Seed',2081);
```

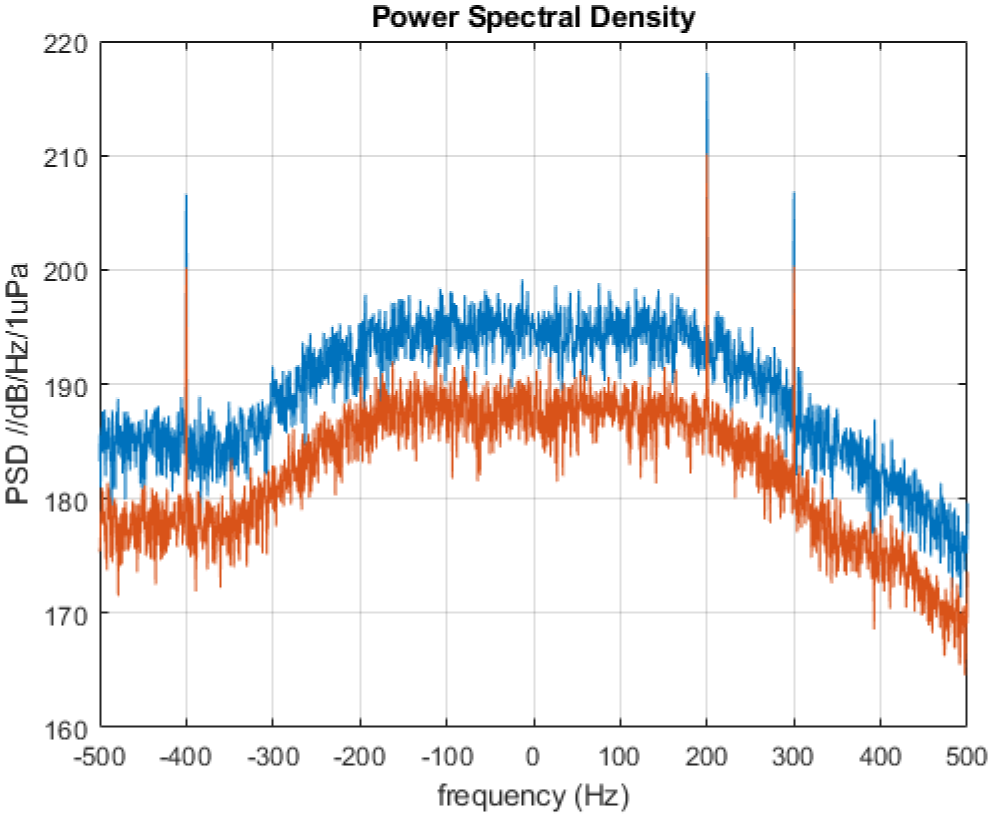
Generate 10000 samples of noise.

```
y = noiseradiator([ang1,ang2]);
```

Plot the noise power spectral density (psd). Convert the psd to intensity referenced to 1uPa.

```
[psd,fr] = pwelch(y,[],[],[],noiseradiator.SampleRate,'psd','centered');
plot(fr,10*log10(psd*1e12));
title('Power Spectral Density')
```

```
xlabel('frequency (Hz)')
ylabel('PSD //dB/Hz/1uPa')
grid
```



The three tones appear over the broadband spectrum.

# More About

## Input and Output Frequency Bands

The specified broadband and tonal noise frequencies must lie inside the operating frequency band,

$[f_c - f_s/2, f_c + f_s/2]$

$f_s$ represents the sample rate set by the SampleRate property and $f_c$ represents the operating frequency, set by the OperatingFrequency property.

However, the output noise spectrum lies in baseband:

$[- f_s/2, f_s/2]$

# phased.URA

**Package:** `phased`

Uniform rectangular array

## Description

The `URA` object constructs a uniform rectangular array (URA).

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform rectangular array. See "Construction" on page 1-2542.
2. Call `step` to compute the response according to the properties of `phased.URA`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.URA` creates a uniform rectangular array System object, `H`. The object models a URA formed with identical sensor elements. Array elements are distributed in the *yz*-plane in a rectangular lattice. The array look direction (boresight) is along the positive *x*-axis.

`H = phased.URA(Name,Value)` creates the object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = phased.URA(SZ,D,Name,Value)` creates a URA object, `H`, with the `Size` property set to `SZ`, the `ElementSpacing` property set to `D` and other specified property Names set to the specified Values. `SZ` and `D` are value-only arguments. When specifying a value-only argument, specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

### `Element`

Phased array toolbox system object

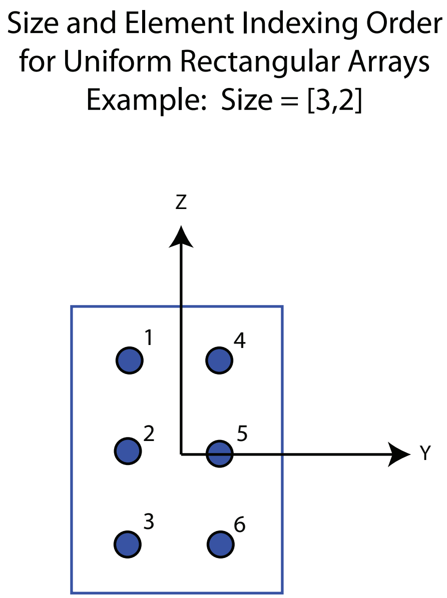
Element specified as a Phased Array System Toolbox object. This object can be an antenna or microphone element.

**Default:** Isotropic antenna element with default properties

### `Size`

Size of array

A 1-by-2 integer vector or a single integer containing the size of the array. If `Size` is a 1-by-2 vector, the vector has the form `[NumberOfRows, NumberOfColumns]`. If `Size` is a scalar, the array has the same number of elements in each row and column. For a URA, array elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this illustration, a `'Size'` value of `[3,2]` array has three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]

**Default:** `[2 2]`

**`ElementSpacing`**

Element spacing

A 1-by-2 vector or a scalar containing the element spacing of the array, expressed in meters. If `ElementSpacing` is a 1-by-2 vector, it is in the form of `[SpacingBetweenRows,SpacingBetweenColumns]`. See “Spacing Between Columns” on page 1-2551 and “Spacing Between Rows” on page 1-2551. If `ElementSpacing` is a scalar, both spacings are the same.

**Default:** `[0.5 0.5]`

**`Lattice`**

Element lattice

Specify the element lattice as one of `'Rectangular' | 'Triangular'`. When you set the `Lattice` property to `'Rectangular'`, all elements in the URA are aligned in both row and column directions. When you set the `Lattice` property to `'Triangular'`, elements in even rows are displaced toward the positive row axis direction. The displacement is one-half the element spacing along the row.

**Default:** `'Rectangular'`

### `ArrayNormal`

Array normal direction

Array normal direction, specified as one of `'x'`, `'y'`, or `'z'`.

URA elements lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction

| ArrayNormal Property Value | Element Positions and Boresight Directions |
|---|---|
| `'x'` | Array elements lie on the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `'y'` | Array elements lie on the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `'z'` | Array elements lie on the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Default:** `'x'`

### `Taper`

Element tapers

Element tapers, specified as a complex-valued scalar, or 1-by-*MN* row vector, *MN*-by-1 column vector, or *M*-by-*N* matrix. Tapers are applied to each element in the sensor array. Tapers are often referred to as element weights. *M* is the number of elements along the *z*-axis, and *N* is the number of elements along *y*-axis. *M* and *N* correspond to the values of `[NumberofRows, NumberOfColumns]` in the `Size` property. If `Taper` is a scalar, the same taper value is applied to all elements. If the value of `Taper` is a vector or matrix, taper values are applied to the corresponding elements. Tapers are used to modify both the amplitude and phase of the received data.

**Default:** 1

## Methods

| | |
|---|---|
| directivity | Directivity of uniform rectangular array |
| collectPlaneWave | Simulate received plane waves |
| getElementNormal | Normal vector to array elements |
| getElementPosition | Positions of array elements |
| getNumElements | Number of elements in array |
| getTaper | Array element tapers |
| pattern | Plot URA array pattern |
| patternAzimuth | Plot URA array directivity or pattern versus azimuth |
| patternElevation | Plot URA array directivity or pattern versus elevation |
| isPolarizationCapable | Polarization capability |
| plotResponse | Plot response pattern of array |
| plotGratingLobeDiagram | Plot grating lobe diagram of array |
| step | Output responses of array elements |
| viewArray | View array geometry |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Azimuth Response of a 3-by-2 URA at Boresight

Construct a 3-by-2 rectangular lattice URA. By default, the array consists of isotropic antenna elements. Find the response of each element at boresight, 0 degrees azimuth and elevation. Assume the operating frequency is 1 GHz.

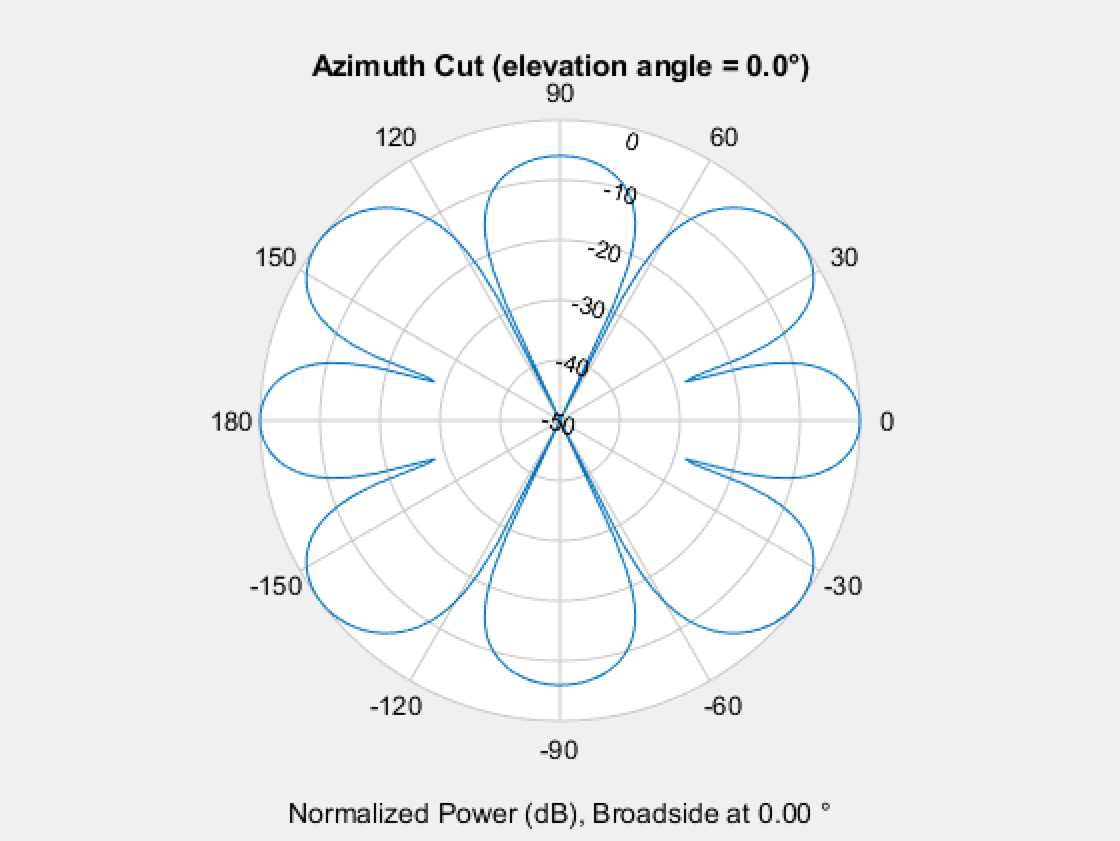
```
array = phased.URA('Size',[3 2]);
fc = 1e9;
```

```
ang = [0;0];
resp = array(fc,ang);
disp(resp)
```

```
     1
     1
     1
     1
     1
     1
```

Plot the azimuth pattern of the array.

```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','polar','Type','powerdb','Normalize',true)
```



### Compare Triangular and Rectangular Lattice URA's

This example shows how to find and plot the positions of the elements of a 5-row-by-6-column URA with a triangular lattice and a URA with a rectangular lattice. The element spacing is 0.5 meters for both lattices.

Create the arrays.

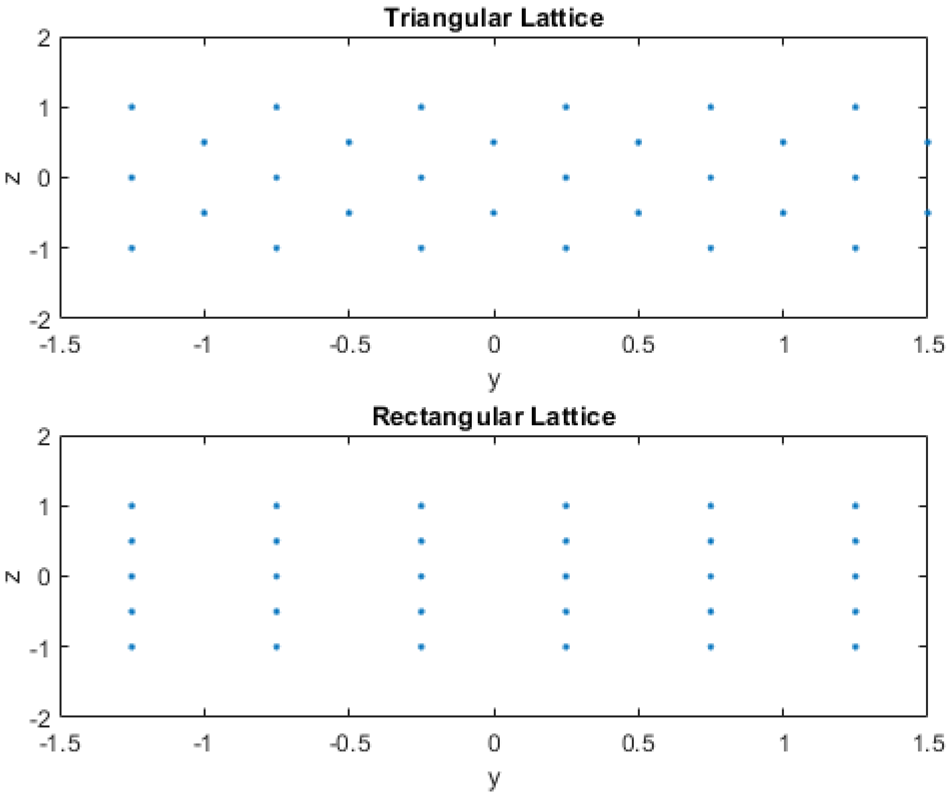
```
h_tri = phased.URA('Size',[5 6],'Lattice','Triangular');
h_rec = phased.URA('Size',[5 6],'Lattice','Rectangular');
```

Get the element y,z positions for each array. All the x coordinates are zero.

```
pos_tri = getElementPosition(h_tri);
pos_rec = getElementPosition(h_rec);
pos_yz_tri = pos_tri(2:3,:);
pos_yz_rec = pos_rec(2:3,:);
```

Plot the element positions in the yz-plane.

```
figure;
gcf.Position = [100 100 300 400];
subplot(2,1,1);
plot(pos_yz_tri(1,:), pos_yz_tri(2,:), '.')
axis([-1.5 1.5 -2 2])
xlabel('y'); ylabel('z')
title('Triangular Lattice')
subplot(2,1,2);
plot(pos_yz_rec(1,:), pos_yz_rec(2,:), '.')
axis([-1.5 1.5 -2 2])
xlabel('y'); ylabel('z')
title('Rectangular Lattice')
```



### Adding Tapers to an Array

Construct a 5-by-2 element URA with a Taylor window taper along each column. The tapers form a 5-by-2 matrix.

```
taper = taylorwin(5);
ha = phased.URA([5,2],'Taper',[taper,taper]);
w = getTaper(ha)
```

```
w = 10×1
```

# directivity

**System object:** phased.URA
**Package:** phased

Directivity of uniform rectangular array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` computes the “Directivity” on page 1-2559 of a uniform rectangular array (URA) of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### H — Uniform rectangular array

System object

Uniform rectangular array specified as a `phased.URA` System object.

Example: `H = phased.URA`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

**ANGLE — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**D — Directivity**
*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Uniform Rectangular Array

Compute the directivity of two uniform rectangular arrays (URA). The first array consists of isotropic antenna elements. The second array consists of cosine antenna elements. In addition, compute the directivity of the first array steered to a specific direction.

**Array of isotropic antenna elements**

First, create a 10-by-10-element URA of isotropic antenna elements spaced one-quarter wavelength apart. Set the signal frequency to 800 MHz.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
myAntIso = phased.IsotropicAntennaElement;
myArray1 = phased.URA;
myArray1.Element = myAntIso;
myArray1.Size = [10,10];
myArray1.ElementSpacing = [lambda*0.25,lambda*0.25];
ang = [0;0];
d = directivity(myArray1,fc,ang,'PropagationSpeed',c)
```

```
d = 15.7753
```

**Array of cosine antenna elements**

Next, create a 10-by-10-element URA of cosine antenna elements also spaced one-quarter wavelength apart.

```
myAntCos = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
myArray2 = phased.URA;
myArray2.Element = myAntCos;
myArray2.Size = [10,10];
myArray2.ElementSpacing = [lambda*0.25,lambda*0.25];
ang = [0;0];
d = directivity(myArray2,fc,ang,'PropagationSpeed',c)
```

```
d = 19.7295
```

The directivity is increased due to the directivity of the cosine antenna elements.

**Steered array of isotropic antenna elements**

Finally, steer the isotropic antenna array to 30 degrees in azimuth and examine the directivity at the steered angle.

```
ang = [30;0];
w = steervec(getElementPosition(myArray1)/lambda,ang);
d = directivity(myArray1,fc,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d = 15.3309
```

The directivity is maximum in the steered direction and equals the directivity of the unsteered array at boresight.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta, \varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# collectPlaneWave

**System object:** phased.URA
**Package:** phased

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

Y = collectPlaneWave(H,X,ANG) returns the received signals at the sensor array, H, when the input signals indicated by X arrive at the array from the directions specified in ANG.

Y = collectPlaneWave(H,X,ANG,FREQ), in addition, specifies the incoming signal carrier frequency in FREQ.

Y = collectPlaneWave(H,X,ANG,FREQ,C), in addition, specifies the signal propagation speed in C.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of X represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

## Output Arguments

**Y**

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

## Examples

### Simulate Received Signal at URA

Simulate two received random signals at a 6-element URA. The array has a rectangular lattice with two elements in the row direction and three elements in the column direction.

The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
array = phased.URA([2 3]);
fc = 100e6;
y = collectPlaneWave(array,randn(4,2),[10 30],fc,physconst('LightSpeed'));
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array.

For further details, see [1].

# getElementNormal

**System object:** `phased.URA`
**Package:** `phased`

Normal vector to array elements

## Syntax

```
normvec = getElementNormal(sURA)
normvec = getElementNormal(sURA,elemidx)
```

## Description

`normvec = getElementNormal(sURA)` returns the normal vectors of the array elements of the `phased.URA` System object, `sURA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sURA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form`[az;el]`. Units are degrees. Array elements are located in the plane selected in the `ArrayNormal` property. Element normal vectors are parallel to the array normal. The normal to a URA array depends upon the selected `ArrayNormal` property.

| ArrayNormal Property Value | Array Normal Direction | Array Plane |
|---|---|---|
| `'x'` | azimuth = 0°, elevation = 0° (*x*-axis) | *yz* |
| `'y'` | azimuth = 90°, elevation = 0° (*y*-axis) | *zx* |
| `'z'` | azimuth = 0°, elevation = 90° (*z*-axis) | *xy* |

The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sURA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Input Arguments

**sURA — Uniform rectangular array**

phased.sURA System object

Uniform line array, specified as a `phased.URA` System object.

Example: `sULA = phased.URA`

**elemidx — Element indices**

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

## Output Arguments

**normvec — Element normal vectors**

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*. You can determine element indices using the `viewArray` method.

## Examples

### URA Element Normals

Construct three 2-by-2 URA's with element normals along the *x*-, *y*-, and *z*-axes. Obtain the element positions and normal directions.

First, choose the array normal along the *x*-axis.

```
sURA1 = phased.URA('Size',[2,2],'ArrayNormal','x');
pos = getElementPosition(sURA1)
```

```
pos = 3×4

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
```

```
normvec = getElementNormal(sURA1)
```

```
normvec = 2×4

     0     0     0     0
     0     0     0     0
```

All elements lie in the *yz*-plane and the element normal vectors point along the *x*-axis *(0°,0°)*.

Next, choose the array normal along the *y*-axis.

```
sURA2 = phased.URA('Size',[2,2],'ArrayNormal','y');
pos = getElementPosition(sURA2)
```

```
pos = 3×4

   -0.2500   -0.2500    0.2500    0.2500
         0         0         0         0
    0.2500   -0.2500    0.2500   -0.2500
```

```
normvec = getElementNormal(sURA2)
```

```
normvec = 2×4

    90    90    90    90
     0     0     0     0
```

All elements lie in the *zx*-plane and the element normal vectors point along the *y*-axis *(90°,0°)*.

Finally, set the array normal along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sURA3 = phased.URA('Size',[2,2],'ArrayNormal','z');
pos = getElementPosition(sURA3)
```

```
pos = 3×4

   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
         0         0         0         0
```

```
normvec = getElementNormal(sURA3,[1,3])
```

```
normvec = 2×2

     0     0
    90    90
```

All elements lie in the *xy*-plane and the element normal vectors point along the *z*-axis *(0°,90°)*.

**Introduced in R2016a**

# getElementPosition

**System object:** phased.URA
**Package:** phased

Positions of array elements

## Syntax

```
POS = getElementPosition(H)
POS = getElementPosition(H,ELEIDX)
```

## Description

POS = getElementPosition(H) returns the element positions of the URA H. POS is a 3-by-N matrix where N is the number of elements in H. Each column of POS defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

For details regarding the local coordinate system of the URA, enter phased.URA.coordinateSystemInfo.

POS = getElementPosition(H,ELEIDX) returns the positions of the elements that are specified in the element index vector, ELEIDX. The index of a URA runs down each column, then to the next column to the right. For example, in a URA with 4 elements in each row and 3 elements in each column, the element in the third row and second column has an index value of 6.

## Examples

### Obtain URA Element Positions

Construct a default URA with a rectangular lattice, and obtain the element positions.

```
array = phased.URA;
pos = getElementPosition(array)
pos = 3×4

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
```

# getNumElements

**System object:** `phased.URA`
**Package:** `phased`

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

`N = getNumElements(H)` returns the number of elements, N, in the URA object `H`.

## Examples

### Obtain Number of URA Elements

Construct a default URA, and obtain the number of elements.

```
array = phased.URA;
N = getNumElements(array)
```

```
N = 4
```

# getTaper

**System object:** `phased.URA`
**Package:** `phased`

Array element tapers

## Syntax

```
wts = getTaper(h)
```

## Description

`wts = getTaper(h)` returns the tapers, `wts`, applied to each element of the phased uniform rectangular array (URA), `h`. Tapers are often referred to as weights.

## Input Arguments

### h — Uniform rectangular array

`phased.URA` System object

Uniform rectangular array specified as a`phased.URA` System object.

## Output Arguments

### `wts` — Array element tapers

*N*-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector, where *N* is the number of elements in the array.

## Examples

### Create Tapered URA

Construct a 5-by-2 element URA with a Taylor window taper along each column. Then, draw the array showing the element taper shading.

```
taper = taylorwin(5);
array = phased.URA([5,2],'Taper',[taper,taper]);
w = getTaper(array)
```

```
w = 10×1

# pattern

**System object:** `phased.URA`
**Package:** `phased`

Plot URA array pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-2583 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

**`sArray` — Uniform rectangular array**

System object

Uniform rectangular array, specified as a `phased.URA` System object.

Example: `sArray= phased.URA;`

**`FREQ` — Frequency for computing directivity and patterns**

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

**`AZ` — Azimuth angles**

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### CoordinateSystem — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| **'Polarization'** | **Display** |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

**PropagationSpeed — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**Weights — Array weights**
1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| **Weights Dimension** | **FREQ Dimension** | **Purpose** |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: 'Weights',ones(N,M)

Data Types: double
Complex Number Support: Yes

## Output Arguments

### PAT — Array pattern

*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

### AZ_ANG — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

### EL_ANG — Elevation angles

scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

### Pattern of 5x7-Element URA Antenna Array

Create a 5x7-element URA operating at 1 GHz. Assume the elements are spaced one-half wavelength apart. Show the 3-D array patterns.

#### Create the array

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
fc = 500e6;
c = physconst('LightSpeed');
lam = c/fc;
sURA = phased.URA('Element',sSD,...
    'Size',[5,7],...
    'ElementSpacing',0.5*lam);
```

#### Call the `step` method

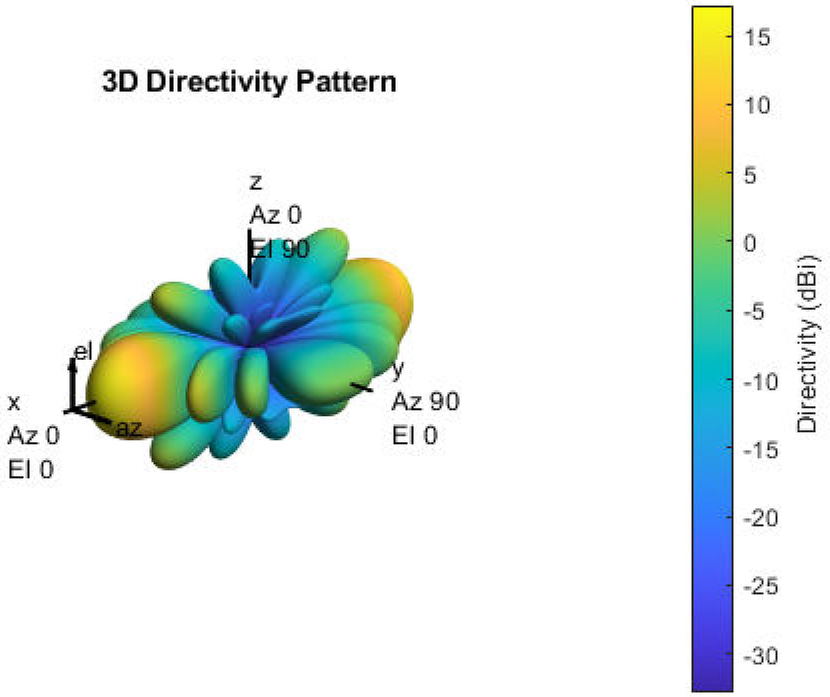
Evaluate the fields of the first five elements at 45 degrees azimuth and 0 degrees elevation.

```
ang = [45;0];
resp = step(sURA,fc,ang);
disp(resp.V(1:5))
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

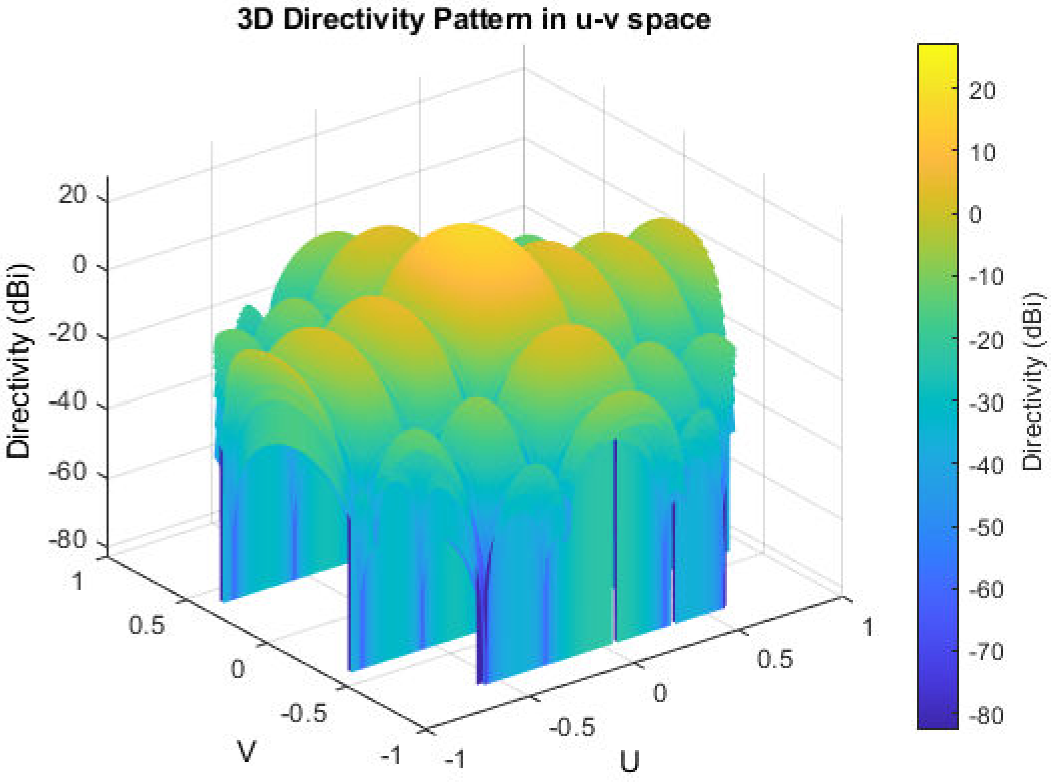
#### Display the 3-D directivity pattern at 1 GHz in polar coordinates

```
pattern(sURA,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','directivity','PropagationSpeed',c)
```



### Display the 3-D directivity pattern at 1 GHz in UV coordinates

```
pattern(sURA,fc,[-1.0:.01:1.0],[-1.0:.01:1.0],...
    'CoordinateSystem','uv',...
    'Type','directivity','PropagationSpeed',c)
```



## More About

### Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are the `azimuthPattern` and `elevationPattern` methods.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or *UV* space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.<br>Set the display axis using either the 'AzimuthAngles' or 'ElevationAngles' name-value pairs.</td></tr>
<tr><td>Angle space (3D)</td><td>Set 'RespCut' to '3D'. Set 'Format' to 'line' or 'polar'.<br>Set the display axis using both the 'AzimuthAngles'</td></tr>

# patternAzimuth

**System object:** `phased.URA`
**Package:** `phased`

Plot URA array directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

### sArray — Uniform rectangular array

System object

Uniform rectangular array, specified as a `phased.URA` System object.

Example: `sArray= phased.URA;`

### `FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### `EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `Azimuth` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Azimuth Pattern of 5x7-Element URA Antenna Array

Create a 5x7-element URA of short-dipole antenna elements operating at 1 GHz. Assume the elements are spaced one-half wavelength apart. Plot the array azimuth directivity patterns for two different elevation angles, 0 and 15 degrees. The `patternAzimuth` method always plots the array pattern in polar coordinates.

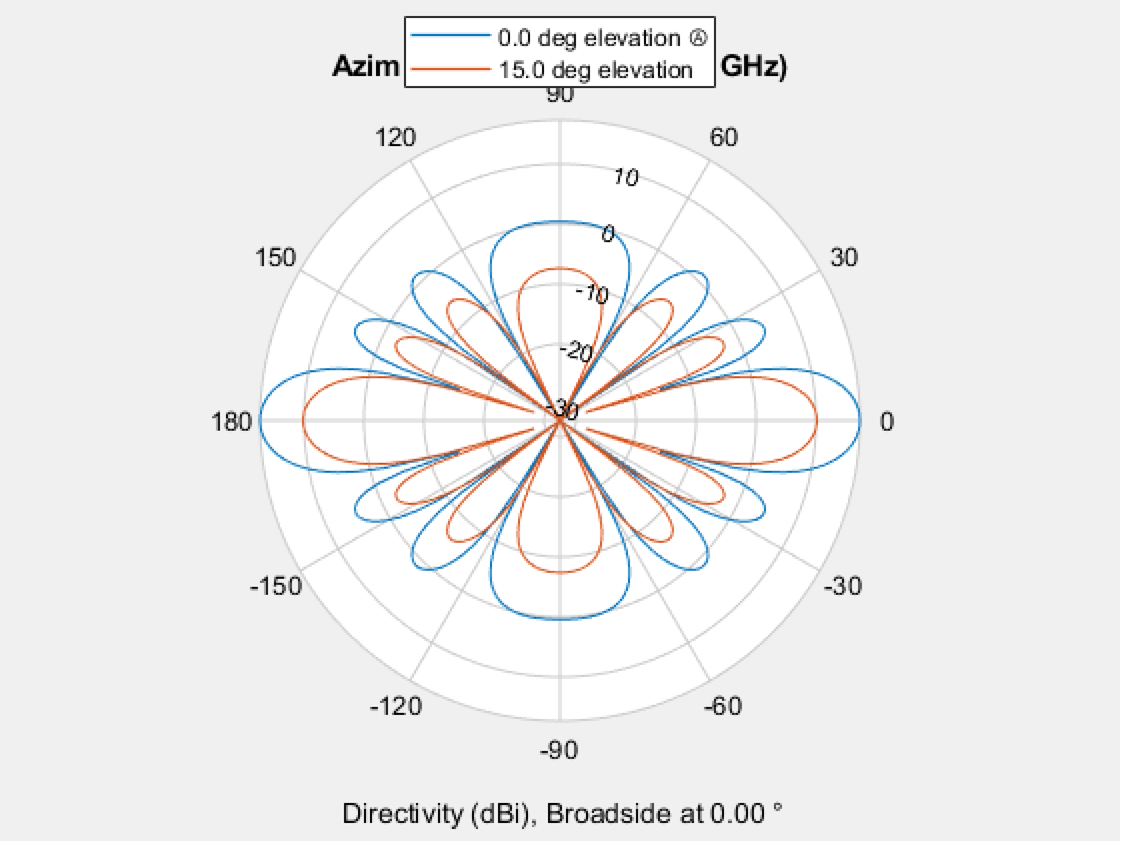
### Create the array

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
fc = 1e9;
c = physconst('LightSpeed');
lam = c/fc;
sURA = phased.URA('Element',sSD,...
    'Size',[5,7],...
    'ElementSpacing',0.5*lam);
```

### Display the pattern

Display the azimuth directivity pattern at 1 GHz in polar coordinates

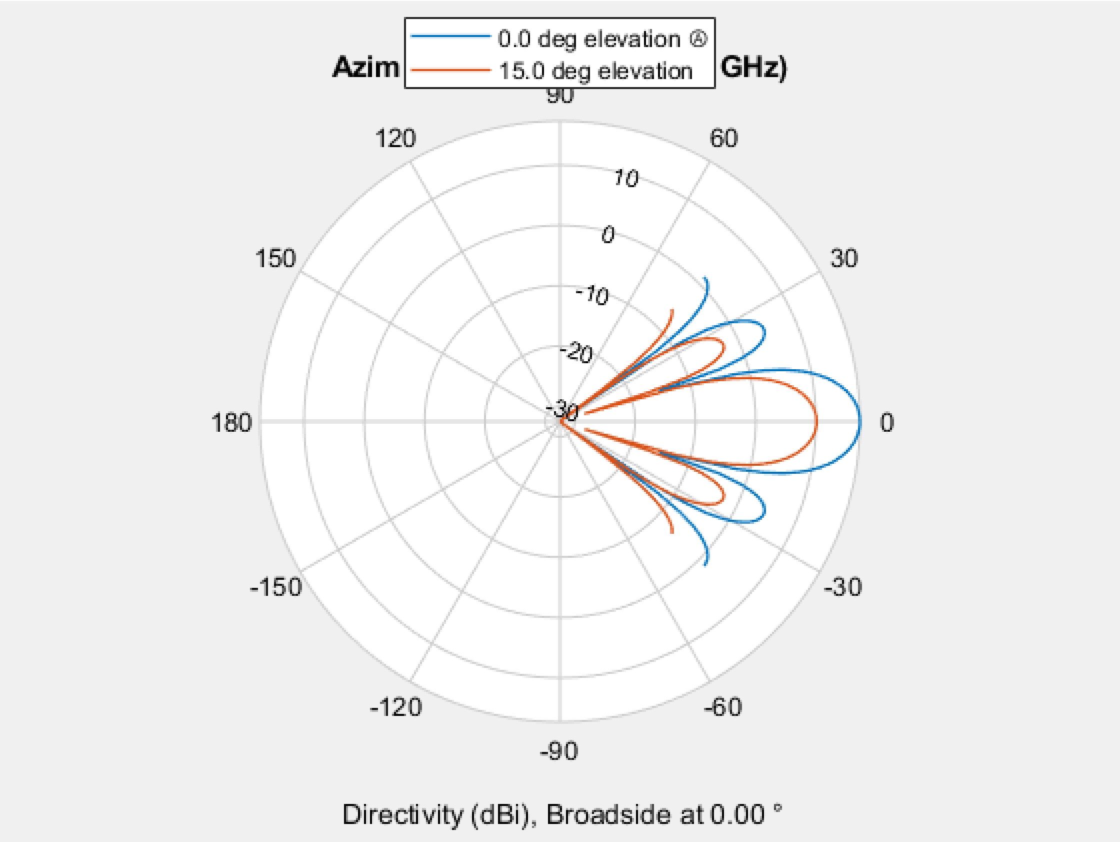
```
patternAzimuth(sURA,fc,[0 15],...
    'PropagationSpeed',c,...
    'Type','directivity')
```



### Display a subset of angles

You can plot a smaller range of azimuth angles by setting the `Azimuth` parameter.

```
patternAzimuth(sURA,fc,[0 15],...
    'PropagationSpeed',c,...
    'Type','directivity',...
    'Azimuth',[-45:45])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta, \varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternElevation`

**Introduced in R2015a**

# patternElevation

**System object:** `phased.URA`
**Package:** `phased`

Plot URA array directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

### `sArray` — Uniform rectangular array

System object

Uniform rectangular array, specified as a phased.URA System object.

Example: sArray= phased.URA;

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, FREQ must lie within the range of values specified by the FrequencyRange or the FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: 1e8

Data Types: double

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: [0,10,20]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Type` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Elevation Pattern of 7x7-Element URA Acoustic Array

Create a 7x7-element URA of backbaffled omnidirectional transducer elements operating at 2 kHz. Assume the speed of sound in water is 1500 m/s. The elements are spaced less than one-half wavelength apart. Plot the array elevation directivity patterns for three different azimuth angles, -20, 0, and 15 degrees. The `patternElevation` method always plots the array pattern in polar coordinates.

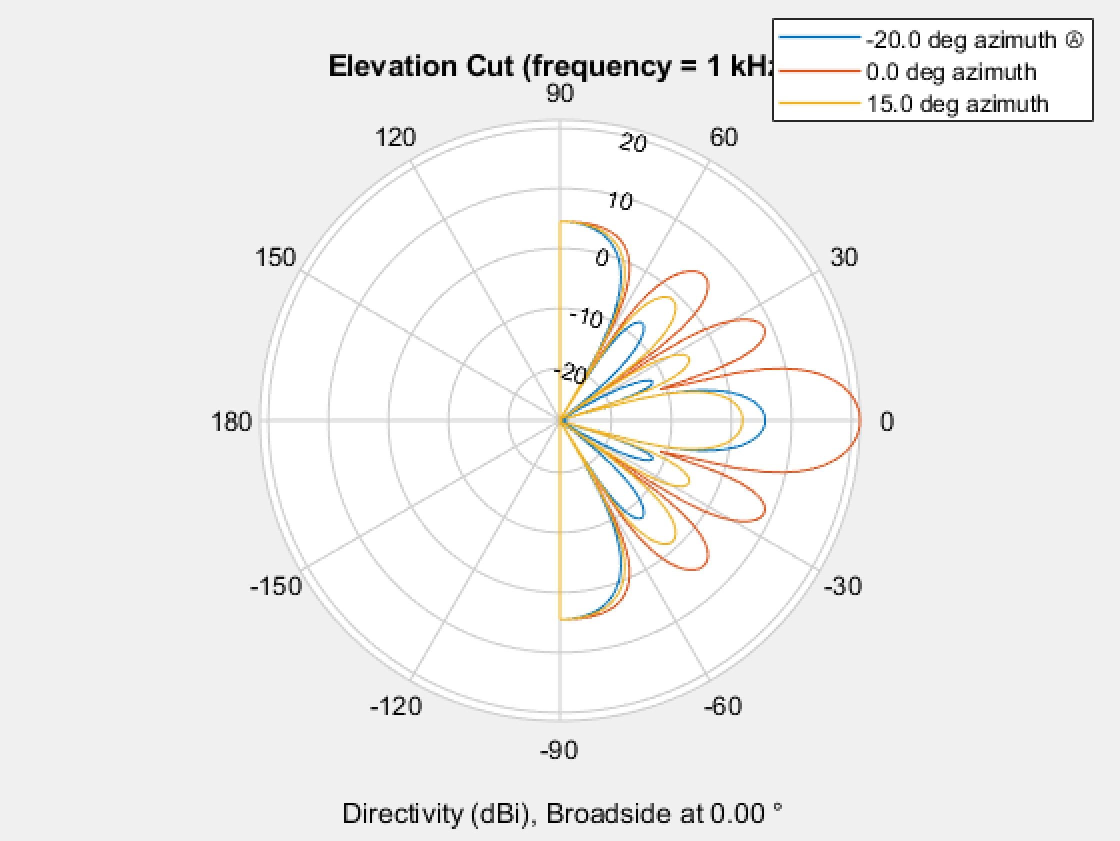
### Create the array

```
sSD = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20,3000],...
    'BackBaffled',true);
fc = 1000;
c = 1500;
lam = c/fc;
sURA = phased.URA('Element',sSD,...
    'Size',[7,7],...
    'ElementSpacing',0.5*lam);
```

### Display the pattern

Display the azimuth directivity pattern at 1 GHz in polar coordinates

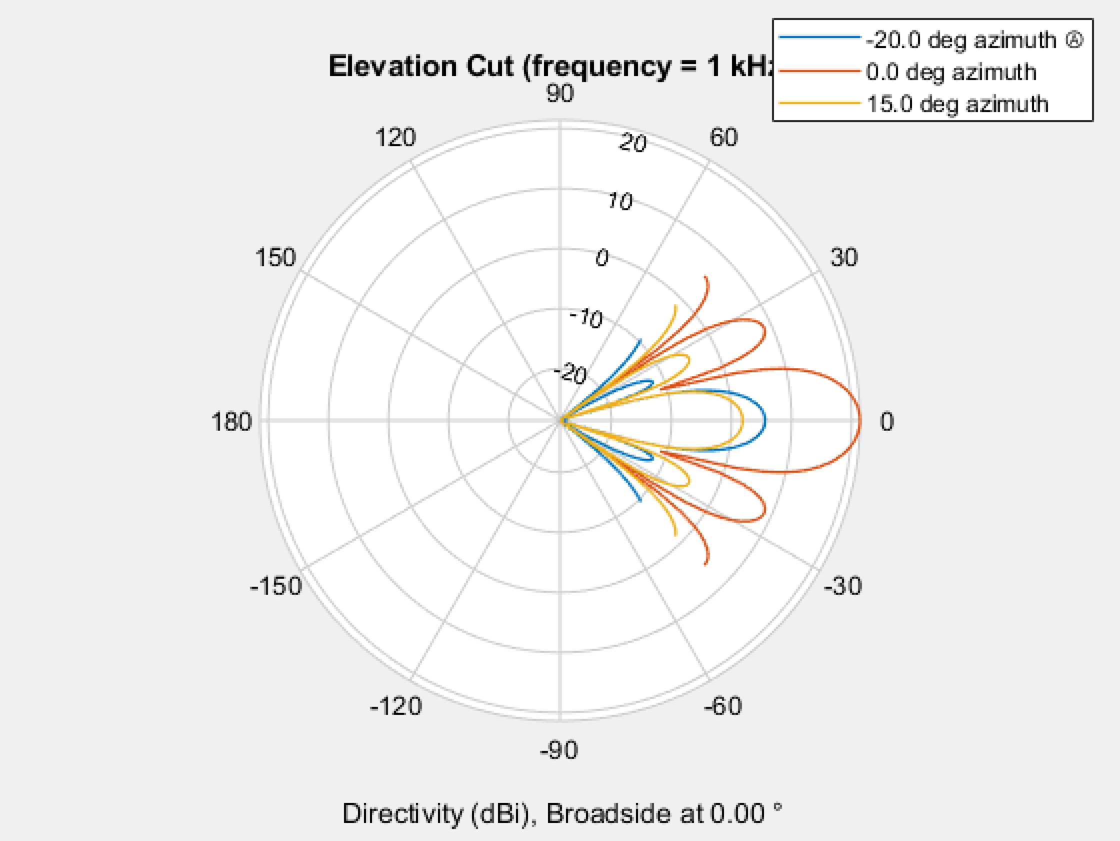
```
patternElevation(sURA,fc,[-20, 0, 15],...
    'PropagationSpeed',c,...
    'Type','directivity')
```



### Display a subset of elevation angles

You can plot a smaller range of elevation angles by setting the `Elevation` parameter.

```
patternElevation(sURA,fc,[-20, 0, 15],...
    'PropagationSpeed',c,...
    'Type','directivity',...
    'Elevation',[-45:45])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** `phased.URA`
**Package:** `phased`

Polarization capability

## Syntax

`flag = isPolarizationCapable(h)`

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

### h — Uniform rectangular array

Uniform rectangular array specified as `phased.URA` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability flag returned as a Boolean value, `true`, if the array supports polarization or, `false`, if it does not.

## Examples

### Short-Dipole URA Supports Polarization

Show that a URA array of `phased.ShortDipoleAntennaElement` short-dipole antenna elements supports polarization.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
array = phased.URA([3,2],'Element',antenna);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

The returned value `1` shows that this array supports polarization.

# plotResponse

**System object:** `phased.URA`
**Package:** `phased`

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse(___)
```

## Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse(___)` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Array object

**`FREQ`**

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no

response at frequencies outside that range. If you set the 'RespCut' property of H to '3D', FREQ must be a scalar. When FREQ is a row vector, plotResponse draws multiple frequency responses on the same axes.

**V**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CutAngle**

Cut angle as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

**Default:** 0

**Format**

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

**Default:** 'Line'

**NormalizeResponse**

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** true

**OverlayFreq**

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, FREQ must be a vector with at least two entries.

This parameter applies only when Format is not 'Polar' and RespCut is not '3D'.

**Default:** true

**Polarization**

Specify the polarization options for plotting the array response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

**RespCut**

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

**Unit**

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### Weights

Weight values applied to the array, specified as a length-$N$ column vector or $N$-by-$M$ matrix. The dimension $N$ is the number of elements in the array. The interpretation of $M$ depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimensions | FREQ Dimension | Purpose |
|---|---|---|
| $N$-by-1 column vector | Scalar or 1-by-$M$ row vector | Apply one set of weights for the same single frequency or all $M$ frequencies. |
| $N$-by-$M$ matrix | Scalar | Apply all of the $M$ different columns in `Weights` for the same single frequency. |
|  | 1-by-$M$ row vector | Apply each of the $M$ different columns in `Weights` for the corresponding frequency in `FREQ`. |

### AzimuthAngles

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

**ElevationAngles**

Elevation angles for plotting array response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

**UGrid**

*U* coordinate values for plotting array response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

**VGrid**

*V* coordinate values for plotting array response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set VGrid and UGrid parameters simultaneously.

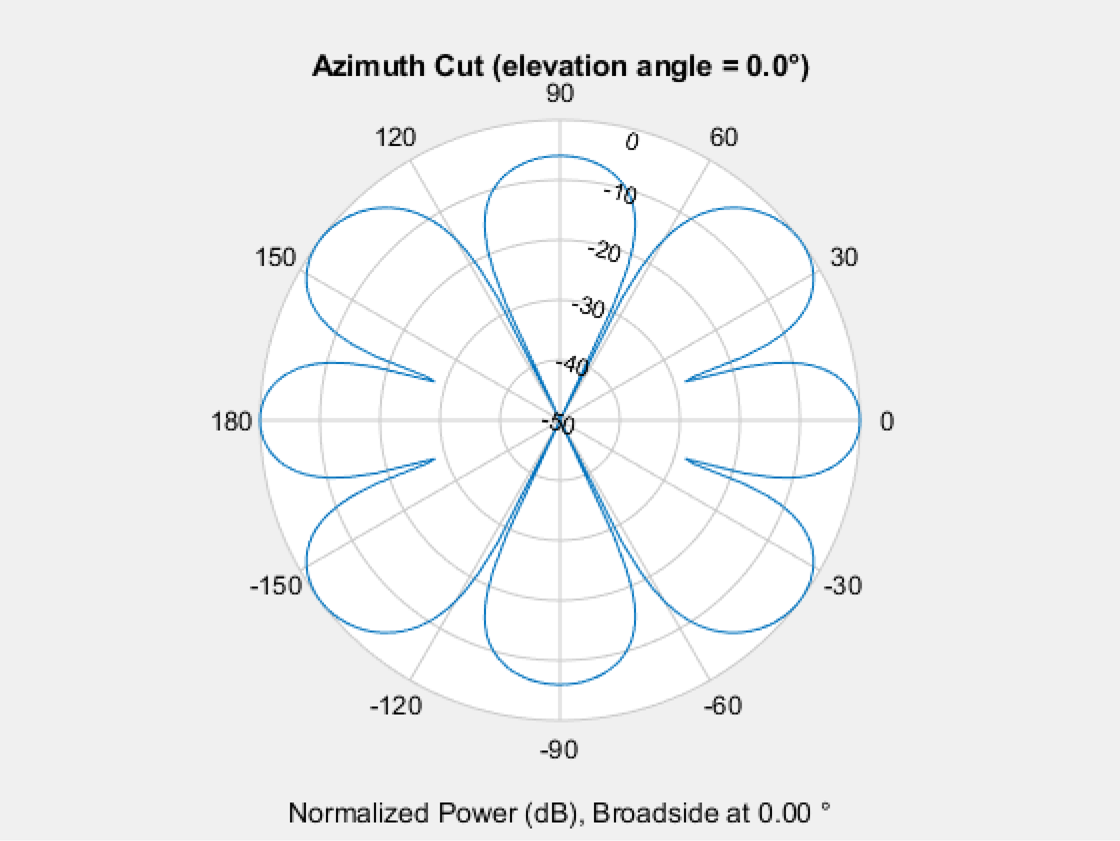
**Default:** [-1:0.01:1]

# Examples

### Azimuth Response of URA

This example shows how to construct a rectangular lattice 3-by-2 URA and plot that array's azimuth response.

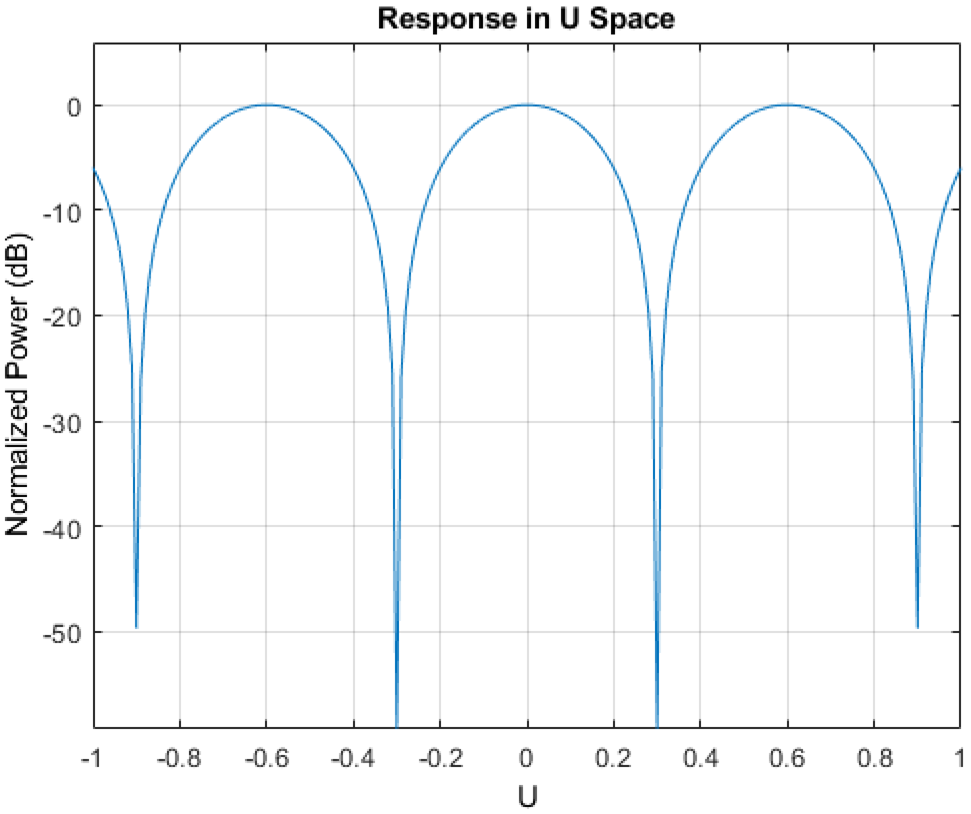
```
ha = phased.URA('Size',[3 2]);
fc = 1e9;
c = physconst('LightSpeed');
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar');
```



### Array Response and Directivity of URA in U/V Space

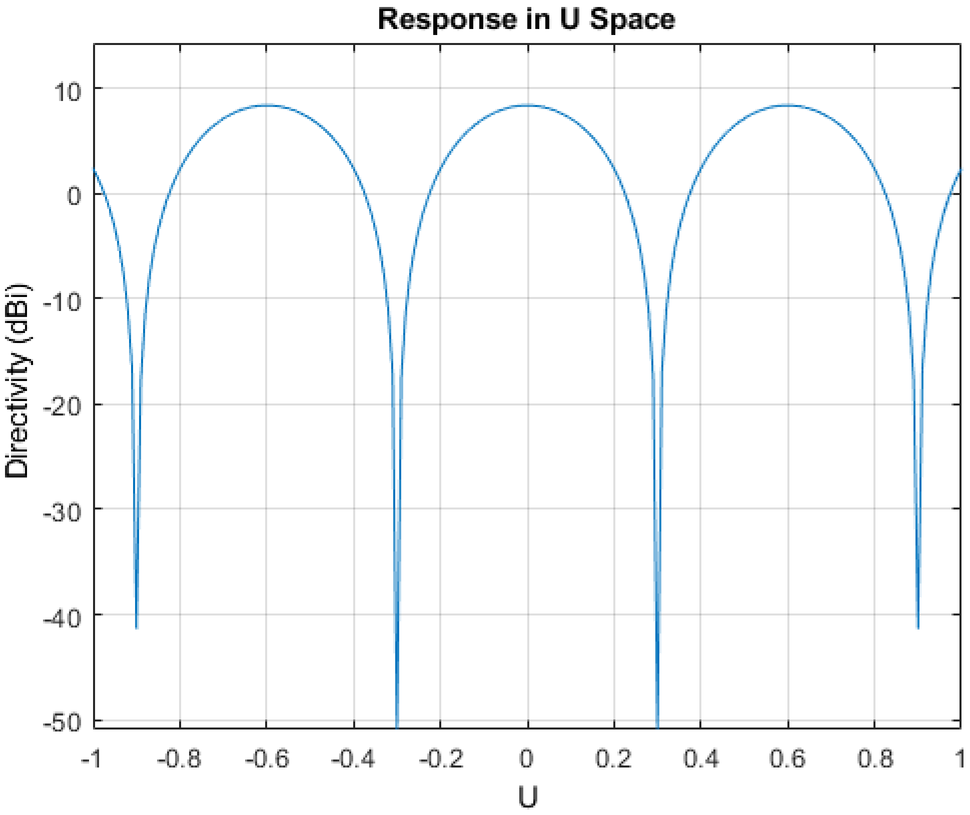
This example shows how to construct a rectangular lattice 3-by-2 URA. Plot the $u$ cut of the array response in $u-v$ space.

```
ha = phased.URA('Size',[3 2]);
c = physconst('lightspeed');
plotResponse(ha,1e9,c,'Format','UV');
```



Plot the directivity.

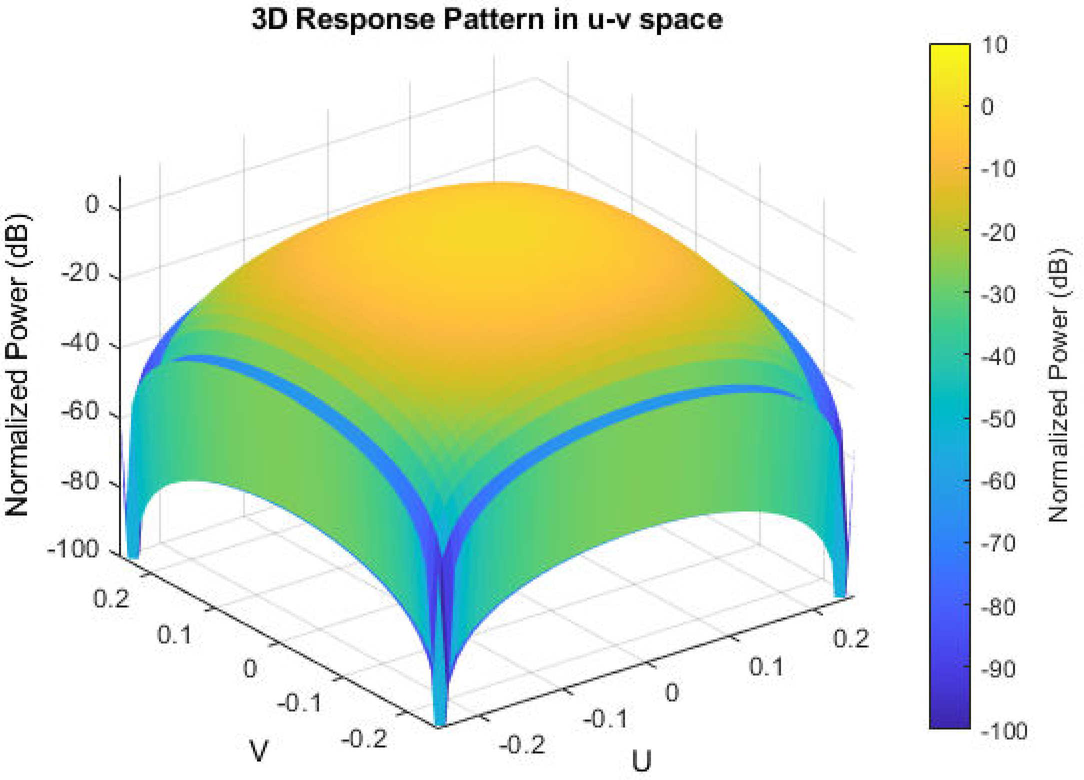
```
plotResponse(ha,1e9,c,'Format','UV','Unit','dbi');
```



### Array Response of URA for Subrange of U/V Space

This example shows how to construct a 5-by-5 square URA and plot the 3-D response in *u*/*v* space. However, restrict the range in *u*/*v* space using the `UGrid` and `VGrid` parameters.

```
ha = phased.URA([5,5]);
fc = 5e8;
c = physconst('LightSpeed');
plotResponse(ha,fc,c,'RespCut','3D','Format','UV',...
    'UGrid',[-0.25:.01:.25],'VGrid',[-0.25:.01:.25]);
```



### Array Response of URA with Two Sets of Weights

This example shows how to construct a square 5-by-5 URA array having elements spaced 0.3 meters apart. Apply both uniform weights and tapered weights at a single frequency using the `Weights` parameter. Choose the tapered weight values to be smallest at the edges and increasing towards the center. Then, show that the tapered weight set reduces the adjacent sidelobes while broadening the main lobe.

```
ha = phased.URA('Size',[5 5],'ElementSpacing',[0.3,0.3]);
fc = 1e9;
c = physconst('LightSpeed');
```

```
wts1 = ones(5,5);
wts1 = wts1(:);
wts1 = wts1/sum(wts1);
wts2 = 0.3*ones(5,5);
wts2(2:4,2:4) = 0.7;
wts2(3,3) = 1;
wts2 = wts2(:);
wts2 = wts2/sum(wts2);
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar','Weights',[wts1,wts2]);
```

# plotGratingLobeDiagram

**System object:** `phased.URA`
**Package:** `phased`

Plot grating lobe diagram of array

## Syntax

```
plotGratingLobeDiagram(H,FREQ)
plotGratingLobeDiagram(H,FREQ,ANGLE)
plotGratingLobeDiagram(H,FREQ,ANGLE,C)
plotGratingLobeDiagram(H,FREQ,ANGLE,C,F0)
hPlot = plotGratingLobeDiagram( ___ )
```

## Description

`plotGratingLobeDiagram(H,FREQ)` plots the grating lobe diagram of an array in the *u-v* coordinate system. The System object `H` specifies the array. The argument `FREQ` specifies the signal frequency and phase-shifter frequency. The array, by default, is steered to 0° azimuth and 0° elevation.

A grating lobe diagram displays the positions of the peaks of the narrowband array pattern. The array pattern depends only upon the geometry of the array and not upon the types of elements which make up the array. Visible and nonvisible grating lobes are displayed as open circles. Only grating lobe peaks near the location of the mainlobe are shown. The mainlobe itself is displayed as a filled circle.

`plotGratingLobeDiagram(H,FREQ,ANGLE)`, in addition, specifies the array steering angle, `ANGLE`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C)`, in addition, specifies the propagation speed by `C`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C,F0)`, in addition, specifies an array phase-shifter frequency, `F0`, that differs from the signal frequency, `FREQ`. This argument is useful when the signal no longer satisfies the narrowband assumption and, allows you to estimate the size of beam squint.

`hPlot = plotGratingLobeDiagram( ___ )` returns the handle to the plot for any of the input syntax forms.

## Input Arguments

**`H`**

Antenna or microphone array, specified as a System object.

**`FREQ`**

Signal frequency, specified as a scalar. Frequency units are hertz. Values must lie within a range specified by the frequency property of the array elements contained in `H.Element`. The frequency property is named `FrequencyRange` or `FrequencyVector`, depending on the element type.

**`ANGLE`**

Array steering angle, specified as either a 2-by-1 vector or a scalar. If `ANGLE` is a vector, it takes the form `[azimuth;elevation]`. The azimuth angle must lie in the range `[-180°,180°]`. The elevation angle must lie in the range `[-90°,90°]`. All angle values are specified in degrees. If the argument `ANGLE` is a scalar, it specifies only the azimuth angle where the corresponding elevation angle is 0°.

**Default:** `[0;0]`

**`C`**

Signal propagation speed, specified as a scalar. Units are meters per second.

**Default:** Speed of light in vacuum

**`F0`**

Phase-shifter frequency of the array, specified as a scalar. Frequency units are hertz When this argument is omitted, the phase-shifter frequency is assumed to be the signal frequency, `FREQ`.

**Default:** `FREQ`

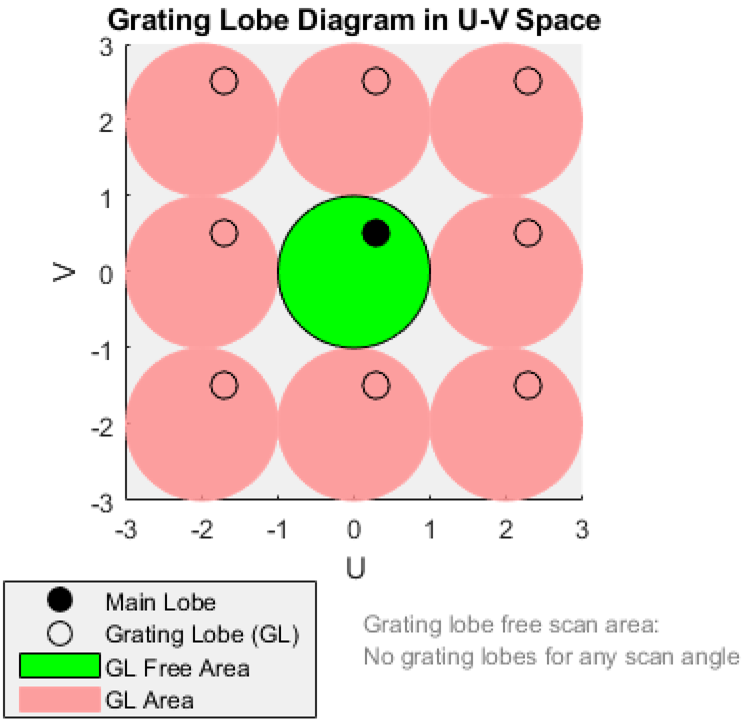
## Examples

### Grating Lobe Diagram for Microphone URA

Plot the grating lobe diagram for an 11-by-9-element uniform rectangular array having element spacing equal to one-half wavelength.

Assume the operating frequency of the array is 10 kHz. All elements are omnidirectional microphone elements. Steer the array in the direction 20 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is 344.21 m/s at 21 deg C.

```
cair = 344.21;
f = 10.0e3;
lambda = cair/f;
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
array = phased.URA('Element',microphone,'Size',[11,9],...
    'ElementSpacing',0.5*lambda*[1,1]);
plotGratingLobeDiagram(array,f,[20;30],cair);
```



Plot the grating lobes. The main lobe of the array is indicated by a filled black circle. The grating lobes in visible and nonvisible regions are indicated by unfilled black circles. The visible region is the region in u-v coordinates for which $u^2 + v^2 \leq 1$. The visible region is shown as a unit circle centered at the origin. Because the array spacing is less than one-half wavelength, there are no grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it coincides with the visible region.

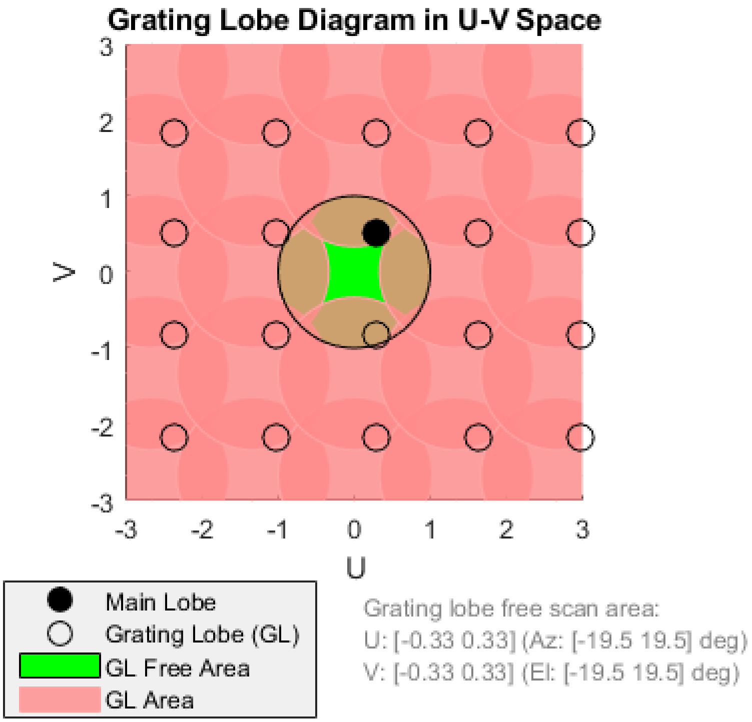
The white areas of the diagram indicate a region where no grating lobes are possible.

### Create Grating Lobe Diagram for Undersampled Microphone URA

Plot the grating lobe diagram for an 11-by-9-element uniform rectangular array having element spacing greater than one-half wavelength. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 10 kHz and the spacing between elements is 0.75 of a wavelength. All elements are omnidirectional microphone elements. Steer the array in the direction 20 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is 344.21 m/s at 21 deg C.

```
cair = 344.21;
f = 10000;
lambda = cair/f;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
sURA = phased.URA('Element',sMic,'Size',[11,9],...
    'ElementSpacing',0.75*lambda*[1,1]);
plotGratingLobeDiagram(sURA,f,[20;30],cair);
```



The main lobe of the array is indicated by a filled black circle. The grating lobes in visible and nonvisible regions are indicated by unfilled black circles. The visible region is the region in u-v coordinates for which $u^2 + v^2 \leq 1$. The visible region is shown as a unit circle centered at the origin. Because the array spacing is greater than one-half wavelength, there are grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

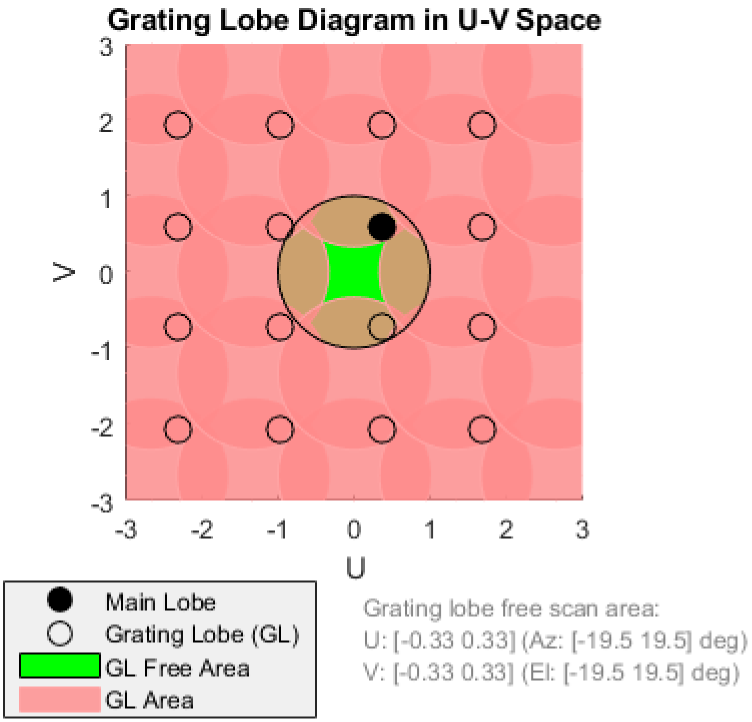
The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the visible region. Because the mainlobe is outside the green area, there is a grating lobe within the visible region.

### Create Grating Lobe Diagram for Microphone URA with Frequency Shift

Plot the grating lobe diagram for an 11-by-9-element uniform rectangular array having element spacing greater than one-half wavelength. Apply a 20% phase-shifter frequency offset. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 10 kHz and the spacing between elements is 0.75 of a wavelength. All elements are omnidirectional microphone elements. Steer the array in the direction 20 degrees in azimuth and 30 degrees in elevation. The shifted frequency is 12000 Hz. The speed of sound in air is 344.21 m/s at 21 deg C.

```
cair = 344.21;
f = 10000;
f0 = 12000;
lambda = cair/f;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
sURA = phased.URA('Element',sMic,'Size',[11,9],...
    'ElementSpacing',0.75*lambda*[1,1]);
plotGratingLobeDiagram(sURA,f,[20;30],cair,f0);
```



The mainlobe of the array is indicated by a filled black circle. The mainlobe has moved from its position in the previous example due to the frequency shift. The grating lobes in visible and nonvisible regions are indicated by unfilled black circles. The visible region is the region in u-v coordinates for which $u^2 + v^2 \leq 1$. The visible region is shown as a unit circle centered at the origin. Because the array spacing is greater than one-half wavelength, there are grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the visible region. Because the mainlobe is outside the green area, there is a grating lobe within the visible region.

# Concepts

## Grating Lobes

Spatial undersampling of a wavefield by an array produces visible grating lobes. If you think of the wavenumber, $k$, as analogous to angular frequency, then you must sample the signal at spatial intervals smaller than $\pi/k_{max}$ (or $\lambda_{min}/2$) to remove aliasing. The appearance of visible grating lobes is also known as spatial aliasing. The variable $k_{max}$ is the largest wavenumber value present in the signal.

The directions of maximum spatial response of a URA are determined by the peaks of the array pattern (alternatively called the beam pattern or array factor.) Peaks other than the main lobe peak are called grating lobes. For a URA, the array pattern depends only on the wavenumber component of the wavefield in the array plane (the $y$ and $z$ directions for the `phased.URA` System object). The wavenumber components are related to the look-direction of an arriving wavefield by $k_y = –2\pi \sin az \cos el/\lambda$ and $k_z = –2\pi \sin el/\lambda$. The angle $az$ is azimuth angle of the arriving wavefield. The angle $el$ is elevation angle of the arriving wavefield. The look-direction points away from the array to the wavefield source.

The array pattern possesses an infinite number of periodically spaced peaks that are equal in strength to the mainlobe peak. If you steer the array to the $az_0, el_0$ azimuth and elevation direction, the array pattern for the URA has its mainlobe peak at the wavenumber value, $k_{y0} = –2\pi \sin az_0 \cos el_0/\lambda$, $k_{z0} = –2\pi \sin el_0/\lambda$. The array pattern has strong peaks at $k_{ym} = k_{y0} + 2\pi\ m/d_y$, $k_{zn} = k_{z0} + 2\pi\ n/d_z$ for integer values of $m$ and $n$. The quantities $d_y$ and $d_z$ are the inter-element spacings in the $y$- and $z$-directions, respectively. Expressed in terms of direction cosines, the grating lobes occur at $u_m = u_0 –m\lambda/d_y$ and $v_n = v_0 –n\lambda/d_z$. The main lobe direction cosines are determined by $u_0 = \sin az_0 \cos el_0$ and $v_0 = \sin el_0$ when expressed in terms of the look-direction.

Grating lobes can be visible or nonvisible, depending upon the value of $u_m^2 + v_n^2$. When $u_m^2 + v_n^2 \leq 1$, the look direction represents a visible direction. When the value is greater than one, the grating lobe is non-visible. For each visible grating lobe, you can compute a look direction $(az_{m,n},el_{m,n})$ from $u_m = \sin az_m \cos el_m$ and $v_n = \sin el_n$. The spacing of grating lobes depends upon $\lambda/d$. When $\lambda/d$ is small enough, multiple grating lobe peaks can correspond to physical look-directions.

# step

**System object:** `phased.URA`
**Package:** `phased`

Output responses of array elements

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the responses of the array elements, `RESP`, at the operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Array object

### FREQ

Operating frequencies of array in hertz. FREQ is a row vector of length *L*. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

### ANG

Directions in degrees. ANG is either a 2-by-*M* matrix or a row vector of length *M*.

If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

## Output Arguments

### RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each

of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

## Examples

### Response of 2-by-2 URA of Short-Dipole Antennas

Construct a 2-by-2 rectangular lattice URA of short-dipole antenna elements. Then, find the response of each element at boresight. Assume the operating frequency is 1 GHz.

```
sSD = phased.ShortDipoleAntennaElement;
sURA = phased.URA('Element',sSD,'Size',[2 2]);
fc = 1e9;
ang = [0;0];
resp = step(sURA,fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

# viewArray

**System object:** `phased.URA`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray(___)
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray(___)` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### ShowIndex

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

### ShowNormals

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

### ShowTaper

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

### Title

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

### hPlot

Handle of array elements in figure window.

## Examples

### Geometry, Normal Directions, and Indices of URA Elements

This example shows how to display the element positions, normal directions, and indices for all elements of a 4-by-4 square URA.

```
ha = phased.URA(4);
viewArray(ha,'ShowNormals',true,'ShowIndex','All');
```

# phased.WidebandBackscatterRadarTarget

**Package:** `phased`

Backscatter wideband signal from radar target

## Description

The `phased.WidebandBackscatterRadarTarget` System object models the backscattering of a wideband signal from a target. Backscattering is a special case of radar target scattering where the incident and reflected angles are the same. This type of scattering applies to monostatic radar configurations. The radar cross-section determines the backscattering response of a target to an incoming signal. This System object lets you specify an angle-dependent radar cross-section model that covers a range of incident angles. The wideband signal is decomposed into frequency subbands which are backscattered independently and then recombined.

This System object creates a backscattered signal for polarized or nonpolarized signals. Although electromagnetic radar signals are polarized, you can often ignore polarization in your simulation and process the signals as scalars. To ignore polarization, specify the `EnablePolarization` property as `false`. To employ polarization, specify `EnablePolarization` as `true`.

For nonpolarized signals, specify the radar cross section (RCS) as an array of values at discrete azimuth and elevation angles and discrete frequencies. The System object interpolates values for incident angles between array points. For polarized signals, specify the radar scattering matrix (SCM) using three arrays defined at discrete azimuth and elevation angles and discrete frequencies. These three arrays correspond to the *HH*, *HV*, and *VV* polarization components. The *VH* component is computed from the conjugate symmetry of the *HV* component. *H* and *V* stand for the horizontal and vertical polarization components, respectively.

For both nonpolarized and polarized signals, you can employ one of four Swerling models to generate random fluctuations in the RCS or radar scattering matrix. Choose which model using the `Model` property. Then, use the `SeedSource` and `Seed` properties to randomize the fluctuations.

| EnablePolarization | Radar cross-section patterns |
|---|---|
| false | RCSPattern |
| true | ShhPattern, SvvPattern, and ShvPattern |

To compute the propagation delay for specified source and receiver points:

1. Define and set up your radar target. You can set phased.WidebandBackscatterRadarTarget System object properties at construction time or leave them set to their default values. See “Construction” on page 1-2636. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the propagated signal, call the step method . The output of the method depends on the properties of the object. You can change tunable properties at any time.

**Note** Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

target = phased.WidebandBackscatterRadarTarget creates a wideband backscatter radar target System object, target.

target = phased.WidebandBackscatterRadarTarget(Name,Value) creates a wideband backscatter radar target object, with each specified property Name set to the specified Value. You can specify additional name and value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### EnablePolarization — Enable polarized signals

false (default) | true

Option to enable processing of polarized signals, specified as `false` or `true`. Set this property to `true` to allow the target to simulate the reflection of polarized radiation. Set this property to `false` to ignore polarization.

Example: `true`

### `FrequencyVector` — Wideband backscatter pattern frequencies

`[0,1e20]` (default) | real-valued row vector in strictly increasing order

Specify the wideband backscatter pattern frequencies used in the RCS or SCM matrices. The elements of this vector must be in strictly increasing order. The target has no response outside this frequency range. Frequencies are defined with respect to the physical frequency band, not the baseband. Frequency units are in hertz.

### `AzimuthAngles` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the azimuth angles as a length *P* vector. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

### `ElevationAngles` — Elevation angles

`[-90:90]` (default) | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the elevation angles as a length *Q* vector. *Q* must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

### `RCSPattern` — Radar cross-section pattern

`ones(181,361)` (default) | *Q*-by-*P* real-valued matrix | *Q*-by-*P*-by-*K* real-valued array | 1-by-*P*-by-*K* real-valued array | *K*-by-*P* real-valued matrix

Radar cross-section pattern, specified as a real-valued matrix or array.

| Dimensions | Application |
|---|---|
| *Q*-by-*P* matrix | Specifies a matrix of RCS values as a function of *Q* elevation angles and *P* azimuth angles. The same RCS matrix is used for all frequencies. |
| *Q*-by-*P*-by-*K* array | Specifies an array of RCS patterns as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If K = 1, the RCS pattern is equivalent to a *Q*-by-*P* matrix. |
| 1-by-*P*-by-*K* array | Specifies a matrix of RCS values as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle. |
| *K*-by-*P* matrix | |

- *Q* is the length of the vector specified by the `ElevationAngles` property.
- *P* is the length of the vector specified by the `AzimuthAngles` property.
- *K* is the number of frequencies specified by the `FrequencyVector` property.

You can specify patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the `step` method. Howerver, you can use one pattern to model *L* multiple targets.

RCS units are in square meters.

Example: `[1,1;1,1]`

**Dependencies**

To enable this property, set the `EnablePolarization` property to `false`.

Data Types: `double`

### `ShhPattern` — Radar scattering matrix *HH* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*K* complex-valued array | 1-by-*P*-by-*K* complex-valued array | *K*-by-*P* complex-valued matrix

Radar scattering matrix (SCM) *HH* polarization component, specified as a complex-valued matrix or array.

| Dimensions | Application |
|---|---|
| *Q*-by-*P* matrix | Specifies the scattering matrix polarization component as a function of *Q* elevation angles and *P* azimuth angles. The same SCM matrix is used for all frequencies. |
| *Q*-by-*P*-by-*K* array | Specifies the scattering matrix polarization component as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If *K* = *1*, the RCS pattern is equivalent to a *Q*-by-*P* matrix. |
| 1-by-*P*-by-*K* array | Specifies the scattering matrix polarization component as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle. |
| *K*-by-*P* matrix | |

- *Q* is the length of the vector specified by the `ElevationAngles` property.
- *P* is the length of the vector specified by the `AzimuthAngles` property.
- *K* is the number of frequencies specified by the `FrequencyVector` property.

You can specify polarization component patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the `step` method. You can, however, use one pattern to model *L* multiple targets.

SCM units are in square-meters.

Example: `[1,1;1i,1i]`

#### Dependencies

To enable this property, set the `EnablePolarization` property to `true`.

Data Types: `double`
Complex Number Support: Yes

### `SvvPattern` — Radar scattering matrix *VV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*K* complex-valued array | 1-by-*P*-by-*K* complex-valued array | *K*-by-*P* complex-valued matrix

Radar scattering matrix *VV-pol* component, specified as a complex-valued vector, matrix, or array. Different dimension cases have different applications.

| Dimensions | Application |
|---|---|
| $Q$-by-$P$ matrix | Specifies the scattering matrix polarization component as a function of $Q$ elevation angles and $P$ azimuth angles. The same SCM matrix is used for all frequencies. |
| $Q$-by-$P$-by-$K$ array | Specifies the scattering matrix polarization component as a function of $Q$ elevation angles, $P$ azimuth angles, and $K$ frequencies. If $K = 1$, the RCS pattern is equivalent to a $Q$-by-$P$ matrix. |
| 1-by-$P$-by-$K$ array | Specifies the scattering matrix polarization component as a function of $P$ azimuth angles and $K$ frequencies. These dimension formats apply when there is only one elevation angle. |
| $K$-by-$P$ matrix | |

- $Q$ is the length of the vector specified by the `ElevationAngles` property.
- $P$ is the length of the vector specified by the `AzimuthAngles` property.
- $K$ is the number of frequencies specified by the `FrequencyVector` property.

You can specify polarization component patterns for $L$ targets by putting $L$ patterns into a cell array. All patterns must have the same dimensions. The value of $L$ must match the column dimensions of the signals passed as input into the `step` method. You can, however, use one pattern to model $L$ multiple targets.

SCM units are in square-meters.

Example: `[1,1;1i,1i]`

#### Dependencies

To enable this property, set the `EnablePolarization` property to `true`.

Data Types: `double`
Complex Number Support: Yes

### `ShvPattern` — Radar scattering matrix *HV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*K* complex-valued array | 1-by-*P*-by-*K* complex-valued vector | *K*-by-*P* complex-valued matrix

Radar scattering matrix (SCM) *HV-pol* component, specified as a complex-valued vector, matrix, or array. Different dimension cases have different applications.

| Dimensions | Application |
|---|---|
| *Q*-by-*P* matrix | Specifies the scattering matrix polarization component as a function of *Q* elevation angles and *P* azimuth angles. The same SCM matrix is used for all frequencies. |
| *Q*-by-*P*-by-*K* array | Specifies the scattering matrix polarization component as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If *K* = *1*, the RCS pattern is equivalent to a *Q*-by-*P* matrix. |
| 1-by-*P*-by-*K* array | Specifies the scattering matrix polarization component as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle. |
| *K*-by-*P* matrix | |

- *Q* is the length of the vector specified by the `ElevationAngles` property.
- *P* is the length of the vector specified by the `AzimuthAngles` property.
- *K* is the number of frequencies specified by the `FrequencyVector` property.

You can specify polarization component patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the `step` method. You can, however, use one pattern to model *L* multiple targets.

SCM units are in square-meters.

Example: `[1,1;1i,1i]`

#### Dependencies

To enable this property, set the `EnablePolarization` property to `true`.

Data Types: `double`

Complex Number Support: Yes

### `Model` — Target fluctuation model

`'Nonfluctuating'` (default) | `'Swerling1'` | `'Swerling2'` | `'Swerling3'` | `'Swerling4'`

Target fluctuation model, specified as `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, use the `update` input argument when calling the `step` method.

Example: `'Swerling3'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

### `NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

### `SeedSource` — Seed source of random number generator for RCS fluctuation model

`'Auto'` (default) | `'Property'`

Seed source of random number generator for RCS fluctuation model, specified as `'Auto'` or `'Property'`. When you set this property to:

- `'Auto'`, the object generates random numbers using the default MATLAB random number generator.
- `'Property'`, you specify the random number generator seed using the `Seed` property.

When using this object with Parallel Computing Toolbox software, set this property to `'Auto'`.

#### Dependencies

To enable this property, set the `Model` property to `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`.

Data Types: `char`

### `Seed` — Random number generator seed

`0` (default) | nonnegative integer less than $2^{32}$

Random number generator seed, specified as a nonnegative integer less than $2^{32}$. .

Example: `32301`

#### Dependencies

To enable this property, set the `SeedSource` property to `'Property'`.

Data Types: `double`

## Methods

| | |
|---|---|
| reset | Reset states of System object |
| step | Backscatter wideband signal from radar target |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

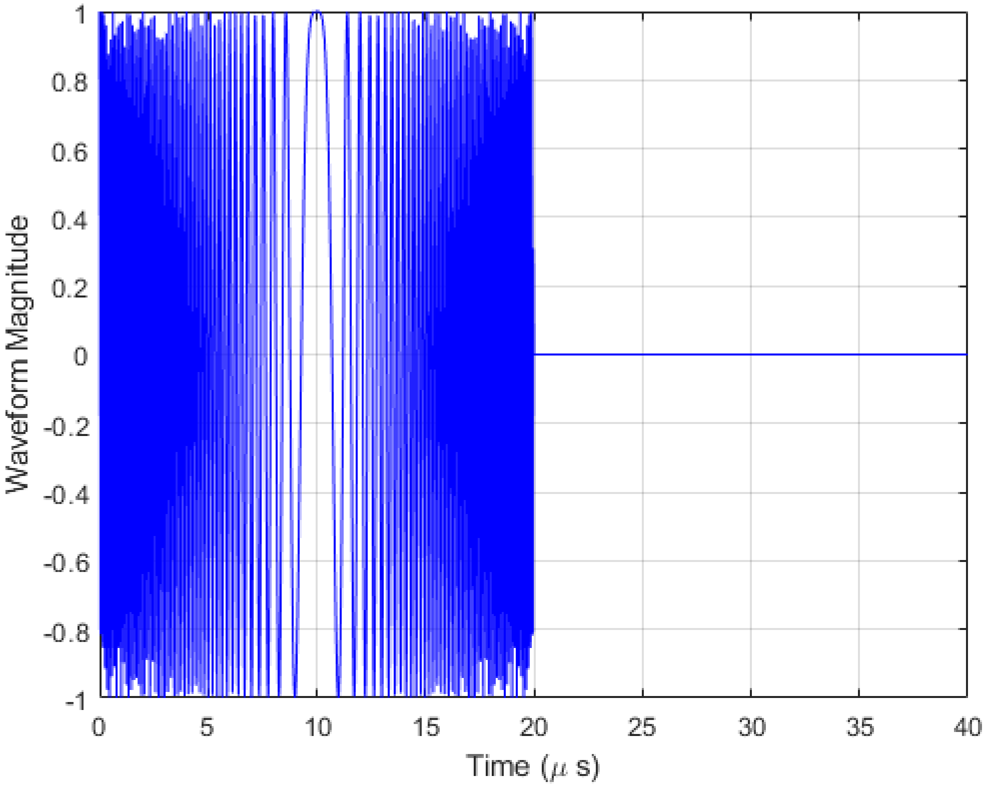
## Examples

### Backscatter Nonpolarized Wideband Signal

Calculate the reflected radar signal from a nonfluctuating point target having a peak RCS of 10.0 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10��30� in azimuth and 5��15� in elevation. The RCS peaks at 20� azimuth and 10� elevation. The RCS also has a frequency dependence and is specified at 5 frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform having a 20 MHz bandwidth.

Create and plot the wideband signal.

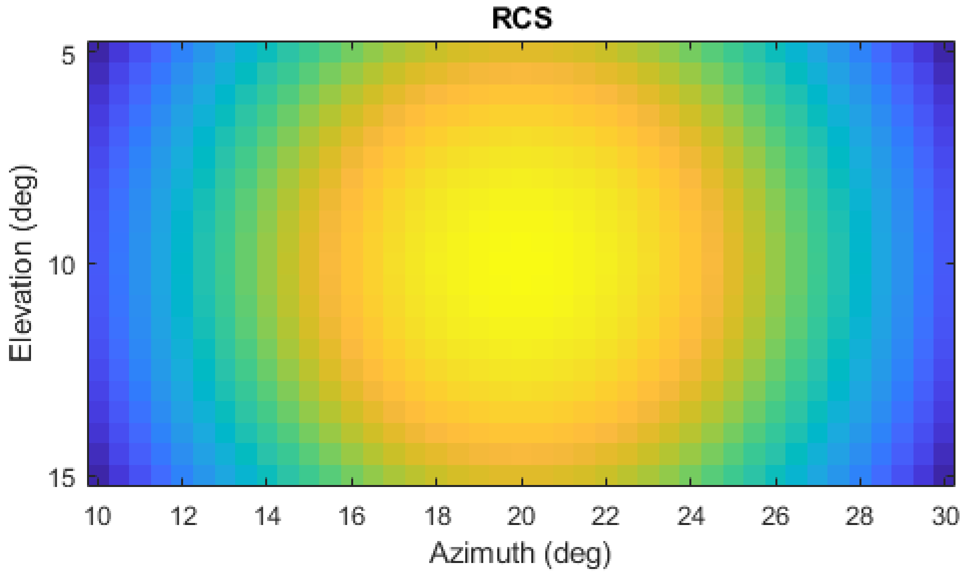
```
c = physconst('LightSpeed');
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100e6;
bw = 20e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
grid
```



Create an RCS pattern at five different frequencies within the signal bandwidth using a simplified frequency dependence. The frequency dependence is unity at the operating frequency and falls off outside that frequency. Realistic frequency dependencies are more complicated. Plot the RCS pattern for one of the frequencies.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azpattern = [10.0:0.5:30.0];
elpattern = [5.0:0.5:15.0];
rcspattern0 = 10.0*cosd(4*(elpattern - elmax))'*cosd(4*(azpattern - azmax));
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
```

```
end
imagesc(azpattern,elpattern,abs(rcspattern(:,:,1)))
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```

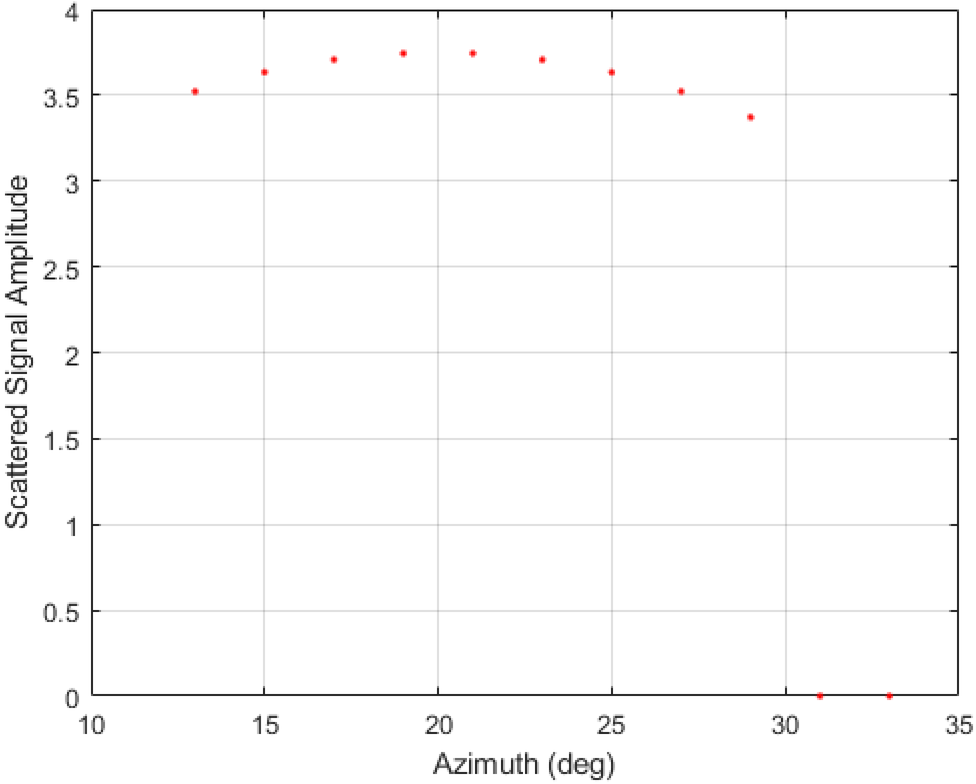


Create the `phased.WidebandBackscatterRadarTarget` System object�.

```
target = phased.WidebandBackscatterRadarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpattern,'ElevationAngles',elpattern,...
    'RCSPattern',rcspattern,'OperatingFrequency',fc,'NumSubbands',32, ...
    'FrequencyVector',fvec);
```

For a sequence of incident azimuth angles at constant elevation, find and plot the reflected signal amplitude.

```
az0 = 13.0;
el = 10.0;
az = az0 + [0:2:20];
naz = length(az);
magsig = zeros(1,naz);
for k = 1:naz
    y = target(wav,[az(k);el]);
    magsig(k) = max(abs(y));
end
plot(az,magsig,'r.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



### Backscatter Nonpolarized Wideband Signal from Fluctuating Target

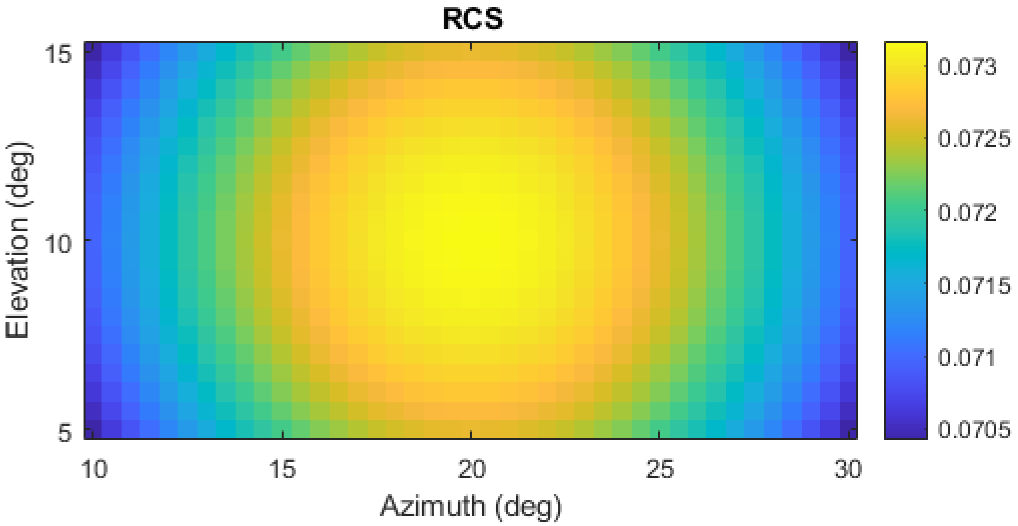
Calculate the reflected radar signal from a Swerling 4 fluctuating point target with a peak RCS of 0.1 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10��30� in azimuth and 5��15� in elevation. The RCS peaks at 20� azimuth and 10� elevation at a value of 0.1 m^2. The RCS also has a frequency dependence and is specified at five frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform with a 20 MHz bandwidth. The sampling frequency is 50 MHz.

Create and plot the wideband signal.

```
c = physconst('LightSpeed');
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100.0e6;
bw = 20.0e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
```

Create an RCS pattern at five different frequencies within the signal bandwidth using a simple frequency dependence. The frequency dependence is designed to be unity at the operating frequency and fall off outside that band. Realistic frequency dependencies are more complicated.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azangs = [10.0:0.5:30.0];
elangs = [5.0:0.5:15.0];
rcspattern0 = 0.1*(cosd((elangs - elmax))'*cosd((azangs - azmax))).^2;
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
end
imagesc(azangs,elangs,abs(rcspattern(:,:,5)))
axis image
axis xy
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
colorbar
```



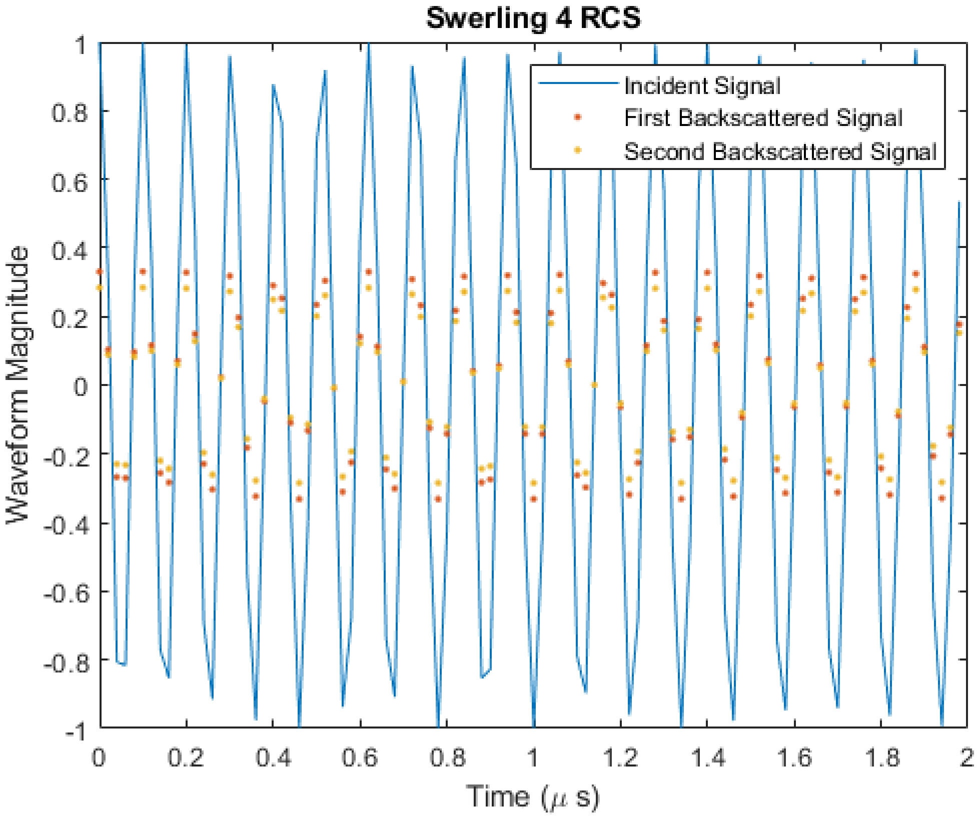
Create the `phased.WidebandBackscatterRadarTarget` System object�.

```
target = phased.WidebandBackscatterRadarTarget('Model','Swerling4', ...
    'SeedSource','Property','Seed',100213,'AzimuthAngles',azangs, ...
    'ElevationAngles',elangs,'RCSPattern',rcspattern, ...
    'OperatingFrequency',fc,'NumSubbands',32,'FrequencyVector',fvec);
```

Find and plot 100 samples of the incident signal and two sequential reflected signals at 10� azimuth and 10� elevation. Update the RCS at each execution of the System object�.

```
az = 10.0;
el = 10.0;
refl_wav1 = target(wav,[az;el],true);
```

```
refl_wav2 = target(wav,[az;el],true);
n = 100;
plot([0:(n-1)]/fs*1e6,real(wav(1:n)))
hold on
plot([0:(n-1)]/fs*1e6,real(refl_wav1(1:n)),'.')
plot([0:(n-1)]/fs*1e6,real(refl_wav2(1:n)),'.')
hold off
legend('Incident Signal','First Backscattered Signal','Second Backscattered Signal')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
title('Swerling 4 RCS')
```



# More About

## Backscattered Wideband Signals

Wideband signals are decomposed into narrowband signals which are reflected from the target independently.

For a narrowband nonpolarized signal, the reflected signal, *Y*, is

$$Y = \sqrt{G} \cdot X,$$

where:

- *X* is the incoming signal.
- *G* is the target gain factor, a dimensionless quantity given by

$$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, *X*, is replaced by a vector signal, $(E_H, E_V)$, with horizontal and vertical components. The scattering matrix, *S*, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see [1] or [2].

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_{\mathrm{B}}$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_{\mathrm{s}}/N_{\mathrm{B}}$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N_B - 1)f_s}{2N_B} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

“Swerling Target Models”

**Introduced in R2016b**

# reset

**System object:** `phased.WidebandBackscatterRadarTarget`<br>
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(target)
```

## Description

`reset(target)` resets the internal state of the `phased.WidebandBackscatterRadarTarget` object, `target`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

## Input Arguments

**`target` — Wideband backscatter radar target**

`phased.WidebandBackscatterRadarTarget` System object

Wideband backscatter radar target, specified as a `phased.WidebandBackscatterRadarTarget` System object.

**Introduced in R2016b**

# step

**System object:** `phased.WidebandBackscatterRadarTarget`
**Package:** `phased`

Backscatter wideband signal from radar target

## Syntax

```
refl_sig = step(target,sig,ang)
refl_sig = step(target,sig,ang,update)

refl_sig = step(target,sig,ang,laxes)
refl_sig = step(target,sig,ang,laxes,update)
```

## Description

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`refl_sig = step(target,sig,ang)` returns the reflected signal, `refl_sig`, of an incident nonpolarized signal, `sig`. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to `'Nonfluctuating'`. In this case, the values specified in the `RCSPattern` property are used to compute the RCS values for the incident and reflected directions, `ang`.

`refl_sig = step(target,sig,ang,update)` uses `update` to control whether to update the RCS values. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to one of the fluctuating RCS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new RCS value is generated. If `update` is `false`, the previous RCS value is used.

`refl_sig = step(target,sig,ang,laxes)` returns the reflected signal, `refl_sig`, of an incident polarized signal, `sig`. This syntax applies when you set

EnablePolarization to true and the Model property to 'Nonfluctuating'. The values specified in the ShhPattern, SvvPattern, and ShvPattern properties are used to compute the backscattering matrices for the incident directions, ang. The laxes argument specifies a local coordinate system used to define the horizontal and vertical polarization components.

refl_sig = step(target,sig,ang,laxes,update) uses the update argument to control whether to update the scattering matrix values. This syntax applies when you set the EnablePolarization property to true and the Model property to one of the fluctuating RCS models: 'Swerling1', 'Swerling2', 'Swerling3', or 'Swerling4'. If update is true, a new RCS value is generated. If update is false, the previous RCS value is used.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### target — Wideband backscatter radar target

phased.WidebandBackscatterRadarTarget System object

Backscatter target, specified as a phased.WidebandBackscatterRadarTarget System object.

### sig — Wideband signal

*N*-by-*M* complex-valued matrix | *1*-by-*M* struct array containing complex-valued fields

- Wideband nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples and *M* is the number of independent signals reflecting off the target. Each column contains an independent signal reflected from the target.

  The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

- Wideband polarized signal, specified as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target. Each `struct` element contains three *N*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

**`ang` — Incident signal direction**
2-by-1 real-valued column vector of positive values | 2-by-*M* real-valued matrix of positive values

Incident signal direction, specified as a real-valued column 2-by-1 vector or 2-by-*M* matrix of positive values. Each column of `ang` specifies the incident direction of the corresponding signal in the form `[AzimuthAngle;ElevationAngle]`. The number of columns in `ang` must match the number of independent signals in `sig`. Units are in degrees.

Example: `[30;45]`

Data Types: `double`

**`update` — Update RCS**
`false` (default) | `true`

Option to enable the RCS values for fluctuation models to update, specified as `false` or `true`. When `update` is `true`, a new RCS value is generated with each call to the `step` method. If `update` is `false`, the RCS remains unchanged with each call to `step`.

Data Types: `logical`

**`laxes` — Local coordinate matrix**
`eye(3,3)` (default) | 3-by-3 real-valued orthonormal matrix | 3-by-3-by-*M* real-valued array

Local coordinate system matrix, specified as a 3-by-3 real-valued orthonormal matrix or a 3-by-3-by-*M* real-valued array. The matrix columns specify the local coordinate system orthonormal *x*-axis, *y*-axis, and *z*-axis, respectively. Each axis is a vector of the form *(x;y;z)* with respect to the global coordinate system. When `sig` has only one signal, `laxes` is a 3-by-3 matrix. When `sig` has multiple signals, you can use a single 3-by-3 matrix for multiple signals in `sig`. In this case, all targets have the same local coordinate systems. When you specify `laxes` as a 3-by-3-by-*M* array, each page (third index) defines a 3-by-3 local coordinate matrix for the corresponding target.

Example: `[1,0,0;0,0.7071,-0.7071;0,0.7071,0.7071]`

Data Types: `double`

## Output Arguments

### `refl_sig` — Wideband reflected signal

*N*-by-*M* complex-valued matrix | *1*-by-*M* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, returned as an *N*-by-*M* complex-valued matrix. Each column contains an independent signal reflected from the target.
- Wideband polarized signal, returned as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target.

The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to a reflecting angle.

For polarized fields, the `struct` element contains three *N*-by-1 complex-valued column vectors: `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The output `refl_sig` contains signal samples arriving at the signal destination within the current input time frame. When the propagation time from source to destination exceeds the current time frame duration, the output does not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

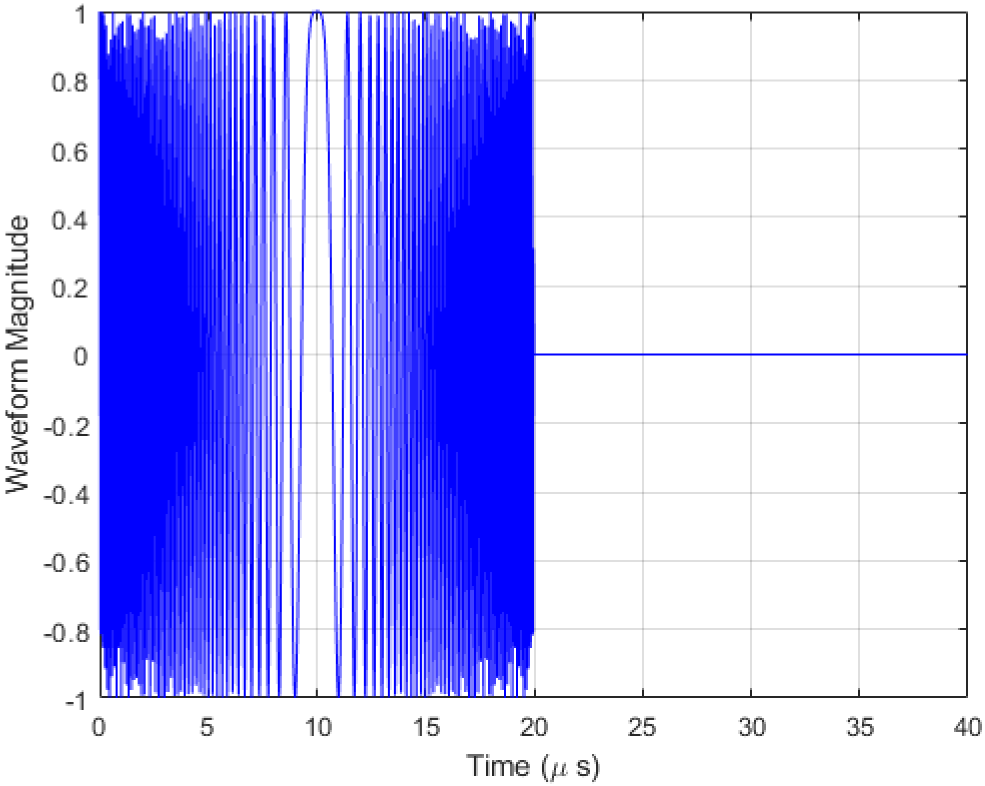
## Examples

### Backscatter Nonpolarized Wideband Signal

Calculate the reflected radar signal from a nonfluctuating point target having a peak RCS of 10.0 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10��30� in azimuth and 5��15� in elevation. The RCS peaks at 20� azimuth and 10� elevation. The RCS also has a frequency dependence and is specified at 5 frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform having a 20 MHz bandwidth.

Create and plot the wideband signal.

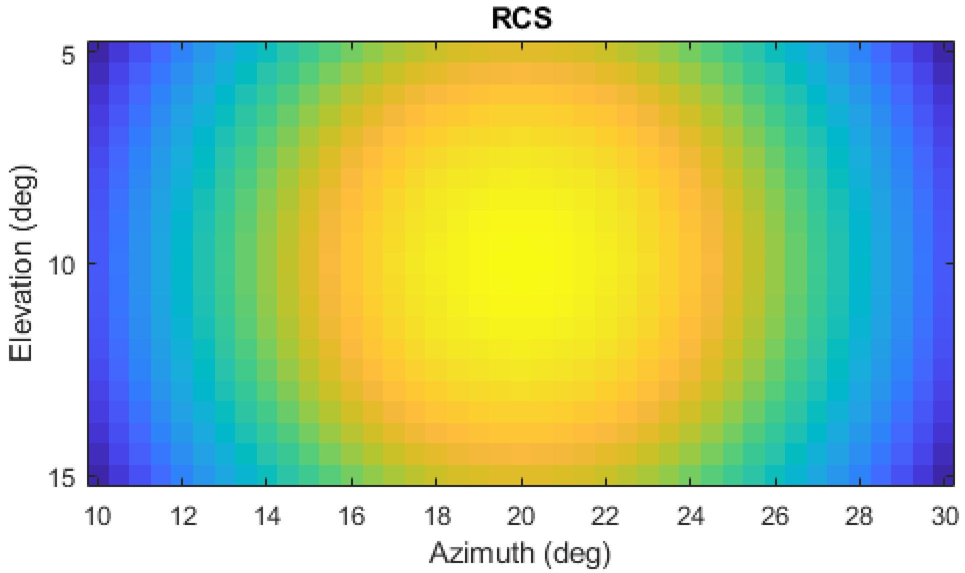
```
c = physconst('LightSpeed');
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100e6;
bw = 20e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
grid
```



Create an RCS pattern at five different frequencies within the signal bandwidth using a simplified frequency dependence. The frequency dependence is unity at the operating frequency and falls off outside that frequency. Realistic frequency dependencies are more complicated. Plot the RCS pattern for one of the frequencies.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azpattern = [10.0:0.5:30.0];
elpattern = [5.0:0.5:15.0];
rcspattern0 = 10.0*cosd(4*(elpattern - elmax))'*cosd(4*(azpattern - azmax));
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
```

```
end
imagesc(azpattern,elpattern,abs(rcspattern(:,:,1)))
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```

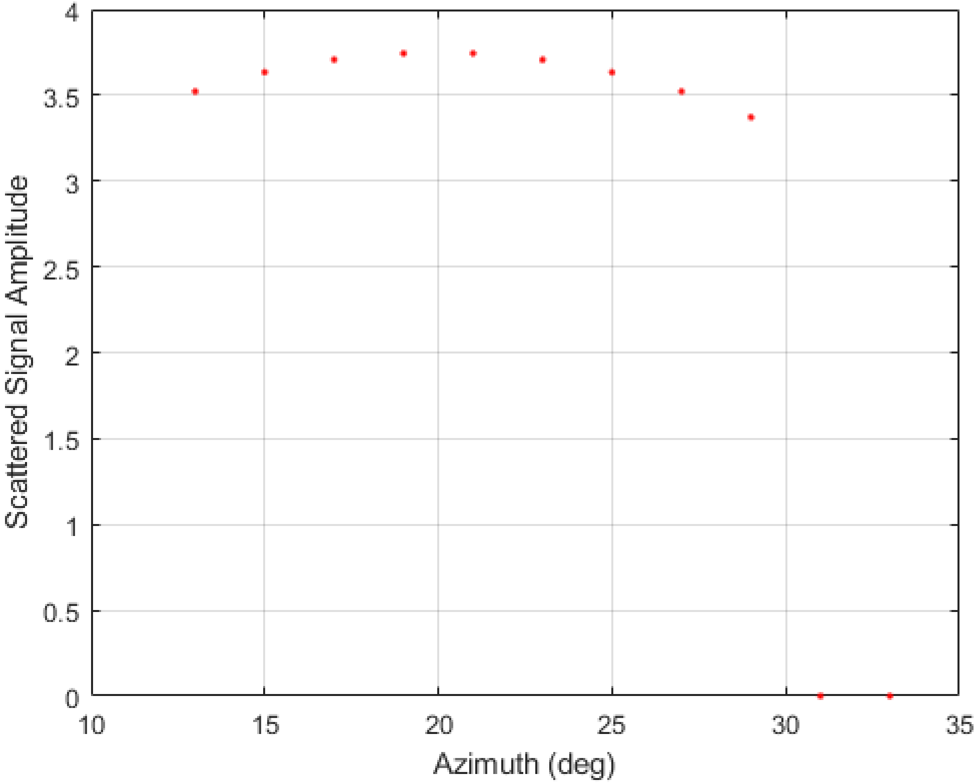


Create the `phased.WidebandBackscatterRadarTarget` System object�.

```
target = phased.WidebandBackscatterRadarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpattern,'ElevationAngles',elpattern,...
    'RCSPattern',rcspattern,'OperatingFrequency',fc,'NumSubbands',32, ...
    'FrequencyVector',fvec);
```

For a sequence of incident azimuth angles at constant elevation, find and plot the reflected signal amplitude.

```
az0 = 13.0;
el = 10.0;
az = az0 + [0:2:20];
naz = length(az);
magsig = zeros(1,naz);
for k = 1:naz
    y = target(wav,[az(k);el]);
    magsig(k) = max(abs(y));
end
plot(az,magsig,'r.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



### Backscatter Nonpolarized Wideband Signal from Fluctuating Target

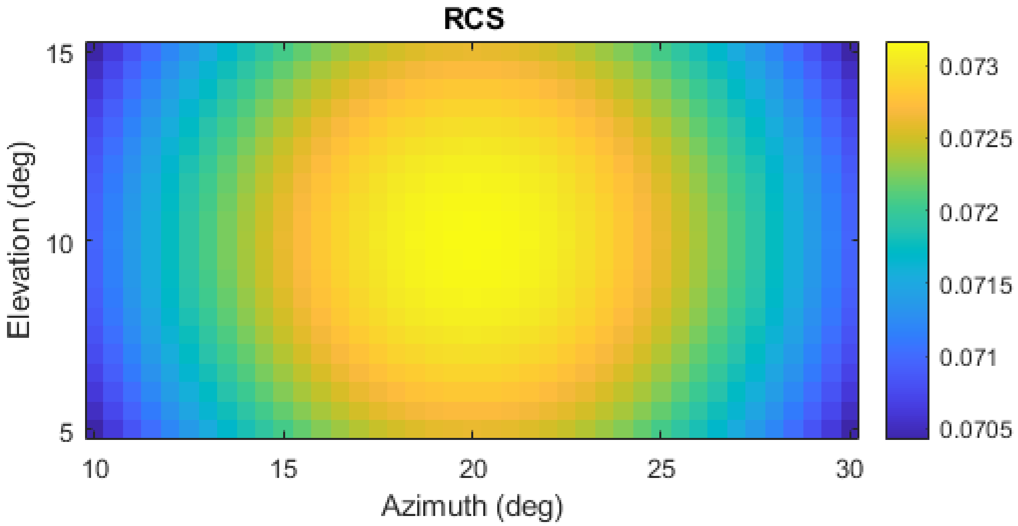
Calculate the reflected radar signal from a Swerling 4 fluctuating point target with a peak RCS of 0.1 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10��30� in azimuth and 5��15� in elevation. The RCS peaks at 20� azimuth and 10� elevation at a value of 0.1 m^2. The RCS also has a frequency dependence and is specified at five frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform with a 20 MHz bandwidth. The sampling frequency is 50 MHz.

Create and plot the wideband signal.

```
c = physconst('LightSpeed');
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100.0e6;
bw = 20.0e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
```

Create an RCS pattern at five different frequencies within the signal bandwidth using a simple frequency dependence. The frequency dependence is designed to be unity at the operating frequency and fall off outside that band. Realistic frequency dependencies are more complicated.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azangs = [10.0:0.5:30.0];
elangs = [5.0:0.5:15.0];
rcspattern0 = 0.1*(cosd((elangs - elmax))'*cosd((azangs - azmax))).^2;
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
end
imagesc(azangs,elangs,abs(rcspattern(:,:,5)))
axis image
axis xy
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
colorbar
```



Create the `phased.WidebandBackscatterRadarTarget` System object�.

```
target = phased.WidebandBackscatterRadarTarget('Model','Swerling4', ...
    'SeedSource','Property','Seed',100213,'AzimuthAngles',azangs, ...
    'ElevationAngles',elangs,'RCSPattern',rcspattern, ...
    'OperatingFrequency',fc,'NumSubbands',32,'FrequencyVector',fvec);
```

Find and plot 100 samples of the incident signal and two sequential reflected signals at 10� azimuth and 10� elevation. Update the RCS at each execution of the System object�.

```
az = 10.0;
el = 10.0;
refl_wav1 = target(wav,[az;el],true);
```

```
refl_wav2 = target(wav,[az;el],true);
n = 100;
plot([0:(n-1)]/fs*1e6,real(wav(1:n)))

# phased.WidebandCollector

**Package:** `phased`

Wideband signal collector

## Description

The `phased.WidebandCollector` System object implements a wideband signal collector. A collector converts incident wideband wave fields arriving from specified directions into signals to be further processed. Wave fields are incident on antenna and microphone elements, sensor arrays, or subarrays. The object collects signals in one of two ways controlled by the `Wavefront` Wavefront property.

- If the Wavefront property is set to `'Plane'`, the collected signals at each element or subarray are the coherent sum of all incident plane wave fields sampled at each array element or subarray.
- If the Wavefront property is set to `'Unspecified'`, the collected signals are formed from an independent field incident on each individual sensor element.

You can use this object to

- model arriving signals as polarized or non-polarized fields depending upon whether the element or array supports polarization and the value of the Polarization property. Using polarization, you can receive a signal as a polarized electromagnetic field, or receive two independent signals using orthogonal polarization directions.
- model acoustic fields by using nonpolarized microphone and sonar transducer array elements and by setting the “Polarization” on page 1-0 to `'None'`. You must also set the PropagationSpeed to a value appropriate for the medium.
- collect fields at subarrays created by the `phased.ReplicatedSubarray` and `phased.PartitionedArray` objects. You can steer all subarrays in the same direction using the steering angle argument, `STEERANG`, or steer each subarray in a different direction using the subarray element weights argument, `WS`. You cannot set the Wavefront property to `'Unspecified'` for subarrays.

To collect arriving signals at the elements or arrays:

1. Create the `phased.WidebandCollector` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

# Syntax

```
collector = phased.WidebandCollector
collector = phased.WidebandCollector(Name,Value)
```

## Description

`collector = phased.WidebandCollector` creates a wideband signal collector object, `collector`, with default property values.

`collector = phased.WidebandCollector(Name,Value)` creates a wideband signal collector with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `collector = phased.WidebandCollector('Sensor',phased.URA,'CarrierFrequency',300e6)` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The beamformer assumes a carrier frequency of 300 MHz.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `Sensor` — Sensor element or sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox sensor or array

Sensor element or sensor array, specified as a System object belonging to Phased Array System Toolbox. A sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

### `ModulatedInput` — Assume modulated input

`true` (default) | `false`

Set this property to `true` to indicate the input signal is demodulated at a carrier frequency.

Data Types: `logical`

### `CarrierFrequency` — Carrier frequency

`1e9` (default) | positive real-valued scalar

Carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

### NumSubbands — Number of processing subbands

64 (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: 128

Data Types: double

### SensorGainMeasure — Specify sensor gain

'dB' (default) | 'dBi'

Sensor gain measure, specified as 'dB' or 'dBi'.

- When you set this property to 'dB', the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.
- When you set this property to 'dBi', the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values predicted by the radar equation that uses dBi to specify the antenna gain. The computation using the 'dBi' option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor.

Data Types: char

### Wavefront — Type of incoming wavefront

'Plane' (default) | 'Unspecified'

The type of incoming wavefront, specified as 'Plane' or 'Unspecified':

- 'Plane' — input signals are multiple plane waves impinging on the entire array. Each plane wave is received by all collecting elements.
- 'Unspecified' — collected signals are independent fields incident on individual sensor elements. If the Sensor property is an array that contains subarrays, you cannot set the Wavefront property to 'Unspecified'.

Data Types: char

### Polarization — Polarization configuration

'None' (default) | 'Combined' | 'Dual'

Polarization configuration, specified as 'None', 'Combined', or 'Dual'. When you set this property to 'None', the incident fields are considered scalar fields. When you set this property to `'Combined'`, the incident fields are polarized and represent a single arriving signal whose polarization reflects the sensor's inherent polarization. When you set this property to `'Dual'`, the *H* and *V* polarization components of the fields are independent signals.

Example: `'Dual'`

Data Types: `char`

**`WeightsInputPort` — Enable weights input**
`false` (default) | `true`

Enable weights input, specified as `false` or `true`. When `true`, use the object input argument `W` to specify weights. Weights are applied to individual array elements (or at the subarray level when subarrays are supported).

Data Types: `logical`

# Usage

# Syntax

```
Y = collector(X,ANG)
Y = collector(X,ANG,LAXES)
[YH,YV] = collector(X,ANG,LAXES)
[___] = collector(___,W)
[___] = collector(___,STEERANG)
[___] = collector(___,WS)
```

## Description

`Y = collector(X,ANG)` collects the signals, `X`, arriving from the directions specified by `ANG`. `Y` contains the collected signals.

`Y = collector(X,ANG,LAXES)` also specifies `LAXES` as the local coordinate system axes directions. To use this syntax, set the property to `'Combined'`.

`[YH,YV] = collector(X,ANG,LAXES)` returns an H-polarization component of the field, `YH`, and a V-polarization component, `YV`. To use this syntax, set the Polarization property to `'Dual'`.

`[___] = collector(___,W)` also specifies `W` as array element or subarray weights. To use this syntax, set the WeightsInputPort property to `true`.

`[___] = collector(___,STEERANG)` also specifies `STEERANG` as the subarray steering angle. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`.

`[___] = collector(___,WS)` also specifies `WS` as the weights applied to each element within each subarray. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` of that array to `'Custom'`.

## Input Arguments

### X — Arriving signals

complex-valued *M*-by-*L* matrix | complex-valued 1-by-*L* cell array of structures

Arriving signals, specified as a complex-valued *M*-by-*L* matrix or complex-valued 1-by-*L* cell array of structures. *M* is the number of signal samples and *L* is the number of arrival angles. This argument represents the arriving fields.

- If the `Polarization` property value is set to `'None'`, `X` is an *M*-by-*L* matrix.
- If the `Polarization` property value is set to `'Combined'` or `'Dual'`, `X` is a 1-by-*L* cell array of structures. Each cell corresponds to a separate arriving signal. Each `struct` contains three column vectors containing the *X*, *Y*, and *Z* components of the polarized fields defined with respect to the global coordinate system.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Dependencies**

To enable this argument, set the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### ANG — Arrival directions of signals

real-valued 2-by-*L* matrix

Arrival directions of signals, specified as a real-valued 2-by-*L* matrix. Each column specifies an arrival direction in the form `[AzimuthAngle;ElevationAngle]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive. When the Wavefront property is `false`, the number of angles must equal the number of array elements, *N*. Units are in degrees.

Example: `[30,20;45,0]`

Data Types: `double`

### `LAXES` — Local coordinate system

real-valued 3-by-3 orthogonal matrix

Local coordinate system, specified as a real-valued 3-by-3 orthogonal matrix. The matrix columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes with respect to the global coordinate system.

Example: `rotx(30)`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Combined'` or `'Dual'`.

Data Types: `double`

### `W` — Element or subarray weights

*N*-by-1 column vector

Element or subarray weights, specified as a complex-valued *N*-by-1 column vector where *N* is the number of array elements (or subarrays when the array supports subarrays).

#### Dependencies

To enable this argument, set the WeightsInputPort property to `true`.

Data Types: `double`
Complex Number Support: Yes

### `WS` — Subarray element weights

complex-valued $N_{SE}$-by-*N* matrix | 1-by-*N* cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-*N* matrix or 1-by-*N* cell array where *N* is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

#### Dependencies

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

### `STEERANG` — Subarray steering angle

real-valued 2-by-1 vector

Subarray steering angle, specified as a length-2 column vector. The vector has the form `[azimuthAngle;elevationAngle]`. The azimuth angle must be between –180° and

180°, inclusive. The elevation angle must be between –90° and 90°, inclusive. Units are in degrees.

Example: `[20;15]`

**Dependencies**

To enable this argument, set the `Sensor` property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`

Data Types: `double`

## Output Arguments

**Y — Collected signal**
complex-valued *M*-by-*N* matrix

Collected signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the length of the input signal. *N* is the number of array elements (or subarrays when subarrays are supported). Each column corresponds to the signal collected by the corresponding array element (or corresponding subarrays when subarrays are supported).

**Dependencies**

To enable this argument, set the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`

**YH — Collected horizontal polarization signal**
complex-valued *M*-by-*N* matrix

Collected horizontal polarization signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the length of the input signal. *N* is the number of array elements (or subarrays when subarrays are supported). Each column corresponds to the signal collected by the corresponding array element (or corresponding subarrays when subarrays are supported).

**Dependencies**

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`

**YV — Collected vertical polarization signal**
complex-valued *M*-by-*N* matrix

Collected horizontal polarization signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the length of the input signal. *N* is the number of array elements (or subarrays when subarrays are supported). Each column corresponds to the signal collected by the corresponding array element (or corresponding subarrays when subarrays are supported).

**Dependencies**

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Collect Wideband Signal at Single Antenna

Use the `phased.WidebandCollector` System object™ to construct a signal arriving at a single isotropic antenna from 10° azimuth and 30° elevation.

```
antenna = phased.IsotropicAntennaElement;
collector = phased.WidebandCollector('Sensor',antenna);
x = [1;0;-1];
incidentAngle = [10;30];
y = collector(x,incidentAngle);
disp(y)
```

```
   1.0000 + 0.0000i
   0.0000 + 0.0000i
  -1.0000 - 0.0000i
```

### Collect Wideband Signal at 5-Element ULA

Use the wideband collector to construct the signal impinging upon a 5-element ULA of isotropic antennas from 10 degrees azimuth and 30 degrees elevation.

```
array = phased.ULA('NumElements',5);
collector = phased.WidebandCollector('Sensor',array);
x = [1;1;1];
incidentAngle = [10;30];
y = collector(x,incidentAngle);
disp(y)
```

```
  Columns 1 through 4

  -0.9997 + 0.0102i  -0.0051 - 0.9999i   1.0000 + 0.0000i  -0.0051 + 1.0001i
  -0.9999 + 0.0102i  -0.0051 - 1.0000i   1.0000 + 0.0000i  -0.0051 + 1.0000i
  -1.0002 + 0.0102i  -0.0051 - 1.0001i   1.0000 - 0.0000i  -0.0051 + 0.9999i

  Column 5

  -1.0002 - 0.0102i
  -0.9999 - 0.0102i
  -0.9997 - 0.0102i
```

### Collect Different Signals at 3-Element ULA

Collect three signals incoming into a 3-element array of isotropic antenna elements. Each antenna collects a separate input signal from a separate direction.

```
array = phased.ULA('NumElements',3);
collector = phased.WidebandCollector('Sensor',array,...
    'Wavefront','Unspecified');
rng default
x = rand(10,3);
incidentAngles = [10 20 45; 0 5 2];
```

```
y = collector(x,incidentAngles);
disp(y)

   0.8147 + 0.0000i   0.1576 + 0.0000i   0.6557 + 0.0000i
   0.9058 + 0.0000i   0.9706 + 0.0000i   0.0357 + 0.0000i
   0.1270 + 0.0000i   0.9572 + 0.0000i   0.8491 + 0.0000i
   0.9134 + 0.0000i   0.4854 + 0.0000i   0.9340 + 0.0000i
   0.6324 + 0.0000i   0.8003 + 0.0000i   0.6787 + 0.0000i
   0.0975 + 0.0000i   0.1419 + 0.0000i   0.7577 + 0.0000i
   0.2785 + 0.0000i   0.4218 + 0.0000i   0.7431 + 0.0000i
   0.5469 + 0.0000i   0.9157 + 0.0000i   0.3922 + 0.0000i
   0.9575 + 0.0000i   0.7922 + 0.0000i   0.6555 + 0.0000i
   0.9649 + 0.0000i   0.9595 + 0.0000i   0.1712 + 0.0000i
```

# More About

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_{\mathrm{B}}$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_{\mathrm{s}}/N_{\mathrm{B}}$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, \quad N_B \text{ even} \\ f_c - \dfrac{(N_B - 1)f_s}{2N_B} + (m-1)\Delta f, \quad N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.WidebandCollector` System object uses the narrowband phased approximation of the time delays across receiving elements in the far field for each subband.

# Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.WidebandCollector` does the following for each plane wave signal:

1. Decomposes the signal into multiple subbands.
2. Uses the phase approximation of the time delays across collecting elements in the far field for each subband.
3. Regroups the collected signals in all the subbands to form the output signal.

If the `Wavefront` property value is `'Unspecified'`, the object collects each channel independently.

For further details, see [1].

Collect signals

## Syntax

```
Y = step(H,X,ANG)
Y = step(H,X,ANG,LAXES)
Y = step(H,X,ANG,WEIGHTS)
Y = step(H,X,ANG,STEERANGLE)
Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,ANG)` collects signals `X` arriving from directions `ANG`. The collection process depends on the `Wavefront` property of `H`, as follows:

- If `Wavefront` has the value `'Plane'`, each collecting element collects all the far field signals in `X`. Each column of `Y` contains the output of the corresponding element in response to all the signals in `X`.
- If `Wavefront` has the value `'Unspecified'`, each collecting element collects only one impinging signal from `X`. Each column of `Y` contains the output of the corresponding element in response to the corresponding column of `X`. The `'Unspecified'` option is available when the `Sensor` property of `H` does not contain subarrays.

Y = step(H,X,ANG,LAXES) uses LAXES as the local coordinate system axes directions. This syntax is available when you set the EnablePolarization property to true.

Y = step(H,X,ANG,WEIGHTS) uses WEIGHTS as the weight vector. This syntax is available when you set the WeightsInputPort property to true.

Y = step(H,X,ANG,STEERANGLE) uses STEERANGLE as the subarray steering angle. This syntax is available when you configure H so that H.Sensor is an array that contains subarrays and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE) combines all input arguments. This syntax is available when you configure H so that H.WeightsInputPort is true, H.Sensor is an array that contains subarrays, and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### H

Collector object.

### X

Arriving signals. Each column of X represents a separate signal. The specific interpretation of X depends on the Wavefront property of H.

| Wavefront Property Value | Description |
|---|---|
| 'Plane' | Each column of X is a far field signal. |

| Wavefront Property Value | Description |
|---|---|
| 'Unspecified' | Each column of X is the signal impinging on the corresponding element. In this case, the number of columns in X must equal the number of collecting elements in the Sensor property. |

- If the EnablePolarization property value is set to false, X is a matrix. The number of columns of the matrix equals the number of separate signals.

  The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.
- If the EnablePolarization property value is set to true, X is a row vector of MATLAB struct type. The dimension of the struct array equals the number of separate signals. Each struct member contains three column-vector fields, X, Y, and Z, representing the *x*, *y*, and *z* components of the polarized wave vector signals in the global coordinate system.

  The size of the first dimension of the matrix fields within the struct can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

### ANG

Incident directions of signals, specified as a two-row matrix. Each column specifies the incident direction of the corresponding column of X. Each column of ANG has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

### LAXES

Local coordinate system. LAXES is a 3-by-3 matrix whose columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively. Each axis is specified in terms of [x;y;z] with respect to the global coordinate system. This argument is only used when the EnablePolarization property is set to true.

### WEIGHTS

Vector of weights. WEIGHTS is a column vector of length M, where M is the number of collecting elements.

**Default:** `ones(M,1)`

### STEERANGLE

Subarray steering angle, specified as a length-2 column vector. The vector has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

## Output Arguments

### Y

Collected signals. Each column of `Y` contains the output of the corresponding element. The output is the response to all the signals in `X`, or one signal in `X`, depending on the `Wavefront` property of `H`.

## Examples

### Collect Wideband Signal at Single Antenna

Use the `phased.WidebandCollector` System object™ to construct a signal arriving at a single isotropic antenna from 10° azimuth and 30° elevation.

```
antenna = phased.IsotropicAntennaElement;
collector = phased.WidebandCollector('Sensor',antenna);
x = [1;0;-1];
incidentAngle = [10;30];
y = collector(x,incidentAngle);
disp(y)
```

```
   1.0000 + 0.0000i
   0.0000 + 0.0000i
  -1.0000 - 0.0000i
```

### Collect Wideband Signal at 5-Element ULA

Use the wideband collector to construct the signal impinging upon a 5-element ULA of isotropic antennas from 10 degrees azimuth and 30 degrees elevation.

```
array = phased.ULA('NumElements',5);
collector = phased.WidebandCollector('Sensor',array);
x = [1;1;1];
incidentAngle = [10;30];
y = collector(x,incidentAngle);
disp(y)
```

```
  Columns 1 through 4

  -0.9997 + 0.0102i  -0.0051 - 0.9999i   1.0000 + 0.0000i  -0.0051 + 1.0001i
  -0.9999 + 0.0102i  -0.0051 - 1.0000i   1.0000 + 0.0000i  -0.0051 + 1.0000i
  -1.0002 + 0.0102i  -0.0051 - 1.0001i   1.0000 - 0.0000i  -0.0051 + 0.9999i

  Column 5

  -1.0002 - 0.0102i
  -0.9999 - 0.0102i
  -0.9997 - 0.0102i
```

### Collect Different Signals at 3-Element ULA

Collect three signals incoming into a 3-element array of isotropic antenna elements. Each antenna collects a separate input signal from a separate direction.

```
array = phased.ULA('NumElements',3);
collector = phased.WidebandCollector('Sensor',array,...
    'Wavefront','Unspecified');
rng default
x = rand(10,3);
incidentAngles = [10 20 45; 0 5 2];
y = collector(x,incidentAngles);
disp(y)
```

```

```

## Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.WidebandCollector` does the following for each plane wave signal:

1. Decomposes the signal into multiple subbands.
2. Uses the phase approximation of the time delays across collecting elements in the far field for each subband.
3. Regroups the collected signals in all the subbands to form the output signal.

If the `Wavefront` property value is `'Unspecified'`, the object collects each channel independently.

For further details, see [1].

# phased.WidebandFreeSpace

**Package:** `phased`

Wideband freespace propagation

## Description

The System object models wideband signal propagation from one point to another in a free-space environment. The System object applies range-dependent time delay, gain adjustment, and phase shift to the input signal. The object accounts for doppler shift when either the source or destination is moving. A free-space environment is a boundary-free medium with a speed of signal propagation independent of position and direction. The signal propagates along a straight line from source to destination. For example, you can use this object to model the two-way propagation of a signal from a radar to a target.

For nonpolarized signals, the System object lets you propagate signals from a single point to multiple points or from multiple points to a single point. Multiple-point–to–multiple-point propagation is not supported.

To compute the propagated signal in free space:

1. Define and set up your wideband free space environment as shown in the “Construction” on page 1-2690 section.
2. Call `step` to propagate the signal through free space according to the properties of the System object. The behavior of `step` is specific to each object in the toolbox.

When propagating a round trip signal in free space, you can use one `WidebandFreeSpace` System object to compute the two-way propagation delay. Alternatively, you can use two separate `WidebandFreeSpace` System objects to compute one-way propagation delays in each direction. Due to filter distortion, the total round trip delay when you employ two-way propagation can differ from the delay when you use two one-way `phased.WidebandFreeSpace` System objects. It is more accurate to use a single two-way `phased.WidebandFreeSpace` System object. To set this option, use the `TwoWayPropagation` property.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`sWBFS = phased.WidebandFreeSpace` creates a wideband free space System object, `sWBFS`.

`sWBFS = phased.WidebandFreeSpace(Name,Value)` creates a wideband free space System object, `sWBFS`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1`,`Value1`,...,`NameN`,`ValueN`.

## Properties

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in step. Set this property to false to perform only one-way propagation from the origin to the destination.

Example: true

Data Types: logical

### SampleRate — Sample rate of signal

1e6 (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: 1e6

Data Types: double

### NumSubbands — Number of processing subbands

64 (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: 128

Data Types: double

### MaximumDistanceSource — Source of maximum one-way propagation distance

'Auto' (default) | 'Property'

Source of maximum one-way propagation distance, specified as 'Auto' or 'Property'. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to 'Auto', the System object automatically allocates memory. When you set this property to 'Property', you specify the maximum one-way propagation distance using the value of the MaximumDistance property.

Data Types: char

### MaximumDistance — Maximum one-way propagation distance

10000 (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: 5000

#### Dependencies

To enable this property, set the MaximumDistanceSource property to 'Property'.

Data Types: double

### MaximumNumInputSamplesSource — Source of maximum number of samples

'Auto' (default) | 'Property'

The source of the maximum number of samples of the input signal, specified as 'Auto' or 'Property'. When you set this property to 'Auto', the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to 'Property', you specify the maximum number of samples in the input signal using the MaximumNumInputSamples property. Any input signal longer than that value is truncated.

To use this object with variable-size signals in a MATLAB Function Block in Simulink, set the MaximumNumInputSamplesSource property to 'Property' and set a value for the MaximumNumInputSamples property.

Example: 'Property'

#### Dependencies

To enable this property, set MaximumDistanceSource to 'Property'.

Data Types: char

### MaximumNumInputSamples — Maximum number of input signal samples

100 (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the step method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform OutputFormat property is set to 'Samples', the maximum signal length is the value specified in the NumSamples property.

- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: `2048`

**Dependencies**

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

# Methods

# Examples

### Free-Space Propagation of Wideband Signals

Propagate a wideband signal with three tones in an underwater acoustic with constant speed of propagation. You can model this environment as free space. The center frequency is 100 kHz and the frequencies of the three tones are 75 kHz, 100 kHz, and 125 kHz, respectively. Plot the spectrum of the original signal and the propagated signal to observe the Doppler effect. The sampling frequency is 100 kHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
c = 1500;
fc = 100e3;
```

```
fs = 100e3;
relfreqs = [-25000,0,25000];
```

Set up a stationary radar and moving target and compute the expected Doppler.

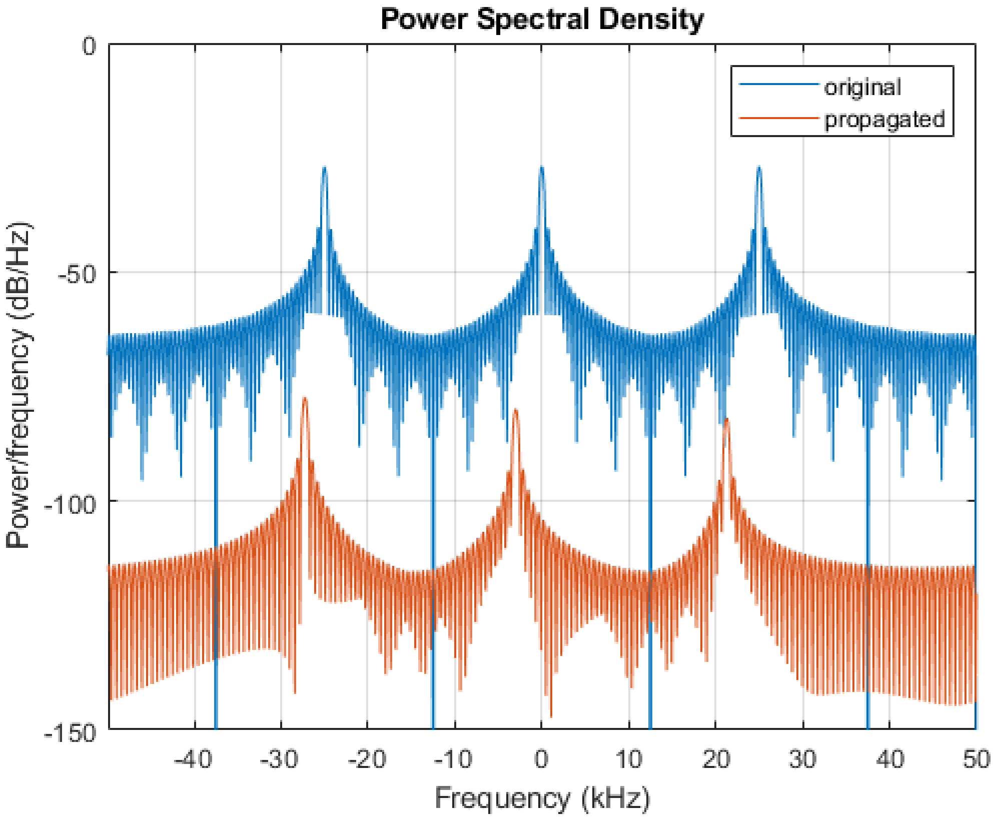
```
rpos = [0;0;0];
rvel = [0;0;0];
tpos = [30/fs*c; 0;0];
tvel = [45;0;0];
dop = -tvel(1)./(c./(relfreqs + fc));
```

Create a signal and propagate the signal to the moving target.

```
t = (0:199)/fs;
x = sum(exp(1i*2*pi*t.'*relfreqs),2);
channel = phased.WidebandFreeSpace(...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'SampleRate',fs);
y = channel(x,rpos,tpos,rvel,tvel);
```

Plot the spectra of the original signal and the Doppler-shifted signal.

```
periodogram([x y],rectwin(size(x,1)),1024,fs,'centered')
ylim([-150 0])
legend('original','propagated');
```



For this wideband signal, you can see that the magnitude of the Doppler shift increases with frequency. In contrast, for narrowband signals, the Doppler shift is assumed constant over the band.

# More About

## Freespace Time Delay and Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t\text{-}\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [2].

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_\mathrm{B}$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_\mathrm{s}/N_\mathrm{B}$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N_B - 1)f_s}{2N_B} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.WidebandFreeSpace` System object uses narrowband time delay and loss algorithms for each subband.

**Package:** phased

Reset states of phased.WidebandFreeSpace System object

## Syntax

```
reset(sWBFS)
```

## Description

`reset(sWBFS)` resets the internal state of the `phased.WidebandFreeSpace` object, `sWBFS`. If the `SeedSource` property applies and has the value `'Property'`, then this method resets the random number generator state.

## Input Arguments

**`sWBFS` — Wideband free space propagator**
System object

Wideband free space propagator, specified as a System object.

Example: `phased.WidebandFreeSpace`

**Introduced in R2015b**

# step

**System object:** `phased.WidebandFreeSpace`
**Package:** `phased`

Propagate wideband signal from point to point using free-space channel model

## Syntax

```
prop_sig = step(sWBFS,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(sWBFS,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a wideband signal `sig` propagates through a free-space channel from the `origin_pos` position to the `dest_pos` position. Either the `origin_pos` or `dest_pos` arguments can specify more than one point but you cannot specify both as having multiple points. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagated through a free-space channel can be polarized or nonpolarized. For nonpolarized fields, such as acoustic fields, the propagating signal field, `sig`, is a vector or matrix. When the fields are polarized, `sig` is a `struct` array. Every structure element represents an electric field vector signal.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `sWBFS` — Wideband free space propagator

System object

Wideband free space propagator, specified as a System object.

Example: `phased.WidebandFreeSpace`

### `sig` — Wideband signal

*M*-by-*N* complex-valued matrix | *1*-by-*N* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, specified as an *M*-by-*N* complex-valued matrix. Each column contains a signal propagated along one of the free-space paths.
- Wideband polarized signal, specified as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing a polarized signal propagating along one of the free-space paths.

The quantity *M* is the number of signal samples and *N* is the number of free-space channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

For polarized fields, each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

**`origin_pos` — Signal origin**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. Position units are in meters. The quantity *N* is the number of free-space channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

**`dest_pos` — Signal destination**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. Position units are in meters. The quantity *N* is the number of free-space channels. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]`.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

**`origin_vel` — Signal origin velocity**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a real-valued 3-by-1 column vector or real-valued 3-by-*N* matrix. Velocity units are in meters per second. The dimension of `origin_vel` must match the dimension of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3–by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`.

Example: `[10;0;5]`

Data Types: `double`

**`dest_vel` — Signal destination velocity**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 column vector or 3–by-*N* matrix. Velocity units are in meters per second. The dimension of `dest_vel` must match the dimension of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3–by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]`.

Example: `[0;0;0]`

Data Types: `double`

## Output Arguments

**`prop_sig` — Wideband propagated signal**
*M*-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, specified as an *M*-by-*N* complex-valued matrix. Each column contains a signal propagated along one of the free-space paths.
- Wideband polarized signal, specified as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing a polarized signal propagating along one of the free-space paths.

The output `prop_sig` contains signal samples arriving at the signal destination within the current `step`time frame. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contribution from the input. The next call to `step` will return more of the propagated signal.

## Examples

### Free-Space Propagation of Wideband Signals

Propagate a wideband signal with three tones in an underwater acoustic with constant speed of propagation. You can model this environment as free space. The center frequency is 100 kHz and the frequencies of the three tones are 75 kHz, 100 kHz, and 125 kHz, respectively. Plot the spectrum of the original signal and the propagated signal to observe the Doppler effect. The sampling frequency is 100 kHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
c = 1500;
fc = 100e3;
fs = 100e3;
relfreqs = [-25000,0,25000];
```

Set up a stationary radar and moving target and compute the expected Doppler.

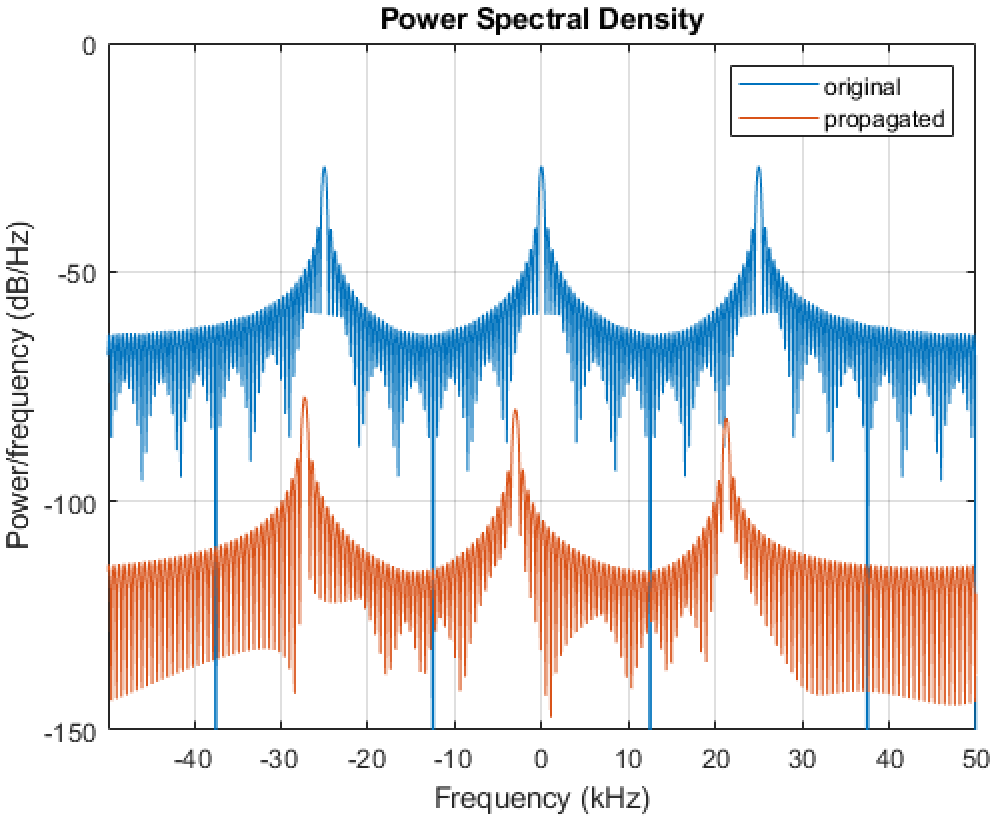
```
rpos = [0;0;0];
rvel = [0;0;0];
tpos = [30/fs*c; 0;0];
tvel = [45;0;0];
dop = -tvel(1)./(c./(relfreqs + fc));
```

Create a signal and propagate the signal to the moving target.

```
t = (0:199)/fs;
x = sum(exp(1i*2*pi*t.'*relfreqs),2);
channel = phased.WidebandFreeSpace(...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'SampleRate',fs);
y = channel(x,rpos,tpos,rvel,tvel);
```

Plot the spectra of the original signal and the Doppler-shifted signal.

```
periodogram([x y],rectwin(size(x,1)),1024,fs,'centered')
ylim([-150 0])
legend('original','propagated');
```



For this wideband signal, you can see that the magnitude of the Doppler shift increases with frequency. In contrast, for narrowband signals, the Doppler shift is assumed constant over the band.

# phased.WidebandLOSChannel

**Package:** `phased`

Wideband LOS propagation channel

## Description

The `phased.WidebandLOSChannel` models the propagation of narrowband electromagnetic signals through a line-of-sight (LOS) channel from a source to a destination. In an LOS channel, propagation paths are straight lines from point to point. The propagation model in the LOS channel includes free-space attenuation in addition to attenuation due to atmospheric gases, rain, fog, and clouds. You can use `phased.WidebandLOSChannel` to model the propagation of signals between multiple points simultaneously. The System object works for all frequencies.

While the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only, the attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.WidebandLOSChannel` System object applies range-dependent time delays to the signals, as well as gains or losses. When either the source or destination is moving, the System object applies Doppler shifts.

Like the `phased.WidebandFreeSpace` System object, the `phased.WidebandLOSChannel` System object supports two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your Wideband LOS channel using the “Construction” on page 1-2707 procedure. You can set the System object properties during construction or leave them at their default values.
2. Call the `step` method to compute the propagated signal using the properties of the `phased.WidebandLOSChannel` System object. You can change tunable properties before or after any call to the `step` method.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`sWBLOS = phased.WidebandLOSChannel` creates a Wideband LOS attenuating propagation channel System object, `sWBLOS`.

`sWBLOS = phased.WidebandLOSChannel(Name,Value)` creates a System object, `sWBLOS`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

### `Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

Example: `7.4`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `RainRate` — Rainfall rate

`0.0` (default) | non-negative real-valued scalar

Rainfall rate, specified as a nonnegative real-valued scalar. Units are in mm/hr. This property applies only when you set `SpecifyAtmosphere` to `true`.

Example: `10.0`

Data Types: `double`

### `TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in `step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

### `SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

### `NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

### `MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

### `MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

**Dependencies**

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

### `MaximumNumInputSamplesSource` — Source of maximum number of samples

`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to 'Property', you specify the maximum number of samples in the input signal using the MaximumNumInputSamples property. Any input signal longer than that value is truncated.

To use this object with variable-size signals in a MATLAB Function Block in Simulink, set the MaximumNumInputSamplesSource property to 'Property' and set a value for the MaximumNumInputSamples property.

Example: 'Property'

#### Dependencies

To enable this property, set MaximumDistanceSource to 'Property'.

Data Types: char

### MaximumNumInputSamples — Maximum number of input signal samples

100 (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the step method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform OutputFormat property is set to 'Samples', the maximum signal length is the value specified in the NumSamples property.
- For pulse waveforms, if the OutputFormat is set to 'Pulses', the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the OutputFormat is set to 'Sweeps', the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: 2048

#### Dependencies

To enable this property, set MaximumNumInputSamplesSource to 'Property'.

Data Types: double

## Methods

| | |
|---|---|
| reset | Reset states of System object |
| step | Propagate signal in Wideband LOS channel |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

## Examples

### Spectrum of Propagated Signal in Wideband LOS Channel

Propagate a wideband signal in a line-of-sight (LOS) channel from a radar at *(0,0,0)* meters to a target at *(35,0,0)* meters in medium fog. Set the fog liquid water density to 0.05 gm/m3. Assume rain is falling at 5 mm/hr. The signal carrier frequency is 20 GHz. The signal is a sum of four cw tones at 19.75, 19.875, 20.125, and 20.25 GHz. Set the signal duration to 0.5 µs and the sample rate to 2.0 GHz. Assume the radar is stationary and the target approaches the radar at 40 m/s. The atmospheric temperature is 12°C.

Set the signal parameters and create the transmitted signal.

```
c = physconst('LightSpeed');
fs = 2e9;
freq = [-0.25,-.125,0.125,0.25]*1e9;
fc = 20.0e9;
dt = 1/fs;
t = [0:dt:.5e-6];
sig = sum(exp(1i*2*pi*t.'*freq),2);
```

Specify the atmosphere parameters and create the `phased.WidebandChannel` System object™.

```
lwd = 0.05;
rainrate = 5.0;
temp = 12.0;
loschannel = phased.WidebandLOSChannel('SampleRate',fs,'PropagationSpeed',c,...
    'SpecifyAtmosphere',true,'OperatingFrequency',fc,'RainRate',rainrate,...
    'LiquidWaterDensity',lwd,'Temperature',temp);
```

Specify the radar and target positions and velocities.

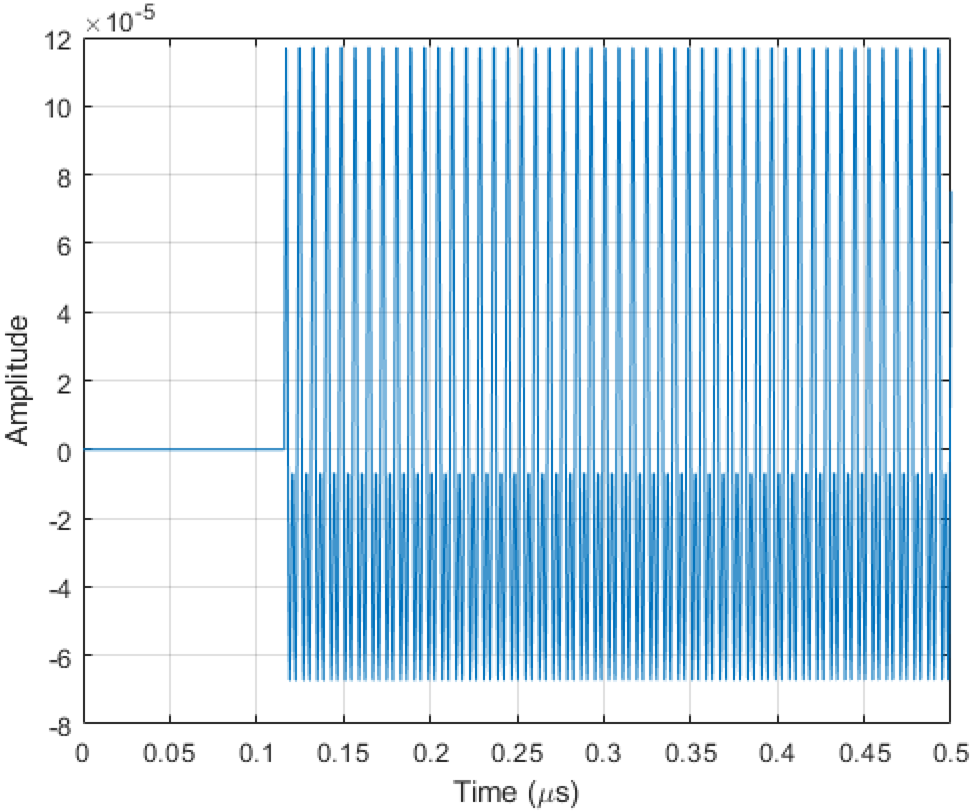
```
xradar = [0,0,0].';
vradar = [0,0,0].';
xtgt = [35,0,0].';
vtgt = [-40,0,0].';
```

Propagated the signal using the `step` method.

```
prop_sig = loschannel(sig,xradar,xtgt,vradar,vtgt);
```

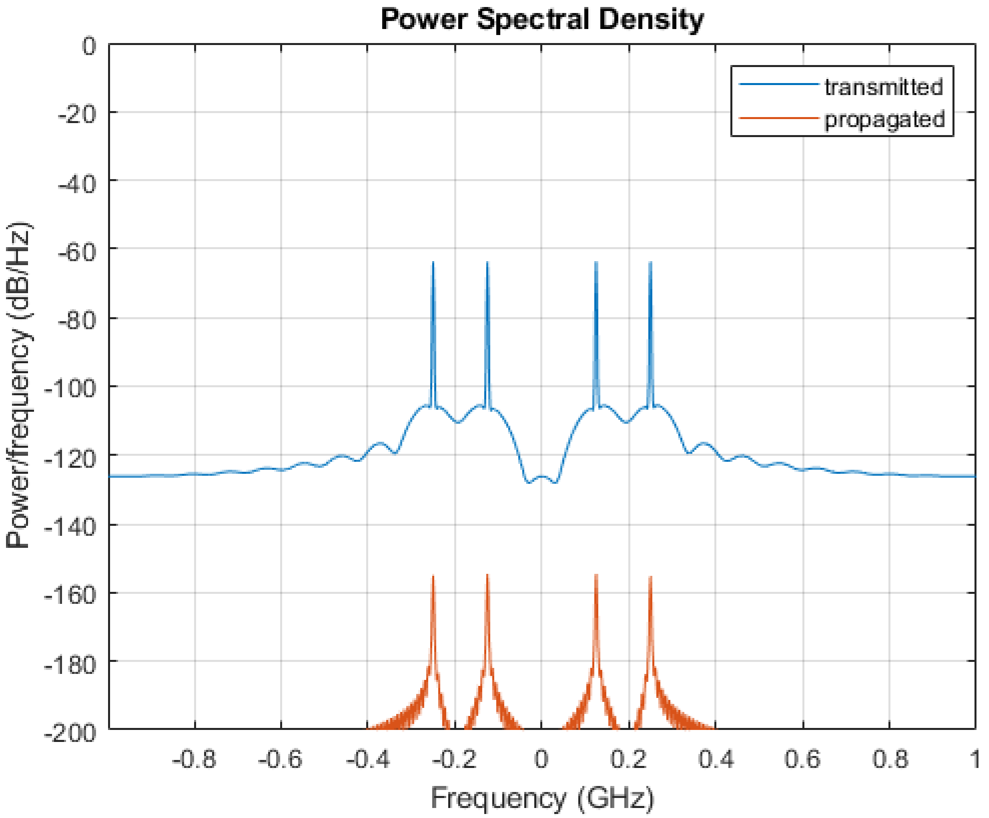
Plot the propagated signal. For a target range of 35 m, the propagation delay is 0.11 µs as seen in the plot.

```
plot(t*1e6,real(prop_sig))
grid
xlabel('Time ({\mu}s)')
ylabel('Amplitude')
```



Using the `periodogram` function with a Taylor window, plot the spectra of the original and propagated signals.

```
nfft = 1024;
nsamp = size(sig,1);
periodogram([sig prop_sig],taylorwin(nsamp),nfft,fs,'centered')
ylim([-200 0])
legend('transmitted','propagated')
```



# More About

## Attenuation and Loss Factors

Attenuation or path loss in the Wideband LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- $L_{fsp}$ is the free-space path attenuation
- $L_g$ is the atmospheric path attenuation

- $L_c$ is the fog and cloud path attenuation
- $L_r$ is the rain path attenuation

Each component is in magnitude units, not in dB.

## Free-space Time Delay and Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t\text{-}\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [5].

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_{\mathrm{i}}$, multiplied by a spectral line strength, *S*$_{\mathrm{i}}$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right]W\,.$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is *P* + *W*.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, $R$. Then, the total attenuation is $L_g$= $R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_B$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N_B-1)f_s}{2N_B} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.WidebandLOSChannel` System object uses narrowband time delay and attenuation algorithms for each subband.

Reset states of System object

## Syntax

```
reset(sWBLOS)
```

## Description

`reset(sWBLOS)` resets the internal state of the `phased.WidebandLOSChannel` System object, `sWBLOS`. If `SeedSource` is a property of this System object and has the value `'Property'`, then this method resets the random number generator state.

## Input Arguments

### `sWBLOS` — Wideband LOS channel

`phased.WidebandLOSChannel` System object

Wideband LOS channel, specified as a `phased.WidebandLOSChannel` System object.

Example: `phased.WidebandLOSChannel`

**Introduced in R2016a**

# step

**System object:** `phased.WidebandLOSChannel`
**Package:** `phased`

Propagate signal in Wideband LOS channel

## Syntax

```
prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a wideband signal, `sig`, propagates through a line-of-sight (LOS) channel from a source located at the `origin_pos` position to a destination at the `dest_pos` position. Only one of the `origin_pos` or `dest_pos` arguments can specify multiple positions. The other must contain a single position. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must match the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagating through an LOS channel can be polarized or nonpolarized. For nonpolarized fields, the propagating signal field, `sig`, is a vector or matrix. For polarized fields, `sig` is an array of structures. The structure elements represent an electric field vector in Cartesian form.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `sWBLOS` — Wideband LOS channel

`phased.WidebandLOSChannel` System object

Wideband LOS channel, specified as a `phased.WidebandLOSChannel` System object.

Example: `phased.WidebandLOSChannel`

### `sig` — Wideband signal

*M*-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Wideband signal, specified as a matrix or `struct` array, depending on whether is signal or polarized or nonpolarized. The quantity *M* is the number of samples in the signal, and *N* is the number of wideband LOS channels. Each channel corresponds to a source-destination pair.

- Wideband nonpolarized scalar signal. Specify `sig` as an *M*-by-*N* complex-valued matrix. Each column contains one signal propagated along the line-of-sight path.
- Wideband polarized signal. Specify `sig` as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` represents a polarized signal propagated along the line-of-sight path. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

### `origin_pos` — Signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

### `dest_pos` — Signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

### `origin_vel` — Velocities of signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

### `dest_vel` — Velocities of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

## Output Arguments

### `prop_sig` — Wideband propagated signal

*M*-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Wideband signal, returned as a matrix or `struct` array, depending on whether the signal is polarized or nonpolarized. The quantity *M* is the number of samples in the signal and *N* is the number of wideband LOS channels. Each channel corresponds to a source-destination pair.

- Wideband nonpolarized scalar signal. `prop_sig` is an *M*-by-*N* complex-valued matrix.

  The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.
- Wideband polarized scalar signal. `prop_sig` is a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

The `prop_sig` output contains signal samples arriving at the signal destination within the current time frame. The current time frame is the time frame of the input signals to `step`. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output might not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

## Examples

### Propagate Wideband Signal in LOS Channel

Propagate a wideband signal in a line-of-sight (LOS) channel from a radar at *(0,0,0)* meters to a target at *(60,0,0)* meters in medium fog. Set the fog liquid water density to 0.05 $g/m^3$. Assume rain is falling at 5 mm/hr. The signal carrier frequency is 20 GHz. The signal is a sum of four cw tones at 19.75, 19.875, 20.125, and 20.25 GHz. Set the signal duration to 0.5 microsecond and the sample rate to 2.0 GHz. Assume the radar is stationary and the target approaches the radar at 40 m/s. The atmospheric temperature is 12°C and the dry air pressure is 101.300 kPa.

Set the signal parameters and create the transmitted signal.

```
c = physconst('LightSpeed');
fs = 2e9;
freq = [-0.25,-.125,0.0,0.125,0.25]*1e9;
fc = 20.0e9;
dt = 1/fs;
t = [0:dt:.5e-6];
sig = sum(exp(1i*2*pi*t.'*freq),2);
```

Specify the atmosphere parameters and create the `phased.WidebandChannel` System object™.

```
lwd = 0.05;
rainrate = 5.0;
dap = 101300.0;
temp = 12.0;
sWBLOS = phased.WidebandLOSChannel('SampleRate',fs,'PropagationSpeed',c,...
    'SpecifyAtmosphere',true,'OperatingFrequency',fc,'RainRate',rainrate,...
    'LiquidWaterDensity',lwd,'Temperature',temp,'DryAirPressure',dap);
```

Specify the radar and target positions and velocities.

```
xradar = [0,0,0].';
vradar = [0,0,0].';
xtgt = [60,0,0].';
vtgt = [-40,0,0].';
```

Propagated the signal using the `step` method.

```
prop_sig = step(sWBLOS,sig,xradar,xtgt,vradar,vtgt);
```

Plot the propagated signal. For a target range of 60 m, the propagation delay is 0.20 µs as shown in the plot.

```
plot(t*1e6,real(prop_sig))
grid
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```

# phased.WidebandRadiator

**Package:** `phased`

Wideband signal radiator

## Description

The `phased.WidebandRadiator` System object implements a wideband signal radiator. A radiator converts signals into radiated wavefields transmitted from arrays and individual sensor elements such as antennas, microphone elements, and sonar transducers. The radiator output represents the fields at a reference distance of one meter from the phase center of the element or array. The algorithm divides the signal at each element into frequency subbands and applies a narrowband time-delay to each signal using the phase-shift approximation. Then, the delayed subbands are coherently added to create the output signal. You can then propagate the signals to the far field using, for example, the `phased.WidebandFreeSpace`, `phased.WidebandLOSChannel`, or `phased.WidebandTwoRayChannel` System objects. You can use this object to

- model radiated signals as polarized or non-polarized fields depending upon whether the element or array supports polarization and the value of the Polarization property. Using polarization, you can transmit a signal as a polarized electromagnetic field, or transmit two independent signals using dual polarizations.
- model acoustic radiated fields by using nonpolarized microphone and sonar transducer array elements and by setting the “Polarization” on page 1-0 to `'None'`. You must also set the PropagationSpeed to a value appropriate for the medium.
- radiate fields from subarrays created by the `phased.ReplicatedSubarray` and `phased.PartitionedArray` objects. You can steer all subarrays in the same direction using the Steering angle argument, `STEERANG`, or steer each subarray in a different direction using the Subarray element weights argument, `WS`. The radiator distributes the signal powers equally among the elements of each subarray.

To radiate signals:

1. Create the `phased.WidebandRadiator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

## Syntax

```
radiator = phased.WidebandRadiator
radiator = phased.WidebandRadiator(Name,Value)
```

### Description

`radiator = phased.WidebandRadiator` creates a wideband signal radiator object, `radiator`, with default property values.

`radiator = phased.WidebandRadiator(Name,Value)` creates a wideband signal radiator with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `radiator = phased.WidebandRadiator('Sensor',phased.URA,'CarrierFrequency',300e6)` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The beamformer has a carrier frequency of 300 MHz.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**`Sensor` — Sensor element or sensor array**

`phased.ULA` array with default property values (default) | Phased Array System Toolbox sensor or array

Sensor element or sensor array, specified as a System object belonging to Phased Array System Toolbox. A sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

### `CarrierFrequency` — Carrier frequency

`1e9` (default) | positive real-valued scalar

Carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

### `NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

### `SensorGainMeasure` — Specify sensor gain

`'dB'` (default) | `'dBi'`

Sensor gain measure, specified as `'dB'` or `'dBi'`.

- When you set this property to `'dB'`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.
- When you set this property to `'dBi'`, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values computed by the radar equation that uses dBi to specify the antenna gain. The computation using the `'dBi'` option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor.

Data Types: `char`

### `Polarization` — Polarization configuration

`'None'` (default) | `'Combined'` | `'Dual'`

Polarization configuration, specified as `'None'`, `'Combined'`, or `'Dual'`. When you set this property to `'None'`, the output field is considered a scalar field. When you set this property to `'Combined'`, the radiated fields are polarized and are interpreted as a single signal in the sensor's inherent polarization. When you set this property to `'Dual'`, the *H* and *V* polarization components of the radiated field are independent signals.

Example: `'Dual'`

Data Types: `char`

### `WeightsInputPort` — Enable weights input

`false` (default) | `true`

Enable weights input, specified as `false` or `true`. When `true`, use the object input argument `W` to specify weights. Weights are applied to individual array elements (or at the subarray level when subarrays are supported).

Data Types: `logical`

# Usage

## Syntax

```
Y = radiator(X,ANG)
Y = radiator(X,ANG,LAXES)
Y = radiator(XH,XV,ANG,LAXES)
```

```
Y = radiator(___,W)
Y = radiator(___,STEERANG)
Y = radiator(___,WS)
Y = radiator(X,ANG,LAXES,W,STEERANG)
```

## Description

`Y = radiator(X,ANG)` radiates the signal `X` in the directions specified by `ANG`. For each direction, the method computes the radiated signal, `Y`, by summing the contributions of each element or subarray.

`Y = radiator(X,ANG,LAXES)` also specifies the local coordinate system of the radiator, `LAXES`. This syntax applies when you set the Polarization property to `'Combined'`.

`Y = radiator(XH,XV,ANG,LAXES)` specifies a horizontal-polarization port signal, `XH`, and a vertical-polarization port signal, `XV`. To use this syntax, set the Polarization property to `'Dual'`.

`Y = radiator(___,W)` also specifies `W` as array element or subarray weights. To use this syntax, set the WeightsInputPort property to `true`.

`Y = radiator(___,STEERANG)` also specifies `STEERANG` as the subarray steering angle. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`.

`Y = radiator(___,WS)` also specifies `WS` as the weights applied to each element within each subarray. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` of that array to `'Custom'`.

You can combine optional input arguments when their enabling properties are set, for example, `Y = radiator(X,ANG,LAXES,W,STEERANG)` combines several input arguments. Optional inputs must be listed in the same order as the order of the enabling properties.

## Input Arguments

### X — Signal to radiate

complex-valued *M*-by-1 vector | complex-valued *M*-by-*N* matrix

Signal to radiate, specified as a complex-valued *M*-by-1 vector or complex-valued *M*-by-*N* matrix. *M* is the length of the signal, and *N* is the number of array elements (or subarrays when subarrays are supported).

### Dimensions of X

| Dimension | Signal |
|---|---|
| *M*-by-1 vector | The same signal is radiated from all array elements (or all subarrays when subarrays are supported). |
| `M-by-N matrix` | Each column corresponds to the signal radiated by the corresponding array element (or corresponding subarrays when subarrays are supported). |

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this argument, set the Polarization property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### ANG — Radiating directions of signals

real-valued 2-by-*L* matrix

Radiating directions of signals, specified as a real-valued 2-by-*L* matrix. Each column specifies a radiating direction in the form `[AzimuthAngle;ElevationAngle]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive. Units are in degrees.

Example: `[30,20;45,0]`

Data Types: `double`

### LAXES — Local coordinate system

real-valued 3-by-3 orthogonal matrix

Local coordinate system, specified as a real-valued 3-by-3 orthogonal matrix. The matrix columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes with respect to the global coordinate system.

Example: `rotx(30)`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Combined'` or `'Dual'`.

Data Types: `double`

### XH — H-polarization port signal to radiate

complex-valued *M*-by-1 vector | complex-valued *M*-by-*N* matrix

H-polarization port signal to radiate, specified as a complex-valued *M*-by-1 vector or complex-valued *M*-by-*N* matrix. *M* is the length of the signal, and *N* is the number of array elements (or subarrays when subarrays are supported).

#### Dimensions of XH

| Dimension | Signal |
|---|---|
| *M*-by-1 vector | The same signal is radiated from all array elements (or all subarrays when subarrays are supported). |
| `M-by-N matrix` | Each column corresponds to the signal radiated by the corresponding array element (or corresponding subarrays when subarrays are supported). |

The dimensions and sizes of `XH` and `XV` must be the same.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this argument, set the Polarization property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### XV — V-polarization port signal to radiate

complex-valued *M*-by-1 vector | complex-valued *M*-by-*N* matrix

V-polarization port signal to radiate, specified as a complex-valued *M*-by-1 vector or complex-valued *M*-by-*N* matrix. *M* is the length of the signal, and *N* is the number of array elements (or subarrays when subarrays are supported).

#### Dimensions of XV

| Dimension | Signal |
|---|---|
| *M*-by-1 vector | The same signal is radiated from all array elements (or all subarrays when subarrays are supported). |
| `M-by-N matrix` | Each column corresponds to the signal radiated by the corresponding array element (or corresponding subarrays when subarrays are supported). |

The dimensions and sizes of `XH` and `XV` must be the same.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Dependencies**

To enable this argument, set the Polarization property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### W — Element or subarray weights

*N*-by-1 column vector

Element or subarray weights, specified as a complex-valued *N*-by-1 column vector where *N* is the number of array elements (or subarrays when the array supports subarrays).

**Dependencies**

To enable this argument, set the WeightsInputPort property to `true`.

Data Types: `double`
Complex Number Support: Yes

### WS — Subarray element weights

complex-valued $N_{SE}$-by-$N$ matrix | 1-by-$N$ cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

**Dependencies**

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

### STEERANG — Subarray steering angle

real-valued 2-by-1 vector

Subarray steering angle, specified as a length-2 column vector. The vector has the form `[azimuthAngle;elevationAngle]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive. Units are in degrees.

Example: `[20;15]`

#### Dependencies

To enable this argument, set the `Sensor` property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`

Data Types: `double`

## Output Arguments

### Y — Radiated signals

complex-valued *M*-by-*L* matrix | complex-valued 1-by-*L* cell array of structures

Radiated signals, specified as a complex-valued *M*-by-*L* matrix or a 1-by-*L* cell array, where *L* is the number of radiating angles, `ANG`. *M* is the length of the input signal, `X`.

- If the Polarization property value is set to `'None'`, the output argument `Y` is an *M*-by-*L* matrix.
- If the Polarization property value is set to `'Combined'` or `'Dual'`, `Y` is a 1-by-*L* cell array of structures. Each cell corresponds to a separate radiating signal. Each `struct` contains three column vectors containing the *X*, *Y*, and *Z* components of the polarized fields defined with respect to the global coordinate system.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Radiate Wideband Energy from Array

Create a 5-by-5 URA and space the elements one-half wavelength apart. The wavelength corresponds to a design frequency of 300 MHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

### Create 5-by-5 URA Array of Cosine Elements

```
c = physconst('LightSpeed');
fc = 100e6;
lam = c/fc;
antenna = phased.CosineAntennaElement('CosinePower',[2,2]);
array = phased.URA('Element',antenna,'Size',[5,5],'ElementSpacing',[0.5,0.5]*lam);
```

### Create and Radiate Wideband Signal

Radiate a wideband signal consisting of three sinusoids at 2, 10 and 11 MHz. Set the sampling rate to 25 MHz. Radiate the fields into two directions: (30,10) degrees azimuth and elevation and (20,50) degrees azimuth and elevation.

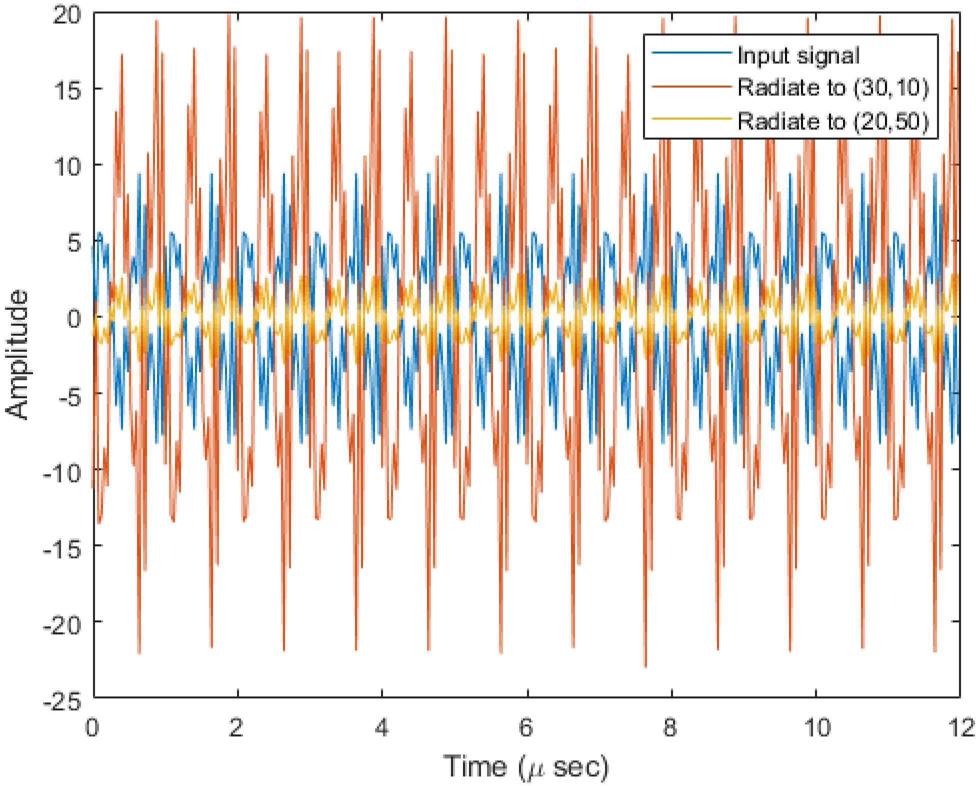
```
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
Tsig = 100e-6;
t = [0:dt:Tsig];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingangles = [30 10; 20 50]';
```

```
radiator = phased.WidebandRadiator('Sensor',array,'CarrierFrequency',fc,'SampleRate',fs
radsig = radiator(sig.',radiatingangles);
```

### Plot Radiated Signal

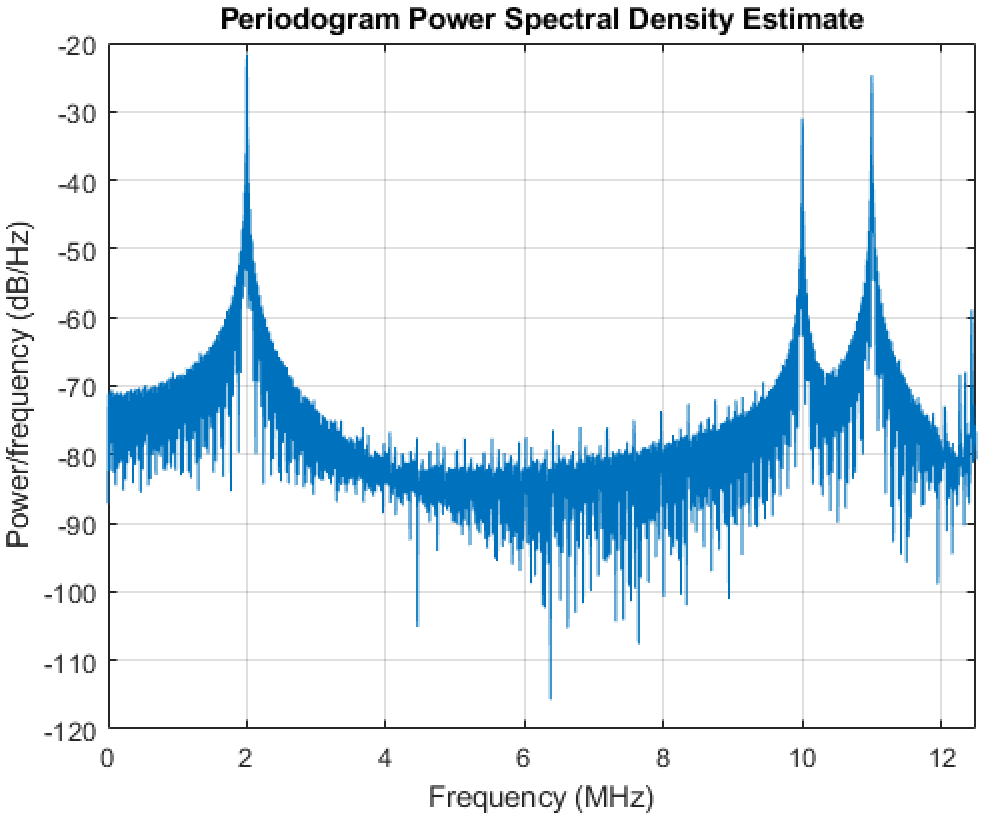
Plot the input signal to the radiator and the radiated signals.

```
plot(t(1:300)*1e6,real(sig(1:300)))
hold on
plot(t(1:300)*1e6,real(radsig(1:300,1)))
plot(t(1:300)*1e6,real(radsig(1:300,2)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Input signal','Radiate to (30,10)','Radiate to (20,50)')
```



Plot the spectra of the signal that is radiated to (30,10) degrees.

```
periodogram(real(radsig(:,1)),rectwin(size(radsig,1)),4096,fs);
```



### Radiate Wideband Polarized Fields from Array

Examine the polarized field produced by the wideband radiator from a five-element uniform line array (ULA) composed of short-dipole antenna elements.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the ULA of five short-dipole antennas with polarization enabled. The element spacing is set to 1/2 wavelength of the carrier frequency. Construct the wideband radiator System object(TM).

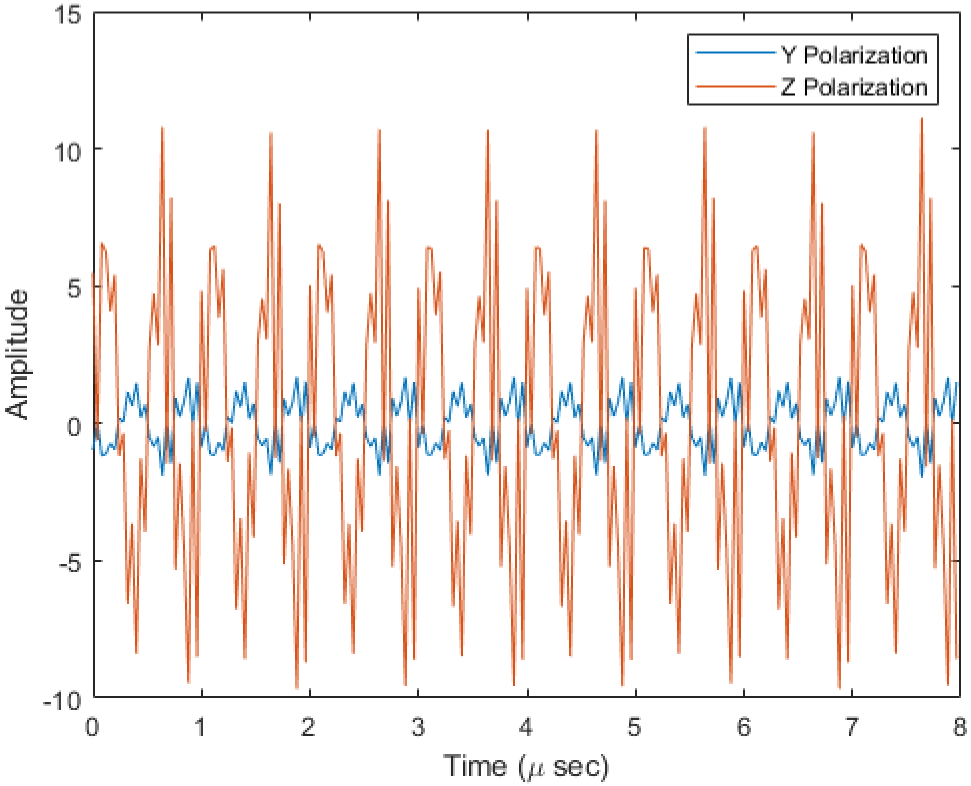
```
fc = 100e6;
c = physconst('LightSpeed');
lam = c/fc;
antenna = phased.ShortDipoleAntennaElement;
array = phased.ULA('Element',antenna,'NumElements',5,'ElementSpacing',lam/2);
```

Radiate a signal consisting of the sum of three sine waves. Radiate the signal into two different directions. Radiated angles are azimuth and elevation angles defined with respect to a local coordinate system. The local coordinate system is defined by 10 degree rotation around the x-axis from the global coordinates.

```
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
fc = 100e6;
t = [0:dt:100e-6];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingAngle = [30 30; 0 20];
laxes = rotx(10);
radiator = phased.WidebandRadiator('Sensor',array,'SampleRate',fs,...
    'CarrierFrequency',fc,'Polarization','Combined');
y = radiator(sig.',radiatingAngle,laxes);
```

Plot the first 200 samples of the *y* and *z* components of the polarized field propagating in the [30,0] direction.

```
plot(10^6*t(1:200),real(y(1).Y(1:200)))
hold on
plot(10^6*t(1:200),real(y(1).Z(1:200)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Y Polarization','Z Polarization')
```



# More About

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_B$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N_B-1)f_s}{2N_B} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# See Also

`phased.Collector` | `phased.Radiator` | `phased.WidebandCollector` | `phased.WidebandFreeSpace`

**Introduced in R2015b**

# reset

**System object:** phased.WidebandRadiator
**Package:** phased

Reset states of System object

## Syntax

```
reset(sWBR)
```

## Description

reset(sWBR) resets the internal state of the phased.WidebandRadiator object, sWBR. If the SeedSource property applies, and has the value 'Property', then this method resets the state of the random number generator.

## Input Arguments

**sWBR — Wideband radiator**
System object

Wideband radiator, specified as a System object.

Example: phased.WidebandRadiator

**Introduced in R2015b**

# step

**System object:** `phased.WidebandRadiator`
**Package:** `phased`

Radiate wideband signals

## Syntax

```
sigrad = step(sWBR,sig,ang)
sigrad = step(sWBR,sig,ang,laxes)
sigrad = step(sWBR,sig,ang,wts)
sigrad = step(sWBR,sig,ang,steerang)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`sigrad = step(sWBR,sig,ang)` radiates the signal `sig` in the directions specified by `ang`. For each direction, the method computes the radiated signal, `sigrad`, by summing the contributions of each element or subarray.

`sigrad = step(sWBR,sig,ang,laxes)` radiates the signal using the specified the local coordinate system of the radiator, `laxes`. This syntax applies when you set the `EnablePolarization` property to `true`.

`sigrad = step(sWBR,sig,ang,wts)` radiates the signal using `wts` as the weight vector when the `WeightsInputPort` property is `true`.

`sigrad = step(sWBR,sig,ang,steerang)` radiates the signal and uses `steerang` as the subarray steering angle. `steerang` must be a length-2 column vector in the form of `[AzimuthAngle; ElevationAngle]`. This syntax applies when you use a subarray as the `Sensor` property and set the `SubarraySteering` property of the sensor to `'Phase'` or `'Time'`.

You can combine optional input arguments when you set their enabling properties in the System object during construction. Optional inputs must be listed in the same order as their enabling properties. For example, `sigrad = step(sWBR,sig,laxes,wts, steerang)` is valid when you set both `EnablePolarization` and `WeightsInputPort` to `true` and set the `SubarraySteering` property of the sensor.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `sWBR` — Wideband radiator

System object

Wideband radiator, specified as a `phased.WidebandRadiator` System object.

Example: `phased.WidebandRadiator`

### `sig` — Input signals

*M*-by-1 complex-valued column vector | *M*-by-*N* complex-valued matrix

Input signals, specified as an *M*-by-1 complex-valued column vector or *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) of the signal. If `sig` is a column vector, the same signal is radiated through all elements. If `sig` is a matrix, *N* is the number of sensor elements in the array. For subarrays, *N* is the number of subarrays. Each column of `sig` represents the field radiated by the corresponding element or subarray.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `double`
Complex Number Support: Yes

**`ang` — Radiating directions**
2-by-*L* real-valued matrix | 1-by-*L* real-valued row vector

Radiating directions of the signal, specified as 2-by-*L* real-valued matrix or 1-by-*L* real-valued row vector. The quantity *L* is the number of directions to radiate. If `ang` is a matrix, each column has the form `[azimuth;elevation]`. If `ang` is a row vector, each entry represents the azimuthal direction. The elevation direction is zero degrees. Angle units are in degrees. Angles are defined with respect to the local coordinate system of the array.

When the sensory array is a uniform linear array, `ang` represents the broadside angle.

Data Types: `double`

**`laxes` — Local coordinate system axes**
`eye(3,3)` (default) | 3-by-3 real-valued orthonormal matrix

Local coordinate system axes, specified as a 3-by-3 real-valued matrix orthonormal matrix. The matrix columns specify the *x*, *y*, and *z* axes of the local coordinate system. Each column takes the form `[x;y;z]` with respect to the global coordinate system. This argument only applies when the `EnablePolarization` property is set to `true`.

Data Types: `double`

**`wts` — Weight vector**
`ones(N,1)` (default) | *N*-by-1 complex-valued column vector

Weight vector, specified as an *N*-by-1 complex-valued column vector. Each weight vector element multiplies the signal at the corresponding element or subarray. *N* is the number of radiating elements or subarrays. This argument only applies when the `WeightsInputPort` property is `true`.

Data Types: `double`
Complex Number Support: Yes

**`steerang` — Subarray steering angle**
2-by-1 real-valued column vector

Subarray steering angle, specified as a 2-by-1 real-valued column vector in the form of `[AzimuthAngle; ElevationAngle]`. This argument applies only when the `Sensor` property refers to a subarray and the SubarraySteering property of the sensor is set to 'Phased' or 'Time'. Angles are defined with respect to the local coordinate system axes. Angle units are in degrees.

Data Types: double

## Output Arguments

### sigrad — Radiated signal

*M*-by-*L* complex-valued matrix | 1-by-*L* array of struct type

Radiated signal, returned as an *M*-by-*L* complex-valued matrix or 1-by-*L* array of struct type depending on whether polarization is enabled. The radiated field is the combined far-field output from all elements or subarrays. The quantity *M* is the number of sample values (snapshots) of the signal. The quantity *L* is the number of entries in ang.

- If you set EnablePolarization to false, sigrad is an *M*-by-*L* complex-valued matrix.
- If you set EnablePolarization is true, sigrad is a 1-by-*L* array of struct type. Each struct in the array has three data fields: sigrad.X, sigrad.Y, sigrad.Z which correspond to the *x*, *y*, and *z* components of the electromagnetic field. Electromagnetic field components are defined with respect to the global coordinate system. Each data field is an *M*-by-1 column vector.

## Examples

### Radiate Wideband Energy from Array

Create a 5-by-5 URA and space the elements one-half wavelength apart. The wavelength corresponds to a design frequency of 300 MHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

### Create 5-by-5 URA Array of Cosine Elements

```
c = physconst('LightSpeed');
fc = 100e6;
```

```
lam = c/fc;
antenna = phased.CosineAntennaElement('CosinePower',[2,2]);
array = phased.URA('Element',antenna,'Size',[5,5],'ElementSpacing',[0.5,0.5]*lam);
```

### Create and Radiate Wideband Signal

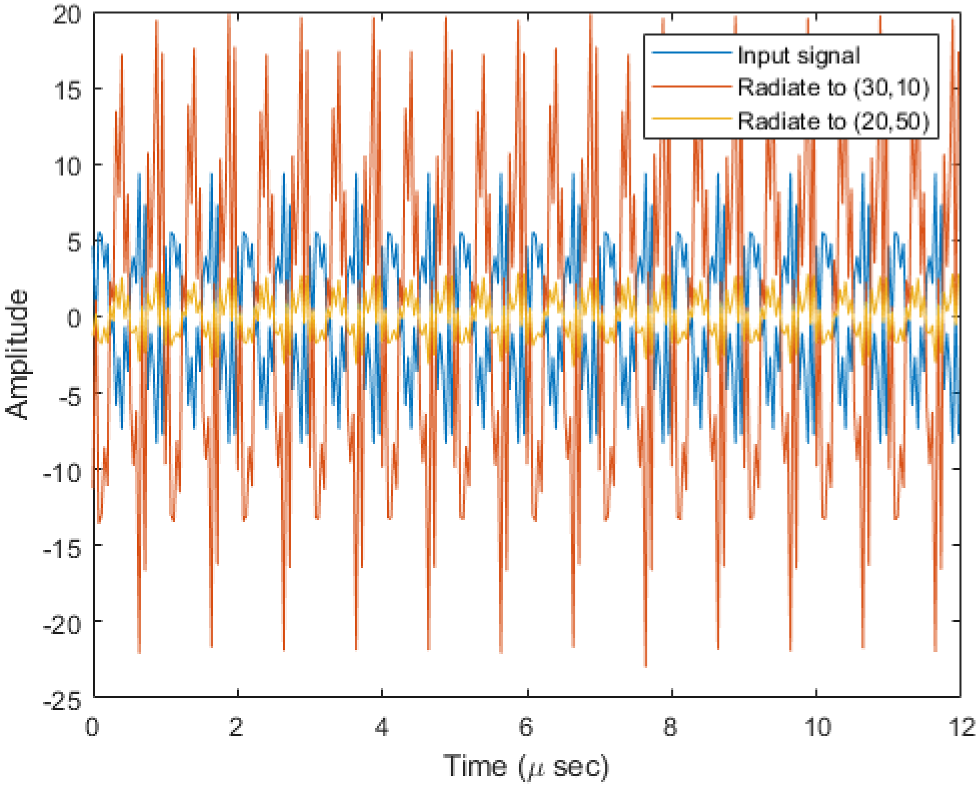
Radiate a wideband signal consisting of three sinusoids at 2, 10 and 11 MHz. Set the sampling rate to 25 MHz. Radiate the fields into two directions: (30,10) degrees azimuth and elevation and (20,50) degrees azimuth and elevation.

```
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
Tsig = 100e-6;
t = [0:dt:Tsig];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingangles = [30 10; 20 50]';
radiator = phased.WidebandRadiator('Sensor',array,'CarrierFrequency',fc,'SampleRate',fs
radsig = radiator(sig.',radiatingangles);
```

### Plot Radiated Signal

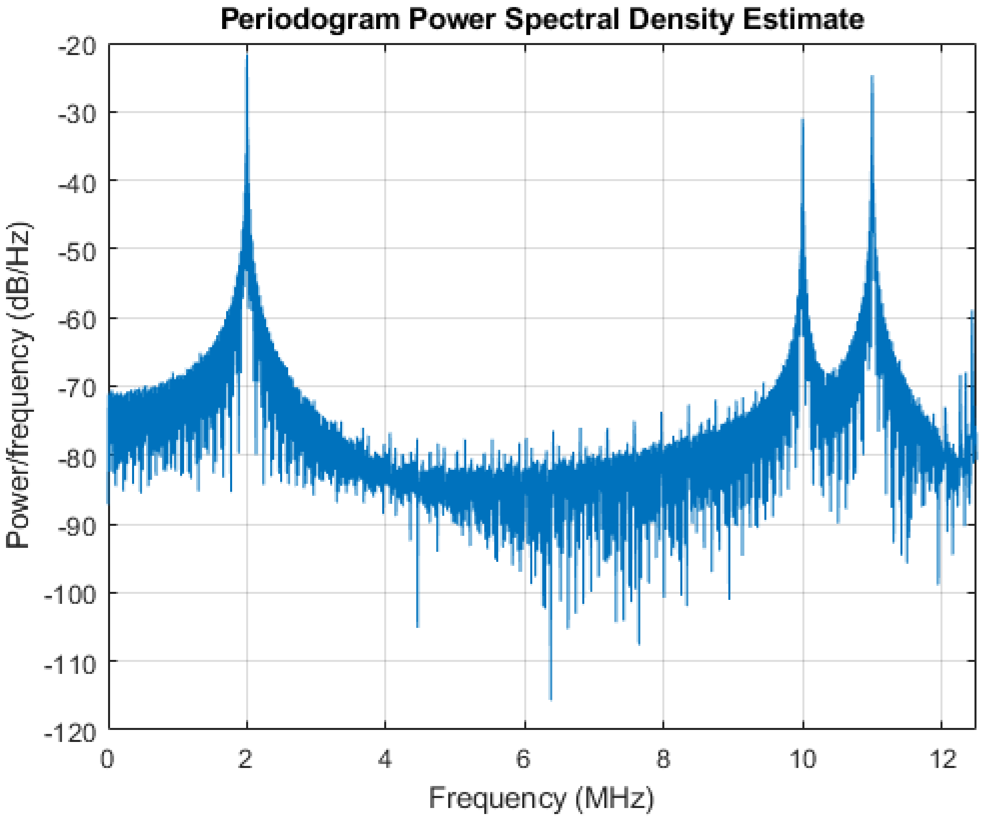
Plot the input signal to the radiator and the radiated signals.

```
plot(t(1:300)*1e6,real(sig(1:300)))
hold on
plot(t(1:300)*1e6,real(radsig(1:300,1)))
plot(t(1:300)*1e6,real(radsig(1:300,2)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Input signal','Radiate to (30,10)','Radiate to (20,50)')
```



Plot the spectra of the signal that is radiated to (30,10) degrees.

```
periodogram(real(radsig(:,1)),rectwin(size(radsig,1)),4096,fs);
```



### Radiate Wideband Polarized Fields from Array

Examine the polarized field produced by the wideband radiator from a five-element uniform line array (ULA) composed of short-dipole antenna elements.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the ULA of five short-dipole antennas with polarization enabled. The element spacing is set to 1/2 wavelength of the carrier frequency. Construct the wideband radiator System object(TM).

```
fc = 100e6;
c = physconst('LightSpeed');
lam = c/fc;
antenna = phased.ShortDipoleAntennaElement;
array = phased.ULA('Element',antenna,'NumElements',5,'ElementSpacing',lam/2);
```

Radiate a signal consisting of the sum of three sine waves. Radiate the signal into two different directions. Radiated angles are azimuth and elevation angles defined with respect to a local coordinate system. The local coordinate system is defined by 10 degree rotation around the x-axis from the global coordinates.

```
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
fc = 100e6;
t = [0:dt:100e-6];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingAngle = [30 30; 0 20];
laxes = rotx(10);
radiator = phased.WidebandRadiator('Sensor',array,'SampleRate',fs,...
    'CarrierFrequency',fc,'Polarization','Combined');
y = radiator(sig.',radiatingAngle,laxes);
```

Plot the first 200 samples of the *y* and *z* components of the polarized field propagating in the `[30,0]` direction.

```
plot(10^6*t(1:200),real(y(1).Y(1:200)))
hold on
plot(10^6*t(1:200),real(y(1).Z(1:200)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Y Polarization','Z Polarization')
```

# phased.WidebandTwoRayChannel

**Package:** `phased`

Wideband two-ray propagation channel

## Description

The `phased.WidebandTwoRayChannel` models a wideband two-ray propagation channel. A two-ray propagation channel is the simplest type of multipath channel. You can use a two-ray channel to simulate propagation of signals in a homogeneous, isotropic medium with a single reflecting boundary. This type of medium has two propagation paths: a line-of-sight (direct) propagation path from one point to another and a ray path reflected from the boundary.

You can use this System object for short-range radar and mobile communications applications where the signals propagate along straight paths and the earth is assumed to be flat. You can also use this object for sonar and microphone applications. For acoustic applications, you can choose nonpolarized fields and adjust the propagation speed to be the speed of sound in air or water. You can use `phased.WidebandTwoRayChannel` to model propagation from several points simultaneously.

Although the System object works for all frequencies, the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only. The attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.WidebandTwoRayChannel` System object applies range-dependent time delays to the signals, as well as gains or losses, phase shifts, and boundary reflection loss. When either the source or destination is moving, the System object applies Doppler shifts to the signals.

Signals at the channel output can be kept *separate* or be *combined*. If you keep the signals separate, both signals arrive at the destination separately and are not combined. If you choose to combine the signals, the two signals from the source propagate separately but are coherently summed at the destination into a single quantity. Choose this option when the difference between the sensor or array gains in the directions of the two paths is insignificant.

In contrast to the `phased.WidebandFreeSpace` and `phased.WidebandLOSChannel` System objects, this System object does not support two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your two-ray channel. See “Construction” on page 1-2325.
2. Call the `step` method to compute the propagated signal using the properties of the `phased.WidebandTwoRayChannel` System object.

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`channel = phased.WidebandTwoRayChannel` creates a two-ray propagation channel System object, `channel`.

`channel = phased.WidebandTwoRayChannel(Name,Value)` creates a System object, `channel`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

### `Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

Example: `7.4`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

### `NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

### `EnablePolarization` — Enable polarized fields

`false` (default) | `true`

Option to enable polarized fields, specified as `false` or `true`. Set this property to `true` to enable polarization. Set this property to `false` to ignore polarization.

Data Types: `logical`

### `GroundReflectionCoefficient` — Ground reflection coefficient

`-1` (default) | complex-valued scalar | complex-valued 1-by-*N* row vector

Ground reflection coefficient for the field at the reflection point, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. Each coefficient has an absolute value less than or equal to one. The quantity *N* is the number of two-ray channels. Units are dimensionless. Use this property to model nonpolarized signals. To model polarized signals, use the `GroundRelativePermittivity` property.

Example: `-0.5`

#### Dependencies

To enable this property, set `EnablePolarization` to `false`.

Data Types: `double`
Complex Number Support: Yes

### `GroundRelativePermittivity` — Ground relative permittivity

`15` (default) | positive real-valued scalar | real-valued 1-by-*N*row vector of positive values

Relative permittivity of the ground at the reflection point, specified as a positive real-valued scalar or a 1-by-*N* real-valued row vector of positive values. The dimension *N* is the number of two-ray channels. Permittivity units are dimensionless. Relative permittivity is defined as the ratio of actual ground permittivity to the permittivity of free space. This property applies when you set the `EnablePolarization` property to `true`. Use this property to model polarized signals. To model nonpolarized signals, use the `GroundReflectionCoefficient` property.

Example: `5`

**Dependencies**

To enable this property, set `EnablePolarization` to `true`.

Data Types: `double`

**`CombinedRaysOutput` — Option to combine two rays at output**
`true` (default) | `false`

Option to combine the two rays at channel output, specified as `true` or `false`. When this property is `true`, the object coherently adds the line-of-sight propagated signal and the reflected path signal when forming the output signal. Use this mode when you do not need to include the directional gain of an antenna or array in your simulation.

Data Types: `logical`

**`MaximumDistanceSource` — Source of maximum one-way propagation distance**
`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

**`MaximumDistance` — Maximum one-way propagation distance**
`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

**Dependencies**

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

**`MaximumNumInputSamplesSource` — Source of maximum number of samples**
`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

To use this object with variable-size signals in a MATLAB Function Block in Simulink, set the `MaximumNumInputSamplesSource` property to `'Property'` and set a value for the `MaximumNumInputSamples` property.

Example: `'Property'`

**Dependencies**

To enable this property, set `MaximumDistanceSource` to `'Property'`.

Data Types: `char`

**`MaximumNumInputSamples` — Maximum number of input signal samples**
`100` (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the `step` method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform `OutputFormat` property is set to `'Samples'`, the maximum signal length is the value specified in the `NumSamples` property.
- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: `2048`

**Dependencies**

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

# Methods

| | |
|---|---|
| reset | Reset states of System object |
| step | Propagate wideband signal from point to point using two-ray channel model |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

# Examples

### Scalar Wideband Signal Propagating in Two-Ray Channel

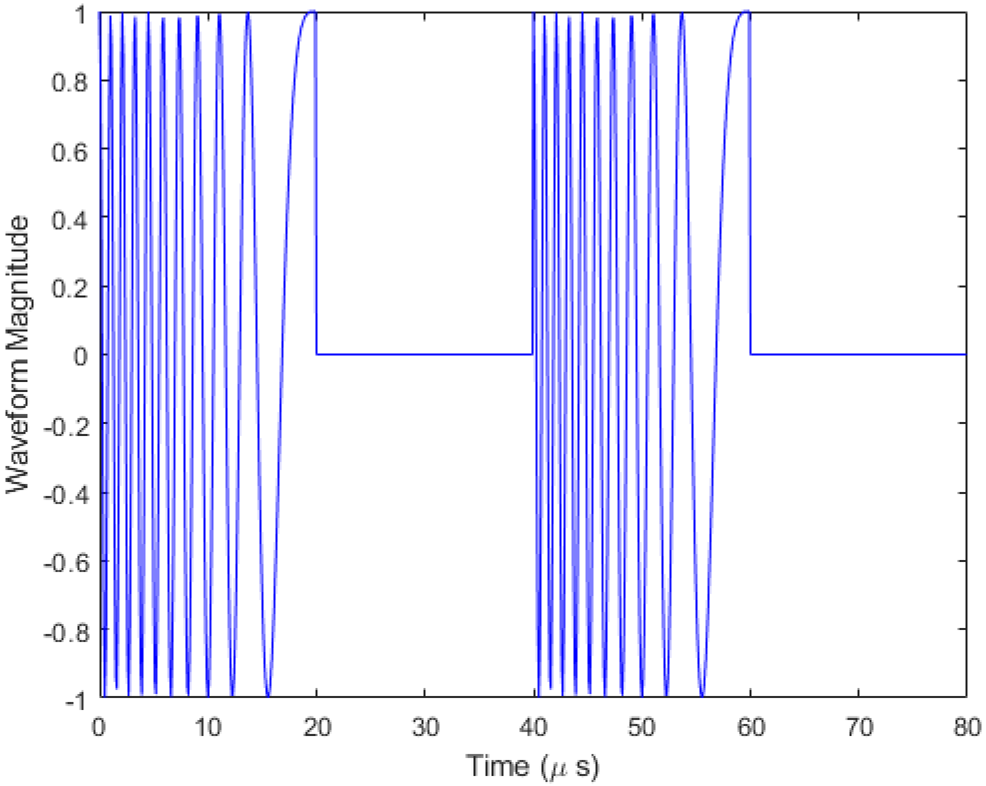
This example illustrates the two-ray propagation of a wideband signal, showing how the signals from the line-of-sight path and reflected path arrive at the receiver at different times.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

### Create and Plot Transmitted Waveform

Create a nonpolarized electromagnetic field consisting of two linear FM waveform pulses at a carrier frequency of 100 MHz. Assume the pulse width is 20 µs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle so that the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Set the `GroundReflectionCoefficient` to –0.9 to model strong ground reflectivity. Propagate the field from a stationary source to a stationary receiver. The vertical separation of the source and receiver is approximately 10 km.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 20e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
lambda = c/fc;
bw = 1e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
```



### Specify the Location of Source and Receiver

Place the source and receiver about 1 km apart horizontally and approximately 5 km apart vertically.

```
pos1 = [0;0;100];
pos2 = [1e3;0;5.0e3];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

### Create a Wideband Two-Ray Channel System Object

Create a two-ray propagation channel System object™ and propagate the signal along both the line-of-sight and reflected ray paths. The same signal is propagated along both paths.

```
channel = phased.WidebandTwoRayChannel('SampleRate',fs,...
    'GroundReflectionCoefficient',-0.9,'OperatingFrequency',fc,...
    'CombinedRaysOutput',false);
prop_signal = channel([wav,wav],pos1,pos2,vel1,vel2);

[rng2,angs] = rangeangle(pos2,pos1,'two-ray');
```

Calculate time delays in µs.

```
tm = rng2/c*1e6;
disp(tm)
```

```
   16.6815   17.3357
```

Display the calculated propagation paths azimuth and elevation angles in degrees.

```
disp(angs)
```

```
         0         0
   78.4654  -78.9063
```

### Plot the Propagated Signals

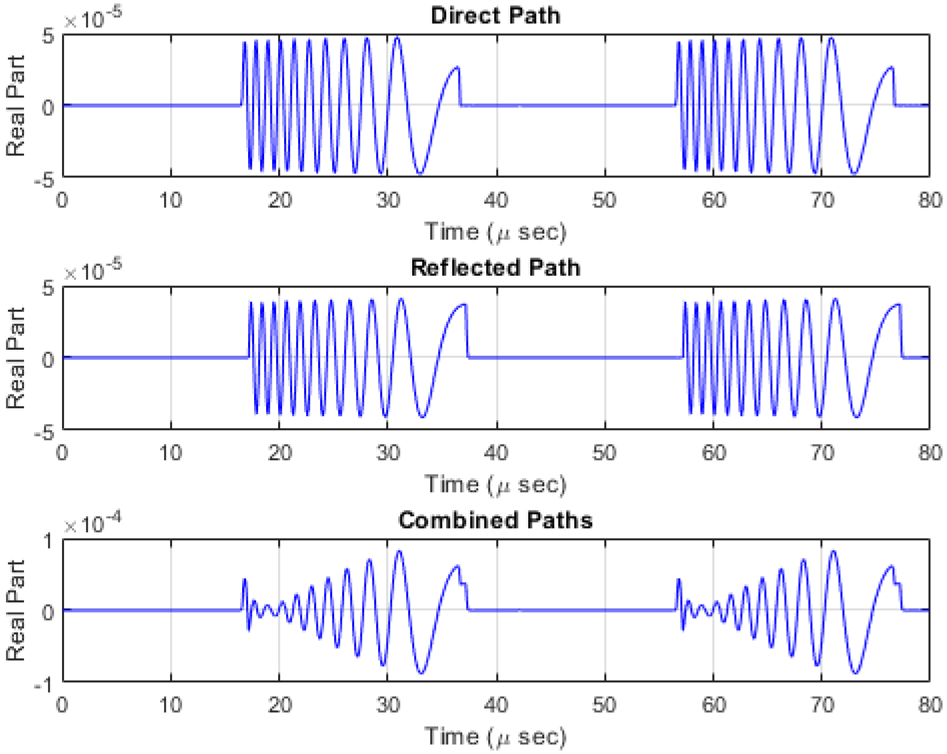
1. Plot the real part of the signal propagated along the line-of-sight path.
2. Plot the real part of the signal propagated along the reflected path.
3. Plot the real part of the coherent sum of the two signals.

```
n = size(prop_signal,1);
delay = [0:(n-1)]/fs*1e6;
subplot(3,1,1)
plot(delay,real([prop_signal(:,1)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Direct Path')

subplot(3,1,2)
plot(delay,real([prop_signal(:,2)]),'b')
```

```
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Reflected Path')

subplot(3,1,3)
plot(delay,real([prop_signal(:,1) + prop_signal(:,2)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Combined Paths')
```



The delay of the reflected path signal agrees with the predicted delay. The magnitude of the coherently combined signal is less than either of the propagated signals. This result indicates that the two signals contain some interference.

### Compare Wideband Two-Ray Channel Propagation to Free Space

Calculate the result of propagating a wideband LFM signal in a two-ray environment from a radar 10 meters above the origin *(0,0,10)* to a target at *(3000,2000,2000)* meters. Assume that the radar and target are stationary and that the transmitting antenna is isotropic. Combine the signal from the two paths and compare the signal to a signal propagating in free space. The system operates at 300 MHz. Set the `CombinedRaysOutput` property to `true` to combine the direct path and reflected path signals when forming the output signal.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create a linear FM waveform.

```
fop = 300.0e6;
fs = 1.0e6;
waveform = phased.LinearFMWaveform();
x = waveform();
```

Specify the target position and velocity.

```
posTx = [0; 0; 10];
posTgt = [3000; 2000; 2000];
velTx = [0;0;0];
velTgt = [0;0;0];
```

Model the free space propagation.

```
fschannel = phased.WidebandFreeSpace('SampleRate',waveform.SampleRate);
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
```

Model two-ray propagation from the position of the radar to the target.

```
tworaychannel = phased.WidebandTwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',true);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
```

```
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Location','best')
xlabel('Samples')
ylabel('Signal Magnitude')
hold on
```

Move the radar by 10 meters horizontally to a second position.

```
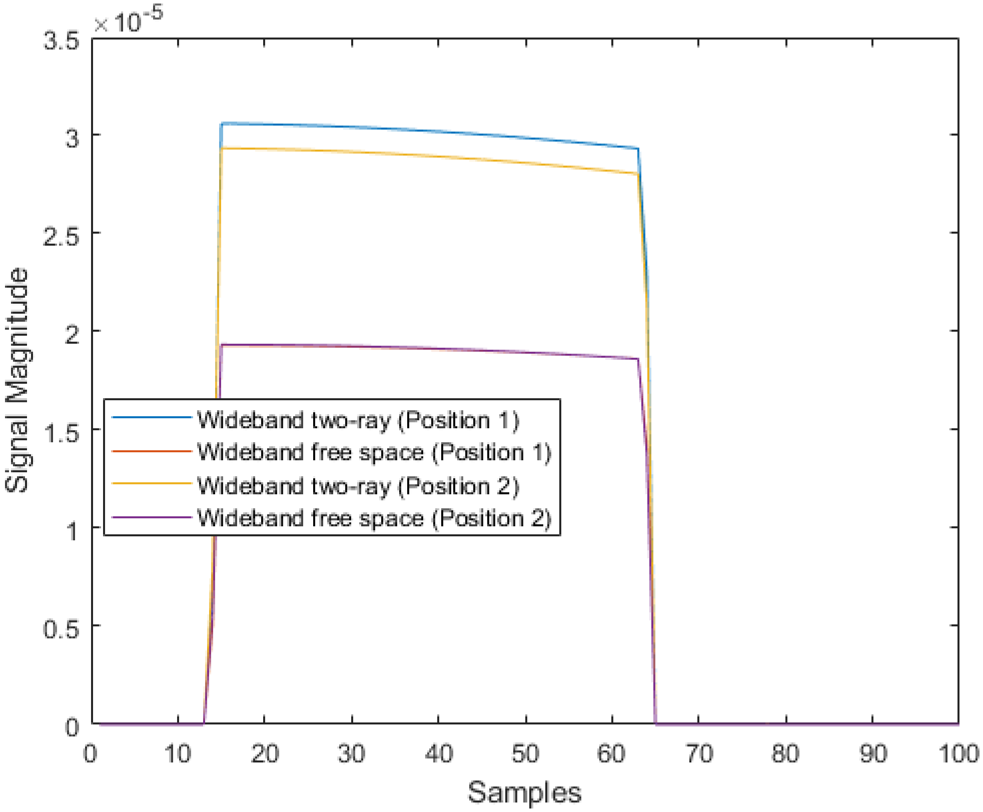
posTx = posTx + [10;0;0];
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
y_tworay = twoorayhannel(x,posTx,posTgt,velTx,velTgt);
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Wideband two-ray (Position 2)','Wideband free space (Position 2)',...
    'Location','best')
hold off
```



The free-space propagation losses are the same for both the first and second positions of the radar. The two-ray losses are different due to the interference effect of the two-ray paths.

### Wideband Polarized Field Propagation in Two-Ray Channel

Create a polarized electromagnetic field consisting of linear FM waveform pulses. Propagate the field from a stationary source with a crossed-dipole antenna element to a stationary receiver approximately 10 km away. The transmitting antenna is 100 m above the ground. The receiving antenna is 150 m above the ground. The receiving antenna is also a crossed-dipole. Plot the received signal.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

#### Set Radar Waveform Parameters

Assume the pulse width is10$\mu s$ and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle in which the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Assume a carrier frequency of 100 MHz.

```
c = physconst('LightSpeed');
fs = 20e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
bw = 1e6;
lambda = c/fc;
```

#### Set Up Required System Objects

Use a `GroundRelativePermittivity` of 10.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[50,200]*1e6);
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc,...
    'Polarization','Combined');
channel = phased.WidebandTwoRayChannel('SampleRate',fs,...
    'OperatingFrequency',fc,'CombinedRaysOutput',false,...
    'EnablePolarization',true,'GroundRelativePermittivity',10);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc,...
    'Polarization','Combined');
```

### Set Up Scene Geometry

Specify transmitter and receiver positions, velocities, and orientations. Place the source and receiver approximately 1000 m apart horizontally and approximately 50 m apart vertically.

```
posTx = [0;100;100];
posRx = [1000;0;150];
velTx = [0;0;0];
velRx = [0;0;0];
laxRx = rotz(180);
laxTx = rotx(1)*eye(3);
```

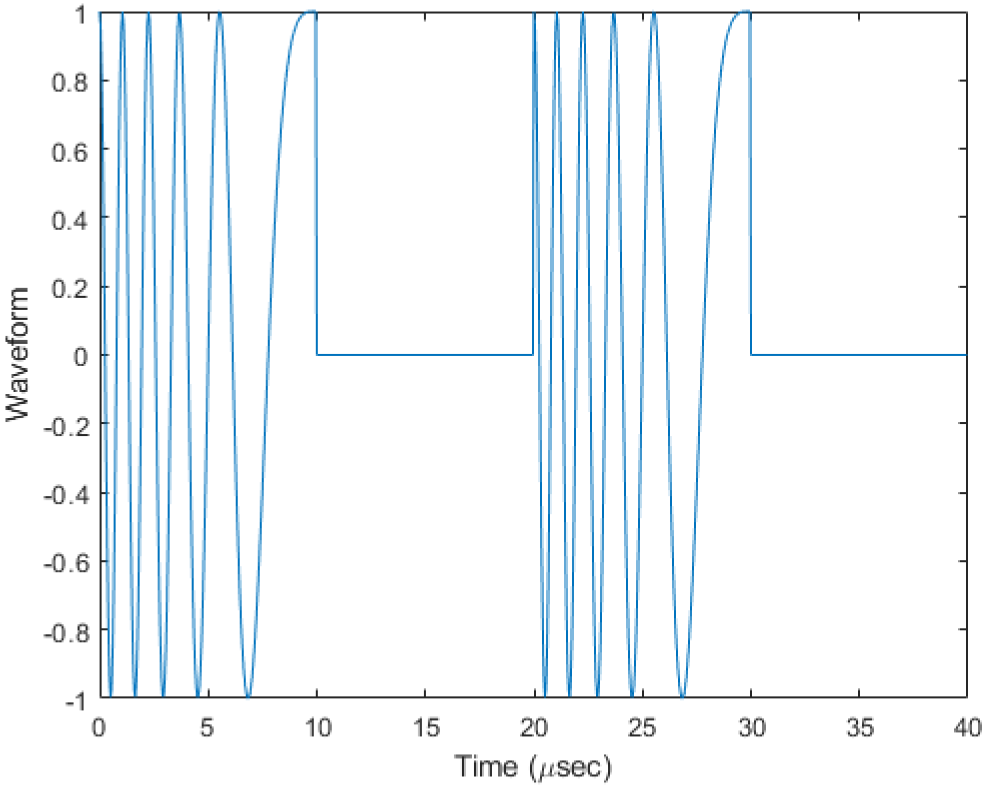
### Create and Radiate Signals from Transmitter

Compute the transmission angles for the two rays traveling toward the receiver. These angles are defined with respect to the transmitter local coordinate system. The `phased.Radiator` System object(TM) uses these angles to apply separate antenna gains to the two signals.

```
[rng,angsTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
wav = waveform();
```

Plot the transmitted waveform.

```
n = size(wav,1);
plot([0:(n-1)]/fs*1000000,real(wav))
xlabel('Time ({\mu}sec)')
ylabel('Waveform')
```



```
sig = radiator(wav,angsTx,laxTx);
```

Propagate the signals to the receiver via a two-ray channel.

```
prop_sig = channel(sig,posTx,posRx,velTx,velRx);
```

### Receive Propagated Signal

Compute the reception angles for the two rays arriving at the receiver. These angles are defined with respect to the receiver local coordinate system. The `phased.Collector` System object(TM) uses these angles to apply separate antenna gains to the two signals.

```
[rng1,angsRx] = rangeangle(posTx,posRx,laxRx,'two-ray');
delays = rng1/c*1e6
delays = 1×2

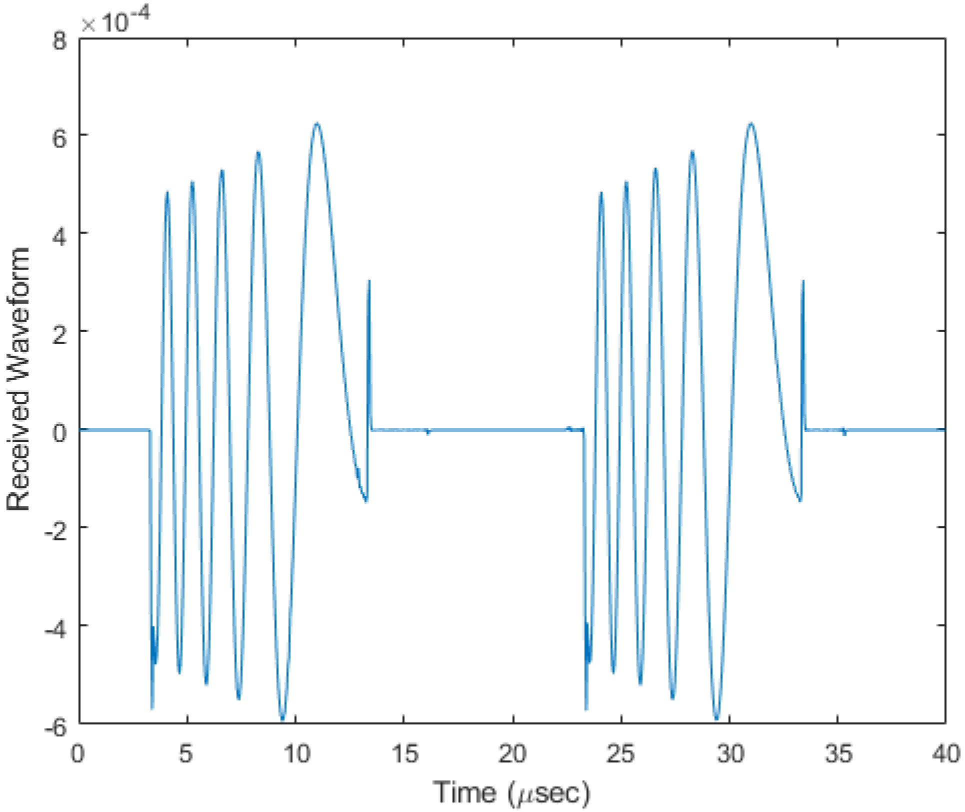
    3.3564    3.4544
```

Collect and combine the received rays.

```
y = collector(prop_sig,angsRx,laxRx);
```

Plot the received waveform.

```
plot([0:(n-1)]/fs*1000000,real(y))
xlabel('Time ({\mu}sec)')
ylabel('Received Waveform')
```



### Two-Ray Propagation of Wideband LFM Waveform with Atmospheric Losses

Propagate a wideband linear FM signal in a two-ray channel. The signal bandwidth is 15% of the carrier frequency. Assume there is signal loss caused by atmospheric gases and rain. The signal propagates from a transmitter located at `(0,0,0)` meters in the global coordinate system to a receiver at `(10000,200,30)` meters. Assume that the transmitter and the receiver are stationary and that they both have cosine antenna patterns. Plot the received signal. Set the dry air pressure to 102.0 Pa and the rain rate to 5 mm/hr.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

### Set Radar Waveform Parameters

```
c = physconst('LightSpeed');
fs = 40e6;
pw = 10e-6;
pri = 2.5*pw;
PRF = 1/pri;
fc = 100e6;
bw = 15e6;
lambda = c/fc;
```

### Set Up Radar Scenario

Create the required System objects.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
collector = phased.Collector('Sensor',antenna);
channel = phased.WidebandTwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',false,'GroundReflectionCoefficient',0.95,...
    'SpecifyAtmosphere',true,'Temperature',20,...
    'DryAirPressure',102.5,'RainRate',5.0);
```

Set up the scene geometry. Specify transmitter and receiver positions and velocities. The transmitter and receiver are stationary.

```
posTx = [0;0;0];
posRx = [10000;200;30];
velTx = [0;0;0];
velRx = [0;0;0];
```

Specify the transmitting and receiving radar antenna orientations with respect to the global coordinates. The transmitting antenna points along the positive *x*-direction and the receiving antenna points close to the negative *x*-direction.

```
laxTx = eye(3);
laxRx = rotx(5)*rotz(170);
```

Compute the transmission angles which are the angles at which the two rays traveling toward the receiver leave the transmitter. The `phased.Radiator` System object™ uses these angles to apply separate antenna gains to the two signals. Because the antenna gains depend on path direction, you must transmit and receive the two rays separately.

```
[~,angTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
```

### Create and Radiate Signals from Transmitter

Radiate the signals along the transmission directions.

```
wavfrm = waveform();
wavtrans = radiator(wavfrm,angTx);
```

Propagate the signals to the receiver via a two-ray channel.

```
wavrcv = channel(wavtrans,posTx,posRx,velTx,velRx);
```

### Collect Signal at Receiver

Compute the angle at which the two rays traveling from the transmitter arrive at the receiver. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

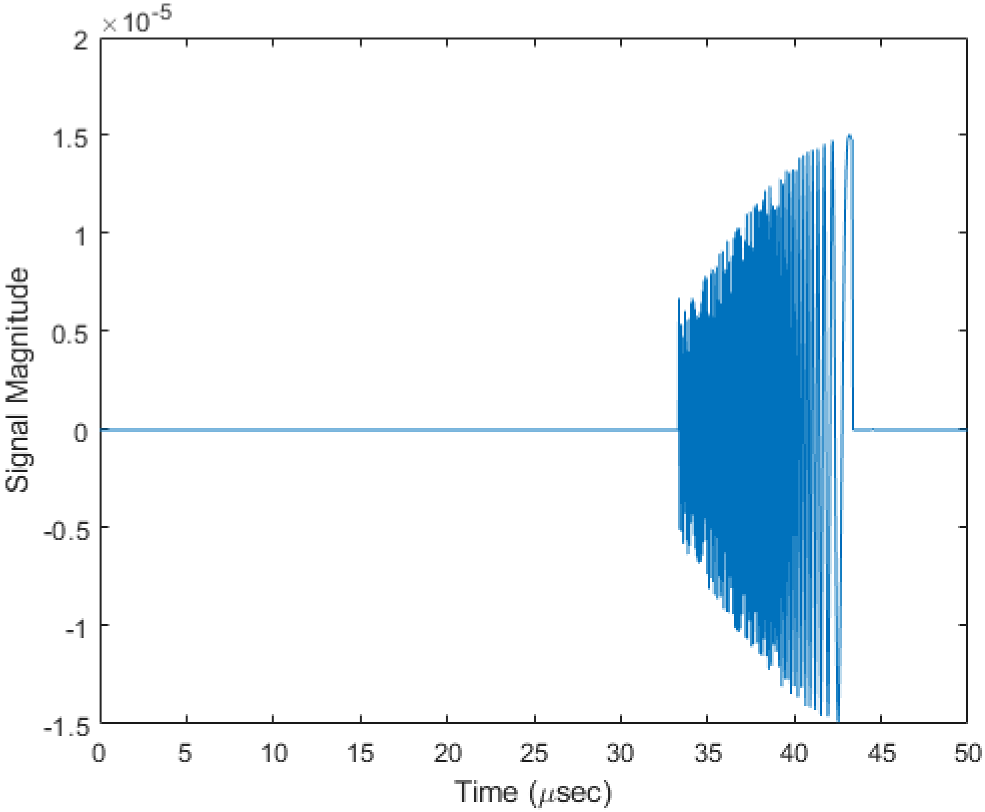
```
[~,angRcv] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine the two received rays.

```
yR = collector(wavrcv,angRcv);
```

### Plot Received Signal

```
dt = 1/waveform.SampleRate;
n = size(yR,1);
plot([0:(n-1)]*dt*1e6,real(yR))
xlabel('Time ({\mu}sec)')
ylabel('Signal Magnitude')
```



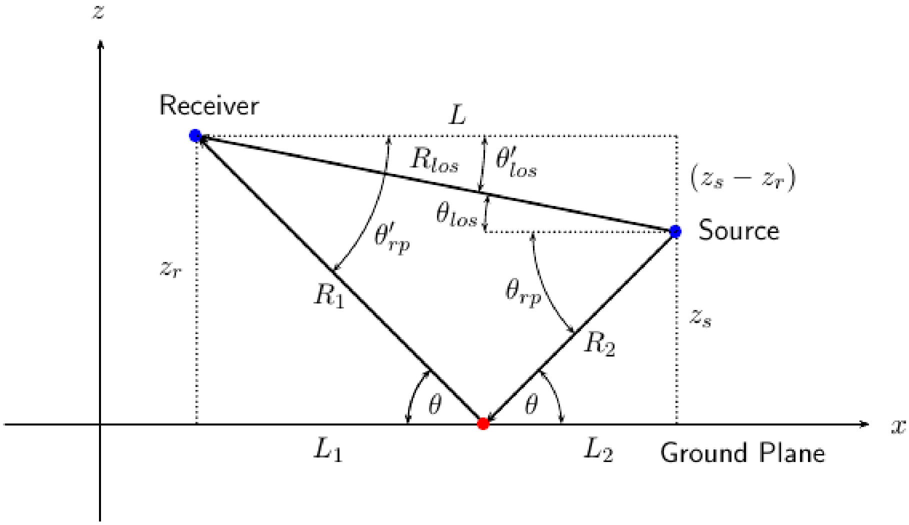
# More About

## Two-Ray Propagation Paths

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at *z = 0*. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel (see the `phased.FreeSpace` System object). The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The `phased.TwoRayChannel` and `phased.WidebandTwoRayChannel` System objects model propagation time delay, phase shift, Doppler shift, and loss effects for both paths. For the reflected path, loss effects include reflection loss at the boundary.

The figure illustrates two propagation paths. From the source position, $s_s$, and the receiver position, $s_r$, you can compute the arrival angles of both paths, $\theta'_{los}$ and $\theta'_{rp}$. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, $\theta_{los}$ and $\theta_{rp}$. In the global coordinates, the angle of reflection at the boundary is the same as the angles $\theta_{rp}$ and $\theta'_{rp}$. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by $R_{los}$ which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp}= R_1 + R_2$. The quantity $L$ is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$\overrightarrow{R} = \overrightarrow{x}_s - \overrightarrow{x}_r$$

$$R_{los} = \left|\overrightarrow{R}\right| = \sqrt{(z_r - z_s)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{(z_r + z_s)^2 + L^2}$$

$$\tan\theta_{los} = \frac{(z_s - z_r)}{L}$$

$$\tan\theta_{rp} = -\frac{(z_s + z_r)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

## Two-Ray Attenuation

Attenuation or path loss in the two-ray channel is the product of five components, $L = L_{tworay}\, L_G\, L_g\, L_c\, L_r$, where

- $L_{tworay}$ is the two-ray geometric path attenuation
- $L_G$ is the ground reflection attenuation
- $L_g$ is the atmospheric path attenuation
- $L_c$ is the fog and cloud path attenuation
- $L_r$ is the rain path attenuation

Each component is in magnitude units, not in dB.

## Ground Reflection and Propagation Loss

Losses occurs when a signal is reflected from a boundary. You can obtain a simple model of ground reflection loss by representing the electromagnetic field as a scalar field. This approach also works for acoustic and sonar systems. Let $E$ be a scalar free-space electromagnetic field having amplitude $E_0$ at a reference distance $R_0$ from a transmitter (for example, one meter). The propagating free-space field at distance $R_{los}$ from the transmitter is

$$E_{los} = E_0\left(\frac{R_0}{R_{los}}\right)e^{i\omega(t - R_{los}/c)}$$

for the line-of-sight path. You can express the ground-reflected $E$-field as

$$E_{rp} = L_G E_0\left(\frac{R_0}{R_{rp}}\right)e^{i\omega\left(t - R_{rp}/c\right)}$$

where $R_{rp}$ is the reflected path distance. The quantity $L_G$ represents the loss due to reflection at the ground plane. To specify $L_G$, use the `GroundReflectionCoefficient` property. In general, $L_G$ depends on the incidence angle of the field. If you have empirical information about the angular dependence of $L_G$, you can use `rangeangle` to compute the incidence angle of the reflected path. The total field at the destination is the sum of the line-of-sight and reflected-path fields.

For electromagnetic waves, a more complicated but more realistic model uses a vector representation of the polarized field. You can decompose the incident electric field into two components. One component, $E_p$, is parallel to the plane of incidence. The other component, $E_s$, is perpendicular to the plane of incidence. The ground reflection coefficients for these components differ and can be written in terms of the ground permittivity and incidence angle.

$$G_p = \frac{Z_1\cos\theta_1 - Z_2\cos\theta_2}{Z_1\cos\theta_1 + Z_2\cos\theta_2} = \frac{\cos\theta_1 - \frac{Z_2}{Z_1}\cos\theta_2}{\cos\theta_1 + \frac{Z_2}{Z_1}\cos\theta_2}$$

$$G_s = \frac{Z_2\cos\theta_1 - Z_1\cos\theta_2}{Z_2\cos\theta_1 + Z_1\cos\theta_2} = \frac{\cos\theta_2 - \frac{Z_2}{Z_1}\cos\theta_1}{\cos\theta_2 + \frac{Z_2}{Z_1}\cos\theta_1}$$

$$Z_1 = \sqrt{\frac{\mu_1}{\varepsilon_1}}$$

$$Z_2 = \sqrt{\frac{\mu_2}{\varepsilon_2}}$$

where *Z* is the impedance of the medium. Because the magnetic permeability of the ground is almost identical to that of air or free space, the ratio of impedances depends primarily on the ratio of electric permittivities

$$G_p = \frac{\sqrt{\rho}\cos\theta_1 - \cos\theta_2}{\sqrt{\rho}\cos\theta_1 + \cos\theta_2}$$

$$G_s = \frac{\sqrt{\rho}\cos\theta_2 - \cos\theta_1}{\sqrt{\rho}\cos\theta_2 + \cos\theta_1}$$

where the quantity $\rho = \varepsilon_2/\varepsilon_1$ is the *ground relative permittivity* set by the `GroundRelativePermittivity` property. The angle $\theta_1$ is the incidence angle and the angle $\theta_2$ is the refraction angle at the boundary. You can determine $\theta_2$ using Snell's law of refraction.

After reflection, the full field is reconstructed from the parallel and perpendicular components. The total ground plane attenuation, $L_G$, is a combination of $G_s$ and $G_p$.

When the origin and destination are stationary relative to each other, you can write the output `Y` of `step` as $Y(t) = F(t\text{-}\tau)/L$. The quantity $\tau$ is the signal delay and $L$ is the free-space path loss. The delay $\tau$ is given by $R/c$. $R$ is either the line-of-sight propagation path distance or the reflected path distance, and $c$ is the propagation speed. The path loss

$$L_{tworay} = \frac{(4\pi R)^2}{\lambda^2},$$

where $\lambda$ is the signal wavelength.

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f) .$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_\mathrm{i}$, multiplied by a spectral line strength, *S*$_\mathrm{i}$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right] P .$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right] W .$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7} .$$

The total atmospheric pressure is *P* + *W*.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, *R*. Then, the total attenuation is $L_g$= $R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_B$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, \quad N_B \text{ even} \\ f_c - \dfrac{(N_B-1)f_s}{2N_B} + (m-1)\Delta f, \quad N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

# reset

**System object:** `phased.WidebandTwoRayChannel`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(channel)
```

## Description

`reset(channel)` resets the internal state of the `phased.WidebandTwoRayChannel` System object, `channel`.

## Input Arguments

### `channel` — Wideband two-ray channel

`phased.WidebandTwoRayChannel` System object

Wideband two-ray channel, specified as a System object.

**Introduced in R2016b**

# step

**System object:** `phased.WidebandTwoRayChannel`
**Package:** `phased`

Propagate wideband signal from point to point using two-ray channel model

## Syntax

```
prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

## Description

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a wideband signal, `sig`, propagates through a two-ray channel from the `origin_pos` position to the `dest_pos` position. Either the `origin_pos` or `dest_pos` arguments can have multiple points but you cannot specify both as having multiple points. Specify the velocity of the signal origin in `origin_vel` and the velocity of the signal destination in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

In the two-ray environment, two signal paths connect every signal origin and destination pair. For *N* signal origins (or *N* signal destinations), there are *2N* paths. The signals for each origin-destination pair do not have to be identical. The signals along the two paths for any source-destination pair can have different amplitudes or phases.

The `CombinedRaysOutput` property controls whether the two signals at the destination are kept *separate* or *combined*. *Combined* means that the signals at the source propagate separately along the two paths but are coherently summed at the destination into a single quantity. *Separate*means that the two signals are not summed at the destination. To use the *combined* option, set `CombinedRaysOutput` to `true`. To use the *separate* option, set `CombinedRaysOutput` to `false`. The *combined* option is convenient when the difference between the sensor or array gains in the directions of the two paths is not significant.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `channel` — Wideband two-ray channel

System object

Wideband two-ray channel, specified as a System object.

Example: `phased.WidebandTwoRayChannel`

### `sig` — Wideband signal

*M*-by-*N* complex-valued matrix | *M*-by-2*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-2*N* `struct` array containing complex-valued fields

Electromagnetic fields propagated through a two-ray channel can be polarized or nonpolarized. For nonpolarized fields, such as an acoustic field, the propagating signal field, `sig`, is a vector or matrix. When the fields are polarized, `sig` is an array of structures. Every structure element contains an array of electric field vectors in Cartesian form.

- Specify wideband nonpolarized scalar signals as a
  - *M*-by-*N* complex-valued matrix. The same signal is propagated along both the line-of-sight path and the reflected path.
  - *M*-by-2*N* complex-valued matrix. Each adjacent pair of columns represents a different channel. Within each pair, the first column represents the signal propagated along the line-of-sight path and the second column represents the signal propagated along the reflected path.

- Specify wideband polarized signals as a
  - 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`. The same signal is propagated along both the line-of-sight path and the reflected path.
  - 1-by-2*N* `struct` array containing complex-valued fields. Each pair of array columns represents a different source-receiver channel. The first column of the pair represents the signal along the line-of-sight path and the second column represents the signal along the reflected path. Each structure element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`.

For nonpolarized fields, the quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

For polarized fields, the `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

### `origin_pos` — Signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: [1000;100;500]

Data Types: double

**dest_pos — Signal destinations**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels propagating from or to *N* signal origins. If dest_pos is a 3-by-1 column vector, it takes the form [x;y;z]. If dest_pos is a matrix, each column specifies a different signal destination and takes the form [x;y;z] Position units are in meters.

You cannot specify both origin_pos and dest_pos as matrices. At least one must be a 3-by-1 column vector.

Example: [0;0;0]

Data Types: double

**origin_vel — Velocity of signal origin**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of origin_vel must match the dimensions of origin_pos. If origin_vel is a column vector, it takes the form [Vx;Vy;Vz]. If origin_vel is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form [Vx;Vy;Vz]. Velocity units are in meters per second.

Example: [10;0;5]

Data Types: double

**dest_vel — Velocity of signal destinations**
3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3–by-*N* real-valued matrix. The dimensions of dest_vel must match the dimensions of dest_pos. If dest_vel is a column vector, it takes the form [Vx;Vy;Vz]. If dest_vel is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form [Vx;Vy;Vz] Velocity units are in meters per second.

Example: [0;0;0]

Data Types: double

## Output Arguments

**prop_sig — Propagated signal**

*M*-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix | 1-by-*N* struct array containing complex-valued fields | 1-by-*2N* struct array containing complex-valued fields

- Wideband nonpolarized scalar signal, returned as an:
  - *M*-by-*N* complex-valued matrix. To return this format, set the CombinedRaysOutput property to true. Each matrix column contains the coherently combined signals from the line-of-sight path and the reflected path.
  - *M*-by-*2N* complex-valued matrix. To return this format set the CombinedRaysOutput property to false. Alternate columns of the matrix contain the signals from the line-of-sight path and the reflected path.
- Wideband polarized scalar signal, returned as:
  - 1-by-*N* struct array containing complex-valued fields. To return this format, set the CombinedRaysOutput property to true. Each column of the array contains the coherently combined signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector (prop_sig.X,prop_sig.Y,prop_sig.Z).
  - 1-by-*2N* struct array containing complex-valued fields. To return this format, set the CombinedRaysOutput property to false. Alternate columns contains the signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector (prop_sig.X,prop_sig.Y,prop_sig.Z).

The output prop_sig contains signal samples arriving at the signal destination within the current input time frame. Sometimes it can take longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contributions from the input of the current time frame. In this case, the output does not need to contain all contributions from the input of the current time frame. The remaining output appears in the next call to step.

## Examples

### Scalar Wideband Signal Propagating in Two-Ray Channel

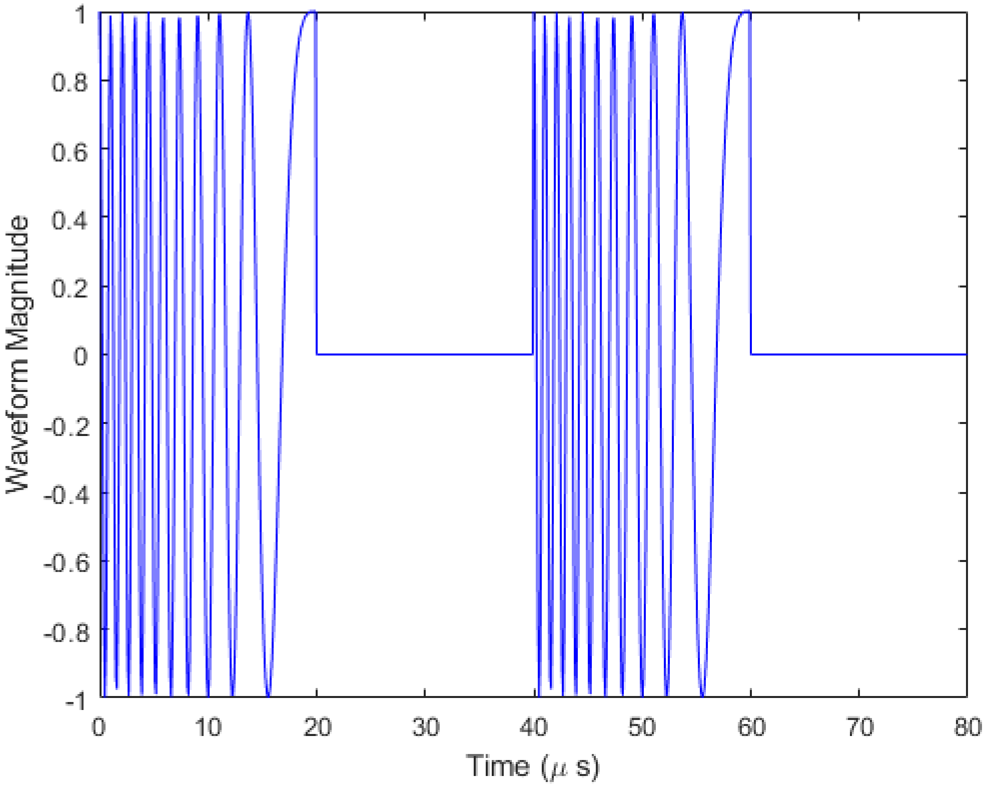
This example illustrates the two-ray propagation of a wideband signal, showing how the signals from the line-of-sight path and reflected path arrive at the receiver at different times.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

#### Create and Plot Transmitted Waveform

Create a nonpolarized electromagnetic field consisting of two linear FM waveform pulses at a carrier frequency of 100 MHz. Assume the pulse width is 20 µs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle so that the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Set the `GroundReflectionCoefficient` to –0.9 to model strong ground reflectivity. Propagate the field from a stationary source to a stationary receiver. The vertical separation of the source and receiver is approximately 10 km.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 20e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
lambda = c/fc;
bw = 1e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
```



### Specify the Location of Source and Receiver

Place the source and receiver about 1 km apart horizontally and approximately 5 km apart vertically.

```
pos1 = [0;0;100];
pos2 = [1e3;0;5.0e3];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

### Create a Wideband Two-Ray Channel System Object

Create a two-ray propagation channel System object™ and propagate the signal along both the line-of-sight and reflected ray paths. The same signal is propagated along both paths.

```
channel = phased.WidebandTwoRayChannel('SampleRate',fs,...
    'GroundReflectionCoefficient',-0.9,'OperatingFrequency',fc,...
    'CombinedRaysOutput',false);
prop_signal = channel([wav,wav],pos1,pos2,vel1,vel2);

[rng2,angs] = rangeangle(pos2,pos1,'two-ray');
```

Calculate time delays in µs.

```
tm = rng2/c*1e6;
disp(tm)
```

```
   16.6815   17.3357
```

Display the calculated propagation paths azimuth and elevation angles in degrees.

```
disp(angs)
```

```
         0         0
   78.4654  -78.9063
```

### Plot the Propagated Signals

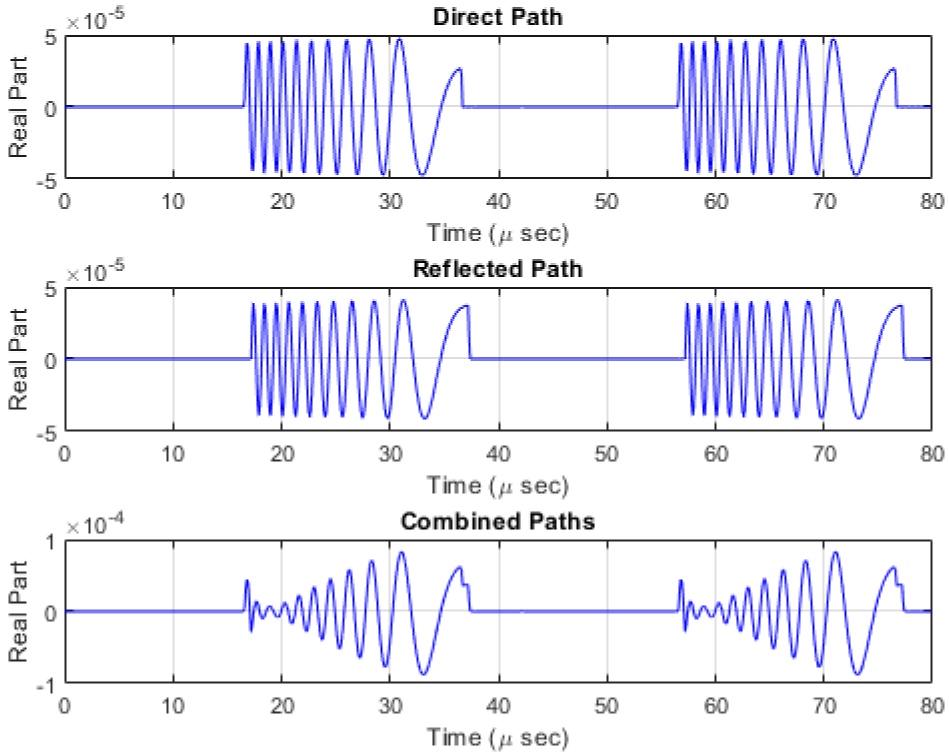
1. Plot the real part of the signal propagated along the line-of-sight path.
2. Plot the real part of the signal propagated along the reflected path.
3. Plot the real part of the coherent sum of the two signals.

```
n = size(prop_signal,1);
delay = [0:(n-1)]/fs*1e6;
subplot(3,1,1)
plot(delay,real([prop_signal(:,1)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Direct Path')

subplot(3,1,2)
plot(delay,real([prop_signal(:,2)]),'b')
```

```
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Reflected Path')

subplot(3,1,3)
plot(delay,real([prop_signal(:,1) + prop_signal(:,2)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Combined Paths')
```



The delay of the reflected path signal agrees with the predicted delay. The magnitude of the coherently combined signal is less than either of the propagated signals. This result indicates that the two signals contain some interference.

### Compare Wideband Two-Ray Channel Propagation to Free Space

Calculate the result of propagating a wideband LFM signal in a two-ray environment from a radar 10 meters above the origin *(0,0,10)* to a target at *(3000,2000,2000)* meters. Assume that the radar and target are stationary and that the transmitting antenna is isotropic. Combine the signal from the two paths and compare the signal to a signal propagating in free space. The system operates at 300 MHz. Set the `CombinedRaysOutput` property to `true` to combine the direct path and reflected path signals when forming the output signal.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create a linear FM waveform.

```
fop = 300.0e6;
fs = 1.0e6;
waveform = phased.LinearFMWaveform();
x = waveform();
```

Specify the target position and velocity.

```
posTx = [0; 0; 10];
posTgt = [3000; 2000; 2000];
velTx = [0;0;0];
velTgt = [0;0;0];
```

Model the free space propagation.

```
fschannel = phased.WidebandFreeSpace('SampleRate',waveform.SampleRate);
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
```

Model two-ray propagation from the position of the radar to the target.

```
tworaychannel = phased.WidebandTwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',true);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
```

```
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Location','best')
xlabel('Samples')
ylabel('Signal Magnitude')
hold on
```

Move the radar by 10 meters horizontally to a second position.

```
posTx = posTx + [10;0;0];
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Wideband two-ray (Position 2)','Wideband free space (Position 2)',...
    'Location','best')
hold off
```

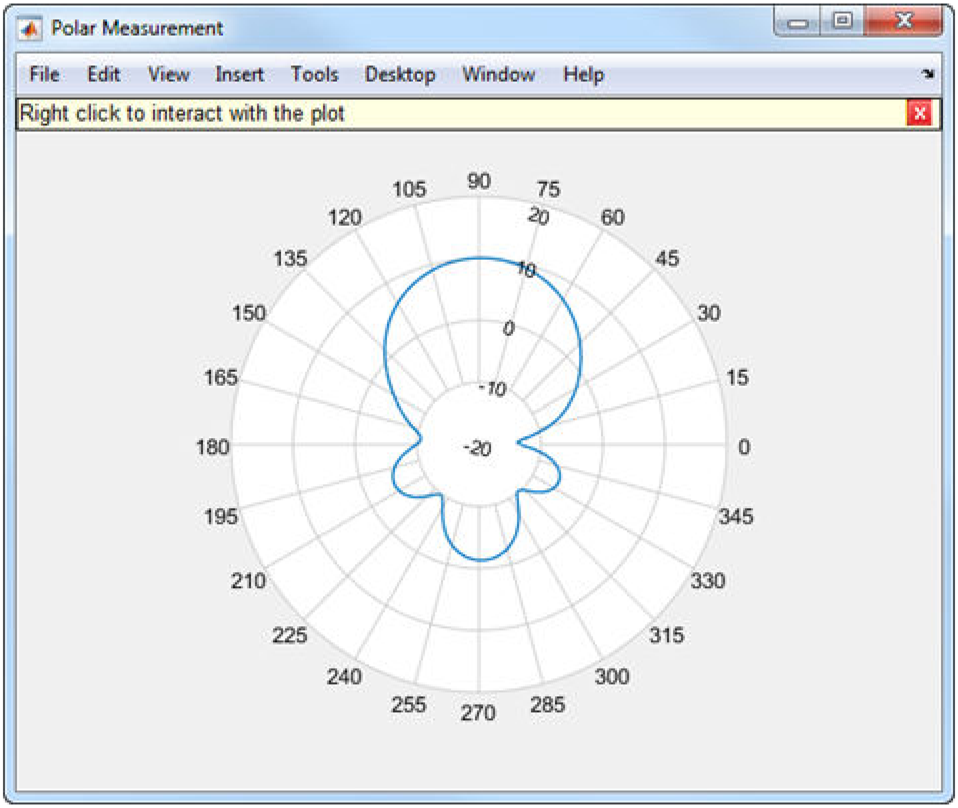
The free-space propagation losses are the same for both the first and second positions of the radar. The two-ray losses are different due to the interference effect of the two-ray paths.

**Introduced in R2016b**

# polarpattern class

Interactive plot of radiation patterns in polar format

## Description



Right click to interact with the plot

`polarpattern` class plots antenna or array radiation patterns in interactive polar format. You can also plot other types of polar data. Use these plots when interactive data visualization or measurement is required. Right-click the **Polar Measurement** window to change the properties, zoom in, or add more data to the plot.

## Construction

`polarpattern` plots antenna or array radiation patterns and other types of data in polar format. `polarpattern` plots field value data of radiation patterns for visualization and measurement. Right-click the polar plot to interact.

`polarpattern(data)` creates a polar plot with magnitude values in the vector `d`. In this polar plot, angles are uniformly spaced on the unit circle, starting at `0` degrees.

`polarpattern(angle,magnitude)` creates a polar plot from a set of angle vectors and corresponding magnitudes. You can also create polar plots from multiple sets for angle vectors and corresponding sets of magnitude using the syntax: `polarpattern(angle1, magnitude1, angle2, magnitude2...)`.

`p = polarpattern( ___ )` returns an object handle that you can use to customize the plot or add measurements. You can specify any of the arguments from the previous syntaxes.

`p = polarpattern('gco')` returns an object handle from polar pattern in the current figure.

`polarpattern( ___ ,Name,Value)` creates a polar plot, with additional properties specified by one or more name-value pair arguments. `Name` is the property name and `Value` is the corresponding property value. You can specify several name-value pair arguments in any order as `Name1`, `Value1`, `...`, `NameN`, `ValueN`. Properties not specified retain their default values. To list all the property `Name,Value` pairs, use `details(p)`. To list all the property `Name,Value` pairs, use `details(p)`. You can use the properties to extract any data from the radiation pattern from the polar plot. For example, `p = polarpattern(data,'Peaks',3)` identifies and displays the three highest peaks in the pattern data.

For a list of properties, see PolarPattern.

`polarpattern(ax, ___ )` creates a polar plot using axes handle, `ax` instead of the current axes handle.

## Input Arguments

### data — Antenna or array data

real length-*M* vector | real *M*-by-*N* matrix | real *N-D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0{:}M-1)}{M} \times 360^{\circ}$ degrees.
- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0{:}M-1)}{M} \times 360^{\circ}$ degrees.
- A real *N-D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*x*, *y*) of each point. *x* contains the real (`data`) and *y* contains the imaginary (`data`).

When data is in a logarithmic form, such as dB, magnitude values can be negative. In this case,`polarpattern` plots the smallest magnitude values at the origin of the polar plot and largest magnitude values at the maximum radius.

**`angle` — Set of angles**

vector in degrees

Set of angles, specified as a vector in degrees.

**`magnitude` — Set of magnitude values**

vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

## Methods

| | |
|---|---|
| `add` | Add data to existing polar plot |
| `addCursor` | Add cursor to polar plot angle |
| `animate` | Replace existing data with new data for animation |
| `createLabels` | Create legend labels |

| | |
|---|---|
| `findLobes` | Main, back and side lobe data |
| `replace` | Replace existing data with new data in polar plot |
| `showPeaksTable` | Show or hide peak marker table |
| `showSpan` | Show or hide angle span between two markers |

# Examples

### Plot Cosine Pattern in Polar Coordinates

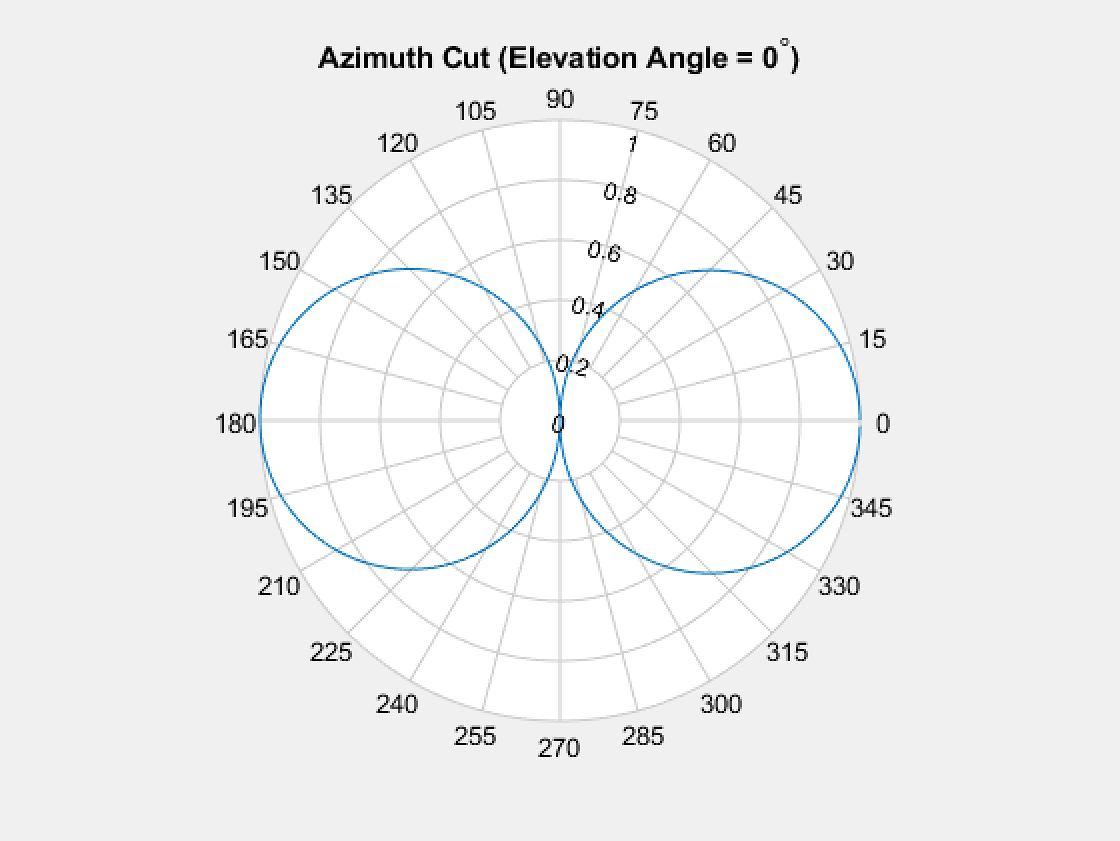
Specify a cosine antenna pattern from 0° to 360° in azimuth at 0° elevation. Then, plot the antenna pattern using `polarpattern`.

Create the pattern.

```
az = [0:360];
p = abs(cosd(az));
```

Plot the polar pattern of the antenna for an azimuth cut at 0° elevation.

```
polarpattern(p,'TitleTopTextInterpreter','tex','TitleTop','Azimuth Cut (Elevation Angle
```



### Azimuth Pattern of a 3-by-2 URA

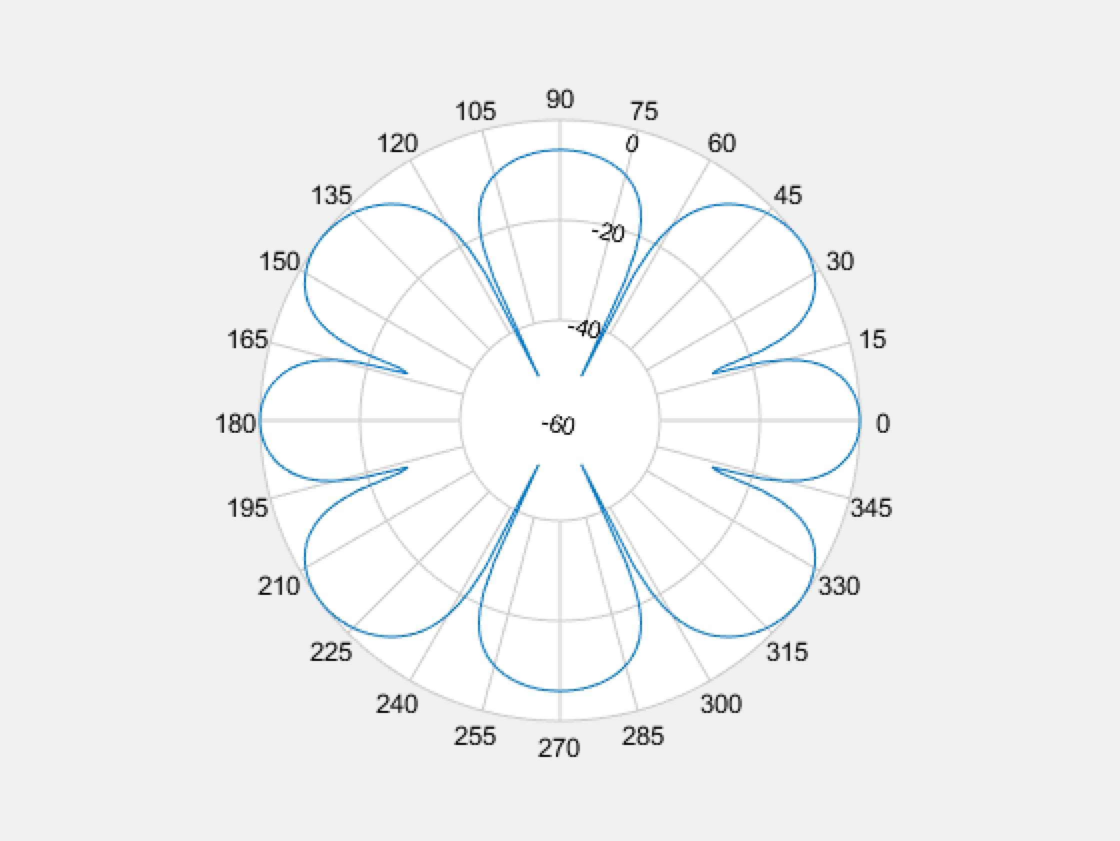
Construct a 3-by-2 rectangular lattice URA. By default, the array consists of isotropic antenna elements. Assume the operating frequency is 1 GHz. Then, plot the antenna pattern using `polarpattern`.

Create the array.

```
array = phased.URA('Size',[3 2]);
fc = 1.0e9;
```

Plot the polar pattern of the array for an elevation cut at 0° azimuth.

```
c = physconst('LightSpeed');
p = pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem',...
    'polar','Type','powerdb','Normalize',true);
polarpattern([-180:180],p);
```



### Polar Pattern Display with Title for Short-Dipole Antenna

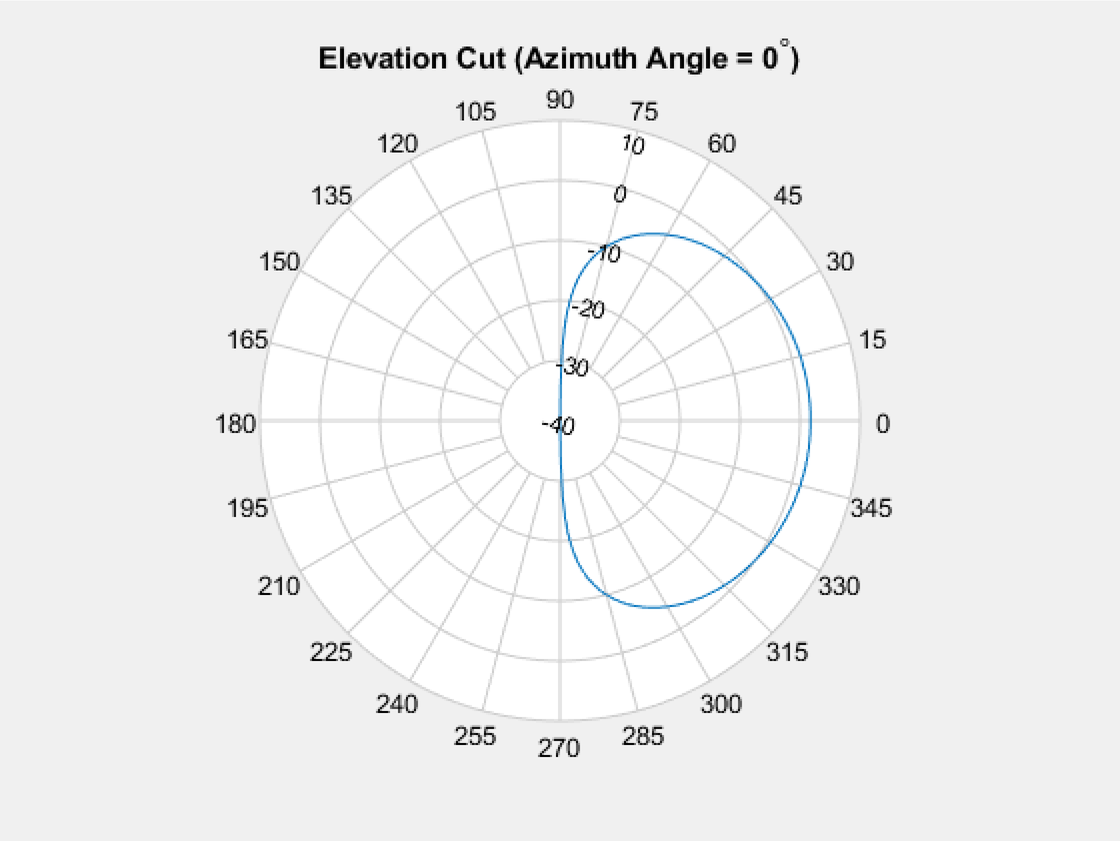
Specify a short-dipole antenna with the dipole oriented along the *z*-axis and operating at 250 MHz. Then, plot the antenna pattern using `polarpattern` and specifying a title.

Create the short-dipole antenna element System object™.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6,600e6],...
    'AxisDirection','Z');
fc = 250.0e6;
```

Plot the polar pattern of the antenna for an elevation cut at 0° azimuth.

```
v = pattern(antenna,fc,0,-90:90);
polarpattern([-90:90],v,'TitleTopTextInterpreter','tex',...
    'TitleTop','Elevation Cut (Azimuth Angle = 0^{\circ})');
```



### Polar Pattern Properties

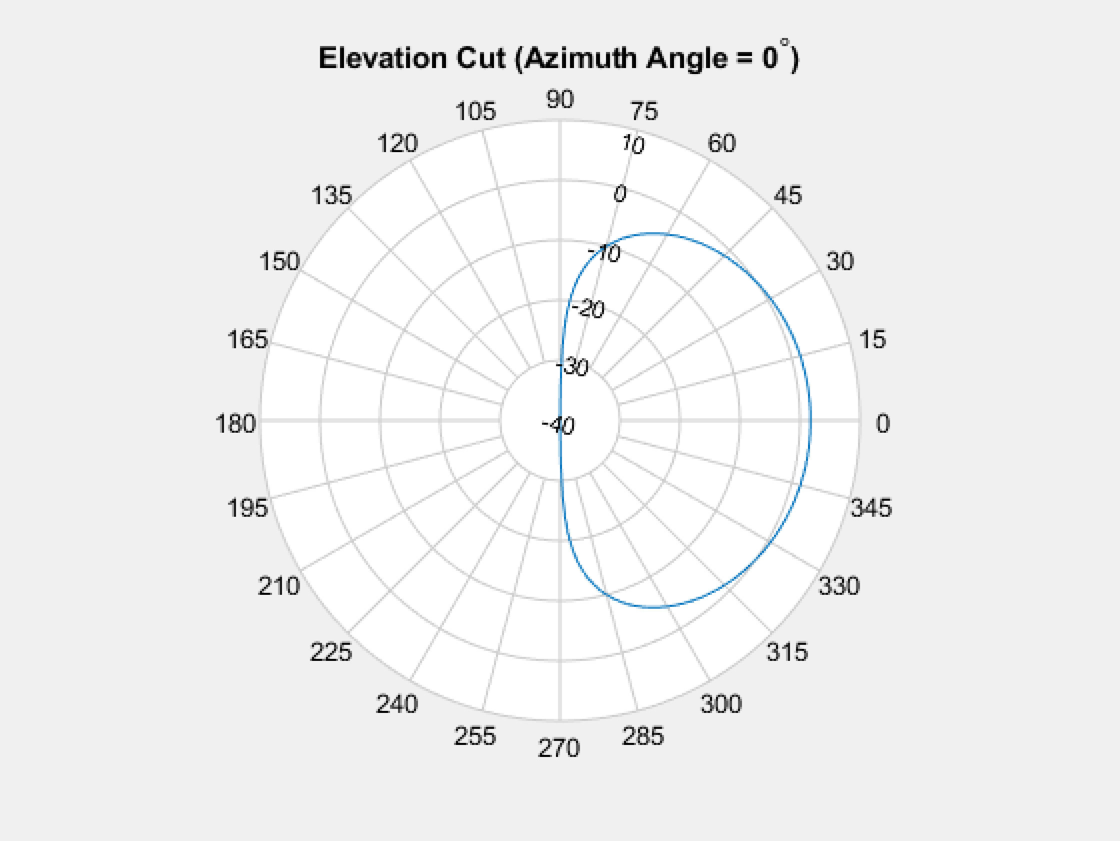
Specify a short-dipole antenna with the dipole oriented along the *z*-axis and operating at 250 MHz. Then, plot the antenna pattern using `polarpattern` and specifying a title.

Create the short-dipole antenna element System object™.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6,600e6],...
    'AxisDirection','Z');
fc = 250.0e6;
```

Create the polar pattern of the antenna for an elevation cut at 0° azimuth.

```
p = pattern(antenna,fc,0,-90:90);
P = polarpattern([-90:90],p,'TitleTopTextInterpreter','tex',...
    'TitleTop','Elevation Cut (Azimuth Angle = 0^{\circ})');
```



Display the properties of the plot.

```
details(P)
```

```

# See Also

**Introduced in R2016a**

# add

**Class:** `polarpattern`

Add data to polar plot

## Syntax

```
add(p,d)
add(p,angle,magnitude)
```

## Description

`add(p,d)` adds new antenna data to the polar plot, `p` based on the real amplitude values, `data`.

`add(p,angle,magnitude)` adds data sets of `angle` vectors and corresponding `magnitude` matrices to polar plot `p`.

## Input Arguments

### p — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

### data — Antenna or array data

real length-$M$ vector | real $M$-by-$N$ matrix | real $N$-$D$ array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-$M$ vector, where $M$ contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M} \times 360^{\circ}$ degrees.

- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0:M-1)}{M} \times 360^{\circ}$ degrees. The set of each angle can vary for each column.
- A real *N-D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*(x,y)* of each point. *x* contains the real part of `data` and *y* contains the imaginary part of `data`.

When data is in a logarithmic form such as dB, magnitude values can be negative. In this case,`polarpattern` plots the lowest magnitude values at the origin of the polar plot and highest magnitude values at the maximum radius.

**`angle` — Set of angles**
vector in degrees

Set of angles, specified as a vector in degrees.

**`magnitude` — Set of magnitude values**
vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

## Examples

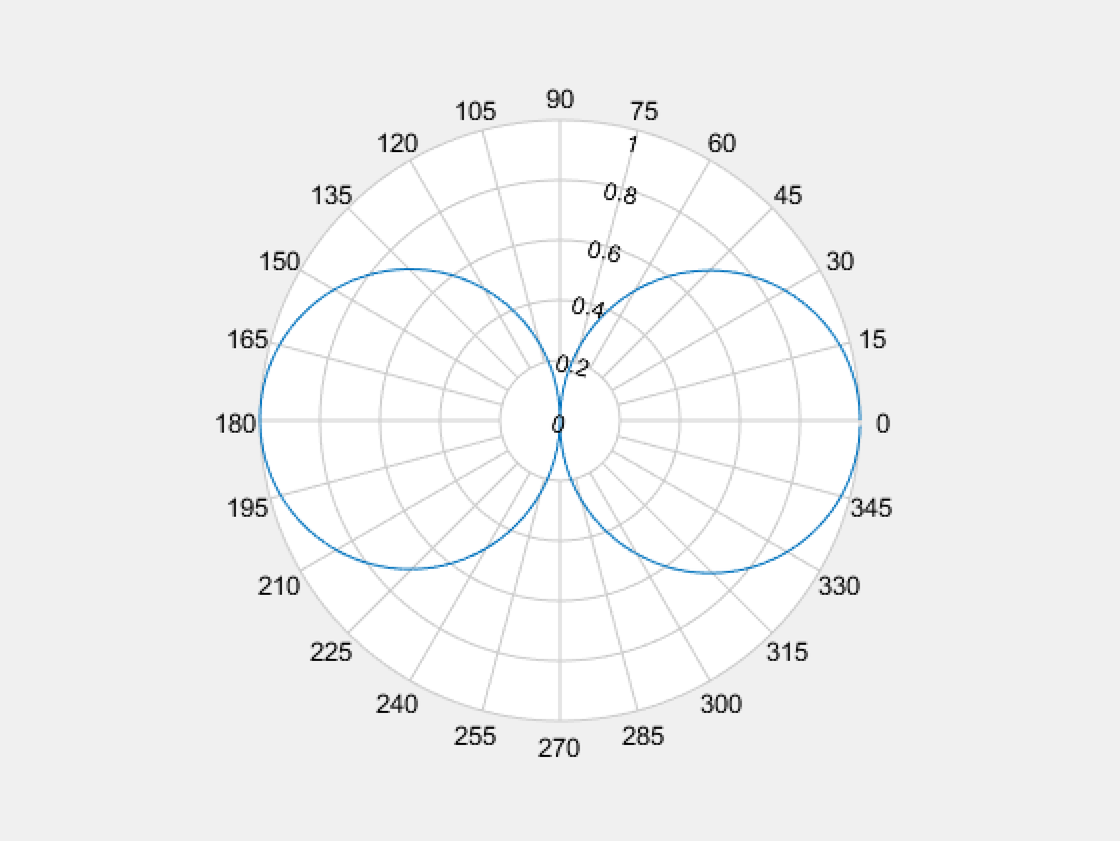
### Add Data To Existing Polar Plot

Create a cosine-pattern antenna and plot the pattern from 0° to 360&deg.

```
az = [0:360];
p1 = abs(cosd(az));
```

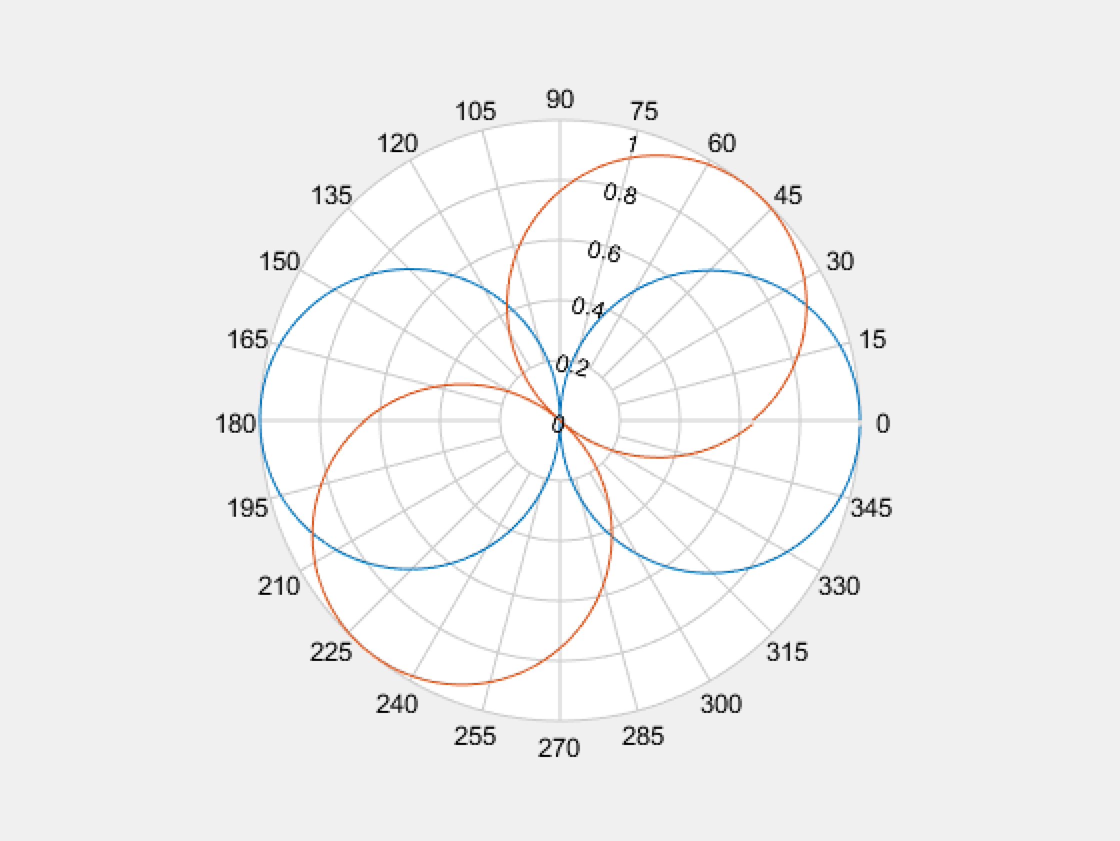
Plot the polar pattern.

```
P = polarpattern(p1);
```



Create a second cosine-pattern antenna rotated by 60°. Add this pattern to the existing pattern.

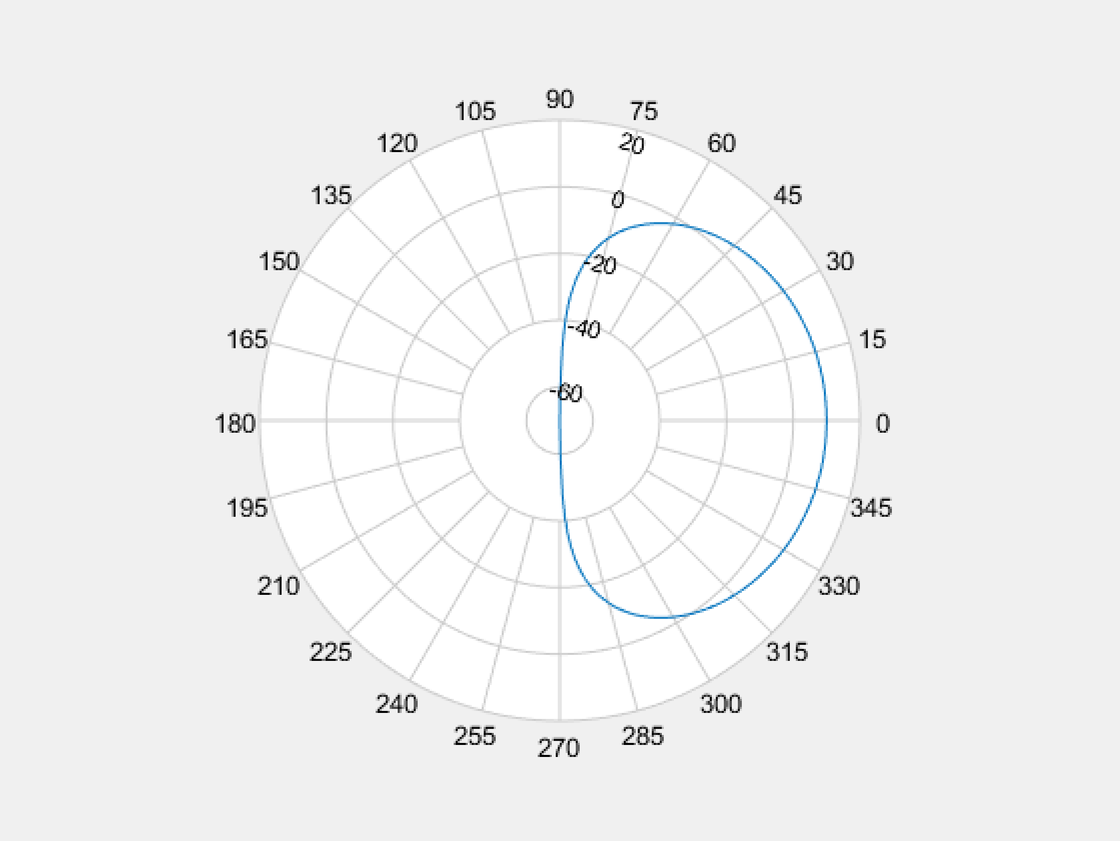
```
p2 = abs(cosd(az - 50));
add(P,p2);
```



### Add Second Plot to Polar Pattern

Create a cosine antenna and plot the polar pattern of its directivity at 75 MHz.

```
cosineantenna = phased.CosineAntennaElement('FrequencyRange',[1.0e0 100.0e9],...
    'CosinePower',[2,2]);
p1 = pattern(cosineantenna,75.0e6,[-90:90],0,'Type','Directivity');
P = polarpattern([-90:90],p1);
```

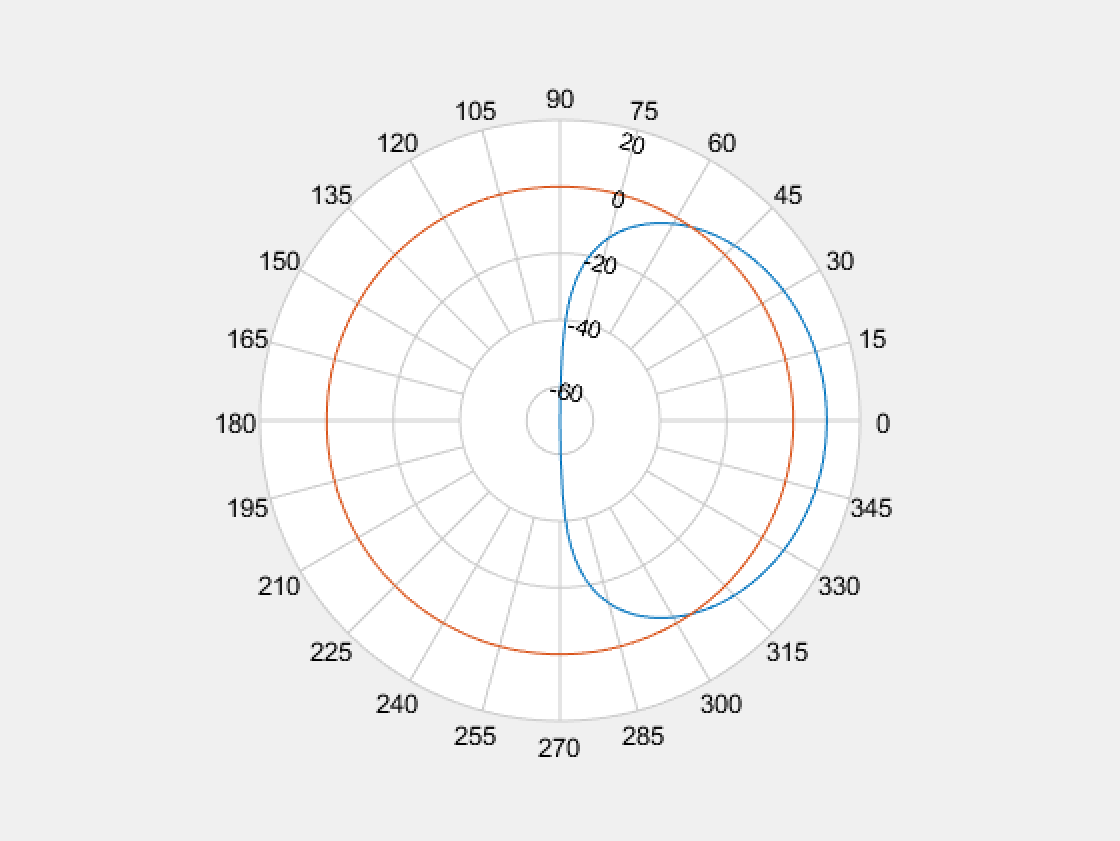


Create an isotropic antenna. Calculate the directivity of this antenna at 75 MHz.

```
isoantenna = phased.IsotropicAntennaElement('FrequencyRange',...
    [1.0e0 100.0e9]);
p2 = pattern(isoantenna,75.0e6,[-180:180],0,'Type','Directivity');
```

Add the directivity plot of the isotropic antenna to the directivity plot of the cosine antenna.

```
add(P,[-180:180],p2);
```



## See Also

`addCursor` | `animate` | `createLabels` | `findLobes` | `replace` | `showPeaksTable` | `showSpan`

**Introduced in R2016a**

# addCursor

**Class:** `polarpattern`

Add cursor to polar plot angle

## Syntax

```
addCursor(p,angle)
addCursor(p,angle,index)
id = addCursor(___)
```

## Description

`addCursor(p,angle)` adds a cursor to the active polar plot, `p`, at the data point closest to the specified `angle`. Angle units are in degrees.

The first cursor added is called `'C1'`, the second `'C2'`, and so on.

`addCursor(p,angle,index)` adds a cursor at a specified data set `index`. `index` can be a vector of indices.

`id = addCursor(___)` returns a cell array with one ID for each cursor created. You can specify any of the arguments from the previous syntaxes.

## Input Arguments

**p — Polar plot**
scalar handle

Polar plot, specified as a scalar handle.

**`angle` — Angle values**
scalar in degrees | vector in degrees

Angle values at which the cursor is added, specified as a scalar or a vector in degrees.

**index — Data set index**
scalar | vector

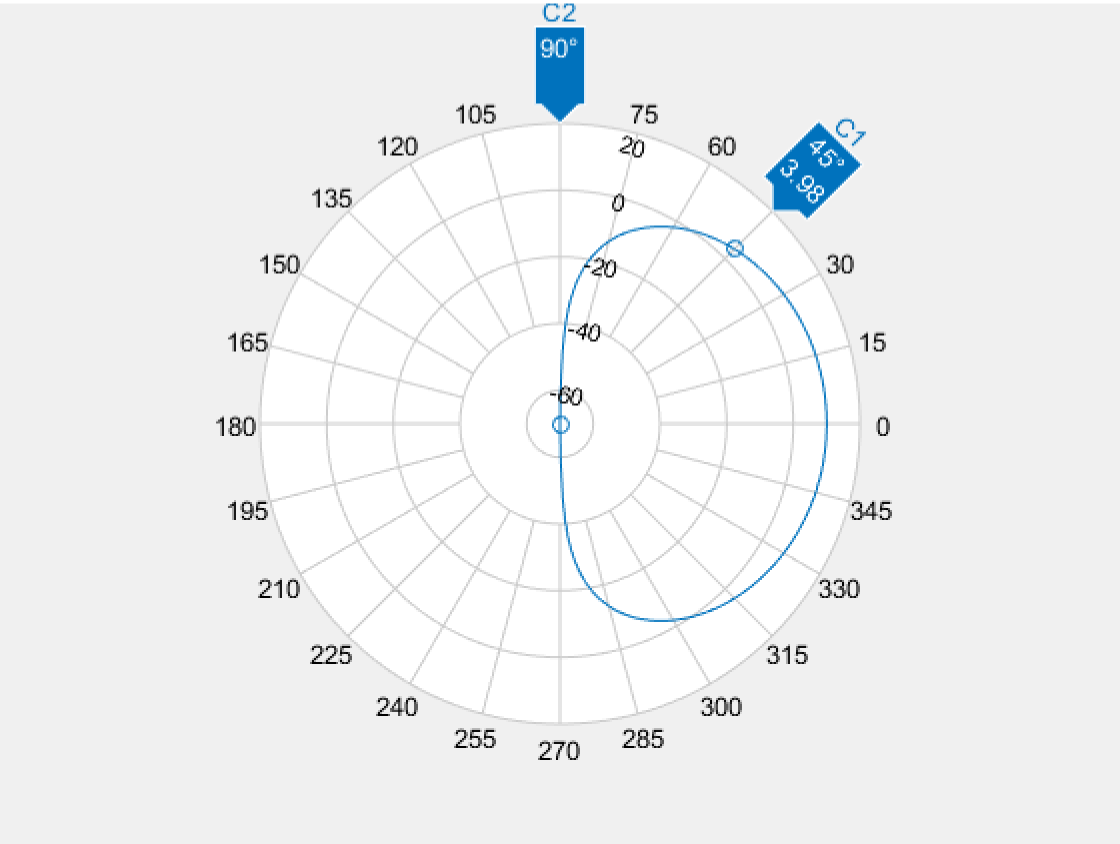
Data set index, specified as a scalar or a vector.

## Examples

### Add Cursors to Single Polar Pattern Plot

Create a cosine antenna and plot the polar pattern of its directivity at 75 MHz. Then add cursors at two 150° and 270°.

```
cosineantenna = phased.CosineAntennaElement('FrequencyRange',[1.0e0 100.0e9],...
    'CosinePower',[2,2]);
p = pattern(cosineantenna,75.0e6,[-90:90],0,'Type','Directivity');
P = polarpattern([-90:90],p);
addCursor(P,[45 135]);
```

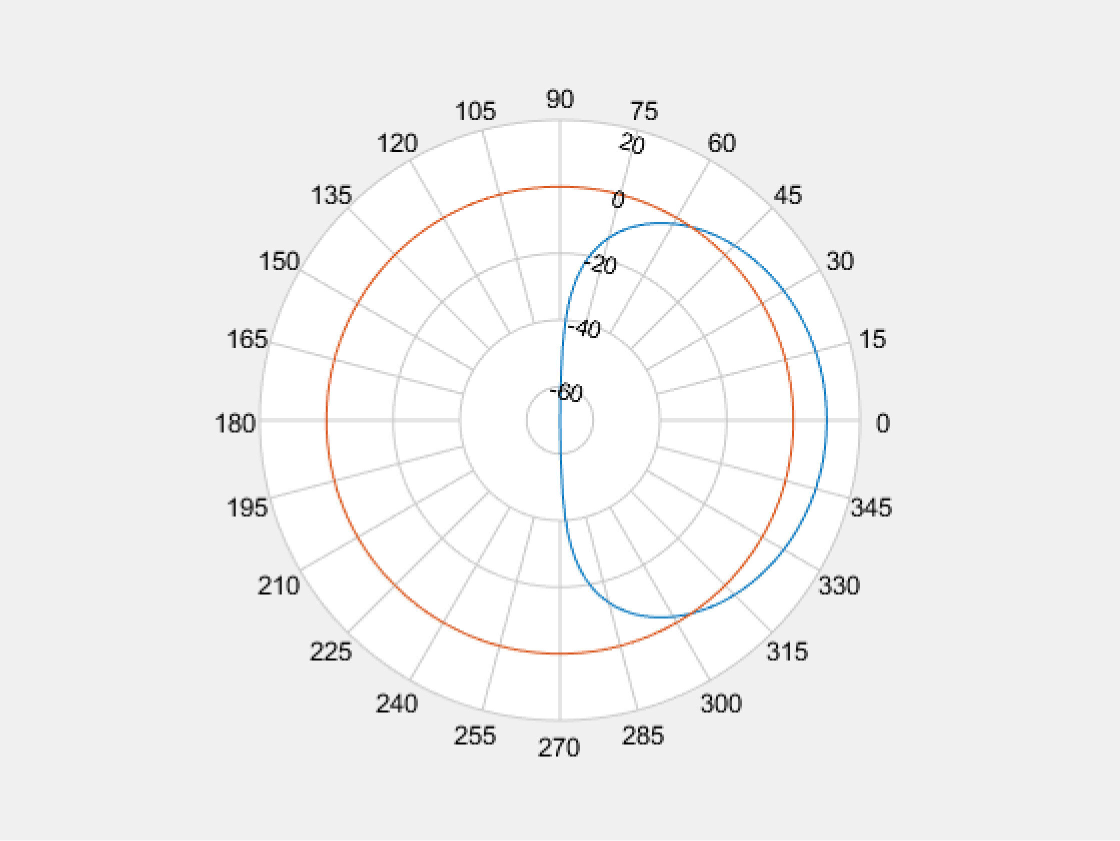


### Add Cursors to Multiple Polar Pattern Plots

Create a cosine antenna and plot the polar pattern of its directivity at 75 MHz. Then create an isotropic antenna. Also calculate the directivity of this antenna at 75 MHz. Add the directivity plot of the isotropic antenna to the directivity plot of the cosine antenna. Then add cursors at several points,

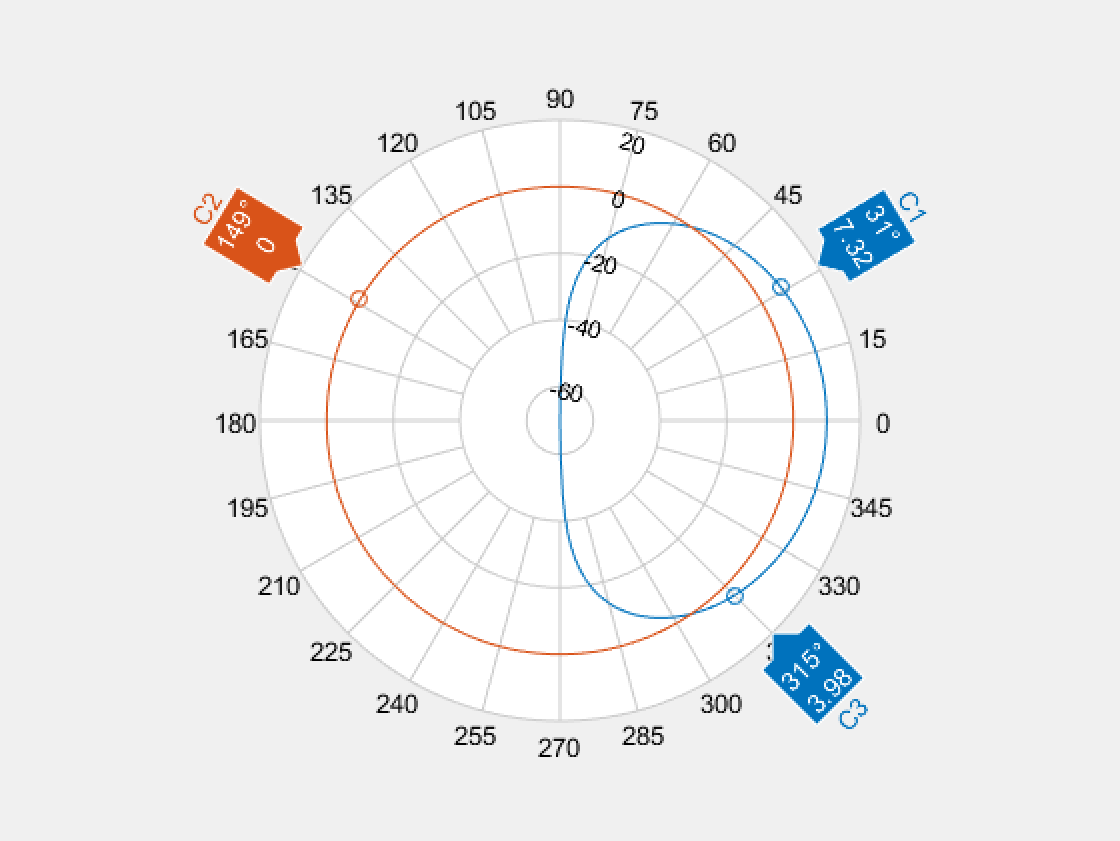
```
cosineantenna = phased.CosineAntennaElement('FrequencyRange',[1.0e0 100.0e9],...
    'CosinePower',[2,2]);
p1 = pattern(cosineantenna,75.0e6,[-90:90],0,'Type','Directivity');
P = polarpattern([-90:90],p1);
```

```
isoantenna = phased.IsotropicAntennaElement('FrequencyRange',...
    [1.0e0 100.0e9]);
p2 = pattern(isoantenna,75.0e6,[-180:180],0,'Type','Directivity');
add(P,[-180:180],p2);
```



Add a cursor at approximately 30� to the cosine antenna pattern (designated by index 1) and at 150� and 270� to the isotropic polar pattern (designated by index 2).

```
addCursor(P,[30.5 149.0 314.7],[1 2 1]);
```



## See Also

`add` | `animate` | `createLabels` | `findLobes` | `replace` | `showPeaksTable` | `showSpan`

**Introduced in R2016a**

# animate

**Class:** `polarpattern`

Replace existing data with new data for animation

## Syntax

```
animate(p,data)
animate(p,angle,magnitude)
```

## Description

`animate(p,data)` removes all the current data from polar plot, `p` and adds new data, based on real amplitude values, `data`.

`animate(p,angle,magnitude)` removes all the current data polar plot, `p` and adds new data sets of angle vectors and corresponding magnitude matrices.

## Input Arguments

**p — Polar plot**
scalar handle

Polar plot, specified as a scalar handle.

**data — Antenna or array data**
real length-*M* vector | real *M*-by-*N* matrix | real *N-D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M} \times 360^{\circ}$ degrees.

- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0:M-1)}{M} \times 360^{\circ}$ degrees. The set of each angle can vary for each column.
- A real *N-D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*(x,y)* of each point. *x* contains the real part of `data` and *y* contains the imaginary part of `data`.

When data is in a logarithmic form such as dB, magnitude values can be negative. In this case,`polarpattern` plots the lowest magnitude values at the origin of the polar plot and highest magnitude values at the maximum radius.

**`angle` — Set of angles**
vector in degrees

Set of angles, specified as a vector in degrees.

**`magnitude` — Set of magnitude values**
vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

# Examples

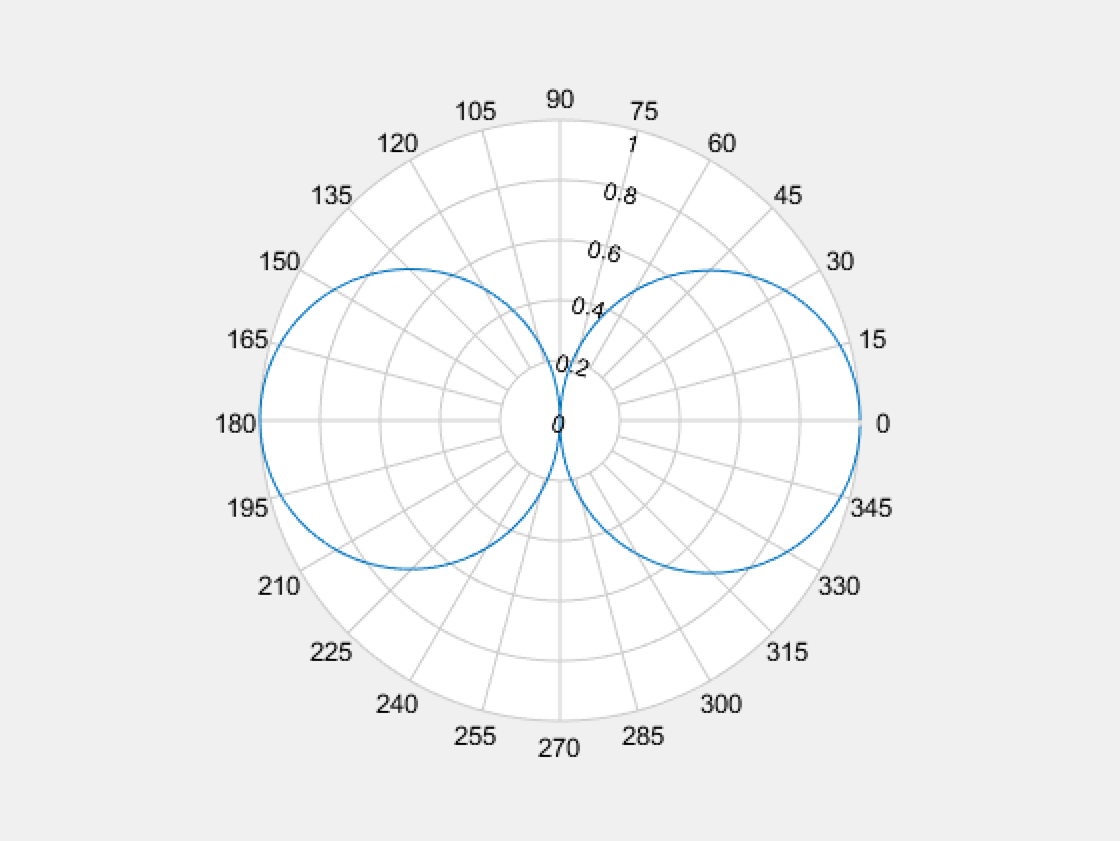
### Animate Cosine Pattern Antenna Plot

Create a cosine-pattern antenna and plot the pattern from 0° to 360°.

```
az = [0:360];
p1 = abs(cosd(az));
```

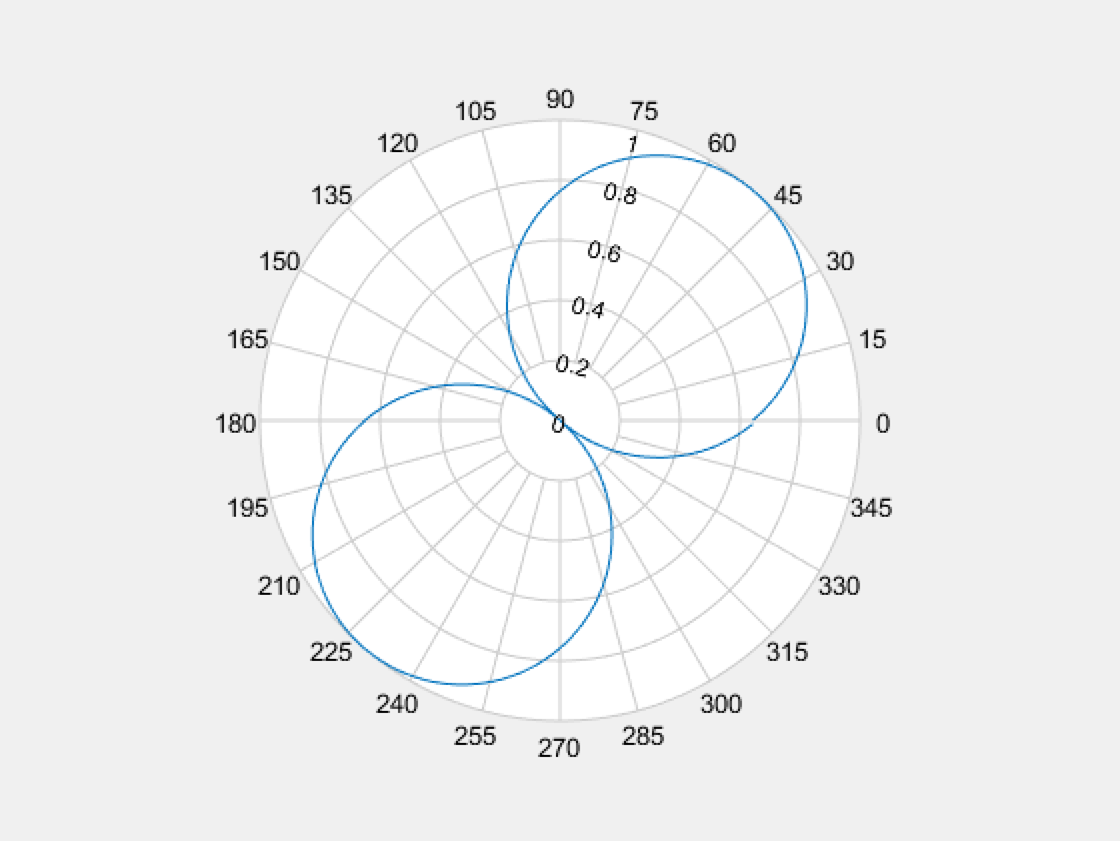
Plot the polar pattern.

```
P = polarpattern(p1);
```



Create a second cosine-pattern antenna rotated by 60°. Animate the pattern by adding this pattern.

```
p2 = abs(cosd(az - 50));
animate(P,p2);
```



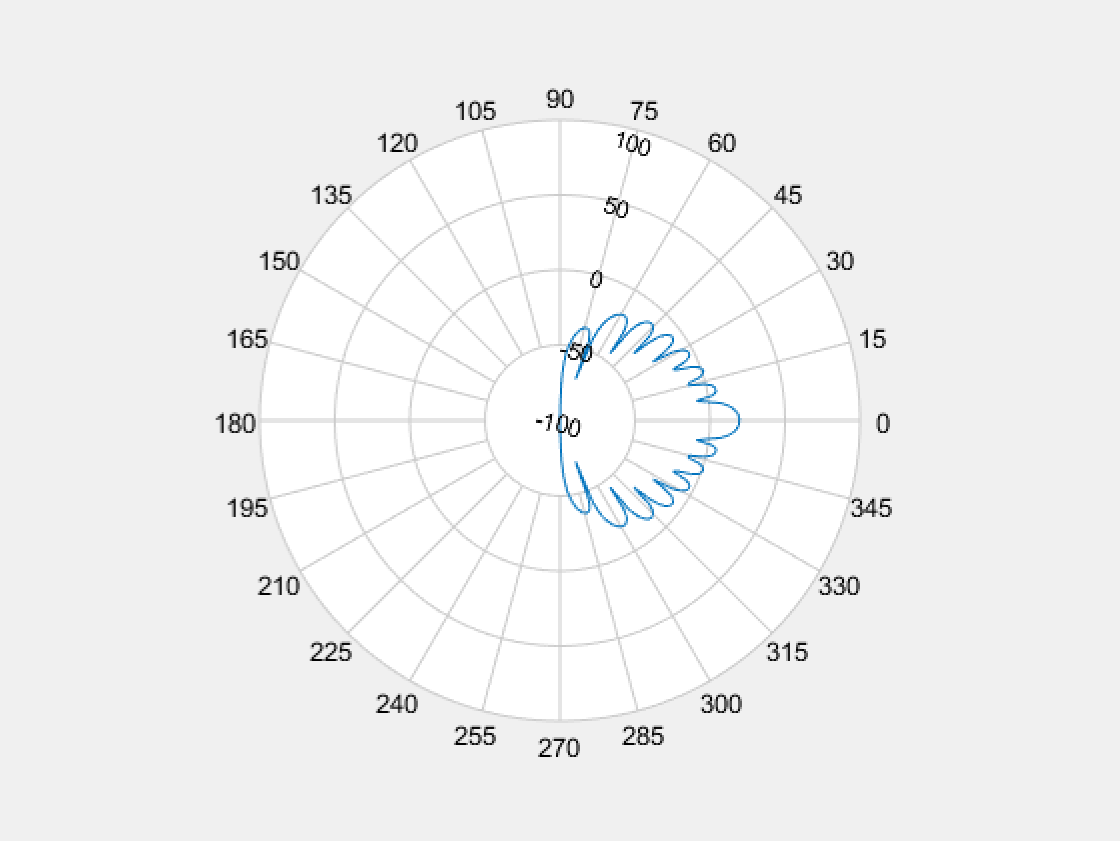
### Animate Existing Polar Azimuth Plot Data

Create a 15-element ULA of cosine antennas with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
fc = 20.0e9;
c = physconst('Lightspeed');
```

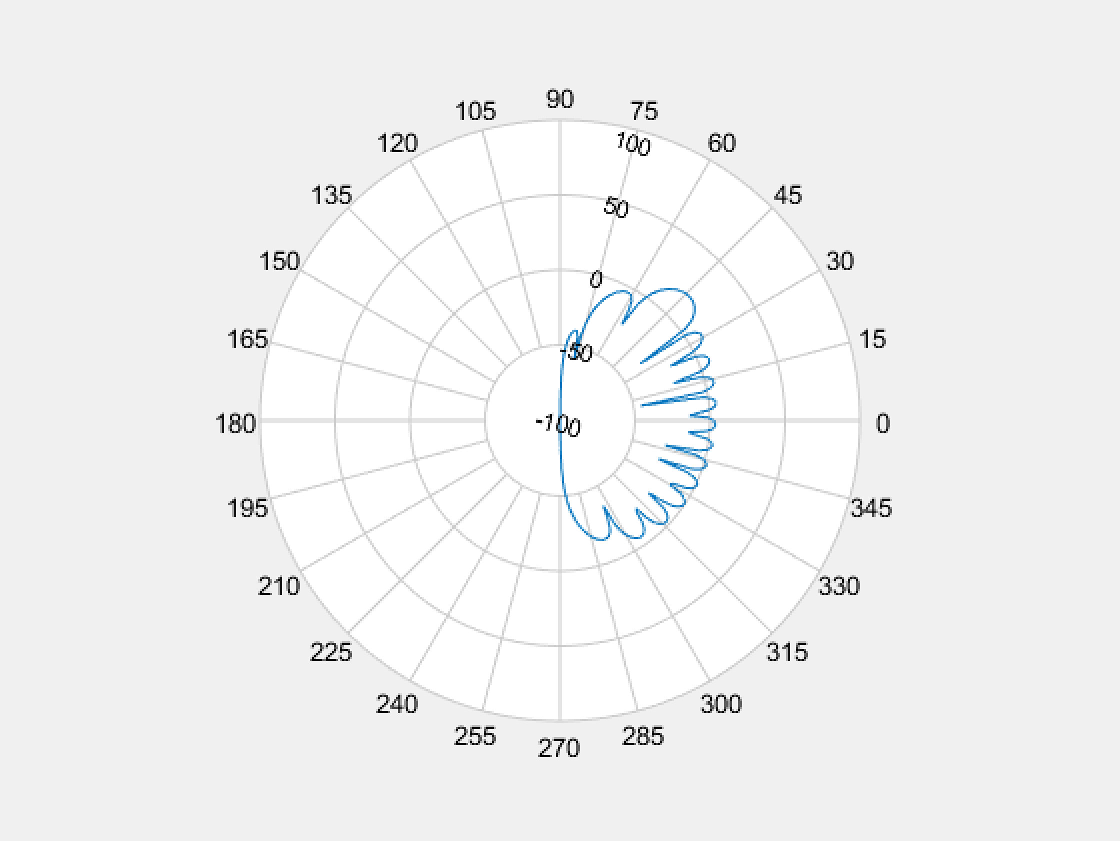
```
lam = c/fc;
angs = [-180:1:180];
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0e9,100.0e9],...
    'CosinePower',[2.5 2.5]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
```



Then, steer the array to 45° and, using the `animate` method, replace the existing polar plot with the steered array directivity.

```
steervec = phased.SteeringVector('SensorArray',array,'PropagationSpeed',c,...
    'IncludeElementResponse',true);
sv = steervec(fc,[45;0]);
```

```
a1 = pattern(array,fc,angs,0,'Weights',sv);
animate(P,angs,a1);
```



## See Also

add | addCursor | createLabels | findLobes | replace | showPeaksTable | showSpan

**Introduced in R2016a**

# createLabels

**Class:** `polarpattern`

Create legend labels for polar plot

## Syntax

`createLabels(p,format,array)`

## Description

`createLabels(p,format,array)` adds the specified `format` label to each `array` of the polar plot `p`. The labels are stored as a cell array in the `LegendLabels` property of `p`.

## Input Arguments

**`p` — Polar plot**
scalar handle

Polar plot, specified as a scalar handle.

**`format` — Format for legend label**
cell array

Format for legend label added to the polar plot, specified as a cell array. For more information on legend label format see, `legend`.

Data Types: `char`

**`array` — Values to apply to `format`**
array

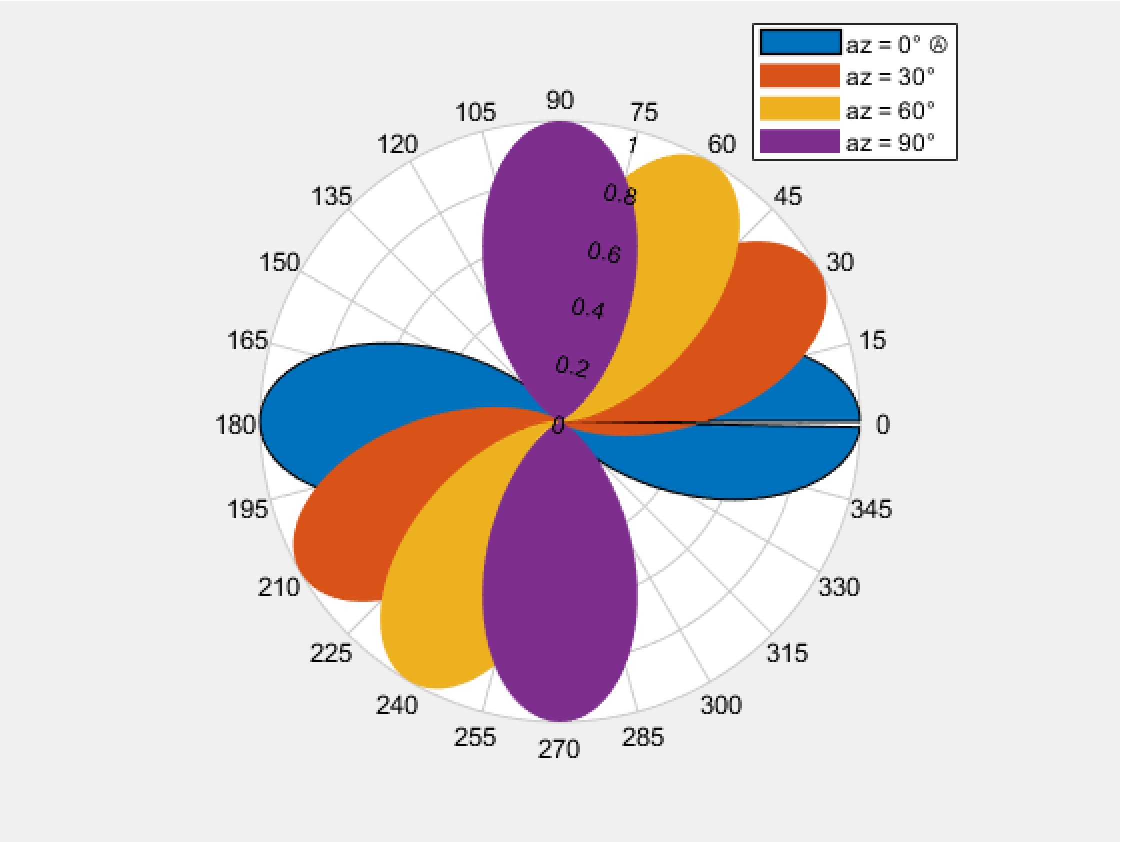
Values to apply to `format` , specified as an array. The values can be an array of angles or array of magnitude.

## Examples

### Add Legend Label to Polar Plot

Create a polar plot of cosine powers rotated in 30° increments. Generate a legend label for this plot.

```
az = [0:359]';
a1 = abs(cosd(az).^5);
a2 = abs(cosd(az - 30).^5);
a3 = abs(cosd(az - 60).^5);
a4 = abs(cosd(az - 90).^5);
P = polarpattern([a1,a2,a3,a4],'Style','filled');
createLabels(P,'az = %d#deg',0:30:90)
```



## See Also

`add` | `addCursor` | `animate` | `findLobes` | `replace` | `showPeaksTable` | `showSpan`

**Introduced in R2016a**

# findLobes

**Class:** `polarpattern`

Main, back, and side lobe data

## Syntax

```
L = findLobes(p)
L = findLobes(p,index)
```

## Description

`L = findLobes(p)` returns a structure, `L`, defining the main, back, and side lobes of the antenna or array radiation pattern in the specified polar plot, `p`.

`L = findLobes(p,index)` returns the radiation pattern lobes from the data set specified in `index`.

## Input Arguments

**p — Polar plot**
scalar handle

Polar plot, specified as a scalar handle.

**`index` — Index of data set**
scalar

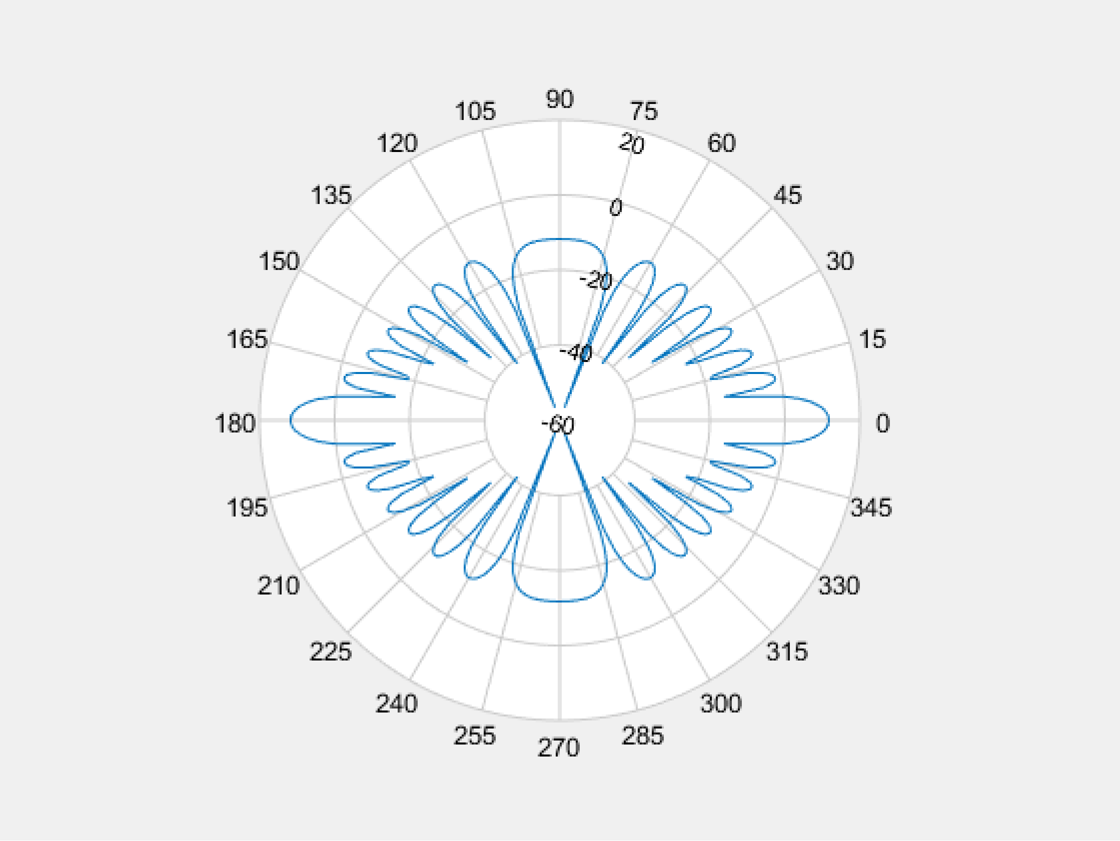
Index of data set, specified as a scalar.

## Examples

### Find Lobes of Isotropic Antenna ULA

Create a 15-element ULA of isotropic antenna with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz. Then, find the mainlobe, sidelobe, and backlobe directions of the array pattern.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.IsotropicAntennaElement('FrequencyRange',[1.0e9,100.0e9]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
```



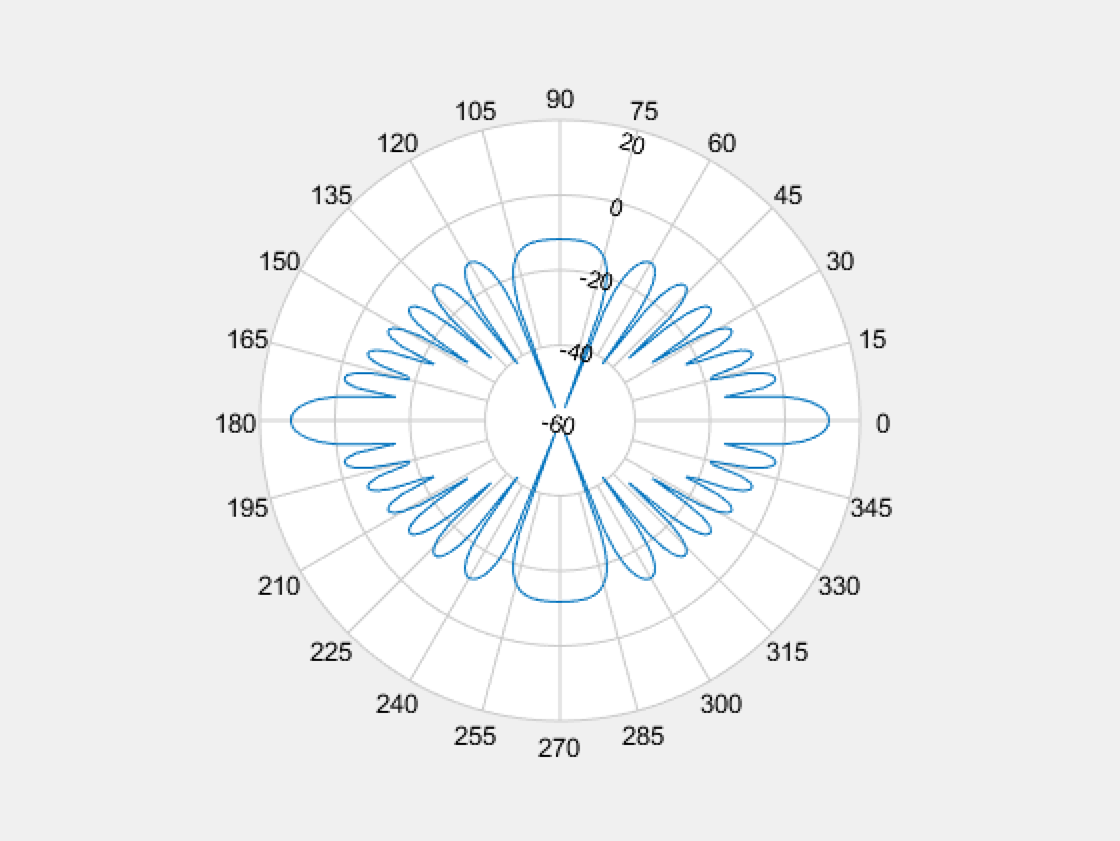
```
L = findLobes(P)
```

```
L = struct with fields:
     mainLobe: [1x1 struct]
     backLobe: [1x1 struct]
    sideLobes: [1x1 struct]
           FB: 0
          SLL: 0
         HPBW: 8.0000
         FNBW: 16.0000
        FBIdx: [181 1]
       SLLIdx: [181 361]
      HPBWIdx: [357 5]
      HPBWAng: [176 -176]
      FNBWIdx: [173 189]
```

### Find Lobes of Steered Isotropic Antenna ULA Patterns

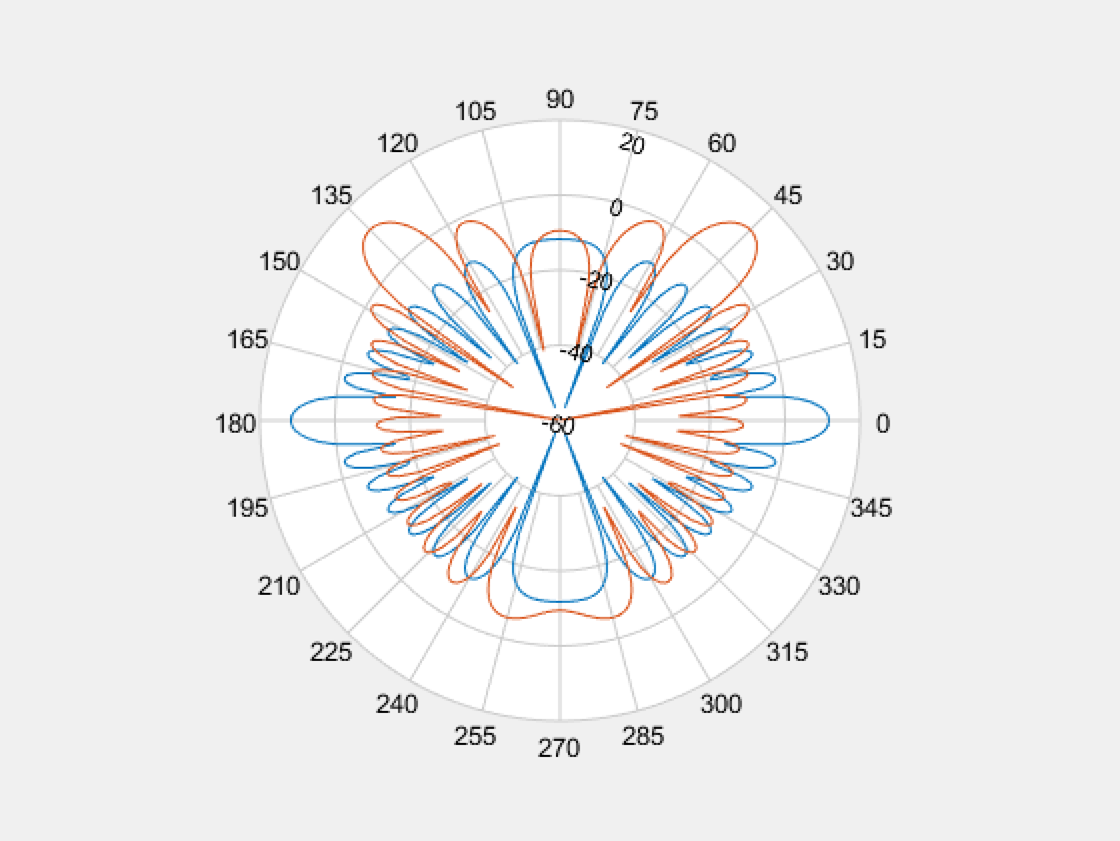
Create a 15-element ULA of isotropic antenna with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz. Then steer the array to 45° azimuth and plot the directivity. Then, find the mainlobe, sidelobe, and backlobe directions of the array pattern.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.IsotropicAntennaElement('FrequencyRange',[1.0e9,100.0e9]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
```



Steer the array to 45&deg azimuth and add the steered pattern to the polar plot.

```
steervec = phased.SteeringVector('SensorArray',array,'PropagationSpeed',c);
sv = steervec(fc,[45;0]);
a1 = pattern(array,fc,angs,0,'Weights',sv);
add(P,angs,a1);
```



Find the lobes of the steered pattern.

```
L = findLobes(P,2);
L.mainLobe
```

```
ans = struct with fields:
        index: 226
    magnitude: 11.7609
        angle: 45
       extent: [216 238]
```

## See Also

**Introduced in R2016a**

# replace

**Class:** `polarpattern`

Replace polar plot data with new data

## Syntax

```
replace(p,data)
replace(p,angle,magnitude)
```

## Description

`replace(p,data)` removes all data from polar plot, `p` and adds new data based on real amplitude values, `data`.

`replace(p,angle,magnitude)` removes all the current data and adds new data sets of angle vectors and corresponding magnitude matrices to the polar plot, `p`.

## Input Arguments

### `p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

### `data` — Antenna or array data

real length-*M* vector | real *M*-by-*N* matrix | real *N*-*D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M} \times 360^{\circ}$ degrees.

- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0{:}M-1)}{M} \times 360^{\circ}$ degrees. The set of each angle can vary for each column.
- A real *N-D* array, where *N* is the number of dimensions. Arrays with dimensions 2 and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates ((*x*,*y*) of each point. *x* contains the real part of `data` and *y* contains the imaginary part of `data`.

When data is in a logarithmic form such as dB, magnitude values can be negative. In this case,`polarpattern` plots the lowest magnitude values at the origin of the polar plot and highest magnitude values at the maximum radius.

**`angle` — Set of angles**
vector in degrees

Set of angles, specified as a vector in degrees.

**`magnitude` — Set of magnitude values**
vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

## Examples

### Replace Cosine Polar Plot With Rotated Cosine Polar Plot

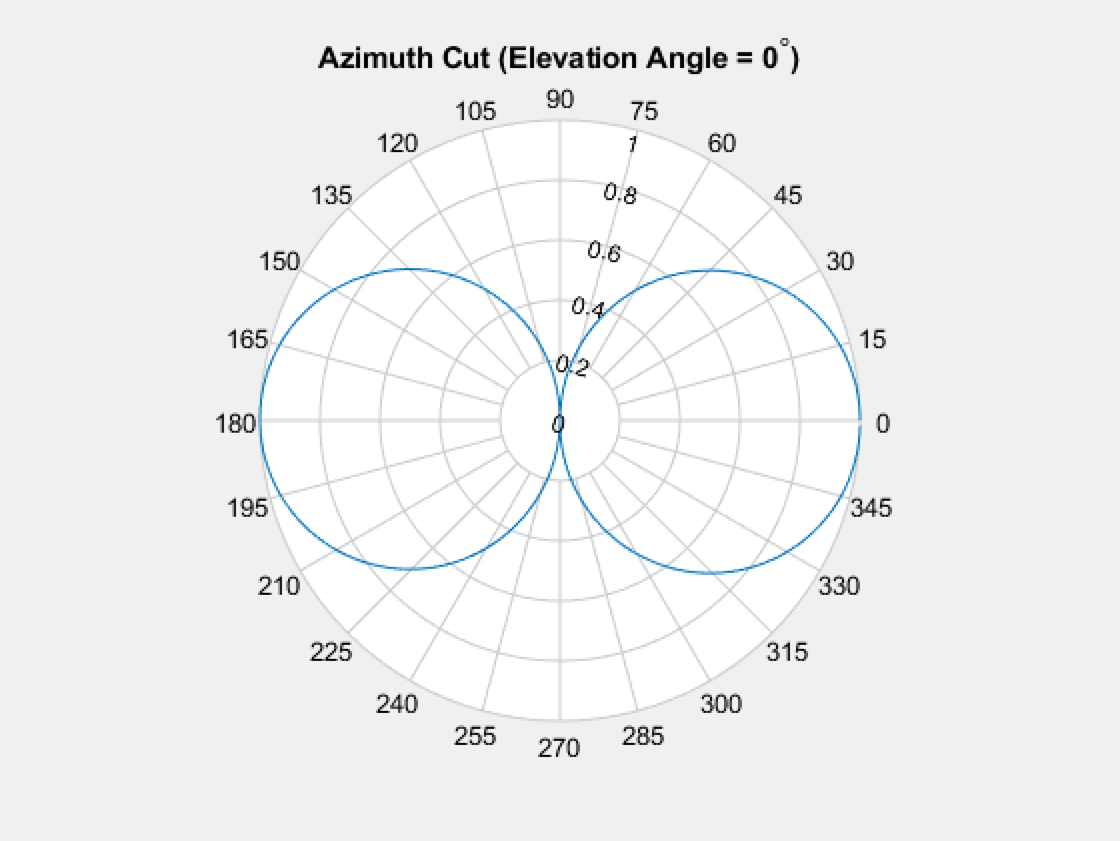
Plot cosine pattern in polar coordinates Specify a cosine antenna pattern from 0° to 360° in azimuth at 0° elevation. Then, plot the antenna pattern using `polarpattern`.

Create the pattern.

```
az = [0:360];
a = abs(cosd(az));
```

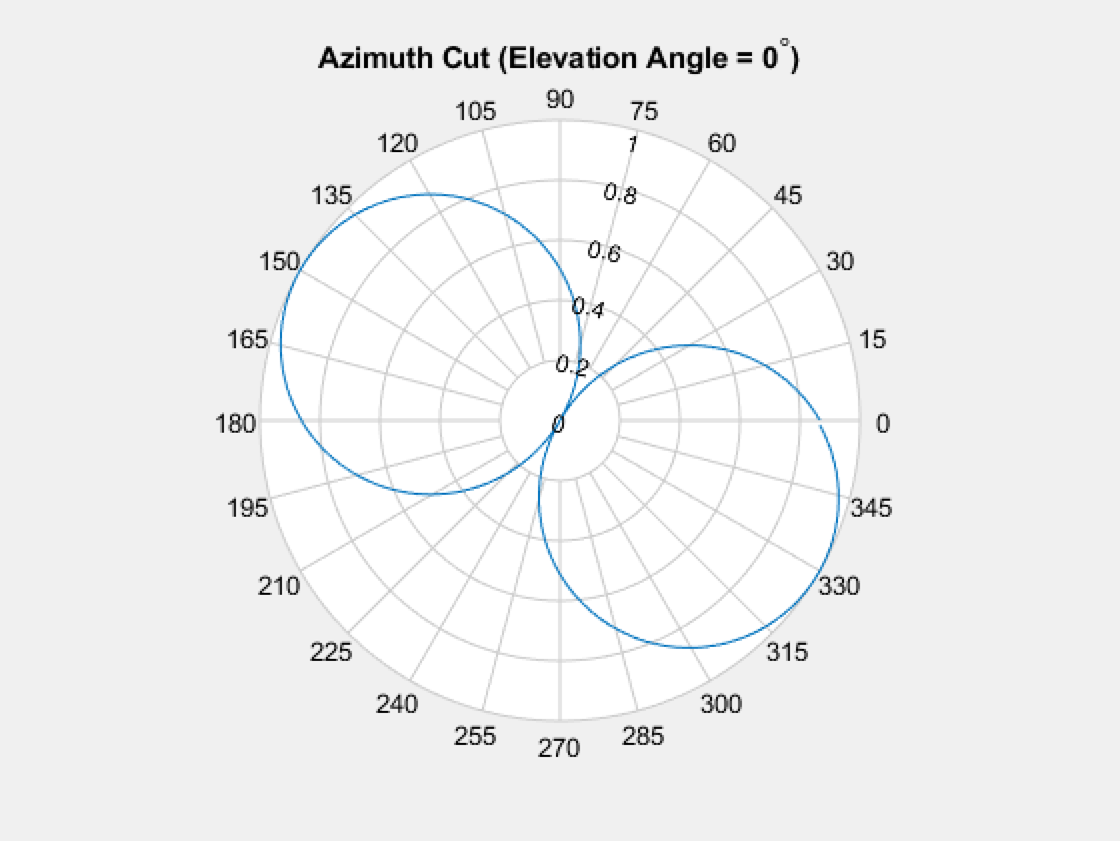
Plot the polar pattern of the antenna for an azimuth cut at 0° elevation.

```
P = polarpattern(a,'TitleTopTextInterpreter','tex','TitleTop','Azimuth Cut (Elevation A
```



Replace this plot with a rotated cosine pattern.

```
a = abs(cosd(az + 30.0));
replace(P,a);
```



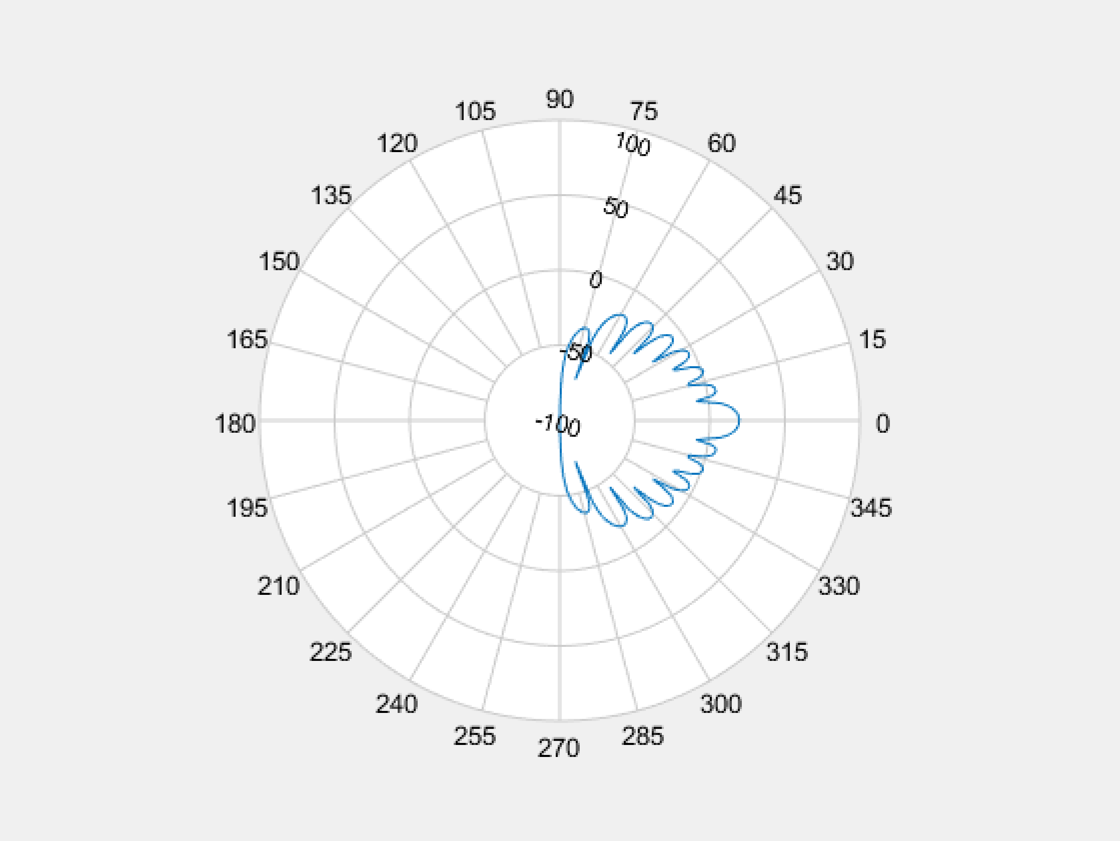
### Replace Polar Plot Data with New Angle-Magnitude Data

Create a 15-element ULA of cosine antennas with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
fc = 20.0e9;
c = physconst('Lightspeed');
```

```
lam = c/fc;
angs = [-180:1:180];
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0e9,100.0e9],...
    'CosinePower',[2.5 2.5]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
```



Then, steer the array to 45° and, using the `replace` method, replace the existing polar plot with the steered array directivity.

```
steervec = phased.SteeringVector('SensorArray',array,'PropagationSpeed',c,...
    'IncludeElementResponse',true);
sv = steervec(fc,[45;0]);
```

```
a1 = pattern(array,fc,angs,0,'Weights',sv);
replace(P,angs,a1);
```

**Introduced in R2016a**

# showPeaksTable

**Class:** `polarpattern`

Show or hide peak marker table

## Syntax

`showPeaksTable(p,vis)`

## Description

`showPeaksTable(p,vis)` shows or hides a table of the peak values. By default, the peak values table is visible.

## Input Arguments

**p — Polar plot**
scalar handle

Polar plot, specified as a scalar handle.

**`vis` — Show or hide peaks table**
`0` | `1`

Show or hide peaks table, specified as `0` or `1`.

## Examples

### Peaks of ULA Array in Polar Pattern

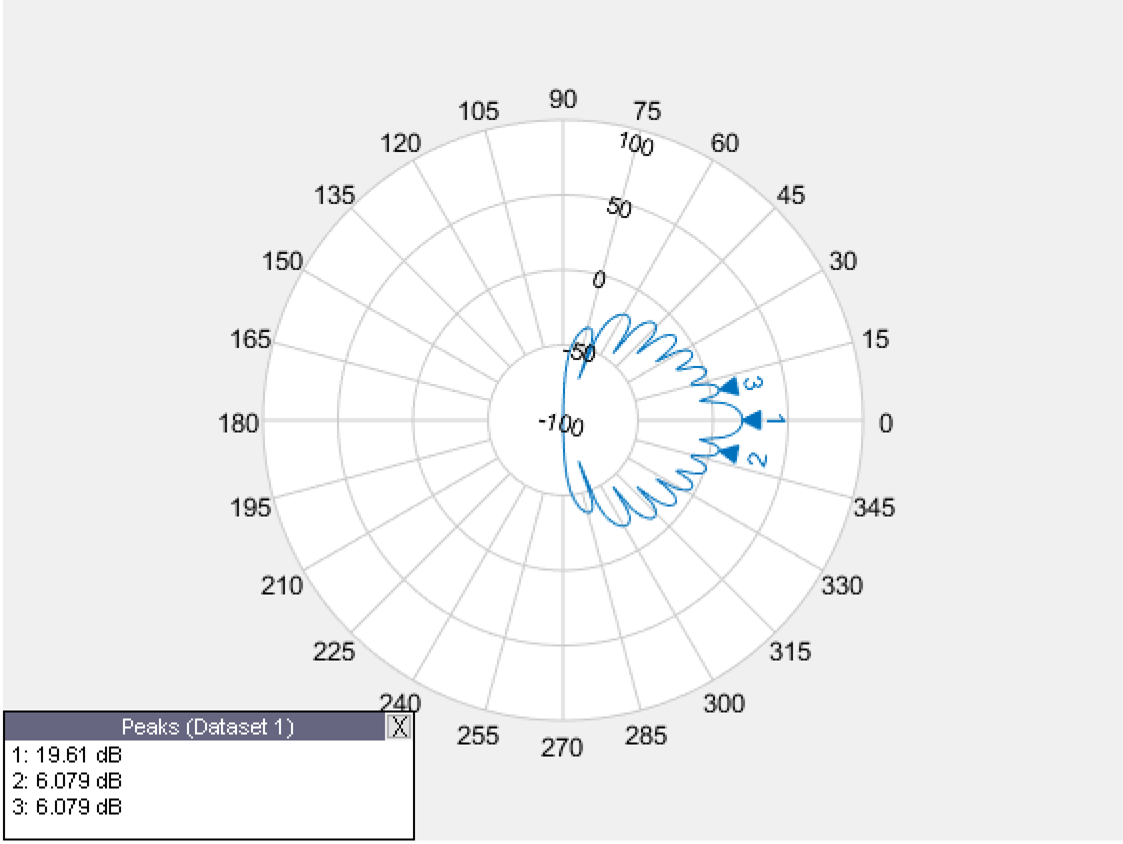
Create a 15-element ULA of cosine antennas with elements spaced one-half wavelength apart. Then, plot the directivity of the array at 20 GHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0e9,100.0e9],...
    'CosinePower',[2.5 2.5]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
```

Plot the polar pattern and show three peaks of the antenna. When creating a `polarpattern` plot, if you specify the Peaks property, the peaks table is displayed by default.

```
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a,'Peaks',3);
```



Peaks (Dataset 1)

1: 19.61 dB
2: 6.079 dB
3: 6.079 dB

Hide the table. When the peaks table is hidden, the peak markers display the peak values.

```
showPeaksTable(P,0);
```

# PolarPattern Properties

Control appearance and behavior of polar plot

## Description

Polar pattern properties control the appearance and behavior of the polar pattern object. By changing property values, you can modify certain aspects of the polar plot. To change the default properties use:

```
p = polarpattern(____,Name,Value)
```

To view all the properties of the polar pattern object use:

```
details(p)
```

## Properties

### Antenna Metrics

**'AntennaMetrics' — Show antenna metric**
0 (default) | 1

Show antenna metrics, specified as a comma-separated pair consisting of 'AntennaMetrics' and 0 or 1. Antenna metric displays main, back, and side lobes of antenna/array pattern passed as input.

Data Types: logical

**'Peaks' — Maximum number of peaks to compute for each data set**
positive integer | vector of integers

Maximum number of peaks to compute for each data set, specified as a comma-separated pair consisting of 'Peaks' and a positive scalar or vector of integers.

Data Types: double

### Angle Properties

**'AngleAtTop' — Angle at top of polar plot**
90 (default) | scalar in degrees

Angle at the top of the polar plot, specified as a comma-separated pair consisting of 'AngleAtTop' and a scalar in degrees.

Data Types: double

**'AngleLim' — Visible polar angle span**
[0 360] (default) | 1-by-2 vector of real values

Visible polar angle span, specified as a comma-separated pair consisting of 'AngleLim' and a 1-by-2 vector of real values.

Data Types: double

**'AngleLimVisible' — Show interactive angle limit cursors**
0 (default) | 1

Show interactive angle limit cursors, specified as a comma-separated pair consisting of 'AngleLimVisible' and 0 or 1.

Data Types: logical

**'AngleDirection' — Direction of increasing angle**
'ccw' (default) | 'cw'

Direction of increasing angle, specified as a comma-separated pair consisting of 'AngleDirection' and 'ccw' (counterclockwise) or 'cw' (clockwise).

Data Types: char

**'AngleResolution' — Number of degrees between radial lines**
15 (default) | scalar in degrees

Number of degrees between radial lines depicting angles in the polar plot, specified as a comma-separated pair consisting of 'AngleResolution' and a scalar in degrees.

Data Types: double

**'AngleTickLabelRotation' — Rotate angle tick labels**
0 (default) | 1

Rotate angle tick labels, specified as a comma-separated pair consisting of `'AngleTickLabelRotation'` and `0` or `1`.

Data Types: `logical`

**`'AngleTickLabelVisible'` — Show angle tick labels**
`1` (default) | `0`

Show angle tick labels, specified as a comma-separated pair consisting of `'AngleTickLabelVisible'` and `0` or `1`.

Data Types: `logical`

**`'AngleTickLabelFormat'` — Format for angle tick labels**
`360` (default) | `180`

Format for angle tick labels, specified as a comma-separated pair consisting of `'AngleTickLabelFormat'` and `360` degrees or `180` degrees.

Data Types: `double`

**`'AngleFontSizeMultiplier'` — Scale factor of angle tick font**
`1` (default) | numeric value greater than zero

Scale factor of angle tick font, specified as a comma-separated pair consisting of `'AngleFontSizeMultiplier'` and a numeric value greater than zero.

Data Types: `double`

**`'Span'` — Show angle span measurement**
`0` (default) | `1`

Show angle span measurement, specified as a comma-separated pair consisting of `'Span'` and `0` or `1`.

Data Types: `logical`

**`'ZeroAngleLine'` — Highlight radial line at zero degrees**
`0` (default) | `1`

Highlight radial line at zero degrees, specified as a comma-separated pair consisting of `'ZeroAngleLine'` and `0` or `1`.

Data Types: `logical`

### 'DisconnectAngleGaps' — Show gaps in line plots with nonuniform angle spacing

1 (default) | 0

Show gaps in line plots with nonuniform angle spacing, specified as a comma-separated pair consisting of 'DisconnectAngleGaps' and 0 or 1.

Data Types: logical

#### Magnitude Properties

### 'MagnitudeAxisAngle' — Angle of magnitude tick label radial line

75 (default) | real scalar in degrees

Angle of magnitude tick label radial line, specified as a comma-separated pair consisting of 'MagnitudeAxisAngle' and real scalar in degrees.

Data Types: double

### 'MagnitudeTick' — Magnitude ticks

[0 0.2 0.4 0.6 0.8] (default) | 1-by-N vector

Magnitude ticks, specified as a comma-separated pair consisting of 'MagnitudeTick' and a 1-by-N vector, where N is the number of magnitude ticks.

Data Types: double

### 'MagnitudeTickLabelVisible' — Show magnitude tick labels

1 (default) | 0

Show magnitude tick labels, specified as a comma-separated pair consisting of 'MagnitudeTickLabelVisible' and 0 or 1.

Data Types: logical

### 'MagnitudeLim' — Minimum and maximum magnitude limits

[0 1] (default) | two-element vector of real values

Minimum and maximum magnitude limits, specified as a comma-separated pair consisting of 'MagnitudeLim' and a two-element vector of real values.

Data Types: double

### 'MagnitudeLimMode' — Determine magnitude dynamic range

'auto' (default) | 'manual'

Determine magnitude dynamic range, specified as a comma-separated pair consisting of `'MagnitudeLimMode'` and `'auto'` or `'manual'`.

Data Types: `char`

**`'MagnitudeAxisAngleMode'` — Determine angle for magnitude tick labels**
`'auto'` (default) | `'manual'`

Determine angle for magnitude tick labels, specified as a comma-separated pair consisting of `'MagnitudeAxisAngleMode'` and `'auto'` or `'manual'`.

Data Types: `char`

**`'MagnitudeTickMode'` — Determine magnitude tick locations**
`'auto'` (default) | `'manual'`

Determine magnitude tick locations, specified as a comma-separated pair consisting of `'MagnitudeTickMode'` and `'auto'` or `'manual'`.

Data Types: `char`

**`'MagnitudeUnits'` — Magnitude units**
`'dB'` | `'dBLoss'`

Magnitude units, specified as a comma-separated pair consisting of `'MagnitudeUnits'` and `'db'` or `'dBLoss'`.

Data Types: `char`

**`'MagnitudeFontSizeMultiplier'` — Scale factor of magnitude tick font**
`0.9000` (default) | numeric value greater than zero

Scale factor of magnitude tick font, specified as a comma-separated pair consisting of `'MagnitudeFontSizeMultiplier'` and a numeric value greater than zero.

Data Types: `double`

**Miscellaneous Properties**

**`'NormalizeData'` — Normalize each data trace to maximum value**
`0` (default) | `1`

Normalize each data trace to maximum value, specified as a comma-separated pair consisting of `'NormalizeData'` and `0` or `1`.

Data Types: `logical`

### `'ConnectEndpoints'` — Connect first and last angles

`0` (default) | `1`

Connect first and last angles, specified as a comma-separated pair consisting of `'ConnectEndpoints'` and `0` or `1`.

Data Types: `logical`

### `'Style'` — Style of polar plot display

`'line'` (default) | `'filled'`

Style of polar plot display, specified as a comma-separated pair consisting of `'Style'` and `'line'` or `'filled'`.

Data Types: `char`

### `'TemporaryCursor'` — Create temporary cursor

`0` (default) | `1`

Create a temporary cursor, specified as a comma-separated pair consisting of `'TemporaryCursor'` and `0` or `1`.

Data Types: `logical`

### `'ToolTips'` — Show tool tips

`1` (default) | `0`

Show tool tips when you hover over a polar plot element, specified as a comma-separated pair consisting of `'ToolTips'` and `0` or `1`.

Data Types: `logical`

### `'ClipData'` — Clip data to outer circle

`0` (default) | `1`

Clip data to outer circle, specified as a comma-separated pair consisting of `'ClipData'` and `0` or `1`.

Data Types: `logical`

### `'NextPlot'` — Directive on how to add next plot

`'replace'` (default) | `'new'` | `'add'`

Directive on how to add next plot, specified as a comma-separated pair consisting of `'NextPlot'` and one of the values in the table:

| Property Value | Effect |
|---|---|
| `'new'` | Creates a figure and uses it as the current figure. |
| `'add'` | Adds new graphics objects without clearing or resetting the current figure. |
| `'replace'` | Removes all axes objects and resets figure properties to their defaults before adding new graphics objects. |

#### Legend and Title Properties

### `'LegendLabels'` — Data tables for legend annotation

character vector | cell array of character vectors

Data tables for legend annotation, specified as a comma-separated pair consisting of `'LegendLabels'` and a character vector or cell array of character vectors. Ⓐ denotes the active line for interactive operation.

Data Types: `char`

### `'LegendVisible'` — Show legend label

`0` (default) | `1`

Show legend label, specified as a comma-separated pair consisting of `'LegendVisible'` and `0` or `1`.

Data Types: `logical`

### `'TitleTop'` — Title to display above the polar plot

character vector

Title to display above the polar plot, specified as a comma-separated pair consisting of `'TitleTop'` and a character vector.

Data Types: `char`

### `'TitleBottom'` — Title to display below the polar plot

character vector

Title to display below the polar plot, specified as a comma-separated pair consisting of `'TitleBottom'` and a character vector.

Data Types: `char`

**`'TitleTopOffset'` — Offset between top title and angle ticks**
`0.1500` (default) | scalar

Offset between top title and angle ticks, specified as a comma-separated pair consisting of `'TitleTopOffset'` and a scalar. The value must be in the range [`-0.5`,`0.5`].

Data Types: `double`

**`'TitleBottomOffset'` — Offset between bottom title and angle ticks**
`0.1500` (default) | scalar

Offset between bottom title and angle ticks, specified as a comma-separated pair consisting of `'TitleBottomOffset'` and a scalar. The value must be in the range [`-0.5`,`0.5`].

Data Types: `double`

**`'TitleTopFontSizeMultiplier'` — Scale factor of top title font**
`1.1000` (default) | numeric value greater than zero

Scale factor of top title font, specified as a comma-separated pair consisting of `'TitleTopFontSizeMultiplier'` and a numeric value greater than zero.

Data Types: `double`

**`'TitleBottomFontSizeMultiplier'` — Scale factor of bottom title font**
`0.9000` (default) | numeric value greater than zero

Scale factor of bottom title font, specified as a comma-separated pair consisting of `'TitleBottomFontSizeMultiplier'` and a numeric value greater than zero.

Data Types: `double`

**`'TitleTopFontWeight'` — Thickness of top title font**
`'bold'` (default) | `'normal'`

Thickness of top title font, specified as a comma-separated pair consisting of `'TitleTopFontWeight'` and `'bold'` or `'normal`.

Data Types: `char`

### 'TitleBottomFontWeight' — Thickness of bottom title font

'normal' (default) | 'bold'

Thickness of bottom title font, specified as a comma-separated pair consisting of 'TitleBottomFontWeight' and 'bold' or 'normal.

Data Types: char

### 'TitleTopTextInterpreter' — Interpretation of top title characters

'none' (default) | 'tex' | 'latex'

Interpretation of top title characters, specified as a comma-separated pair consisting of 'TitleTopTextInterpreter' and:

- 'tex' — Interpret using a subset of TeX markup
- 'latex' — Interpret using LaTeX markup
- 'none' — Display literal characters

#### TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text.

This table lists the supported modifiers when the TickLabelInterpreter property is set to 'tex', which is the default value. Modifiers remain in effect until the end of the text, except for superscripts and subscripts which only modify the next character or text within curly braces {}.

| Modifier | Description | Example |
|---|---|---|
| ^{ } | Superscript | 'text^{superscript}' |
| _{ } | Subscript | 'text_{subscript}' |
| \bf | Bold font | '\bf text' |
| \it | Italic font | '\it text' |
| \sl | Oblique font (rarely available) | '\sl text' |
| \rm | Normal font | '\rm text' |

| Modifier | Description | Example |
|---|---|---|
| \fontname{specifier} | Set specifier as the name of a font family to change the font style. You can use this modifier with other modifiers. | '\fontname{Courier} text' |
| \fontsize{specifier} | Set specifier as a scalar numeric value to change the font size. | '\fontsize{15} text' |
| \color{specifier} | Set specifier as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | '\color{magenta} text' |
| \color[rgb]{specifier} | Set specifier as a three-element RGB triplet to change the font color. | '\color[rgb]{0,0.5,0.5} text' |

**LaTeX Markup**

To use LaTeX markup, set the TickLabelInterpreter property to 'latex'. The displayed text uses the default LaTeX font style. The FontName, FontWeight, and FontAngle properties do not have an effect. To change the font style, use LaTeX markup within the text.

The maximum size of the text that you can use with the LaTeX interpreter is 1200 characters. For multiline text, the maximum size reduces by about 10 characters per line.

Data Types: char

### 'TitleBottomTextInterpreter' — Interpretation of bottom title characters

'none' (default) | 'tex' | 'latex'

Interpretation of bottom title characters, specified as a comma-separated pair consisting of 'TitleBottomTextInterpreter' and:

- 'tex' — Interpret using a subset of TeX markup
- 'latex' — Interpret using LaTeX markup

- `'none'` — Display literal characters

### TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the text, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

| Modifier | Description | Example |
|---|---|---|
| `^{ }` | Superscript | `'text^{superscript}'` |
| `_{ }` | Subscript | `'text_{subscript}'` |
| `\bf` | Bold font | `'\bf text'` |
| `\it` | Italic font | `'\it text'` |
| `\sl` | Oblique font (rarely available) | `'\sl text'` |
| `\rm` | Normal font | `'\rm text'` |
| `\fontname{specifier}` | Set `specifier` as the name of a font family to change the font style. You can use this modifier with other modifiers. | `'\fontname{Courier} text'` |
| `\fontsize{specifier}` | Set `specifier` as a scalar numeric value to change the font size. | `'\fontsize{15} text'` |
| `\color{specifier}` | Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`. | `'\color{magenta} text'` |

| Modifier | Description | Example |
|---|---|---|
| \color[rgb]{specifier} | Set specifier as a three-element RGB triplet to change the font color. | '\color[rgb]{0,0.5,0.5} text' |

#### LaTeX Markup

To use LaTeX markup, set the TickLabelInterpreter property to 'latex'. The displayed text uses the default LaTeX font style. The FontName, FontWeight, and FontAngle properties do not have an effect. To change the font style, use LaTeX markup within the text.

The maximum size of the text that you can use with the LaTeX interpreter is 1200 characters. For multiline text, the maximum size reduces by about 10 characters per line.

Data Types: char

#### Grid Properties

### 'GridOverData' — Draw grid over data plots

0 (default) | 1

Draw grid over data plots, specified as a comma-separated pair consisting of 'GridOverData' and 0 or 1.

Data Types: logical

### 'DrawGridToOrigin' — Draw radial lines within innermost circle

0 (default) | 1

Draw radial lines within innermost circle of the polar plot, specified as a comma-separated pair consisting of 'DrawGridToOrigin' and 0 or 1.

Data Types: logical

### 'GridAutoRefinement' — Increase angle resolution

0 (default) | 1

Increase angle resolution in the polar plot, specified as a comma-separated pair consisting of 'GridAutoRefinement' and 0 or 1. This property increases angle resolution by doubling the number of radial lines outside each magnitude.

Data Types: logical

### `'GridWidth'` — Width of grid lines

`0.5000` (default) | positive scalar

Width of grid lines, specified as a comma-separated pair consisting of `'GridWidth'` and a positive scalar.

Data Types: `double`

### `'GridVisible'` — Show grid lines

`1` (default) | `0`

Show grid lines, including magnitude circles and angle radii, specified as a comma-separated pair consisting of `'GridVisible'` and `0` or `1`.

Data Types: `logical`

### `'GridForeGroundColor'` — Color of foreground grid lines

`[0.8000 0.8000 0.8000]` (default) | `'none'` | character vector of color names

Color of foreground grid lines, specified as a comma-separated pair consisting of `'GridForeGroundColor'` and an RGB triplet, character vector of color names, or `'none'`.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|---|---|
| `'red'` | `'r'` | `[1 0 0]` | `'#FF0000'` | 🟥 |
| `'green'` | `'g'` | `[0 1 0]` | `'#00FF00'` | 🟩 |
| `'blue'` | `'b'` | `[0 0 1]` | `'#0000FF'` | 🟦 |

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|---|---|
| `'cyan'` | `'c'` | `[0 1 1]` | `'#00FFFF'` | 🟦 |
| `'magenta'` | `'m'` | `[1 0 1]` | `'#FF00FF'` | 🟪 |
| `'yellow'` | `'y'` | `[1 1 0]` | `'#FFFF00'` | 🟨 |
| `'black'` | `'k'` | `[0 0 0]` | `'#000000'` | ⬛ |
| `'white'` | `'w'` | `[1 1 1]` | `'#FFFFFF'` | ⬜ |

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

| RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|
| `[0 0.4470 0.7410]` | `'#0072BD'` | 🟦 |
| `[0.8500 0.3250 0.0980]` | `'#D95319'` | 🟧 |
| `[0.9290 0.6940 0.1250]` | `'#EDB120'` | 🟨 |
| `[0.4940 0.1840 0.5560]` | `'#7E2F8E'` | 🟪 |
| `[0.4660 0.6740 0.1880]` | `'#77AC30'` | 🟩 |
| `[0.3010 0.7450 0.9330]` | `'#4DBEEE'` | 🟦 |

Data Types: `double` | `char`

### `'GridBackGroundColor'` — Color of background grid lines

`'w'` (default) | character vector of color names | `'none'`

Color of background grid lines, specified as a comma-separated pair consisting of `'GridBackGroundColor'` and an RGB triplet, character vector of color names, or `'none'`.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from `0` to

F. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|---|---|
| `'red'` | `'r'` | `[1 0 0]` | `'#FF0000'` | 🟥 |
| `'green'` | `'g'` | `[0 1 0]` | `'#00FF00'` | 🟩 |
| `'blue'` | `'b'` | `[0 0 1]` | `'#0000FF'` | 🟦 |
| `'cyan'` | `'c'` | `[0 1 1]` | `'#00FFFF'` | 🟦 |
| `'magenta'` | `'m'` | `[1 0 1]` | `'#FF00FF'` | 🟪 |
| `'yellow'` | `'y'` | `[1 1 0]` | `'#FFFF00'` | 🟨 |
| `'black'` | `'k'` | `[0 0 0]` | `'#000000'` | ⬛ |
| `'white'` | `'w'` | `[1 1 1]` | `'#FFFFFF'` | ⬜ |

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

| RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|
| `[0 0.4470 0.7410]` | `'#0072BD'` | 🟦 |
| `[0.8500 0.3250 0.0980]` | `'#D95319'` | 🟧 |
| `[0.9290 0.6940 0.1250]` | `'#EDB120'` | 🟨 |
| `[0.4940 0.1840 0.5560]` | `'#7E2F8E'` | 🟪 |
| `[0.4660 0.6740 0.1880]` | `'#77AC30'` | 🟩 |
| `[0.3010 0.7450 0.9330]` | `'#4DBEEE'` | 🟦 |
| `[0.6350 0.0780 0.1840]` | `'#A2142F'` | 🟥 |

Data Types: `double` | `char`

### Marker, Color, Line, and Font Properties

### `'Marker'` — Marker symbol

`'none'` (default) | character vector of symbols

Marker symbol, specified as a comma-separated pair consisting of 'Marker' and either 'none' or one of the symbols in this table. By default, a line does not have markers. Add markers at selected points along the line by specifying a marker.

| Value | Description |
|---|---|
| 'o' | Circle |
| '+' | Plus sign |
| '*' | Asterisk |
| '.' | Point |
| 'x' | Cross |
| 'square' or 's' | Square |
| 'diamond' or 'd' | Diamond |
| '^' | Upward-pointing triangle |
| 'v' | Downward-pointing triangle |
| '>' | Right-pointing triangle |
| '<' | Left-pointing triangle |
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h' | Six-pointed star (hexagram) |
| 'none' | No markers |

### 'MarkerSize' — Marker size

6 (default) | positive value

Marker size, specified as a comma-separated pair consisting of 'MarkerSize' and a positive value in point units.

Data Types: double

### 'ColorOrder' — Colors to use for multiline plots

seven predefined colors (default) | three-column matrix of RGB triplets

Colors to use for multi-line plots, specified as a comma-separated pair consisting of 'ColorOrder' and a three-column matrix of RGB triplets. Each row of the matrix defines one color in the color order.

Data Types: double

### 'ColorOrderIndex' — Next color to use in color order

1 (default) | positive integer

Next color to use in color order, specified as a comma-separated pair consisting of 'ColorOrderIndex' and a positive integer. New plots added to the axes use colors based on the current value of the color order index.

Data Types: double

### 'EdgeColor' — Color of data lines

'k' (default) | RGB triplet vector

Color of data lines, specified as a comma-separated pair consisting of 'EdgeColor' and a character vector of color names or RGB triplet vector.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|---|---|
| 'red' | 'r' | [1 0 0] | '#FF0000' | 🟥 |
| 'green' | 'g' | [0 1 0] | '#00FF00' | 🟩 |
| 'blue' | 'b' | [0 0 1] | '#0000FF' | 🟦 |
| 'cyan' | 'c' | [0 1 1] | '#00FFFF' | 🟦 |
| 'magenta' | 'm' | [1 0 1] | '#FF00FF' | 🟪 |
| 'yellow' | 'y' | [1 1 0] | '#FFFF00' | 🟨 |
| 'black' | 'k' | [0 0 0] | '#000000' | ⬛ |
| 'white' | 'w' | [1 1 1] | '#FFFFFF' | ⬜ |

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

| RGB Triplet | Hexadecimal Color Code | Appearance |
|---|---|---|
| `[0 0.4470 0.7410]` | `'#0072BD'` | 🟦 |
| `[0.8500 0.3250 0.0980]` | `'#D95319'` | 🟧 |
| `[0.9290 0.6940 0.1250]` | `'#EDB120'` | 🟨 |
| `[0.4940 0.1840 0.5560]` | `'#7E2F8E'` | 🟪 |
| `[0.4660 0.6740 0.1880]` | `'#77AC30'` | 🟩 |
| `[0.3010 0.7450 0.9330]` | `'#4DBEEE'` | 🟦 |
| `[0.6350 0.0780 0.1840]` | `'#A2142F'` | 🟥 |

Data Types: `double` | `char`

**`'LineStyle'` — Line style of the plot**
`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style of the plot, specified as a comma-separated pair consisting of `'LineStyle'` and one of the symbols in the table:

| Symbol | Line Style | Resulting Line |
|---|---|---|
| `'-'` | Solid line | ———— |
| `'--'` | Dashed line | - — — — — |
| `':'` | Dotted line | ……………… |
| `'-.'` | Dash-dotted line | —·—·—·—·- |
| `'none'` | No line | No line |

**`'LineWidth'` — Line width of plot**
`1` (default) | positive scalar | positive vector

Line width of the plot, specified as a comma-separated pair consisting of `'LineWidth'` and a positive scalar or vector.

**`'FontSize'` — Font size of text in plot**
`10` (default) | positive scalar

Font size of text in the plot, specified as a comma-separated pair consisting of `'FontSize'` and a positive scalar.

### `'FontSizeAutoMode'` — Set font size

`'auto'` (default) | `'manual'`

Set font size, specified as a comma-separated pair consisting of `'FontSizeAutoMode'` and `'auto'` or `'manual'`.

Data Types: `char`

# showSpan

**Class:** `polarpattern`

Show or hide angle span between two markers

## Syntax

```
showSpan(p,id1,id2)
showSpan(p,id1,id2,true)
showSpan(p,vis)
showSpan(p)
d = showSpan( ___ )
```

## Description

`showSpan(p,id1,id2)` displays the angle span between two angle markers, `id1` and `id2`. The angle span is calculated counterclockwise.

`showSpan(p,id1,id2,true)` automatically reorders the angle markers such that the initial angle span is less than or equal to 180° counterclockwise.

`showSpan(p,vis)` sets angle span visibility by setting `vis` to `true` or `false`.

`showSpan(p)` toggles the angle span display on and off.

`d = showSpan( ___ )` returns angle span details in a structure, `d` using any of the previous syntaxes.

## Input Arguments

### p — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

### `id1,id2` — Cursor or peak marker identifiers

character vector

Cursor or peak marker identifiers, specified as character vector. Adding cursors to the polar plot creates cursor marker identifiers. Adding peaks to the polar plot creates peak marker identifiers.

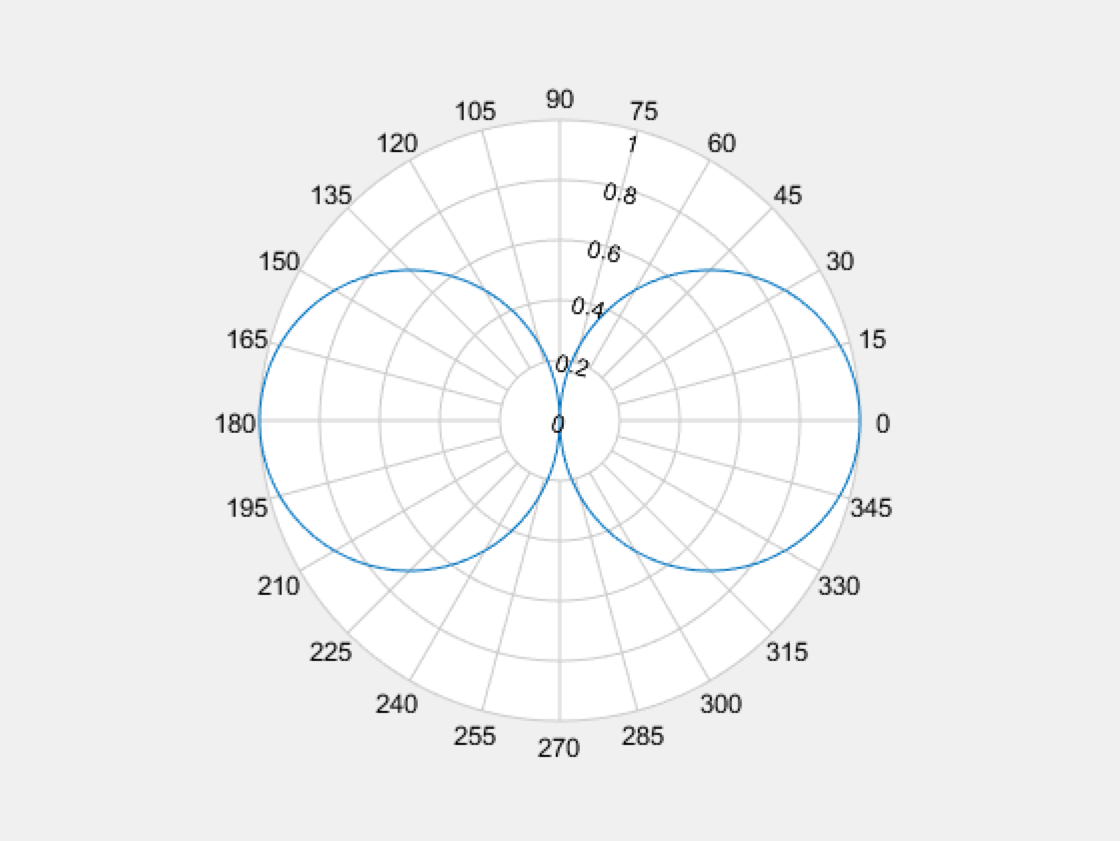
Example: `showspan(p,'C1','C2')`. Displays the angle span between cursors, `C1` and `C2` in polar plot, `p`.

## Examples

### Show Angle Span for Short-Dipole Antenna

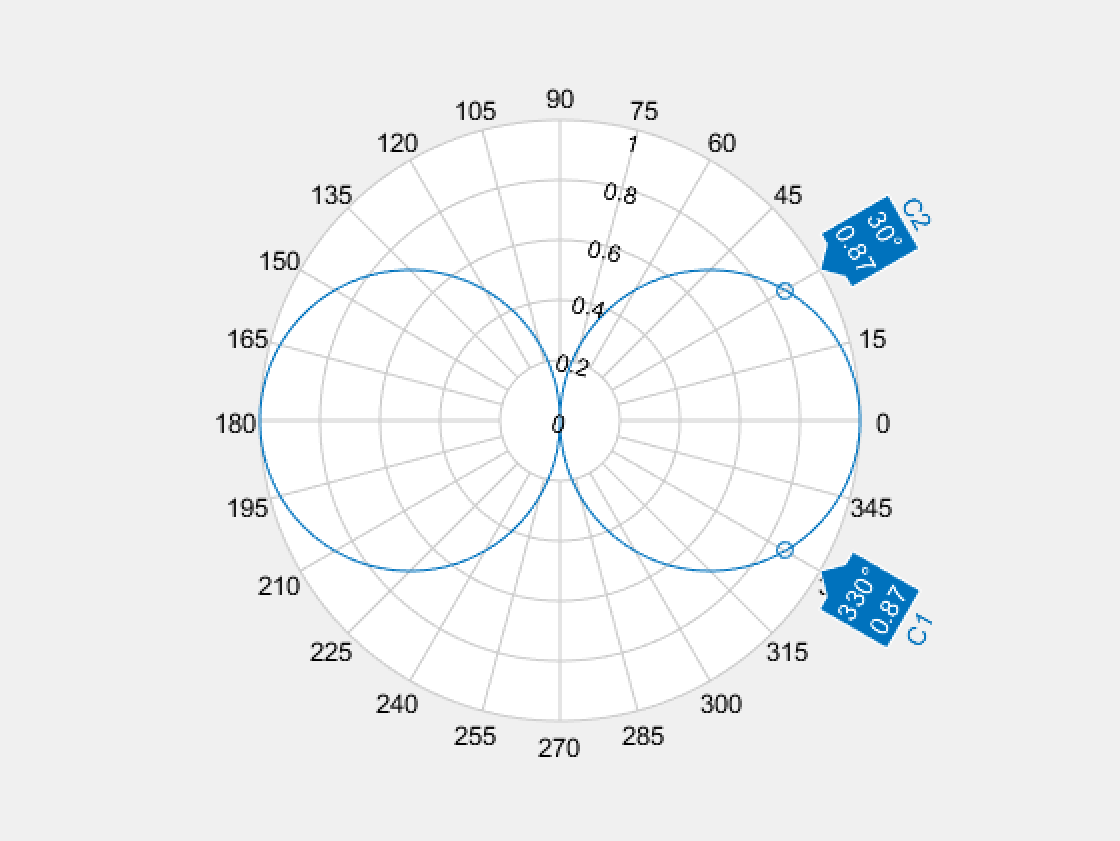
Create a short-dipole antenna element and plot the field values at 250 MHz.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6,...
    'AxisDirection','Y');
angs = [-180:1:180];
fc = 250.0e6;
p = pattern(antenna,250.0e6,angs,0,'CoordinateSystem','polar','Type',...
    'efield','Polarization','H');
P = polarpattern(angs,abs(p));
```



Add cursors to the polar plot at -30° and 30°.

```
addCursor(P,[-30 30]);
```



Show the angle span between the two angles.

```
showSpan(P,'C1','C2');
```

# AlphaBetaFilter

Alpha-beta filter for object tracking

## Description

The AlphaBetaFilter object represents an alpha-beta filter designed for object tracking. Use this tracker for platforms that follow a linear motion model and have a linear measurement model. Linear motion is defined by constant velocity or constant acceleration. Use the filter to predict the future location of an object, to reduce noise for a detected location, or to help associate multiple objects with their tracks.

## Creation

## Syntax

```
abf = AlphaBetaFilter
abf = AlphaBetaFilter(Name,Value,...)
```

### Description

abf = AlphaBetaFilter creates an alpha-beta filter for a discrete time, 2-D constant velocity system. The motion model of the filter corresponds to setting the MotionModel property to '2D Constant Velocity'. In this case, the filter state takes the form [x; vx; y; vy].

abf = AlphaBetaFilter(Name,Value,...) specifies the properties of the filter using one or more Name,Value pair arguments. Any unspecified properties take default values.

## Properties

### MotionModel — Model of target motion

'2D Constant Velocity' (default) | '1D Constant Velocity' | '3D Constant Velocity' | '1D Constant Acceleration' | '2D Constant Acceleration' | '3D Constant Acceleration'

Model of target motion, specified as a character vector or string. Specifying 1D, 2D or 3D sets the dimensions of the targets motion. Specifying Constant Velocity assumes that the target motion has constant velocity at each simulation step. Specifying Constant Acceleration assumes that the target motion has constant acceleration at each simulation step.

Data Types: char | string

### State — Filter state

scalar | real-valued *M*-element vector

Filter state, specified as a scalar or a real-valued *M*-element vector. A scalar input is extended to an *M*-element vector. The state vector is the concatenated states from each dimension.

The state vectors for each motion model are column vectors:

| MotionModel Property | State Vector |
|---|---|
| '1D Constant Velocity' | [x; vx] |
| '2D Constant Velocity' | [x; vx; y; vy] |
| '3D Constant Velocity' | [x; vx; y; vy; z; vz] |
| '1D Constant Acceleration' | [x; vx; ax] |
| '2D Constant Acceleration' | [x; vx; ax; y; vy; ay] |
| '3D Constant Acceleration' | [x; vx; ax; y; vy; ay; z; vz; az] |

where, for example, vx denotes velocity in the *x*-direction and ax denotes acceleration in the *x*-direction.

Example: [200;0.2;150;0.1;0;0.25]

Data Types: double

### `StateCovariance` — State estimation error covariance

*M*-by-*M* matrix | scalar

State error covariance, specified as an *M*-by-*M* matrix where *M* is the size of the filter state. A scalar input is extended to an *M*-by-*M* matrix. The covariance matrix represents the uncertainty in the filter state.

Example: `eye(6)`

### `ProcessNoise` — Process noise covariance

*D*-by-*D* matrix | scalar

Process noise covariance, specified as a scalar or an *D*-by-*D* matrix where *D* is the dimensionality of motion. For example, if `MotionModel` is `'2D Constant Velocity`, then $D = 2$. A scalar input is extended to an *D*-by-*D* matrix.

Example: `[20 0.1; 0.1 1]`

### `MeasurementNoise` — Measurement noise covariance

*D*-by-*D* matrix | scalar

Measurement noise covariance, specified as a scalar or an *D*-by-*D* matrix where *D* is the dimensionality of motion. For example, if `MotionModel` is `'2D Constant Velocity`, then $D = 2$. A scalar input is extended to an *M*-by-*M* matrix.

Example: `[20 0.1; 0.1 1]`

### `Coefficients` — Alpha-beta filter coefficients

scalar | row vector of real values

Alpha-beta filter coefficients, specified as a scalar or row vector of real values. Any scalar input is extended to a row vector. If you specify constant velocity in the `MotionModel` property, the coefficients are `[alpha beta]`. If you specify constant acceleration in the `MotionModel` property, the coefficients are `[alpha beta gamma]`.

Example: `[20 0.1]`

## Object Functions

| | |
|---|---|
| predict | Predict the state and state estimation error covariance |
| correct | Correct the state and state estimation error covariance |
| distance | Distances between measurements and predicted measurements |

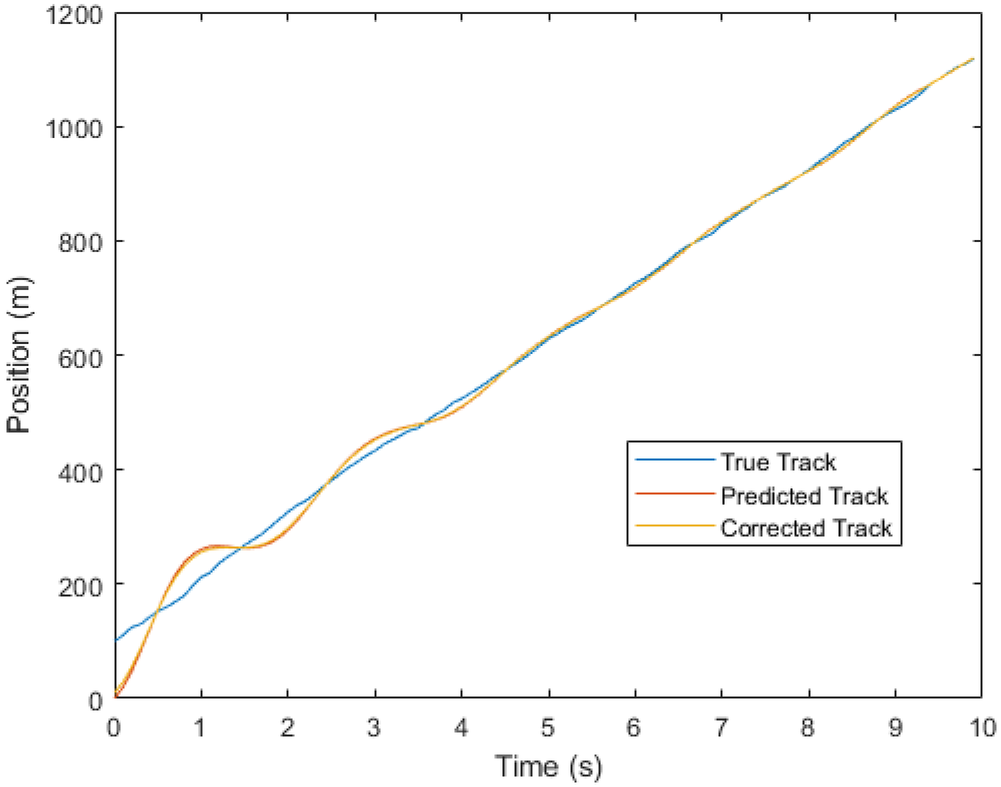
| | |
|---|---|
| likelihood | Likelihood of measurement |
| clone | Create identical object |

## Examples

### Track Constant-Velocity Target Using Alpha-Beta Filter

Apply the alpha-beta filter to track a target moving at constant velocity along the x-axis.

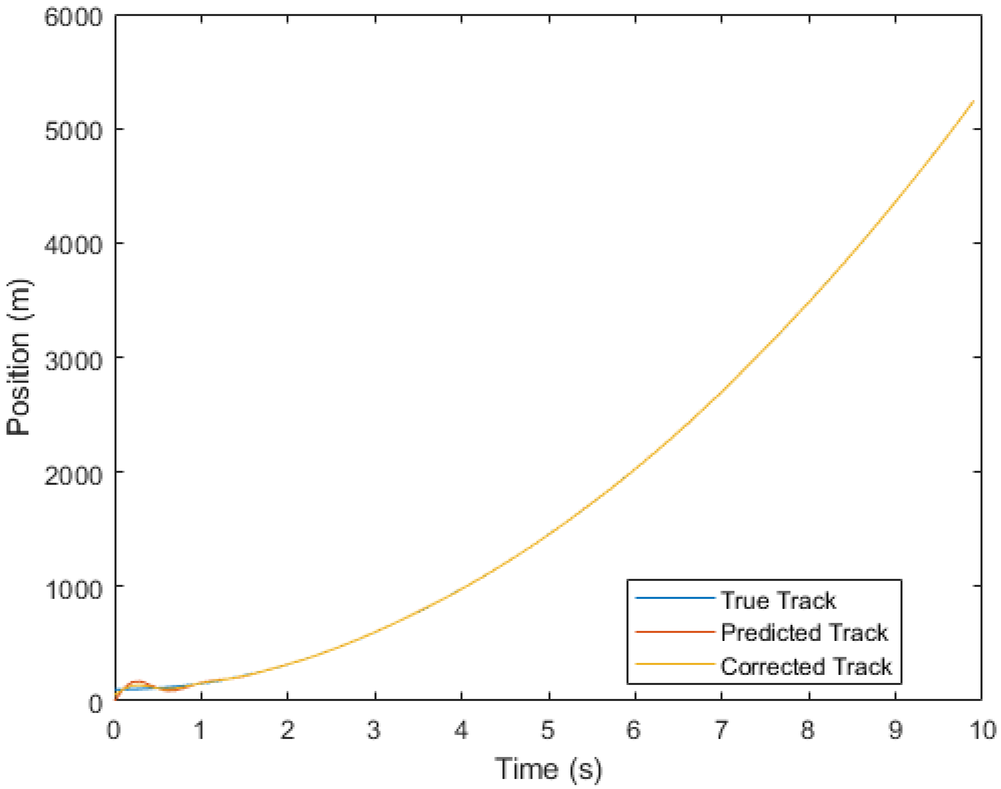
```
T = 0.1;
V0 = 100;
N = 100;
plat = phased.Platform('MotionModel','Velocity', ...
    'VelocitySource','Input port','InitialPosition',[100;0;0]);
abfilt = phased.AlphaBetaFilter('MotionModel','1D Constant Velocity');
Z = zeros(1,N);
Zp = zeros(1,N);
Zc = zeros(1,N);
for m = 1:N
    pos = plat(T,[100+20*randn;0;0]);
    Z(m) = pos(1);
    [~,~,Zp(m)] = predict(abfilt,T);
    [~,~,Zc(m)] = correct(abfilt,Z(m));
end
t = (0:N-1)*T;
plot(t,Z,t,Zp,t,Zc)
xlabel('Time (s)')
ylabel('Position (m)')
legend('True Track','Predicted Track','Corrected Track', ...
    'Location','Best')
```



### Track Constant-Acceleration Target Using Alpha-Beta Filter

Apply the alpha-beta filter to track a target moving at constant acceleration along the x-axis.

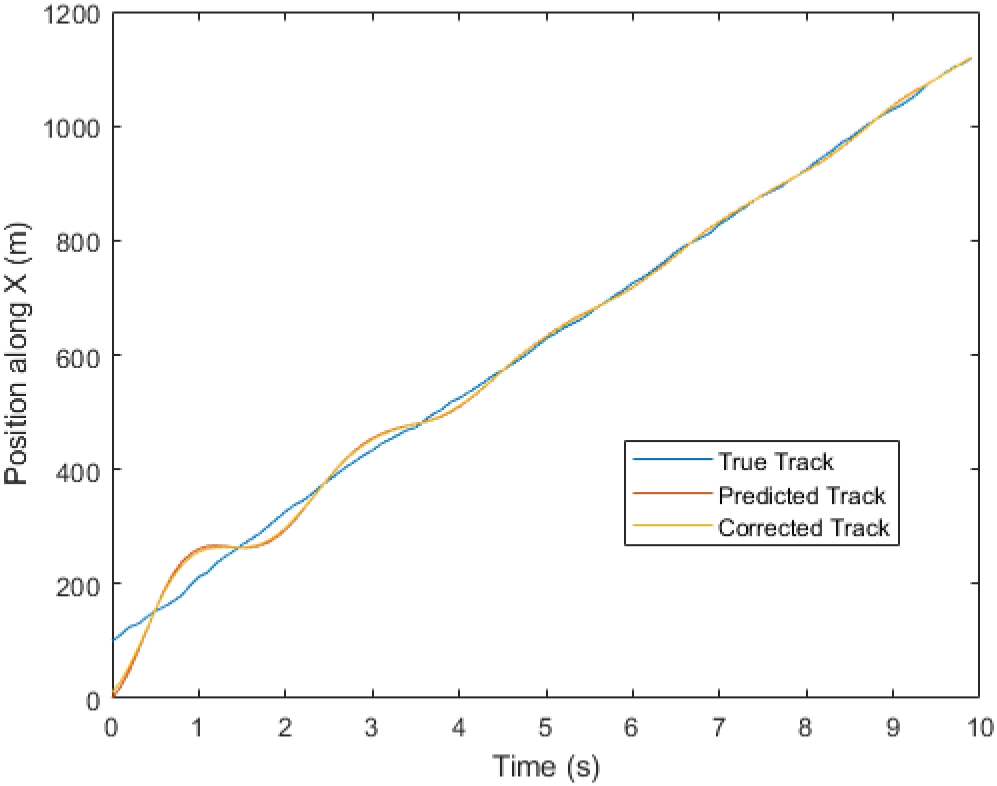
```
T = 0.1;
a0 = 100;
N = 100;
plat = phased.Platform('MotionModel','Acceleration', ...
    'AccelerationSource','Input port','InitialPosition',[100;0;0]);
abfilt = phased.AlphaBetaFilter( ...
    'MotionModel','1D Constant Acceleration', ...
    'Coefficients',[0.5 0.5 0.1]);
Z = zeros(1,N);
Zp = zeros(1,N);
Zc = zeros(1,N);
for m = 1:N
    pos = plat(T,[100+20*randn;0;0]);
    Z(m) = pos(1);
    [~,~,Zp(m)] = predict(abfilt,T);
    [~,~,Zc(m)] = correct(abfilt,Z(m));
end
t = (0:N-1)*T;
plot(t,Z,t,Zp,t,Zc)
xlabel('Time (s)')
ylabel('Position (m)');
legend('True Track','Predicted Track','Corrected Track', ...
    'Location','Best');
```



### Track Target in 3-D Using Alpha-Beta Filter

Apply the alpha-beta filter to track a target moving at constant velocity in three dimensions.

```
T = 0.1;
V0 = 100;
N = 100;
plat = phased.Platform('MotionModel','Velocity', ...
    'VelocitySource','Input port','InitialPosition',[100;0;0]);
abfilt = phased.AlphaBetaFilter('MotionModel', ...
    '3D Constant Velocity','State',zeros(6,1));
Z = zeros(3,N);
Zp = zeros(3,N);
Zc = zeros(3,N);
for m = 1:N
    Z(:,m) = plat(T,[V0+20*randn;0;0]);
    [~,~,Zp(:,m)] = predict(abfilt,T);
    [~,~,Zc(:,m)] = correct(abfilt,Z(:,m));
end
t = (0:N-1)*T;
plot(t,Z(1,:),t,Zp(1,:),t,Zc(1,:))
xlabel('Time (s)')
ylabel('Position along X (m)')
legend('True Track','Predicted Track','Corrected Track', ...
    'Location','Best')
```



# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

## See Also

**Introduced in R2018b**

# clone

Copy of alpha-beta tracking filter

## Syntax

```
abfilter2 = clone(abfilter)
```

## Description

`abfilter2 = clone(abfilter)` creates a copy, `abfilter2`, of the filter object, `abfilter`, with the same property values.

## Input Arguments

**`abfilter` — Alpha-beta tracking filter**
`phased.AlphaBetaFilter` object

Alpha-beta tracking filter, specified as a `phased.AlphaBetaFilter` object.

## Output Arguments

**`abfilter2` — Copy of alpha-beta tracking filter**
`phased.AlphaBetaFilter`

Copy of alpha-beta tracking filter, returned as a `phased.AlphaBetaFilter` object.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

## See Also

**Functions**
`correct` | `distance` | `likelihood` | `predict`

**System Objects**
`phased.Platform`

**Introduced in R2018b**

# correct

Correct the state and state estimation error covariance

## Syntax

```
xCorr = correct(abfilter,zMeas)
[xCorr,pCorr] = correct(abfilter,zMeas)
[xCorr,pCorr,zCorr] = correct(abfilter,zMeas)
```

## Description

`xCorr = correct(abfilter,zMeas)` returns the corrected the state, `xCorr`, of the tracking filter `abfilter` given the measurement, `zMeas`. Calling `correct` overwrites the internal states of the object.

`[xCorr,pCorr] = correct(abfilter,zMeas)` also returns the corrected state covariance matrix, `pCorr`.

`[xCorr,pCorr,zCorr] = correct(abfilter,zMeas)` also returns the corrected measurement, `zCorr`.

## Input Arguments

### `abfilter` — Alpha-beta tracking filter

`phased.AlphaBetaFilter` object

Alpha-beta tracking filter, specified as a `phased.AlphaBetaFilter` object. Calling `correct` overwrites the internal states of the object.

### zMeas — Measurement of tracked object

*K*-by-1 vector

Measurement of tracked object, specified as a *K*-by-1 vector, where *K* is the size of the measurement.

## Output Arguments

### `xCorr` — Corrected state of the filter

*L*-by-1 vector

Corrected state of the filter, returned as an *L*-by-1 vector. The corrected state overrides the value of the `State` property.

### `pCorr` — Corrected state covariance of the filter

*L*-by-*L* matrix

Corrected state covariance of the filter, returned as an *L*-by-*L* matrix. The corrected state covariance overrides the value of the `StateCovariance` property.

### `zCorr` — Corrected measurement of the filter

*K*-by-1 vector

Corrected measurement of the filter, returned as a *K*-by-1 vector.

# Extended Capabilities

# distance

Distances between measurements and predicted measurements

## Syntax

```
dist = distance(abfilter,zMatrix)
```

## Description

`dist = distance(abfilter,zMatrix)` computes the distance between one or more predicted measurements given in `zMatrix` and the measurement predicted by the `abfilter` object.

## Input Arguments

### `abfilter` — Alpha-beta tracking filter

`phased.AlphaBetaFilter` object

Alpha-beta tracking filter, specified as a `phased.AlphaBetaFilter` object.

### `zMatrix` — Measurements of tracked objects

*N*-by-*K* matrix

Measurements of tracked objects, specified as an *N*-by-*K* matrix where *N* is the number of measurements. Each row of the matrix contains a measurement vector. The number of columns, *K*, must match the measurement dimensions of the motion model. This computation takes into account the covariance of the predicted state and the process noise.

## Output Arguments

### `dist` — Distances between measurements and filter predictions

length-*N* row vector

Distances between measurements and filter predictions, returned as a row vector. Each element corresponds to a distance between the predicted measurement coming from the `abfilter` object and a row of `zMatrix`.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

# See Also

**Functions**

# predict

Predict the state and state estimation error covariance

## Syntax

```
xPred = predict(abfilter,tstep)
[xPred,pPred] = predict(abfilter,tstep)
[xPred,pPred,zPred] = predict(abfilter,tstep)
```

## Description

`xPred = predict(abfilter,tstep)` returns the predicted filter state, `xPred`, of the filter, `abfilter`, after the elapsed time, `tstep`.

`[xPred,pPred] = predict(abfilter,tstep)` also returns the estimated state covariance, `pPred`.

`[xPred,pPred,zPred] = predict(abfilter,tstep)` also returns the predicted measurements, `zPred`.

## Input Arguments

### `abfilter` — Alpha-beta tracking filter object

`phased.AlphaBetaFilter` object

Alpha-beta tracking filter, specified as a `phased.AlphaBetaFilter` object. Calling `predict` overwrites the internal states of the object.

### `tstep` — Time step

positive scalar

Time step for next prediction, specified as a positive scalar. The time step is the interval from the last prediction-correction to the current prediction. Units are in seconds.

## Output Arguments

**xPred — Predicted state of the filter**
*L*-by-1 vector

Predicted state of the filter, returned as an *L*-by-1 vector where *L* is the size of the state vector. The predicted state overrides the value of the `State` property.

**pPred — Predicted state covariance of the filter**
*L*-by-*L* matrix

Predicted state covariance of the filter, returned as an *L*-by-*L* matrix. The predicted state covariance overrides the value of the `StateCovariance` property.

**zPred — Predicted measurement**
*K*-by-1 vector

Predicted measurement, returned as a *K*-by-1 vector, where *K* is the size of the measurement.

## Extended Capabilities

# likelihood

Likelihood of measurement

## Syntax

```
lk = likelihood(abfilter,zMeas)
```

## Description

`lk = likelihood(abfilter,zMeas)` computes the likelihood, `lk`, of the current measurement, `zMeas`, from the filter, `abfilter`.

## Input Arguments

### `abfilter` — Alpha-beta tracking filter

`phased.AlphaBetaFilter` object

Alpha-beta tracking filter, specified as a `phased.AlphaBetaFilter` object.

### `zMeas` — Measurements of tracked object

*K*-by-1 vector

Measurements of tracked object, specified as a *K*-by-1 vector, where *K* is the size of the measurement.

## Output Arguments

### `lk` — Likelihood of measurement

scalar

Likelihood of current measurement, returned as a scalar.

# directivity

**Package:** `phased`

Directivity of antenna or transducer element

## Syntax

```
D = directivity(element,FREQ,ANGLE)
```

## Description

`D = directivity(element,FREQ,ANGLE)` returns the “Directivity” on page 1-2896 of the antenna or transducer element, `element`, at frequencies specified by FREQ in direction angles specified by `ANGLE`.

## Input Arguments

**`element` — Antenna or transducer element**
Phased Array System Toolbox System object

Antenna or transducer element, specified as a Phased Array System Toolbox System object.

**`FREQ` — Frequency for computing directivity and patterns**
positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

**`ANGLE` — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

**`D` — Directivity**
*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Azimuth and Elevation Angles

This section describes the convention used to define azimuth and elevation angles.

The azimuth angle of a vector is the angle between the *x*-axis and its orthogonal projection onto the *xy*-plane. The angle is positive when going from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180° and 180° degrees, inclusive. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy*-plane. Elevation angles lie between –90° and 90° degrees, inclusive.

**Introduced in R2019a**

# isPolarizationCapable

**Package:** `phased`

Antenna element polarization capability

## Syntax

```
capflag = isPolarizationCapable(element)
```

## Description

`capflag = isPolarizationCapable(element)` returns a Boolean value, `capflag`, indicating whether the antenna `element` supports polarization. An antenna element supports polarization if it can create or respond to polarized fields.

## Input Arguments

### `element` — Antenna or transducer element

Phased Array System Toolbox System object

Antenna or transducer element, specified as a Phased Array System Toolbox System object.

## Output Arguments

### `capflag` — Polarization-capability flag

`true` | `false`

Polarization-capability flag returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not.

**Introduced in R2019a**

# pattern

**Package:** phased

Plot antenna or transducer element directivity and patterns

## Syntax

```
pattern(element,FREQ)
pattern(element,FREQ,AZ)
pattern(element,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

pattern(element,FREQ) plots the 3-D array directivity pattern (in dBi) for the element specified in element. The operating frequency is specified in FREQ. You can use this function to display the patterns for antennas that support polarization.

pattern(element,FREQ,AZ) plots the element directivity pattern at the specified azimuth angle.

pattern(element,FREQ,AZ,EL) plots the element directivity pattern at specified azimuth and elevation angles.

pattern( ___ ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

[PAT,AZ_ANG,EL_ANG] = pattern( ___ ) returns the element pattern in PAT. The AZ_ANG output contains the coordinate values corresponding to the rows of PAT. The EL_ANG output contains the coordinate values corresponding to the columns of PAT. If the 'CoordinateSystem' parameter is set to 'uv', then AZ_ANG contains the *U* coordinates of the pattern and EL_ANG contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

## Input Arguments

### `element` — Antenna or transducer element

Phased Array System Toolbox System object

Antenna or transducer element, specified as a Phased Array System Toolbox System object.

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `CoordinateSystem,'polar',Type,'directivity'`

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarization type

'combined' (default) | 'H' | 'V'

Polarization type, specified as the comma-separated pair consisting of 'Polarization' and either 'combined', 'H', or 'V'. If Polarization is 'combined', the horizontal and vertical polarization patterns are combined. If Polarization is 'H', only the horizontal polarization is displayed. If Polarization is 'V', only the vertical polarization is displayed.

#### Dependencies

To enable this property, set the element argument to an antenna that supports polarization: phased.CrossedDipoleAntennaElement, phased.ShortDipoleAntennaElement, or phased.CustomAntennaElement, and then set the 'Type' name-value pair to 'efield', 'power', or 'powerdb'.

Data Types: char | string

# Output Arguments

**PAT — Element pattern**
*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified

direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

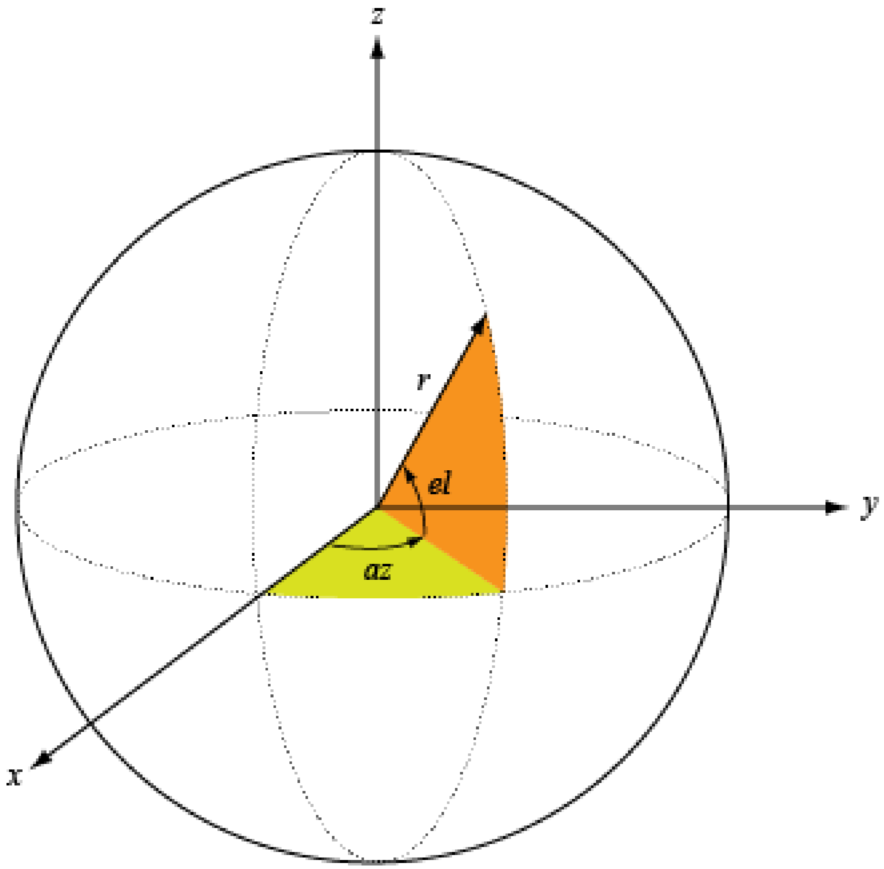
$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Azimuth and Elevation Angles

The azimuth angle of a vector is the angle between the *x*-axis and its orthogonal projection onto the *xy*-plane. The angle is positive when going from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180° and 180° degrees, inclusive. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy*-plane. Elevation angles lie between –90° and 90° degrees, inclusive.



# Algorithms

## Convert plotResponse to Pattern

For antenna, transducer, and array System objects, the `pattern` function replaces the `plotResponse` function. In addition, two new simplified functions exist just to draw 2-D azimuth and elevation pattern plots. These functions are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>

**Package:** `phased`

Plot antenna or transducer element directivity and pattern versus azimuth

## Syntax

```
patternAzimuth(element,FREQ)
patternAzimuth(element,FREQ,EL)
patternAzimuth(element,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(element,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `element` at zero-degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(element,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(element,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**`element` — Antenna or transducer element**

Phased Array System Toolbox System object

Antenna or transducer element, specified as a Phased Array System Toolbox System object.

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Azimuth,[-90:90],Type,'directivity'`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Azimuth` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Azimuth and Elevation Angles

The azimuth angle of a vector is the angle between the *x*-axis and its orthogonal projection onto the *xy*-plane. The angle is positive when going from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180° and 180° degrees, inclusive. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy*-plane. Elevation angles lie between –90° and 90° degrees, inclusive.

**Package:** phased

Plot antenna or transducer element directivity and pattern versus elevation

## Syntax

```
patternElevation(element,FREQ)
patternElevation(element,FREQ,AZ)
patternElevation(element,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(element,FREQ) plots the 2-D element directivity pattern versus elevation (in dBi) for the element element at zero-degrees azimuth angle. The argument FREQ specifies the operating frequency.

patternElevation(element,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(element,FREQ,AZ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**element — Antenna or transducer element**
Phased Array System Toolbox System object

Antenna or transducer element, specified as a Phased Array System Toolbox System object.

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Azimuth,[-90:90],Type,'directivity'`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Elevation — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Azimuth and Elevation Angles

The azimuth angle of a vector is the angle between the *x*-axis and its orthogonal projection onto the *xy*-plane. The angle is positive when going from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180° and 180° degrees, inclusive. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy*-plane. Elevation angles lie between –90° and 90° degrees, inclusive.

# plotSpectrum

**Package:** `phased`

Plot spatial spectrum

## Syntax

```
plotSpectrum(estimator)
plotSpectrum(estimator,Name,Value)
hl = plotSpectrum( ___ )
```

## Description

`plotSpectrum(estimator)` plots the spatial spectrum resulting from the most recent execution of the `estimator` object.

`plotSpectrum(estimator,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`hl = plotSpectrum( ___ )` returns the line handle of the spectrum plot in the figure.

## Input Arguments

**`estimator` — Spectrum estimator**
System object

Spectrum estimator, specified as a Phased Array System Toolbox System object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NormalizedResponse',true,'Unit','pow'`

### `NormalizeResponse` — Plot normalized response

`false` (default) | `true`

Option to enable plotting of normalized response, specified as `false` or `true`. Set this value to `true` to plot the normalized spectrum. Set this value to `false` to plot the spectrum without normalization.

Data Types: `logical`

### `Title` — Title of plot figure

`''` (default) | character vector

Title of plot figure, specified as a character vector.

Example: `'Beamscan Spectrum'`

Data Types: `char`

### `Unit` — Plot units

`'db'` (default) | `'mag'` | `'pow'`

Plot units, specified as

- `'db'` – decibels
- `'mag'` – magnitude
- `'pow'` – power

.

## Output Arguments

### `hl` — Line handle

line handle

Plot line, returned as a handle.

**Introduced in R2012a**

2

# Functions-Alphabetical List

# aictest

Dimension of signal subspace

## Syntax

```
nsig = aictest(X)
nsig = aictest(X,'fb')
```

## Description

`nsig = aictest(X)` estimates the number of signals, `nsig`, present in a snapshot of data, `X`, that impinges upon the sensors in an array. The estimator uses the Akaike Information Criterion test (AIC). The input argument, `X`, is a complex-valued matrix containing a time sequence of data samples for each sensor. Each row corresponds to a single time sample for all sensors.

`nsig = aictest(X,'fb')` estimates the number of signals. Before estimating, it performs forward-backward averaging on the sample covariance matrix constructed from the data snapshot, `X`. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Estimate the Signal Subspace Dimensions for Two Arriving Signals

Construct a data snapshot for two plane waves arriving at a half-wavelength-spaced uniform line array with 10 elements. The plane waves arrive from 0° and –25° azimuth, both with elevation angles of 0°. Assume the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white. For each signal, the SNR is 5 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `aictest`.

```
N = 10;
d = 0.5;
```

```
elementPos = (0:N-1)*d;
angles = [0 -25];
x = sensorsig(elementPos,300,angles,db2pow(-5));
nsig = aictest(x)

nsig = 2
```

The result shows that the number of signals is two, as expected.

### Estimate the Signal Subspace Dimension using Forward-Backward Smoothing

Construct a data snapshot for two plane waves arriving at a half-wavelength-spaced uniform line array with 10 elements. Two correlated plane waves arrive from 0° and 10° azimuth, both with elevation angles of 0°. Assume that the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white. For each signal, the SNR is 10 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `aictest`.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 10];
ncov = db2pow(-10);
scov = [1 .5]'*[1 .5];
x = sensorsig(elementPos,300,angles,ncov,scov);
Nsig = aictest(x)

Nsig = 1
```

This result shows that `aictest` cannot determine the number of signals correctly when the signals are correlated.

Use the forward-backward smoothing option.

```
Nsig = aictest(x,'fb')

Nsig = 2
```

The addition of forward-backward smoothing yields the correct number of signals.

# Input Arguments

**X — Data snapshot**
complex-valued *K*-by-*N* matrix

Data snapshot, specified as a complex-valued, *K*-by-*N* matrix. A snapshot is a sequence of time-samples taken simultaneous at each sensor. In this matrix, *K* represents the number of time samples of the data, while *N* represents the number of sensor elements.

Example: [ –0.1211 + 1.2549i, 0.1415 + 1.6114i, 0.8932 + 0.9765i;]

Data Types: `double`
Complex Number Support: Yes

# Output Arguments

**`nsig` — Dimension of signal subspace**
non-negative integer

Dimension of signal subspace, returned as a non-negative integer. The dimension of the signal subspace is the number of signals in the data.

# More About

## Estimating the Number of Sources

AIC and MDL tests

Direction finding algorithms such as MUSIC and ESPRIT require knowledge of the number of sources of signals impinging on the array or equivalently, the dimension, $d$, of the signal subspace. The Akaike Information Criterion (AIC) and the Minimum Description Length (MDL) formulas are two frequently-used estimators for obtaining that dimension. Both estimators assume that, besides the signals, the data contains spatially and temporally white Gaussian random noise. Finding the number of sources is equivalent to finding the multiplicity of the smallest eigenvalues of the sampled spatial covariance matrix. The sample spatial covariance matrix constructed from a data snapshot is used in place of the actual covariance matrix.

A requirement for both estimators is that the dimension of the signal subspace be less than the number of sensors, *N*, and that the number of time samples in the snapshot, *K*, be much greater than *N*.

A variant of each estimator exists when forward-backward averaging is employed to construct the spatial covariance matrix. Forward-backward averaging is useful for the case when some of the sources are highly correlated with each other. In that case, the spatial covariance matrix may be ill conditioned. Forward-backward averaging can only be used for certain types of symmetric arrays, called centro-symmetric arrays. Then the forward-backward covariance matrix can be constructed from the sample spatial covariance matrix, *S*, using $S_{FB} = S + JS^*J$ where *J* is the exchange matrix. The exchange matrix maps array elements into their symmetric counterparts. For a line array, it would be the identity matrix flipped from left to right.

All the estimators are based on a cost function

$$L_d(d) = K(N-d)\ln\left\{\frac{\frac{1}{N-d}\sum_{i=d+1}^{N}\hat{\lambda}_i}{\left\{\prod_{i=d+1}^{N}\hat{\lambda}_i\right\}^{\frac{1}{N-d}}}\right\}$$

plus an added penalty term. The value $\lambda_i$ represent the smallest *(N–d)* eigenvalues of the spatial covariance matrix. For each specific estimator, the solution for *d* is given by

- AIC

$$\hat{d}_{AIC} = \underset{d}{\operatorname{argmin}}\ \{L_d(d) + d(2N-d)\}$$

- AIC for forward-backward averaged covariance matrices

$$\hat{d}_{AIC:\,FB} = \underset{d}{\operatorname{argmin}}\left\{L_d(d) + \frac{1}{2}d(2N-d+1)\right\}$$

- MDL

$$\hat{d}_{MDL} = \underset{d}{\operatorname{argmin}}\left\{L_d(d) + \frac{1}{2}(d(2N-d)+1)\ln K\right\}$$

- MDL for forward-backward averaged covariance matrices

$$\widehat{d}_{MDL\,FB} = \underset{d}{\operatorname{argmin}} \left\{ L_d(d) + \frac{1}{4} d(2N - d + 1)\ln K \right\}$$

# albersheim

Required SNR using Albersheim’s equation

## Syntax

```
SNR = albersheim(prob_Detection,prob_FalseAlarm)
SNR = albersheim(prob_Detection,prob_FalseAlarm,N)
```

## Description

`SNR = albersheim(prob_Detection,prob_FalseAlarm)` returns the signal-to-noise ratio in decibels. This value indicates the ratio required to achieve the given probabilities of detection `prob_Detection` and false alarm `prob_FalseAlarm` for a single sample.

`SNR = albersheim(prob_Detection,prob_FalseAlarm,N)` determines the required SNR for the noncoherent integration of `N` samples.

## Examples

### Compute Required SNR for Probability of Detection

Compute the required SNR of a single pulse to achieve a detection probability of 0.9 as a function of the false alarm probability.

Set the probability of detection to 0.9 and the probabilities of false alarm from .0001 to .01.

```
Pd=0.9;
Pfa=0.0001:0.0001:.01;
```

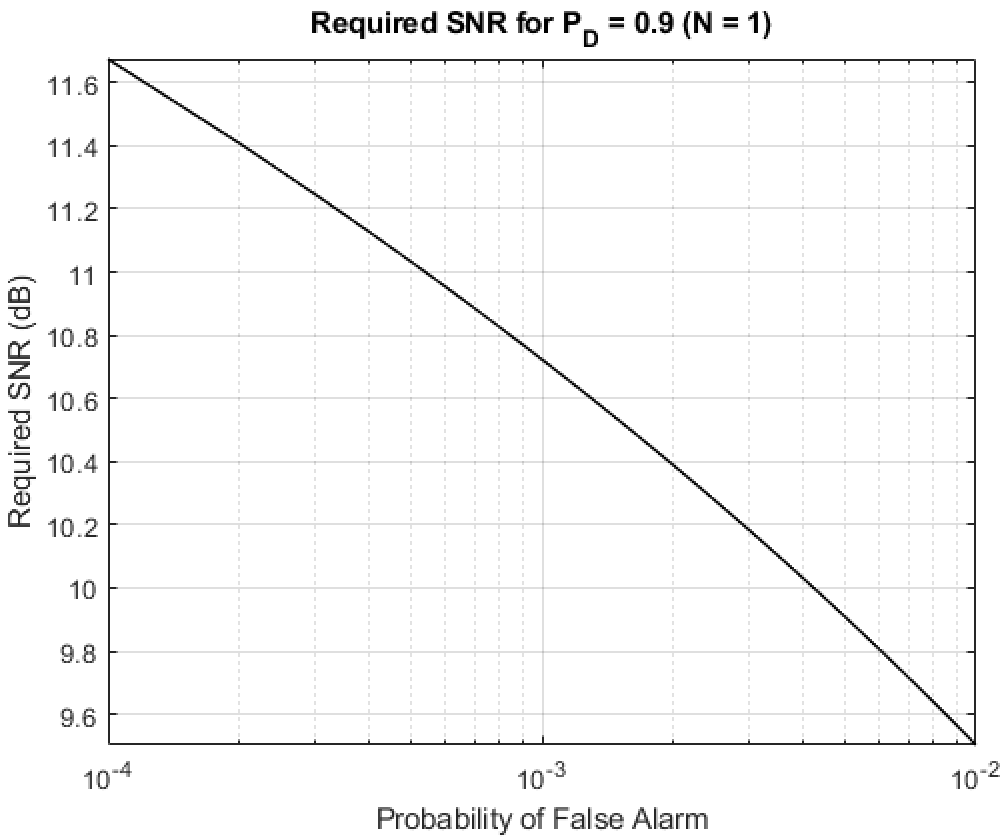
Loop the Albersheim equation over all Pfa's.

```
snr = zeros(1,length(Pfa));
for j=1:length(Pfa)
```

```
    snr(j) = albersheim(Pd,Pfa(j));
end
```

Plot SNR versus Pfa.

```
semilogx(Pfa,snr,'k','linewidth',1)
grid
axis tight
xlabel('Probability of False Alarm')
ylabel('Required SNR (dB)')
title('Required SNR for P_D = 0.9 (N = 1)')
```



### Compute Required SNR for Probability of Detection of 10 Pulses

Compute the required SNR of 10 non-coherently integrated pulse to achieve a detection probability of 0.9 as a function of the false alarm probability.

Set the probability of detection to 0.9 and the probabilities of false alarm from .0001 to .01.

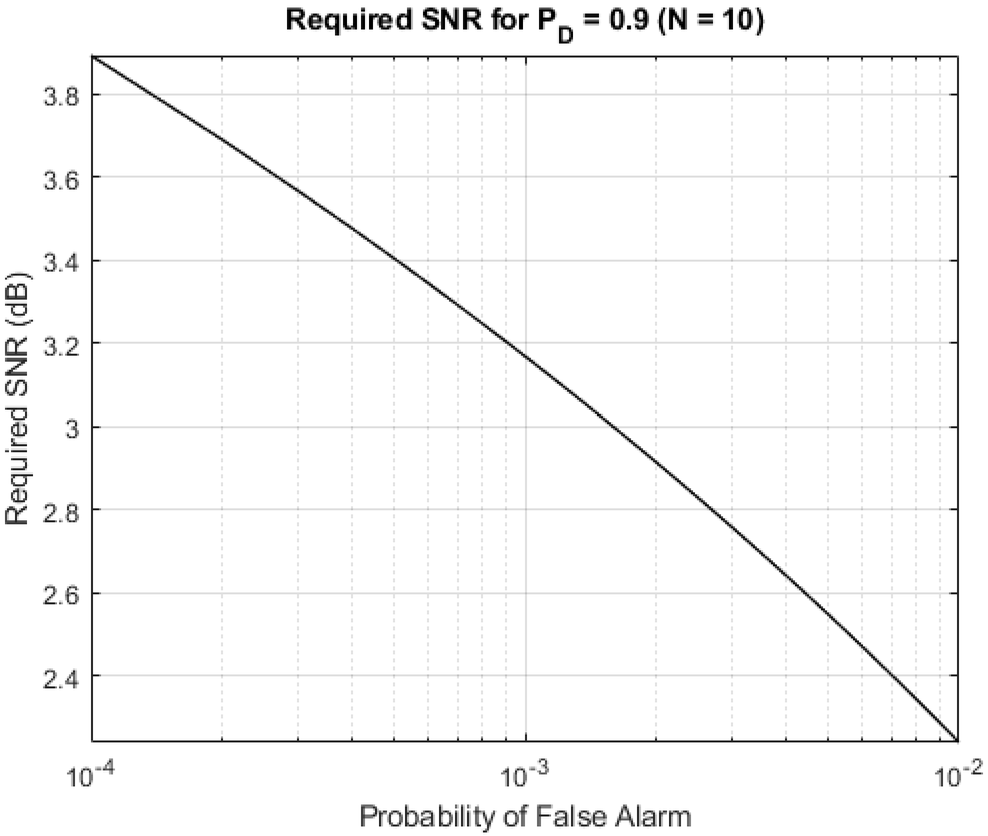
```
Pd=0.9;
Pfa=0.0001:0.0001:.01;
Npulses = 10;
```

Loop over the Albersheim equation over all Pfa's.

```
snr = zeros(1,length(Pfa));
for j=1:length(Pfa)
    snr(j) = albersheim(Pd,Pfa(j),Npulses);
end
```

Plot SNR versus Pfa.

```
semilogx(Pfa,snr,'k','linewidth',1)
grid
axis tight
xlabel('Probability of False Alarm')
ylabel('Required SNR (dB)')
title('Required SNR for P_D = 0.9 (N = 10)')
```



# More About

## Albersheim's Equation

Albersheim's equation uses a closed-form approximation to calculate the SNR. This SNR value is required to achieve the specified detection and false-alarm probabilities for a nonfluctuating target in independent and identically distributed Gaussian noise. The approximation is valid for a linear detector and is extensible to the noncoherent integration of N samples.

Let

$$A = \ln\frac{0.62}{P_{FA}}$$

and

$$B = \ln\frac{P_D}{1 - P_D}$$

where $P_{FA}$ and $P_D$ are the false-alarm and detection probabilities.

Albersheim's equation for the required SNR in decibels is:

$$\mathrm{SNR} = -5\log_{10}N + [6.2 + 4.54/\sqrt{N + 0.44}]\log_{10}(A + 0.12AB + 1.7B)$$

where $N$ is the number of noncoherently integrated samples.

# ambgfun

Ambiguity and crossambiguity function

## Syntax

```
afmag = ambgfun(x,Fs,PRF)
afmag = ambgfun(x,y,Fs,PRF)
[afmag,delay,doppler] = ambgfun( ___ )
[afmag,delay,doppler] = ambgfun( ___ ,'Cut','2D')
[afmag,delay] = ambgfun( ___ ,'Cut','Doppler')
[afmag,delay] = ambgfun( ___ ,'Cut','Doppler','CutValue',V)
[afmag,doppler] = ambgfun( ___ ,'Cut','Delay')
[afmag,doppler] = ambgfun( ___ ,'Cut','Delay','CutValue',V)
ambgfun( ___ )
```

## Description

`afmag = ambgfun(x,Fs,PRF)` returns the magnitude of the normalized ambiguity function for the vector `x`. `Fs` is the sampling rate. `PRF` is the pulse repetition rate.

`afmag = ambgfun(x,y,Fs,PRF)` returns the magnitude of the normalized crossambiguity function between the pulse `x` and the pulse `y`.

`[afmag,delay,doppler] = ambgfun( ___ )` or `[afmag,delay,doppler] = ambgfun( ___ ,'Cut','2D')` returns the time delay vector, `delay`, and the Doppler frequency vector, `doppler`.

`[afmag,delay] = ambgfun( ___ ,'Cut','Doppler')` returns delays from a zero-Doppler cut through the 2-D normalized ambiguity function magnitude.

`[afmag,delay] = ambgfun( ___ ,'Cut','Doppler','CutValue',V)` returns delays from a nonzero Doppler cut through the 2-D normalized ambiguity function magnitude at Doppler value, `V`.

`[afmag,doppler] = ambgfun( ___ ,'Cut','Delay')` returns the Doppler values from zero-delay cut through the 2-D normalized ambiguity function magnitude.

`[afmag,doppler] = ambgfun(___,'Cut','Delay','CutValue',V)` returns the Doppler values from a one-dimensional cut through the 2-D normalized ambiguity function magnitude at a delay value of `V`.

`ambgfun(___)`, with no output arguments, plots the ambiguity or crossambiguity function. When `'Cut'` is `'2D'`, the function produces a contour plot of the periodic ambiguity function. When `'Cut'` is `'Delay'` or '`Doppler'`, the function produces a line plot of the periodic ambiguity function cut.

## Input Arguments

**x — Input pulse waveform**
complex-valued row or column vector

Input pulse waveform.

**y — Second input pulse waveform**
complex-valued row or column vector

Second input pulse waveform.

**`Fs` — Sample rate**
real positive scalar

Sampling rate in hertz.

**PRF — Pulse repetition frequency**
real positive scalar

Pulse repetition frequency in hertz.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Cut','Doppler','CutValue',10` specifies that a vector of ambiguity function values be produced at a Doppler shift of 10 Hz.

### `Cut` — Direction of one-dimensional cut through ambiguity function

`'2D'` (default) | `'Delay'` | `'Doppler'`

Used to generate an ambiguity surface or one-dimensional cut through the ambiguity diagram. The value `'2D'` generates a surface plot of the two-dimensional ambiguity function. The direction of the one-dimensional cut is determined by setting the value of `'Cut'` to `'Delay'` or `'Doppler'`.

The choice of `'Delay'` generates a cut at zero time delay. In this case, the second output argument of `ambgfun`contains the ambiguity function values at Doppler shifted values. You can create a cut at nonzero time delay using the name-value pair `'CutValue'`.

The choice of `'Doppler'` generates a cut at zero Doppler shift. In this case, the second output argument of `ambgfun` contains the ambiguity function values at time-delayed values. You can create cut at nonzero Doppler using the name-value pair `'CutValue'`.

### `CutValue` — Optional time delay or Doppler shift at which ambiguity function cut is taken

0 (default) | real-valued scalar

When setting the name-value pair `'Cut'` to `'Delay'` or `'Doppler'`, you can set `'CutValue'` to specify a cross-section that may not coincide with either zero time delay or zero Doppler shift. However, `'CutValue'` cannot be used when `'Cut'` is set to `'2D'`.

When `'Cut'` is set to `'Delay'` ,`'CutValue'` is the time delay at which the cut is taken. Time delay units are in seconds.

When `'Cut'` is set to `'Doppler'`, `'CutValue'` is the Doppler shift at which the cut is taken. Doppler units are in hertz.

Example: `'CutValue',10.0`

Data Types: `double`

## Output Arguments

### `afmag`

Normalized ambiguity or crossambiguity function magnitudes. `afmag` is an *M*-by-*N* matrix where *M* is the number of Doppler frequencies and *N* is the number of time delays.

**delay**

Time delay vector.

`delay` is an *N*-by-1 vector of time delays.

For the ambiguity function, if $N_x$ is the length of signal `x`, then the delay vector consist of $N = 2N_x - 1$ samples in the range, $-(N_x/2) - 1,...,(N_x/2) - 1)$.

For the crossambiguity function, let $N_y$ be the length of the second signal. The time delay vector consists of $N = N_x + N_y - 1$ equally spaced samples. For an even number of delays, the delay sample times are $-(N/2 - 1)/Fs,...,(N/2 - 1))/Fs$. For an odd number of delays, if $N_f = floor(N/2)$, the delay sample times are $-N_f/Fs,...,(N_f - 1)/Fs$.

**doppler**

Doppler frequency vector.

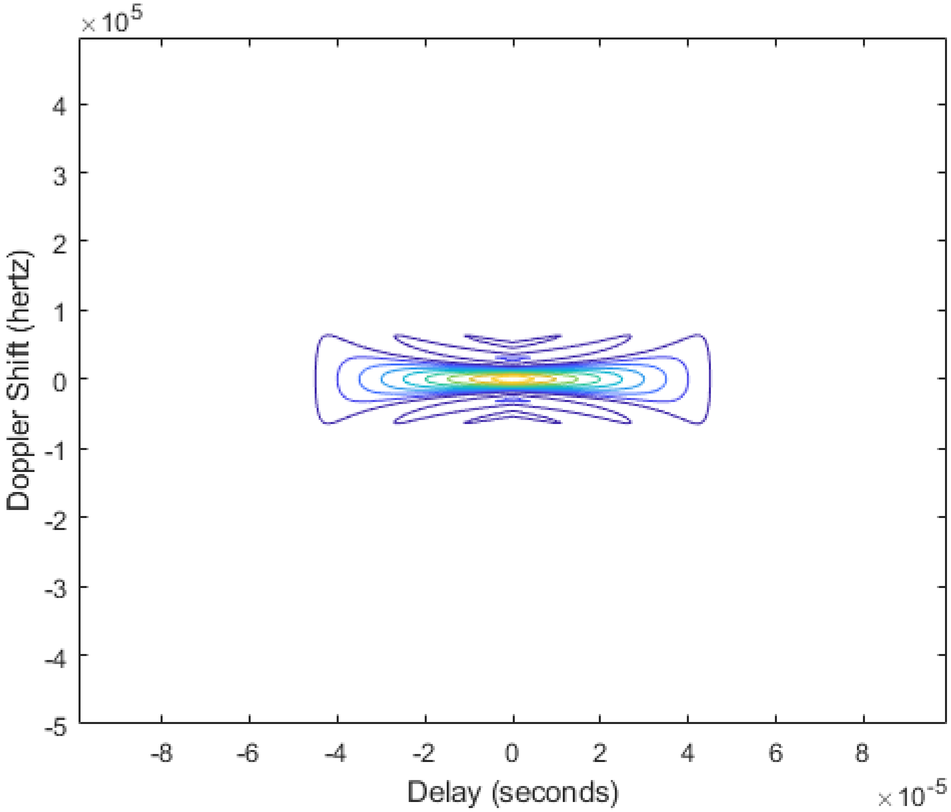
`doppler` is an *M*-by-1 vector of Doppler frequencies. The Doppler frequency vector consists of $M = 2^{ceil(log2\ N)}$ equally-spaced samples. Frequencies are $(-(M/2)F_s,...,(M/2-1)F_s)$.

# Examples

### Plot Ambiguity Function of Rectangular Pulse

Plot the ambiguity function magnitude of a rectangular pulse.

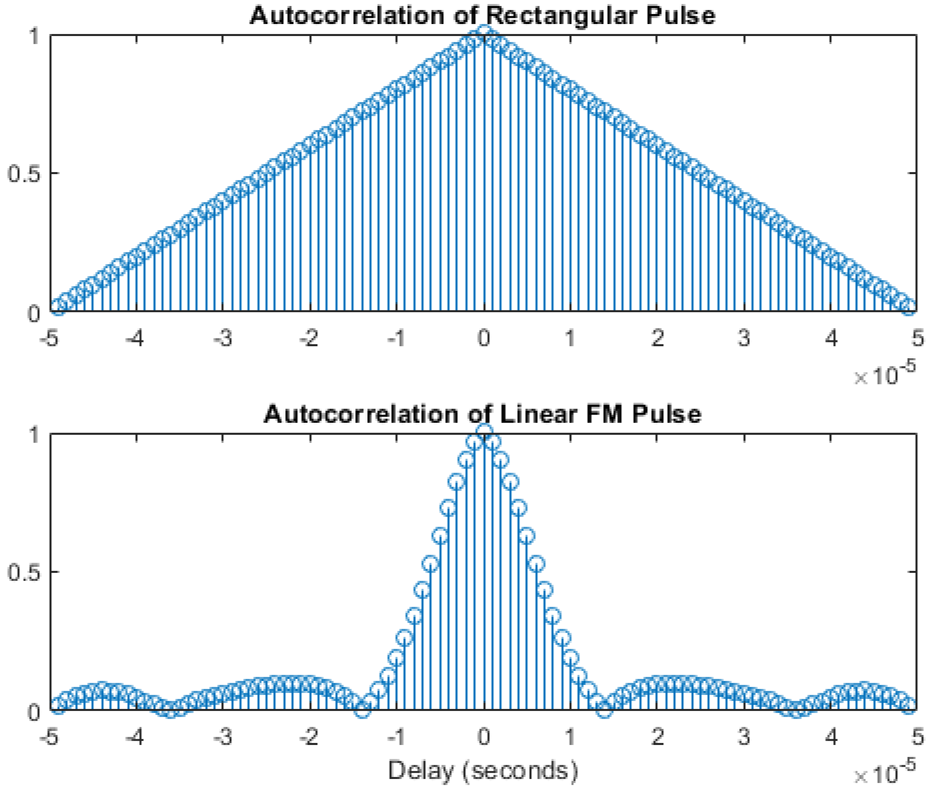
```
waveform = phased.RectangularWaveform;
x = waveform();
PRF = 2e4;
[afmag,delay,doppler] = ambgfun(x,waveform.SampleRate,PRF);
contour(delay,doppler,afmag)
xlabel('Delay (seconds)')
ylabel('Doppler Shift (hertz)')
```



### Plot Autocorrelation Sequences of Rectangular and Linear FM Pulses

This example shows how to plot zero-Doppler cuts of the autocorrelation sequences of rectangular and linear FM pulses of equal duration. Note the pulse compression exhibited in the autocorrelation sequence of the linear FM pulse.

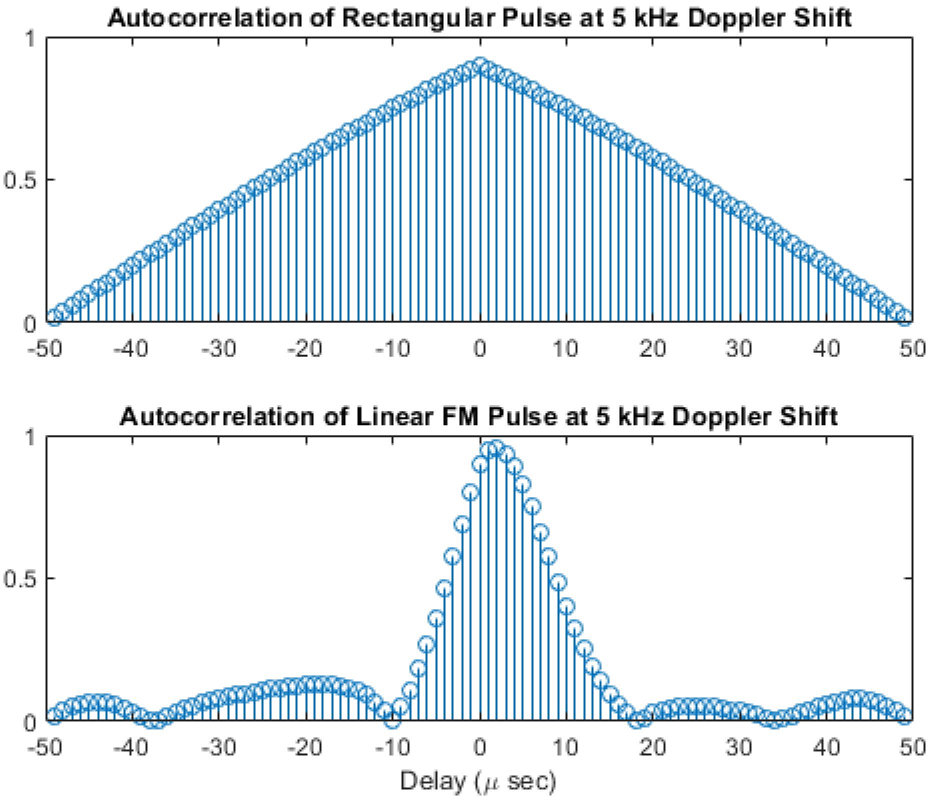
```
hrect = phased.RectangularWaveform('PRF',2e4);
hfm = phased.LinearFMWaveform('PRF',2e4);
xrect = step(hrect);
xfm = step(hfm);
[ambrect,delayrect] = ambgfun(xrect,hrect.SampleRate,...,
    hrect.PRF,'Cut','Doppler');
[ambfm,delayfm] = ambgfun(xfm,hfm.SampleRate,...,
    hfm.PRF,'Cut','Doppler');
figure;
subplot(211);
stem(delayrect,ambrect);
title('Autocorrelation of Rectangular Pulse');
subplot(212);
stem(delayfm,ambfm)
xlabel('Delay (seconds)');
title('Autocorrelation of Linear FM Pulse');
```



### Plot Nonzero-Doppler Cuts of Autocorrelation Sequences

Plot nonzero-Doppler cuts of the autocorrelation sequences of rectangular and linear FM pulses of equal duration. Both cuts are taken at a 5 kHz Doppler shift. Besides the reduction of the peak value, there is a strong shift in the position of the linear FM peak, evidence of range-doppler coupling.

```
hrect = phased.RectangularWaveform('PRF',2e4);
hfm = phased.LinearFMWaveform('PRF',2e4);
xrect = step(hrect);
xfm = step(hfm);
fd = 5000;
[ambrect,delayrect] = ambgfun(xrect,hrect.SampleRate,...,
    hrect.PRF,'Cut','Doppler','CutValue',fd);
[ambfm,delayfm] = ambgfun(xfm,hfm.SampleRate,...,
    hfm.PRF,'Cut','Doppler','CutValue',fd);
figure;
subplot(211);
stem(delayrect*10^6,ambrect);
title('Autocorrelation of Rectangular Pulse at 5 kHz Doppler Shift');
subplot(212);
stem(delayfm*10^6,ambfm)
xlabel('Delay (\mu sec)');
title('Autocorrelation of Linear FM Pulse at 5 kHz Doppler Shift');
```



### Plot Crossambiguity Function

Plot the crossambiguity function between an LFM pulse and a delayed replica. Compare the crossambiguity function with the original ambiguity function. Set the sampling rate to 100 Hz, the pulse width to 0.5 sec, and the pulse repetition frequency to 1 Hz. The delay or lag is 10 samples equal to 100 ms. The bandwidth of the LFM signal is 10 Hz.

```
fs = 100.0;
bw1 = 10.0;
prf = 1;
nsamp = fs/prf;
```

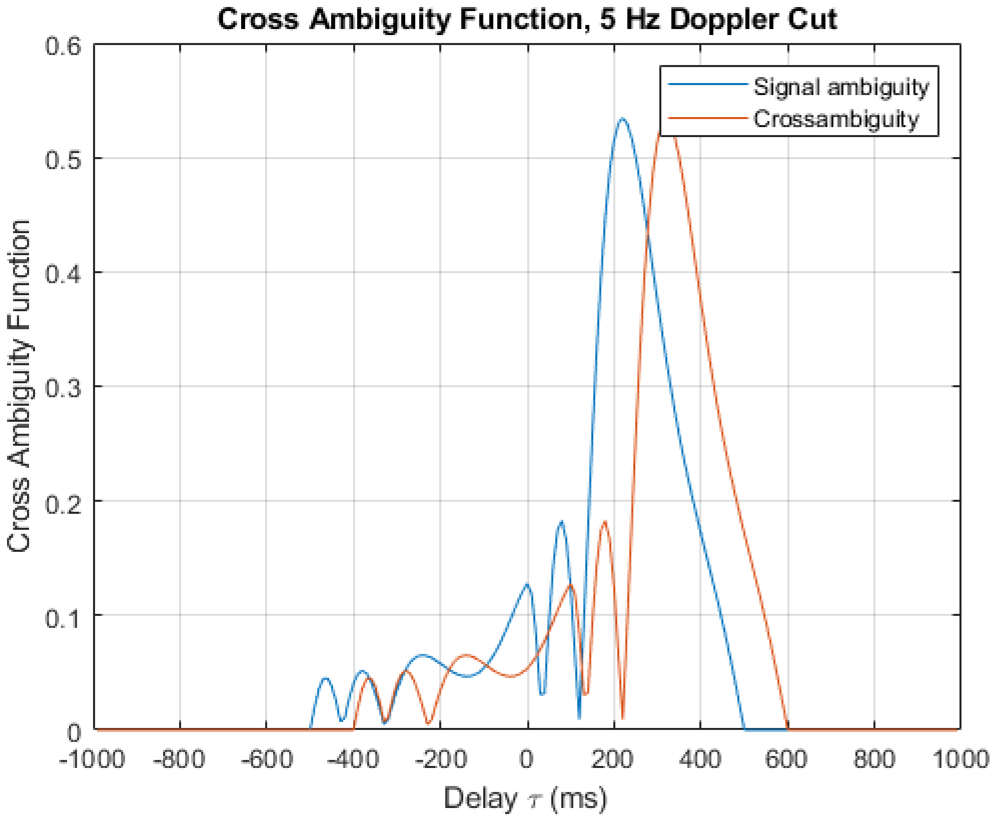
```
pw = 0.5;
nlag = 10;
```

Create the original waveform and its delayed replica.

```
waveform1 = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1,...
    'SweepBandwidth',bw1,'SweepDirection','Up','PulseWidth',pw,'PRF',prf);
wav1 = waveform1();
wav2 = [zeros(nlag,1);wav1(1:(end-nlag))];
```

Plot the ambiguity and crossambiguity functions.

```
ambgfun(wav1,fs,prf,'Cut','Doppler','CutVal',5)
hold on
ambgfun(wav1,wav2,fs,[prf,prf],'Cut','Doppler','CutVal',5)
legend('Signal ambiguity', 'Crossambiguity')
hold off
```



## More About

### Normalized Ambiguity Function

The normalized ambiguity function is

$$A(t, f_d) = \frac{1}{E_x}\left|\int_{\infty}^{\infty} x(u)e^{j2\pi f_d u}x^*(u-t)\,du\right|$$

$$E_x = \int_{\infty}^{\infty} x(u)x^*(u)\,du$$

where $E_x$ is the squared norm of the signal, *x(t)*, *t* is the time delay, and $f_d$ is the Doppler shift. The asterisk (*) denotes the complex conjugate. The ambiguity function describes the effects of time delays and Doppler shifts on the output of a matched filter.

The magnitude of the ambiguity function achieves maximum value at (0,0). At this point, there is perfect correspondence between the received waveform and the matched filter. The maximum value of the normalized ambiguity function is one.

The magnitude of the ambiguity function at zero time delay and Doppler shift, $|A(0,0)|$, is the matched filter output when the received waveform exhibits the time delay and Doppler shift for which the matched filter is designed. Nonzero values of the time delay and Doppler shift variables indicate that the received waveform exhibits mismatches in time delay and Doppler shift from the matched filter.

The crossambiguity function between two different signals is

$$A(t,f_d) = \frac{1}{\sqrt{E_x E_y}}\left|\int_{-\infty}^{\infty} x(u)e^{j2\pi f_d u}y^*(u-t)\,du\right|$$

$$E_x = \int_{-\infty}^{\infty} x(u)x^*(u)\,du$$

$$E_x = \int_{-\infty}^{\infty} y(u)y^*(u)\,du$$

The peak of the crossambiguity function is not necessarily unity.

# aperture2gain

Convert effective aperture to gain

## Syntax

```
G = aperture2gain(A,lambda)
```

## Description

`G = aperture2gain(A,lambda)` returns the antenna gain in decibels corresponding to an effective aperture of `A` square meters for an incident electromagnetic wave with wavelength `lambda` meters. `A` can be a scalar or vector. If `A` is a vector, `G` is a vector of the same size as `A`. The elements of `G` represent the gains for the corresponding elements of `A`. `lambda` must be a scalar.

## Input Arguments

### A

Antenna effective aperture in square meters. The effective aperture describes how much energy is captured from an incident electromagnetic plane wave. The argument describes the functional area of the antenna and is not equivalent to the actual physical area. For a fixed wavelength, the antenna gain is proportional to the effective aperture. `A` can be a scalar or vector. If `A` is a vector, each element of `A` is the effective aperture of a single antenna.

### lambda

Wavelength of the incident electromagnetic wave. The wavelength of an electromagnetic wave is the ratio of the wave propagation speed to the frequency. For a fixed effective aperture, the antenna gain is inversely proportional to the square of the wavelength. `lambda` must be a scalar.

# Output Arguments

**G**

Antenna gain in decibels. G is a scalar or a vector. If G is a vector, each element of G is the gain corresponding to effective aperture of the same element in A.

# Examples

### Compute Antenna Gain

An antenna has an effective aperture of 3 square meters. Find the antenna gain when used to capture an electromagnetic wave with a wavelength of 10 cm.

```
g = aperture2gain(3,0.1)
```

```
g = 35.7633
```

# More About

## Gain and Effective Aperture

The relationship between the gain, $G$, and effective aperture of an antenna, $A_e$ is:

$$G = \frac{4\pi}{\lambda^2} A_e$$

where λ is the wavelength of the incident electromagnetic wave. The gain expressed in decibels is:

$$10\log_{10}(G)$$

# az2broadside

Convert azimuth and elevation angle to broadside angle

## Syntax

```
bsang = az2broadside(az)
bsang = az2broadside(az,el)
```

## Description

`bsang = az2broadside(az)` returns the broadside angle on page 2-30, `bsang`, corresponding to the azimuth angle, `az`, and zero elevation angle. All angles are define with respect to the local coordinate system.

`bsang = az2broadside(az,el)` also specifies the elevation angle, `el`.

## Examples

### Convert Azimuth Angle to Broadside Angle

Return the broadside angle corresponding to 45° azimuth and 0° elevation.

```
bsang = az2broadside(45)
```

```
bsang = 45.0000
```

### Convert Azimuth and Elevation to Broadside Angle

Return the broadside angle corresponding to 45° azimuth and 45° elevation.

```
bsang = az2broadside(45,45)
```

```
bsang = 30.0000
```

### Convert Multiple Azimuth and Elevation Angles to Broadside Angles

Return broadside angles for 10 azimuth-elevation pairs.

```
az = (75:5:120)';
el = (45:5:90)';
bsang = az2broadside(az,el);
```

## Input Arguments

**az — Azimuth angle**
scalar | vector of real values

Azimuth angle, specified as a scalar or vector of real values. Azimuth angles lie in the range from –180° to 180°. Units are in degrees.

Example: `[35;20;-10]`

**el — Elevation angle**
`0` (default) | scalar | vector of real values

Elevation angle, specified as a scalar or vector. The elevation angle lie in the range from –90° to 90°. The length of `el` must equal the length of `az`. Units are in degrees.

Example: `[5;2;-1]`

## Output Arguments

**bsang — Broadside angle**
scalar | vector of real values

Broadside angle, returned as a scalar or vector. The length of `bsang` equals the length of `az`. Units are in degrees.

# More About

## Broadside Angle

Broadside angles are useful in describing the response pattern of a uniform linear array (ULA).

For the definition of the broadside angle and how to convert between azimuth and elevation, and broadside angle see “Broadside Angles”. For definitions of the azimuth and elevation angles, see “Azimuth and Elevation Angles”.

# azel2phitheta

Convert angles from azimuth/elevation form to phi/theta form

## Syntax

```
PhiTheta = azel2phitheta(AzEl)
```

## Description

`PhiTheta = azel2phitheta(AzEl)` converts the azimuth/elevation angle on page 2-32 pairs to their corresponding phi/theta angle on page 2-33 pairs.

## Examples

### Convert Azimuth-Elevation Pair

Find the corresponding φ/θ representation for 30° azimuth and 0° elevation.

```
PhiTheta = azel2phitheta([30; 0])
```

```
PhiTheta = 2×1

         0
   30.0000
```

## Input Arguments

### `AzEl` — Azimuth/elevation angle pairs

two-row matrix

Azimuth and elevation angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation].

Data Types: `double`

# Output Arguments

**`PhiTheta` — Phi/theta angle pairs**
two-row matrix

Phi and theta angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta]. The matrix dimensions of `PhiTheta` are the same as those of `AzEl`.

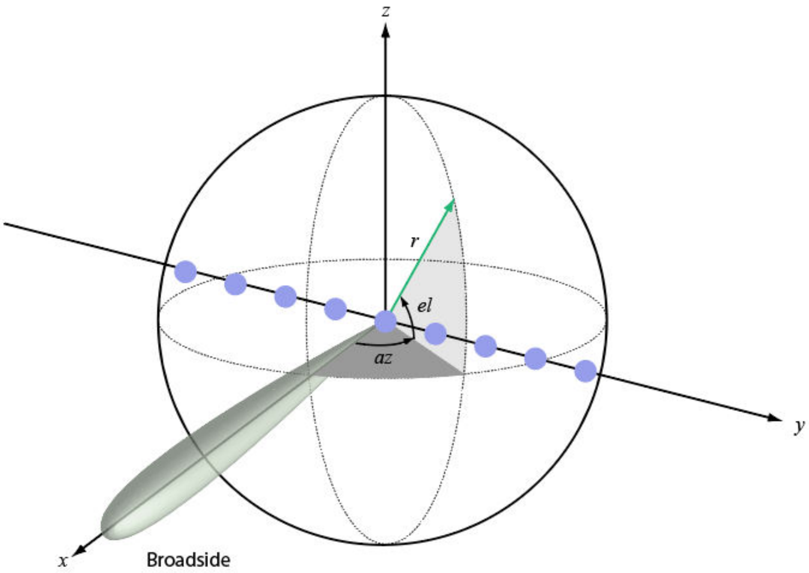
# More About

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

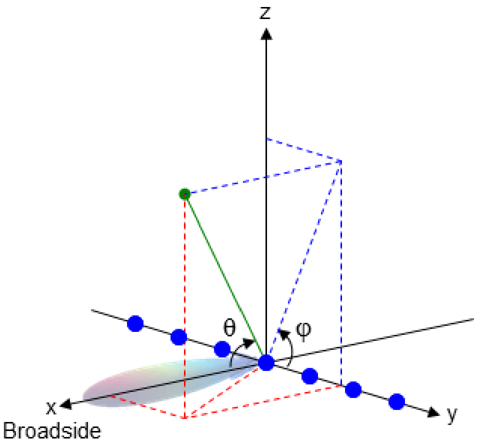
This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.



## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector’s orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

# azel2phithetapat

Convert radiation pattern from azimuth-elevation to phi-theta coordinates

## Syntax

```
pat_phitheta = azel2phithetapat(pat_azel,az,el)
pat_phitheta = azel2phithetapat(pat_azel,az,el,phi,theta)
[pat_phitheta,phi_pat,theta_pat] = azel2phithetapat( ___ )
```

## Description

`pat_phitheta = azel2phithetapat(pat_azel,az,el)` expresses the antenna radiation pattern `pat_azel` in φ/θ angle on page 2-42 coordinates instead of azimuth/elevation angle on page 2-41 coordinates. `pat_azel` samples the pattern at azimuth angles in `az` and elevation angles in `el`. The `pat_phitheta` matrix covers φ values from 0 to 180 degrees and θ values from 0 to 360 degrees. `pat_phitheta` is uniformly sampled with a step size of 1 for φ and θ. The function interpolates to estimate the response of the antenna at a given direction.

`pat_phitheta = azel2phithetapat(pat_azel,az,el,phi,theta)` uses vectors `phi` and `theta` to specify the grid at which to sample `pat_phitheta`. To avoid interpolation errors, `phi` should cover the range [0, 180], and `theta` should cover the range [0, 360].

`[pat_phitheta,phi_pat,theta_pat] = azel2phithetapat( ___ )`returns vectors containing the φ and θ angles at which `pat_phitheta` samples the pattern, using any of the input arguments in the previous syntaxes.

## Examples

### Convert Radiation Pattern to Phi-Theta

Convert a radiation pattern to φ/θ form, with the φ and θ angles spaced 1 degree apart.

Define the pattern in terms of azimuth and elevation.

```
az = -180:180;
el = -90:90;
pat_azel = mag2db(repmat(cosd(el)',1,numel(az)));
```

Convert the pattern to φ/θ space.

```
pat_phitheta = azel2phithetapat(pat_azel,az,el);
```

### Plot Converted Radiation Pattern

Plot the result of converting a radiation pattern to $\phi/\theta$ space with the $\phi$ and $\theta$ angles spaced 1 degree apart.

The radiation pattern is the cosine of the elevation.

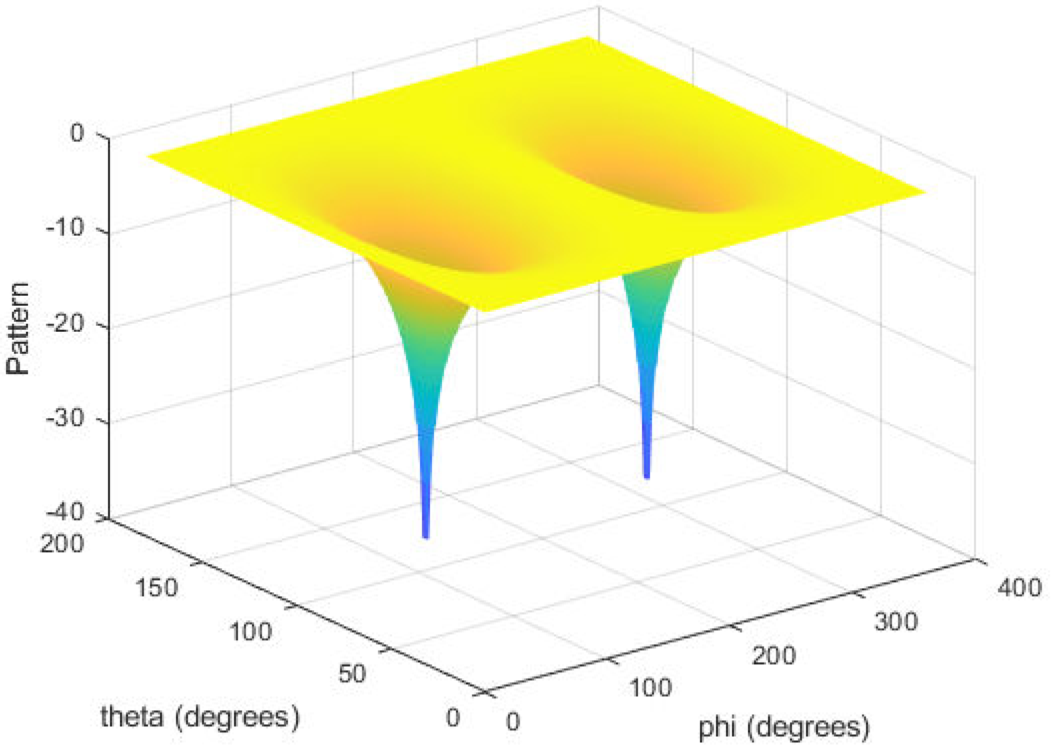
```
az = -180:180;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

Convert the pattern to $\phi/\theta$ space. Use the returned $\phi$ and $\theta$ angles for plotting.

```
[pat_phitheta,phi,theta] = azel2phithetapat(pat_azel,az,el);
```

Plot the result.

```
H = surf(phi,theta,mag2db(pat_phitheta));
H.LineStyle = 'none';
xlabel('phi (degrees)');
ylabel('theta (degrees)');
zlabel('Pattern');
```



### Convert Radiation Pattern For Specific Phi/Theta Values

Convert a radiation pattern to $\phi/\theta$ space with $\phi$ and $\theta$ angles spaced 5 degrees apart.

The radiation pattern is the cosine of the elevation.

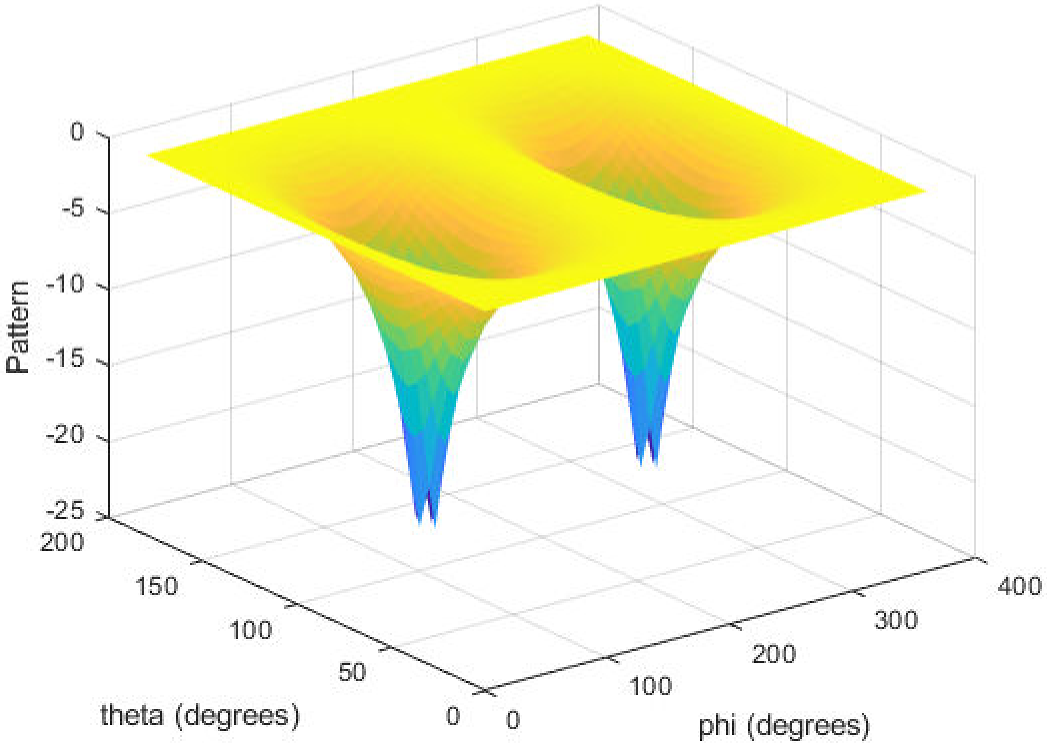
```
az = -180:180;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

Define the set of $\phi$ and $\theta$ angles at which to sample the pattern. Then, convert the pattern.

```
phi = 0:5:360;
theta = 0:5:180;
pat_phitheta = azel2phithetapat(pat_azel,az,el,phi,theta);
```

Plot the result.

```
H = surf(phi,theta,mag2db(pat_phitheta));
H.LineStyle = 'none';
xlabel('phi (degrees)');
ylabel('theta (degrees)');
zlabel('Pattern');
```



## Input Arguments

### pat_azel — Antenna radiation pattern in azimuth/elevation form

Q-by-P matrix

Antenna radiation pattern in azimuth/elevation form, specified as a Q-by-P matrix. pat_azel samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. P is the length of the az vector, and Q is the length of the el vector.

Data Types: double

### az — Azimuth angles

vector of length P

Azimuth angles at which pat_azel samples the pattern, specified as a vector of length P. Each azimuth angle is in degrees, between –180 and 180.

Data Types: double

### el — Elevation angles

vector of length Q

Elevation angles at which pat_azel samples the pattern, specified as a vector of length Q. Each elevation angle is in degrees, between –90 and 90.

Data Types: double

### phi — Phi angles

[0:360] (default) | vector of length L

Phi angles at which pat_phitheta samples the pattern, specified as a vector of length L. Each φ angle is in degrees, between 0 and 360.

Data Types: double

### theta — Theta angles

[0:180] (default) | vector of length M

Theta angles at which pat_phitheta samples the pattern, specified as a vector of length M. Each θ angle is in degrees, between 0 and 180.

Data Types: double

## Output Arguments

**pat_phitheta — Antenna radiation pattern in phi/theta form**
M-by-L matrix

Antenna radiation pattern in phi/theta form, returned as an M-by-L matrix. pat_phitheta samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. L is the length of the phi_pat vector, and M is the length of the theta vector.

**phi_pat — Phi angles**
vector of length L

Phi angles at which pat_phitheta samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

**theta_pat — Theta angles**
vector of length M

Theta angles at which pat_phitheta samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

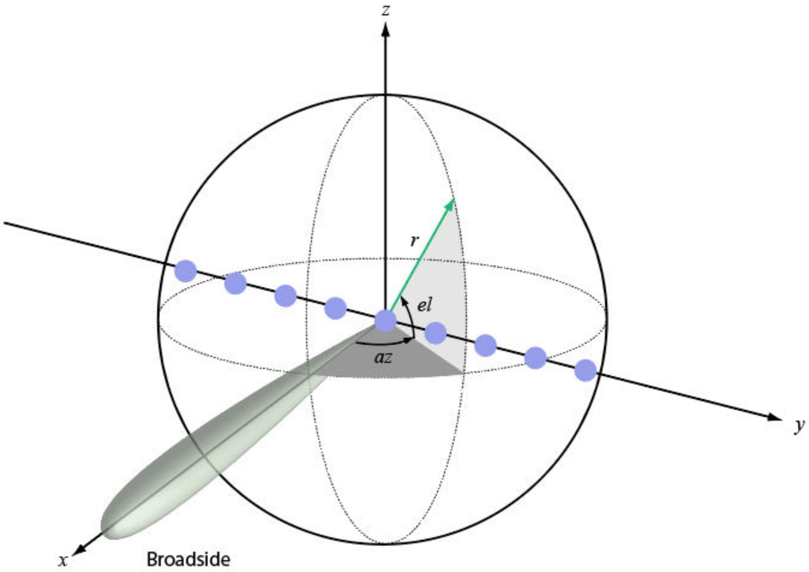
## More About

### Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

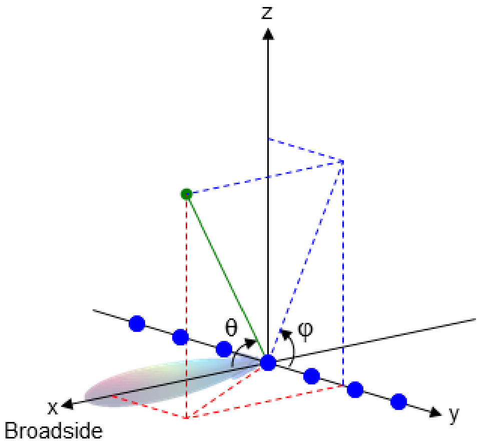
This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.



## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector’s orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

Convert azimuth/elevation angles to u/v coordinates

## Syntax

```
UV = azel2uv(AzEl)
```

## Description

`UV = azel2uv(AzEl)` converts the azimuth/elevation angle on page 2-46 pairs to their corresponding coordinates in *u*/*v* space on page 2-47.

## Examples

### Conversion of Azimuth and Elevation to UV

Find the corresponding *uv* representation for 30° azimuth and 0° elevation.

```
uv = azel2uv([30;0])
```

```
uv = 2×1

    0.5000
         0
```

## Input Arguments

### `AzEl` — Azimuth/elevation angle pairs

two-row matrix

Azimuth and elevation angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation].

Data Types: `double`

## Output Arguments

**UV — Angle in u/v space**
two-row matrix

Angle in *u*/*v* space, returned as a two-row matrix. Each column of the matrix represents an angle in the form [*u*; *v*]. The matrix dimensions of `UV` are the same as those of `AzEl`.

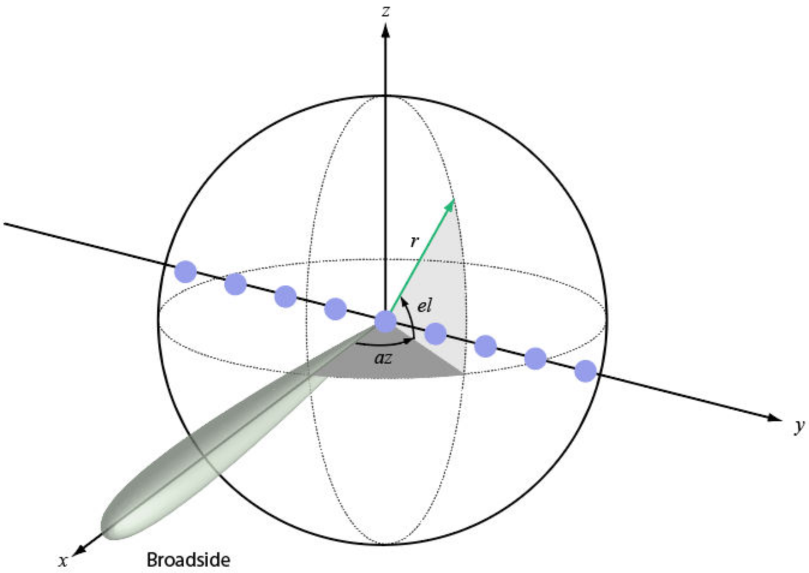
## More About

### Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.



## U/V Space

The *u*/*v* coordinates for the positive hemisphere *x* ≥ 0 can be derived from the phi and theta angles on page 2-48.

The relation between these two coordinates systems is

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \le u \le 1$$

$$-1 \le v \le 1$$

$$u^2 + v^2 \le 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$

$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of *u* and *v*

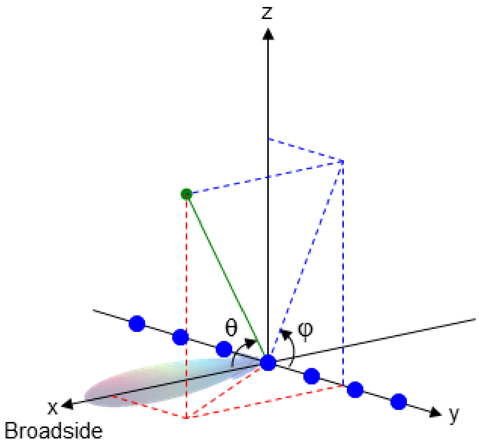
$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el})/\sin(\text{az})$$

# Extended Capabilities

`uv2azel`

## Topics

"Spherical Coordinates"

**Introduced in R2012a**

# azel2uvpat

Convert radiation pattern from azimuth/elevation form to u/v form

## Syntax

```
pat_uv = azel2uvpat(pat_azel,az,el)
pat_uv = azel2uvpat(pat_azel,az,el,u,v)
[pat_uv,u_pat,v_pat] = azel2uvpat( ___ )
```

## Description

`pat_uv = azel2uvpat(pat_azel,az,el)` expresses the antenna radiation pattern `pat_azel` in u/v space on page 2-57 coordinates instead of azimuth/elevation angle on page 2-56 coordinates. `pat_azel` samples the pattern at azimuth angles in `az` and elevation angles in `el`. The `pat_uv` matrix uses a default grid that covers *u* values from –1 to 1 and *v* values from –1 to 1. In this grid, `pat_uv` is uniformly sampled with a step size of 0.01 for *u* and *v*. The function interpolates to estimate the response of the antenna at a given direction. Values in `pat_uv` are NaN for *u* and *v* values outside the unit circle because *u* and *v* are undefined outside the unit circle.

`pat_uv = azel2uvpat(pat_azel,az,el,u,v)` uses vectors `u` and `v` to specify the grid at which to sample `pat_uv`. To avoid interpolation errors, `u` should cover the range [–1, 1] and `v` should cover the range [–1, 1].

`[pat_uv,u_pat,v_pat] = azel2uvpat( ___ )` returns vectors containing the *u* and *v* coordinates at which `pat_uv` samples the pattern, using any of the input arguments in the previous syntaxes.

## Examples

### Convert Radiation Pattern to UV Space

Convert a radiation pattern to *u*-*v* space, with the *u* and *v* coordinates spaced by 0.01.

Define the pattern in terms of azimuth and elevation.

```
az = -90:90;
el = -90:90;
pat_azel = mag2db(repmat(cosd(el)',1,numel(az)));
```

Convert the pattern to *u*-*v* space.

```
pat_uv = azel2uvpat(pat_azel,az,el);
```

### Plot Converted Radiation Pattern

Plot the result of converting a radiation pattern to *u*/*v* space with the *u* and *v* coordinates spaced by 0.01.

The radiation pattern is the cosine of the elevation angle.

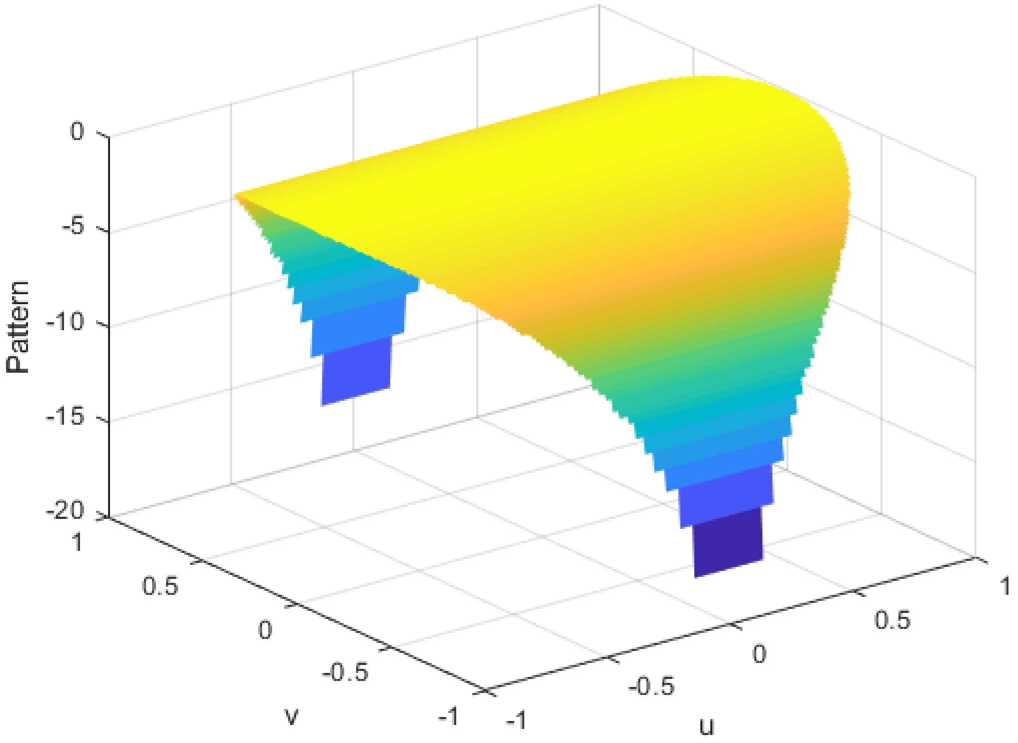
```
az = -90:90;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

Convert the pattern to *u*/*v* space. Use the *u* and *v* coordinates for plotting.

```
[pat_uv,u,v] = azel2uvpat(pat_azel,az,el);
```

Plot the result.

```
H = surf(u,v,mag2db(pat_uv));
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



### Convert Radiation Pattern For Specific U/V Values

Convert a radiation pattern to *u*/*v* form, with the *u* and *v* coordinates spaced by 0.05.

The radiation pattern is cosine of the elevation angle.

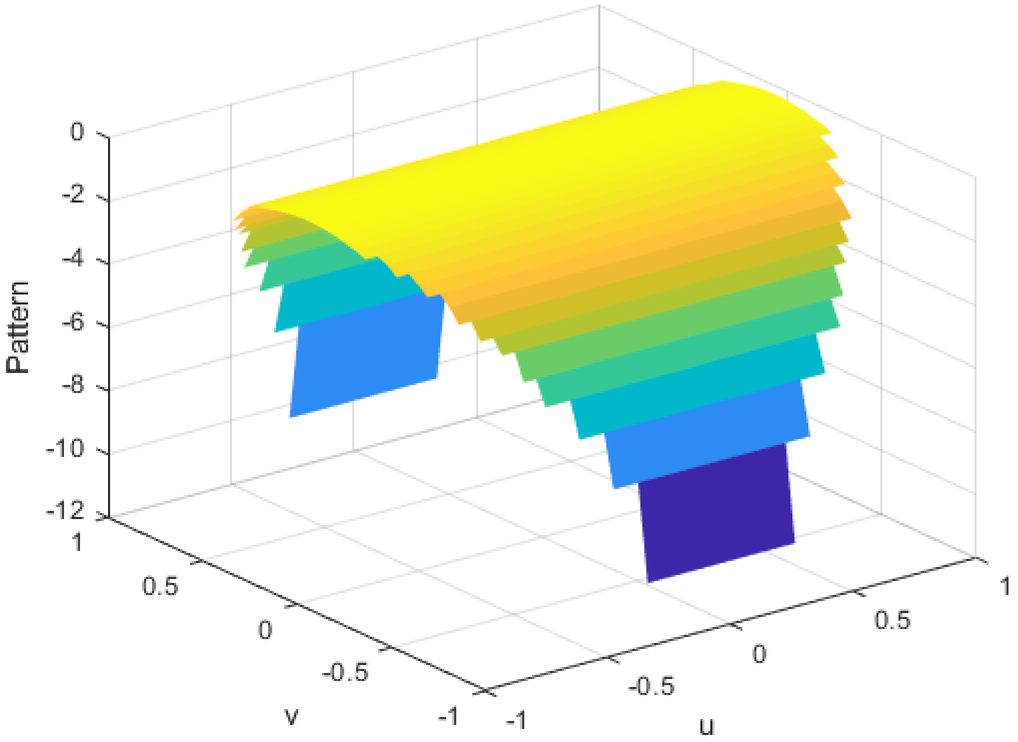
```
az = -90:90;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

Define the set of *u* and *v* coordinates at which to sample the pattern. Then, convert the pattern.

```
u = -1:0.05:1;
v = -1:0.05:1;
pat_uv = azel2uvpat(pat_azel,az,el,u,v);
```

Plot the result.

```
H = surf(u,v,mag2db(pat_uv));
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



## Input Arguments

### `pat_azel` — Antenna radiation pattern in azimuth/elevation form

Q-by-P matrix

Antenna radiation pattern in azimuth/elevation form, specified as a Q-by-P matrix. `pat_azel` samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. P is the length of the `az` vector, and Q is the length of the `el` vector.

Data Types: `double`

### `az` — Azimuth angles

vector of length P

Azimuth angles at which `pat_azel` samples the pattern, specified as a vector of length P. Each azimuth angle is in degrees, between –90 and 90. Such azimuth angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

### `el` — Elevation angles

vector of length Q

Elevation angles at which `pat_azel` samples the pattern, specified as a vector of length Q. Each elevation angle is in degrees, between –90 and 90.

Data Types: `double`

### u — *u* coordinates

`[-1:0.01:1]` (default) | vector of length L

*u* coordinates at which `pat_uv` samples the pattern, specified as a vector of length L. Each *u* coordinate is between –1 and 1.

Data Types: `double`

### v — *v* coordinates

`[-1:0.01:1]` (default) | vector of length M

*v* coordinates at which `pat_uv` samples the pattern, specified as a vector of length M. Each *v* coordinate is between –1 and 1.

Data Types: `double`

# Output Arguments

**pat_uv — Antenna radiation pattern in *u*/*v* form**
M-by-L matrix

Antenna radiation pattern in *u*/*v* form, returned as an M-by-L matrix. `pat_uv` samples the 3-D magnitude pattern in decibels, in terms of *u* and *v* coordinates. L is the length of the `u` vector, and M is the length of the `v` vector. Values in `pat_uv` are NaN for *u* and *v* values outside the unit circle because *u* and *v* are undefined outside the unit circle.

**u_pat — *u* coordinates**
vector of length L

*u* coordinates at which `pat_uv` samples the pattern, returned as a vector of length L.

**v_pat — *v* coordinates**
vector of length M

*v* coordinates at which `pat_uv` samples the pattern, returned as a vector of length M.

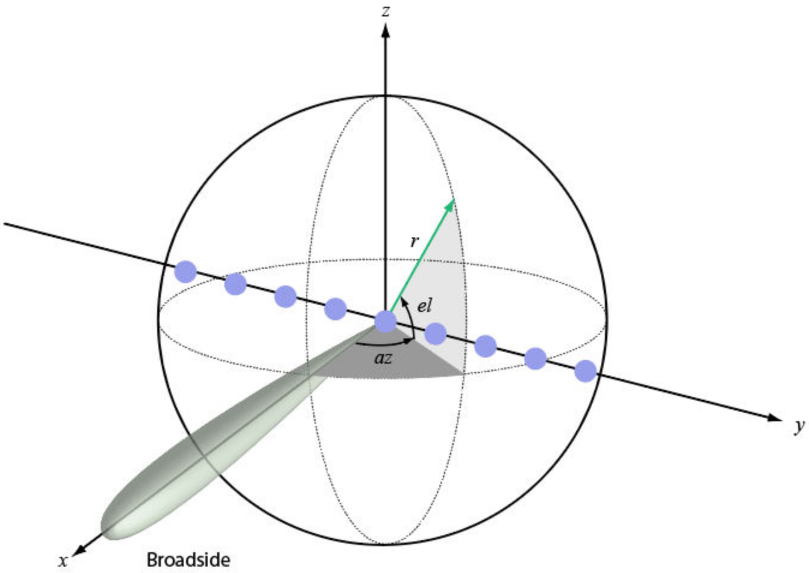
# More About

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.



## U/V Space

The *u* and *v* coordinates are the direction cosines of a vector with respect to the *y*-axis and *z*-axis, respectively.

The *u*/*v* coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles on page 2-58 by:

$$u = \sin\theta\cos\phi$$

$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$

$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \le u \le 1$$

$$-1 \le v \le 1$$

$$u^2 + v^2 \le 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$

$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of *u* and *v*

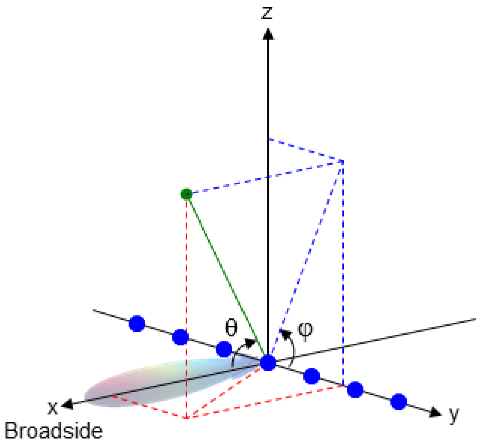
$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

# azelcut2pat

Create 3-D response pattern from azimuth and elevation cuts

## Syntax

```
pat = azelcut2pat(azcut,elcut)
```

## Description

`pat = azelcut2pat(azcut,elcut)` creates a 3-D element response pattern, `pat`, from an azimuth cut, `azcut`, and an elevation cut, `elcut`. An azimuth cut consists of an antenna pattern over all azimuth angles at 0° elevation. An elevation cut consists of the antenna pattern over all elevation angles at 0° azimuth. You can specify cuts for different frequencies at the same time.

## Examples

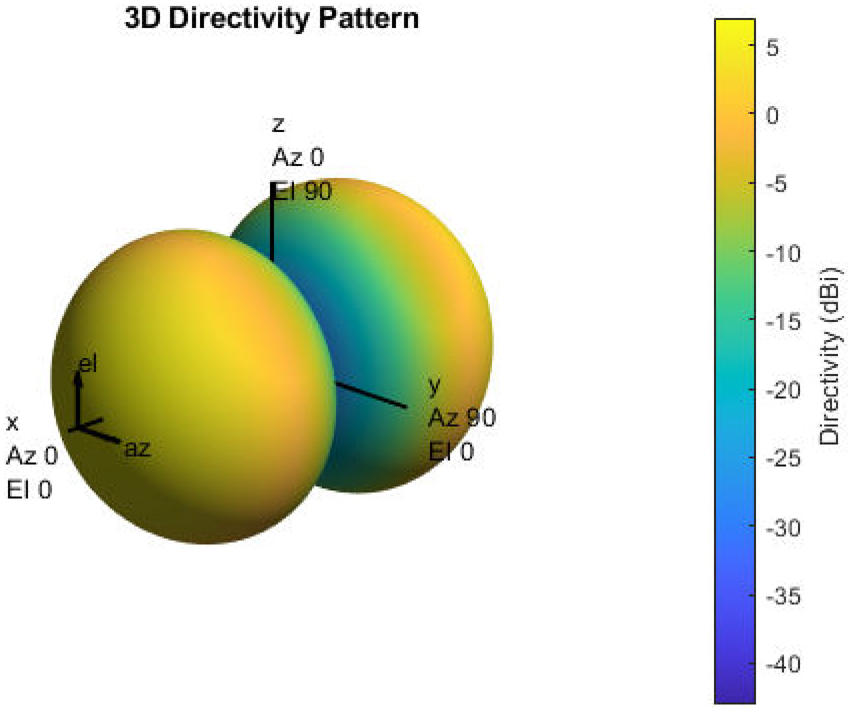
### Create Custom Antenna Pattern from Azimuth and Elevations Cuts

Create a custom antenna pattern from azimuth and elevation cuts of a cosine-squared pattern.

```
az = -180:180;
azcut = mag2db(cosd(az).^2);
el = -90:90;
elcut = mag2db(cosd(el).^2);
pat = azelcut2pat(azcut,elcut);
antenna = phased.CustomAntennaElement('AzimuthAngles',az,...
    'ElevationAngles',el,'MagnitudePattern',pat,...
    'PhasePattern',zeros(size(pat)));
```

Display the antenna pattern for 200 MHz.

```
fs = 200.0e6;
pattern(antenna,fs);
```



## Input Arguments

### `azcut` — Azimuth pattern cut

`zeros(1,361)` (default) | real-valued 1-by-$Q$ vector | real-valued $L$-by-$Q$ matrix

Azimuth pattern cut, specified as a real-valued 1-by-$Q$ vector or a real-valued $L$-by-$Q$ matrix. $Q$ is the number of azimuth angles, and $L$ is the number of frequencies. Azimuth cuts are assumed to be made at 0° elevation. When `azcut` is a matrix, each column represents a different azimuth angle, and each row represents a different frequency. Units are in dB.

Data Types: `double`

**`elcut` — Elevation pattern cut**
`zeros(1,181)` (default) | real-valued 1-by-*P* vector | real-valued *L*-by-*P* matrix

Elevation pattern cut, specified as a real-valued 1-by-*P* vector or a real-valued *L*-by-*P* matrix. *P* is the number of elevation angles, and *L* is the number of frequencies. Elevation cuts are assumed to be made at 0° azimuth. When `elcut` is a matrix, each column represents a different elevation angle, and each row represents a different frequency. Units are in dB.

Data Types: `double`

## Output Arguments

**`pat` — 3-D antenna pattern**
real-valued *P*-by-*Q* matrix | real-valued *P*-by-*Q*-by-*L* array

3-D array or antenna pattern, returned as a real-valued *P*-by-*Q* matrix or real-valued *P*-by-*Q*-by-*L* MATLAB array. Units are in dB.

## Algorithms

The function returns a 3-D antenna pattern at the same azimuth and elevation angles used to define the `azcut` and `elcut` cuts. Because the cuts are specified in dB, the 3-D pattern is computed from the sum of the cut patterns.

pat(az,el) = pat(az) + pat(el)

# Extended Capabilities

## C/C++ Code Generation

**Introduced in R2019a**

# azelaxes

Spherical basis vectors in 3-by-3 matrix form

## Syntax

```
A = azelaxes(az,el)
```

## Description

`A = azelaxes(az,el)` returns a 3-by-3 matrix containing the components of the basis ($\hat{\mathbf{e}}_R$, $\hat{\mathbf{e}}_{az}$, $\hat{\mathbf{e}}_{el}$) at each point on the unit sphere specified by azimuth, `az`, and elevation, `el`. The columns of `A` contain the components of basis vectors in the order of radial, azimuthal and elevation directions.

## Examples

### Compute Spherical Basis Vectors

At the point located at 45° azimuth, 45° elevation, compute the 3-by-3 matrix containing the components of the spherical basis.

```
A = azelaxes(45,45)
```

```
A = 3×3

    0.5000   -0.7071   -0.5000
    0.5000    0.7071   -0.5000
    0.7071         0    0.7071
```

The first column of `A` contains the radial basis vector `[0.5000; 0.5000; 0.7071]`. The second and third columns are the azimuth and elevation basis vectors, respectively.

## Input Arguments

### az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

### el — Elevation angle

scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

## Output Arguments

### A — Spherical basis vectors

3-by-3 matrix

Spherical basis vectors returned as a 3-by-3 matrix. The columns contain the unit vectors in the radial, azimuthal, and elevation directions, respectively. Symbolically we can write the matrix as

$$(\widehat{\mathbf{e}}_R, \widehat{\mathbf{e}}_{az}, \widehat{\mathbf{e}}_{el})$$

where each component represents a column vector.

# More About

## Spherical basis

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

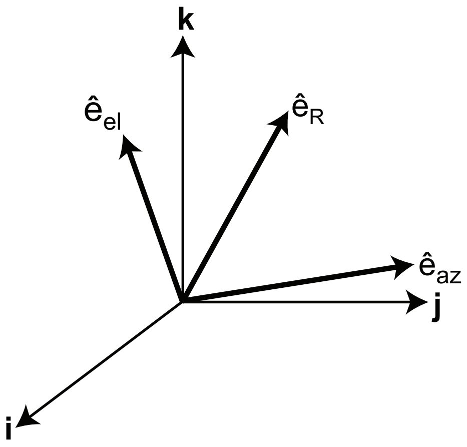
The spherical basis vectors ($\widehat{\mathbf{e}}_R, \widehat{\mathbf{e}}_{az}, \widehat{\mathbf{e}}_{el}$) at the point *(az,el)* can be expressed in terms of the Cartesian unit vectors by

$$\begin{aligned} \widehat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\widehat{\mathbf{i}} + \cos(el)\sin(az)\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}} \\ \widehat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\widehat{\mathbf{i}} + \cos(az)\widehat{\mathbf{j}} \\ \widehat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\widehat{\mathbf{i}} - \sin(el)\sin(az)\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}} \end{aligned}.$$

This set of basis vectors can be derived from the local Cartesian basis by two consecutive rotations: first by rotating the Cartesian vectors around the *y*-axis by the negative elevation angle, *-el*, followed by a rotation around the *z*-axis by the azimuth angle, *az*. Symbolically, we can write

$$\begin{aligned} \widehat{\mathbf{e}}_{\mathbf{R}} &= R_z(az)R_y(-el)\begin{bmatrix}1\\0\\0\end{bmatrix} \\ \widehat{\mathbf{e}}_{\mathbf{az}} &= R_z(az)R_y(-el)\begin{bmatrix}0\\1\\0\end{bmatrix} \\ \widehat{\mathbf{e}}_{\mathbf{el}} &= R_z(az)R_y(-el)\begin{bmatrix}0\\0\\1\end{bmatrix} \end{aligned}$$

The following figure shows the relationship between the spherical basis and the local Cartesian unit vectors.



## Algorithms

MATLAB computes the matrix A from the equations

```
A = [cosd(el)*cosd(az), -sind(az), -sind(el)*cosd(az); ...
        cosd(el)*sind(az),  cosd(az), -sind(el)*sind(az); ...
        sind(el),           0,         cosd(el)];
```

# beat2range

Convert beat frequency to range

## Syntax

```
r = beat2range(fb,slope)
r = beat2range(fb,slope,c)
```

## Description

`r = beat2range(fb,slope)` converts the beat frequency on page 2-72 of a dechirped linear FMCW signal to its corresponding range. `slope` is the slope of the FMCW sweep.

`r = beat2range(fb,slope,c)` specifies the signal propagation speed.

## Examples

### Range of Target in FMCW Radar System

Assume that an FMCW waveform sweeps a band of 3 MHz in 2 ms. The dechirped target return has a beat frequency of 1 kHz. Compute the target range.

```
slope = 30e6/(2e-3);
fb = 1e3;
r = beat2range(fb,slope)
```

```
r = 9.9931
```

## Input Arguments

**`fb` — Beat frequency of dechirped signal**
M-by-1 vector | M-by-2 matrix

Beat frequency of dechirped signal, specified as an M-by-1 vector or M-by-2 matrix in hertz. If the FMCW signal performs an upsweep or downsweep, `fb` is a vector of beat frequencies.

If the FMCW signal has a triangular sweep, `fb` is an M-by-2 matrix in which each row represents a pair of beat frequencies. Each row has the form `[UpSweepBeatFrequency,DownSweepBeatFrequency]`.

Data Types: `single` | `double`

### `slope` — Sweep slope

nonzero scalar

Slope of FMCW sweep, specified as a nonzero scalar in hertz per second. If the FMCW signal has a triangular sweep, `slope` is the sweep slope of the up-sweep half. In this case, `slope` must be positive and the down-sweep half is assumed to have a slope of `-slope`.

Data Types: `single` | `double`

### `c` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `single` | `double`

## Output Arguments

### `r` — Range

M-by-1 column vector

Range, returned as an M-by-1 column vector in meters. Each row of `r` is the range corresponding to the beat frequency in a row of `fb`.

Data Types: `single` | `double`

# More About

## Beat Frequency

For an up-sweep or down-sweep FMCW signal, the beat frequency is $F_t - F_r$. In this expression, $F_t$ is the transmitted signal's carrier frequency, and $F_r$ is the received signal's carrier frequency.

For an FMCW signal with triangular sweep, the upsweep and downsweep have separate beat frequencies.

# Algorithms

If `fb` is a vector, the function computes `c*fb/(2*slope)`.

If `fb` is an M-by-2 matrix with a row `[UpSweepBeatFrequency,DownSweepBeatFrequency]`, the corresponding row in `r` is `c*((UpSweepBeatFrequency - DownSweepBeatFrequency)/2)/(2*slope)`.

This function supports single and double precision for input data and arguments.

# billingsleyicm

Billingsley’s intrinsic clutter motion (ICM) model

## Syntax

```
P = billingsleyicm(fd,fc,wspeed)
P = billingsleyicm(fd,fc,wspeed,c)
```

## Description

`P = billingsleyicm(fd,fc,wspeed)` calculates the clutter Doppler spectrum shape, `P`, due to intrinsic clutter motion (ICM) at Doppler frequencies specified in `fd`. ICM arises when wind blows on vegetation or other clutter sources. This function uses Billingsley’s model in the calculation. `fc` is the operating frequency of the system. `wspeed` is the wind speed.

`P = billingsleyicm(fd,fc,wspeed,c)` specifies the propagation speed `c` in meters per second.

## Input Arguments

### fd

Doppler frequencies in hertz. This value can be a scalar or a vector.

### fc

Operating frequency of the system in hertz

### wspeed

Wind speed in meters per second

### c

Propagation speed in meters per second

**Default:** Speed of light

## Output Arguments

### P

Shape of the clutter Doppler spectrum due to intrinsic clutter motion. The vector size of P is the same as that of fd.

## Examples

### Compute Billingsley Doppler Spectrum

Calculate and plot the Doppler spectrum shape predicted by the Billingsley ICM model. Assume the PRF is 2 kHz, the operating frequency is 1 GHz, and the wind speed is 5 m/s.

```
v = -3:0.1:3;
fc = 1e9;
wspeed = 5;
c = physconst('LightSpeed');
fd = 2*v/(c/fc);
p = billingsleyicm(fd,fc,wspeed);
plot(fd,pow2db(p))
xlabel('Doppler frequency (Hz)')
ylabel('P (dB)')
```

# blakechart

Range-angle-height (Blake) chart

## Syntax

```
blakechart(vcp,vcpangles)
blakechart(vcp,vcpangles,rmax,hmax)
blakechart(___,'Name','Value')
```

## Description

`blakechart(vcp,vcpangles)` creates a range-angle-height plot (also called a Blake chart) for a narrowband radar antenna. This chart shows the maximum radar range as a function of target elevation. In addition, the Blake chart displays lines of constant range and lines of constant height. The input consist of the vertical coverage pattern, `vcp`, and vertical coverage pattern angles, `vcpangles`, produced by `radarvcd`.

`blakechart(vcp,vcpangles,rmax,hmax)`, in addition, specifies the maximum range and height of the Blake chart. You can specify range and height units separately in the Name-Value pairs, `RangeUnit` and `HeightUnit`. This syntax can use any of the input arguments in the previous syntax.

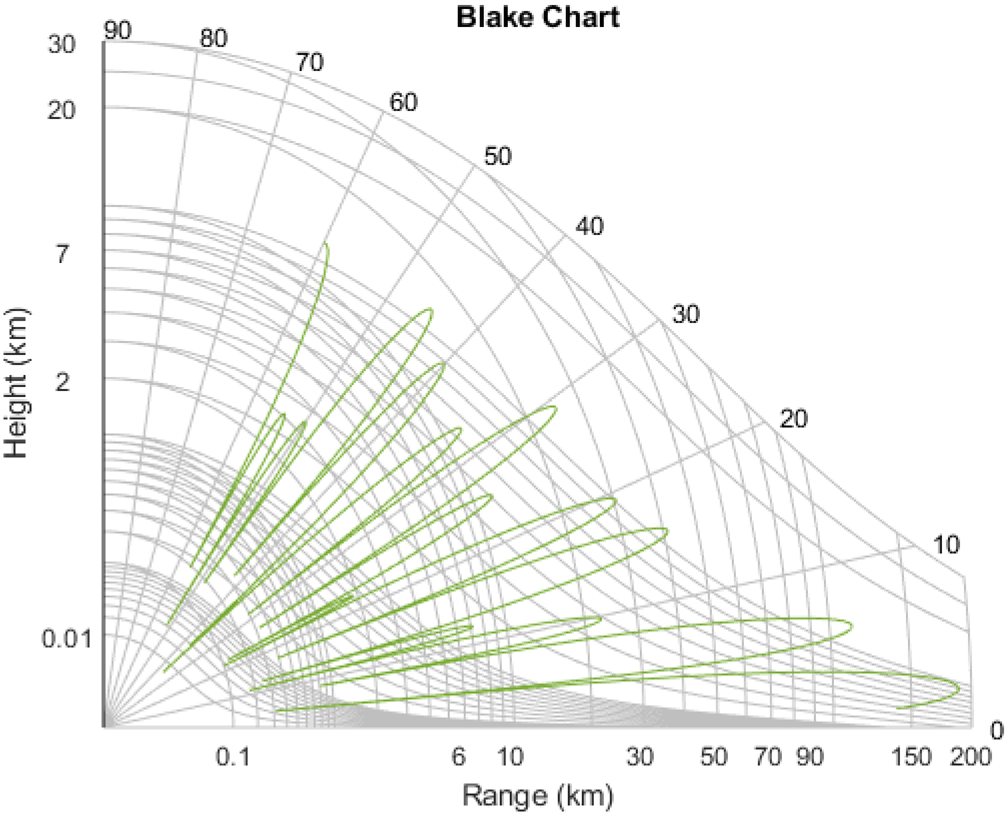
`blakechart(___,'Name','Value')` allows you to specify additional input parameters in the form of Name-Value pairs. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). This syntax can use any of the input arguments in the previous syntaxes.

## Examples

### Display Vertical Coverage Diagram

Display the vertical coverage diagram of an antenna transmitting at 100 MHz and placed 20 meters above the ground. Set the free-space range to 100 km. Use default plotting parameters.

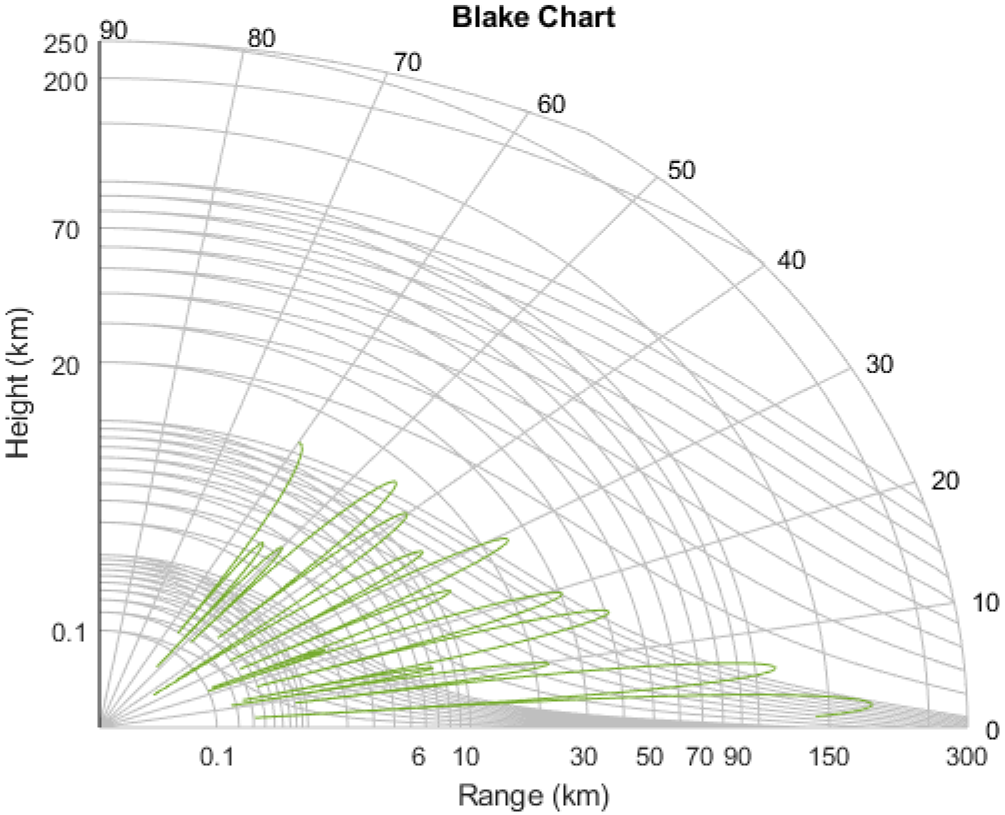
```
freq = 100e6;
ant_height = 20;
rng_fs = 100;
[vcp, vcpangles] = radarvcd(freq,rng_fs,ant_height);
blakechart(vcp, vcpangles);
```



### Display Vertical Coverage Diagram Specifying Maximum Range and Height

Display the vertical coverage diagram of an antenna transmitting at 100 MHz and placed 20 meters above the ground. Set the free-space range to 100 km. Set the maximum plotting range to 300 km and the maximum plotting height to 250 km.

```
freq = 100e6;
ant_height = 20;
rng_fs = 100;
[vcp, vcpangles] = radarvcd(freq,rng_fs,ant_height);
rmax = 300;
hmax = 250;
blakechart(vcp,vcpangles,rmax,hmax);
```



### Display Vertical Coverage Diagram of Sinc Pattern Antenna

Plot the range-height-angle curve of a radar having a sinc-function antenna pattern.

### Specify antenna pattern

Specify the antenna pattern as a sinc function.

```
pat_angles = linspace(-90,90,361)';
pat_u = 1.39157/sind(90/2)*sind(pat_angles);
pat = sinc(pat_u/pi);
```

### Specify radar and environment parameters

Set the transmitting frequency to 100 MHz, the free-space range to 100 km, the antenna tilt angle to 0 degrees, and place the antenna 20 meters above the ground. Assume a surface roughness of one meter.

```
freq = 100e6;
ant_height = 10;
rng_fs = 100;
tilt_ang = 0;
surf_roughness = 1;
```

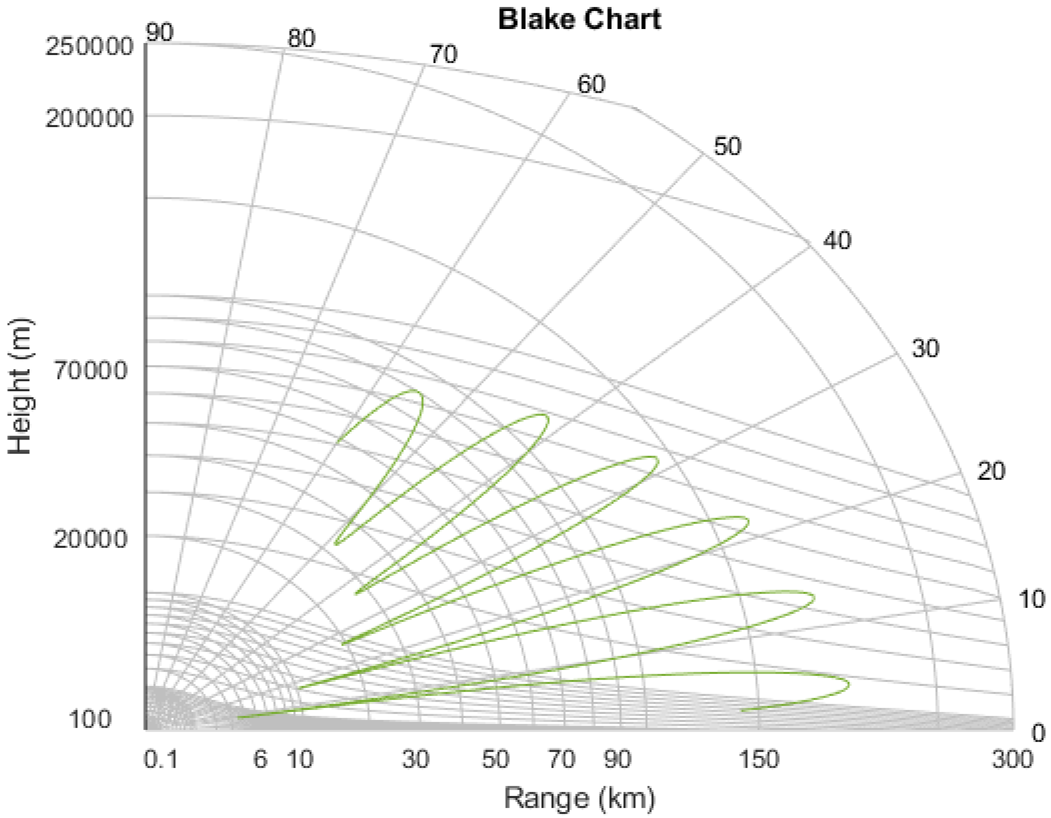
### Create radar range-height-angle data

```
[vcp, vcpangles] = radarvcd(freq,rng_fs,ant_height,...
    'RangeUnit','km','HeightUnit','m',...
    'AntennaPattern',pat,...
    'PatternAngles',pat_angles,'TiltAngle',tilt_ang,...
    'SurfaceRoughness',surf_roughness);
```

### Plot radar range-height-angle data

Set the maximum plotting range to 300 km and the maximum plotting height to 250,000 m. Choose the range units as kilometers, `'km'`, and the height units as meters, `'m'`. Set the range and height axes scale powers to 1/2.

```
rmax = 300;
hmax = 250e3;
blakechart(vcp, vcpangles, rmax, hmax, 'RangeUnit','km',...
    'ScalePower',1/2,'HeightUnit','m');
```



## Input Arguments

### vcp — Vertical coverage pattern

real-valued vector

Vertical coverage pattern specified as a *K*-by-1 column vector. The vertical coverage pattern is the actual maximum range of the radar. Each entry of the vertical coverage pattern corresponds to one of the angles specified in `vcpangles`. Values are expressed in kilometers unless you change the unit of measure using the `'RangeUnit'` Name-Value pair.

Example: [282.3831; 291.0502; 299.4252]

Data Types: `double`

### `vcpangles` — Vertical coverage pattern angles

real-valued vector

Vertical coverage pattern angles specified as a *K*-by-1 column vector. The set of angles range from –90° to 90°.

Example: [2.1480; 2.2340; 2.3199]

Data Types: `double`

### `rmax` — Maximum range of plot

real-valued scalar

Maximum range of plot specified as a real-valued scalar. Range units are specified by the `RangeUnit` Name-Value pair.

Example: 200

Data Types: `double`

### `hmax` — Maximum height of plot

real-valued scalar

Maximum height of plot specified as a real-valued scalar. Height units are specified by the `HeightUnit` Name-Value pair.

Example: 100000

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: ‘RangeUnit’,’m’

### `RangeUnit` — Radar range units

`'km'` (default) | `'nmi'` | `'mi'` | `'ft'` | `'m'`

Range units denoting nautical miles, miles, kilometers, feet or meters. This Name-Value pair specifies the units for the vertical coverage pattern input argument, `vcp`, and the maximum range input argument, `rmax`.

Example: `'mi'`

Data Types: `char`

**`HeightUnit` — Height units**
`'km'` (default) | `'nmi'` | `'mi'` | `'ft'` | `'m'`

Height units specified as one of `'nmi'` | `'mi'` | `'km'` | `'ft'` |`'m'` denoting nautical miles, miles, kilometers, feet or meters. This Name-Value pair specifies the units for the maximum height, `hmax`.

Example: `'m'`

Data Types: `char`

**`ScalePower` — Scale power**
0.25 (default) | real-valued scalar

Scale power, specified as a scalar between 0 and 1. This parameter specifies the range and height axis scale power.

Example: 0.5

Data Types: `double`

**`SurfaceRefractivity` — Surface refractivity**
313 (default) | real-valued scalar

Surface refractivity, specified as a non-negative real-valued scalar. The surface refractivity is a parameter of the "CRPL Exponential Reference Atmosphere Model" on page 2-85 used in this function.

Example: 314

Data Types: `double`

**`RefractionExponent` — Refraction exponent**
0.143859 (default) | real-valued scalar

Refraction exponent specified as a non-negative, real-valued scalar. The refraction exponent is a parameter of the "CRPL Exponential Reference Atmosphere Model" on page 2-85 used in this function.

Example: 0.15

Data Types: `double`

# More About

## CRPL Exponential Reference Atmosphere Model

The `blakechart` function uses the CRPL Exponential Reference Atmosphere to model refraction effects. The index of refraction is a function of height

$$n(h) = 1.0 + \left(N_s \times 10^{-6}\right)e^{-R_{exp}h}$$

where $N_s$ is the atmospheric refractivity value (in units of $10^{-6}$) at the surface of the earth, $R_{exp}$ is a decay constant, and $h$ is the height above the surface in kilometers. The default value of $N_s$ is 313 and can be modified using the `'SurfaceRefractivity'` Name-Value pair. The default value of $R_{exp}$ is 0.143859 and can be modified using the `'RefractionExponent'` Name-Value pair.

# broadside2az

Convert broadside angle to azimuth angle

## Syntax

```
az = broadside2az(bsang)
az = broadside2az(bsang,el)
```

## Description

`az = broadside2az(bsang)` returns the azimuth angle on page 2-88, `az`, corresponding to the broadside angle, `bsang`, for zero elevation angle. Angles are defined with respect to the local coordinate system.

`az = broadside2az(bsang,el)` also specifies the elevation angle, `el`.

## Examples

### Convert Broadside Angle to Azimuth Angle at Zero Elevation

Return the azimuth angle corresponding to a broadside angle of 45° at 0° elevation.

```
az = broadside2az(45.0)
```

```
az = 45.0000
```

### Convert Broadside Angle to Azimuth Angle

Return the azimuth angle corresponding to a broadside angle of 45° and an elevation angle of 20°.

```
az = broadside2az(45,20)
az = 48.8063
```

### Convert Multiple Broadside Angles to Azimuth Angles

Return azimuth angles for 10 pairs of broadside angle and elevation angle.

```
BSang = (45:5:90)';
el = (45:-5:0)';
az = broadside2az(BSang,el);
```

## Input Arguments

**bsang — Broadside angle**
scalar | vector of real values

Broadside angle, specified as a scalar or vector of real values. Units are in degrees. This argument supports single and double precision.

Example: `[10;-22;-80]`

**el — Elevation angle**
`0` (default) | scalar | vector of real values

Elevation angle, specified as a scalar or vector of real values. The length of `el` must match the length of `bsang`. Elevation angles lie in the range from –90° to 90°. Units are in degrees. This argument supports single and double precision.

Example: `[5;2;-1]`

## Output Arguments

**az — Azimuth angle**
scalar | vector of real values

Azimuth angle, returned as a scalar or vector of real values. The length of `az`equals the length of `bsang`. Azimuth angles lie in the range from –180° to 180°. Units are in degrees.

## More About

### Broadside Angle

Broadside angles are useful in describing the response pattern of a uniform linear array (ULA).

For the definition of the broadside angle and how to convert between azimuth and elevation, and broadside angle see “Broadside Angles”. For definitions of the azimuth and elevation angles, see “Azimuth and Elevation Angles”.

# bw2range

Convert bandwidth to range resolution

## Syntax

```
rngres = bw2range(bw)
rngres = range2bw(bw,c)
```

## Description

`rngres = bw2range(bw)` returns the range resolution of a signal corresponding to its bandwidth. Range resolution gives you the minimum range difference needed to distinguish two targets. The function applies to two-way propagation, as in a monostatic radar system.

`rngres = range2bw(bw,c)` specifies the signal propagation speed, `c`.

## Examples

### Compute Range Resolution from Bandwidth

Assume you have a monostatic radar system that uses a rectangular waveform. Calculate the range resolution obtained using a bandwidth of 20 MHz.

```
bw = 20e6;
rngres = bw2range(bw)
```

```
rngres = 7.4948
```

### Compute Sonar Range Resolution from Bandwidth

Calculate the range resolution of a two-way sonar system that uses a rectangular waveform. The signal bandwidth is 2 kHz. The speed of sound is 1520 m/s.

```
bw = 2e3;
c = 1520.0;
rngres = bw2range(bw,c)
```

```
rngres = 0.3800
```

## Input Arguments

**bw — Signal bandwidth**
positive scalar | MATLAB array of positive real values

Signal bandwidth, specified as any array of array of positive real values. Units are in hertz.

**c — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value is the output of `physconst('LightSpeed')`. Units are in meters per second.

Data Types: `double`

## Output Arguments

**`rngres` — Target range resolution**
positive scalar | MATLAB array of positive real values

Target range resolution, returned as a scalar or MATLAB array of positive real numbers. The dimensions of `rngres` are the same as those of `bw`. Units are in meters.

Data Types: `double`

## Tips

- This function assumes two-way propagation. For one-way propagation, you can find the required range resolution by multiplying the output of this function by 2.

## Algorithms

The function computes range resolution from `rngres = c/(2*bw)`.

# cart2sphvec

Convert vector from Cartesian components to spherical representation

## Syntax

```
vs = cart2sphvec(vr,az,el)
```

## Description

`vs = cart2sphvec(vr,az,el)` converts the components of a vector or set of vectors, `vr`, from their representation in a local Cartesian coordinate system to a spherical basis representation contained in `vs`. A spherical basis representation is the set of components of a vector projected into a basis given by $(\widehat{\mathbf{e}}_{az}, \widehat{\mathbf{e}}_{el}, \widehat{\mathbf{e}}_{R})$. The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

## Examples

### Spherical Representation of Unit Z-Vector

Start with a vector in Cartesian coordinates pointing along the *z*-direction and located at 45° azimuth, 45° elevation. Compute its components with respect to the spherical basis at that point.

```
vr = [0;0;1];
vs = cart2sphvec(vr,45,45)
```

```
vs = 3×1

         0
    0.7071
    0.7071
```

## Input Arguments

### `vr` — Vector in Cartesian basis representation

3-by-1 column vector | 3-by-N matrix

Vector in Cartesian basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of `vr` contains the three components of a vector in the right-handed Cartesian basis *x*,*y*,*x*.

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

### `az` — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

### `el` — Elevation angle

scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

# Output Arguments

**vs — Vector in spherical basis**
3-by-1 column vector | 3-by-N matrix

Spherical representation of a vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as `vs`. Each column of `vs` contains the three components of the vector in the right-handed ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$) basis.

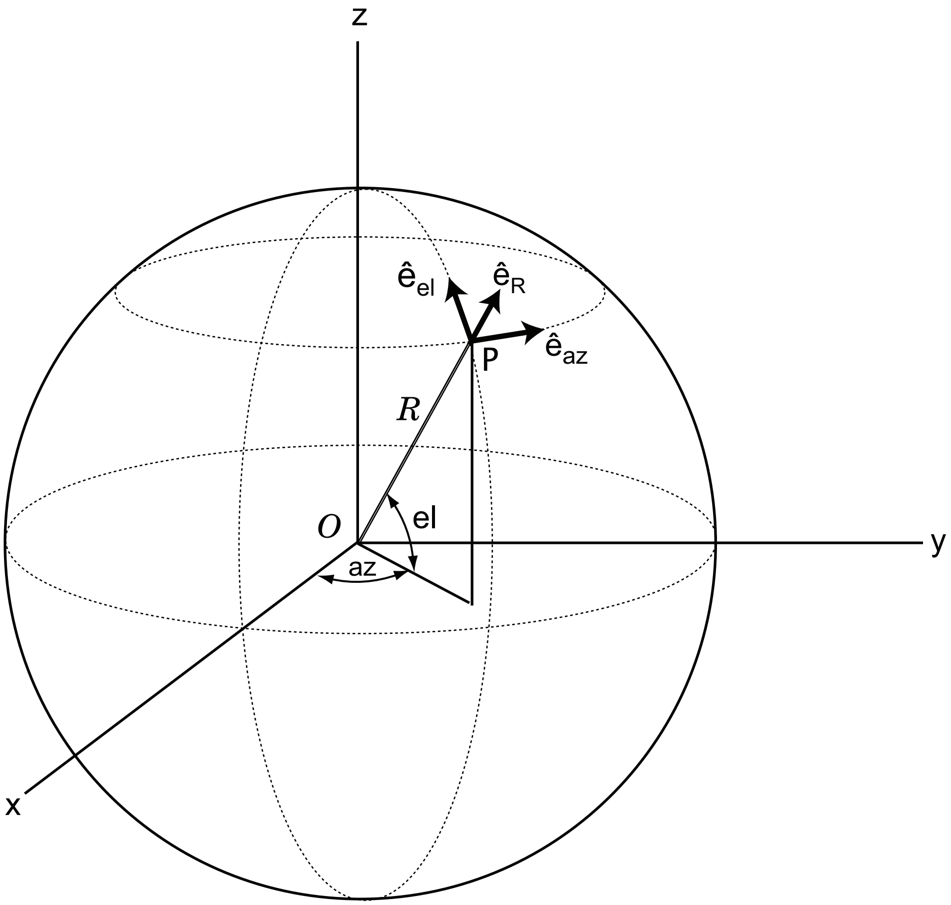
# More About

## Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of *R* so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\begin{aligned}\widehat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\,\widehat{\mathbf{i}} + \cos(az)\,\widehat{\mathbf{j}} \\ \widehat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\,\widehat{\mathbf{i}} - \sin(el)\sin(az)\,\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}} \\ \widehat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\,\widehat{\mathbf{i}} + \cos(el)\sin(az)\,\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}} \quad .\end{aligned}$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\widehat{\mathbf{e}}_{\mathbf{az}} + v_{el}\widehat{\mathbf{e}}_{\mathbf{el}} + v_R\widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

# cbfweights

Conventional beamformer weights

## Syntax

```
wt = cbfweights(pos,ang)
wt = cbfweights(pos,ang,nqbits)
```

## Description

`wt = cbfweights(pos,ang)` returns narrowband conventional beamformer weights. When applied to the elements of a sensor array, these weights steer the response of the array to a specified arrival direction or set of directions. The `pos` argument specifies the sensor positions in the array. The `ang` argument specifies the azimuth and elevation angles of the desired response directions. The output weights, `wt`, are returned as an *N*-by-*M* matrix. In this matrix, *N* represents the number of sensors in the array while *M* represents the number of arrival directions. Each column of `wt` contains the weights for the corresponding direction specified in the `ang`. The argument `wt` is equivalent to the output of the function `steervec` divided by *N*. All elements in the sensor array are assumed to be isotropic.

`wt = cbfweights(pos,ang,nqbits)` returns quantized narrowband conventional beamformer weights when the number of phase-shifter bits is set to `nqbits`.

## Examples

### Conventional Weights for Two Beamformer Directions

Specify a line array of five elements spaced 10 cm apart. Compute the weights for two directions: 30° azimuth, 0° elevation, and 45° azimuth, 0° elevation. Assume the array is tuned to plane waves having a frequency of 1 GHz.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
```

```
fc = 1e9;
lambda = c/fc;
ang = [30 45];
wt = cbfweights(elementPos/lambda,ang)
```

```
wt = 5×2 complex

   0.2000 + 0.0000i   0.2000 + 0.0000i
   0.0999 + 0.1733i   0.0177 + 0.1992i
  -0.1003 + 0.1731i  -0.1969 + 0.0353i
  -0.2000 - 0.0004i  -0.0527 - 0.1929i
  -0.0995 - 0.1735i   0.1875 - 0.0696i
```

### Quantized Weights for Two Beamformer Directions

Specify a line array of five elements spaced 10 cm apart. Compute the weights for two directions: 30° azimuth, 0° elevation, and 45° azimuth, 0° elevation. Assume the array is tuned to plane waves having a frequency of 1 GHz. Assume the weights are quantized to six bits.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
lambda = c/fc;
ang = [30 45];
nqbits = 6;
wt = cbfweights(elementPos/lambda,ang,nqbits)
```

```
wt = 5×2 complex

   0.2000 + 0.0000i   0.2000 + 0.0000i
   0.0943 + 0.1764i   0.0196 + 0.1990i
  -0.0943 + 0.1764i  -0.1962 + 0.0390i

  -0.0943 - 0.1764i   0.1848 - 0.0765i
```

# Input Arguments

### pos — Positions of array sensor elements

1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

### ang — Beamforming directions

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Beamforming directions specified as a 1-by-*M* vector or a 2-by-*M* matrix. In this vector or matrix, *M* represents the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the beamforming direction as `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the beamforming direction vector onto the *xy* plane. The angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the beamforming direction vector and *xy*-plane. It is positive when measured towards the positive *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: `[45;10]`

Data Types: `double`

### `nqbits` — Number of phase shifter quantization bits

0 (default) | non-negative integer

Number of bits used to quantize the phase shift in beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: 5

# Output Arguments

**`wt` — Beamformer weights**

*N*-by-*M* complex-valued matrix

Beamformer weights returned as an *N*-by-*M* complex-valued matrix. In this matrix, *N* represents the number of sensor elements of the array while *M* represents the number of beamforming directions. Each column of `wt` corresponds to a beamforming direction specified in `ang`.

## Introduced in R2013a

# circpol2pol

Convert circular component representation of field to linear component representation

## Syntax

```
fv = circpol2pol(cfv)
```

## Description

`fv = circpol2pol(cfv)` converts the circular polarization components of the field or fields contained in `cfv` to their linear polarization components contained in `fv`. Any polarized field can be expressed as a linear combination of horizontal and vertical components.

## Examples

### Convert Circular to Linear Polarization

Convert a horizontally polarized field, originally expressed in circular polarization components, into linear polarization components.

```
cfv = [1;1];
fv = circpol2pol(cfv)
```

```
fv = 2×1

    1.4142
         0
```

The vertical component of the output is zero for horizontally polarized fields.

### Convert Circular Polarization Ratio to Linear Polarization Ratio

Create a right circularly polarized field. Compute the circular polarization ratio and convert to a linear polarization ratio equivalent. Note that the input circular polarization ratio is `Inf`.

```
cfv = [0;1];
q = cfv(2)/cfv(1);
p = circpol2pol(q)
```

```
p = 0.0000 - 1.0000i
```

## Input Arguments

### `cfv` — Field vector in circular polarization representation

1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in its circular polarization representation specified as a 1-by-*N* complex row vector or a 2-by-*N* complex matrix. If `cfv` is a matrix, each column represents a field in the form of `[El;Er]`, where `El` and `Er` are the left and right circular polarization components of the field. If `cfv` is a row vector, each column in `cfv` represents the polarization ratio, `Er/El`. For a row vector, the value `Inf` can designate the case when the ratio is computed for `El = 0`.

Example: [1;-1]

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `fv` — Field vector in linear polarization representation or Jones vector

1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in linear polarization representation or Jones vector returned as a 1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix. `fv` has the same dimensions as `cfv`. If `cfv` is a matrix, each column of `fv` contains the horizontal and vertical linear polarization components of the field in the form, `[Eh;Ev]`. If `cfv` is a row vector, each entry in `fv` contains the linear polarization ratio, defined as `Ev/Eh`.

# dechirp

Perform dechirp operation on FMCW signal

## Syntax

```
y = dechirp(x,xref)
```

## Description

`y = dechirp(x,xref)` mixes the incoming signal, `x`, with the reference signal, `xref`. The signals can be complex baseband signals. In an FMCW radar system, `x` is the received signal and `xref` is the transmitted signal.

## Examples

### Dechirp FMCW Signal

Dechirp a delayed FMCW signal, and plot the spectrum before and after dechirping.

Create an FMCW signal.

```
Fs = 2e5; Tm = 0.001;
hwav = phased.FMCWWaveform('SampleRate',Fs,'SweepTime',Tm);
xref = step(hwav);
```

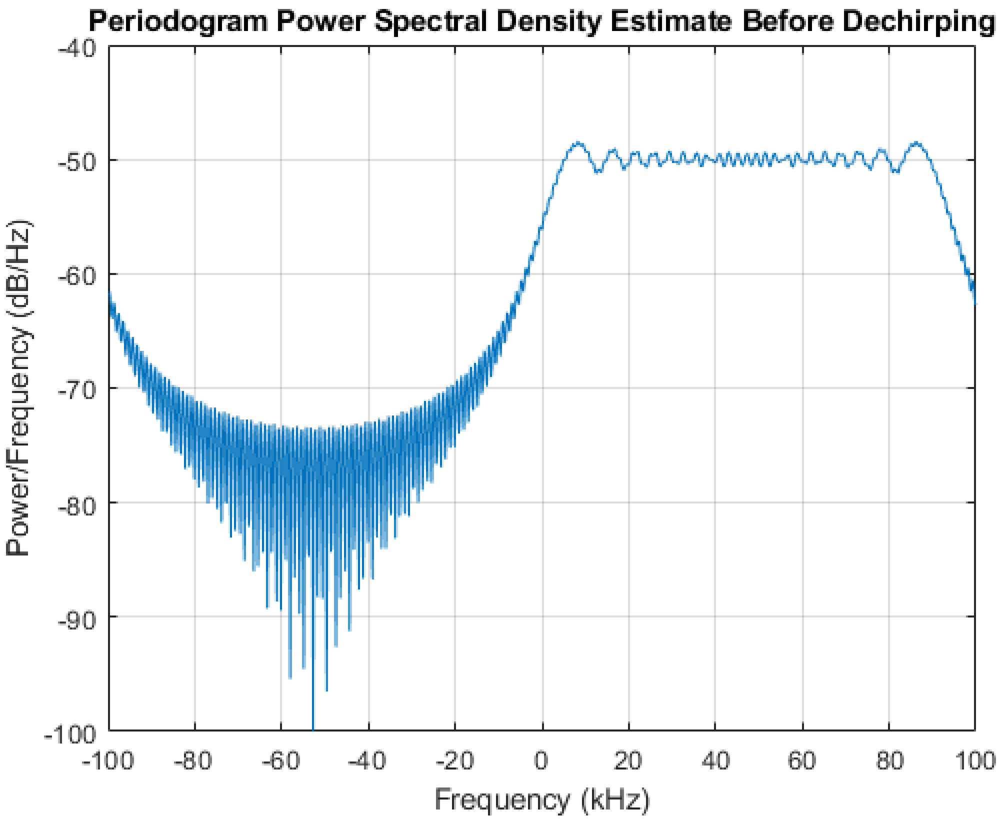
Dechirp a delayed copy of the signal.

```
x = [zeros(10,1); xref(1:end-10)];
y = dechirp(x,xref);
```

Plot the spectrum before dechirping.

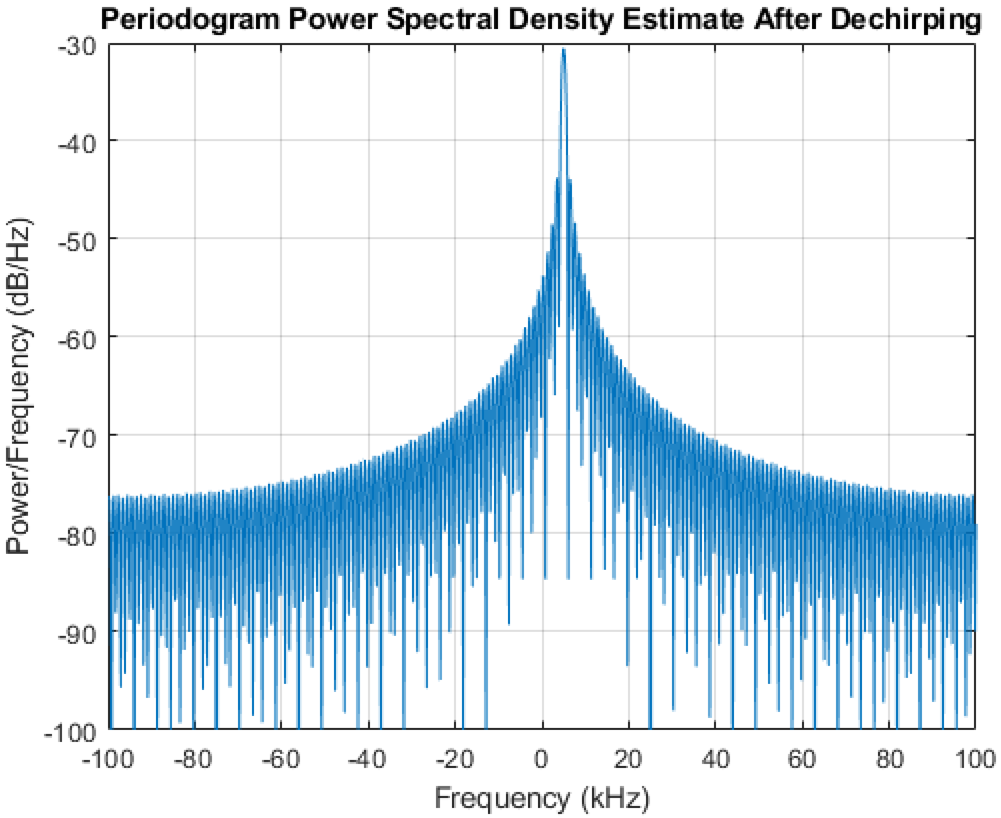
```
[Pxx,F] = periodogram(x,[],1024,Fs,'centered');
plot(F/1000,10*log10(Pxx)); grid;
xlabel('Frequency (kHz)');
```

```
ylabel('Power/Frequency (dB/Hz)');
title('Periodogram Power Spectral Density Estimate Before Dechirping');
```



Plot the spectrum after dechirping.

```
[Pyy,F] = periodogram(y,[],1024,Fs,'centered');
plot(F/1000,10*log10(Pyy));
xlabel('Frequency (kHz)');
ylabel('Power/Frequency (dB/Hz)');
ylim([-100 -30]); grid
title('Periodogram Power Spectral Density Estimate After Dechirping');
```



## Input Arguments

**x — Incoming signal**
*M*-by-*N* matrix

Incoming signal, specified as an *M*-by-*N* matrix. Each column of `x` is an independent signal and is individually mixed with `xref`.

Data Types: `single` | `double`
Complex Number Support: Yes

### `xref` — Reference signal

*M*-by-1 vector

Reference signal, specified as an *M*-by-1 vector.

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### y — Dechirped signal

*M*-by-*N* matrix

Dechirped signal, returned as an *M*-by-*N* matrix. Each column is the mixer output for the corresponding column of `x`.

Data Types: `single` | `double`

## Algorithms

For column vectors `x` and `xref`, the mix operation is defined as `xref .* conj(x)`.

If `x` has multiple columns, the mix operation applies the preceding expression to each column of `x` independently.

The mix operation reverses the Doppler shift embedded in `x`, because of the mixing order of `xref` and `x`. The mixing order affects the sign of the imaginary part of the output argument, `y`. There is no consistent convention in the literature about the mixing order. This function and the `beat2range` function use the same convention. If your program processes the output of `dechirp` in other ways, take the mixing order into account.

This function supports single and double precision for input data and arguments. If the input data, `x`, is single precision, the output data is single precision, regardless of the precision of the arguments. If the input data is double precision, the output data is double precision, regardless of the precision of the arguments.

### Topics

Automotive Adaptive Cruise Control Using FMCW Technology

**Introduced in R2012b**

# delayseq

Delay or advance sequence

## Syntax

```
shifted_data = delayseq(data,DELAY)
shifted_data = delayseq(data,DELAY,Fs)
```

## Description

`shifted_data = delayseq(data,DELAY)` delays or advances the input `data` by `DELAY` samples. Negative values of `DELAY` advance `data`, while positive values delay `data`. Noninteger values of `DELAY` represent fractional delays or advances. In this case, the function interpolates. How the `delayseq` function operates on the columns of `data` depends on the dimensions of `data` and `DELAY`:

- If `DELAY` is a scalar, the function applies that shift to each column of `data`.
- If `DELAY` is a vector whose length equals the number of columns of `data`, the function shifts each column by the corresponding vector entry.
- If `DELAY` is a vector and `data` has one column, the function shifts `data` by each entry in `DELAY` independently. The number of columns in `shifted_data` is the vector length of `DELAY`. The *k*th column of `shifted_data` is the result of shifting `data` by `DELAY(k)`.

`shifted_data = delayseq(data,DELAY,Fs)` specifies `DELAY` in seconds. `Fs` is the sampling frequency of `data`. If `DELAY` is not divisible by the reciprocal of the sampling frequency, `delayseq` interpolates to implement a fractional delay or advance of `data`.

## Input Arguments

### `data`

Vector or matrix of real or complex data. This argument supports single and double precision.

**DELAY**

Amount by which to delay or advance the input. If you specify the optional `Fs` argument, `DELAY` is in seconds; otherwise, `DELAY` is in samples. This argument supports single and double precision.

**Fs**

Sampling frequency of the data in hertz. If you specify this argument, the function assumes `DELAY` is in seconds. This argument supports single and double precision.

**Default:** 1

## Output Arguments

**shifted_data**

Result of delaying or advancing the data. `shifted_data` has the same number of rows as `data`, with appropriate truncations or zero padding.

## Examples

### Delay Signal by Integral Number of Samples

Delay a cosine signal an integral number of samples.

```
fs = 1.0e4;
t = 0:1/fs:0.005;
signal = cos(2*pi*1000*t)';
```

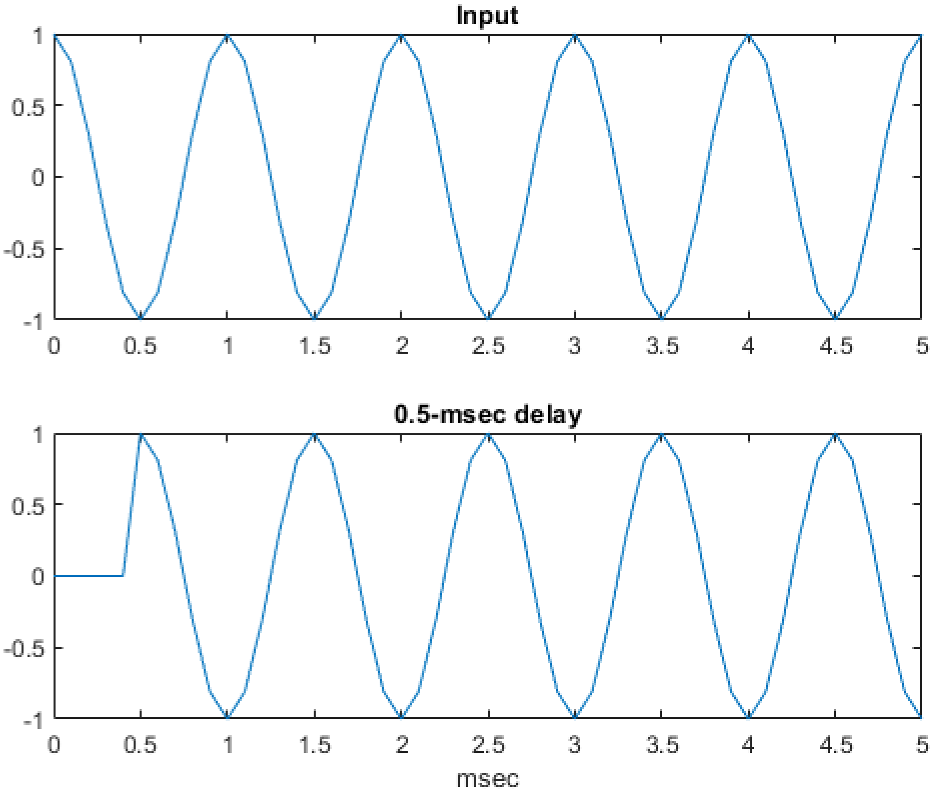
Set the delay to 0.5 ms or 5 samples.

```
shifted_signal = delayseq(signal,0.5e-3,fs);
```

Plot the original and delayed signals.

```
subplot(2,1,1)
plot(t.*1000,signal)
title('Input')
```

```
subplot(2,1,2)
plot(t.*1000,shifted_signal)
title('0.5-msec delay')
xlabel('msec')
```



### Delay Signal by Fractional Number of Samples

Delay a 1 kHz cosine signal by a fractional number of samples. Assume a sampling rate of 10 kHz.

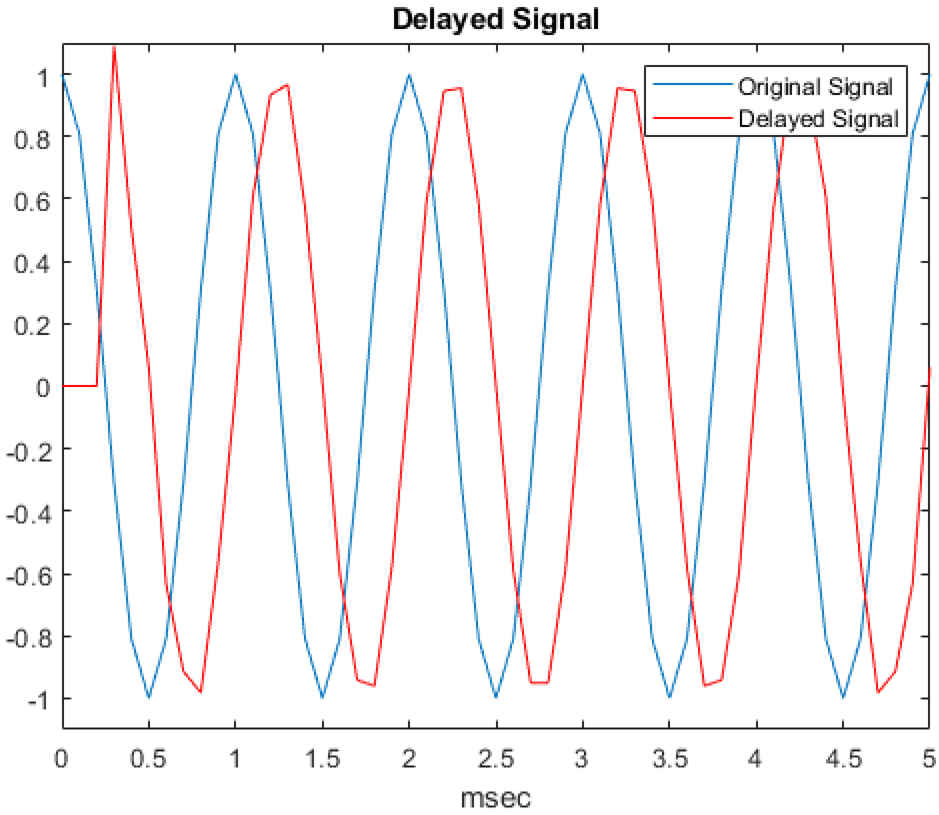
```
fs = 1e4;
t = 0:1/fs:0.005;
signal = cos(2*pi*1000*t)';
```

Set the delay to 0.25 ms or 2.5 samples.

```
delayed_signal = delayseq(signal,0.25e-3,fs);
```

Plot the original signal (blue) and delayed (red) signals.

```
plot(t.*1000,signal)
title('Delayed Signal')
hold on
plot(t.*1000,delayed_signal,'r')
axis([0 5 -1.1 1.1])
xlabel('msec')
legend('Original Signal','Delayed Signal')
hold off
```



The values of the delayed signal amplitudes differ from the original signal due to the interpolation used in implementing the fractional delay.

# Extended Capabilities

# depressionang

Depression angle of surface target

## Syntax

```
depAng = depressionang(H,R)
depAng = depressionang(H,R,MODEL)
depAng = depressionang(H,R,MODEL,Re)
```

## Description

`depAng = depressionang(H,R)` returns the depression angle from the horizontal at an altitude of `H` meters to surface targets. The sensor is `H` meters above the surface. `R` is the range from the sensor to the surface targets. The computation assumes a curved earth model with an effective earth radius of approximately 4/3 times the actual earth radius.

`depAng = depressionang(H,R,MODEL)` specifies the earth model used to compute the depression angle. `MODEL` is either `'Flat'` or `'Curved'`.

`depAng = depressionang(H,R,MODEL,Re)` specifies the effective earth radius. Effective earth radius applies to a curved earth model. When `MODEL` is `'Flat'`, the function ignores `Re`.

## Input Arguments

### H

Height of the sensor above the surface, in meters. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions.

**R**

Distance in meters from the sensor to the surface target. This argument can be a scalar or a vector. If both H and R are nonscalar, they must have the same dimensions. R must be between H and the horizon range determined by H.

**MODEL**

Earth model, as one of | 'Curved' | 'Flat' |.

**Default:** 'Curved'

**Re**

Effective earth radius in meters. This argument requires a positive scalar value.

**Default:** effearthradius, which is approximately 4/3 times the actual earth radius

# Output Arguments

**depAng**

Depression angle, in degrees, from the horizontal at the sensor altitude toward surface targets R meters from the sensor. The dimensions of depAng are the larger of size(H) and size(R).

# Examples

### Compute Depression Angle

Calculate the depression angle for a ground clutter patch that is 1.0 km away from a sensor. The sensor is located on a platform 300 m above the ground.

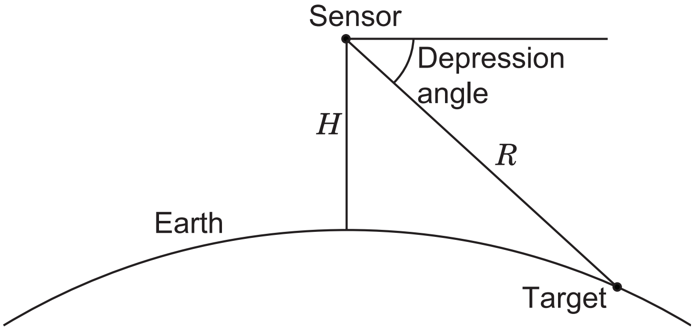
```
depang = depressionang(300,1000)
```

```
depang = 17.4608
```

# More About

## Depression Angle

The depression angle is the angle between a horizontal line containing the sensor and the line from the sensor to a surface target.



For the curved earth model with an effective earth radius of $R_e$, the depression angle is:

$$\sin^{-1}\left(\frac{H^2 + 2HR_e + R^2}{2R(H + R_e)}\right)$$

For the flat earth model, the depression angle is:

$$\sin^{-1}\left(\frac{H}{R}\right)$$

# diagbfweights

Diagonalize MIMO channel

## Syntax

```
[wp,wc] = diagbfweights(chanmat)
[wp,wc,P] = diagbfweights(chanmat)
[wp,wc,P,G] = diagbfweights(chanmat)
[wp,wc,P,G,C] = diagbfweights(chanmat)
[ ___ ] = diagbfweights(chanmat,Pt)
[ ___ ] = diagbfweights(chanmat,Pt Pn)
[ ___ ] = diagbfweights(chanmat,Pt Pn,powdistoption)
```

## Description

`[wp,wc] = diagbfweights(chanmat)` returns precoding weights, `wp`, and combining weights, `wc`, for the channel response matrix, `chanmat`. Together, these weights diagonalize the channel into subchannels so that the matrix `wp*chanmat*wc` is diagonal.

`[wp,wc,P] = diagbfweights(chanmat)` also returns the distributed power, `P`, for each element of the transmitting array.

`[wp,wc,P,G] = diagbfweights(chanmat)` also returns the subcarrier gains, `G`.

`[wp,wc,P,G,C] = diagbfweights(chanmat)` also returns the channel capacity sum, `C`.

`[ ___ ] = diagbfweights(chanmat,Pt)` also specifies total transmit power, `Pt`, and returned values any of the previous output argument combinations.

`[ ___ ] = diagbfweights(chanmat,Pt Pn)` also specifies the noise power per transmitting antenna, `Pn`.

`[ ___ ] = diagbfweights(chanmat,Pt Pn,powdistoption)` also specifies the noise distribution, `powdistoption`, across all transmitting antennas.

# Examples

### Compute and Diagonalize Channel Matrix

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume that three scatterers are randomly located located within a specified angular range. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Constrain the angular span for the transmitting and receiving arrays. Diagonalize the channel matrix to compute the precoding and combining weights.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Set the angular limits for transmitting and receiving.

- The azimuth angle limits for the transmitter are −45° to +45°.
- The azimuth angle limits for the receiver are −75° to +50°.
- The elevation angle limits for the transmitter are −12° to +12°.
- The elevation angle limits for the receiver are −30° to +30°.

```
angrange = [-45 45 -75 50; -12 12 -30 30];
```

Specify three scatterers and create the channel matrix.

```
numscat = 3;
chmat = scatteringchanmtx(txpos,rxpos,numscat,angrange);
```

Diagonalize the channel matrix.

```
[wp,wc] = diagbfweights(chmat);
z = wp*chmat*wc;
```

Show the first four diagonal elements.

```
z(1:4,1:4)
```

```
ans = 4×4 complex

### Distributed Power of Diagonalized Channel Matrix

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume that three scatterers are randomly located within a specified angular range. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away along the *x*-axis. Diagonalize the channel matrix to compute the precoding and combining weights and the distributed power.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Set the angular limits for transmitting and receiving.

- The azimuth angle limits for the transmitter are −45° to +45°.
- The azimuth angle limits for the receiver are −75° to +50°.
- The elevation angle limits for the transmitter are −12° to +12°.
- The elevation angle limits for the receiver are −30° to +30°.

```
angrange = [-45 45 -75 50; -12 12 -30 30];
```

Specify three scatterers and create the channel matrix.

```
numscat = 3;
chmat = scatteringchanmtx(txpos,rxpos,numscat,angrange);
```

Diagonalize the channel matrix and return the distributed power.

```
[wp,wc,P] = diagbfweights(chmat);
disp(P.')
```

### Subchannel Gains of Diagonalized Channel Matrix

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmit array along the *x*-axis. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, and the subchannel gains.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
chmat = scatteringchanmtx(txpos,rxpos,numscat);
```

Diagonalize the channel matrix and return the subchannel gains.

```
[wp,wc,P,G] = diagbfweights(chmat);
disp(G.')
```

### Channel Capacity Sum of Diagonalized Channel Matrix

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, the subchannel gains, and the channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
```

Create two subcarriers.

```
chmat1 = scatteringchanmtx(txpos,rxpos,numscat);
chmat2 = scatteringchanmtx(txpos,rxpos,numscat);
chmat(1,:,:) = chmat1;
chmat(2,:,:) = chmat2;
```

Diagonalize the channel matrix and return the subchannel gains.

```
[wp,wc,P,G,C] = diagbfweights(chmat);
disp(C.')
```

```
    9.5466    9.3605
```

### Diagonalize Channel Matrix with Specified Power

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Specify the total transmitted power at 1000. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, the subchannel gains, and the channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
```

Create two subcarriers.

```
chmat1 = scatteringchanmtx(txpos,rxpos,numscat);
chmat2 = scatteringchanmtx(txpos,rxpos,numscat);
chmat(1,:,:) = chmat1;
chmat(2,:,:) = chmat2;
```

Diagonalize the channel matrix and return the distributed power for both subcarriers.

```
Pt = 1000.0;
[wp,wc,P,G,C] = diagbfweights(chmat,Pt);
disp(P.')
```

```

### Diagonalize Channel Matrix with Specified Noise Power

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Specify the total transmitted power at 1000 and the transmitting antenna noise power at 100. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmit array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, subchannel gains, and channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
```

Create two subcarriers.

```
chmat1 = scatteringchanmtx(txpos,rxpos,numscat);
chmat2 = scatteringchanmtx(txpos,rxpos,numscat);
chmat(1,:,:) = chmat1;
chmat(2,:,:) = chmat2;
```

Diagonalize the channel matrix and return the gain for both subcarriers.

```
Pt = 1000.0;
Pn = 100.0;
[wp,wc,P,G,C] = diagbfweights(chmat,Pt,Pn);
disp(G.')

### Diagonalize Channel Matrix Using Waterfill Power Distribution

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Specify the total transmitted power at 1000 and the transmitting antenna noise power at 100. Specify the transmitted power distribution as `'Waterfill'`. Assume that there are five randomly located scatterers. The element spacing for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Create a channel matrix with two subcarriers.

Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, the subchannel gains, and the channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
```

Create two subcarriers.

```
chmat1 = scatteringchanmtx(txpos,rxpos,numscat);
chmat2 = scatteringchanmtx(txpos,rxpos,numscat);
chmat(1,:,:) = chmat1;
chmat(2,:,:) = chmat2;
```

Diagonalize the channel matrix and return the gain for both subcarriers.

```
Pt = 1000.0;
Pn = 100.0;
[wp,wc,P,G,C] = diagbfweights(chmat,Pt,Pn,'Waterfill');
disp(G.')
```

    0.0000    0.0000
    0.0000    0.0000
```

## Input Arguments

**chanmat — Channel response matrix**

$N_t$-by-$N_r$ complex-valued matrix | $L$-by-$N_t$-by-$N_r$ complex-valued MATLAB array

Channel response matrix, specified as an $N_t$-by-$N_r$ complex-valued matrix or an $L$-by-$N_t$-by-$N_r$ complex-valued MATLAB array.

- $N_t$ is the number of elements in the transmitting array.
- $N_r$ is the number of elements in the receiving array.
- $L$ is the number of subcarriers.

When `chanmat` is a MATLAB array containing subcarriers, each subcarrier is decomposed independently into subchannels.

Data Types: `double`
Complex Number Support: Yes

### `Pt` — Total transmit power

`1` (default) | positive scalar | $L$-element vector of positive values

Total transmit power, specified as a positive scalar or an $L$-element vector of positive values. `Pt` has the same units as the total distributed power, `P`.

Data Types: `double`

### `Pn` — Noise power

`1` (default) | positive scalar

Noise power in each receiving antenna, specified as a positive scalar. `Pn` has the same units as the total transmit power, `Pt`.

Data Types: `double`

### `powdistoption` — Power distribution option

`'Uniform'` (default) | `'Waterfill'`

Power distribution option, specified as `'Uniform'` or `'Waterfill'`. When `powdistoption` is `'Uniform'`, the transmit power is evenly distributed across all $N_t$ channels. If `powdistoption` is `'Waterfill'`, the transmit power is distributed across the $N_t$ channels using a waterfill algorithm.

Data Types: `char`

## Output Arguments

### wp — Precoding weights

$N_t$-by-$N_t$ complex-valued matrix | $L$-by-$N_t$-by-$N_t$ complex-valued MATLAB array

Precoding weights, returned as an $N_t$-by-$N_t$ complex-valued matrix or an $L$-by-$N_t$-by-$N_t$ complex-valued MATLAB array. Units are dimensionless.

Data Types: `double`

### wc — Combining weights

$N_r$-by-$N_r$ complex-valued matrix | $L$-by-$N_r$-by-$N_r$ complex-valued MATLAB array

Combining weights, returned as an $N_r$-by-$N_r$ complex-valued matrix or an $L$-by-$N_r$-by-$N_r$ complex-valued MATLAB array. Units are dimensionless.

Data Types: `double`

### P — Distributed power

1-by-$N_t$ real-valued row vector | $L$-by-$N_t$ real-valued matrix

Distributed power, returned as a vector or matrix.

- When `chanmat` is an $N_t$-by-$N_r$ real-valued matrix, `P` is a 1-by-$N_t$ real-valued row vector.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ real-valued MATLAB array, `P` is an $L$-by-$N_t$ real-valued matrix.

Power units are linear.

Data Types: `double`

### G — Subchannel gains

1-by-$N_g$ complex-valued row vector | $L$-by-$N_g$ complex-valued matrix

Subchannel gains, returned as a vector or matrix.

- When `chanmat` is an $N_t$-by-$N_r$ complex-valued matrix, `G` is a 1-by-$N_g$ complex-valued row vector.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ complex-valued MATLAB array, `G` is an $L$-by-$N_g$ complex-valued matrix.

$N_g$ is the smaller of $N_t$ and $N_r$.

Gain units are linear.

Data Types: `double`

### `C` — Channel capacity sum for each subcarrier

scalar | *L*-by-1 vector

Channel capacity sum for each subcarrier, returned as a scalar or vector.

- When `chanmat` is an $N_t$-by-$N_r$ complex-valued matrix, `C` is a scalar.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ complex-valued MATLAB array, `C` is an $L$-by-1 vector.

Capacity units are in bps/Hz.

Data Types: `double`

# dop2speed

Convert Doppler shift to speed

## Syntax

```
radvel = dop2speed(Doppler_shift,wavelength)
```

## Description

`radvel = dop2speed(Doppler_shift,wavelength)` returns the radial velocity in meters per second. This value corresponds to the one-way Doppler shift, `Doppler_shift`, for the wavelength, `wavelength`, in meters.

This function supports single and double precision for input data and arguments.

## Examples

### Calculate Speed of Car

Calculate the radial velocity of an automobile based on the Doppler shift of a continuous-wave radar. The radar carrier frequency is 24.15 GHz. Assume a doppler shift of 2.880 kHz.

```
f0 = 24.15e9;
lambda = physconst('LightSpeed')/f0;
dopshift = 2.880e3;
radvel = dop2speed(dopshift,lambda)
```

```
radvel = 35.7516
```

The radial velocity is approximately 35.75 meters per second or 80 miles/hour.

# More About

## Doppler-Radial Velocity Relation

The radial velocity of a source relative to a receiver can be computed from the one-way Doppler shift:

$$V_{s,r} = \Delta f \lambda$$

where $V_{s,r}$ denotes the radial velocity of the source relative to the receiver, $\Delta f$ is the Doppler shift in hertz, and $\lambda$ is the carrier frequency wavelength in meters.

`dopsteeringvec` | `speed2dop`

**Introduced in R2011a**

# dopsteeringvec

Doppler steering vector

## Syntax

```
DSTV = dopsteeringvec(dopplerfreq,numpulses)
DSTV = dopsteeringvec(dopplerfreq,numpulses,PRF)
```

## Description

`DSTV = dopsteeringvec(dopplerfreq,numpulses)` returns the N-by-1 temporal (time-domain) Doppler steering vector for a target at a normalized Doppler frequency of `dopplerfreq` in hertz. The pulse repetition frequency is assumed to be 1 Hz.

`DSTV = dopsteeringvec(dopplerfreq,numpulses,PRF)` specifies the pulse repetition frequency, `PRF`.

## Input Arguments

### `dopplerfreq`

The Doppler frequency in hertz. The normalized Doppler frequency is the Doppler frequency divided by the pulse repetition frequency. This argument supports single and double precision.

### `numpulses`

The number of pulses. The time-domain Doppler steering vector consists of `numpulses` samples taken at intervals of `1/PRF` (slow-time samples). This argument supports single and double precision.

### `PRF`

Pulse repetition frequency in hertz. The time-domain Doppler steering vector consists of `numpulses` samples taken at intervals of `1/PRF` (slow-time samples). The normalized

Doppler frequency is the Doppler frequency divided by the pulse repetition frequency. This argument supports single and double precision.

# Output Arguments

### DSTV

Temporal (time-domain) Doppler steering vector. DSTV is an N-by-1 column vector where N is the number of pulses, numpulses.

# Examples

### Compute Steering Vector for Doppler Shift

Calculate the steering vector corresponding to a Doppler frequency of 200 Hz. Assume there are 10 pulses and the PRF is 1 kHz.

```
dstv = dopsteeringvec(200,10,1000)
```

```
dstv = 10×1 complex

   1.0000 + 0.0000i
   0.3090 + 0.9511i
  -0.8090 + 0.5878i
  -0.8090 - 0.5878i
   0.3090 - 0.9511i
   1.0000 - 0.0000i
   0.3090 + 0.9511i
  -0.8090 + 0.5878i
  -0.8090 - 0.5878i
   0.3090 - 0.9511i
```

# More About

## Temporal Doppler Steering Vector

The temporal (time-domain) steering vector corresponding to a point scatterer is:

$$e^{j2\pi f_d T_p n}$$

where *n=0,1,2, ..., N-1* are slow-time samples (one sample from each pulse), $f_d$ is the Doppler frequency, and $T_p$ is the pulse repetition interval. The product of the Doppler frequency and the pulse repetition interval is the normalized Doppler frequency.

# Algorithms

## Single Precision

This functions supports single and double precision for input arguments. If the input arguments are single precision, the output is single precision. If the input arguments are double precision, the output is double precision.

# effearthradius

Effective earth radius

## Syntax

```
Re = effearthradius
Re = effearthradius(RGradient)
```

## Description

`Re = effearthradius` returns the effective radius of spherical earth in meters. The calculation uses a refractivity gradient of `-39e-9`. As a result, `Re` is approximately 4/3 of the actual earth radius.

`Re = effearthradius(RGradient)` specifies the refractivity gradient.

## Input Arguments

### RGradient

Refractivity gradient in units of 1/meter. This value must be a nonpositive scalar.

**Default:** `-39e-9`

## Output Arguments

### Re

Effective earth radius in meters.

# More About

## Effective Earth Radius

The effective earth radius is a scaling of the actual earth radius. The scale factor is:

$$\frac{1}{1 + r \cdot \mathrm{RGradient}}$$

where *r* is the actual earth radius in meters and `RGradient` is the refractivity gradient. The refractivity gradient, which depends on the altitude, is the rate of change of refraction index with altitude. The refraction index for a given altitude is the ratio between the free-space propagation speed and the propagation speed in the air band at that altitude.

The most commonly used scale factor is 4/3. This value corresponds to a refractivity gradient of $-39 \times 10^{-9}\ \mathrm{m}^{-1}$.

# See Also

`depressionang` | `horizonrange`

**Introduced in R2011b**

# espritdoa

Direction of arrival using TLS ESPRIT

## Syntax

```
ang = espritdoa(R,nsig)
ang = espritdoa( ___ ,Name,Value)
```

## Description

`ang = espritdoa(R,nsig)` estimates the directions of arrival, `ang`, of a set of plane waves received on a uniform line array (ULA). The estimation employs the TLS ESPRIT, the total least-squares ESPRIT, algorithm. The input arguments are the estimated spatial covariance matrix between sensor elements, `R`, and the number of arriving signals, `nsig`. In this syntax, sensor elements are spaced one-half wavelength apart.

`ang = espritdoa( ___ ,Name,Value)` estimates the directions of arrival with additional options specified by one or more `Name,Value` pair arguments. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Three Signals Arriving at Half-Wavelength-Spaced ULA

Assume a half-wavelength spaced uniform line array with 10 elements. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white. The SNR for each signal is 5 dB. Find the arrival angles.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
```

```
R = sensorcov(elementPos,angles,db2pow(-5));
doa = espritdoa(R,Nsig)
```

```
doa = 1×3

   30.0000    0.0000  -25.0000
```

The `espritdoa` function returns the correct angles.

### Three Signals Arriving at 0.4-Wavelength-Spaced ULA

Assume a uniform line array with 10 elements. The element spacing is 0.4 wavelength. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white. The SNR for each signal is 5 dB. Find the arrival angles.

```
N = 10;
d = 0.4;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = espritdoa(R,Nsig,'ElementSpacing',d)
```

```
doa = 1×3

  -25.0000   -0.0000   30.0000
```

`espritdoa` returns the correct angles.

## Input Arguments

**R — Spatial covariance matrix**
complex-valued positive-definite *N*-by-*N* matrix.

Spatial covariance matrix, specified as a complex-valued, positive-definite, *N*-by-*N* matrix. In this matrix, *N* represents the number of elements in the ULA array. If `R` is not

Hermitian, a Hermitian matrix is formed by averaging the matrix and its conjugate transpose, `(R+R')/2`.

Example: [ 4.3162, –0.2777 – 0.2337i; –0.2777 + 0.2337i , 4.3162]

Data Types: `double`
Complex Number Support: Yes

**`nsig` — Number of arriving signals**
positive integer

Number of arriving signals, specified as a positive integer.

Example: 3

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: ‘ElementSpacing’, 0.45

**`ElementSpacing` — ULA element spacing**
0.5 (default) | real-valued positive scalar

ULA element spacing, specified as a real-valued, positive scalar. Position units are measured in terms of signal wavelength.

Example: 0.4

Data Types: `double`

**`RowWeighting` — Row weights**
1 (default) | real-valued positive scalar

Row weights specified as a real-valued positive scalar. These weights are applied to the selection matrices which determine the ESPRIT subarrays. A larger value is generally better but the value must be less than or equal to $(N_s–1)/2$, where $N_s$ is the number of subarray elements. The number of subarray elements is $N_s = N–1$. The value of $N$ is the number of ULA elements, as specified by the dimensions of the spatial covariance matrix,

R. A detailed discussion of selection matrices and row weighting can be found in Van Trees [1], p. 1178.

Example: 5

Data Types: `double`

## Output Arguments

**ang — Directions of arrival angles**
real-valued 1-by-*M* row vector

Directions of arrival angle returned as a real-valued, 1-by-*M* vector. The dimension *M* is the number of arriving signals specified in the argument, `nsig`. This angle is the broadside angle. Angle units are degrees and angle values lie between –90° and 90°.

# fogpl

RF signal attenuation due to fog and clouds

## Syntax

```
L = fogpl(R,freq,T,den)
```

## Description

`L = fogpl(R,freq,T,den)` returns attenuation, `L`, when signals propagate in fog or clouds. `R` represents the signal path length. `freq` represents the signal carrier frequency, `T` is the ambient temperature, and `den` specifies the liquid water density in the fog or cloud.

The `fogpl` function applies the International Telecommunication Union (ITU) cloud and fog attenuation model to calculate path loss of signals propagating through clouds and fog [1]. Fog and clouds are the same atmospheric phenomenon, differing only by height above ground. Both environments are parameterized by their liquid water density. Other model parameters include signal frequency and temperature. This function applies when the signal path is contained entirely in a uniform fog or cloud environment. The liquid water density does not vary along the signal path. The attenuation model applies only for frequencies at 10–1000 GHz.

## Examples

### Attenuation in Cumulus Clouds

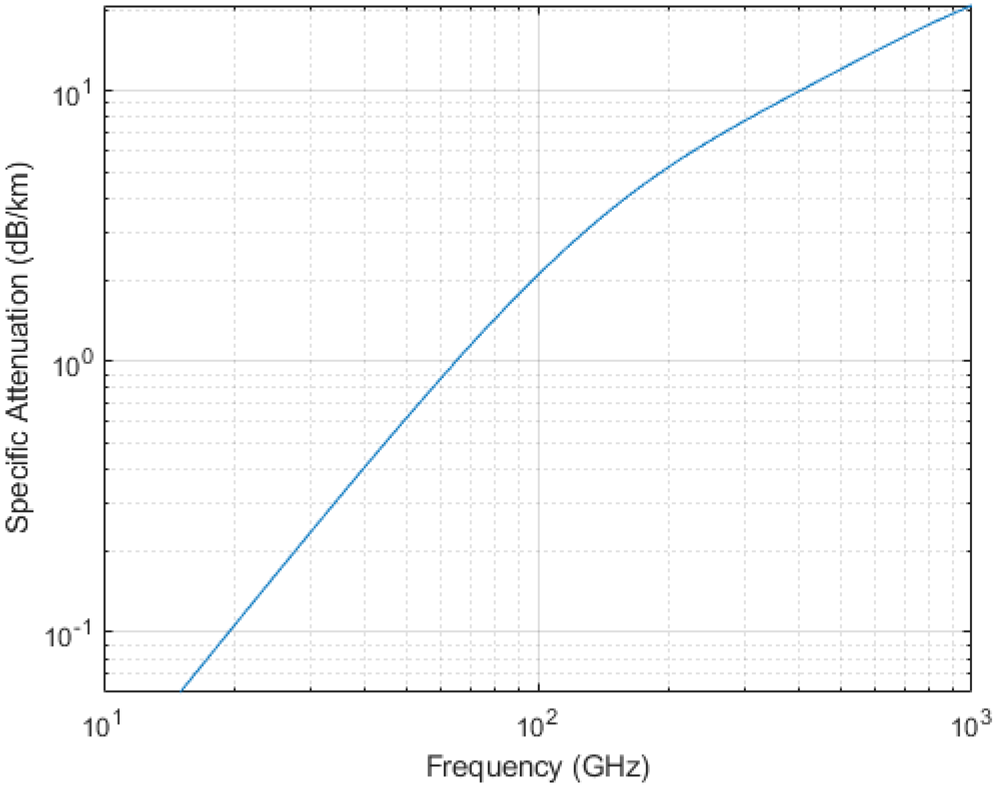
Compute the attenuation of signals propagating through a cloud that is 1 km long at 1000 meters altitude. Compute the attenuation for frequencies from 15 to 1000 GHz. A typical value for the cloud liquid water density is 0.5 $g/m^3$. Assume the atmospheric temperature at 1000 meters is 20°C.

```
R = 1000.0;
freq = [15:5:1000]*1e9;
```

```
T = 20.0;
lwd = 0.5;
L = fogpl(R,freq,T,lwd);
```

Plot the specific attenuation as a function of frequency. Specific attenuation is the attenuation or loss per kilometer.

```
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```



## Input Arguments

### R — Signal path length

positive real-valued scalar | *M*-by-1 nonnegative real-valued vector | 1-by-*M* nonnegative real-valued vector

Signal path length, specified as a scalar or as an *M*-by-1 or 1-by-*M* vector of nonnegative real-values. Total attenuation is the specific attenuation multiplied by the path length. Units are meters.

Example: `[1300.0,1400.0]`

### `freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. Frequencies must lie in the range 10–1000 GHz.

Example: `[14.0e9,15.0e9]`

### T — Ambient temperature

real-valued scalar

Ambient temperature in fog or cloud, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

### den — Liquid water density

nonnegative real-valued scalar

Liquid water density, specified as a nonnegative real-valued scalar. Units are g/m$^3$. Typical values for liquid water density in fog range from approximately 0.05 g/m$^3$ for medium fog to approximately 0.5 g/m$^3$ for thick fog. For medium fog, visibility is about 300 meters. For heavy fog, visibility is about 50 meters. Cumulus cloud liquid water density is typically 0.5 g/m$^3$.

Example: `0.01`

# Output Arguments

**L — Signal attenuation**
real-valued $M$-by-$N$ matrix

Signal attenuation, returned as a real-valued $M$-by-$N$ matrix. Each matrix row represents a different path where $M$ is the number of paths. Each column represents a different frequency where $N$ is the number of frequencies. Units are in dB.

# More About

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

# fspl

Free space path loss

## Syntax

```
L = fspl(R,lambda)
```

## Description

`L = fspl(R,lambda)` returns the free space path loss in decibels for a waveform with wavelength `lambda` propagated over a distance of `R` meters. The minimum value of `L` is zero, indicating no path loss.

## Input Arguments

### `R`

real-valued 1-by-*M* or *M*-by-1 vector

Propagation distance of signal. Units are in meters.

### `lambda`

real-valued 1-by-*N* or *N*-by-1 vector

The wavelength is the speed of propagation divided by the signal frequency. Wavelength units are meters.

## Output Arguments

### `L`

Path loss in decibels. *M*-by-*N* nonnegative matrix. A value of zero signifies no path loss. When `lambda` is a scalar, `L` has the same dimensions as `R`.

# Examples

### Calculate Free-Space Path Loss

Calculate the free-space path loss (in dB) of a 10 GHz radar signal over a distance of 10 km.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
R = 10e3;
L = fspl(R,lambda)
```

```
L = 132.4478
```

# More About

## Free Space Path Loss

The free-space path loss, *L*, in decibels is:

$$L = 20\log_{10}(\frac{4\pi R}{\lambda})$$

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in a loss smaller than 0 dB, equivalent to a signal gain. For this reason, the loss is set to 0 dB for range values $R \leq \lambda/4\pi$.

# gain2aperture

Convert gain to effective aperture

## Syntax

```
A = gain2aperture(G,lambda)
```

## Description

`A = gain2aperture(G,lambda)` returns the effective aperture in square meters corresponding to a gain of `G` decibels for an incident electromagnetic wave with wavelength `lambda` meters. `G` can be a scalar or vector. If `G` is a vector, `A` is a vector of the same size as `G`. The elements of `A` represent the effective apertures for the corresponding elements of `G`. `lambda` must be a scalar.

## Input Arguments

### `G`

Antenna gain in decibels. `G` is a scalar or a vector. If `G` is a vector, each element of `G` is the gain in decibels of a single antenna.

### `lambda`

Wavelength of the incident electromagnetic wave. The wavelength of an electromagnetic wave is the ratio of the wave propagation speed to the frequency. For a fixed effective aperture, the antenna gain is inversely proportional to the square of the wavelength. `lambda` must be a scalar.

# Output Arguments

**A**

Antenna effective aperture in square meters. The effective aperture describes how much energy is captured from an incident electromagnetic plane wave. The argument describes the functional area of the antenna and is not equivalent to the actual physical area. For a fixed wavelength, the antenna gain is proportional to the effective aperture. A can be a scalar or vector. If A is a vector, each element of A is the effective aperture of the corresponding gain in G.

# Examples

### Compute Effective Aperture

An antenna has a gain of 3 dB. Calculate the antenna's effective aperture when used to capture an electromagnetic wave with a wavelength of 10 cm.

```
a = gain2aperture(3,0.1)
```

```
a = 0.0016
```

# More About

## Gain and Effective Aperture

The relationship between the gain, $G$, in decibels of an antenna and the antenna’s effective aperture is:

$$A_e = 10^{G/10}\frac{\lambda^2}{4\pi}$$

where λ is the wavelength of the incident electromagnetic wave.

# gaspl

RF signal attenuation due to atmospheric gases

## Syntax

```
L = gaspl(range,freq,T,P,den)
```

## Description

`L = gaspl(range,freq,T,P,den)` returns the attenuation, `L`, when signals propagate through the atmosphere. `range` represents the signal path length, and `freq` represents the signal carrier frequency. `T` represents the ambient temperature, `P` represents the atmospheric pressure, and `den` represents the atmospheric water vapor density.

The `gaspl` function applies the International Telecommunication Union (ITU) atmospheric gas attenuation model [1] to calculate path loss for signals primarily due to oxygen and water vapor. The model computes attenuation as a function of ambient temperature, pressure, water vapor density, and signal frequency. The function requires that the signal path is contained entirely in a uniform environment. Atmospheric parameters do not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

## Examples

### Atmospheric Gas Attenuation Spectrum

Compute the attenuation spectrum from 1 to 1000 GHz for an atmospheric pressure of 101.300 kPa and a temperature of 15˚C. Plot the spectrum for a water vapor density of 7.5 $g/m^3$ and then plot the spectrum for dry air (zero water vapor density).

Set the attenuation frequencies.

```
freq = [1:1000]*1e9;
```

Assume a 1 km path distance.

```
R = 1000.0;
```

Compute the attenuation for air containing water vapor.

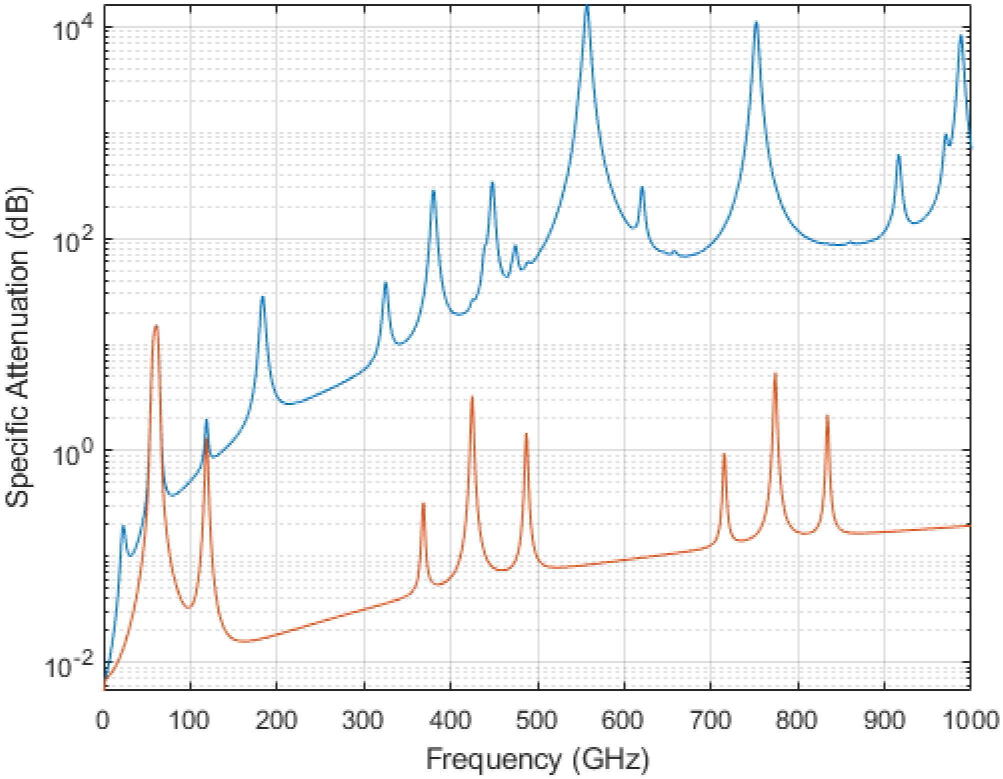
```
T = 15;
P = 101300.0;
W = 7.5;
L = gaspl(R,freq,T,P,W);
```

Compute the attenuation for dry air.

```
L0 = gaspl(R,freq,T,P,0.0);
```

Plot the attenuations.

```
semilogy(freq/1e9,L)
hold on
semilogy(freq/1e9,L0)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB)')
hold off
```



### Plot Attenuation Due to Atmospheric Gases and Free Space

First, plot the specific attenuation of atmospheric gases for frequencies from 1 GHz to 1000 GHz. Assume a sea-level dry air pressure of 101.325e5 kPa and a water vapor density of 7.5 $g/m^3$. The air temperature is 20˚C. Specific attenuation is defined as dB loss per kilometer. Then, plot the actual attenuation at 10 GHz for a span of ranges.

### Plot Specific Atmospheric Gas Attenuation

Set the atmosphere temperature, pressure, water vapor density.

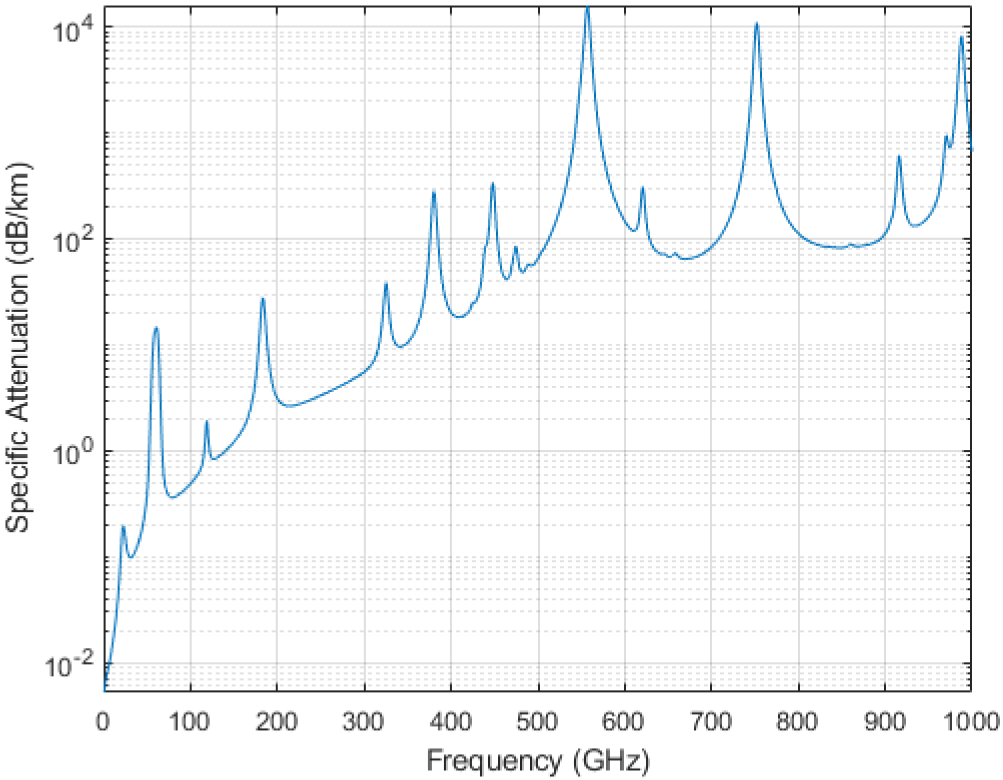
```
T = 20.0;
Patm = 101.325e3;
rho_wv = 7.5;
```

Set the propagation distance, speed of light, and frequencies.

```
km = 1000.0;
c = physconst('LightSpeed');
freqs = [1:1000]*1e9;
```

Compute and plot the atmospheric gas loss.

```
loss = gaspl(km,freqs,T,Patm,rho_wv);
semilogy(freqs/1e9,loss)
grid on
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```

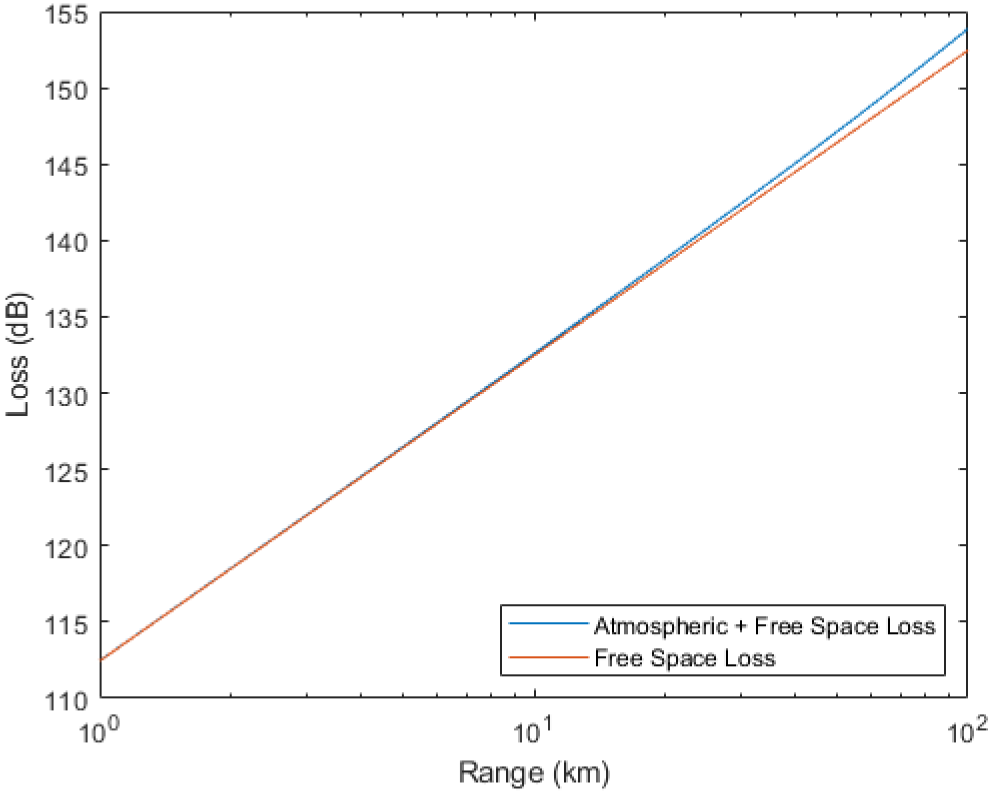


### Plot Actual Atmospheric and Free Space Attenuation

Compute both free space loss and atmospheric gas loss at 10 GHz for ranges from 1 to 100 km. The frequency corresponds to an *X*-band radar. Then, plot the free space loss and the total (atmospheric + free space) loss.

```
ranges = [1:100]*1000;
freq_xband = 10e9;
loss_gas = gaspl(ranges,freq_xband,T,Patm,rho_wv);
lambda = c/freq_xband;
loss_fsp = fspl(ranges,lambda);
semilogx(ranges/1000,loss_gas + loss_fsp.',ranges/1000,loss_fsp)
legend('Atmospheric + Free Space Loss','Free Space Loss','Location','SouthEast')
```

```
xlabel('Range (km)')
ylabel('Loss (dB)')
```



## Input Arguments

**range — Signal path length**

nonnegative real-valued scalar | *M*-by-1 nonnegative real-valued column vector | 1-by-*M* nonnegative real-valued row vector

Signal path length used to compute attenuation, specified as a nonnegative real-valued scalar or vector. You can specify multiple path lengths simultaneously. Units are in meters.

Example: `[13000.0,14000.0]`

### `freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar, or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. You can specify multiple frequencies simultaneously. Frequencies must lie in the range 1–1000 GHz. Units are in hertz.

Example: `[1.4e9,2.0e9]`

### T — Ambient temperature

real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

### P — Dry air pressure

positive real-valued scalar

Dry air pressure, specified as a positive real-valued scalar. Units are in Pa. One standard atmosphere at sea level is 101325 Pa.

Example: `101300.0`

### den — Water vapor density

nonnegative real-valued scalar

Water vapor density or absolute humidity, specified as a nonnegative real-valued scalar. Units are g/m$^3$. The maximum water vapor density of air at 30° C is approximately 30.0 g/m$^3$. The maximum water vapor density of air at 0°C is approximately 5.0 g/m$^3$.

Example: `4.0`

## Output Arguments

### L — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

# More About

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f) \,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_i$, multiplied by a spectral line strength, *S*$_i$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right] P \,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right] W \,.$$

$P$ is the dry air pressure, $W$ is the water vapor partial pressure, and $T$ is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, $W$, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}.$$

The total atmospheric pressure is $P + W$.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, $R$. Then, the total attenuation is $L_g= R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

`LOSChannel` | `WidebandLOSChannel` | `fogpl` | `fspl` | `rainpl`

**Introduced in R2016a**

# gccphat

Generalized cross-correlation

## Syntax

```
tau = gccphat(sig,refsig)
tau = gccphat(sig,refsig,fs)
[tau,R,lag] = gccphat( ___ )

[ ___ ] = gccphat(sig)
[ ___ ] = gccphat(sig,fs)
```

## Description

`tau = gccphat(sig,refsig)` computes the time delay, `tau`, between the signal, `sig`, and a reference signal, `refsig`. Both `sig` and `refsig` can have multiple channels. The function assumes that the signal and reference signal come from a single source. To estimate the delay, `gccphat` finds the location of the peak of the cross-correlation between `sig` and `refsig`. The cross-correlation is computed using the generalized cross-correlation phase transform (GCC-PHAT) algorithm. Time delays are multiples of the sample interval corresponding to the default sampling frequency of one hertz.

`tau = gccphat(sig,refsig,fs)`, specifies the sampling frequency of the signal. Time delays are multiples of the sample interval corresponding to the sampling frequency. All input signals should have the same sample rate.

`[tau,R,lag] = gccphat( ___ )` returns, in addition, the cross-correlation values and correlation time lags, using any of the arguments from previous syntaxes. The lags are multiples of the sampling interval. The number of cross-correlation channels equals the number of channels in `sig`.

`[ ___ ] = gccphat(sig)` or `[ ___ ] = gccphat(sig,fs)` returns the estimated delays and cross correlations between all pairs of channels in `sig`. If `sig` has $M$ columns, the resulting `tau` and `R` have $M^2$ columns. In these syntaxes, no reference signal input is used. The first $M$ columns of `tau` and `R` contain the delays and cross correlations that use the first channel as the reference. The second *M* columns contain the delays and cross-correlations that use the second channel as the reference, and so on.

## Examples

### Cross-Correlation Between Two Signals and Reference Signal

Load a gong sound signal. First, use the gong signal as a reference signal. Then, duplicate the signal twice, introducing time delays of 5 and 25 seconds. Leave the sampling rate to its default of one hertz. Use `gccphat` to estimate the time delays between the delayed signals and the reference signal.

```
load gong;
refsig = y;
delay1 = 5;
delay2 = 25;
sig1 = delayseq(refsig,delay1);
sig2 = delayseq(refsig,delay2);
tau_est = gccphat([sig1,sig2],refsig)
```

```
tau_est = 1×2

     5    25
```

### Cross-Correlation Between Signal and Reference Signal

Load a gong sound signal. Use the gong signal as a reference signal. Then, duplicate the signal, introducing a time delays of 5 milliseconds. Use the sampling rate of 8192 Hz. Use `gccphat` to estimate the time delay between the delayed signal and the reference signal.

```
load gong;
delay = 0.005;
refsig = y;
sig = delayseq(refsig,delay,Fs);
tau_est = gccphat(sig,refsig,Fs)
```

```
tau_est = 0.0050
```

### Plot Cross-Correlation of Three Signals with Reference Signal

Load a musical sound signal with a sample rate is 8192 hertz. Then, duplicate the signal three times and introduce time delays between the signals. Estimate the time delays between the delayed signals and the reference signals. Plot the correlation values.

```
load handel;
dt = 1/Fs;
refsig = y;
```

Create three delayed versions of the signal.

```
delay1 = -5.2*dt;
delay2 = 10.3*dt;
delay3 = 7*dt;
sig1 = delayseq(refsig,delay1,Fs);
sig2 = delayseq(refsig,delay2,Fs);
sig3 = delayseq(refsig,delay3,Fs);
```

Cross-correlate the delayed signals with the reference signal.

```
[tau_est,R,lags] = gccphat([sig1,sig2,sig3],refsig,Fs);
```

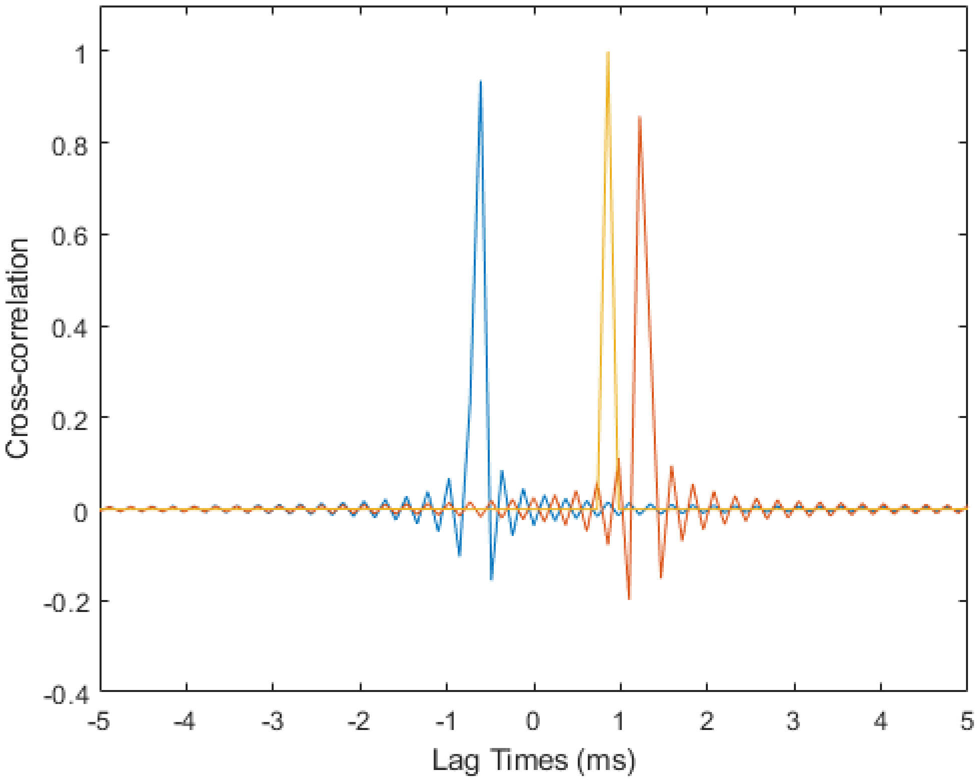
The `gccphat` functions estimates the delay to the nearest sample interval.

```
disp(tau_est*Fs)
```

```
    -5    10     7
```

Plot the correlation functions.

```
plot(1000*lags,real(R(:,1)))
xlabel('Lag Times (ms)')
ylabel('Cross-correlation')
axis([-5,5,-.4,1.1])
hold on
plot(1000*lags,real(R(:,2)))
plot(1000*lags,real(R(:,3)))
hold off
```



### Plot Cross-Correlation of Several Signals

Load a musical sound signal with a sample rate is 8192 hertz. Then, duplicate the signal two times and introduce time delays between the two signals and the reference signal. Estimate the time delays and plot the cross-correlation function between all pairs of signals.

```
load handel;
dt = 1/Fs;
refsig = y;
```

Create three delayed versions of the signal.

```
delay1 = -5.7*dt;
delay2 = 10.2*dt;
sig1 = delayseq(refsig,delay1,Fs);
sig2 = delayseq(refsig,delay2,Fs);
```

Cross-correlate all signals with the other signal.

```
[tau_est,R,lags] = gccphat([refsig,sig1,sig2],Fs);
```

Show the time delays in units of sample interval. The algorithm estimates time delays quantized to the nearest sample interval. Cross-correlation of three signals produce 9 possible time delays, one for each possible signal pair.

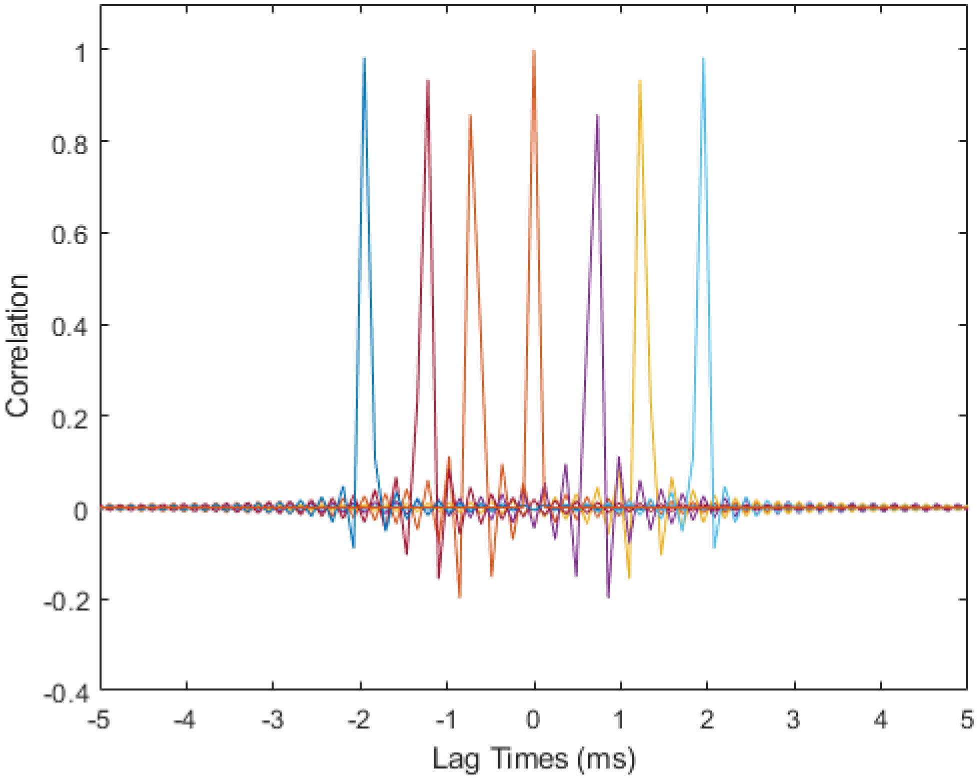
```
disp(tau_est*Fs)
```

```
     0    -6    10     6     0    16   -10   -16     0
```

A signal correlated with itself gives zero lag.

Plot the correlation functions.

```
for n=1:9
    plot(1000*lags,real(R(:,n)))
    if n==1
        hold on
        xlabel('Lag Times (ms)')
        ylabel('Correlation')
        axis([-5,5,-.4,1.1])
    end
end
hold off
```



## Input Arguments

### `sig` — Sensor signals

*N*-by-1 complex-valued column vector | *N*-by-*M* complex-valued matrix

Sensor signals, specified as an *N*-by-1 column vector or an *N*-by-*M* matrix. *N* is the number of time samples and *M* is the number of channels. If `sig` is a matrix, each column is a different channel.

Example: `[0,1,2,3,2,1,0]`

Data Types: `single` | `double`

Complex Number Support: Yes

### `refsig` — Reference sensor signals

*N*-by-1 complex-valued column vector | *N*-by-*M* complex-valued matrix

Reference signals, specified as an *N*-by-1 complex-valued column vector or an *N*-by-*M* complex-valued matrix. If `refsig` is a column vector, then all channels in `sig` use `refsig` as the reference signal when computing the cross-correlation.

If `refsig` is a matrix, then the size of `refsig` must match the size of `sig`. The `gccphat` function computes the cross-correlation between corresponding channels in `sig` and `refsig`. The signals can come from different sources.

Example: `[1,2,3,2,1,0,0]`

Data Types: `single` | `double`
Complex Number Support: Yes

### `fs` — Signal sample rate

1 (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. All signals should have the same sample rate. Sample rate units are in hertz.

Example: 8000

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### `tau` — Time delay

1-by-*K* real-valued row vector

Time delay, returned as a 1-by-*K* real-valued row vector. The value of *K* depends upon the input argument syntax.

- When a reference signal, `refsig`, is used, the value of *K* equals the column dimension of `sig`, *M*. Each entry in `tau` specifies the estimated delay for the corresponding signal pairs in `sig` and `refsig`.

- When no reference signal is used, the value of *K* equals the square of the column dimension of `sig`, $M^2$. Each entry in `tau` specifies the estimated delay for the corresponding signal pairs in `sig`.

Units are seconds.

**R — Cross-correlation between signals**
(2*N*+1)-by-*K* complex-valued matrix

Cross-correlation between signals at different sensors, returned as a (2*N*+1)-by-*K* complex-valued matrix.

- When a reference signal, `refsig`, is used, the value of *K* equals the column dimension of `sig`, *M*. Each column is the cross-correlation between the corresponding signal pairs in `sig` and `refsig`.
- When no reference signal is used, the value of *K* equals the square of the column dimension of `sig`, $M^2$. Each column is the cross-correlation between the corresponding signal pairs in `sig`.

**`lag` — Cross-correlation lag times**
(2*N*+1) real-valued column vector

Correlation lag times, returned as a *(2N+1)* real-valued column vector. Each row of `lag` contains the lag time for the corresponding row of `R`. Lag values are constrained to be multiples of the sampling interval. Lag units are in seconds.

# More About

## Generalized Cross-Correlation

You can use generalized cross-correlation to estimate the time difference of arrival of a signal at two different sensors.

A model of a signal emitted by a source and received at two sensors is given by:

$$r_1(t) = s(t) + n_1(t)$$

$$r_2(t) = s(t - D) + n_2(t)$$

where $D$ is the time difference of arrival (*TDOA*), or time lag, of the signal at one sensor with respect to the arrival time at a second sensor. You can estimate the time delay by finding the time lag that maximizes the cross-correlation between the two signals.

From the TDOA, you can estimate the broadside arrival angle of the plane wave with respect to the line connecting the two sensors. For two sensors separated by distance $L$, the broadside arrival angle, “Broadside Angles”, is related to the time lag by

$$\sin\beta = \frac{c\tau}{L}$$

where $c$ is the propagation speed in the medium.

A common method of estimating time delay is to compute the cross-correlation between signals received at two sensors. To identify the time delay, locate the peak in the cross-correlation. When the signal-to-noise ratio (SNR) is large, the correlation peak, $\tau$, corresponds to the actual time delay $D$.

$$R(\tau) = E\{r_1(t)r_2(t+\tau)\}$$

$$\widehat{D} \;=\; \underset{\tau}{\operatorname{argmax}} R(\tau)$$

When the correlation function is more sharply peaked, performance improves. You can sharpen a cross correlation peak using a weighting function that whitens the input signals. This technique is called generalized cross-correlation (GCC). One particular weighting function normalizes the signal spectral density by the spectrum magnitude, leading to the generalized cross-correlation phase transform method (*GCC-PHAT*).

$$S(f) = \int_{-\infty}^{\infty} R(\tau)e^{-i2\pi f\tau}d\tau$$

$$\tilde{R}(\tau) = \int_{-\infty}^{\infty} \frac{S(f)}{|S(f)|}e^{+i2\pi f\tau}df$$

$$\tilde{D} \;=\; \underset{\tau}{\operatorname{argmax}}\ \tilde{R}(\tau)$$

If you use just two sensor pairs, you can only estimate the broadside angle of arrival. However, if you use multiple pairs of non-collinear sensors, for example, in a URA, you can estimate the arrival azimuth and elevation angles of the plane wave using least-square estimation. For $N$ sensors, you can write the delay time $\tau_{kj}$ of a signal arriving at the $k^{th}$ sensor with respect to the $j^{th}$ sensor by

$$c\tau_{kj} = -\left(\overrightarrow{x}_k - \overrightarrow{x}_j\right) \cdot \overrightarrow{u}$$

$$\overrightarrow{u} = \cos\alpha\sin\theta\widehat{i} + \sin\alpha\sin\theta\widehat{j} + \cos\theta\widehat{k}$$

where $u$ is the unit propagation vector of the plane wave. The angles α and θ are the azimuth and elevation angles of the propagation vector. All angles and vectors are defined with respect to the local axes. You can solve the first equation using least-squares to yield the three components of the unit propagation vector. Then, you can solve the second equation for the azimuth and elevation angles.

# global2localcoord

Convert global to local coordinates

## Syntax

```
lclCoord = global2localcoord(gCoord, OPTION)
gCoord = global2localcoord( ___ ,localOrigin)
gCoord = global2localcoord( ___ ,localAxes)
```

## Description

`lclCoord = global2localcoord(gCoord, OPTION)` converts global coordinates `gCoord` to local coordinates `lclCoord`. `OPTION` determines the type of global-to-local coordinate transformation. In this syntax, the global coordinate origin is located at (0,0,0) and the coordinate axes are the unit vectors in the *x*, *y*, and *z* directions.

`gCoord = global2localcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system, `localOrigin`.

`gCoord = global2localcoord( ___ ,localAxes)` specifies the axes of the local coordinate system, `localAxes`.

## Input Arguments

### `gCoord`

Global coordinates in rectangular or spherical coordinate, specified as a is a 3-by-*N* matrix. Each column represents one set of global coordinates.

If the coordinates are in rectangular form, each column contains the (*x*,*y*,*z*) components. Units are in meters.

If the coordinates are in spherical form, each column contains (*az*,*el*,*r*) components. *az* is the azimuth angle on page 2-182 in degrees, *el* is the elevation angle on page 2-182 in degrees, and *r* is the radius in meters.

The origin of the global coordinate system is assumed to be located at (0, 0, 0). The global system axes are the standard unit basis vectors in three-dimensional space, (1, 0, 0), (0, 1, 0), and (0, 0, 1).

### `OPTION`

Type of coordinate transformation, specified as a character vector. Valid types are

| OPTION | Transformation |
|---|---|
| `'rr'` | Global rectangular to local rectangular |
| `'rs'` | Global rectangular to local spherical |
| `'sr'` | Global spherical to local rectangular |
| `'ss'` | Global spherical to local spherical |

### `localOrigin`

Origin of local coordinate system, specified as a 3-by-*N* matrix containing the rectangular coordinates of the local coordinate system origin with respect to the global coordinate system. *N* must match the number of columns of `gCoord`. Each column represents a separate origin. However, you can specify `localOrigin` as a 3-by-*1* vector. In this case, `localOrigin` is expanded into a 3-by-*N* matrix with identical columns.

**Default:** `[0;0;0]`

### `localAxes`

Axes of local coordinate system, specified as a 3-by-3-by-*N* array. Each page contains a 3-by-3 matrix representing a different local coordinate system axes. The columns of the 3-by-3 matrices specify the local *x*, *y*, and *z* axes in rectangular form with respect to the global coordinate system. However, you can specify `localAxes` as a single 3-by-3 matrix. In this case, `localAxes` is expanded into a 3-by-3-by-*N* array with identical 3-by-3 matrices. The default is the identity matrix.

**Default:** `[1 0 0;0 1 0;0 0 1]`

## Output Arguments

**`lclCoord`**

Local coordinates in rectangular or spherical coordinate form, returned as a 3-by-*N* matrix. The dimensions of `lclCoord` match the dimensions of `gCoord`.

## Examples

### Convert Global Coordinates to Local Coordinates

Convert global rectangular coordinates, *(0,1,0)*, to local rectangular coordinates. The local coordinate origin is *(1,1,1)*.

```
lclCoord = global2localcoord([0;1;0],'rr',[1;1;1])
```

```
lclCoord = 3×1

    -1
     0
    -1
```

Convert global spherical coordinates to local rectangular coordinates.

```
lclCoord = global2localcoord([45;45;50],'sr',[50;50;50])
```

```
lclCoord = 3×1

  -25.0000
  -25.0000
  -14.6447
```

### Convert Two Vectors Between Local and Global Coordinates

Convert two vectors in global coordinates into two vectors in global coordinates using the `global2local` function. Then convert them back to local coordinates using the `local2global` function.

Start with two vectors in global coordinates, *(0,1,0) and (1,1,1)*. The local coordinate origins are *(1,5,2)* and *(-4,5,7)*.

```
gCoord = [0 1; 1 1; 0 1]
```

```
gCoord = 3×2

     0     1
     1     1
     0     1
```

```
lclOrig = [1 -4; 5 5; 2 7];
```

Construct two rotation matrices using the rotation functions.

```
lclAxes(:,:,1) = rotz(45)*roty(-15);
lclAxes(:,:,2) = roty(45)*rotx(35);
```

Convert the vectors in global coordinates into local coordinates.

```
lclCoord = global2localcoord(gCoord,'rr',lclOrig,lclAxes)
```

```
lclCoord = 3×2

   -3.9327    7.7782
   -2.1213   -3.6822
   -1.0168    1.7151
```

Convert the vectors in local coordinates back into global coordinates.

```
gCoord1 = local2globalcoord(lclCoord,'rr',lclOrig,lclAxes)
```

```
gCoord1 = 3×2

   -0.0000    1.0000
    1.0000    1.0000
         0    1.0000
```

# More About

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.

# grazingang

Grazing angle of surface target

## Syntax

```
grazAng = grazingang(H,R)
grazAng = grazingang(H,R,MODEL)
grazAng = grazingang(H,R,MODEL,Re)
```

## Description

`grazAng = grazingang(H,R)` returns the grazing angle for a sensor `H` meters above the surface, to surface targets `R` meters away. The computation assumes a curved earth model with an effective earth radius of approximately 4/3 times the actual earth radius.

`grazAng = grazingang(H,R,MODEL)` specifies the earth model used to compute the grazing angle. `MODEL` is either `'Flat'` or `'Curved'`.

`grazAng = grazingang(H,R,MODEL,Re)` specifies the effective earth radius. Effective earth radius applies to a curved earth model. When `MODEL` is `'Flat'`, the function ignores `Re`.

## Input Arguments

### H

Height of the sensor above the surface, in meters. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions.

### R

Distance in meters from the sensor to the surface target. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions. `R` must be between `H` and the horizon range determined by `H`.

**`MODEL`**

Earth model, as one of | `'Curved'` | `'Flat'` |.

**Default:** `'Curved'`

**`Re`**

Effective earth radius in meters. This argument requires a positive scalar value.

**Default:** `effearthradius`, which is approximately 4/3 times the actual earth radius

# Output Arguments

**`grazAng`**

Grazing angle, in degrees. The size of `grazAng` is the larger of `size(H)` and `size(R)`.

# Examples

### Compute Grazing Angle

Determine the grazing angle (in degrees) of a path to a ground target located 1.0 km from a sensor. The sensor is mounted on a platform that is 300 m above the ground.

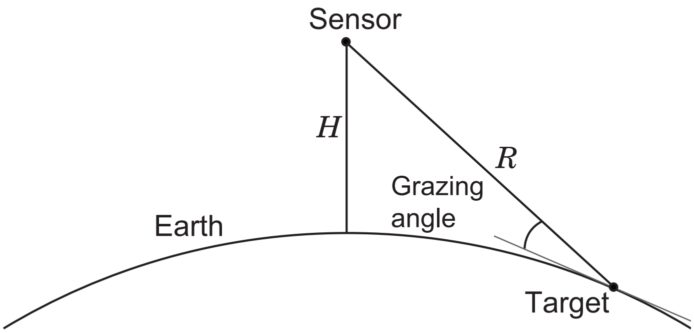
```
grazAng = grazingang(300,1.0e3)
```

```
grazAng = 17.4544
```

# More About

## Grazing Angle

The grazing angle is the angle between a line from the sensor to a surface target, and a tangent to the earth at the site of that target.



For the curved earth model with an effective earth radius of $R_e$, the grazing angle is:

$$\sin^{-1}\left(\frac{H^2 + 2HR_e - R^2}{2RR_e}\right)$$

For the flat earth model, the grazing angle is:

$$\sin^{-1}\left(\frac{H}{R}\right)$$

# horizonrange

Horizon range

## Syntax

```
Rh = horizonrange(H)
Rh = horizonrange(H,Re)
```

## Description

`Rh = horizonrange(H)` returns the horizon range of a radar system `H` meters above the surface. The computation uses an effective earth radius of approximately 4/3 times the actual earth radius.

`Rh = horizonrange(H,Re)` specifies the effective earth radius.

## Input Arguments

### H

Height of radar system above surface, in meters. This argument can be a scalar or a vector.

### Re

Effective earth radius in meters. This argument must be a positive scalar.

**Default:** `effearthradius`, which is approximately 4/3 times the actual earth radius

## Output Arguments

### Rh

Horizon range in meters of radar system at altitude `H`.

# Examples

### Compute Range to Horizon

Determine the range to horizon for an antenna that is 30 m high.

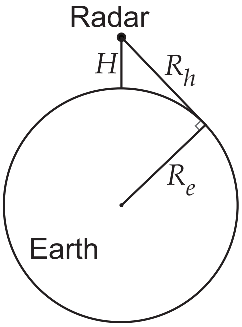
```
Rh = horizonrange(30)
```

```
Rh = 2.2553e+04
```

# More About

## Horizon Range

The horizon range of a radar system is the distance from the radar system to the earth along a tangent. Beyond the horizon range, the radar system detects no return from the surface through a direct path.



The value of the horizon range is:

$$\sqrt{2R_eH + H^2}$$

where $R_e$ is the effective earth radius and $H$ is the altitude of the radar system.

# lcmvweights

Narrowband linearly constrained minimum variance (LCMV) beamformer weights

## Syntax

```
wt = lcmvweights(constr,resp,cov)
```

## Description

`wt = lcmvweights(constr,resp,cov)` returns narrowband linearly-constrained minimum variance (LCMV) beamformer weights, `wt`, for a phased array. When applied to the elements of the array, these weights steer the response of the array toward a specific arrival direction or set of directions. LCMV beamforming requires that the beamformer response to signals from a direction of interest are passed with specified gain and phase delay. However, power from interfering signals and noise from all other directions is minimized. Additional constraints may be imposed to specifically nullify output power coming from known directions. The constraints are contained in the matrix, `constr`. Each column of `constr` represents a separate constraint vector. The desired response to each constraint is contained in the response vector, `resp`. The argument `cov` is the sensor spatial covariance matrix. All elements in the sensor array are assumed to be isotropic.

## Examples

### LCMV Beamformer with Nulls at -40 and 20 degrees

Construct a 10-element half-wavelength-spaced line array. Then, compute the LCMV weights for a desired arrival direction of 0 degrees azimuth. Impose three direction constraints : a null at -40 degrees, a unit desired response in the arrival direction 0 degrees, and another null at 20 degrees. The sensor spatial covariance matrix includes two signals arriving from -60 and 60 degrees and -10 dB isotropic white noise.

```
N = 10;
d = 0.5;
```

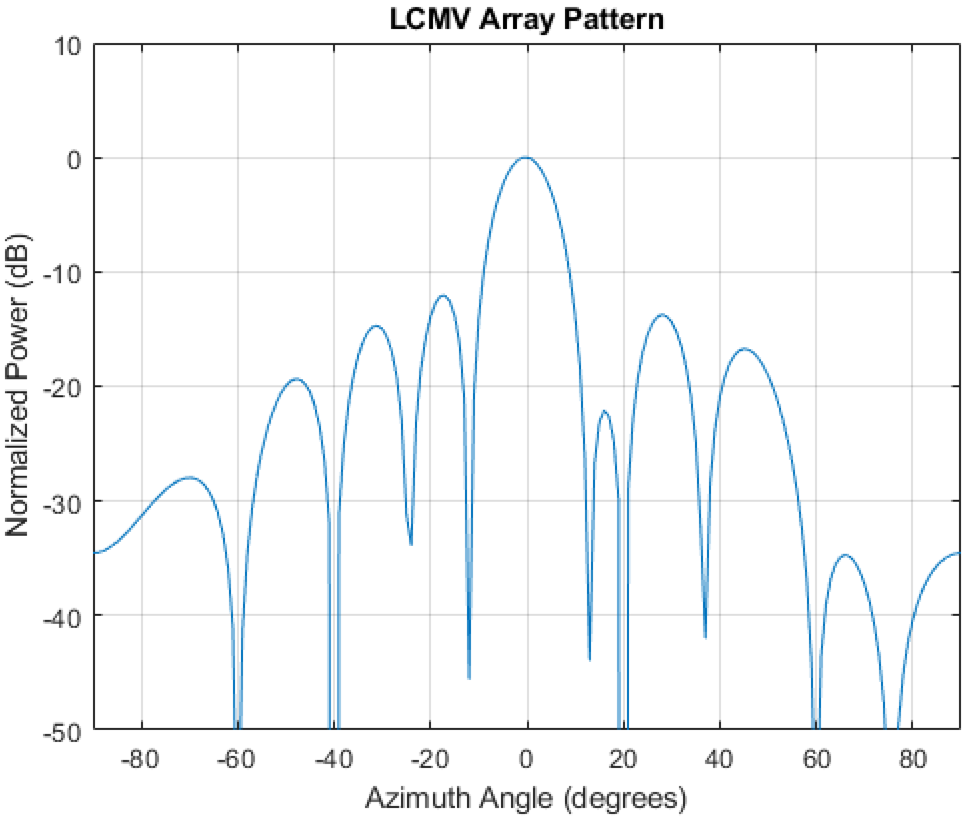
```
elementPos = (0:N-1)*d;
sv = steervec(elementPos,[-40 0 20]);
resp = [0 1 0]';
Sn  = sensorcov(elementPos,[-60 60],db2pow(-10));
```

Compute the beamformer weights.

```
w = lcmvweights(sv,resp,Sn);
```

Plot the array pattern for the computed weights.

```
vv = steervec(elementPos,[-90:90]);
plot([-90:90],mag2db(abs(w'*vv)))
grid on
axis([-90,90,-50,10]);
xlabel('Azimuth Angle (degrees)');
ylabel('Normalized Power (dB)');
title('LCMV Array Pattern');
```



The above figure shows that maximum gain is attained at 0 degrees as expected. In addition, the constraints impose nulls at -40 and 20 degrees and these can be seen in the plot. The nulls at -60 and 60 degrees arise from the fundamental property of the LCMV beamformer of suppressing the power contained in the two plane waves that contributed to the sensor spatial covariance matrix.

## Input Arguments

**`constr` — Constraint matrix**

*N*-by-*K* complex-valued matrix

Constraint matrix specified as a complex-valued, *N*-by-*K*, complex-valued matrix. In this matrix *N* represents the number of elements in the sensor array while *K* represents the number of constraints. Each column of the matrix specifies a constraint on the beamformer weights. The number of *K* must be less than or equal to *N*.

Example: [0, 0, 0; .1, .2, .3; 0,0,0]

Data Types: `double`
Complex Number Support: Yes

### `resp` — Desired response

*K*-by-1 complex-valued column vector.

Desired response specified as complex-valued, *K*-by-1 column vector where *K* is the number of constraints. The value of each element in the vector is the desired response to the constraint specified in the corresponding column of `constr`.

Example: [45;0]

Data Types: `double`
Complex Number Support: Yes

### `cov` — Sensor spatial covariance matrix

*N*-by-*N* complex-valued matrix

Sensor spatial covariance matrix specified as a complex-valued, *N*-by-*N* matrix. In this matrix, *N* represents the number of sensor elements. The covariance matrix consists of the variances of the element data and the covariance between sensor elements. It contains contributions from all incoming signals and noise.

Example: [45;0]

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `wt` — Beamformer weights

*N*-by-1 complex-valued vector

Beamformer weights returned as an *N*-by-1, complex-valued vector. In this vector, *N* represents the number of elements in the array.

# More About

## Linear-Constrained Minimum Variance Beamformers

The LCMV beamformer computes weights that minimize the total output power of an array but that are subject to some constraints (see Van Trees [1], p. 527). In order to steer the response of the array to a particular arrival direction, weights are chosen to produce unit gain when applied to the steering vector for that direction. This requirement can be thought of as a constraint on the weights. Additional constraints may be applied to nullify the array response to signals from other arrival directions such as those containing noise sources. Let $(az_1,el_1),(az_2,el_2),\ldots,(az_K,el_K)$ be the set of directions for which a constraint is to be imposed. Each direction has a corresponding steering vector, $\mathbf{c}_k$, and the response of the array to that steering vector is given by $\mathbf{c}_k^H\mathbf{w}$. The transpose conjugate of a vector is denoted by the superscript symbol $H$. A constraint is imposed when a desired response is required when the beamformer weights act on a steering vector, $\mathbf{c}_k$,

$$\mathbf{c}_k^H\mathbf{w} = r_k$$

This response could be specified as unity to allow the array to pass through the signal from a certain direction. It could be zero to nullify the response from that direction. All the constraints can be collected into a single matrix, $C$, and all the response into a single column vector, $\mathbf{R}$. This allows the constraints to be represented together in matrix form

$$C^H\mathbf{w} = \mathbf{R}$$

The LCMV beamformer chooses weights to minimize the total output power

$$P = \mathbf{w}^H S\mathbf{w}$$

subject to the above constraints. $S$ denotes the sensor spatial correlation matrix. The solution to the power minimization is

$$\mathbf{w} = S^{-1}C\left(C^H S^{-1}C\right)^{-1}\mathbf{R}$$

and its derivation can be found in [2].

# local2globalcoord

Convert local to global coordinates

## Syntax

```
gCoord = local2globalcoord(lclCoord,OPTION)
gCoord = local2globalcoord( ___ ,localOrigin)
gCoord = local2globalcoord( ___ ,localAxes)
```

## Description

`gCoord = local2globalcoord(lclCoord,OPTION)` converts local coordinates `lclCoord` to global coordinates `gCoord`. `OPTION` determines the type of local-to-global coordinate transformation.

`gCoord = local2globalcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system, `localOrigin`.

`gCoord = local2globalcoord( ___ ,localAxes)` specifies the axes of the local coordinate system, `localAxes`.

## Input Arguments

### `lclCoord`

Local coordinates in rectangular or spherical coordinate form, specified as a 3-by-*N* matrix. Each column represents one set of local coordinates.

If the coordinates are in rectangular form, each column contains the (*x*,*y*,*z*) components. Units are in meters.

If the coordinates are in spherical form, each column contains (*az*,*el*,*r*) components. *az* is the azimuth angle on page 2-182 in degrees, *el* is the elevation angle on page 2-182 in degrees, and *r* is the radius in meters.

### OPTION

Types of coordinate transformations, specified as a character vector. Valid values are

| OPTION | Transformation |
|---|---|
| 'rr' | Local rectangular to global rectangular |
| 'rs' | Local rectangular to global spherical |
| 'sr' | Local spherical to global rectangular |
| 'ss' | Local spherical to global spherical |

### localOrigin

Origin of local coordinate system, specified as a 3-by-*N* matrix containing the rectangular coordinates of the local coordinate system origin with respect to the global coordinate system. *N* must match the number of columns of `gCoord`. Each column represents a separate origin. However, you can specify `localOrigin` as a 3-by-*1* vector. In this case, `localOrigin` is expanded into a 3-by-*N* matrix with identical columns.

**Default:** `[0;0;0]`

### localAxes

Axes of local coordinate system, specified as a 3-by-3-by-*N* array. Each page contains a 3-by-3 matrix representing a different local coordinate system axes. The columns of the 3-by-3 matrices specify the local *x*, *y*, and *z* axes in rectangular form with respect to the global coordinate system. However, you can specify `localAxes` as a single 3-by-3 matrix. In this case, `localAxes` is expanded into a 3-by-3-by-*N* array with identical 3-by-3 matrices. The default is the identity matrix.

**Default:** `[1 0 0;0 1 0;0 0 1]`

## Output Arguments

### gCoord

Glabal coordinates in rectangular or spherical coordinate form, returned as a 3-by-*N* matrix. The dimensions of `gCoord` match the dimensions of `lclCoord`. The origin of the global coordinate system is assumed to be located at (0, 0, 0). The global system axes are the standard unit basis vectors in three-dimensional space, (1, 0, 0), (0, 1, 0), and (0, 0, 1).

## Examples

### Convert Local Rectangular Coordinates to Global Rectangular Coordinates

Convert from local rectangular coordinates to global rectangular coordinates. The local coordinate origin is a *(1,1,1)*

```
globalcoord = local2globalcoord([0;1;0], 'rr',[1;1;1])
```

```
globalcoord = 3×1

     1
     2
     1
```

### Convert Local Spherical Coordinates to Global Rectangular Coordinates

Convert local spherical coordinate to global rectangular coordinate.

```
globalcoord = local2globalcoord([30;45;4],'sr')
```

```
globalcoord = 3×1

    2.4495
    1.4142
    2.8284
```

### Convert Two Vectors Between Local and Global Coordinates

Convert two vectors in global coordinates into two vectors in global coordinates using the `global2local` function. Then convert them back to local coordinates using the `local2global` function.

Start with two vectors in global coordinates, *(0,1,0) and (1,1,1)*. The local coordinate origins are *(1,5,2)* and *(-4,5,7)*.

```
gCoord = [0 1; 1 1; 0 1]
```

```
gCoord = 3×2

     0     1
     1     1
     0     1
```

```
lclOrig = [1 -4; 5 5; 2 7];
```

Construct two rotation matrices using the rotation functions.

```
lclAxes(:,:,1) = rotz(45)*roty(-15);
lclAxes(:,:,2) = roty(45)*rotx(35);
```

Convert the vectors in global coordinates into local coordinates.

```
lclCoord = global2localcoord(gCoord,'rr',lclOrig,lclAxes)
```

```
lclCoord = 3×2

   -3.9327    7.7782
   -2.1213   -3.6822
   -1.0168    1.7151
```

Convert the vectors in local coordinates back into global coordinates.

```
gCoord1 = local2globalcoord(lclCoord,'rr',lclOrig,lclAxes)
```

```
gCoord1 = 3×2

   -0.0000    1.0000
    1.0000    1.0000
         0    1.0000
```

# More About

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.

nsig = mdltest(X,'fb')
```

## Description

`nsig = mdltest(X)` estimates the number of signals, `nsig`, present in a snapshot of data, `X`, that impinges upon the sensors in an array. The estimator uses the Minimum Description Length (MDL) test. The input argument, `X`, is a complex-valued matrix containing a time sequence of data samples for each sensor. Each row corresponds to a single time sample for all sensors.

`nsig = mdltest(X,'fb')` estimates the number of signals. Before estimating, it performs forward-backward averaging on the sample covariance matrix constructed from the data snapshot, `X`. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Estimate the Signal Subspace Dimensions for Two Arriving Signals

Construct a data snapshot of two plane waves arriving at a half-wavelength-spaced uniform line array having 10 elements. The plane waves arrive from 0° and –25° azimuth, both with elevation angles of 0°. Assume the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white. For each signal, the SNR is 5 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `mdltest`.

```
N = 10;
d = 0.5;
```

```
elementPos = (0:N-1)*d;
angles = [0 -25];
x = sensorsig(elementPos,300,angles,db2pow(-5));
Nsig = mdltest(x)
```

```
Nsig = 2
```

The result shows that the number of signals is two, as expected.

### Estimate the Signal Subspace Dimensions Using Forward-Backward Averaging

Construct a data snapshot for two plane waves arriving at a half-wavelength-spaced uniform line array with 10 elements. Correlated plane waves arrive from 0° and 10° azimuth, both with elevation angles of 0°. Assume the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white noise. For each signal, the SNR is 10 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `mdltest`.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 10];
ncov = db2pow(-10);
scov = [1 .5]'*[1 .5];
x = sensorsig(elementPos,300,angles,ncov,scov);
Nsig = mdltest(x)
```

```
Nsig = 1
```

This result shows that `mdltest` cannot determine the number of signals correctly when the signals are correlated.

Now, try the forward-backward smoothing option.

```
Nsig = mdltest(x,'fb')
```

```
Nsig = 2
```

The addition of forward-backward smoothing yields the correct number of signals.

# Input Arguments

**X — Data snapshot**

complex-valued *K*-by-*N* matrix

Data snapshot, specified as a complex-valued, *K*-by-*N* matrix. A snapshot is a sequence of time-samples taken simultaneous at each sensor. In this matrix, *K* represents the number of time samples of the data, while *N* represents the number of sensor elements.

Example: [ –0.1211 + 1.2549i, 0.1415 + 1.6114i, 0.8932 + 0.9765i; ]

Data Types: `double`
Complex Number Support: Yes

# Output Arguments

**`nsig` — Dimension of signal subspace**

non-negative integer

Dimension of signal subspace, returned as a non-negative integer. The dimension of the signal subspace is the number of signals in the data.

# More About

## Estimating the Number of Sources

AIC and MDL tests

Direction finding algorithms such as MUSIC and ESPRIT require knowledge of the number of sources of signals impinging on the array or equivalently, the dimension, $d$, of the signal subspace. The Akaike Information Criterion (AIC) and the Minimum Description Length (MDL) formulas are two frequently-used estimators for obtaining that dimension. Both estimators assume that, besides the signals, the data contains spatially and temporally white Gaussian random noise. Finding the number of sources is equivalent to finding the multiplicity of the smallest eigenvalues of the sampled spatial covariance matrix. The sample spatial covariance matrix constructed from a data snapshot is used in place of the actual covariance matrix.

A requirement for both estimators is that the dimension of the signal subspace be less than the number of sensors, *N*, and that the number of time samples in the snapshot, *K*, be much greater than *N*.

A variant of each estimator exists when forward-backward averaging is employed to construct the spatial covariance matrix. Forward-backward averaging is useful for the case when some of the sources are highly correlated with each other. In that case, the spatial covariance matrix may be ill conditioned. Forward-backward averaging can only be used for certain types of symmetric arrays, called centro-symmetric arrays. Then the forward-backward covariance matrix can be constructed from the sample spatial covariance matrix, *S*, using $S_{FB} = S + JS^*J$ where *J* is the exchange matrix. The exchange matrix maps array elements into their symmetric counterparts. For a line array, it would be the identity matrix flipped from left to right.

All the estimators are based on a cost function

$$L_d(d) = K(N-d)\ln\left\{\frac{\frac{1}{N-d}\sum_{i=d+1}^{N}\widehat{\lambda}_i}{\left\{\prod_{i=d+1}^{N}\widehat{\lambda}_i\right\}^{\frac{1}{N-d}}}\right\}$$

plus an added penalty term. The value $\lambda_i$ represent the smallest *(N–d)* eigenvalues of the spatial covariance matrix. For each specific estimator, the solution for *d* is given by

- AIC

$$\widehat{d}_{AIC} = \underset{d}{\operatorname{argmin}}\ \{L_d(d) + d(2N-d)\}$$

- AIC for forward-backward averaged covariance matrices

$$\widehat{d}_{AIC:FB} = \underset{d}{\operatorname{argmin}}\left\{L_d(d) + \frac{1}{2}d(2N-d+1)\right\}$$

- MDL

$$\widehat{d}_{MDL} = \underset{d}{\operatorname{argmin}}\left\{L_d(d) + \frac{1}{2}(d(2N-d)+1)\ln K\right\}$$

- MDL for forward-backward averaged covariance matrices

$$\widehat{d}_{MDL\,FB} = \underset{d}{\operatorname{argmin}} \left\{ L_d(d) + \frac{1}{4} d(2N - d + 1)\ln K \right\}$$

# mvdrweights

Minimum variance distortionless response (MVDR) beamformer weights

## Syntax

```
wt = mvdrweights(pos,ang,cov)
wt = mvdrweights(pos,ang,nqbits)
```

## Description

`wt = mvdrweights(pos,ang,cov)` returns narrowband minimum variance distortionless response (MVDR) beamformer weights for a phased array. When applied to the elements of an array, the weights steer the response of a sensor array in a specific arrival direction or set of directions. The `pos` argument specifies the sensor positions of the array. The `ang` argument specifies the azimuth and elevation angles of the desired response directions. `cov` is the sensor spatial covariance matrix between sensor elements. The output argument, `wt`, is a matrix contains the beamformer weights for each sensor and each direction. Each column of `wt` contains the weights for the corresponding direction specified in `ang`. All elements in the sensor array are assumed to be isotropic.

`wt = mvdrweights(pos,ang,nqbits)` returns quantized narrowband MVDR beamformer weights when the number of phase shifter bits is set to `nqbits`.

## Examples

### MVDR Beamformer with Arrival Directions of 30 and 45 Degrees

Construct a 10-element, half-wavelength-spaced line array. Choose two arrival directions of interest - one at 30° azimuth and the other at 45° azimuth. Assume both directions are at 0° elevation. Compute the MVDR beamformer weights for each direction. Specify a sensor spatial covariance matrix that contains signals arriving from -60° and 60° and noise at -10 dB.

Set up the array and sensor spatial covariance matrix.

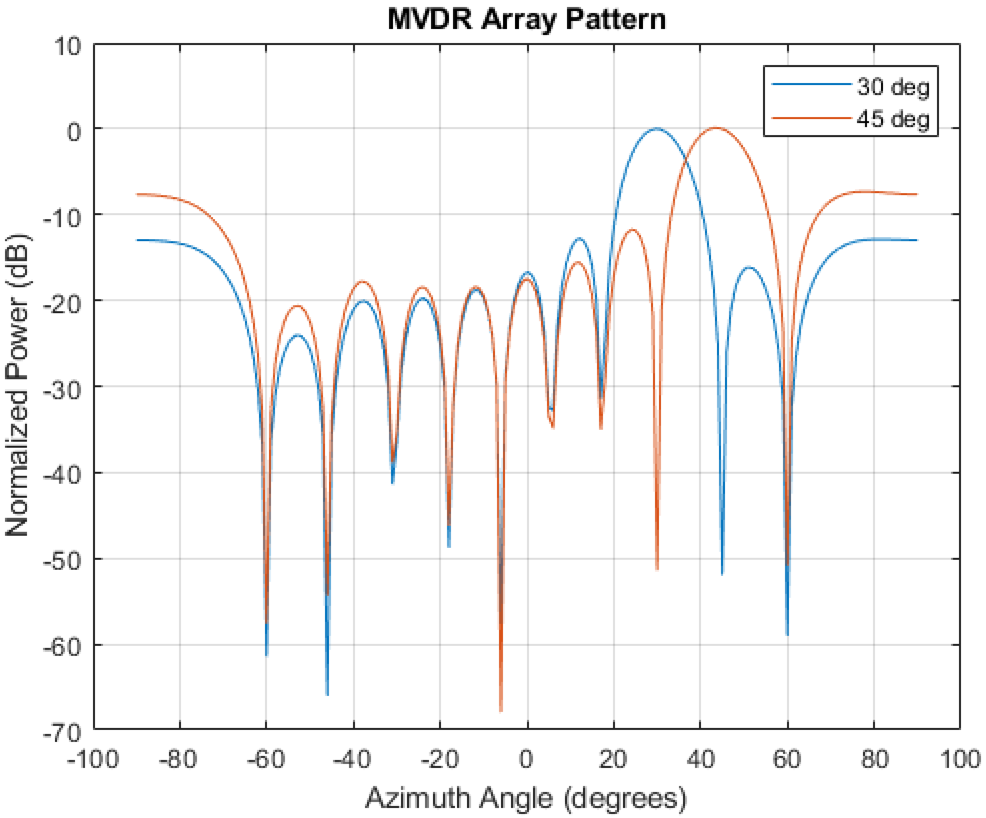
```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
Sn  = sensorcov(elementPos,[-60 60],db2pow(-10));
```

Solve for the MVDR beamformer weights.

```
w = mvdrweights(elementPos,[30 45],Sn);
```

Plot the two MVDR array patterns.

```
plotangl = -90:90;
vv = steervec(elementPos,plotangl);
plot(plotangl,mag2db(abs(w'*vv)))
grid on
xlabel('Azimuth Angle (degrees)');
ylabel('Normalized Power (dB)');
legend('30 deg','45 deg');
title('MVDR Array Pattern')
```



The figure shows plots for each beamformer direction. One plot has the expected maximum gain at 30 degrees and the other at 45 degrees. The nulls at -60 and 60 degrees arise from the fundamental property of the MVDR beamformer of suppressing power in all directions except for the arrival direction.

### Quantized Weights in MVDR Beamformer

Construct a 10-element, half-wavelength-spaced line array. Choose the arrival direction of interest to be 18.5° azimuth and 10° elevation. Compute the MVDR beamformer weights and then compute the weights for 3-bit quantization. Specify a sensor spatial covariance matrix that contains signals arriving from -60° and 60° and noise at -10 dB.

Set up the array and the sensor spatial covariance matrix.

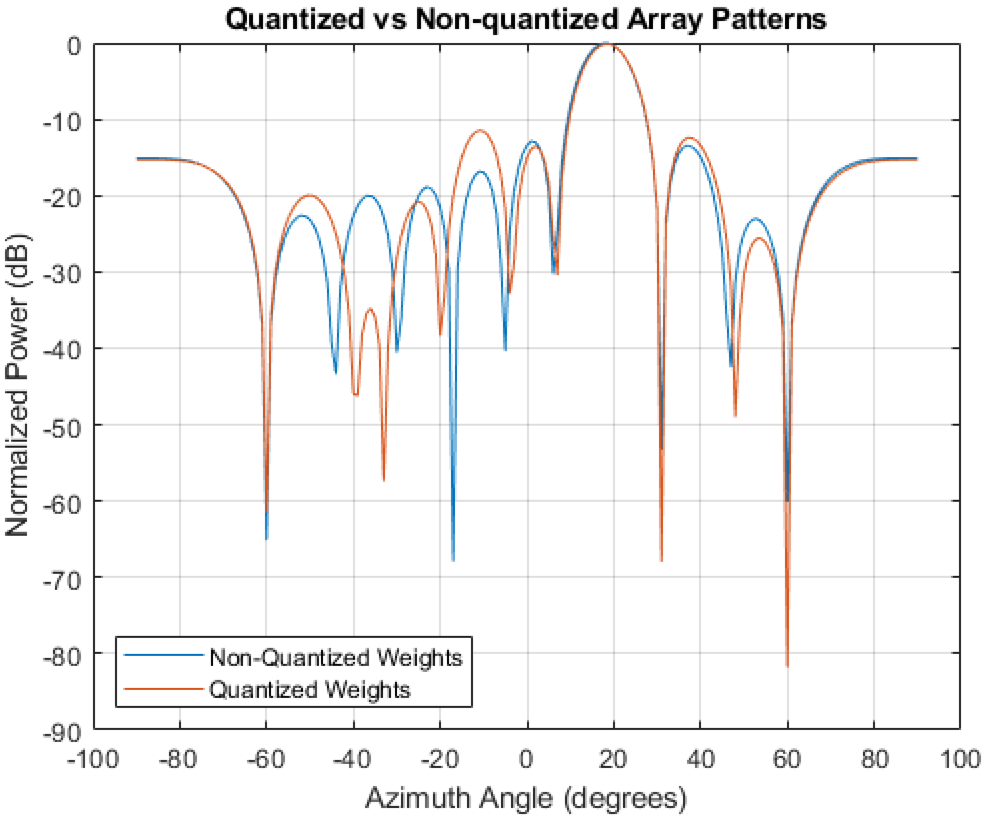
```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
SN  = sensorcov(elementPos,[-60 60],db2pow(-10));
```

Solve for the MVDR beamformer weights with and without quantization.

```
w = mvdrweights(elementPos,[18.5;10],SN);
wq = mvdrweights(elementPos,[18.5;10],SN,3);
```

Plot both MVDR array patterns.

```
plotangl = -90:90;
vv = steervec(elementPos,plotangl);
plot(plotangl,mag2db(abs(w'*vv)))
hold on
plot(plotangl,mag2db(abs(wq'*vv)))
grid on
xlabel('Azimuth Angle (degrees)')
ylabel('Normalized Power (dB)')
legend('Non-Quantized Weights','Quantized Weights','Location','SouthWest');
title('Quantized vs Non-quantized Array Patterns')
hold off
```



## Input Arguments

**pos — Positions of array sensor elements**

1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

**ang — Beamforming directions**
1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Beamforming directions specified as a 1-by-*M* vector or a 2-by-*M* matrix. In this vector or matrix, *M* represents the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the beamforming direction as `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the beamforming direction vector onto the *xy* plane. The angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the beamforming direction vector and *xy*-plane. It is positive when measured towards the positive *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: `[45;10]`

Data Types: `double`

**cov — Sensor spatial covariance matrix**
*N*-by-*N* complex-valued matrix

Sensor spatial covariance matrix specified as an *N*-by-*N*, complex-valued matrix. In this matrix, *N* represents the number of sensor elements.

Example: `[5,0.1;0.1,2]`

Data Types: `double`
Complex Number Support: Yes

**`nqbits` — Number of phase shifter quantization bits**
0 (default) | non-negative integer

Number of bits used to quantize the phase shift in beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: 5

# Output Arguments

**`wt` — Beamformer weights**

*N*-by-*M* complex-valued matrix

Beamformer weights returned as a complex-valued, *N*-by-*M* matrix. In this matrix, *N* represents the number of sensor elements of the array while *M* represents the number of beamforming directions. Each column of `wt` corresponds to a beamforming direction specified in `ang`.

# More About

## Minimum Variance Distortionless Response

MVDR beamformer weights minimize the total array output power while setting the gain in the desired response direction to unity (see Van Trees [1], p. 442). MVDR weights are given by

$$\mathbf{w} = \frac{S^{-1|}\mathbf{v_0}}{\mathbf{v_0}^{H}S^{-1}\mathbf{v_0}}$$

where $\mathbf{v}_0$ is the steering vector corresponding to the desired response direction. $S$ is the spatial covariance matrix. The covariance matrix consists of the variances of the element data and the covariances of the data between the sensor elements. The covariance contains contributions from all incoming signals and noise.

# musicdoa

Estimate arrival directions of signals using MUSIC

## Syntax

```
doas = musicdoa(covmat,nsig)
[doas,spec,specang] = musicdoa(covmat,nsig)
[ ___ ] = musicdoa(covmat,nsig, ___ ,'ScanAngles',scanangle)
[ ___ ] = musicdoa(covmat,nsig, ___ ,'ElementSpacing',dist)
```

## Description

`doas = musicdoa(covmat,nsig)` uses the MUSIC algorithm to estimate the directions of arrival, `doas`, of `nsig` plane waves received on a uniform linear array (ULA). The argument `covmat` is a positive-definite Hermitian matrix representing the sensor covariance matrix. Detected sources appear as peaks in the spatial spectrum. The argument `nsig` is the number of arriving signals. Sensor elements are spaced one-half wavelength apart in units of wavelengths. The function forces exact conjugate symmetry of `covmat` by averaging the covariance matrix with its conjugate transpose.

`[doas,spec,specang] = musicdoa(covmat,nsig)` also returns the spatial spectrum, `spec`, and the `nsig` angles of the spectrum peaks, `specang`.

`[ ___ ] = musicdoa(covmat,nsig, ___ ,'ScanAngles',scanangle)` specifies the grid of broadside angles to search for spectrum peaks.

`[ ___ ] = musicdoa(covmat,nsig, ___ ,'ElementSpacing',dist)` specifies the spacing between array elements.

## Examples

### Estimate DOA of Multiple Signals Using MUSIC

Calculate the directions of arrival of 3 uncorrelated signals arriving at an 11-element ULA with half-wavelength spacing. Assume the signals are coming from the broadside angles of 0°, –12°, and 85°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 5 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.5;
snr = 5.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 3;
angles = [0.0 -12.0 85.0];
```

Create the sensor covariance matrix.

```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Estimate the broadside arrival angles.

```
doas = musicdoa(covmat,nsig)
```

```
doas = 1×3

    85     0   -12
```

The estimated angles match the specified angles.

### Display MUSIC Spectrum of Multiple Signals

Calculate the directions of arrival of 3 uncorrelated signals arriving at an 11-element ULA with half-wavelength spacing. Assume the signals are coming from the broadside angles of 0°, –12°, and 85°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 2 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.5;
snr = 2.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 3;
angles = [0.0 -12.0 85.0];
```

Create the sensor covariance matrix.

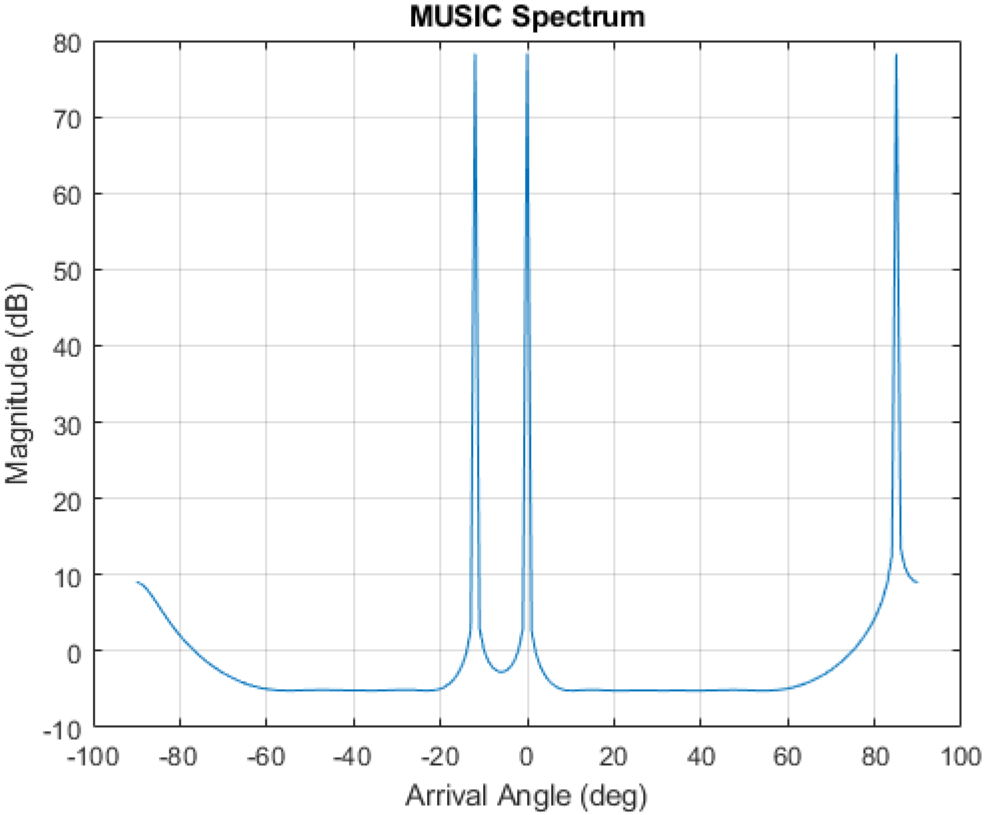
```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Compute the MUSIC spectrum and estimate the broadside arrival angles.

```
[doas,spec,specang] = musicdoa(covmat,nsig);
```

Plot the MUSIC spectrum.

```
plot(specang,10*log10(spec))
xlabel('Arrival Angle (deg)')
ylabel('Magnitude (dB)')
title('MUSIC Spectrum')
grid
```



The estimated angles match the specified angles.

### Display MUSIC Spectrum Over Specified Direction Span

Calculate the directions of arrival of 4 uncorrelated signals arriving at an 11-element ULA. The element spacing is 0.5 wavelengths. Assume the signals are coming from the broadside angles of –60.2°, –20.7°, 0.5°, and 84.8°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 0 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.5;
snr = 5.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 4;
angles = [-60.2 -20.7 0.5 84.8];
```

Create the sensor covariance matrix.

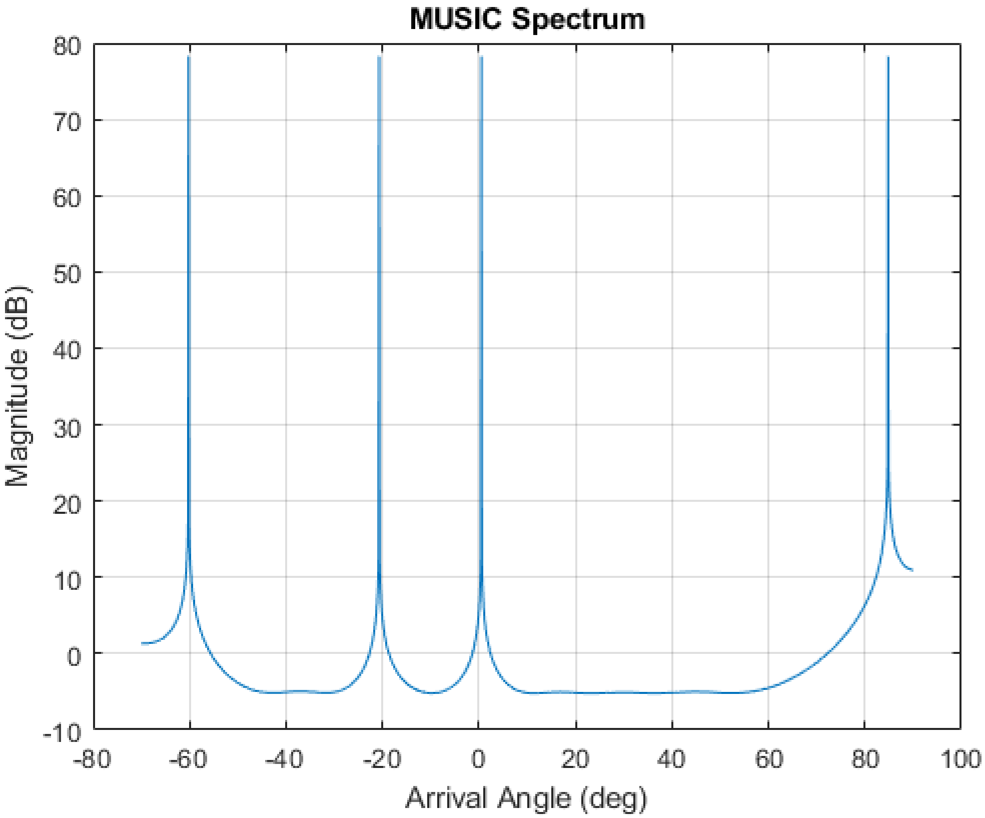
```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Compute the MUSIC spectrum and estimate the broadside arrival angles in the range from -70° to 90° in 0.1° increments.

```
[doas,spec,specang] = musicdoa(covmat,nsig,'ScanAngles',[-70:.1:90]);
```

Plot the MUSIC spectrum.

```
plot(specang,10*log10(spec))
xlabel('Arrival Angle (deg)')
ylabel('Magnitude (dB)')
title('MUSIC Spectrum')
grid
```



```
disp(doas)
```

```
    84.8000    0.5000  -60.2000  -20.7000
```

The estimated angles match the specified angles.

### Display MUSIC Spectrum with Specified Element Spacing

Calculate the directions of arrival of 4 uncorrelated signals arriving at an 11-element ULA. The element spacing is 0.4 wavelengths spacing. Assume the signals are coming from the broadside angles of –60°, –20°, 0°, and 85°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 0 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.4;
snr = 0.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 4;
angles = [-60.0 -20.0 0.0 85.0];
```

Create the sensor covariance matrix.

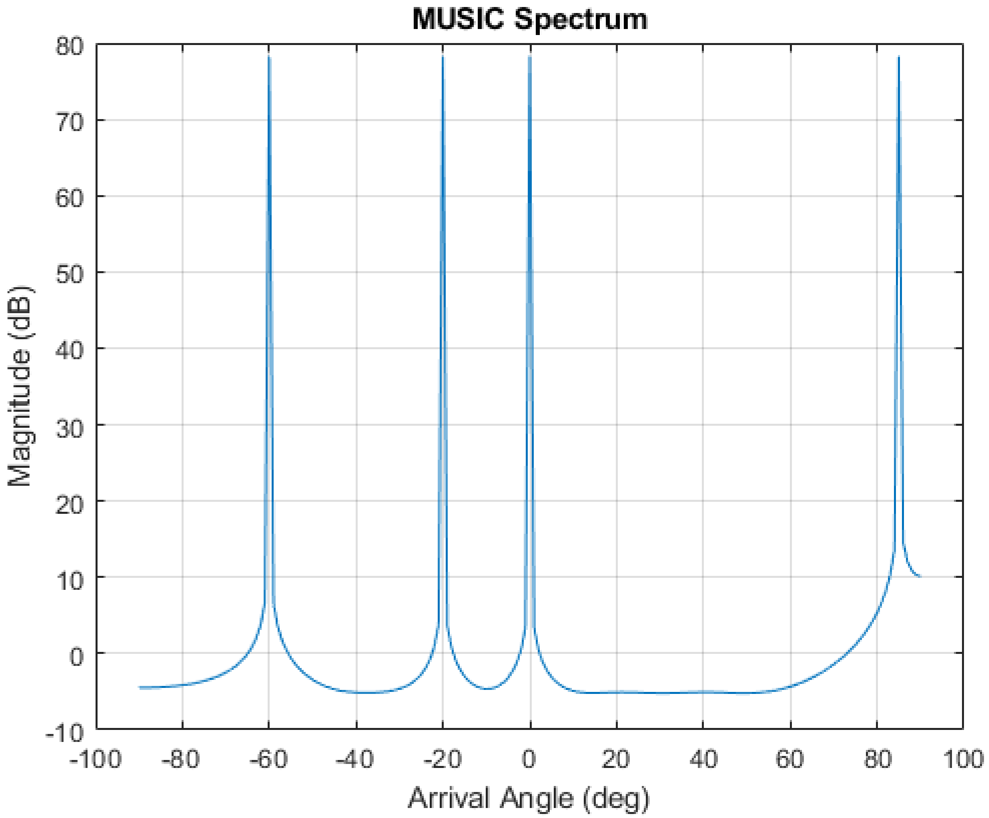
```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Compute the MUSIC spectrum and estimate the broadside arrival angles.

```
[doas,spec,specang] = musicdoa(covmat,nsig,'ElementSpacing',d);
```

Plot the MUSIC spectrum.

```
plot(specang,10*log10(spec))
xlabel('Arrival Angle (deg)')
ylabel('Magnitude (dB)')
title('MUSIC Spectrum')
grid
```



The estimated angles match the specified angles.

## Input Arguments

### **`covmat` — Sensor covariance matrix**

(default) | positive-definite complex-valued *M*-by-*M* matrix

Sensor covariance matrix, specified as a complex-valued, positive-definite *M*-by-*M* matrix. The quantity *M* is the number of elements in the ULA array. The function forces Hermiticity property by averaging the matrix and its conjugate transpose.

Data Types: `double`

Complex Number Support: Yes

### `nsig` — Number of arriving signals

positive integer

Number of arriving signals, specified as a positive integer. The number of signals must be smaller than the number of elements in the ULA array.

Example: `2`

Data Types: `double`

### `scanangle` — Broadside search angles

`[-90:90]` (default) | real-valued vector

Broadside search angles, specified as a real-valued vector. Angles must lie in the range (–90°,90°) and must be in increasing order.

Example: `[-40:0.5:50]`

Data Types: `double`

### `dist` — Distance between array elements

`0.5` (default) | real-valued positive scalar

Distance between array elements, specified as a real-valued positive scalar.

Example: `0.45`

Data Types: `double`

## Output Arguments

### `doas` — Directions of arrival angles

real-valued vector

Directions of arrival angle, returned as a real-valued 1-by-*D* vector, where *D* is the number of arriving signals specified in `nsig`. Angle units are in degrees. Angle values lie in the range specified by `scanangle`.

### `spec` — Spatial spectrum

positive real-valued vector

Spatial spectrum, returned as a positive real-valued vector. The dimension of `spec` equals the dimension of `scanangle`.

**specang — Broadside angles of spectrum peaks**
real-valued vector

Broadside angle of spectrum, returned as a real-valued vector. The dimension of `specang` equals the dimension of `scanangle`.

# noisepow

Receiver noise power

## Syntax

```
NPOWER = noisepow(NBW,NF,REFTEMP)
```

## Description

`NPOWER = noisepow(NBW,NF,REFTEMP)` returns the noise power, `NPOWER`, in watts for a receiver. This receiver has a noise bandwidth `NBW` in hertz, noise figure `NF` in decibels, and reference temperature `REFTEMP` in degrees kelvin.

## Input Arguments

### NBW

The noise bandwidth of the receiver in hertz. For a superheterodyne receiver, the noise bandwidth is approximately equal to the bandwidth of the intermediate frequency stages [1].

### NF

Noise figure. The noise figure is a dimensionless quantity that indicates how much a receiver deviates from an ideal receiver in terms of internal noise. An ideal receiver only produces the expected thermal noise power for a given noise bandwidth and temperature. A noise figure of 1 indicates that the noise power of a receiver equals the noise power of an ideal receiver. Because an actual receiver cannot exhibit a noise power value less than an ideal receiver, the noise figure is always greater than or equal to one.

### REFTEMP

Reference temperature in degrees kelvin. The temperature of the receiver. Typical values range from 290–300 degrees kelvin.

## Output Arguments

**NPOWER**

Noise power in watts. The internal noise power contribution of the receiver to the signal-to-noise ratio.

## Examples

### Compute Receiver Noise Power with Specified Temperature

Calculate the noise power of a receiver having a noise bandwidth of 10 kHz, a noise figure of 1 dB, and a reference temperature of 300 K.

```
npower = noisepow(10e3,1,300)
```

```
npower = 5.2144e-17
```

# npwgnthresh

Detection SNR threshold for signal in white Gaussian noise

## Syntax

```
snrthresh = npwgnthresh(pfa)
snrthresh = npwgnthresh(pfa,numpulses)
snrthresh = npwgnthresh(pfa,numpulses,dettype)
snrthresh = npwgnthresh(pfa,numpulses,dettype,outscale)
```

## Description

`snrthresh = npwgnthresh(pfa)` calculates the SNR threshold in decibels for detecting a deterministic signal in white Gaussian noise. The detection uses the Neyman-Pearson (NP) decision rule to achieve a specified probability of false alarm, `pfa`. This function uses a square-law detector.

**Note** The output of `npwgnthresh` determines the detection threshold required to achieve a particular Pfa. The threshold increases when pulse integration is used in the receiver. This threshold is not the single sample SNR that is used as an input to `rocsnr` or as the output of `rocpfa`, `albersheim`, and `shnidman`. For any fixed Pfa, you can decrease the single sample SNR required to achieve a particular Pd when pulse integration is used in the receiver. See “Signal Detection in White Gaussian Noise” and “Source Localization Using Generalized Cross Correlation” for examples of how to use `npwgnthresh` in a detection system.

`snrthresh = npwgnthresh(pfa,numpulses)` specifies `numpulses` as the number of pulses used in the pulse integration.

`snrthresh = npwgnthresh(pfa,numpulses,dettype)` specifies `dettype` as the type of detection. A square law detector is used in noncoherent detection.

`snrthresh = npwgnthresh(pfa,numpulses,dettype,outscale)` specifies the output scale.

## Input Arguments

### `pfa`

Probability of false alarm.

### `numpulses`

Number of pulses used in the integration.

**Default:** `1`

### `dettype`

Detection type.

Specifies the type of pulse integration used in the NP decision rule. Valid choices for `dettype` are `'coherent'`, `'noncoherent'`, and `'real'`. `'coherent'` uses magnitude and phase information of complex-valued samples. `'noncoherent'` uses squared magnitudes. `'real'` uses real-valued samples.

**Default:** `'noncoherent'`

### `outscale`

Output scale.

Specifies the scale of the output value as one of `'db'` or `'linear'`. When `outscale` is set to `'linear'`, the returned threshold represents amplitude.

**Default:** `'db'`

## Output Arguments

### `snrthresh`

Detection threshold expressed in signal-to-noise ratio in decibels or linear if `outscale` is set to `'linear'`. The relationship between the linear threshold and the threshold in dB is

$$T_{dB} = 20\log_{10}T_{lin}$$

## Examples

### Compute detection threshold from Pfa

Calculate the detection threshold that achieves a probability of false alarm (pfa) of 0.01. Assume a single pulse with a `real` detection type. Then, verify that this threshold produces a pfa of approximately 0.01. Do this by constructing 10000 real white gaussian noise (wgn) samples and computing the fraction of samples exceeding the threshold.

Compute the threshold from pfa. The detection threshold is expressed as a signal-to-noise ratio in db.

```
pfa = 0.01;
numpulses = 1;
snrthreshold = npwgnthresh(pfa,numpulses,'real')
```

```
snrthreshold = 7.3335
```

Compute fraction of simulated noise samples exceeding the threshold. The noise has unit power with 10000 samples.

```
noisepower = 1;
Ntrial = 10000;
noise = sqrt(noisepower)*randn(1,Ntrial);
```

Express the threshold in amplitude units.

```
threshold = sqrt(noisepower*db2pow(snrthreshold));
calculated_Pfa = sum(noise>threshold)/Ntrial
```

```
calculated_Pfa = 0.0107
```

### Detection Threshold Versus Number of Pulses

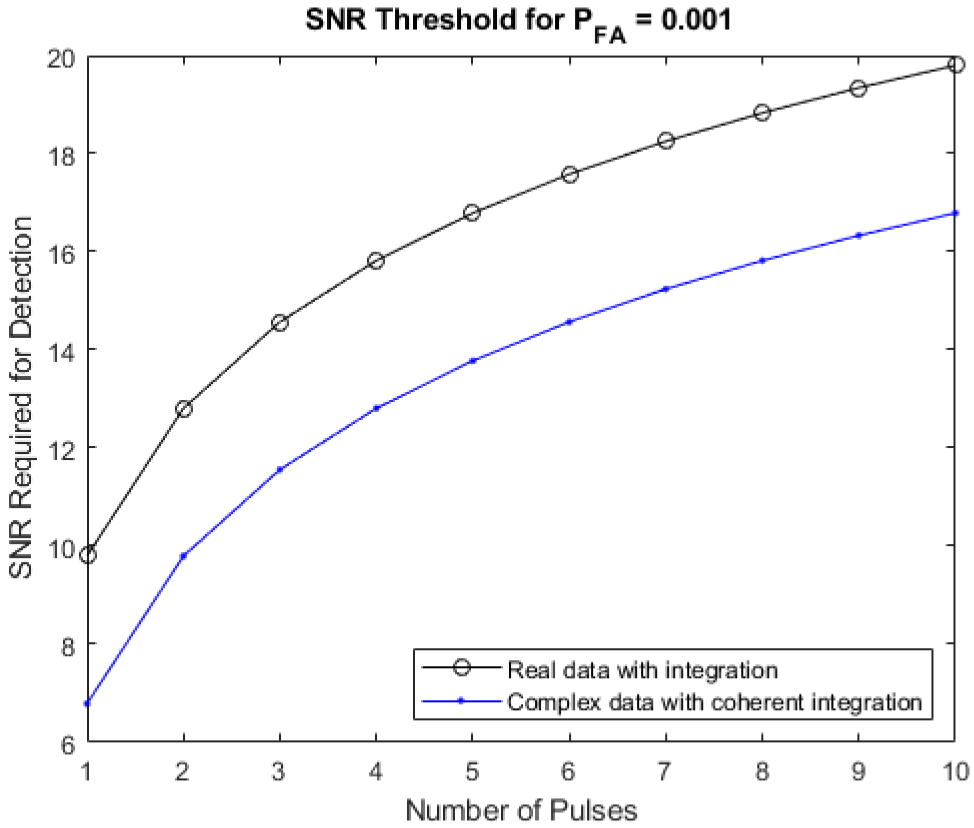
Plot the SNR detection threshold against the number of pulses, for real and complex noise. In each case, the SNR detection threshold is set for a probability of false alarm (pfa) of 0.001.

Compute detection threshold for 1 to 10 pulses of real and complex noise.

```
Npulses = 10;
snrcoh = zeros(1,Npulses);
snrreal = zeros(1,Npulses);
Pfa = 1e-3;
for num = 1:Npulses
    snrreal(num) = npwgnthresh(Pfa,num,'real');
    snrcoh(num)  = npwgnthresh(Pfa,num,'coherent');
end
```

Plot the detection thresholds against number of pulses.

```
plot(snrreal,'ko-')
hold on
plot(snrcoh,'b.-')
legend('Real data with integration',...
    'Complex data with coherent integration',...
    'location','southeast')
xlabel('Number of Pulses')
ylabel('SNR Required for Detection')
title('SNR Threshold for P_F_A = 0.001')
hold off
```



### Linear detection threshold versus number of pulses

Plot the linear detection threshold against the number of pulses, for real and complex data. In each case, the threshold is set for a probability of false alarm of 0.001.

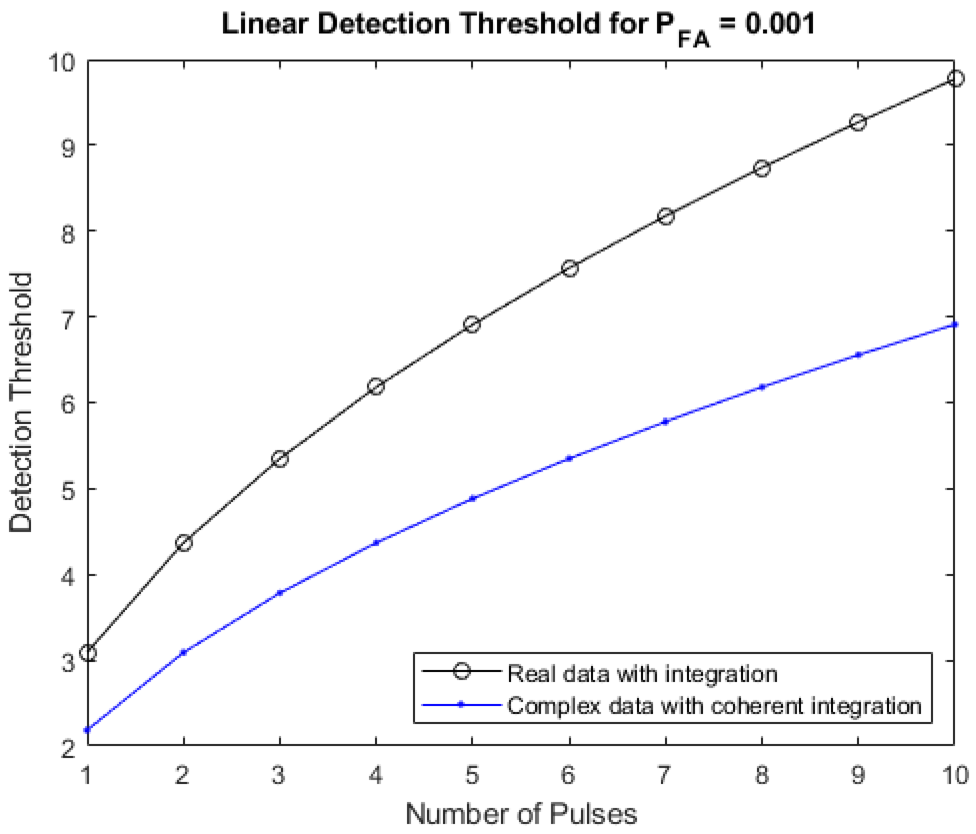
Compute detection threshold for 1 to 10 pulses of real and complex noise.

```
Npulses = 10;
snrcoh = zeros(1,Npulses); % preallocate space
snrreal = zeros(1,Npulses);
Pfa = 1e-3;
```

```
for num = 1:Npulses
    snrreal(num) = npwgnthresh(Pfa,num,'real','linear');
    snrcoh(num)  = npwgnthresh(Pfa,num,'coherent','linear');
end
```

Plot the detection thresholds against number of pulses.

```
plot(snrreal,'ko-')
hold on
plot(snrcoh,'b.-')
legend('Real data with integration',...
    'Complex data with coherent integration',...
    'location','southeast');
xlabel('Number of Pulses')
ylabel('Detection Threshold')
str = sprintf('Linear Detection Threshold for P_F_A = %4.3f',Pfa);
title(str)
hold off
```



# More About

## Detection in Real-Valued White Gaussian Noise

This function is designed for the detection of a nonzero mean in a sequence of Gaussian random variables. The function assumes that the random variables are independent and identically distributed, with zero mean. The linear detection threshold $\lambda$ for an NP detector is

$$\frac{\lambda}{\sigma} = \sqrt{2N}\,\mathrm{erfc}^{-1}(2P_{fa})$$

This threshold can also be expressed as a signal-to-noise ratio in decibels

$$10\log_{10}\left(\frac{\lambda^2}{\sigma^2}\right) = 10\log_{10}\left(2N\left(\mathrm{erfc}^{-1}(2P_{fa})\right)^2\right)$$

In these equations

- $\sigma^2$ is the variance of the white Gaussian noise sequence
- *N* is the number of samples
- *erfc*$^{-1}$ is the inverse of the complementary error function
- $P_{fa}$ is the probability of false alarm

**Note** For probabilities of false alarm greater than or equal to 1/2, the formula for detection threshold as SNR is invalid because erfc$^{-1}$ is less than or equal to zero for values of its argument greater than or equal to one. In that case, use the linear output of the function invoked by setting `outscale` to`'linear'`.

## Detection in Complex-Valued White Gaussian Noise (Coherent Samples)

The NP detector for complex-valued signals is similar to that discussed in "Source Localization Using Generalized Cross Correlation". In addition, the function makes these assumptions:

- The variance of the complex-valued Gaussian random variable is divided equally among the real and imaginary parts.
- The real and imaginary parts are uncorrelated.

Under these assumptions, the linear detection threshold for an NP detector is

$$\frac{\lambda}{\sigma} = \sqrt{N}\,\mathrm{erfc}^{-1}(2P_{fa})$$

and expressed as a signal-to-noise ratio in decibels is:

$$10\log_{10}\left(\frac{\lambda^2}{\sigma^2}\right) = 10\log_{10}\left(N\left(\mathrm{erfc}^{-1}(2P_{fa})\right)^2\right)$$

**Note** For probabilities of false alarm greater than or equal to 1/2, the formula for detection threshold as SNR is invalid because $\text{erfc}^{-1}$ is less than or equal to zero for when its argument is greater than or equal to one. In that case, select linear output for the function by setting `outscale` to `'linear'`.

### Detection of Noncoherent Samples in White Gaussian Noise

For noncoherent samples in white Gaussian noise, detection of a nonzero mean leads to a square-law detector. For a detailed derivation, see [2], pp. 324–329.

The linear detection threshold for the noncoherent NP detector is:

$$\frac{\lambda}{\sigma} = \sqrt{P^{-1}(N, 1 - P_{fa})}$$

The threshold expressed as a signal-to-noise ratio in decibels is:

$$10\log_{10}\left(\frac{\lambda^2}{\sigma^2}\right) = 10\log_{10}P^{-1}(N, 1 - P_{fa})$$

where $P^{-1}(x, y)$is the inverse of the lower incomplete gamma function, $P_{fa}$ is the probability of false alarm, and $N$ is the number of pulses.

# omphybweights

Compute hybrid beamforming weights using orthogonal matching pursuit

## Syntax

```
[wpbb,wprf] = omphybweights(chanmat,ns,ntrf,at)
[wpbb,wprf,wcbb,wcrf] = omphybweights(chanmat,ns,ntrf,at,nrrf,ar)
[ ___ ] = omphybweights(chanmat,ns,ntrf,at,nrrf,ar,npow)
```

## Description

`[wpbb,wprf] = omphybweights(chanmat,ns,ntrf,at)` returns the hybrid precoding weights `wpbb` and `wprf` for the channel matrix `chanmat`. The weights are computed using an orthogonal matching pursuit algorithm. `ns` is the number of independent data streams propagated through the channel. `ntrf` specifies the number of RF chains in the transmit array. `at` is a collection of possible analog weights for `wprf`. Together, the precoding weights approximate the optimal full digital precoding weights of `chanmat`.

`[wpbb,wprf,wcbb,wcrf] = omphybweights(chanmat,ns,ntrf,at,nrrf,ar)` also returns the hybrid combining weights `wcbb` and `wcrf`. The input `nrrf` specifies the number of RF chains in the receive array. `ar` is a collection of possible analog weights for `wcrf`.

`[ ___ ] = omphybweights(chanmat,ns,ntrf,at,nrrf,ar,npow)` also specifies the noise power `npow` in each receive antenna element. All subcarriers are assumed to have the same noise power.

## Examples

### Calculate Effective Channel Matrix

Assume a 8-by-4 MIMO system with four RF chains in a transmit array and two RF chains in a receive array. Show that the hybrid weights can support transmitting two data streams simultaneously.

Specify the positions of the transmitters and receivers in uniform line arrays.

```
txpos = (0:7)*0.5;
rxpos = (0:3)*0.5;
```

Construct the channel matrix.

```
chanmat = scatteringchanmtx(txpos,rxpos,10);
```

Specify the number of transmit and receive RF chains.

```
ntrf = 4;
nrrf = 2;
```

Specify two data streams.

```
ns = 2;
```

Set up the steering vector dictionaries for the transmitting and receiving arrays.

```
txdict = steervec(txpos,-90:90);
rxdict = steervec(rxpos,-90:90);
```

Compute the precoding and combining weights.

```
[Fbb,Frf,Wbb,Wrf] = omphybweights(chanmat,ns,ntrf,txdict,nrrf,rxdict);
```

Calculate the effective channel matrix from the weights. A diagonal effective channel matrix indicates the capability of simultaneous transmission of multiple data streams.

```
chan_eff = Fbb*Frf*chanmat*Wrf*Wbb
```

```
chan_eff = 2×2 complex

   1.0000 - 0.0000i   0.0000 + 0.0000i
   0.0000 - 0.0000i   1.0000 - 0.0000i
```

## Input Arguments

### `chanmat` — Channel response matrix

complex-valued $N_t$-by-$N_r$ matrix | complex-valued $L$-by-$N_t$-by-$N_r$ array

Channel response matrix, specified as an $N_t$-by-$N_r$ matrix or a complex-valued $L$-by-$N_t$-by-$N_r$ array where

- $N_t$ is the number of elements in the transmitting array.
- $N_r$ is the number of elements in the receiving array.
- $L$ is the number of subcarriers.

Data Types: `double`
Complex Number Support: Yes

### `ns` — Number of independent data streams

positive integer

Number of independent data streams propagated through the channel, specified as a positive integer.

Data Types: `double`

### `ntrf` — Number of RF chains in transmit array

positive integer

Number of RF chains in the transmit array, specified as a positive integer.

Data Types: `double`

### `at` — Collection of possible analog weights

complex-valued $N_t$-by-$P$ matrix | complex-valued $N_t$-by-$P$-by-$L$ array

Collection of possible analog weights for `wprf`, specified as a complex-valued matrix or array.

- When `chanmat` is an $N_t$-by-$N_r$ matrix, `at` is a complex-valued $N_t$-by-$P$ matrix. Each column represents a vector of analog weights.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ array, `at` is a complex-valued $N_t$-by-$P$-by-$L$ array. Each page is an $N_t$-by-$P$ matrix. Each column represents a vector of analog weights.
- $N_t$ is the number of elements in the transmitting array.

- $N_\mathrm{r}$ is the number of elements in the receiving array.
- $L$ is the number of subcarriers.
- $P$ is the number of vectors of analog weights in the collection.

Data Types: `double`
Complex Number Support: Yes

### `nrrf` — Number of RF chains in receive array

positive integer

Number of RF chains in the receive array, specified as a positive integer.

Data Types: `double`

### `ar` — Collection of possible analog weights

complex-valued $N_\mathrm{r}$-by-$Q$ matrix | complex-valued $N_\mathrm{r}$-by-$Q$-by-$L$ array

Collection of possible analog weights for `wprf`, specified as a complex-valued matrix or array.

- When `chanmat` is an $N_\mathrm{t}$-by-$N_\mathrm{r}$ matrix, `ar` is a complex-valued $N_\mathrm{r}$-by-$Q$ matrix. Each column represents a vector of analog weights.
- When `chanmat` is an $L$-by-$N_\mathrm{t}$-by-$N_\mathrm{r}$ array, `ar` is a complex-valued $N_\mathrm{r}$-by-$Q$-by-$L$ array. Each page is an $N_\mathrm{r}$-by-$Q$ matrix. Each column represents a vector of analog weights.
- $N_t$ is the number of elements in the transmitting array.
- $N_r$ is the number of elements in the receiving array.
- $L$ is the number of subcarriers.
- $Q$ is the number of vectors of analog weights in the collection.

Data Types: `double`
Complex Number Support: Yes

### `npow` — Noise power

0 (default) | nonnegative scalar

Noise power in each receive antenna element, specified as a nonnegative scalar. All subcarriers have the same noise power.

Data Types: `double`

## Output Arguments

### `wpbb` — Hybrid baseband precoding weights

complex-valued $N_s$-by-$N_{trf}$ matrix | complex-valued $L$-by-$N_s$-by-$N_{trf}$ array

Hybrid baseband precoding weights, returned as a complex-valued matrix or array.

- When `chanmat` is an $N_t$-by-$N_r$ matrix, `wpbb` is a complex-valued $N_s$-by-$N_{trf}$ matrix.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ array, `wpbb` is a complex-valued $L$-by-$N_s$-by-$N_{trf}$ array.
- $N_s$ is the number of independent data streams specified by the `ns` argument.
- $N_{trf}$ is the number of RF chains in the transmit array specified by the `ntrf` argument.
- $L$ is the number of subcarriers.

### `wprf` — Hybrid RF precoding weights

complex-valued $N_{trf}$-by-$N_t$ matrix | complex-valued $L$-by-$N_{trf}$-by-$N_t$ array

Hybrid RF precoding weights, returned as a complex-valued matrix or array.

- When `chanmat` is an $N_t$-by-$N_r$ matrix, `wprf` is a complex-valued $N_{trf}$-by-$N_t$ matrix.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ array, `wprf` is a complex-valued $L$-by-$N_{trf}$-by-$N_t$ array.
- $N_t$ is the number of elements in the transmitting array.
- $N_{trf}$ is the number of RF chains in the transmit array specified by the `ntrf` argument.
- $L$ is the number of subcarriers.

### `wcbb` — Hybrid baseband combining weights

complex-valued $N_{rrf}$-by-$N_s$ matrix | complex-valued $L$-by-$N_{rrf}$-by-$N_s$ array

Hybrid baseband combining weights, returned as a complex-valued matrix or array.

- When `chanmat` is an $N_t$-by-$N_r$ matrix, `wcbb` is a complex-valued $N_{rrf}$-by-$N_s$ matrix.
- When `chanmat` is an $L$-by-$N_t$-by-$N_r$ array, `wcbb` is a complex-valued $L$-by-$N_{rrf}$-by-$N_s$ array.
- $N_s$ is the number of independent data streams specified by the `ns` argument.
- $N_{rrf}$ is the number of RF chains in the receive array specified by the `nrrf` argument.
- $L$ is the number of subcarriers.

**`wcrf` — Hybrid RF combining weights**
complex-valued $N_\mathrm{r}$-by-$N_\mathrm{rrf}$ | complex-valued $L$-by-$N_\mathrm{r}$-by-$N_\mathrm{rrf}$ array

Hybrid RF combining weights, returned as a complex-valued matrix or array.

- When `chanmat` is an $N_\mathrm{t}$-by-$N_\mathrm{r}$ matrix, `wcrf` is a complex-valued $N_\mathrm{r}$-by-$N_\mathrm{rrf}$ matrix.
- When `chanmat` is an $L$-by-$N_\mathrm{t}$-by-$N_\mathrm{r}$ array, `wcrf` is a complex-valued $L$-by-$N_\mathrm{r}$-by-$N_\mathrm{rrf}$ array.
- $N_t$ is the number of elements in the transmitting array.
- $N_{rrf}$ is the number of RF chains in the receive array specified by the `nrrf` argument.
- $L$ is the number of subcarriers.

# More About

## Precoding Weights

The matrix product of the precoding weights `wpbb` x `wprf` approximates the optimal full digital precoding weights of the channel matrix `chanmat`.

## Combining Weights

The combining weights `wcbb` and `wcrf`, together with the precoding weights, diagonalize the channel into independent subchannels. The matrix product `wpbb` x `wprf` x `chanmat` x `wcrf`x `wcbb` is approximately diagonal.

# ompdecomp

Decompose signal using orthogonal matching pursuit

## Syntax

```
[coeff,dictatom,atomidx,errnorm] = ompdecomp(X,dict)
[coeff,dictatom,atomidx,errnorm] = ompdecomp(X,dict,'MaxSparsity',
nm)
[coeff,dictatom,atomidx,errnorm] = ompdecomp(X,dict,'NormWeight',
wts)
```

## Description

`[coeff,dictatom,atomidx,errnorm] = ompdecomp(X,dict)` computes the decomposition matrices `coeff` and `dictatom` of the signal `X`. The product of the decomposition matrices, `dictatom` x `coeff`, approximates `X`. The atoms in `dictatom` are selected from `dict`. `atomidx` are the indices in `dict` corresponding to `dictatom`. `errnorm` is the decomposition error. The decomposition is based on an *orthogonal matching pursuit* (OMP) algorithm that minimizes the Frobenius norm `||X – dictatom` x `coeff||`.

`[coeff,dictatom,atomidx,errnorm] = ompdecomp(X,dict,'MaxSparsity',nm)` also specifies the maximum sparsity `nm`.

`[coeff,dictatom,atomidx,errnorm] = ompdecomp(X,dict,'NormWeight',wts)` minimizes the weighted Frobenius norm `||wts`$^{1/2}$(`X – dictatom` x `coeff`)`||` using the weights `wts`.

## Examples

### Decompose ULA Beamsteering Weights

Given a set of optimal, full-digital, beamforming weights for an 8-element ULA, decompose the weights into a product of analog and digital beamforming weights.

Assume the system has two RF chains. Show that the combined weights achieve similar performance as the optimal weights.

Specify the optimal, full-digital, beamforming weigths.

```
wopt = steervec((0:7)*0.5,[20 -40]);
```

Create a dictionary of steering vectors.

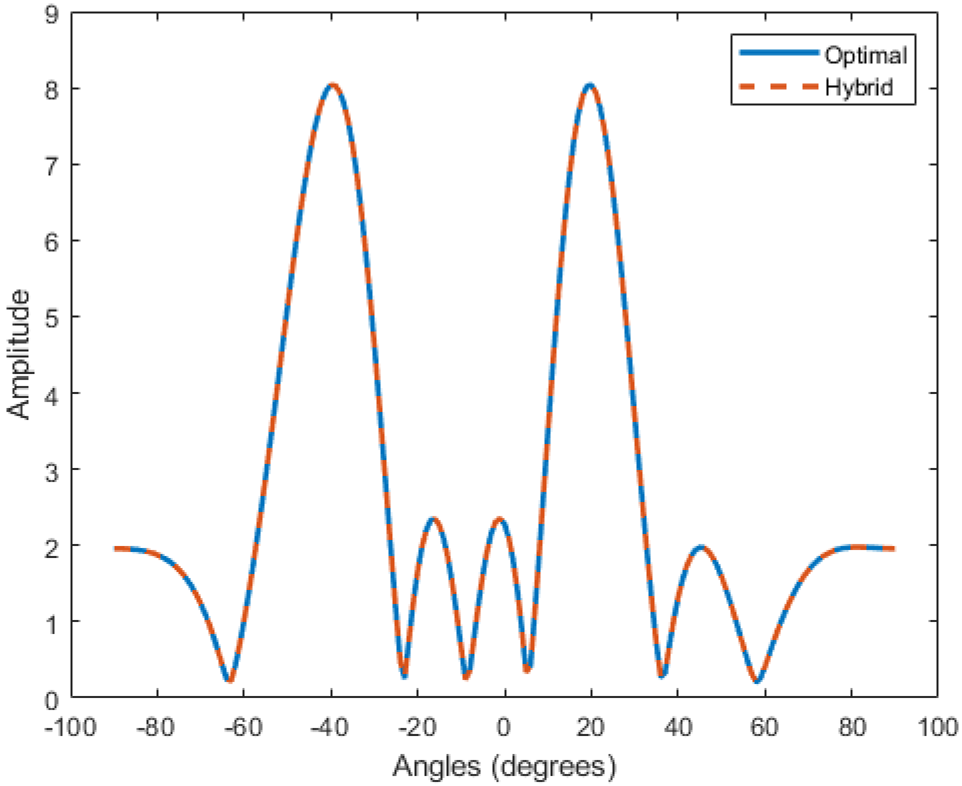
```
stvdict = steervec((0:7)*0.5,-90:90);
```

Perform the weights decomposition using OMP. Set the maximum sparsity to two.

```
[wbb,wrf,wdictidx,normerr] = ompdecomp(wopt,stvdict,'MaxSparsity',2);
```

Compare the beam patterns derived from the optimal weights and the hybrid weights. The plot shows that the decomposition of `wopt` into `wrf` and `wbb` is almost exact.

```
plot(-90:90,abs(sum(wopt'*stvdict)),'-', ...
    -90:90,abs(sum((wrf*wbb)'*stvdict)),'--','LineWidth',2)
xlabel('Angles (degrees)')
ylabel('Amplitude')
legend('Optimal','Hybrid')
```



## Input Arguments

### X — Input data

complex-valued $N$-by-$N_c$ matrix

Input data to be decomposed, specified as a complex-valued $N$-by-$N_c$ matrix.

Data Types: `double`
Complex Number Support: Yes

### `dict` — Dictionary of atoms

complex-valued matrix

Dictionary of atoms, specified as a complex-valued matrix. The function uses a subset of atoms from the dictionary to construct the data.

Data Types: `double`
Complex Number Support: Yes

### `nm` — Maximum sparsity

`1` (default) | positive integer

Maximum sparsity of the decomposition, specified as a positive integer. The decomposition stops when the sparsity of `nm` is achieved.

Example: `5`

**Dependencies**

Use this argument with the syntax specifying `'MaxSparsity'`.

Data Types: `double`

### `wts` — Norm weights

*N*-by-*N* identity matrix (default) | complex-valued *N*-by-*N* matrix

Norm weights used by OMP to minimize the weighted Frobenius norm of `||wts`$^{1/2}$ x (`X` – `dictatom` x `coeff`)`||`, specified as a complex-valued *N*-by-*N* matrix.

Example: `5`

**Dependencies**

Use this argument with the syntax specifying `'NormWeight'`.

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `coeff` — Coefficients of basis atoms

$N_s$-by-$N_c$ matrix

Coefficients of basis atoms, returned as an $N_s$-by-$N_c$ matrix. The rows represent the coefficients for the corresponding atoms in `dictatom`. $N_s$ represents the number of atoms selected from the dictionary and is a measure of signal sparsity.

Data Types: double
Complex Number Support: Yes

**dictatom — Signal basis atoms**
$N$-by-$N_s$ matrix

Signal basis atoms, returned as an $N$-by-$N_s$ matrix. The columns are the atoms forming the basis of the signal. These atoms are a subset of the dictionary specified in dict. $N_s$ represents the number of selected atoms and is a measure of signal sparsity.

Data Types: double
Complex Number Support: Yes

**atomidx — Indices of selected atoms**
integer-valued length-$N_s$ row vector

Indices of the atoms selected from the dictionary dict, returned as a length-$N_s$ row vector where dict(:,atomidx) = dictatom.

Data Types: double

**errnorm — Norm of decomposition error**
0 (default) | nonnegative scalar

Norm of the decomposition error, returned as a nonnegative scalar.

Data Types: double

# More About

## Hybrid Beamforming Weights

In the context of hybrid beamforming, the coeff argument represents digital weights. dictatom represents analog weights and dict is a collection of steering vectors that can be used as analog weights.

# pambgfun

Periodic ambiguity function

## Syntax

```
pafmag = pambgfun(X,fs)
[pafmag,delay,doppler] = pambgfun(X,fs)
[pafmag,delay,doppler] = pambgfun(X,fs,P)

[pafmag,delay] = pambgfun( ___ ,'Cut','Doppler')
[pafmag,delay] = pambgfun( ___ ,'Cut','Doppler','CutValue',V)
[pafmag,doppler] = pambgfun( ___ ,'Cut','Delay')
[pafmag,doppler] = pambgfun( ___ ,'Cut','Delay','CutValue',V)
[pafmag,delay,doppler] = pambgfun( ___ ,'Cut','2D')

pambgfun( ___ )
```

## Description

`pafmag = pambgfun(X,fs)` returns the magnitude of the normalized periodic ambiguity function (PAF) for one period of the periodic signal `X`. `fs` is the sampling rate.

`[pafmag,delay,doppler] = pambgfun(X,fs)` also returns the time delay vector, `delay`, and the Doppler shift vector, `doppler`. The delay vector is along the zero Doppler cut of the PAF. The Doppler shift vector is along the zero delay cut.

`[pafmag,delay,doppler] = pambgfun(X,fs,P)` returns the magnitude of the normalized PAF for `P` periods of the periodic signal `X`.

`[pafmag,delay] = pambgfun( ___ ,'Cut','Doppler')` returns the PAF, `pafmag`, along a zero Doppler cut. The `delay` argument contains the time delay vector corresponding to the columns of `pafmag`.

`[pafmag,delay] = pambgfun( ___ ,'Cut','Doppler','CutValue',V)` returns the PAF, `pafmag`, along a nonzero Doppler cut specified by `V`. The `delay` argument contains the time delay vector corresponding to the columns of `pafmag`.

[pafmag,doppler] = pambgfun( ___ ,'Cut','Delay') returns the PAF, pafmag, along the zero delay cut. The doppler argument contains the Doppler shift vector corresponding to the rows of pafmag.

[pafmag,doppler] = pambgfun( ___ ,'Cut','Delay','CutValue',V) returns the PAF, pafmag, along a nonzero delay cut specified by V. The doppler argument contains the Doppler shift vector corresponding to the rows of pafmag.

[pafmag,delay,doppler] = pambgfun( ___ ,'Cut','2D') returns the PAF, pafmag, for all delays and Doppler shifts. The doppler argument contains the Doppler shift vector corresponding to the rows of pafmag. The delay argument contains the time delay vector corresponding to the columns of pafmag. You cannot use 'CutValue' when 'Cut' is set to '2D'.

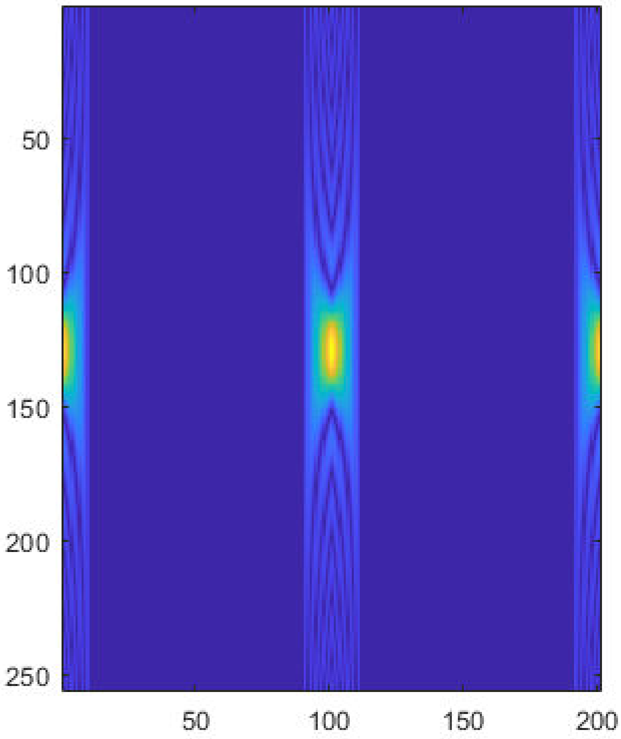
pambgfun( ___ ) with no output arguments plots the PAF. When 'Cut' is '2D', the function produces a contour plot of the PAF function. When 'Cut' is 'Delay' or 'Doppler', the function produces a line plot of the PAF cut.

## Examples

### Periodic Ambiguity Function for Rectangular Waveform

Plot the PAF function of a rectangular pulse waveform for one period. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF.

```
PRF = 10.0e3;
fs = 101*PRF;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
pamf = pambgfun(wav,fs);
imagesc(pamf)
axis equal
axis tight
```



### Periodic Ambiguity Function with Delay and Doppler Output

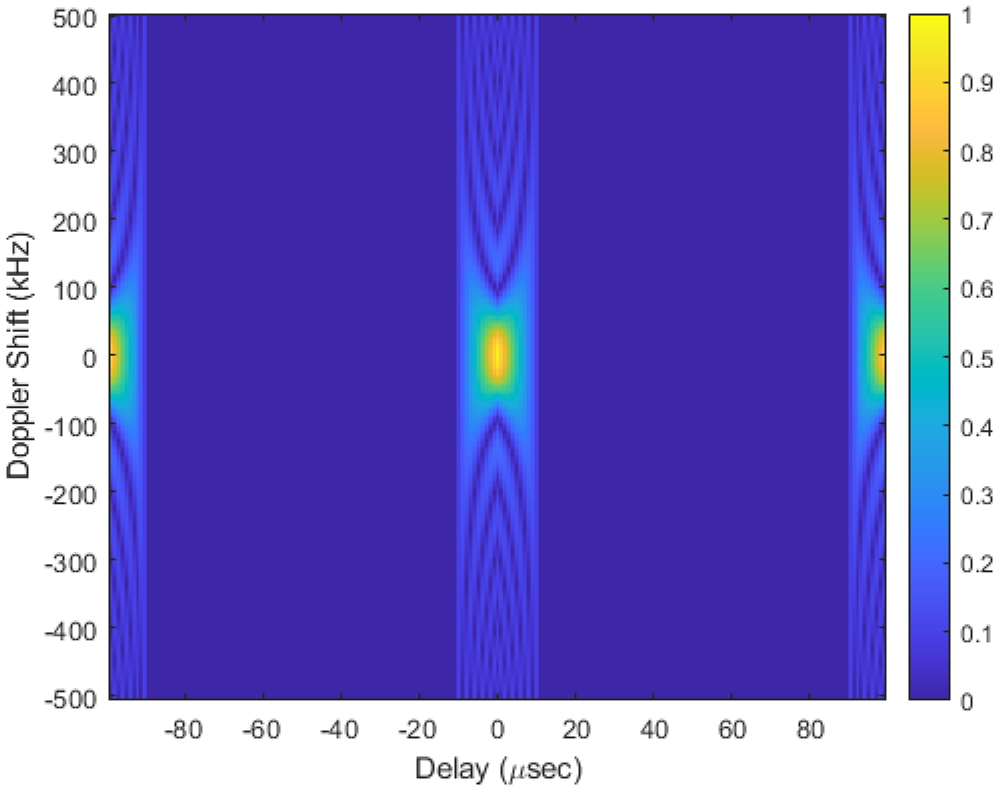
Plot the periodic ambiguity function of a rectangular pulse waveform for one period. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF. Return the Doppler and delay values from the `pambgfun` function.

```
PRF = 10.0e3;
fs = 101*PRF;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
```

```
wav = waveform();
[pamf,delays,doppler] = pambgfun(wav,fs);
```

Plot the periodic ambiguity function.

```
imagesc(delays*1e6,doppler/1000,pamf)
axis xy
xlabel('Delay (\musec)')
ylabel('Doppler Shift (kHz)')
colorbar
```



### Zero Delay Cut of Periodic Ambiguity Function

Plot a cut at zero delay for the periodic ambiguity function of a rectangular pulse waveform for five periods. Assume the pulse repetition frequency is 10.0 kHz and that the sampling frequency is a multiple of the PRF. Return the Doppler and delay values from the function.

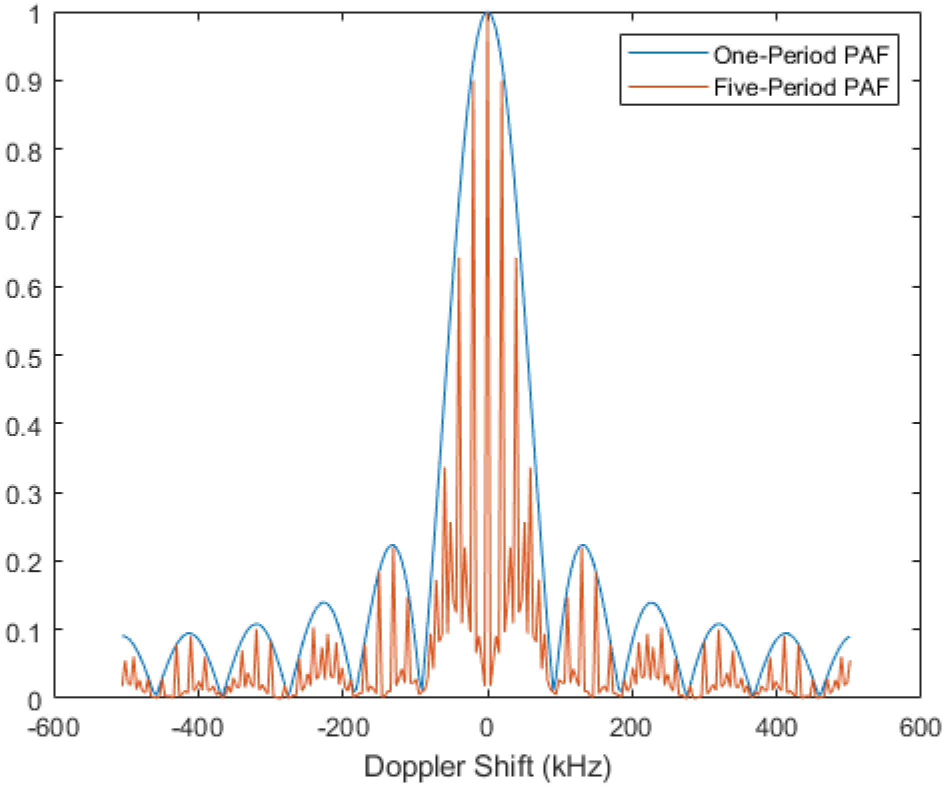
```
PRF = 10.0e3;
fs = 101*PRF;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the periodic ambiguity functions along a zero delay cut for one and for five periods.

```
[pamf,delays,doppler] = pambgfun(wav,fs,1);
f1 = pamf(:,101);
[pamf,delays,doppler] = pambgfun(wav,fs,5);
f2 = pamf(:,101);
```

Plot the periodic ambiguity functions.

```
plot(doppler/1000,f1)
hold on
plot(doppler/1000,f2)
xlabel('Doppler Shift (kHz)')
legend('One-Period PAF','Five-Period PAF')
```



### Zero Doppler Cut of LFM Periodic Ambiguity Function

Plot the zero Doppler cut for the five-period periodic ambiguity function of a linear FM pulse waveform. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF. Return the Doppler and delay values from the `pambgfun` function.

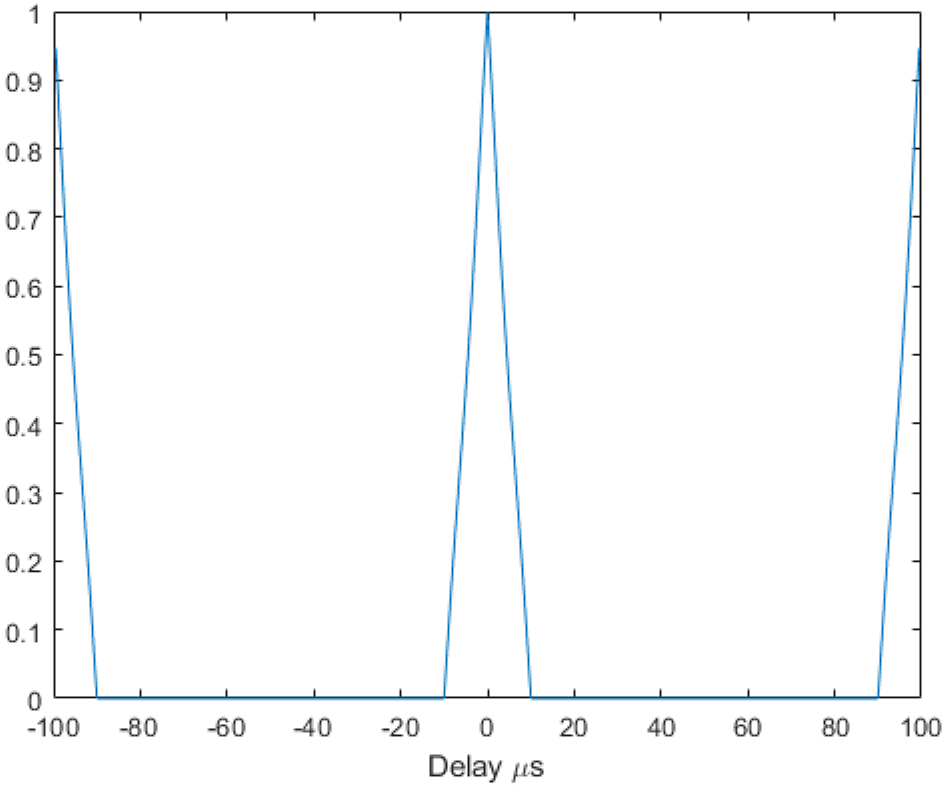
```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the five-period periodic ambiguity function along a zero Doppler cut.

```
[pamf,delays] = pambgfun(wav,fs,5,'Cut','Doppler');
```

Plot the periodic ambiguity functions.

```
plot(delays*1.0e6,pamf)
xlabel('Delay \mus')
```



### Non-Zero Doppler Cut of LFM Periodic Ambiguity Function

Plot a non-zero Doppler cut for the 5-period periodic ambiguity function of a linear FM pulse waveform by explicitly specifying the cut value. Assume the pulse repetition frequency is 10.0e3 Hz and that the sampling frequency is a multiple of the PRF. Return the doppler and delay values from the function.

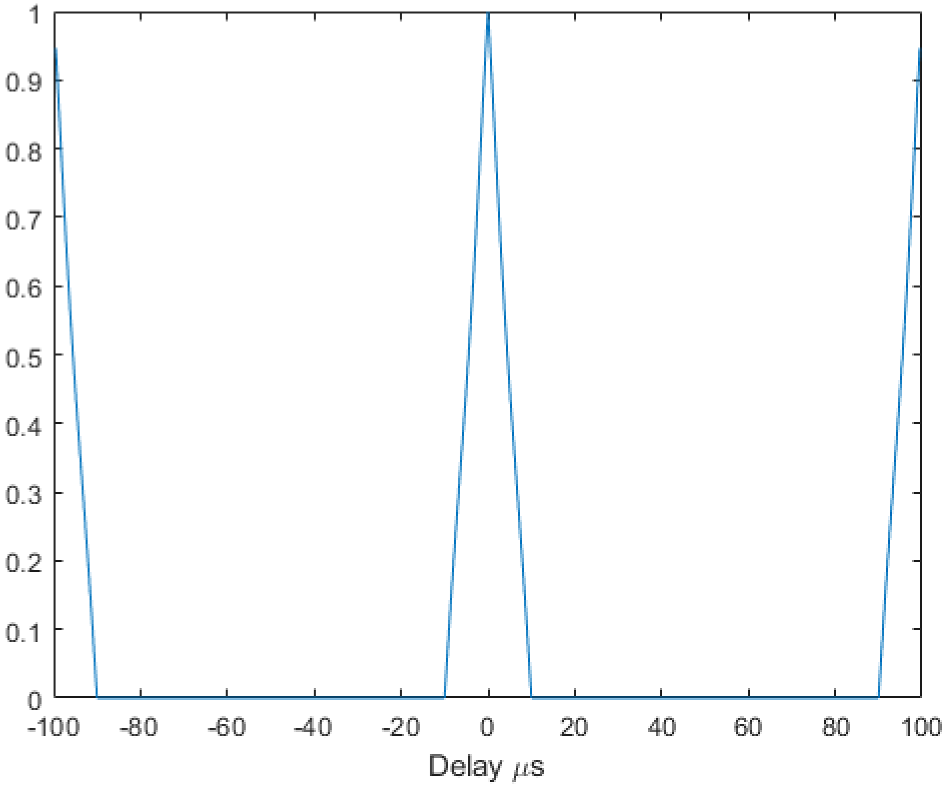
```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5,...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the 5-period periodic ambiguity function along a non-zero Doppler cut.

```
dopval = 20.0;
[pamf,delays] = pambgfun(wav,fs,5,'Cut','Doppler','CutValue',dopval);
```

Plot the periodic ambiguity functions.

```
plot(delays*1.0e6,pamf)
xlabel('Delay \mus')
```



### Zero Delay Cut of FMCW Periodic Ambiguity Function

Plot a zero delay cut for the three-period periodic ambiguity function of an FMCW waveform. Assume a sweep bandwidth of 100 kHz with a sampling frequency of 1 MHz. Return and plot the Doppler shift values.

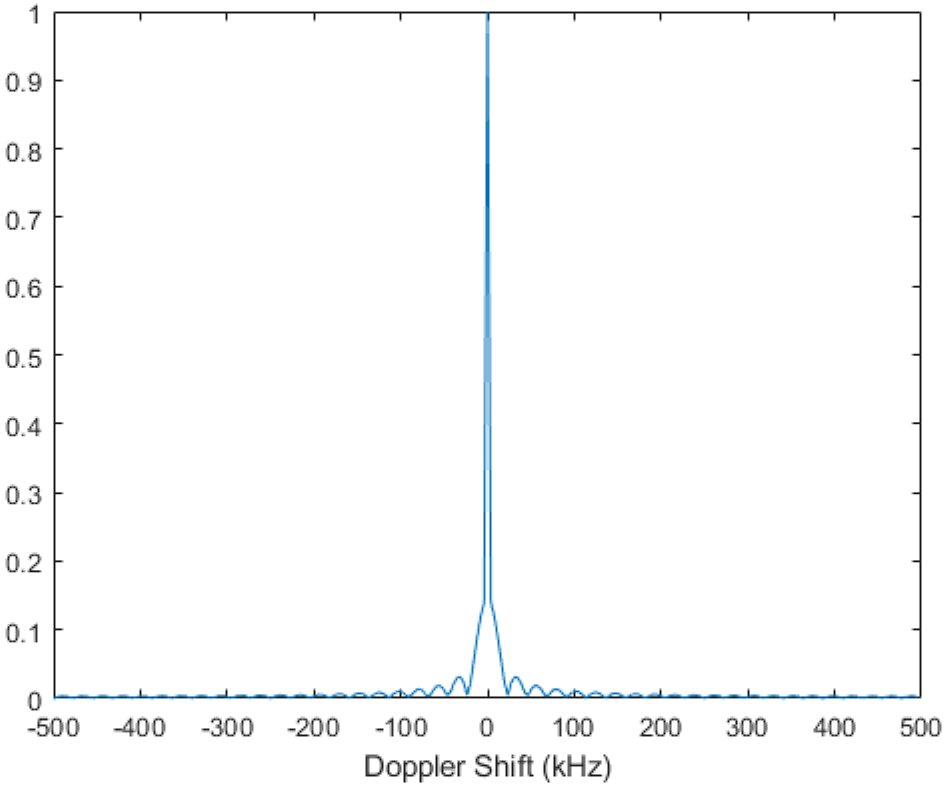
```
fs = 1.0e6;
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,'SampleRate',fs, ...
    'OutputFormat','Sweeps','NumSweeps',1);
wav = waveform();
```

Find the three-period periodic ambiguity function along a zero delay cut.

```
[pamf,doppler] = pambgfun(wav,fs,3,'Cut','Delay');
```

Plot the zero delay cut of the periodic ambiguity function.

```
plot(doppler/1.0e3,pamf)
xlabel('Doppler Shift (kHz)')
```



### Nonzero Delay Cut of FMCW Periodic Ambiguity Function

Plot a non-zero delay cut of -20 μs for the three-period periodic ambiguity function of an FMCW waveform. Assume a sweep bandwidth of 100 kHz with a sampling frequency of 1 MHz. Return and plot the Doppler shift values.

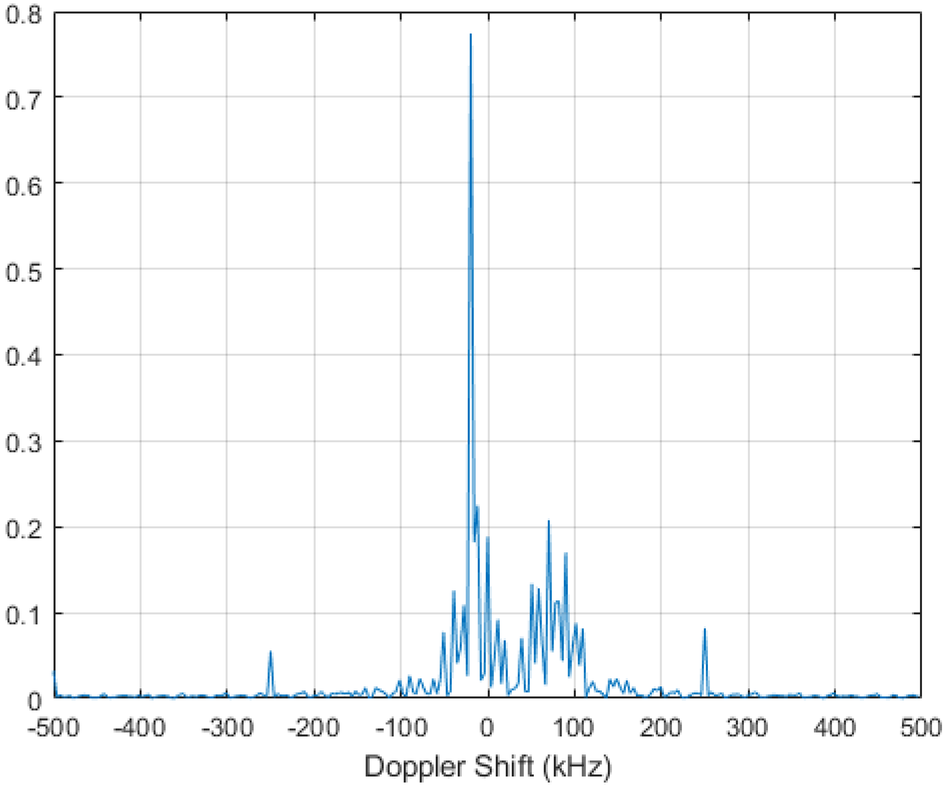
```
fs = 1.0e6;
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,'SampleRate',fs, ...
    'OutputFormat','Sweeps','NumSweeps',1,'SweepTime',100e-6);
wav = waveform();
```

Find the three-period periodic ambiguity function along a nonzero Delay cut.

```
delayval = -20.0e-6;
[pamf,doppler] = pambgfun(wav,fs,3,'Cut','Delay','CutValue',delayval);
```

Plot the nonzero delay cut of the periodic ambiguity function.

```
plot(doppler/1.0e3,pamf)
grid
xlabel('Doppler Shift (kHz)')
```



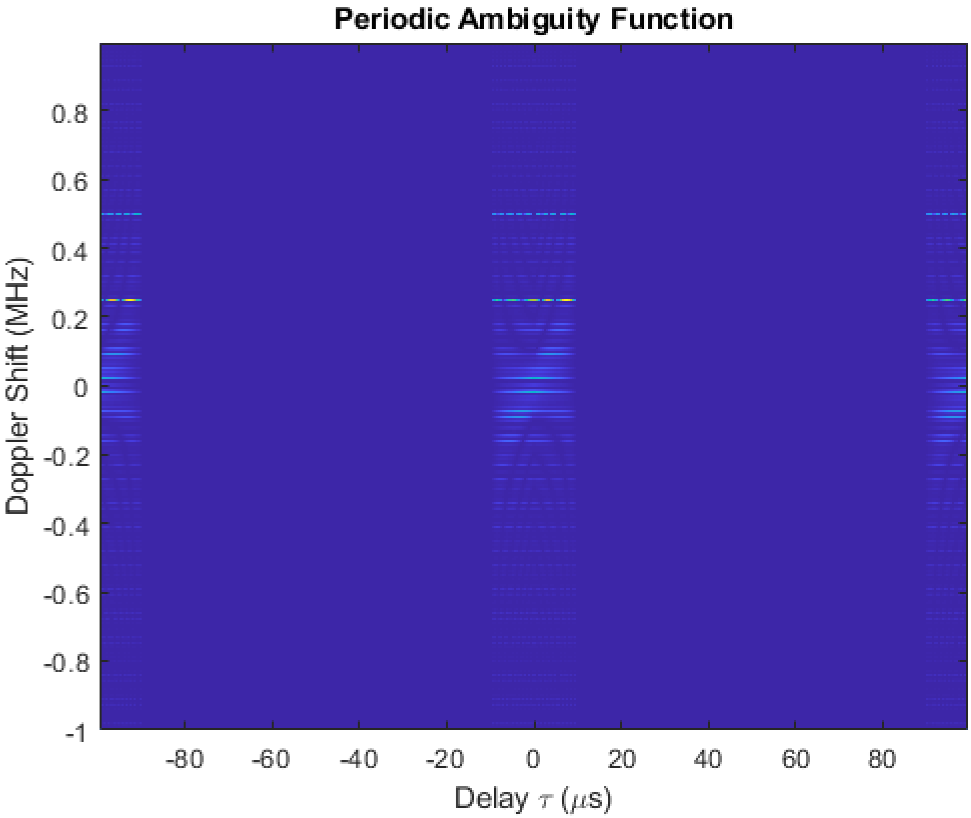
### Linear FM Periodic Ambiguity Diagram Image

Display an image of the 9-period periodic ambiguity function for a linear FM pulse waveform. Assume the pulse repetition frequency is 10.0e3 Hz and that the sampling frequency is a multiple of the PRF.

```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5,...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Compute and display the 9-period periodic ambiguity function for all delays and frequencies.

```
[pamf,delays,doppler] = pambgfun(wav,fs,9,'Cut','2D');
imagesc(delays*1e6,doppler/1e6,pamf)
title('Periodic Ambiguity Function')
xlabel('Delay \tau ({\mu}s)')
ylabel('Doppler Shift (MHz)')
axis xy
```



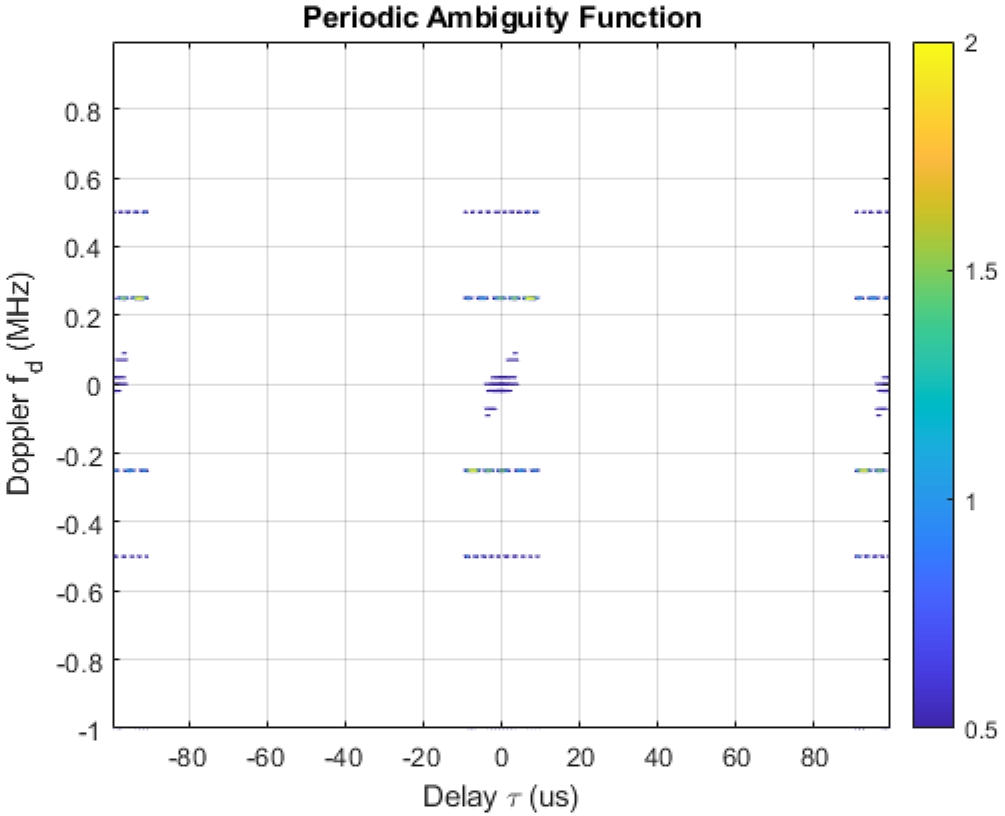
### Linear FM Periodic Ambiguity Diagram

Plot the seven-period periodic ambiguity function of a linear FM pulse waveform. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF.

```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the periodic ambiguity function.

```
pambgfun(wav,fs,7,'Cut','2D')
```



## Input Arguments

### X — Input pulse waveform

complex-valued vector

Input pulse waveform, specified as a complex-valued vector.

Example: `[0,.1,.3,.4,.3,.1.0]`

Data Types: `double`
Complex Number Support: Yes

### `fs` — Sampling frequency

positive scalar

Sampling frequency, specified as a positive scalar. Units are in hertz.

Example: `3e3`

Data Types: `double`

### `P` — Number of periods

`1` (default) | positive integer

Number of periods, specified as a positive integer.

Example: `5`

Data Types: `double`

### `V` — Optional time delay or Doppler shift at which ambiguity function cut is taken

0 (default) | real-valued scalar

When you set `'Cut'` to `'Delay'` or `'Doppler'`, use `V` to specify a nonzero cut value. You cannot use `V` when you set `'Cut'` to `'2D'`.

When `'Cut'` is set to `'Delay'`, `V` is the time delay at which the cut is taken. Time delay units are in seconds.

When `'Cut'` is set to `'Doppler'`, `V` is the Doppler frequency shift at which the cut is taken. Doppler units are in hertz.

Example: `10.0`

Data Types: `double`

## Output Arguments

### `pafmag` — Normalized PAF function magnitude

real-valued *M*-by-*N* matrix | real-valued *M*-element column vector | real-valued *N*-element row vector

Normalized PAF function magnitude, returned as a vector or a matrix of nonnegative real values. The dimensions of `pafmag` depend on the value of `'Cut'`.

| `'Cut'` | `pafmag`dimensions |
|---|---|
| `'2D'` | *M*-by-*N* matrix. |
| `'Delay'` | *M*-element column vector. |
| `'Doppler'` | *N*-element row vector. |

*M* is the number of Doppler frequencies and *N* is the number of time delays.

**`delay` — Time delay vector**
real-valued *N*-element vector

Time delay vector, returned as an *N*-by-1 vector. If *N* is the length of signal `X`, then the delay vector consist of $2N – 1$ samples in the range, $–(N/2) – 1,...,(N/2) – 1)$.

**`doppler` — Doppler shift vector**
real-valued *M* vector

Doppler shift vector, returned as an *M*-by-1 vector of Doppler frequencies. The Doppler frequency vector consists of $M = 2^{ceil(log2\ N)}$ equally-spaced samples. Frequencies are $(–(M/2)F_s,...,(M/2–1)F_s)$.

# More About

## Periodic Ambiguity Function

The periodic ambiguity function (PAF) is an extension of the ordinary ambiguity function to periodic waveforms.

Use this function analyze the response of a correlation receiver to a time-delayed or Doppler-shifted narrowband periodic waveform. Narrowband periodic signals consist of CW tones modulated by a periodic complex envelope. These types of signals are commonly used in radar systems to form transmitted pulse trains.

A time periodic waveform has the property $y(t + T) = y(t)$, where *T* is the period. The PAF function for an *N*-period waveform is defined as

$$A_{NT}(\tau,\nu) = \frac{1}{NT}\int_0^{NT} y(t+\frac{\tau}{2})y^*(t-\frac{\tau}{2})e^{i2\pi\nu t}dt$$

Taking advantage of the periodicity, you can rewrite the function as

$$A_{NT}(\tau,\nu) = \frac{1}{NT}\sum_{n=1}^{N} e^{i2\pi\nu(n-1)T}\int_0^{T} u(t+\frac{\tau}{2})u^*(t-\frac{\tau}{2})e^{i2\pi\nu s}ds$$

The last term on the right side is the one-period PAF function, $A_T(\tau,\nu)$. The first term on the right side is due to Doppler only. The Doppler term is proportional to the periodic *sinc()* function and you can rewrite the periodic ambiguity function as

$$A_{NT}(\tau,\nu) = \frac{\sin 2\pi\nu NT}{N\sin 2\pi\nu T}e^{i2\pi\nu(N-1)T}A_T(\tau,\nu)$$

The Doppler term improves the Doppler resolution by a factor of *1/NT*.

The one-period PAF function is not the same as the ordinary ambiguity because the integration limits are different.

# phitheta2azel

Convert angles from phi/theta form to azimuth/elevation form

## Syntax

```
AzEl = phitheta2azel(PhiTheta)
```

## Description

`AzEl = phitheta2azel(PhiTheta)` converts the phi/theta angle on page 2-272 pairs to their corresponding azimuth/elevation angle on page 2-273 pairs.

## Examples

### Convert Phi and Theta to Azimuth and Elevation

Find the azimuth and elevation representation for φ = 30° and θ = 0°.

```
azel = phitheta2azel([30;0]);
```

## Input Arguments

**`PhiTheta` — Phi/theta angle pairs**
two-row matrix

Phi and theta angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta].

Data Types: `double`

## Output Arguments

### `AzEl` — Azimuth/elevation angle pairs

two-row matrix

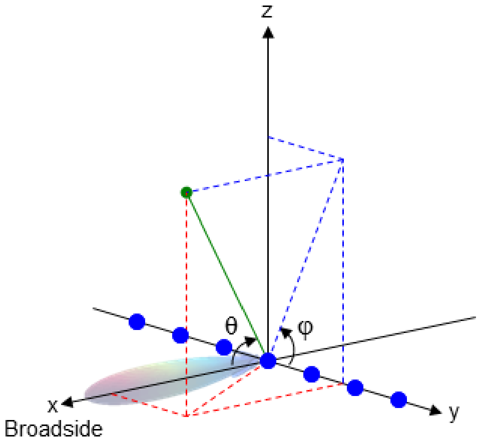
Azimuth and elevation angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation]. The matrix dimensions of `AzEl` are the same as those of `PhiTheta`.

## More About

### Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$

$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$

$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.

# phitheta2azelpat

Convert radiation pattern from phi/theta form to azimuth/elevation form

## Syntax

```
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta)
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta,az,el)
[pat_azel,az_pat,el_pat] = phitheta2azelpat( ___ )
```

## Description

pat_azel = phitheta2azelpat(pat_phitheta,phi,theta) expresses the antenna radiation pattern pat_phitheta in azimuth/elevation angle on page 2-282 coordinates instead of φ/θ angle on page 2-281 coordinates. pat_phitheta samples the pattern at φ angles in phi and θ angles in theta. The pat_azel matrix uses a default grid that covers azimuth values from –90 to 90 degrees and elevation values from –90 to 90 degrees. In this grid, pat_azel is uniformly sampled with a step size of 1 for azimuth and elevation. The function interpolates to estimate the response of the antenna at a given direction.

pat_azel = phitheta2azelpat(pat_phitheta,phi,theta,az,el) uses vectors az and el to specify the grid at which to sample pat_azel. To avoid interpolation errors, az should cover the range [–180, 180] and el should cover the range [–90, 90].

[pat_azel,az_pat,el_pat] = phitheta2azelpat( ___ ) returns vectors containing the azimuth and elevation angles at which pat_azel samples the pattern, using any of the input arguments in the previous syntaxes.

## Examples

### Convert Radiation Pattern to Azimuth and Elevation

Convert a radiation pattern to azimuth/elevation form, with the azimuth and elevation angles spaced 1° apart.

Define the pattern in terms of φ and θ.

```
phi = 0:360;
theta = 0:180;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to azimuth/elevation space.

```
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta);
```

### Plot Converted Radiation Pattern

Convert a radiation pattern from theta/phi coordinates to azimuth/elevation coordinates, with azimuth and elevation angles spaced 1° apart.

Define the pattern in terms of phi, $\phi$, and theta, $\theta$, coordinates.

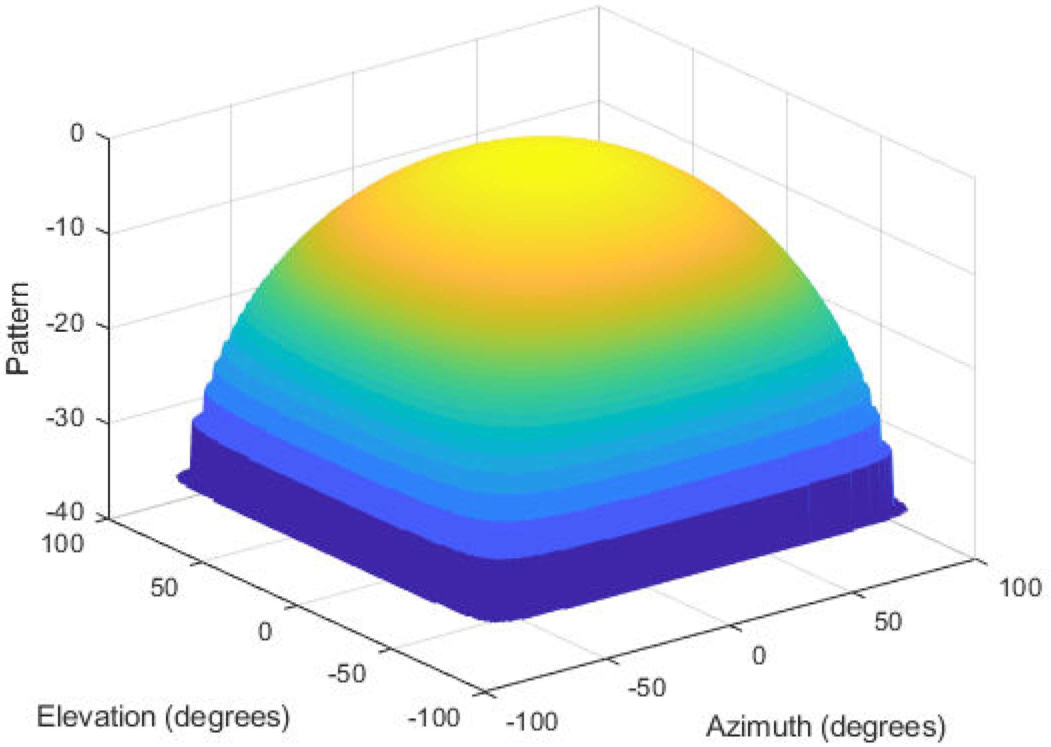
```
phi = 0:360;
theta = 0:180;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to azimuth/elevation coordinates. Get the azimuth and elevation angles for use in plotting.

```
[pat_azel,az,el] = phitheta2azelpat(pat_phitheta,phi,theta);
```

Plot the radiation pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)');
ylabel('Elevation (degrees)');
zlabel('Pattern');
```



### Convert Radiation Pattern For Specific Azimuth/Elevation Values

Convert a radiation pattern from phi/theta coordinates to azimuth/elevation coordinates, with the azimuth and elevation angles spaced 5° apart.

Define the pattern in terms of phi and theta.

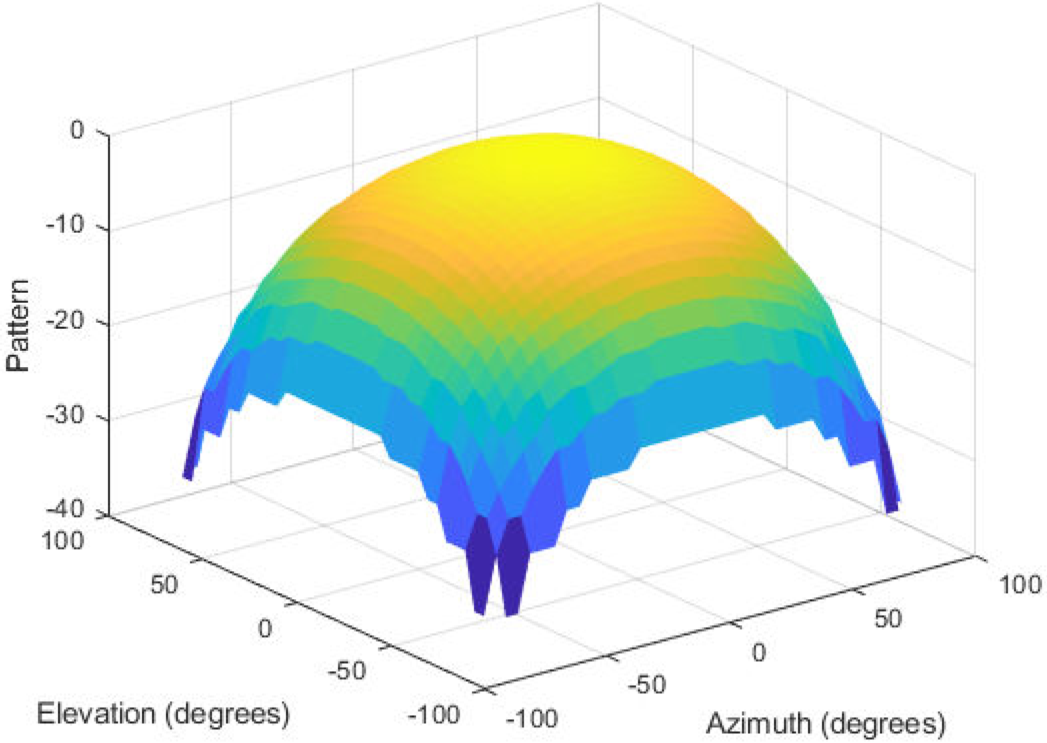
```
phi = 0:360;
theta = 0:180;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Define the set of azimuth and elevation angles at which to sample the pattern. Then, convert the pattern.

```
az = -180:5:180;
el = -90:5:90;
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta,az,el);
```

Plot the radiation pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)');
ylabel('Elevation (degrees)');
zlabel('Pattern');
```



## Input Arguments

### pat_phitheta — Antenna radiation pattern in phi/theta form

Q-by-P matrix

Antenna radiation pattern in phi/theta form, specified as a Q-by-P matrix. pat_phitheta samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. P is the length of the phi vector, and Q is the length of the theta vector.

Data Types: double

### phi — Phi angles

vector of length P

Phi angles at which pat_phitheta samples the pattern, specified as a vector of length P. Each φ angle is in degrees, between 0 and 360.

Data Types: double

### theta — Theta angles

vector of length Q

Theta angles at which pat_phitheta samples the pattern, specified as a vector of length Q. Each θ angle is in degrees, between 0 and 180.

Data Types: double

### az — Azimuth angles

[-180:180] (default) | vector of length L

Azimuth angles at which pat_azel samples the pattern, specified as a vector of length L. Each azimuth angle is in degrees, between –180 and 180.

Data Types: double

### el — Elevation angles

[-90:90] (default) | vector of length M

Elevation angles at which pat_azel samples the pattern, specified as a vector of length M. Each elevation angle is in degrees, between –90 and 90.

Data Types: double

# Output Arguments

### pat_azel — Antenna radiation pattern in azimuth/elevation form

M-by-L matrix

Antenna radiation pattern in azimuth/elevation form, returned as an M-by-L matrix. pat_azel samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. L is the length of the az vector, and M is the length of the el vector.

### az_pat — Azimuth angles

vector of length L

Azimuth angles at which pat_azel samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

### el_pat — Elevation angles

vector of length M

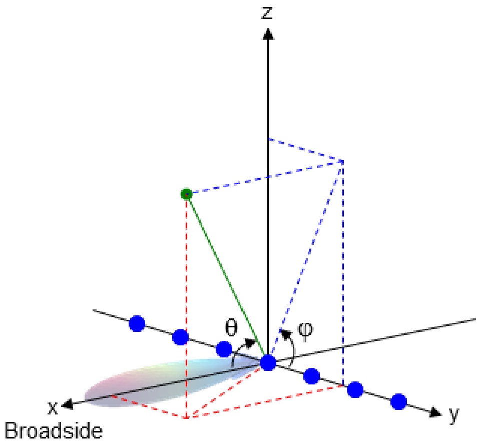
Elevation angles at which pat_azel samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

# More About

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el})/\sin(\text{az})$$

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.

# phitheta2uv

Convert phi/theta angles to u/v coordinates

## Syntax

```
UV = phitheta2uv(PhiTheta)
```

## Description

`UV = phitheta2uv(PhiTheta)` converts the phi/theta angle on page 2-286 pairs to their corresponding *u*/*v* space on page 2-287 coordinates.

## Examples

### Conversion of Phi-Theta Pair

Find the corresponding *u*-*v* representation for φ = 30° and φ = 0°.

```
uv = phitheta2uv([30; 0])
```

```
uv = 2×1

     0
     0
```

## Input Arguments

### `PhiTheta` — Phi/theta angle pairs

two-row matrix

Phi and theta angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta].

Data Types: `double`

## Output Arguments

**UV — Angle in u/v space**
two-row matrix

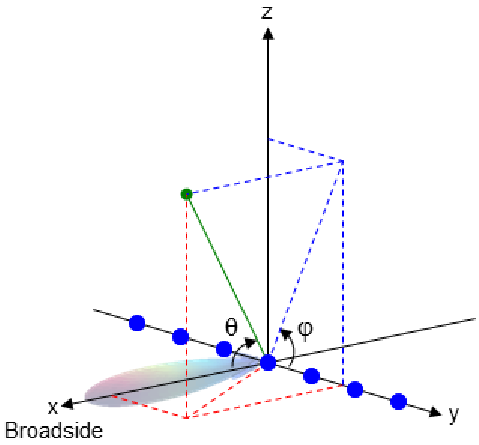
Angle in *u*/*v* space, returned as a two-row matrix. Each column of the matrix represents an angle in the form [*u*; *v*]. The matrix dimensions of UV are the same as those of `PhiTheta`.

## More About

### Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

## U/V Space

The *u/v* coordinates for the hemisphere *x* ≥ 0 are derived from the phi and theta angles on page 2-286.

The relations are

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \le u \le 1$$
$$-1 \le v \le 1$$
$$u^2 + v^2 \le 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of *u* and *v*

$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

# Extended Capabilities

# phitheta2uvpat

Convert radiation pattern from phi/theta form to u/v form

## Syntax

```
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta)
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta,u,v)
[pat_uv,u_pat,v_pat] = phitheta2uvpat( ___ )
```

## Description

`pat_uv = phitheta2uvpat(pat_phitheta,phi,theta)` expresses the antenna radiation pattern `pat_phitheta` in u/v space on page 2-295 coordinates instead of φ/θ angle on page 2-294 coordinates. `pat_phitheta` samples the pattern at φ angles in `phi` and θ angles in `theta`. The `pat_uv` matrix uses a default grid that covers *u* values from –1 to 1 and *v* values from –1 to 1. In this grid, `pat_uv` is uniformly sampled with a step size of 0.01 for *u* and *v*. The function interpolates to estimate the response of the antenna at a given direction. Values in `pat_uv` are NaN for *u* and *v* values outside the unit circle because *u* and *v* are undefined outside the unit circle.

`pat_uv = phitheta2uvpat(pat_phitheta,phi,theta,u,v)` uses vectors `u` and `v` to specify the grid at which to sample `pat_uv`. To avoid interpolation errors, `u` should cover the range [–1, 1] and `v` should cover the range [–1, 1].

`[pat_uv,u_pat,v_pat] = phitheta2uvpat( ___ )` returns vectors containing the *u* and *v* coordinates at which `pat_uv` samples the pattern, using any of the input arguments in the previous syntaxes.

## Examples

### Conversion of Radiation Pattern

Convert a radiation pattern to *u*-*v* form, with the *u* and *v* coordinates spaced by 0.01.

Define the pattern in terms of φ and θ.

```
phi = 0:360;
theta = 0:90;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to *u*-*v* form.

```
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta);
```

### Convert and Plot Radiation Pattern

Convert a radiation pattern to $u - v$ coordinates, with the $u$ and $v$ coordinates spaced by 0.01.

Define the pattern in terms of $\phi$ and $\theta$.

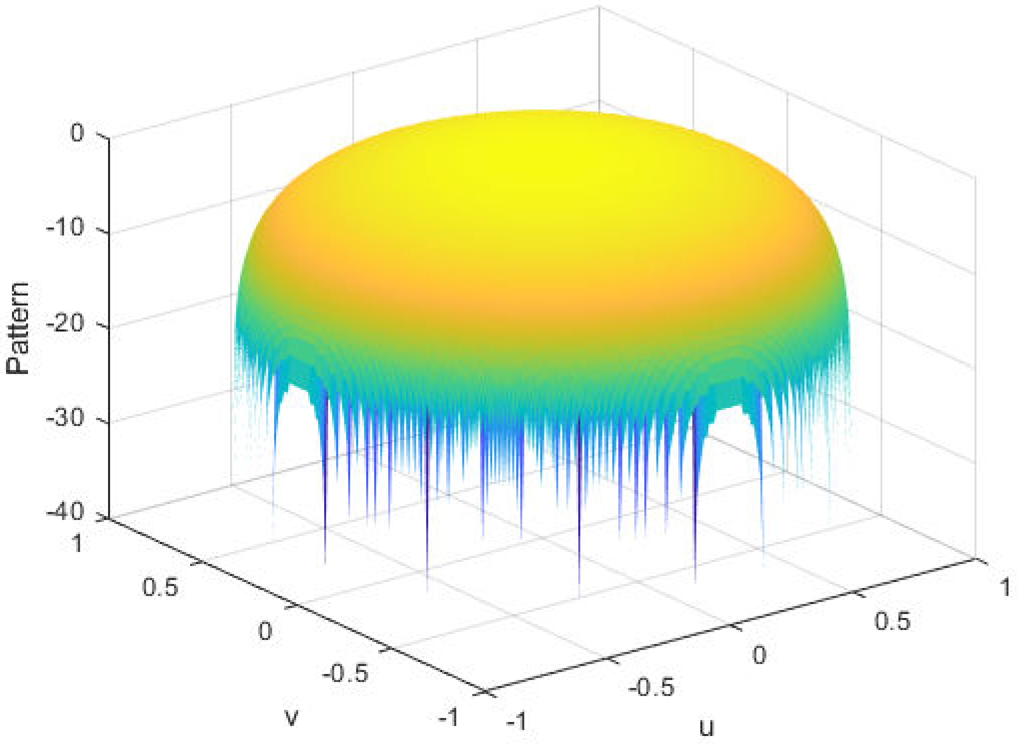
```
phi = 0:360;
theta = 0:90;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to $u - v$ coordinates. Store the $u$ and $v$ coordinates for use in plotting.

```
[pat_uv,u,v] = phitheta2uvpat(pat_phitheta,phi,theta);
```

Plot the result.

```
H = surf(u,v,pat_uv);
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



### Convert Radiation Pattern For Specific U/V Values

Convert a radiation pattern to $u - v$ coordinates, with the $u$ and $v$ coordinates spaced by 0.05.

Define the pattern in terms of $\phi$ and $\theta$.

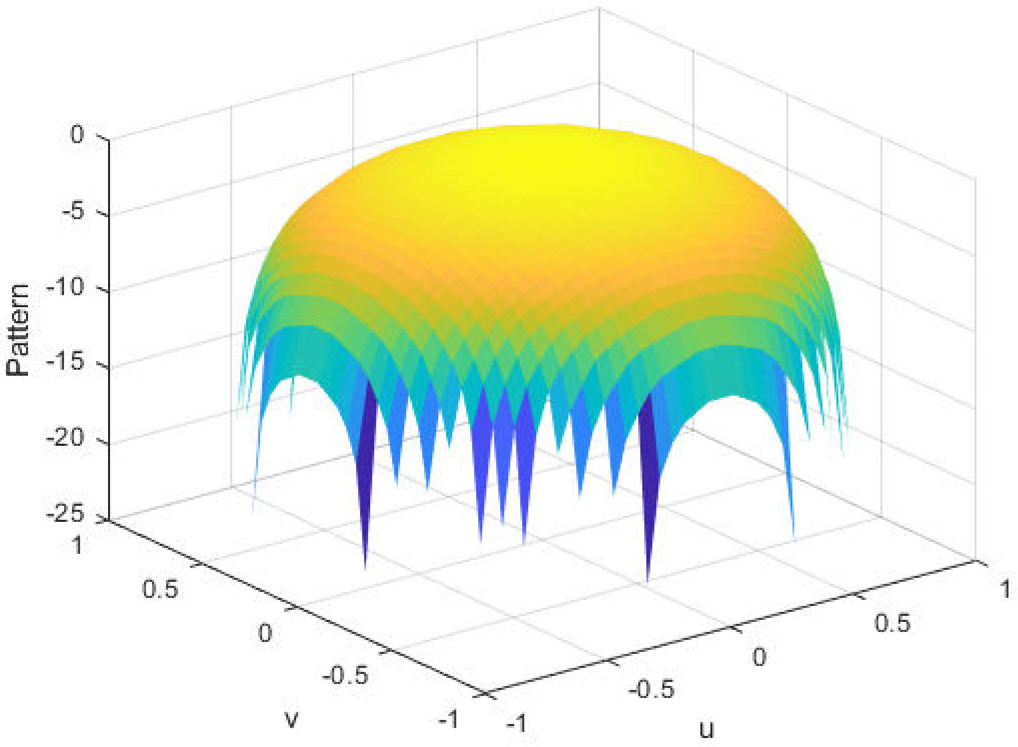
```
phi = 0:360;
theta = 0:90;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Define the set of *u* and *v* coordinates at which to sample the pattern. Then, convert the pattern.

```
u = -1:0.05:1;
v = -1:0.05:1;
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta,u,v);
```

Plot the result.

```
H = surf(u,v,pat_uv);
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



## Input Arguments

### `pat_phitheta` — Antenna radiation pattern in phi/theta form

Q-by-P matrix

Antenna radiation pattern in phi/theta form, specified as a Q-by-P matrix. `pat_phitheta` samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. P is the length of the `phi` vector, and Q is the length of the `theta` vector.

Data Types: `double`

### `phi` — Phi angles

vector of length P

Phi angles at which `pat_phitheta` samples the pattern, specified as a vector of length P. Each φ angle is in degrees, between 0 and 180.

Data Types: `double`

### `theta` — Theta angles

vector of length Q

Theta angles at which `pat_phitheta` samples the pattern, specified as a vector of length Q. Each θ angle is in degrees, between 0 and 90. Such angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

### u — *u* coordinates

`[-1:0.01:1]` (default) | vector of length L

*u* coordinates at which `pat_uv` samples the pattern, specified as a vector of length L. Each *u* coordinate is between –1 and 1.

Data Types: `double`

### v — *v* coordinates

`[-1:0.01:1]` (default) | vector of length M

*v* coordinates at which `pat_uv` samples the pattern, specified as a vector of length M. Each *v* coordinate is between –1 and 1.

Data Types: `double`

# Output Arguments

**`pat_uv` — Antenna radiation pattern in *u*/*v* form**
M-by-L matrix

Antenna radiation pattern in *u*/*v* form, returned as an M-by-L matrix. `pat_uv` samples the 3-D magnitude pattern in decibels, in terms of *u* and *v* coordinates. L is the length of the `u` vector, and M is the length of the `v` vector. Values in `pat_uv` are NaN for *u* and *v* values outside the unit circle because *u* and *v* are undefined outside the unit circle.

**`u_pat` — *u* coordinates**
vector of length L

*u* coordinates at which `pat_uv` samples the pattern, returned as a vector of length L.

**`v_pat` — *v* coordinates**
vector of length M

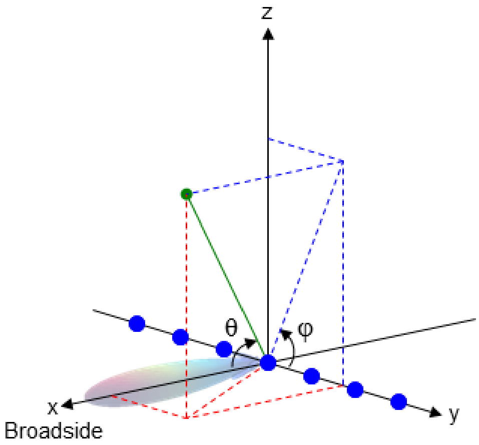
*v* coordinates at which `pat_uv` samples the pattern, returned as a vector of length M.

# More About

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector’s orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

## U/V Space

The *u* and *v* coordinates are the direction cosines of a vector with respect to the *y*-axis and *z*-axis, respectively.

The *u*/*v* coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles on page 2-294, as follows:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \le u \le 1$$
$$-1 \le v \le 1$$
$$u^2 + v^2 \le 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of *u* and *v*

$$\sin el = v$$
$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

# physconst

Physical constants

## Syntax

```
Const = physconst(Name)
```

## Description

`Const = physconst(Name)` returns the constant specified in the `Name` argument. Valid values are `'LightSpeed'`, `'Boltzmann'`, or `'EarthRadius'`. Values are in SI units.

## Input Arguments

### `Name`

Character vector that indicates which physical constant the function returns. Values are not case sensitive.

## Output Arguments

### `Const`

Value of physical constant specified in the input argument `Name`.

## Examples

### Convert Frequency to Wavelength

Determine the wavelength of a 1 GHz electromagnetic wave.

```
freq = 1e9;
lambda = physconst('LightSpeed')/freq
```

```
lambda = 0.2998
```

### Thermal Noise Power

Approximate the thermal noise power per unit bandwidth in the I and Q channels of a receiver.

Specify the receiver temperature and Boltzmann constant.

```
T = 290;
k = physconst('Boltzmann');
```

Compute the noise power per unit bandwidth, split evenly between the in-phase and quadrature channels.

```
Noise_power = 10*log10(k*T/2);
```

# More About

## Physical Constants

This table lists the supported constants and their values in SI units.

| Constant | Description | Value |
|---|---|---|
| `'LightSpeed'` | Speed of light in vacuum | 299,792,458 m/s. Most commonly denoted by *c*. |
| `'Boltzmann'` | Boltzmann constant relating energy to temperature | $1.38 \times 10^{-23}$ J/K. Most commonly denoted by *k*. |
| `'EarthRadius'` | Mean radius of the Earth | 6,371,000 m |

# pilotcalib

Array calibration using pilot sources

## Syntax

```
estpos = pilotcalib(nompos,x,pilotang)
[estpos,esttaper] = pilotcalib(nompos,x,pilotang)
[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper)
[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper,uncerts)
```

## Description

`estpos = pilotcalib(nompos,x,pilotang)` returns the estimated element positions, `estpos`, of a sensor array. The argument `nompos` represents the relative nominal positions of the sensor array before calibration. The nominal position is relative to the first element of the array. The argument `x` represents the signals received by the array coming from the pilot sources. The argument `pilotang` contains the known directions of each of the pilot sources. Three or more pilot sources are required in this case.

`[estpos,esttaper] = pilotcalib(nompos,x,pilotang)` also returns the estimated array taper, `esttaper`. Each element of `esttaper` contains the estimated taper value of the corresponding array element. In this case, the prior nominal taper is one for each element. Four or more pilot sources are required in this case.

`[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper)` specifies `nomtaper` as the nominal taper of the array. Four or more pilot sources are required in this case.

`[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper,uncerts)` specifies `uncerts` as the configuration settings to use for calibrating array uncertainties. Configuration settings determine which parameters to estimate.

## Examples

### Estimate ULA Element Positions Using Pilot Calibration

Construct a 7-element ULA array of isotropic antenna elements spaced one-half wavelength apart. Assume the array is geometrically perturbed in three dimensions. Perform pilot calibration on the array using 4 pilot sources at azimuth and elevation angles of (-60,0), (10,-40), (40,0), and (120,45) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal contains 10,000 samples. Assume the signals have a frequency of 600 MHz.

#### Set up the ULA with nominal parameters

```
fc = 600e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
Nelem = 7;
NominalTaper = ones(1,Nelem);
sULA = phased.ULA('Element',sIso,'NumElements',Nelem,'ElementSpacing',d,...
    'Taper',NominalTaper);
```

#### Create the pilot signals

Randomly perturb the element positions with a gaussian distribution having 0.1 wavelength standard deviation. Do not perturb the position of the first element or the tapers.

```
posstd = 0.1;
rng default
NominalElementPositions = getElementPosition(sULA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
ActualTaper = NominalTaper;
```

Generate the signals using the actual positions and tapers.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,120; 0,-40,0,45];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,...
        Nsamp,PilotAng(:,n),ncov,'Taper',ActualTaper.');
end
```

### Perform the pilot calibration

```
estpos = pilotcalib(NominalElementPositions - ReferenceElement*ones(1,Nelem),...
    X,PilotAng);
```

Add back the position of the reference sensor

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

### Examine the root mean squared (RMS) error of the calibrated parameters

Compute the RMS value of the initial position error.

```
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to the initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```
   2.3493e-04
```

## Estimate ULA Element Position and Taper Errors Using Pilot Calibration

Construct a 7-element ULA array of isotropic antenna elements spaced one-half wavelength apart. Assume the array is geometrically perturbed in three dimensions. Perform pilot calibration on the array using 4 pilot sources at azimuth and elevation angles of (-60,0), (10,80), (40,-40), and (-80,0) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal contains 10,000 samples. Assume the signals have a frequency of 600 MHz.

### Set up the ULA with nominal parameters

```
fc = 600e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
```

```
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
Nelem = 7;
NominalTaper = ones(1,Nelem);
sULA = phased.ULA('Element',sIso,'NumElements',Nelem,'ElementSpacing',d,...
    'Taper',NominalTaper);
```

### Create the pilot signals

Randomly perturb the element positions using a Gaussian distribution that has a standard deviation of 0.1 wavelength. Do not perturb the position of the first element.

```
posstd = 0.1;
rng default
NominalElementPositions = getElementPosition(sULA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
```

Perturb the taper in magnitude and phase. Do not perturb the first taper.

```
tapermagstd = 0.15;
taperphasestd = 0.15;
tapermagpert = tapermagstd*[0; randn(Nelem-1,1)];
ActualTaper = NominalTaper' + tapermagpert;
taperphasepert = taperphasestd*[0;randn(Nelem-1,1)];
ActualTaper = ActualTaper.*exp(1i*taperphasepert);
```

Generate the signals using the perturbed positions, tapers and four pilot sources.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,-80; 10,80,-40,0];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,Nsamp,...,
        PilotAng(:,n),ncov,'Taper',ActualTaper);
end
```

### Perform the pilot calibration

```
[estpos,esttaper] = pilotcalib(...
    NominalElementPositions - ReferenceElement*ones(1,Nelem),...
    X,PilotAng);
```

Add back the position of the reference sensor

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

### Examine the root mean square (RMS) error of the calibrated parameters

Compute the RMS values of the initial taper perturbations.

```
tapermagpertRMSE = sqrt(tapermagpert'*tapermagpert/Nelem);
taperphasepertRMSE = sqrt(taperphasepert'*taperphasepert/Nelem);
```

Compute the RMS value of the calibrated taper magnitude error.

```
diff = abs(ActualTaper) - abs(esttaper);
diff2 = diff'*diff;
tapermagsolvRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS magnitude error to the initial RMS magnitude error. The calibration reduces the RMS magnitude error.

```
disp(tapermagsolvRMSE/tapermagpertRMSE)
```

```
   6.7715e-04
```

Compute the RMS value of the calibrated taper phase error.

```
diff = unwrap(angle(ActualTaper) - angle(esttaper));
diff2 = diff'*diff;
tapersolvphaseRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS phase error to the initial RMS phase error. The calibration reduces the RMS phase error.

```
disp(tapersolvphaseRMSE/taperphasepertRMSE)
```

```
    0.0021
```

```
% Compute the RMS value of the initial position error.
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to the initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```
   3.6308e-04
```

### Estimate URA Element Position Errors Using Pilot Calibration

Construct a 9-element URA of isotropic antenna elements spaced one-half wavelength apart. Assume the array has been geometrically perturbed in all directions except for the first element. Perform pilot calibration on the array using 5 pilot sources at azimuth and elevation angles of (-60,0), (10,-40), (40,0), (120,45), and (170,50) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal contains 10,000 samples. Assume the signals have a frequency of 600 MHz.

#### Create the array

For convenience, use a `phased.URA` System object� to set the nominal position and taper values.

```
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
sURA = phased.URA('Element',sIso,'Size',[3,3],...
    'ElementSpacing',d,'Taper',ones(3,3));
Nelem = getNumElements(sURA);
taper = getTaper(sURA);
```

#### Create the pilot signals

Randomly perturb the element positions using a Gaussian distribution that has a standard deviation of 0.1 wavelength. Do not perturb the position of the first element.

```
posstd = 0.1;
rng default
NominalElementPositions = getElementPosition(sURA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
```

Perturb the taper in magnitude and phase. Do not perturb the first taper.

```
NominalTaper = getTaper(sURA);
tapermagstd = 0.1;
taperphasestd = 0.1;
tapermagpert = tapermagstd*[0; randn(Nelem-1,1)];
ActualTaper = NominalTaper + tapermagpert;
taperphasepert = taperphasestd*[0;randn(Nelem-1,1)];
ActualTaper = ActualTaper.*exp(1i*taperphasepert);
```

Generate the pilot signals using the perturbed positions and tapers.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,120,170; 0,-40,0,45,50];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,Nsamp,...
        PilotAng(:,n),ncov,'Taper',ActualTaper);
end
```

### Perform the pilot calibration

```
[estpos,esttaper] = pilotcalib(NominalElementPositions - ReferenceElement*ones(1,Nelem)
    X,PilotAng,NominalTaper);
```

Add back the position of the reference sensor.

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

### Examine the root mean square (RMS) error of the calibrated parameters

Compute the RMS values of the initial taper perturbations to compare with the RMS values of the calibrated parameters.

```
tapermagpertRMSE = sqrt(tapermagpert'*tapermagpert/Nelem);
taperphasepertRMSE = sqrt(taperphasepert'*taperphasepert/Nelem);
```

Compute the RMS value of the calibrated taper magnitude error.

```
diff = abs(ActualTaper) - abs(esttaper);
diff2 = diff'*diff;
tapermagsolvRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS magnitude error to the initial RMS error. The calibration reduces the RMS magnitude error.

```
disp(tapermagsolvRMSE/tapermagpertRMSE)

    0.0014
```

Compute the RMS value of the calibrated taper phase error.

```
diff = unwrap(angle(ActualTaper) - angle(esttaper));
diff2 = diff'*diff;
tapersolvphaseRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS phase error to the initial RMS error. The calibration reduces the RMS phase error.

```
disp(tapersolvphaseRMSE/taperphasepertRMSE)

    0.0015
```

Compute the RMS value of the initial position error.

```
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)

   7.1582e-04
```

### Estimate Selected ULA Parameters Using Pilot Calibration

Construct a 6-element ULA of isotropic antenna elements that are spaced one-half wavelength apart. Assume the array has been geometrically perturbed in the *x*-*y* plane and contains an unknown taper error. Perform pilot calibration on the array using four pilot sources at azimuth and elevation angles of (-60,0), (10,-40), (40,0), and (120,45) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal contains 10,000 samples. Assume the signals have a frequency of 600 MHz.

### Set up the ULA with nominal parameters

```
fc = 600e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
Nelem = 6;
NominalTaper = ones(1,Nelem);
sULA = phased.ULA('Element',sIso,'NumElements',Nelem,'ElementSpacing',d,...
    'Taper',NominalTaper);
```

### Create the pilot signals

Randomly perturb the element positions using a Gaussian distribution that has a standard deviation of 0.13 wavelength. Do not perturb the position of the first element.

```
posstd = 0.13;
rng default
NominalElementPositions = getElementPosition(sULA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
```

Perturb the taper in magnitude and phase. Do not perturb the first taper.

```
tapermagstd = 0.15;
taperphasestd = 0.15;
tapermagpert = tapermagstd*[0; randn(Nelem-1,1)];
ActualTaper = NominalTaper' + tapermagpert;
taperphasepert = taperphasestd*[0;randn(Nelem-1,1)];
ActualTaper = ActualTaper.*exp(1i*taperphasepert);
```

Generate the signals using the perturbed positions and tapers.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,120; 0,-40,0,45];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,Nsamp,...
        PilotAng(:,n),ncov,'Taper',ActualTaper);
end
```

### Perform the pilot calibration

Turn off estimation of taper weights.

```
[estpos,esttaper] = pilotcalib(NominalElementPositions - ReferenceElement*ones(1,Nelem)
    X,PilotAng,NominalTaper.',[1,1,1,0]');
```

Add back the position of the reference sensor

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

### Examine the root mean square (RMS) error of the calibrated parameters

Compute the RMS values of the initial taper perturbations to compare with the RMS values of the calibrated parameters.

```
tapermagpertRMSE = sqrt(tapermagpert'*tapermagpert/Nelem);
taperphasepertRMSE = sqrt(taperphasepert'*taperphasepert/Nelem);
```

Compute the RMS value of the calibrated taper magnitude error.

```
diff = abs(ActualTaper) - abs(esttaper);
diff2 = diff'*diff;
tapermagsolvRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS magnitude error to the initial RMS error. The calibration reduces the RMS magnitude error.

```
disp(tapermagsolvRMSE/tapermagpertRMSE)
```

```
    1.0000
```

Compute the RMS value of the calibrated taper phase error

```
diff = unwrap(angle(ActualTaper) - angle(esttaper));
diff2 = diff'*diff;
tapersolvphaseRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS phase error to the initial RMS error. The calibration reduces the RMS phase error.

```
disp(tapersolvphaseRMSE/taperphasepertRMSE)
```

```
     1
```

Compute the RMS value of the initial position error.

```
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```
    0.1502
```

## Input Arguments

### nompos — Nominal relative element positions

real-valued 3-by-*N* matrix

Nominal relative element positions, specified as a real-valued 3-by-*N* matrix. The dimension *N* is the number of elements in the sensor array. Elements positions are relative to the first element of the array and are specified in units of signal wavelength. Each column of `nompos` represents the `[x;y;z]` coordinates of the corresponding element. The nominal position of all sensors must be within one-half of a wavelength of their actual positions for successful calibration.

Data Types: `double`

### x — Pilot signals

complex-valued *L*-by-*N*-by-*M* matrix

Pilot signals, specified as a complex-valued *L*-by-*N*-by-*M* matrix. The argument `x` represents the signals received by the array when pilot sources are transmitting. The dimension *L* is the number of snapshots of each pilot source signal. The dimension *N* is the number of array elements. The dimension *M* is the number of pilot sources.

Data Types: `double`
Complex Number Support: Yes

### pilotang — Pilot angles

real-valued 2-by-*M* matrix

Pilot angles, specified as a real-valued 2-by-*M* matrix. The dimension *M* is the number of pilot sources. Each column contains the direction of the pilot source in the form `[azimuth; elevation]`. Angle units are in degrees. The azimuth angle must lie between -180° and 180° and the elevation angle must lie between -90° and 90°. The azimuth angle is measured from the *x*-axis to the projection of the source direction into the *xy* plane, positive toward the *y*-axis. The elevation angle is defined as the angle from the *xy* plane to the source direction, positive toward the *z*-axis. Calibration source directions must span sufficiently diverse azimuth and elevation angles.

Data Types: `double`

### `nomtaper` — Nominal taper

1 (default) | complex-valued *N*-by-1 column vector

Nominal taper of array elements, specified as a complex-valued *N*-by-1 column vector. The dimension *N* is the number of array elements. Each component represents the nominal taper of the corresponding element.

Data Types: `double`
Complex Number Support: Yes

### `uncerts` — Uncertainty estimation configuration

`[1,1,1,1]` (default) | 1-by-4 vector of ones and zeros

Uncertainty estimation configuration, specified as a 1-by-4 vector consisting of `0`’s and `1`’s. The vector `uncerts` determines which uncertainties to estimated. The vector takes the form of `[xflag; yflag; zflag; taperflag]`. Set `xflag`, `yflag`, or `zflag` to `1` to estimate uncertainties in the *x*, *y*, or *z* axes. Set `taperflag` to `1` to estimate uncertainties in the taper. The number of pilot sources must greater than or equal to the number of `1`’s in the vector.

For example, set `uncerts` to `[0;1;1;1]` to estimate uncertainties in the *y* and *z* element position components and the taper simultaneously.

Data Types: `double`

## Output Arguments

### `estpos` — Estimated positions

real-valued 3-by-*N* matrix

Estimated element positions, returned as a real-valued 3-by-*N* matrix. Units are in signal wavelength. The dimension *N* is the number of array elements. Each column of `estpos` represents the `[x;y;z]` coordinates of the corresponding element.

**`esttaper` — Estimated taper**
complex-valued *N*-by-1 column vector

Estimated taper values, returned as a complex-valued *N*-by-1 column vector. The dimension *N* is the number of array elements. Each element of `esttaper` represents the taper of the corresponding sensor element.

# Algorithms

This algorithm requires that the pilot sources be independent narrowband plane-wave signals incoming from the far field region of the array. In addition, signals must not exhibit multipath propagation effects or coherence. All elements in the sensor array are assumed to be isotropic.

The algorithm calibrates relative positions of the array sensors with respect to the first sensor. To use the algorithm, first subtract the position of the first element from each element, then pass the relative array into the function as the nominal position argument to produced the calibrated relative positions. Finally, add back the first element position to all the relative positions to create the fully calibrated array.

# Extended Capabilities

# C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Does not support variable-size inputs.

## See Also

**Introduced in R2015a**

# pol2circpol

Convert linear component representation of field to circular component representation

## Syntax

```
cfv = pol2circpol(fv)
```

## Description

`cfv = pol2circpol(fv)` converts the linear polarization components of the field or fields contained in `fv` to their equivalent circular polarization components in `cfv`. The expression of a field in terms of a two-row vector of linear polarization components is called the Jones vector formalism.

## Examples

### Convert Linear To Circular Polarization Components

Express a 45° linear polarized field in terms of right-circular and left-circular components.

```
fv = [2;2]
```

```
fv = 2×1

     2
     2
```

```
cfv = pol2circpol(fv)
```

```
cfv = 2×1 complex

   1.4142 - 1.4142i
   1.4142 + 1.4142i
```

### Convert Linear Polarization Components to Circular Polarization Components

Specify two input fields [1+1i;-1+1i] and [1;1] in the same matrix. The first field is a linear representation of a left-circularly polarized field and the second is a linearly polarized field.

```
fv=[1+1i 1;-1+1i 1]
```

```
fv = 2×2 complex

   1.0000 + 1.0000i   1.0000 + 0.0000i
  -1.0000 + 1.0000i   1.0000 + 0.0000i
```

```
cfv = pol2circpol(fv)
```

```
cfv = 2×2 complex

   1.4142 + 1.4142i   0.7071 - 0.7071i
   0.0000 + 0.0000i   0.7071 + 0.7071i
```

## Input Arguments

### fv — Field vector in linear component representation

1-by-*N* complex-valued row vector or a 2-by-*N* complex-valued matrix

Field vector in its linear component representation specified as a 1-by-*N* complex row vector or a 2-by-*N* complex matrix. If fv is a matrix, each column in fv represents a field in the form of [Eh;Ev], where Eh and Ev are the field's horizontal and vertical polarization components. If fv is a vector, each entry in fv is assumed to contain the polarization ratio, Ev/Eh. For a row vector, the value Inf designates the case when the ratio is computed for a field with Eh = 0.

Example: [1;-i]

Example: 2 + pi/3*i

Data Types: `double`
Complex Number Support: Yes

# Output Arguments

**`cfv` — Field vector in circular component representation**
1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in circular component representation returned as a 1-by-*N* complex-valued row vector or 2-by-*N*complex-valued matrix. `cfv` has the same dimensions as `fv`. If `fv` is a matrix, each column of `cfv` contains the circular polarization components, `[El;Er]`, of the field where `El` and `Er` are the left-circular and right-circular polarization components. If `fv` is a row vector, then `cfv` is also a row vector and each entry in `cfv` contains the circular polarization ratio, defined as `Er/El`.

# polellip

Parameters of ellipse traced out by tip of a polarized field vector

## Syntax

```
tau = polellip(fv)
[tau,epsilon] = polellip(fv)
[tau,epsilon,ar] = polellip(fv)
[tau,epsilon,ar,rs] = polellip(fv)

polellip(fv)
```

## Description

`tau = polellip(fv)` returns the tilt angle, in degrees, of the polarization ellipse of a field or set of fields specified in `fv`. `fv` contains the linear polarization components of a field in either one of two forms: (1) each column represents a field in the form of `[Eh;Ev]`, where `Eh` and `Ev` are the field's horizontal and vertical linear polarization components or (2) each column contains the polarization ratio, `Ev/Eh`. The expression of a field in terms of a two-row vector of linear polarization components is called the Jones vector formalism.

`[tau,epsilon] = polellip(fv)` returns, in addition, a row vector, `epsilon`, containing the ellipticity angle (in degrees) of the polarization ellipses. The ellipticity angle is the angle determined by the ratio of the length of the semi-minor axis to semi-major axis and lies in the range `[-45°,45°]`. This syntax can use any of the input arguments in the previous syntax.

`[tau,epsilon,ar] = polellip(fv)` returns, in addition, a row vector, `ar`, containing the axial ratios of the polarization ellipses. The axial ratio is defined as the ratio of the lengths of the semi-major axis of the ellipse to the semi-minor axis. This syntax can use any of the input arguments in the previous syntaxes.

`[tau,epsilon,ar,rs] = polellip(fv)` returns, in addition, a cell array of character vectors, `rs`, containing the rotation senses of the polarization ellipses. Each entry in the array is one of `'Linear'`, `'Left Circular'`, `'Right Circular'`, `'Left`

`Elliptical'` or `'Right Elliptical'`. This syntax can use any of the input arguments in the previous syntaxes.

`polellip(fv)` plots the polarization ellipse of the field specified in `fv`. This syntax requires that `fv` have only one column. Unlike the returned arguments, the size of the drawn ellipse depends upon the magnitude of `fv`.

# Examples

### Tilt Angle for Linearly Polarized Field

Create an input field that is linearly polarized by setting both the horizontal and vertical components to have the same phase. Then, compute the tilt angle.

```
fv = [2;1];
tau = polellip(fv)
```

```
tau = 26.5651
```

For linear polarization, `tau` is computed using `tau = atan(fv(2)/fv(1))*180/pi`.

### Tilt Angle and Ellipticity for Elliptically Polarized Field

Start with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase). Choose the phase difference to be 90°.

```
fv = [3*exp(-i*pi/2);1];
[tau,epsilon] = polellip(fv)
```

```
tau = 1.3156e-15
```

```
epsilon = 18.4349
```

The tilt vanishes because of the 90° phase difference between the horizontal and vertical components of the field.

### Tilt Angle, Ellipticity and Axial Ratio for Elliptically Polarized Field

Start with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase). Choose the phase difference to be 60°.

```
fv = [2*exp(-i*pi/3);1];
[tau,epsilon,ar] = polellip(fv)
```

```
tau = 16.8450

epsilon = 21.9269

ar = -2.4842
```

The nonzero tilt occurs because of the 60° phase difference. The negative value of the axial ratio indicates left elliptical polarization.

### Tilt Angle, Ellipticity, Axial Ratio and Rotation Sense for Elliptically Polarized Field

Start with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase). Choose the phase difference to be 60°.

```
fv = [2*exp(-i*pi/3);1];
[tau,epsilon,ar,rs] = polellip(fv)
```

```
tau = 16.8450

epsilon = 21.9269

ar = -2.4842

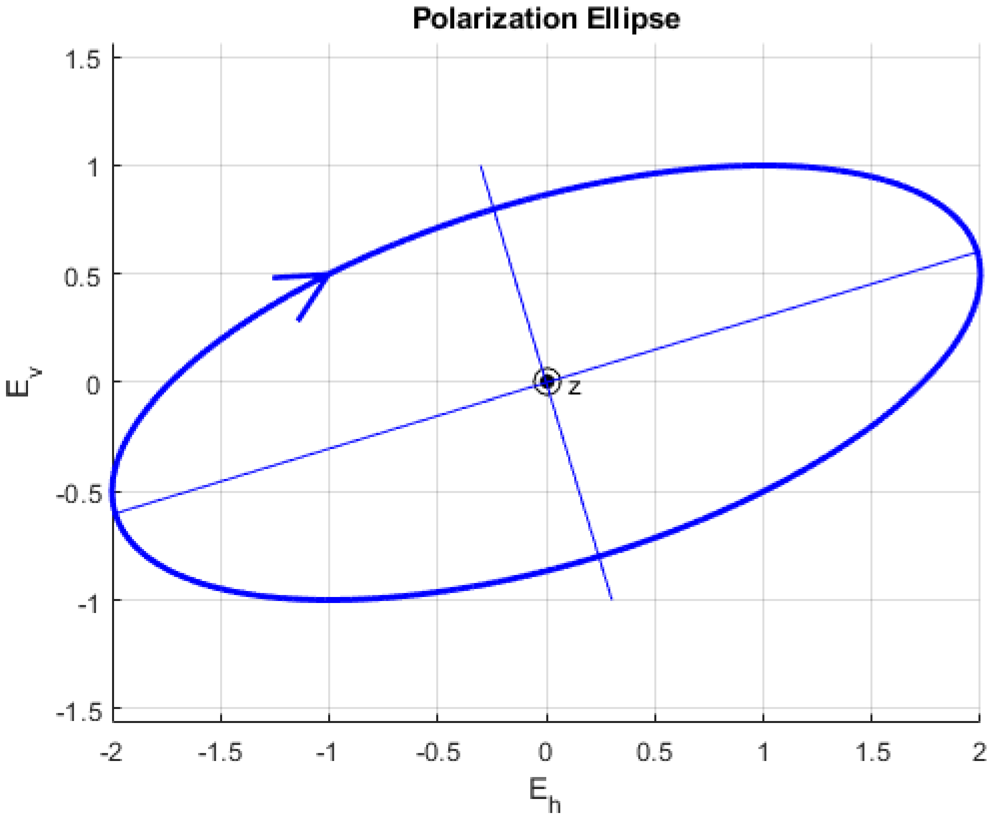
rs = 1x1 cell array
    {'Left Elliptical'}
```

A nonzero tilt occurs because of the 60° phase difference. The rotation sense is `'Left Elliptical'` indicating that the tip of the field vector is moving clockwise when looking towards the source of the field.

### Polarization Ellipse

Draw the figure of an elliptically polarized field. Begin with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase) and choose the phase difference to be 60 degrees.

```
fv = [2*exp(-i*pi/3);1];
polellip(fv)
```



The rotation sense is `'Left Elliptical'` as shown by the direction of the arrow on the ellipse. The filled circle at the origin indicates that the observer is looking towards the source of the field.

## Input Argument

### `fv` — Field vector in linear component representation

1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in linear component representation specified as a 1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix. Each column contains an instance of a field specification. If `fv` is a matrix, each column in `fv` represents a field in the form of `[Eh;Ev]`, where `Eh` and `Ev` are the field's linear horizontal and vertical polarization components. If `fv` is a row vector, then the row contains the ratio of the vertical to horizontal components of the field `Ev/Eh`. For a row vector, the value `Inf` is allowed to designate the case when the ratio is computed for `Eh = 0`. `Eh` and `Ev` cannot both be set to zero.

Example: `[1;-i]`

Example: `2 + pi/3*i`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `tau` — Tilt angle of polarization ellipse

1-by-*N* real-valued row vector

Tilt angle of polarization ellipse returned as a 1-by-*N* real-valued row vector. Each entry in `tau` contains the tilt angle of the polarization ellipse associated with each column of the field `fv`. The tilt angle is the angle between the semi-major axis of the ellipse and the horizontal axis (i.e. *x*axis) and lies in the range `[-90,90]°`.

### `epsilon` — Ellipticity angle of the polarization ellipse

1-by-*N* real-valued row vector

Ellipticity angle of the polarization ellipse returned as 1-by-*N* real-valued row vector. Each entry in `epsilon` contains the ellipticity angle of the polarization ellipse associated with each column of the field `fv`. The ellipticity angle describes the shape of the ellipse and lies in the range `[-45°,45°]`.

### `ar` — Axial ratio of the polarization ellipse

1-by-*N* real-valued row vector

Axial ratio of the polarization ellipse returned as a 1-by-*N* real-valued row vector. Each entry in `ar` contains the axial ratio of the polarization ellipse associated with each column of the field `fv`. The axial ratio is the signed ratio of the major-axis length to the minor-axis length of the polarization ellipse. Its absolute value is always greater than or equal to one. The sign of `ar` carries the rotational sense of the vector – a negative sign denotes left-handed rotation and a positive sign denotes right-handed rotation.

**`rs` — Rotation sense of the polarization ellipse**
1-by-*N* cell array of character vectors

Rotation sense of the polarization ellipse returned as a 1-by-*N* cell array of character vectors. Each entry in `rs` contains the rotation sense of the polarization ellipse associated with each column of the field `fv`. The rotation sense can be one of `'Linear'`, `'Left Circular'`, `'Right Circular'`, `'Left Elliptical'` or `'Right Elliptical'`.

# polloss

Polarization loss

## Syntax

```
rho = polloss(fv_tr,fv_rcv)
rho = polloss(fv_tr,fv_rcv,pos_rcv)
rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv)
rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr)
rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr,axes_tr)
```

## Description

`rho = polloss(fv_tr,fv_rcv)` returns the loss, in decibels, because of mismatch between the polarization of a transmitted field, `fv_tr`, and the polarization of the receiving antenna, `fv_rcv`. The field vector lies in a plane orthogonal to the direction of propagation from the transmitter to the receiver. The transmitted field is represented as a 2-by-1 column vector `[Eh;Ev]`. In this vector, `Eh` and `Ev` are the field's horizontal and vertical linear polarization components with respect to the transmitter's local coordinate system. The receiving antenna's polarization is specified by a 2-by-1 column vector, `fv_rcv`. You can also specify this polarization in the form of `[Eh;Ev]` with respect to the receiving antenna's local coordinate system. In this syntax, both local coordinate axes align with the global coordinate system.

`rho = polloss(fv_tr,fv_rcv,pos_rcv)` specifies, in addition, the position of the receiver. The receiver is defined as a 3-by-1 column vector, `[x;y;z]`, with respect to the global coordinate system (position units are in meters). This syntax can use any of the input arguments in the previous syntax.

`rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv)` specifies, in addition, the orthonormal axes, `axes_rcv`. These axes define the receiver's local coordinate system as a 3-by-3 matrix. The first column gives the *x*-axis of the local system with respect to the global coordinate system. The second and third columns give the *y* and *z* axes, respectively. This syntax can use any of the input arguments in the previous syntaxes.

rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr) specifies, in addition, the position of the transmitter as a 3-by-1 column vector, [x;y;z], with respect to the global coordinate system (position units are in meters). This syntax can use any of the input arguments in the previous syntaxes.

rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr,axes_tr) specifies, in addition, the orthonormal axes, axes_tr. These axes define the transmitter's local coordinate system as a 3-by-3 matrix. The first column gives the *x*-axis of the local system with respect to the global coordinate system. The second and third columns give the *y* and *z* axes, respectively. This syntax can use any of the input arguments in the previous syntaxes.

# Examples

### Mismatch Between 45° Polarized Field and Horizontally Polarized Receiver

Begin with a 45° polarized transmitted field and a receiver that is horizontally polarized. By default, the transmitter and receiver local axes coincide with the global coordinate system. Compute the polarization loss in dB.

```
fv_tr = [1;1];
fv_rcv = [1;0];
rho = polloss(fv_tr,fv_rcv)
```

```
rho = 3.0103
```

The loss is 3 dB as expected because only half the power of the field matches to the receive antenna polarization.

### Polarization Loss Unaffected by Receiver Position

Begin with identical transmitter and receiver polarizations. Place the receiver at a position 100 meters along the *y*-axis. The transmitter is at the origin (its default position) and both local coordinate axes coincide with the global coordinate system (by default). First, compute the polarization loss. Then, move the receiver 100 meters along the_x_-axis, and compute the polarization loss again.

```
fv_tr = [1;0];
fv_rcv = [1;0];
pos_rcv = [0;100;0];
rho(1) = polloss(fv_tr,fv_rcv,pos_rcv);
pos_rcv = [100;100;0];
rho(2) = polloss(fv_tr,fv_rcv,pos_rcv)
```

```
rho = 1×2

     0     0
```

No polarization loss occurs at either position. The spherical basis vectors of each antenna are parallel to other antenna and the polarization vectors are the same.

### Loss Due to Receiver Axes Rotation

Start with identical transmitter and receiver polarizations. Put the receiver at a position 100 meters along the *y*-axis. The transmitter is at the origin (default) and both local coordinate axes coincide with the global coordinate system (default). Compute the loss, and then rotate the receiver 30° around the *y*-axis. This rotation changes the azimuth and elevation of the transmitter with respect to the receiver and, therefore, the direction of polarization.

```
fv_tr = [1;0];
fv_rcv = [1;0];
pos_rcv = [0;100;0];
ax_rcv = azelaxes(0,0);
rho(1) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv);
ax_rcv = roty(30)*ax_rcv;
rho(2) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv)
```

```
rho = 1×2

         0    1.2494
```

The receiver polarization vector remains unchanged. However, rotating the local coordinate system changes the direction of the field of the receiving antenna polarization with respect to global coordinates. This change results in a 1.2 dB loss.

### Polarization Loss Unaffected by Transmitter Position

Start with identical transmitter and receiver polarizations. Put the receiver at a position 100 meters along the_y_-axis. The transmitter is at the origin (default) and both local coordinate axes coincide with the global coordinate system (default). First, compute the polarization loss. Then, move the transmitter 100 meters along the *x*-axis and 100 meters along the *y*-axis, and compute the polarization loss again.

```
fv_tr = [1;0];
fv_rcv = [1;0];
pos_rcv = [0;100;0];
ax_rcv = azelaxes(0,0);
pos_tr = [0;0;0];
rho(1) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv,pos_tr);
pos_tr = [100;100;0];
rho(2) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv,pos_tr)
```

```
rho = 1×2

     0     0
```

There is no polarization loss at either position because the spherical basis vectors of each antenna are parallel to their counterparts and the polarization vectors are the same.

### Plot Polarization Loss as Receiving Antenna Rotates

Specifying identical transmitter and receiver polarizations, plot the loss as the local receiving antenna axes rotate around the *x*-axis.

```
fv_tr = [1;0];
fv_rcv = [1;0];
```

The position of the transmitting antenna is at the origin and its local axes align with the global coordinate system. The position of the receiving antenna is 100 meters along the global *x*-axis. However, its local *x*-axis points towards the transmitting antenna.

```
pos_tr = [0;0;0];
axes_tr = azelaxes(0,0);
```

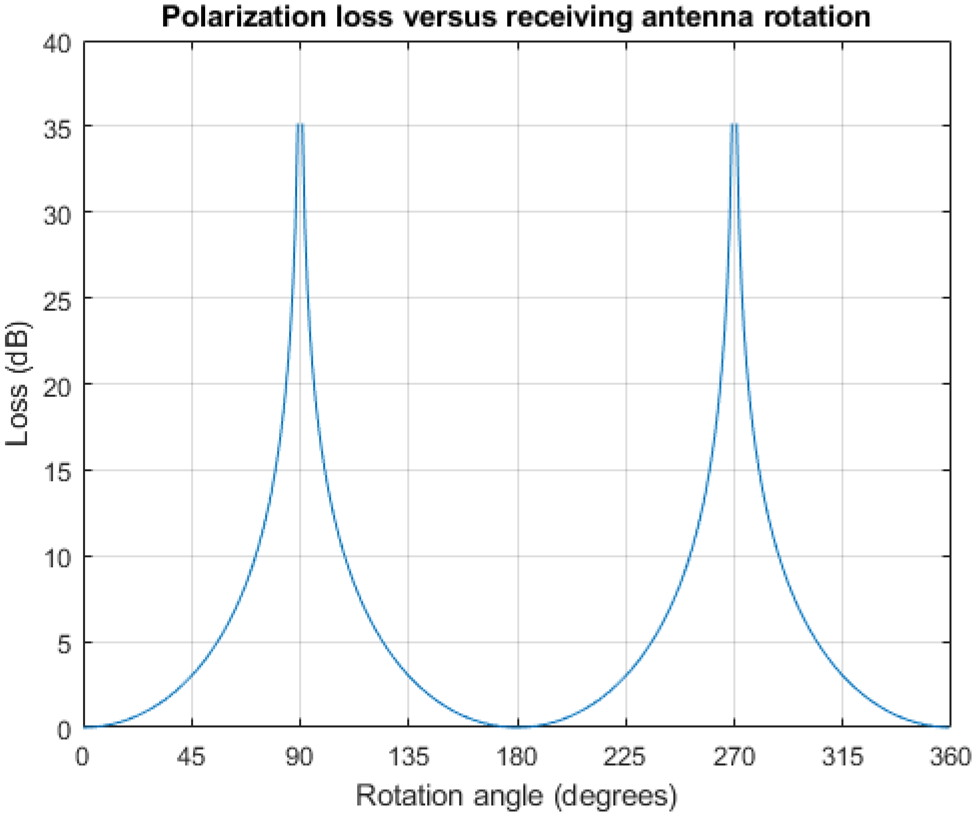
```
pos_rcv = [100;0;0];
axes_rcv0 = rotz(180)*azelaxes(0,0);
```

Rotate the receiving antenna around its local *x*-axis in one-degree increments. Compute the loss for each angle.

```
angles = [0:1:359];
n = size(angles,2);
rho = zeros(1,n); % Initialize space
for k = 1:n
    axes_rcv = rotx(angles(k))*axes_rcv0;
    rho(k) = polloss(fv_tr,fv_rcv,pos_tr,axes_tr,...
        pos_rcv,axes_rcv);
end
```

Plot the polarization loss.

```
hp = plot(angles,rho);
hax = hp.Parent;
hax.XLim = [0,360];
xticks = (0:(n-1))*45;
hax.XTick = xticks;
grid;
title('Polarization loss versus receiving antenna rotation')
xlabel('Rotation angle (degrees)');
ylabel('Loss (dB)');
```



The angle-loss plot shows nulls (`Inf` dB) at 90 degrees and 270 degrees where the polarizations are orthogonal.

## Input Arguments

**`fv_tr` — Transmitted field vector in linear component representation**
2-by-1 complex-valued column vector

The transmitted field vector in linear component representation specified as a 2-by-1, complex-valued column vector `[Eh;Ev]`. In this vector, `Eh` and `Ev` are the field's horizontal and vertical linear components.

Example: [1;1]

Data Types: `double`
Complex Number Support: Yes

### `fv_rcv` — Receiver polarization vector in linear component representation

2-by-1 complex-valued column vector

Receiver polarization vector in linear component representation specified as a 2-by-1, complex-valued column vector `[Eh;Ev]`. In this vector, `Eh` and `Ev` are the polarization vector’s horizontal and vertical linear components.

Example: [0;1]

Data Types: `double`
Complex Number Support: Yes

### `pos_rcv` — Receiving antenna position

[0;0;0] (default) | 3-by-1 real-valued column vector

Receiving antenna position specified as a 3-by-1, real-valued column vector. The components of `pos_rcv` are specified in the global coordinate system as `[x;y;z]`.

Example: [1000;0;0]

Data Types: `double`

### `axes_rcv` — Receiving antenna local coordinate axes

3-by-3 identity matrix (default) | 3-by-3 real-valued matrix

Receiving antenna local coordinate axes specified as a 3-by-3, real-valued matrix. Each column is a unit vector specifying the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively, with respect to the global coordinate system. Each column is written in `[x;y;z]` form. If `axes_rcv` is specified as the identity matrix, the local coordinate system is aligned with the global coordinate system.

Example: [1, 0, 0; 0, 1, 0; 0, 0 ,1]

Data Types: `double`

### `pos_tr` — Transmitter position

[0;0;0] (default) | 3-by-1 real-valued column vector

Transmitter position specified as a 3-by-1, real-valued column vector. The components of `pos_tr` are specified in the global coordinate system as `[x;y;z]`.

Example: [0;0;0]

Data Types: `double`

**`axes_tr` — Transmitting antenna local coordinate axes**
3-by-3 identity matrix (default) | 3-by-3 real-valued matrix

Transmitting antenna local coordinate axes specified as a 3-by-3, real-valued matrix. Each column is a unit vector specifying the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively, with respect to the global coordinate system. Each column is written in `[x;y;z]` form. If `axes_tr` is the identity matrix, the local coordinate system is aligned with the global coordinate system.

Example: [1, 0, 0; 0, 1, 0; 0, 0 ,1]

Data Types: `double`

# Output Arguments

**`rho` — Polarization loss**
scalar

Polarization loss returned as scalar in decibel units. The polarization loss is the projection of the normalized transmitted field vector into the normalized receiving antenna polarization vector. Its value lies between zero and unity. When converted into dB, (and a sign changed to show loss as positive) its value lies between 0 and `-Inf`.

# More About

## Polarization Loss Due to Field and Receiver Mismatch

Loss occurs when a receiver is not matched to the polarization of an incident electromagnetic field.

In the case of the polarization of a field emitted by a transmitting antenna, first, look at the far zone of the transmitting antenna, as shown in the following figure. At this location—which is the location of the receiving antenna—the electromagnetic field is orthogonal to the direction from transmitter to receiver.

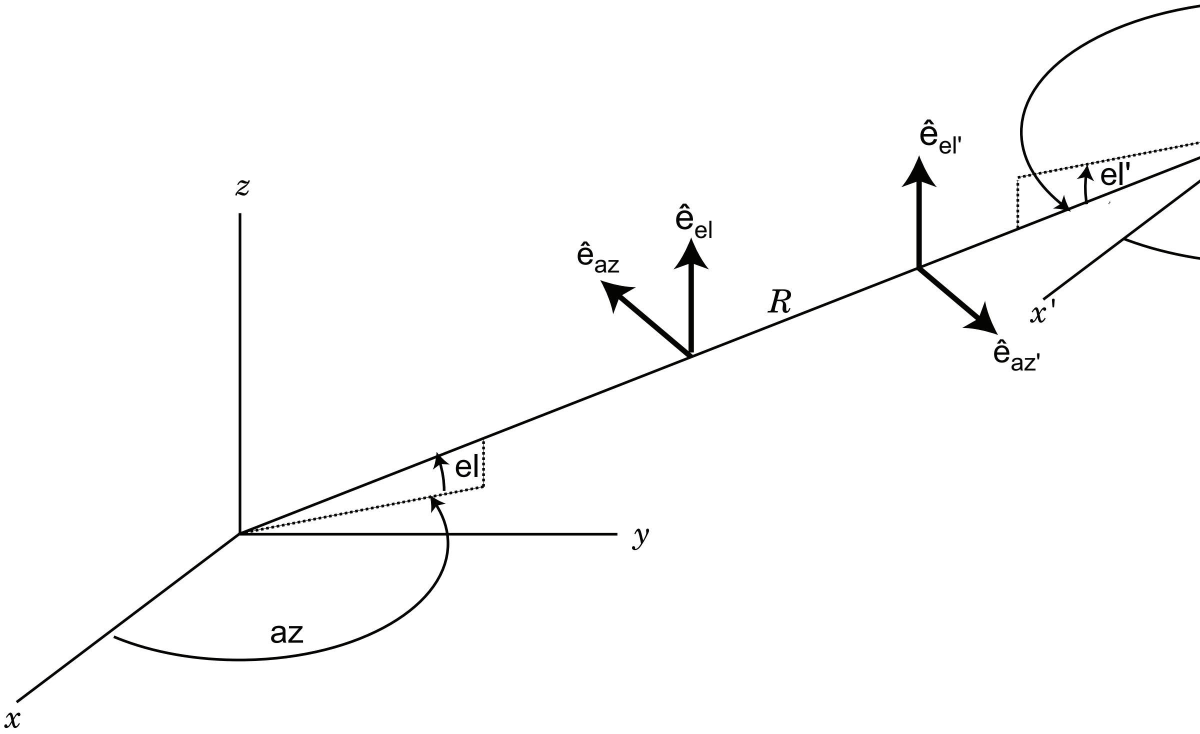
You can represent the transmitted electromagnetic field, `fv_tr`, by the components of a vector with respect to a spherical basis of the transmitter's local coordinate system. The orientation of this basis depends on its direction from the origin. The direction is specified by the azimuth and elevation of the receiving antenna with respect to the transmitter's local coordinate system. Then, the transmitter's polarization, in terms of the spherical basis vectors of the transmitter's local coordinate system, is

$$\mathbf{E} = E_H\widehat{\mathbf{e}}_{az} + E_V\widehat{\mathbf{e}}_{el} = E_m\mathbf{P}_i$$

In the same manner, the receiver's polarization vector, `fv_rcv`, is defined with respect to a spherical basis in the receiver's local coordinate system. Now, the azimuth and elevation specify the transmitter's position with respect to the receiver's local coordinate system. You can write the receiving antennas polarization in terms of the spherical basis vectors of the receiver's local coordinate system:

$$\mathbf{P} = P_H\widehat{\mathbf{e}}'_{az} + P_V\widehat{\mathbf{e}}'_{el}$$

This figure shows the construction of the different transmitter and receiver local coordinate systems. It also shows the spherical basis vectors with which to write the field components.



The polarization loss is the projection (or dot product) of the normalized transmitted field vector onto the normalized receiver polarization vector. Notice that the loss occurs because of the mismatch in direction of the two vectors not in their magnitudes. Because the vectors are defined in different coordinate systems, they must be converted to the global coordinate system in order to form the projection. The polarization loss is defined by:

$$\rho = \frac{|\mathbf{E}_i \cdot \mathbf{P}|^2}{|\mathbf{E}_i|^2\,|\mathbf{P}|^2}$$

# polratio

Ratio of vertical to horizontal linear polarization components of a field

## Syntax

```
p = polratio(fv)
```

## Description

`p = polratio(fv)` returns the ratio of the vertical to horizontal component of the field or set of fields contained in `fv`.

Each column of `fv` contains the linear polarization components of a field in the form `[Eh;Ev]`, where `Eh` and `Ev` are the field’s linear horizontal and vertical polarization components. The expression of a field in terms of a two-row vector of linear polarization components is called the Jones vector formalism. The argument `fv` can refer to either the electric or magnetic part of an electromagnetic wave.

Each entry in `p` contains the ratio `Ev/Eh` of the components of `fv`.

## Examples

### Polarization Ratio for 45° Linearly Polarized Field

Determine the polarization ratio for a linearly polarized field (when the horizontal and vertical components of a field have the same phase).

```
fv = [2;2];
p = polratio(fv)
```

```
p = 1
```

The polarization ratio is real. Because the components have equal amplitudes, the polarization ratio is unity.

### Polarization Ratios for Two Fields

Compute the polarization ratios for two fields. The first field is *(2;i)* and the second is *(i;1)*.

```
fv = [2,1i;1i,1];
p = polratio(fv)
```

```
p = 1×2 complex

   0.0000 + 0.5000i   0.0000 - 1.0000i
```

### Polarization Ratio for Vertically Polarized Field

Determine the polarization ratio for a vertically polarized field (the horizontal component of the field vanishes).

```
fv = [0;2];
p = polratio(fv)
```

```
p = Inf
```

The polarization ratio is infinite as expected from the definition,_Ev/Eh_.

## Input Arguments

### `fv` — Field vector in linear component representation

2-by-*N* complex-valued matrix

Field vector in linear component representation specified as a 2-by-*N* complex-valued matrix. Each column of `fv` contains an instance of a field specified by `[Eh;Ev]`, where `Eh` and `Ev` are the field's linear horizontal and vertical polarization components. Two rows of the same column cannot both be zero.

Example: [2 , i; i, 1]

Data Types: `double`

Complex Number Support: Yes

# Output Arguments

**p — Polarization ratio**
1-by-*N* complex-valued row vector

Polarization ratio returned as a 1-by-*N* complex-valued row vector. `p` contains the ratio of the components of the second row of `fv` to the first row, `Ev/Eh`.

# polsignature

Copolarization and cross-polarization signatures

## Syntax

```
resp = polsignature(rcsmat)
resp = polsignature(rcsmat,type)
resp = polsignature(rcsmat,type,epsilon)
resp = polsignature(rcsmat,type,epsilon,tau)

polsignature( ___ )
```

## Description

`resp = polsignature(rcsmat)` returns the normalized radar cross-section copolarization (co-pol) signature, `resp` (in square meters), determined from the scattering cross section matrix, `rcsmat` of an object. The signature is a function of the transmitting antenna polarization, specified by the ellipticity angle and the tilt angle of the polarization ellipse. In this syntax case, the ellipticity angle takes the values `[-45:45]` and the tilt angle takes the values `[-90:90]`. The output `resp` is a 181-by-91 matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair.

`resp = polsignature(rcsmat,type)`, in addition, specifies the polarization signature type as one of `'c'|'x'`, where `'c'` creates the copolarization signature and `'x'` creates the cross-polarization (cross-pol) signature. The default value of this parameter is `'c'`. The output `resp` is a 181-by-91 matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair. This syntax can use the input arguments in the previous syntax.

`resp = polsignature(rcsmat,type,epsilon)`, in addition, specifies the transmit antenna polarization's ellipticity angle (in degrees) as a length-*M* vector. The angle `epsilon` must lie between –45° and 45°. The argument `resp` is a 181-by-*M* matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair. This syntax can use any of the input arguments in the previous syntaxes.

`resp = polsignature(rcsmat,type,epsilon,tau)`, in addition, specifies the tilt angle of the polarization ellipse of the transmitted wave (in degrees) as a length-*N* vector.

The angle `tau` must be between –90° and 90°. The signature, `resp`, is represented as a function of the transmitting antenna polarization. The transmitting antenna polarization is characterized by the ellipticity angle, `epsilon`, and the tilt angle, `tau`. The argument `resp` is a *N*-by-*M* matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair. This syntax can use any of the input arguments in the previous syntaxes.

`polsignature( ___ )` plots a three dimensional surface using any of the syntax forms specified above.

## Examples

### Copolarization Signature of a Dihedral

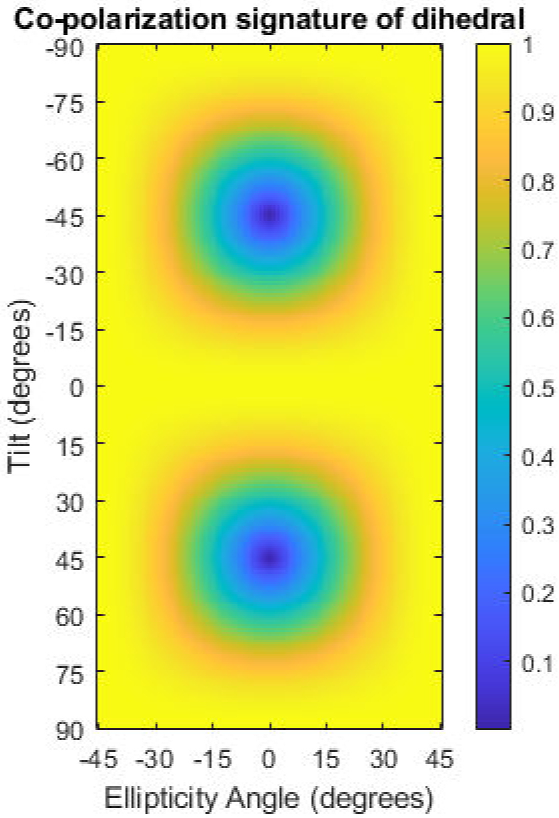
Calculate and plot the copolarization response to the scattering cross-section matrix, `rscmat`, of a dihedral object. Specify the ellipticity angle values as `[-45:45]` and the tilt angle values as `[-90:90]`. Display the response matrix as an image.

Calculate the copolarization response.

```
rscmat = [-1,0;0,1];
resp = polsignature(rscmat);
```

Plot the copolarization response.

```
el = [-45:45];
tilt = [-90:90];
imagesc(el,tilt,resp);
ylabel('Tilt (degrees)');
xlabel('Ellipticity Angle (degrees)')
axis image
ax = gca;
ax.XTick = [-45:15:45];
ax.YTick = [-90:15:90];
title('Co-polarization signature of dihedral');
colorbar;
```



### Cross-Polarization Signature of a Dihedral

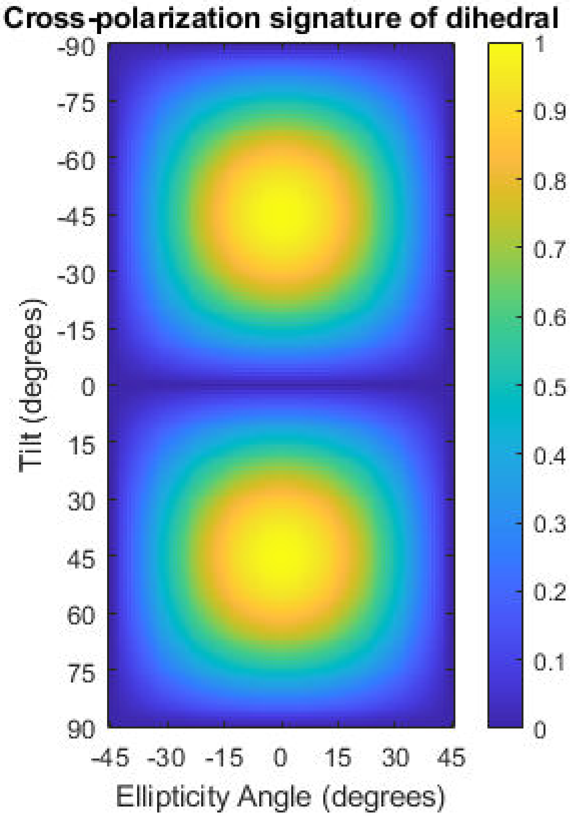
Calculate and plot the cross-polarization response to the scattering cross-section matrix, `rscmat`, of a dihedral object. Specify the ellipticity angle values as [-45:45] and the tilt angle values as [-90:90]. Display the response matrix as an image.

Calculate the cross-polarization response. To do this, set the `type` argument to `'x'`.

```
rscmat = [-1,0;0,1];
resp = polsignature(rscmat,'x');
```

Plot the cross-polarization response.

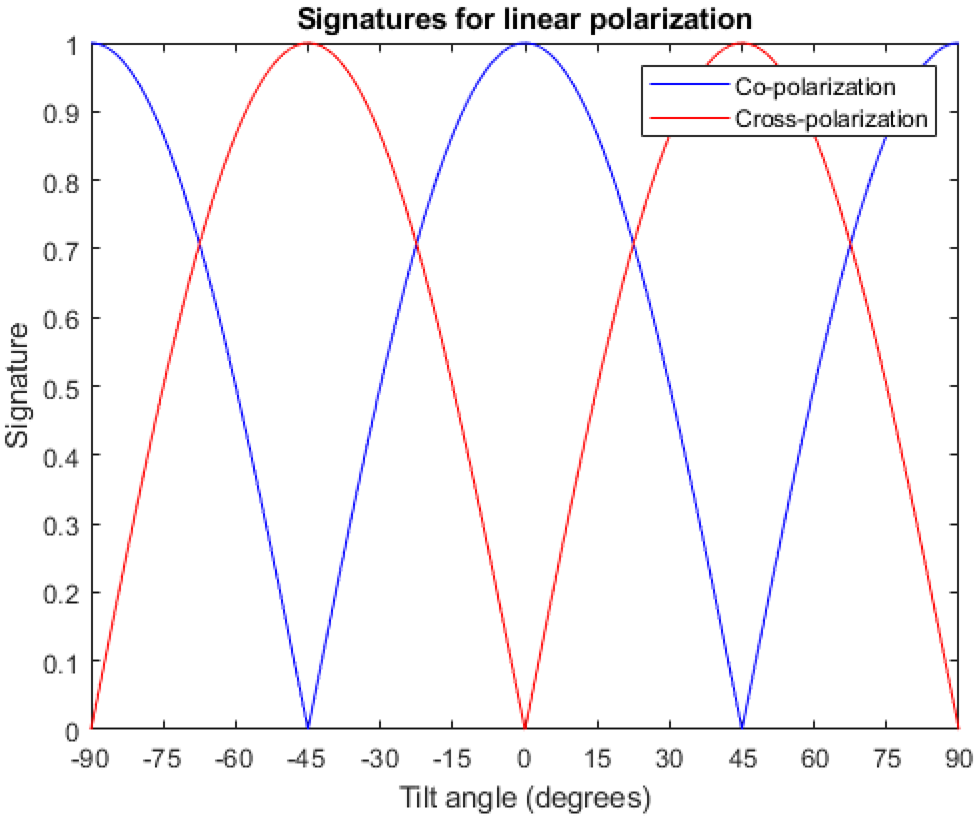
```
el = [-45:45];
tilt = [-90:90];
imagesc(el,tilt,resp);
ylabel('Tilt (degrees)');
xlabel('Ellipticity Angle (degrees)');
axis image
ax = gca;
ax.XTick = [-45:15:45];
ax.YTick = [-90:15:90];
title('Cross-polarization signature of dihedral');
colorbar;
```



### Signatures for Linear Polarization with Varied Tilt Angles

Set the ellipticity angle to zero, and vary the tilt angle from -90 to +90 degrees to generate all possible linear polarization directions. Then, plot both the copolarization and cross-polarization signatures.

```
rscmat = [-1,0;0,1];
el = [0];
respc = polsignature(rscmat,'c',el);
respx = polsignature(rscmat,'x',el);
tilt = [-90:90];
plot(tilt,respc,'b',tilt,respx,'r')
ax = gca;
ax.XLim = [-90,90];
ax.XTick = [-90:15:90];
legend('Co-polarization','Cross-polarization')
title('Signatures for linear polarization')
xlabel('Tilt angle (degrees)')
ylabel('Signature')
```



### Copolarization Signature of Dihedral for Left and Right Circular Polarizations

This example shows how to obtain numerical values for the polarization signatures of a dihedral target for left and right circularly polarized incident waves.

Specify the radar cross-section matrix of a dihedral

```
rscmat = [-1,0;0,1];
```

Specify a left circularly-polarized wave and obtain its tilt angle and ellipticity.

```
fv = 1/sqrt(2)*[1;1i];
[tilt_lcp,el_lcp] = polellip(fv);
disp([tilt_lcp,el_lcp])

    45    45
```

Specify a right circularly-polarized wave by complex conjugation of a left circularly-polarized wave. Obtain the polarization ellipse tilt angle and ellipticity.

```
[tilt_rcp,el_rcp] = polellip(conj(fv));
disp([tilt_rcp,el_rcp])

    45   -45
```

Both tilt angles are 45 degrees. Compute the copolarization and cross-polarization signatures for the two waves.

```
el = [el_lcp, el_rcp];
tilt = tilt_rcp;
respc = polsignature(rscmat,'c',el,tilt);
respx = polsignature(rscmat,'x',el,tilt);
disp(respc)

     1     1

disp(respx)

     1     1
```

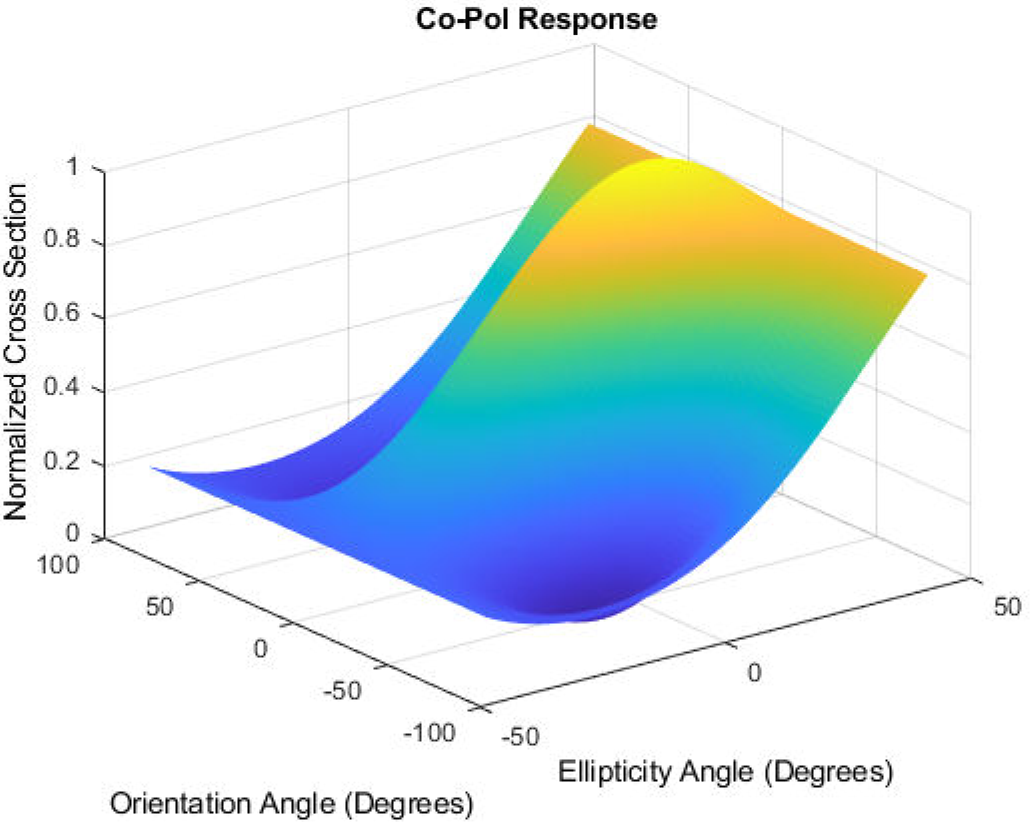
### Surface Plot of Copolarization Signature of General Target

Use a general RCSM matrix to create a 3-D surface plot.

```
rscmat = [1i*2,0.5; 0.5, -1i];
el = [-45:45];
tilt = [-90:90];
```

With no output arguments, `polsignature` automatically creates a surface plot.

```
polsignature(rscmat,'c',el,tilt);
```



## Input Arguments

**`rcsmat` — Radar cross-section scattering matrix**
2-by-2 complex-valued matrix

Radar cross-section scattering matrix (RCSM) of an object specified as a 2-by-2, complex-valued matrix. The radar cross-section scattering matrix describes the polarization of a scattered wave as a function of the polarization of an incident wave upon a target. The response to an incident wave can be construct from the individual responses to the incident field's horizontal and vertical polarization components. These components are taken with respect to the transmit antenna or array local coordinate system. The scattered wave can be decomposed into horizontal and vertical polarization components with respect to the receive antenna or array local coordinate system. The matrix *RCSM* contains four components `[rcs_hh rcs_hv;rcs_vh rcs_vv]` where each component is the radar cross section defined by the polarization of the transmit and receive antennas.

- `rcs_hh` – Horizontal response due to horizontal transmit polarization component
- `rcs_hv` – Horizontal response due to vertical transmit polarization component
- `rcs_vh` – Vertical response due to horizontal transmit polarization component
- `rcs_vv` – Vertical response due to vertical transmit polarization component

In the monostatic radar case, when the wave is backscattered, the RCSM matrix is symmetric.

Example: `[-1,1i;1i,1]`

Data Types: `double`
Complex Number Support: Yes

### `type` — Polarization signature type

`'c'` (default) | single character `'c'` | `'x'`

Polarization signature type of the scattered wave specified by a single character: `'c'` denoting the copolarized signature or `'x'` denoting the cross-polarized signature.

Example: `'x'`

Data Types: `char`

### `epsilon` — Ellipticity angle of the polarization ellipse of the transmitted wave

`[-45:45]` (default) | scalar or 1-by-*M* real-valued row vector

Ellipticity angle of the polarization ellipse of the transmitted wave specified as a length-*M* vector. Units are degrees. The ellipticity angle describes the shape of the ellipse. By definition, the tangent of the ellipticity angle is the signed ratio of the semiminor axis to semimajor axis of the polarization ellipse. Since the absolute value of this ratio cannot exceed unity, the ellipticity angle lies between ±45°.

Example: `[-45:0.5:45]`

Data Types: `double`

### `tau` — Tilt angle of the polarization ellipse of the transmitted wave

`[-90:90]` (default) | scalar or 1-by-*N* real-valued row vector.

Tilt angle of the polarization ellipse of the transmitted wave specified as a length-*N* vector. Units are degrees. The tilt angle is defined as the angle between the semimajor axis of the ellipse and the *x*-axis. Because the ellipse is symmetrical, an ellipse with a tilt angle of 100° is the same ellipse as one with a tilt angle of –80°. Therefore, the tilt angle need only be specified between ±90°.

Example: `[-30:2:30]`

Data Types: `double`

## Output Arguments

**`resp` — Normalized magnitude response**
scalar or *N*-by-*M* real-valued matrix.

Normalized magnitude response returned as a scalar or *N*-by-*M*, real-valued matrix having values between 0 and 1. `resp` returns a value for each ellipticity-tilt angle pair.

## More About

### Scattering Cross-Section Matrix

Scattering cross-section matrix determines response of an object to incident polarized electromagnetic field.

When a polarized plane wave is incident on an object, the amplitude and polarization of the scattered wave may change with respect to the incident wave polarization. The polarization may depend upon the direction from which the scattered wave is observed. The exact way that the polarization changes depends upon the properties of the scattering object. The quantity describing the response of an object to the incident field is called the scattering cross-section matrix, *S*. The scattering matrix can be measured as follows: when a unit amplitude horizontally polarized wave is scattered, both a horizontal and vertical scattered component are produced. Call these two components $S_{HH}$ and $S_{VH}$. These are complex numbers containing the amplitude and phase changes from the incident wave. Similarly, when a unit amplitude vertically polarized wave is scattered, the horizontal and vertical scattered component produced are $S_{HV}$ and $S_{VV}$. Because any incident field can be decomposed into horizontal and vertical components, stack these quantities into a matrix and write the scattered field in terms of the incident field

$$\begin{bmatrix} E_H^{(sc)} \\ E_V^{(sc)} \end{bmatrix} = \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = S \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

The scattering cross section matrix depends upon the angles that the incident and scattered fields make with the object. When the incident field is backscattered to the transmitting antenna, the scattering matrix is symmetric.

## Polarization Signature

Polarization signature for visualizing scattering cross-section matrix.

To understand how the scattered wave depends upon the polarization of the incident wave, an examination of all possible scattered field polarizations for each incident polarization is required. Because this amount of data is difficult to visualize, you can look at two particular scattered polarizations:

- Choose one polarization that has the same polarization as the incident field (copolarization)
- Choose a second one that is orthogonal to the polarization of the incident field (cross-polarization)

Both the incident and orthogonal polarization states can be specified in terms of the tilt angle-ellipticity angle pair $(\tau, \varepsilon)$. From the incident field tilt and ellipticity angles, the unit incident polarization vector can be expressed as

$$\begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \begin{bmatrix} \cos\tau & -\sin\tau \\ \sin\tau & \cos\tau \end{bmatrix} \begin{bmatrix} \cos\varepsilon \\ j\sin\varepsilon \end{bmatrix}$$

while the orthogonal polarization vector is

$$\begin{bmatrix} E_H^{(inc)\perp} \\ E_V^{(inc)\perp} \end{bmatrix} = \begin{bmatrix} -\sin\tau & -\cos\tau \\ \cos\tau & -\sin\tau \end{bmatrix} \begin{bmatrix} \cos\varepsilon \\ -j\sin\varepsilon \end{bmatrix}$$

To form the copolarization signature, use the RCSM matrix, $S$, to compute:

$$P^{(co)} = \begin{bmatrix} E_H^{(inc)} & E_V^{(inc)} \end{bmatrix}^* S \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

where $[\,]^*$ denotes complex conjugation. For the cross-polarization signature, compute

$$P^{(cross)} = \left[E_H^{(inc)\perp} \;\; E_V^{(inc)\perp}\right]^* S \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

The output of this function is the absolute value of each signature normalized by its maximum value.

# pulsint

Pulse integration

## Syntax

```
Y = pulsint(X)
Y = pulsint(X,METHOD)
```

## Description

`Y = pulsint(X)` performs video (noncoherent) integration of the pulses in `X` and returns the integrated output in `Y`. Each column of `X` is one pulse.

`Y = pulsint(X,METHOD)` performs pulse integration using the specified method. `METHOD` is `'coherent'` or `'noncoherent'`.

## Input Arguments

### X

Pulse input data. Each column of `X` is one pulse.

### METHOD

Pulse integration method. `METHOD` is the method used to integrate the pulses in the columns of `X`. Valid values of `METHOD` are `'coherent'` and `'noncoherent'`. The values are not case sensitive.

**Default:** `'noncoherent'`

## Output Arguments

### Y

Integrated pulse. Y is an N-by-1 column vector where N is the number of rows in the input X.

## Examples

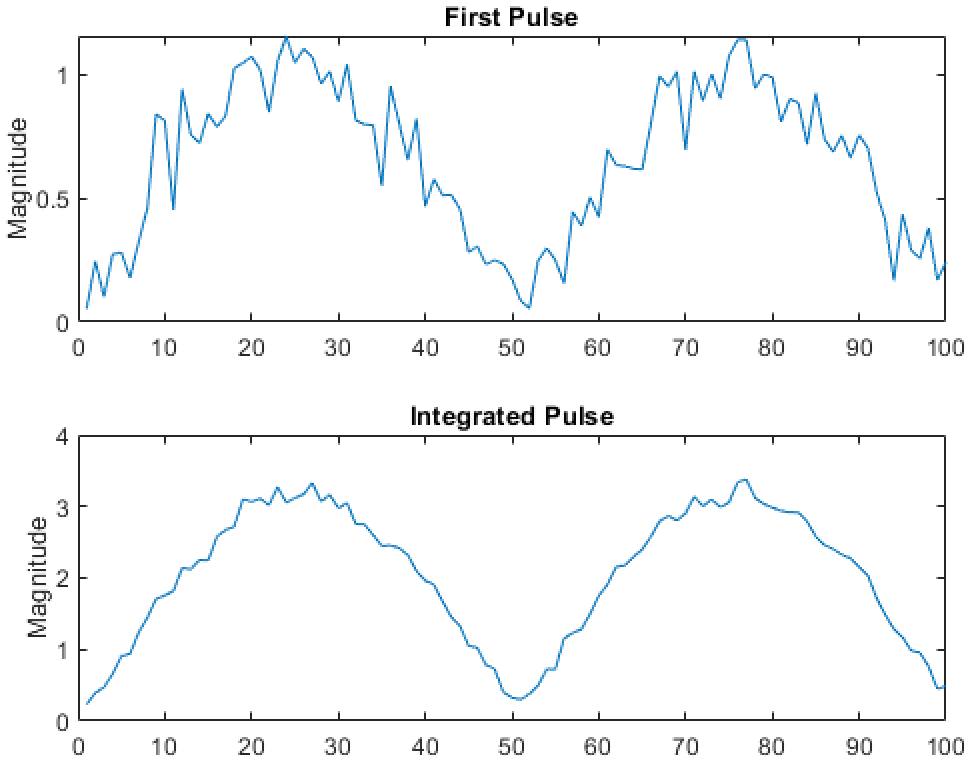
### Noncoherent Integration of Pulses

Noncoherently integrate 10 pulses of a sinusoid with added gaussian white noise.

```
npulse = 10;
x = repmat(sin(2*pi*(0:99)'/100),1,npulse) + 0.1*randn(100,npulse);
y = pulsint(x);
```

Plot a single pulse and then the integrated pulses.

```
subplot(2,1,1)
plot(abs(x(:,1)))
ylabel('Magnitude')
title('First Pulse')
subplot(2,1,2)
plot(abs(y))
ylabel('Magnitude')
title('Integrated Pulse')
```



# More About

## Coherent Integration

Let $X_{ij}$ denote the *(i,j)*-th entry of an M-by-N matrix of pulses *X*.

The coherent integration of the pulses in *X* is:

$$Y_i = \sum_{j=1}^{N} X_{ij}$$

### Noncoherent (video) Integration

Let $X_{ij}$ denote the *(i,j)*-th entry of an M-by-N matrix of pulses *X*.

The noncoherent (video) integration of the pulses in *X* is:

$$Y_i = \sqrt{\sum_{j=1}^{N} \left| X_{ij} \right|^2}$$

# radareqpow

Peak power estimate from radar equation

## Syntax

```
Pt = radareqpow(lambda,tgtrng,SNR,Tau)
Pt = radareqpow(...,Name,Value)
```

## Description

`Pt = radareqpow(lambda,tgtrng,SNR,Tau)` estimates the peak transmit power required for a radar operating at a wavelength of `lambda` meters to achieve the specified signal-to-noise ratio `SNR` in decibels for a target at a range of `tgtrng` meters. The target has a nonfluctuating radar cross section (RCS) of 1 square meter.

`Pt = radareqpow(...,Name,Value)` estimates the required peak transmit power with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `lambda`

Wavelength of radar operating frequency (in meters). The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light. Denoting the speed of light by *c* and the frequency (in hertz) of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

### `tgtrng`

Target range in meters. When the transmitter and receiver are colocated (monostatic radar), `tgtrng` is a real-valued positive scalar. When the transmitter and receiver are not colocated (bistatic radar), `tgtrng` is a 1-by-2 row vector with real-valued positive elements. The first element is the target range from the transmitter, and the second element is the target range from the receiver.

### SNR

The minimum output signal-to-noise ratio at the receiver in decibels.

### Tau

Single pulse duration in seconds.

## Name-Value Pair Arguments

### Gain

Transmitter and receiver gain in decibels (dB). When the transmitter and receiver are colocated (monostatic radar), `Gain` is a real-valued scalar. The transmit and receive gains are equal. When the transmitter and receiver are not colocated (bistatic radar), `Gain` is a 1-by-2 row vector with real-valued elements. The first element is the transmitter gain and the second element is the receiver gain.

**Default:** 20

### Loss

System loss in decibels (dB). `Loss` represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

**Default:** 0

### RCS

Radar cross section in square meters. The target RCS is nonfluctuating.

**Default:** 1

### Ts

System noise temperature in kelvin. The system noise temperature is the product of the system temperature and the noise figure.

**Default:** 290 kelvin

# Output Arguments

**Pt**

Transmitter peak power in watts.

# Examples

### Compute Required Transmit Power

Estimate the required peak transmit power required to achieve a minimum SNR of 6 dB for a target at a range of 50 km. The target has a nonfluctuating RCS of 1 m². The radar operating frequency is 1 GHz. The pulse duration is 1 µs.

```
fc = 1.0e9;
lambda = physconst('LightSpeed')/fc;
tgtrng = 50e3;
tau = 1e-6;
SNR = 6;
Pt = radareqpow(lambda,tgtrng,SNR,tau)
```

```
Pt = 2.1996e+05
```

### Compute Required Transmit Power at Specified System Temperature

Estimate the required peak transmit power required to achieve a minimum SNR of 10 dB for a target with an RCS of 0.5 m² at a range of 50 km. The radar operating frequency is 10 GHz. The pulse duration is 1 µs. Assume a transmit and receive gain of 30 dB and an overall loss factor of 3 dB. The system temperature is 300 K.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
Pt = radareqpow(lambda,50e3,10,1e-6,'RCS',0.5,...
    'Gain',30,'Ts',300,'Loss',3)
```

```
Pt = 2.2809e+06
```

### Compute Required Transmit Power for Bistatic Radar

Estimate the required peak transmit power for a bistatic radar to achieve a minimum SNR of 6 dB for a target with an RCS of 1 m². The target is 50 km from the transmitter and 75 km from the receiver. The radar operating frequency is 10 GHz and the pulse duration is 10 μs. The transmitter and receiver gains are 40 dB and 20 dB, respectively.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
SNR = 6;
tau = 10e-6;
TxRng = 50e3;
RvRng = 75e3;
TxRvRng =[TxRng RvRng];
TxGain = 40;
RvGain = 20;
Gain = [TxGain RvGain];
Pt = radareqpow(lambda,TxRvRng,SNR,tau,'Gain',Gain)
```

```
Pt = 4.9492e+04
```

# More About

## Point Target Radar Range Equation

The point target radar range equation estimates the power at the input to the receiver for a target of a given radar cross section at a specified range. The model is deterministic and assumes isotropic radiators. The equation for the power at the input to the receiver is

$$P_r = \frac{P_t G_t G_r \lambda^2 \sigma}{(4\pi)^3 R_t^2 R_r^2 L}$$

where the terms in the equation are:

- $P_t$ — Peak transmit power in watts
- $G_t$ — Transmitter gain in decibels
- $G_r$ — Receiver gain in decibels. If the radar is monostatic, the transmitter and receiver gains are identical.

- $\lambda$ — Radar operating frequency wavelength in meters
- $\sigma$ — Target's nonfluctuating radar cross section in square meters
- $L$ — General loss factor in decibels that accounts for both system and propagation loss
- $R_t$ — Range from the transmitter to the target
- $R_r$ — Range from the receiver to the target. If the radar is monostatic, the transmitter and receiver ranges are identical.

Terms expressed in decibels such as the loss and gain factors enter the equation in the form $10^{x/10}$ where $x$ denotes the variable. For example, the default loss factor of 0 dB results in a loss term of $10^{0/10}=1$.

## Receiver Output Noise Power

The equation for the power at the input to the receiver represents the *signal* term in the signal-to-noise ratio. To model the noise term, assume the thermal noise in the receiver has a white noise power spectral density (PSD) given by:

$$P(f) = kT$$

where $k$ is the Boltzmann constant and $T$ is the effective noise temperature. The receiver acts as a filter to shape the white noise PSD. Assume that the magnitude squared receiver frequency response approximates a rectangular filter with bandwidth equal to the reciprocal of the pulse duration, $1/\tau$. The total noise power at the output of the receiver is:

$$N = \frac{kTF_n}{\tau}$$

where $F_n$ is the receiver *noise factor*.

The product of the effective noise temperature and the receiver noise factor is referred to as the *system temperature* and is denoted by $T_s$, so that $\mathrm{T_s}=TF_n$ .

## Receiver Output SNR

Using the equation for the received signal power in “Point Target Radar Range Equation” on page 2-359 and the output noise power in “Receiver Output Noise Power” on page 2-360, the receiver output SNR is:

$$\frac{P_r}{N} = \frac{P_t\tau G_tG_r\lambda^2\sigma}{(4\pi)^3kT_sR_t^2R_r^2L}$$

Solving for the peak transmit power

$$P_t = \frac{P_r(4\pi)^3 k T_s R_t^2 R_r^2 L}{N\tau G_t G_r \lambda^2 \sigma}$$

# radareqrng

Maximum theoretical range estimate

## Syntax

```
maxrng = radareqrng(lambda,SNR,Pt,Tau)
maxrng = radareqrng(...,Name,Value)
```

## Description

`maxrng = radareqrng(lambda,SNR,Pt,Tau)` estimates the theoretical maximum detectable range `maxrng` for a radar operating with a wavelength of `lambda` meters with a pulse duration of `Tau` seconds. The signal-to-noise ratio is `SNR` decibels, and the peak transmit power is `Pt` watts.

`maxrng = radareqrng(...,Name,Value)` estimates the theoretical maximum detectable range with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `lambda`

Wavelength of radar operating frequency (in meters). The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light. Denoting the speed of light by *c* and the frequency (in hertz) of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

### `Pt`

Transmitter peak power in watts.

### SNR

The minimum output signal-to-noise ratio at the receiver in decibels.

### Tau

Single pulse duration in seconds.

## Name-Value Pair Arguments

### Gain

Transmitter and receiver gain in decibels (dB). When the transmitter and receiver are colocated (monostatic radar), `Gain` is a real-valued scalar. The transmit and receive gains are equal. When the transmitter and receiver are not colocated (bistatic radar), `Gain` is a 1-by-2 row vector with real-valued elements. The first element is the transmitter gain, and the second element is the receiver gain.

**Default:** 20

### Loss

System loss in decibels (dB). `Loss` represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

**Default:** 0

### RCS

Radar cross section in square meters. The target RCS is nonfluctuating.

**Default:** 1

### Ts

System noise temperature in kelvins. The system noise temperature is the product of the system temperature and the noise figure.

**Default:** 290 kelvin

### `unitstr`

Units of the estimated maximum theoretical range. `unitstr` takes one of the following values

- `'km'` kilometers
- `'m'` meters
- `'mi'` miles
- `'nmi'` nautical miles (U.S.)

**Default:** `'m'`

## Output Arguments

### `maxrng`

The estimated theoretical maximum detectable range. The units of `maxrng` depends on the value of `unitstr`. By default `maxrng` is in meters. For bistatic radars, `maxrng` is the geometric mean of the range from the transmitter to the target and the receiver to the target.

## Examples

### Estimate Maximum Detectable Range

Estimate the theoretical maximum detectable range for a monostatic radar operating at 10 GHz using a pulse duration of 10 µs. Assume the output SNR of the receiver is 6 dB.

```
lambda = physconst('LightSpeed')/10e9;
SNR = 6;
tau = 10e-6;
Pt = 1e6;
maxrng = radareqrng(lambda,SNR,Pt,tau)
```

```
maxrng = 4.1057e+04
```

### Estimate Maximum Detectable Range With Target RCS

Estimate the theoretical maximum detectable range for a monostatic radar operating at 10 GHz using a pulse duration of 10 µs. The target RCS is 0.1 m². Assume the output SNR of the receiver is 6 dB. The transmitter-receiver gain is 40 dB. Assume a loss factor of 3 dB.

```
lambda = physconst('LightSpeed')/10e9;
SNR = 6;
tau = 10e-6;
Pt = 1e6;
RCS = 0.1;
Gain = 40;
Loss = 3;
maxrng2 = radareqrng(lambda,SNR,Pt,tau,'Gain',Gain,...
    'RCS',RCS,'Loss',Loss)
```

```
maxrng2 = 1.9426e+05
```

# More About

## Point Target Radar Range Equation

The point target radar range equation estimates the power at the input to the receiver for a target of a given radar cross section at a specified range. The model is deterministic and assumes isotropic radiators. The equation for the power at the input to the receiver is

$$P_r = \frac{P_t G_t G_r \lambda^2 \sigma}{(4\pi)^3 R_t^2 R_r^2 L}$$

where the terms in the equation are:

- $P_t$ — Peak transmit power in watts
- $G_t$ — Transmitter gain in decibels
- $G_r$ — Receiver gain in decibels. If the radar is monostatic, the transmitter and receiver gains are identical.
- $\lambda$ — Radar operating frequency wavelength in meters

- $\sigma$ — Target's nonfluctuating radar cross section in square meters
- $L$ — General loss factor in decibels that accounts for both system and propagation loss
- $R_t$ — Range from the transmitter to the target
- $R_r$ — Range from the receiver to the target. If the radar is monostatic, the transmitter and receiver ranges are identical.

Terms expressed in decibels, such as the loss and gain factors, enter the equation in the form $10^{x/10}$ where $x$ denotes the variable. For example, the default loss factor of 0 dB results in a loss term of $10^{0/10}$=1.

## Receiver Output Noise Power

The equation for the power at the input to the receiver represents the *signal* term in the signal-to-noise ratio. To model the noise term, assume the thermal noise in the receiver has a white noise power spectral density (PSD) given by:

$$P(f) = kT$$

where $k$ is the Boltzmann constant and $T$ is the effective noise temperature. The receiver acts as a filter to shape the white noise PSD. Assume that the magnitude squared receiver frequency response approximates a rectangular filter with bandwidth equal to the reciprocal of the pulse duration, $1/\tau$. The total noise power at the output of the receiver is:

$$N = \frac{kTF_n}{\tau}$$

where $F_n$ is the receiver *noise factor*.

The product of the effective noise temperature and the receiver noise factor is referred to as the *system temperature*. This value is denoted by $T_s$, so that $T_s = TF_n$ .

## Receiver Output SNR

The receiver output SNR is:

$$\frac{P_r}{N} = \frac{P_t \tau G_t G_r \lambda^2 \sigma}{(4\pi)^3 k T_s R_t^2 R_r^2 L}$$

You can derive this expression using the following equations:

- Received signal power in “Point Target Radar Range Equation” on page 2-365
- Output noise power in “Receiver Output Noise Power” on page 2-366

### Theoretical Maximum Detectable Range

For monostatic radars, the range from the target to the transmitter and receiver is identical. Denoting this range by $R$, you can express this relationship as $R^4 = R_t^2 R_r^2$.

Solving for $R$

$$R = (\frac{NP_t\tau G_t G_r\lambda^2\sigma}{P_r(4\pi)^3 kT_sL})^{1/4}$$

For bistatic radars, the theoretical maximum detectable range is the geometric mean of the ranges from the target to the transmitter and receiver:

$$\sqrt{R_tR_r} = (\frac{NP_t\tau G_t G_r\lambda^2\sigma}{P_r(4\pi)^3 kT_sL})^{1/4}$$

# radareqsnr

SNR estimate from radar equation

## Syntax

```
SNR = radareqsnr(lambda,tgtrng,Pt,tau)
SNR = radareqsnr(...,Name,Value)
```

## Description

`SNR = radareqsnr(lambda,tgtrng,Pt,tau)` estimates the output signal-to-noise ratio (SNR) at the receiver based on the wavelength `lambda` in meters, the range `tgtrng` in meters, the peak transmit power `Pt` in watts, and the pulse width `tau` in seconds.

`SNR = radareqsnr(...,Name,Value)` estimates the output SNR at the receiver with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `lambda`

Wavelength of radar operating frequency in meters. The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light. Denoting the speed of light by *c* and the frequency in hertz of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

### `tgtrng`

Target range in meters. When the transmitter and receiver are colocated (monostatic radar), `tgtrng` is a real-valued positive scalar. When the transmitter and receiver are not colocated (bistatic radar), `tgtrng` is a 1-by-2 row vector with real-valued positive elements. The first element is the target range from the transmitter, and the second element is the target range from the receiver.

**Pt**

Transmitter peak power in watts.

**tau**

Single pulse duration in seconds.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Gain**

Transmitter and receiver gain in decibels (dB). When the transmitter and receiver are colocated (monostatic radar), `Gain` is a real-valued scalar. The transmit and receive gains are equal. When the transmitter and receiver are not colocated (bistatic radar), `Gain` is a 1-by-2 row vector with real-valued elements. The first element is the transmitter gain, and the second element is the receiver gain.

**Default:** 20

**Loss**

System loss in decibels (dB). `Loss` represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

**Default:** 0

**RCS**

Target radar cross section in square meters. The target RCS is nonfluctuating.

**Default:** 1

### Ts

System noise temperature in kelvin. The system noise temperature is the product of the effective noise temperature and the noise figure.

**Default:** 290 kelvin

# Output Arguments

### SNR

The estimated output signal-to-noise ratio at the receiver in decibels. SNR is $10\log_{10}(P_r/N)$. The ratio $P_r/N$ is defined in “Receiver Output SNR” on page 2-374.

# Examples

### Compute SNR Using Radar Equation

Estimate the output SNR for a target with an RCS of 1 m² at a range of 50 km. The system is a monostatic radar operating at 1 GHz with a peak transmit power of 1 MW and pulse width of 0.2 μs. The transmitter and receiver gain is 20 dB. The system temperature has the default value of 290 K.

```
fc = 1.0e9;
lambda = physconst('LightSpeed')/fc;
tgtrng = 50e3;
Pt = 1e6;
tau = 0.2e-6;
snr = radareqsnr(lambda,tgtrng,Pt,tau)
```

```
snr = 5.5868
```

### Compute SNR with Specified System Temperature

Estimate the output SNR for a target with an RCS of 0.5 m² at 100 km. The system is a monostatic radar operating at 10 GHz with a peak transmit power of 1 MW and pulse width of 1 µs. The transmitter and receiver gain is 40 dB. The system temperature is 300 K and the loss factor is 3 dB.

```
fc = 10.0;
T = 300.0;
lambda = physconst('LightSpeed')/10e9;
snr = radareqsnr(lambda,100e3,1e6,1e-6,'RCS',0.5,...
    'Gain',40,'Ts',T,'Loss',3)
```

```
snr = 14.3778
```

### Compute SNR for Bistatic Radar

Estimate the output SNR for a target with an RCS of 1 m². The radar is bistatic. The target is located 50 km from the transmitter and 75 km from the receiver. The radar operating frequency is 10.0 GHz. The transmitter has a peak transmit power of 1 MW with a gain of 40 dB. The pulse width is 1 µs. The receiver gain is 20 dB.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
tau = 1e-6;
Pt = 1e6;
txrvRng =[50e3 75e3];
Gain = [40 20];
snr = radareqsnr(lambda,txrvRng,Pt,tau,'Gain',Gain)
```

```
snr = 9.0547
```

# More About

## Point Target Radar Range Equation

The point target radar range equation estimates the power at the input to the receiver for a target of a given radar cross section at a specified range. The model is deterministic and assumes isotropic radiators. The equation for the power at the input to the receiver is

$$P_r = \frac{P_t G_t G_r \lambda^2 \sigma}{(4\pi)^3 R_t^2 R_r^2 L}$$

where the terms in the equation are:

- $P_t$ — Peak transmit power in watts
- $G_t$ — Transmitter gain in decibels
- $G_r$ — Receiver gain in decibels. If the radar is monostatic, the transmitter and receiver gains are identical.
- $\lambda$ — Radar operating frequency wavelength in meters
- $\sigma$ — Nonfluctuating target radar cross section in square meters
- $L$ — General loss factor in decibels that accounts for both system and propagation losses
- $R_t$ — Range from the transmitter to the target in meters
- $R_r$ — Range from the receiver to the target in meters. If the radar is monostatic, the transmitter and receiver ranges are identical.

Terms expressed in decibels such as the loss and gain factors enter the equation in the form $10^{x/10}$ where $x$ denotes the variable value in decibels. For example, the default loss factor of 0 dB results in a loss term equal to one in the equation ($10^{0/10}$).

## Receiver Output Noise Power

The equation for the power at the input to the receiver represents the signal term in the signal-to-noise ratio. To model the noise term, assume the thermal noise in the receiver has a white noise power spectral density (PSD) given by:

$$P(f) = kT$$

where $k$ is the Boltzmann constant and $T$ is the effective noise temperature. The receiver acts as a filter to shape the white noise PSD. Assume that the magnitude squared receiver frequency response approximates a rectangular filter with bandwidth equal to the reciprocal of the pulse duration, $1/\tau$. The total noise power at the output of the receiver is:

$$N = \frac{kTF_n}{\tau}$$

where $F_n$ is the receiver *noise factor*.

The product of the effective noise temperature and the receiver noise factor is referred to as the *system temperature* and is denoted by $T_s$, so that $\mathrm{T_s}=TF_n$ .

### Receiver Output SNR

The receiver output SNR is:

$$\frac{P_r}{N} = \frac{P_t \tau G_t G_r \lambda^2 \sigma}{(4\pi)^3 k T_s R_t^2 R_r^2 L}$$

You can derive this expression using the following equations:

- Received signal power in “Point Target Radar Range Equation” on page 2-372
- Output noise power in “Receiver Output Noise Power” on page 2-373

# radarvcd

Vertical coverage diagram

## Syntax

```
[vcp,vcpangles] = radarvcd(freq,rfs,anht)
[vcp,vcpangles] = radarvcd( ___ ,Name,Value)

radarvcd( ___ )
```

## Description

`[vcp,vcpangles] = radarvcd(freq,rfs,anht)` calculates the vertical coverage pattern of a narrowband radar antenna. The "Vertical Coverage Pattern" on page 2-384 is the radar's range, `vcp`, as a function of elevation angle, `vcpangles`. The vertical coverage pattern depends upon three parameters. These parameters are the radar's maximum free-space detection range, `rfs`, the radar frequency, `freq`, and the antenna height, `anht`.

`[vcp,vcpangles] = radarvcd( ___ ,Name,Value)` allows you to specify additional input parameters as Name-Value pairs. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). This syntax can use any of the input arguments in the previous syntax.

`radarvcd( ___ )` displays the vertical coverage diagram for a radar system. The plot is the locus of points of maximum radar range as a function of target elevation. This plot is also known as the Blake chart. To create this chart, `radarvcd` invokes the function `blakechart` using default parameters. To produce a Blake chart with different parameters, first call `radarvcd` to obtain `vcp` and `vcpangles`. Then, call `blakechart` with user-specified parameters. This syntax can use any of the input arguments in the previous syntaxes.

## Examples

### Plot Vertical Coverage Pattern Using Default Parameters

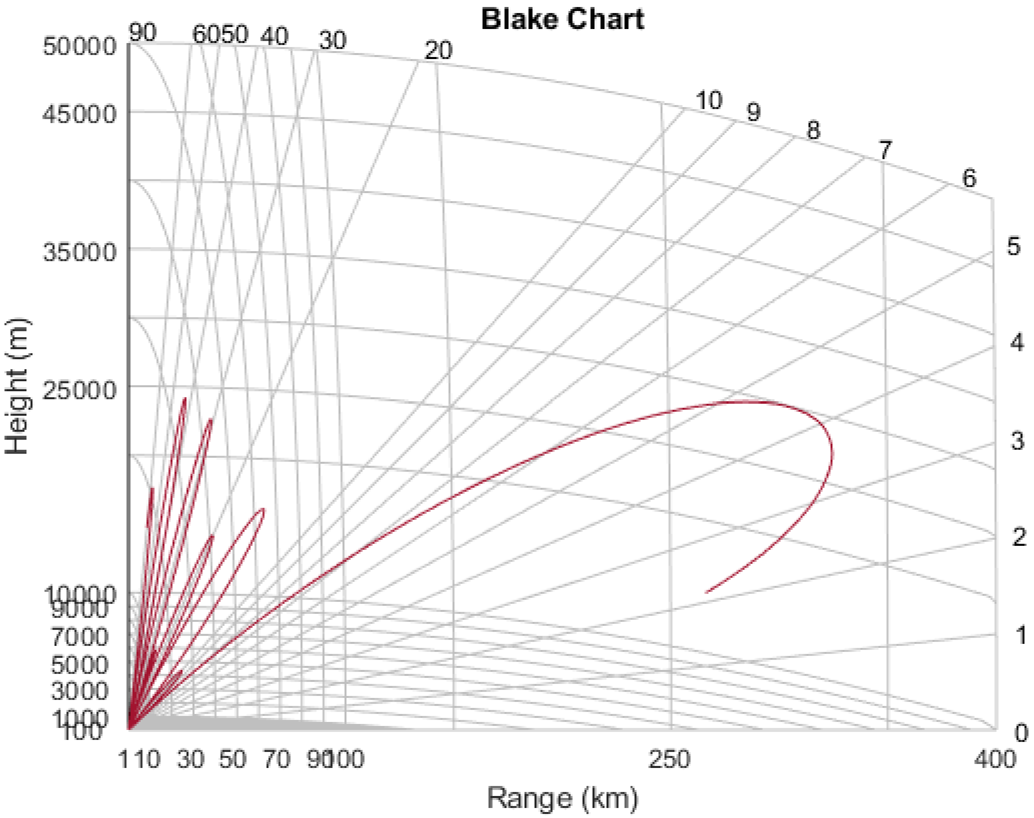
Set the frequency to 100 MHz, the antenna height to 10 m, and the free-space range to 200 km. The antenna pattern, surface roughness, antenna tilt angle, and field polarization assume their default values as specified in the `AntennaPattern`, `SurfaceRoughness`, `TiltAngle`, and `Polarization` properties.

Obtain an array of vertical coverage pattern values and angles.

```
freq = 100e6;
ant_height = 10;
rng_fs = 200;
[vcp,vcpangles] = radarvcd(freq,rng_fs,ant_height);
```

To see the vertical coverage pattern, omit the output arguments.

```
freq = 100e6;
ant_height = 10;
rng_fs = 200;
radarvcd(freq,rng_fs,ant_height);
```



### Vertical Coverage Pattern with Specified Antenna Pattern

Set the frequency to 100 MHz, the antenna height to 10 m, and the free-space range to 200 km. The antenna pattern is a sinc function with 45° half-power width. The surface roughness is set to 1 m. The antenna tilt angle is set to 0°, and the field polarization is horizontal.

```
pat_angles = linspace(-90,90,361)';
pat_u = 1.39157/sind(45/2)*sind(pat_angles);
pat = sinc(pat_u/pi);
freq = 100e6;
```

```
ant_height = 10;
rng_fs = 200;
tilt_ang = 0;
[vcp,vcpangles] = radarvcd(freq,rng_fs,ant_height,...
    'RangeUnit','km','HeightUnit','m',...
    'AntennaPattern',pat,...
    'PatternAngles',pat_angles,...
    'TiltAngle',tilt_ang,'SurfaceRoughness',1);
```

### Plot Vertical Coverage Diagram For User-Specified Antenna

Plot the range-height-angle curve (Blake Chart) for a radar with a user-specified antenna pattern.

Define a sinc-function antenna pattern with a half-power beamwidth of 90 degrees.

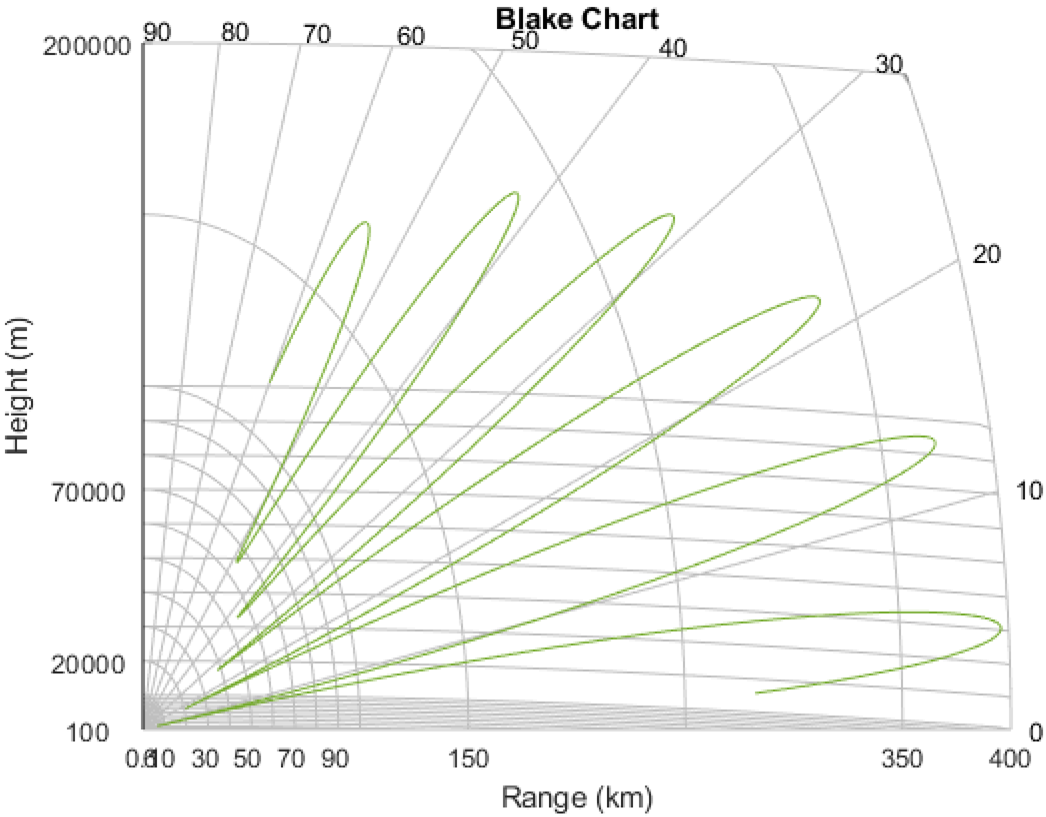
```
pat_angles = linspace(-90,90,361)';
pat_u = 1.39157/sind(90/2)*sind(pat_angles);
pat = sinc(pat_u/pi);
```

Specify a radar that transmits at 100 MHz. The free-space range is 200 km, the antenna height is 10 meters, the antenna tilt angle is zero degrees, and the surface roughness is one meter.

```
freq = 100e6;
ant_height = 10;
rng_fs = 200;
tilt_ang = 0;
surf_roughness = 1;
```

Create the radar range-height-angle plot.

```
radarvcd(freq,rng_fs,ant_height,...
    'RangeUnit','km','HeightUnit','m',...
    'AntennaPattern',pat,...
    'PatternAngles',pat_angles,...
    'TiltAngle',tilt_ang,...
    'SurfaceRoughness',surf_roughness);
```



## Input Arguments

### `freq` — Radar frequency

real-valued scalar less than 10 GHz

Radar frequency specified as a real-valued scalar less than 10 GHz (10e9).

Example: 100e6

Data Types: `double`

### `rfs` — Free-space range

real-valued scalar

Free-space range specified as a real-valued scalar. Range units are set by the `RangeUnit` Name-Value pair.

Example: 100e3

Data Types: `double`

### `anht` — Radar antenna height

real-valued scalar

Radar antenna height specified as a real-valued scalar. Height units are set by the `HeightUnit` Name-Value pair.

Example: 10

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: ‘HeightUnit’, k‘m’

### `RangeUnit` — Radar range units

`'km'` (default) | `'nmi'` | `'mi'` | `'ft'` | `'m'`

Radar range units denoting kilometers, nautical miles, miles, feet or meters. This name-value pair specifies the units for the free-space range argument, `rfs`, and the output vertical coverage pattern, `vcp`.

Example: `'mi'`

Data Types: `char`

### `HeightUnit` — Antenna height units

`'m'` (default) | `'nmi'` | `'mi'` | `'km'` | `'ft'`

Antenna height units denoting meters, nautical miles, miles, kilometers, or feet. This name-value pair specifies the units for the antenna height, `anht`, and the `'SurfaceRoughness'` name-value pair.

Example: `'m'`

Data Types: `char`

### `Polarization` — Transmitted wave polarization

`'H'` (default) | `'H'` | `'V'`

Transmitted wave polarization specified as `'H'` for horizontal polarization and `'V'` for vertical polarization.

Example: `'V'`

Data Types: `char`

### `SurfaceDielectric` — Dielectric constant of reflecting surface

frequency dependent model (default) | complex-valued scalar

Dielectric constant of reflecting surface specified as complex-valued scalar. When omitted, the dielectric constant is taken from a frequency-dependent seawater dielectric model derived in Blake[1].

Example: 70

Data Types: `double`

### `SurfaceRoughness` — Surface roughness

0 (default) | real-valued scalar

Surface roughness specified as a non-negative real scalar. Surface roughness is a measure of the height variation of the reflecting surface. The roughness is modeled as a sinusoid wave with crest-to-trough height given by this value. A value of 0 indicates a smooth surface. The units for surface roughness height is specified by the value of the `'HeightUnit'` Name-Value pair.

Example: 2

Data Types: `double`

### `AntennaPattern` — Antenna elevation pattern

real-valued *N*-by-1 column vector

Antenna elevation pattern, specified as a real-valued *N*-by-1 column vector. Values for `'AntennaPattern'` must be specified together with values for `'PatternAngles'`.

Example: `cosd([–90:90])`

Data Types: `double`

**`PatternAngles` — Antenna pattern elevation angles**
real-valued *N*-by-1 column vector

Antenna pattern elevation angles specified as a real-valued *N*-by-1 column vector. The size of the vector specified by `'PatternAngles'` must be the same as that specified by `'AntennaPattern'`. Angle units are expressed in degrees and must lie between –90° and 90°. In general, to properly compute the coverage, the antenna pattern should fill the whole range from –90° to 90°.

Example: `[-90:90]`

Data Types: `double`

**`TiltAngle` — Antenna tilt angle**
real-valued scalar

Antenna tilt angle specified as a real-valued scalar. The tilt angle is the elevation angle of the antenna with respect to the surface. Angle units are expressed in degrees.

Example: 10

Data Types: `double`

**`MaxElevation` — Maximum elevation angle**
real-valued scalar

Maximum elevation angle, specified as a real-valued scalar. The maximum elevation angle is the largest angle for which the vertical coverage pattern is calculated. Angle units are expressed in degrees.

Example: 70

Data Types: `double`

## Output Arguments

**`vcp` — Vertical coverage pattern**
real-valued vector

Vertical coverage pattern returned as a real-valued, *K*-by-1 column vector. The vertical coverage pattern is the actual maximum range of the radar. Each entry of the vertical coverage pattern corresponds to one of the angles returned in `vcpangles`.

**`vcpangles` — Vertical coverage pattern angles**
real-valued vector

Vertical coverage pattern angles returned as a *K*-by-1 column vector. The angles range from –90° to 90°.

## More About

### Vertical Coverage Pattern

The maximum detection range of a radar antenna can differ, depending on placement. Suppose you place a radar antenna near a reflecting surface, such as the earth's land or sea surface and computed maximum detection range. If you then move the same radar antenna to free space far from any boundaries, a different maximum detection range would result. This is an effect of multi-path interference that occurs when waves, reflected from the surface, constructively add to or nullify the direct path signal from the radar to a target. Multipath interference gives rise to a series of lobes in the vertical plane. The vertical coverage pattern is the plot of the actual maximum detection range of the radar versus target elevation and depends upon the maximum free-space detection range and target elevation angle. See Blake [1].

# radialspeed

Relative radial speed

## Syntax

```
Rspeed = radialspeed(Pos,V)
Rspeed = radialspeed(Pos,V,RefPos)
Rspeed = radialspeed(Pos,V,RefPos,RefV)
```

## Description

`Rspeed = radialspeed(Pos,V)` returns the radial speed of the given platforms relative to a reference platform. The platforms have positions `Pos` and velocities `V`. The reference platform is stationary and is located at the origin.

`Rspeed = radialspeed(Pos,V,RefPos)` specifies the position of the reference platform.

`Rspeed = radialspeed(Pos,V,RefPos,RefV)` specifies the velocity of the reference platform.

## Input Arguments

### Pos

Positions of platforms, specified as a 3-by-N matrix. Each column specifies a position in the form [*x*; *y*; *z*], in meters.

### V

Velocities of platforms, specified as a 3-by-N matrix. Each column specifies a velocity in the form [*x*; *y*; *z*], in meters per second.

### `RefPos`

Position of reference platform, specified as a 3-by-1 vector. The vector has the form [*x*; *y*; *z*], in meters.

**Default:** `[0; 0; 0]`

### `RefV`

Velocity of reference platform, specified as a 3-by-1 vector. The vector has the form [*x*; *y*; *z*], in meters per second.

**Default:** `[0; 0; 0]`

## Output Arguments

### `Rspeed`

Radial speed in meters per second, as an N-by-1 vector. Each number in the vector represents the radial speed of the corresponding platform. Positive numbers indicate that the platform is approaching the reference platform. Negative numbers indicate that the platform is moving away from the reference platform.

## Examples

### Radial Speed of Target Relative to Stationary Platform

Calculate the radial speed of a target relative to a stationary platform. Assume the target is located at *(20,20,0)* meters in cartesian coordinates and is moving with velocity *(10,10,0)* meters per second. The reference platform is located at *(1,1,0)*.

```
rspeed = radialspeed([20; 20; 0],[10; 10; 0],[1; 1; 0])
```

```
rspeed = -14.1421
```

Negative radial speed indicates that the target is receding from the platform.

# rainpl

RF signal attenuation due to rainfall

## Syntax

```
L = rainpl(range,freq,rainrate)
L = rainpl(range,freq,rainrate,elev)
L = rainpl(range,freq,rainrate,elev,tau)
```

## Description

`L = rainpl(range,freq,rainrate)` returns the signal attenuation, `L`, due to rainfall. In this syntax, attenuation is a function of signal path length, `range`, signal frequency, `freq`, and rain rate, `rainrate`. The path elevation angle and polarization tilt angles are assumed to zero.

The `rainpl` function applies the International Telecommunication Union (ITU) rainfall attenuation model to calculate path loss of signals propagating in a region of rainfall [1]. The function applies when the signal path is contained entirely in a uniform rainfall environment. Rain rate does not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

`L = rainpl(range,freq,rainrate,elev)` specifies the elevation angle, `elev`, of the propagation path.

`L = rainpl(range,freq,rainrate,elev,tau)` specifies the polarization tilt angle, `tau`, of the signal.

## Examples

### Signal Attenuation Due to Rainfall

Compute the signal attenuation due to rainfall for a 20 GHz signal over a distance of 10 km in light and heavy rain.

Propagate the signal in a light rainfall of 1 mm/hr.

```
rr = 1.0;
L = rainpl(10000,20.0e9,rr)
```

```
L = 0.7104
```

```
L = 0.7104
```

```
L = 0.7104
```

Propagate the signal in a heavy rainfall of 10 mm/hr.

```
rr = 10.0;
L = rainpl(10000,20.0e9,rr)
```

```
L = 7.8413
```

```
L = 7.8413
```

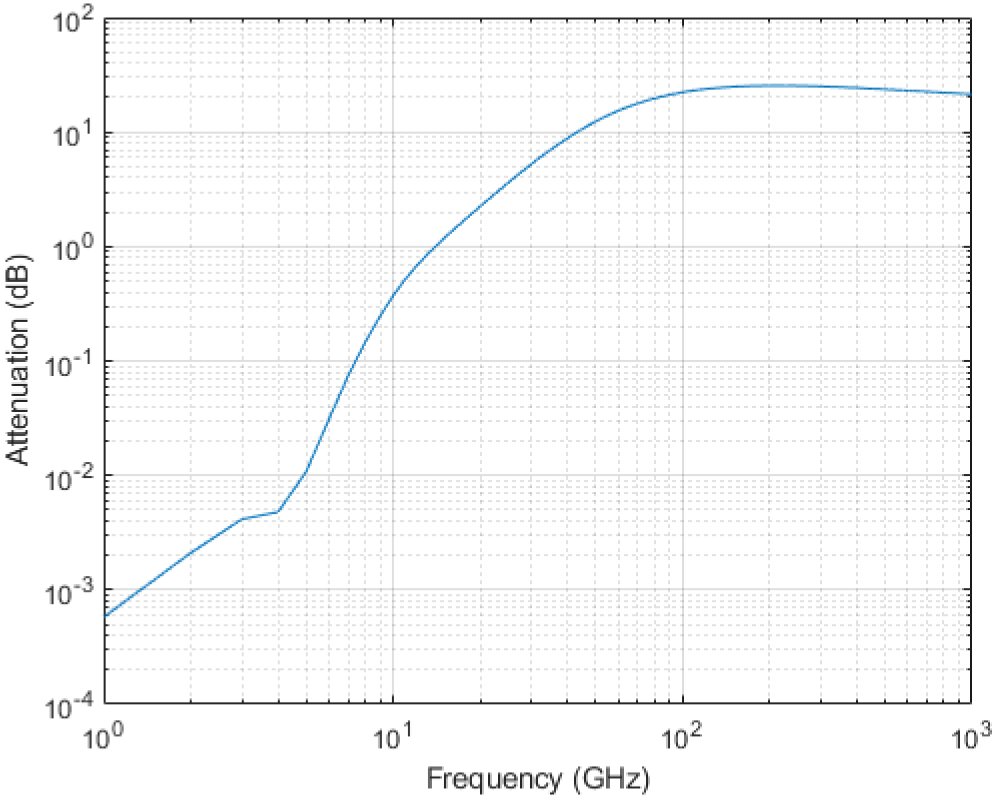
```
L = 7.8413
```

### Signal Attenuation Due to Rainfall as Function of Frequency

Plot the signal attenuation due to moderate rainfall for signals in the frequency range from 1 to 1000 GHz. The path distance is 10 km.

Set the rain rate value for moderate rainfall to 3 mm/hr.

```
rr = 3.0;
freq = [1:1000]*1e9;
L = rainpl(10000,freq,rr);
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```



### Signal Attenuation Due to Rainfall as Function of Elevation Angle

Compute the signal attenuation due to heavy rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 100 km and a signal frequency of 100 GHz.

Set the rain rate to 10 mm/hr.

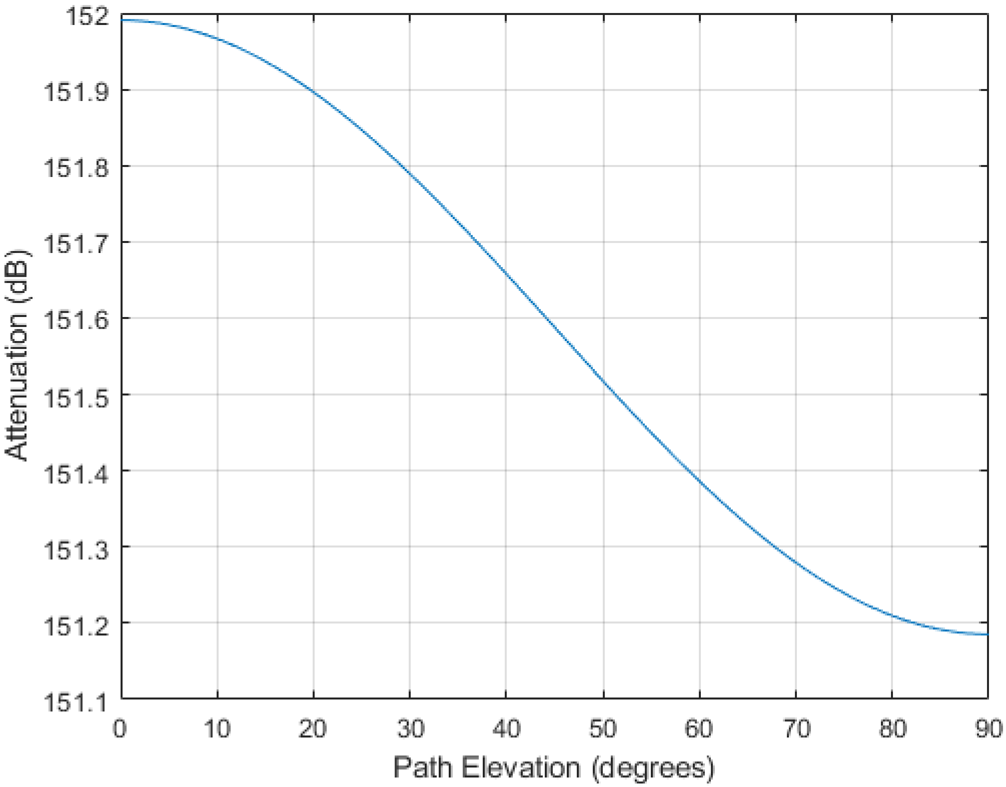
```
rr = 10.0;
```

Set the elevation angles, frequency, range.

```
elev = [0:1:90];
freq = 100.0e9;
rng = 100000.0*ones(size(elev));
```

Compute and plot the loss.

```
L = rainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```



### Signal Attenuation Due to Rainfall as Function of Polarization

Compute the signal attenuation due to heavy rainfall as a function of the polarization tilt angle. Assume a path distance of 100 km, a signal frequency of 100 GHz signal, and a path elevation angle of 0 degrees. Set the rainfall rate to 10 mm/hour. Plot the signal attenuation versus polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

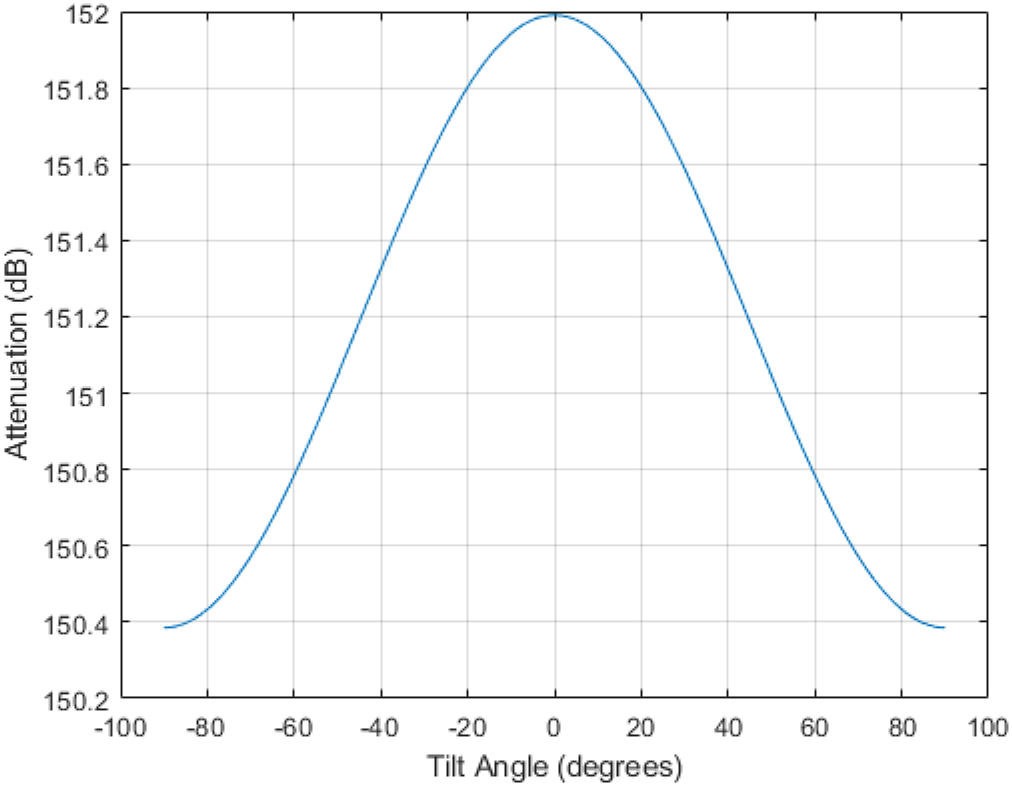
```
tau = -90:90;
```

Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 100.0e9;
rng = 100e3*ones(size(tau));
rr = 10.0;
```

Compute and plot the attenuation.

```
L = rainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```



## Input Arguments

### `range` — Signal path length

nonnegative real-valued scalar | nonnegative real-valued *M*-by-1 column vector | nonnegative real-valued 1-by-*M* row vector

Signal path length, specified as a nonnegative real-valued scalar, or as a *M*-by-1 or 1-by-*M* vector. Units are in meters.

Example: `[13000.0,14000.0]`

### `freq` — Signal frequency

positive real-valued scalar | nonnegative real-valued *N*-by-1 column vector | nonnegative real-valued 1-by-*N* row vector

Signal frequency, specified as a positive real-valued scalar, or as a nonnegative *N*-by-1 or 1-by-*N* vector. Frequencies must lie in the range 1–1000 GHz.

Example: `[1400.0e6,2.0e9]`

### `rainrate` — Rain rate

nonnegative real-valued scalar

Rain rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

Example: `1.5`

### `elev` — Signal path elevation angle

0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Signal path elevation angle, specified as a real-valued scalar, or as an *M*-by-1 or 1-by- *M* vector. Units are in degrees between –90° and 90°. If `elev` is a scalar, all propagation paths have the same elevation angle. If `elev` is a vector, its length must match the dimension of `range` and each element in `elev` corresponds to a propagation range in `range`.

Example: `[0,45]`

### `tau` — Tilt angle of polarization ellipse

0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Tilt angle of the signal polarization ellipse, specified as a real-valued scalar, or as an *M*-by-1 or 1-by- *M* vector. Units are in degrees between –90° and 90°. If `tau` is a scalar, all signals have the same tilt angle. If `tau` is a vector, its length must match the dimension of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semimajor axis of the polarization ellipse and the *x*-axis. Because the ellipse is symmetrical, a tilt angle of 100° corresponds to the same polarization state as a tilt angle of -80°. Thus, the tilt angle need only be specified between ±90°.

Example: `[45,30]`

# Output Arguments

**L — Signal attenuation**
real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

# More About

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = k r^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

# range2beat

Convert range to beat frequency

## Syntax

```
fb = range2beat(r,slope)
fb = range2beat(r,slope,c)
```

## Description

`fb = range2beat(r,slope)` converts the range of a dechirped linear FMCW signal to the corresponding beat frequency on page 2-400. `slope` is the slope of the FMCW sweep.

`fb = range2beat(r,slope,c)` specifies the signal propagation speed.

## Examples

### Maximum Beat Frequency in FMCW Radar System

Calculate the maximum beat frequency in MHz for an upsweep FMCW waveform. The waveform sweeps a 300 MHz band in 1 ms. Assume that the waveform can detect a stationary target as far as 18 km.

```
slope = 300e6/1e-3;
r = 18e3;
fb = range2beat(r,slope)/1e6
```

```
fb = 36.0249
```

## Input Arguments

### `r` — Range

array of nonnegative numbers

Range, specified as an array of nonnegative numbers in meters.

Data Types: `double`

### `slope` — Sweep slope

nonzero scalar

Slope of FMCW sweep, specified as a nonzero scalar in hertz per second.

Data Types: `double`

### `c` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

## Output Arguments

### `fb` — Beat frequency of dechirped signal

array of nonnegative numbers

Beat frequency of dechirped signal, returned as an array of nonnegative numbers in hertz. Each entry in `fb` is the beat frequency corresponding to the corresponding range in `r`. The dimensions of `fb` match the dimensions of `r`.

Data Types: `double`

# More About

## Beat Frequency

For an up-sweep or down-sweep FMCW signal, the beat frequency is $F_t$ – $F_r$. In this expression, $F_t$ is the transmitted signal's carrier frequency, and $F_r$ is the received signal's carrier frequency.

For an FMCW signal with triangular sweep, the upsweep and downsweep have separate beat frequencies.

# Algorithms

The function computes `2*r*slope/c`.

# range2bw

Convert range resolution to required bandwidth

## Syntax

```
bw = range2bw(rngres)
bw = range2bw(rngres,c)
```

## Description

`bw = range2bw(rngres)` returns the bandwidth needed to distinguish two targets separated by a given range. Such capability is often referred to as range resolution. The propagation is assumed to be two-way, as in a monostatic radar system.

`bw = range2bw(rngres,c)` specifies the signal propagation speed.

## Examples

### Pulse Width for Specified Range Resolution

Assume you have a monostatic radar system that uses a rectangular waveform. Calculate the required pulse bandwidth in MHz of the waveform so that the system can achieve a range resolution of 10 m.

```
rngres = 10;
c = physconst('LightSpeed');
bw = range2bw(rngres,c)/1e6;
```

The required bandwidth is approximately 15 MHz.

## Input Arguments

**rngres — Target range resolution**
positive scalar | MATLAB array of positive real values

Target range resolution in meters, specified as a scalar or a MATLAB array of positive real values.

Data Types: `double`

**c — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second.

Data Types: `double`

## Output Arguments

**bw — Required bandwidth**
positive scalar | MATLAB array of positive real values

Required bandwidth in hertz, returned as a MATLAB array of positive real values. The dimensions of `bw` are the same as those of `rngres`.

## Tips

- This function assumes two-way propagation. For one-way propagation, you can find the required bandwidth by multiplying the output of this function by 2.

## Algorithms

The function computes `c/(2*rngres)`.

# range2time

Convert propagation distance to propagation time

## Syntax

```
t = range2time(r)
t = range2time(r,c)
```

## Description

`t = range2time(r)` returns the time a signal takes to propagate a given distance. The propagation is assumed to be two-way, as in a monostatic radar system.

`t = range2time(r,c)` specifies the signal propagation speed.

## Examples

### PRF for Specified Unambiguous Range

Calculate the required PRF in Hertz for a monostatic radar system so that it can have a maximum unambiguous range of 15 km.

```
r = 15.0e3;
prf = 1/range2time(r)
```

```
prf = 9.9931e+03
```

## Input Arguments

**r — Signal range**
array of nonnegative numbers

Signal range in meters, specified as an array of nonnegative numbers.

Data Types: `double`

**`c` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

## Output Arguments

**`t` — Propagation time**
array of nonnegative numbers

Propagation time in seconds, returned as an array of nonnegative numbers. The dimensions of `t`are the same as those of `r`.

## Algorithms

The function computes `2*r/c`.

# range2tl

Compute underwater sound transmission loss from range

## Syntax

```
tl = range2tl(rng,freq,depth)
```

## Description

`tl = range2tl(rng,freq,depth)` returns the transmission loss, `tl`, for a sound wave of frequency `freq` arriving from a source at distance `rng`. The channel depth is `depth`. The transmission loss is due to geometrical spreading and frequency-dependent absorption. This function is the inverse of `tl2range`.

## Examples

### Estimate Transmission Loss from Range

Find the transmission loss (in dB) for a sonar operating at 2 kHz in a channel that is 200 m deep. The sound path is 1000.0 m long.

```
rng = 1000.0;
freq = 2000.0;
depth = 200;
tl = range2tl(rng,freq,depth)
```

```
tl = 50.1261
```

## Input Arguments

**`rng` — Distance from sound source to receiver**
positive scalar

Distance from sound source to receiver, specified as a positive scalar. Units are in meters.

Example: `10e3`

Data Types: `double`

### `freq` — Frequency of sound

positive scalar

Frequency of sound, specified as a positive scalar. Units are in Hz.

Example: `1e3`

Data Types: `double`

### `depth` — Channel depth

positive scalar

Channel depth, specified as a positive scalar. Units are in meters.

Example: `200`

Data Types: `double`

## Output Arguments

### `tl` — Transmission loss

positive scalar

Transmission loss, returned as a positive scalar. Units are in dB.

Data Types: `double`

## Limitations

- The transmission loss model assumes that seawater salinity is 35 ppt, pH is 8, and temperature is 10°C.
- The transmission loss model is valid for frequencies less than or equal to 2.0 MHz.

# rcscylinder

Radar cross section of cylinder

## Syntax

```
rcspat = rcscylinder(r1,r2,height,c,fc)
rcspat = rcscylinder(r1,r2,height,c,fc,az,el)
[rcspat,azout,elout] = rcscylinder(___)
```

## Description

`rcspat = rcscylinder(r1,r2,height,c,fc)` returns the radar cross section pattern of an elliptical cylinder having a semi-major axis, `r1`, a semi-minor axis, `r2`, and a height, `height`. The radar cross section is a function of signal frequency, `fc`, and signal propagation speed,`c`. The bottom of the cylinder lies on the *xy*-plane. The height of the cylinder points along the positive *z*-axis.

`rcspat = rcscylinder(r1,r2,height,c,fc,az,el)` also specifies the azimuth angles, `az`, and elevation angles, `el`, at which to compute the radar cross section.

`[rcspat,azout,elout] = rcscylinder(___)` also returns the azimuth angles, `azout`, and elevation angles, `elout`, at which the radar cross sections are computed. You can use these output arguments with any of the previous syntaxes.

## Examples

### Radar Cross Section of Elliptical Cylinder

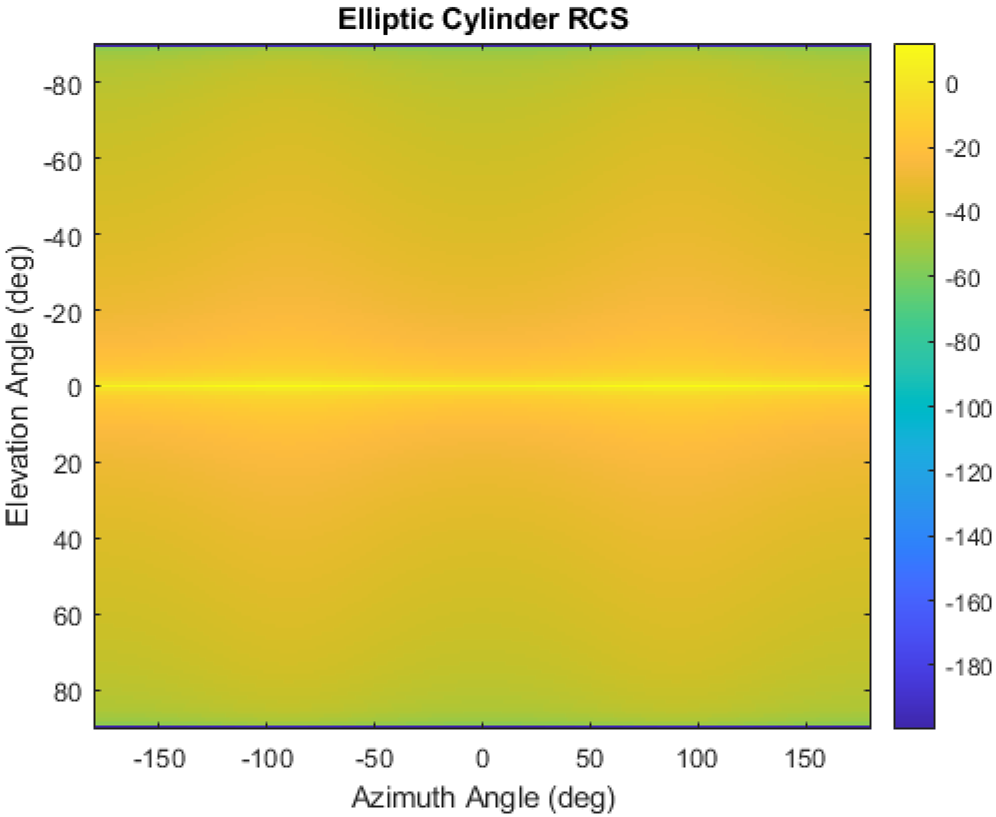
Display the radar cross section (RCS) pattern as a function of azimuth and elevation for an elliptical cylinder whose semi-major axis is 12.5 cm and whose semi-minor axis is 9 cm. The cylinder height is 1 m. The operating frequency is 4.5 GHz.

Specify the cylinder geometry and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
rada = 0.125;
radb = 0.090;
hgt = 1;
```

Compute the RCS for all directions using the default direction values.

```
[rcspat,azresp,elresp] = rcscylinder(rada,radb,hgt,c,fc);
imagesc(azresp,elresp,pow2db(rcspat))
colorbar
xlabel('Azimuth Angle (deg)')
ylabel('Elevation Angle (deg)')
title('Elliptic Cylinder RCS')
```



### Radar Cross Section of Elliptical Cylinder as Function of Elevation

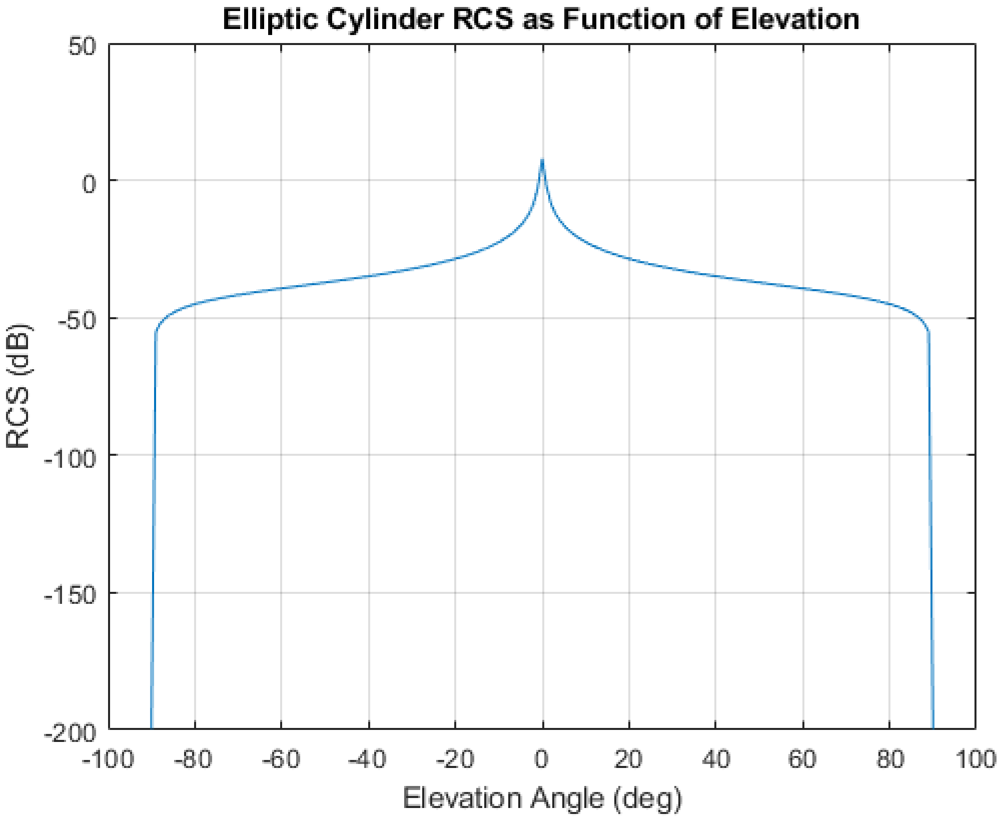
Plot the radar cross section (RCS) pattern of an elliptical cylinder as a function of elevation at a constant azimuth angle of 5 degrees. The cylinder has a semi-major axis of 12.5 cm and a semi-minor axis of 9 cm. The cylinder height is 1 m. The operating frequency is 4.5 GHz.

Specify the cylinder geometry and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
rada = 0.125;
radb = 0.090;
hgt = 1;
```

Compute the RCS for all elevation angles at a fixed azimuth angle of 5 degrees.

```
el = -90:90;
az = 5;
[rcspat,azresp,elresp] = rcscylinder(rada,radb,hgt,c,fc,az,el);
plot(elresp,pow2db(rcspat))
xlabel('Elevation Angle (deg)')
ylabel('RCS (dB)')
title('Elliptic Cylinder RCS as Function of Elevation')
grid on
```



### Radar Cross Section of Elliptical Cylinder as Function of Frequency

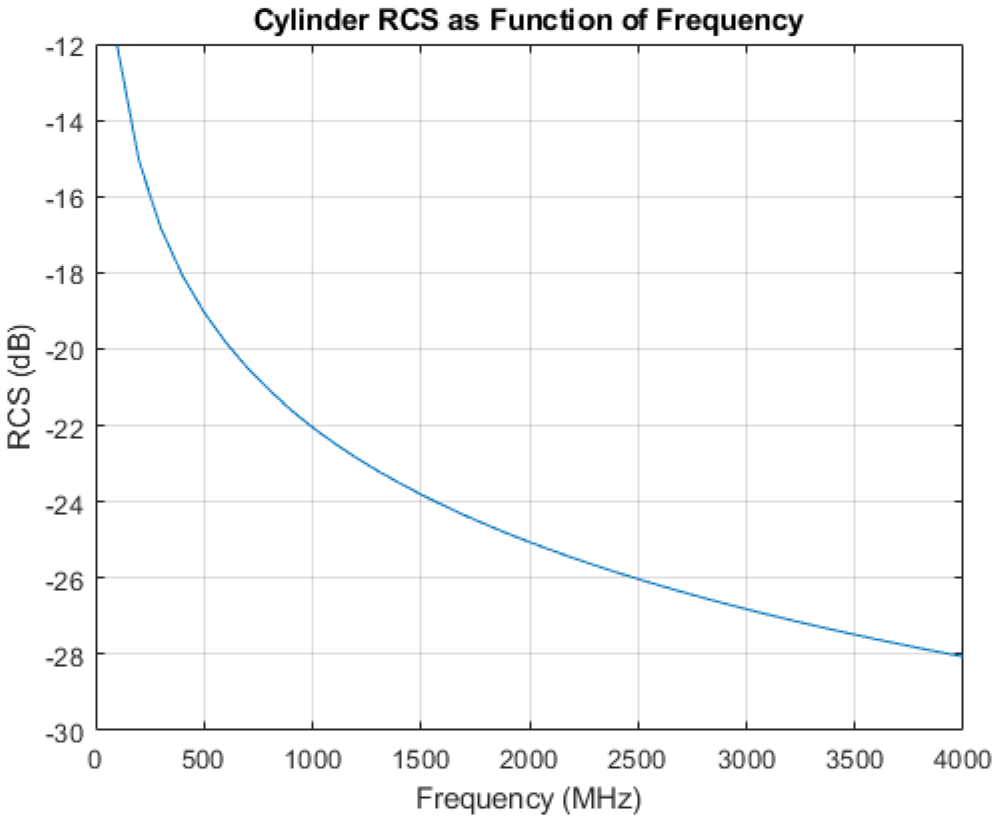
Plot the radar cross section (RCS) of an elliptical cylinder as a function of frequency for a fixed direction. The cylinder has as semi-major axis of 12.5 cm and a semi-minor axis of 9 cm. The cylinder height is 1 m.

Specify the cylinder geometry and signal parameters.

```
c = physconst('Lightspeed');
rada = 0.125;
radb = 0.090;
hgt = 1;
```

Compute radar cross sections as a function of frequency for a fixed azimuth and elevation.

```
az = 5.0;
el = 20.0;
fc = (100:100:4000)*1e6;
rcspat = rcscylinder(rada,radb,hgt,c,fc,az,el);
plot(fc/1e6,pow2db(squeeze(rcspat)))
xlabel('Frequency (MHz)')
ylabel('RCS (dB)')
title('Cylinder RCS as Function of Frequency')
grid on
```



## Input Arguments

### `r1` — Length of semi-major axis of cylinder

positive scalar

Length of semi-major axis of cylinder, specified as a positive scalar. Units are in meters.

Example: `5.5`

Data Types: `double`

### `r2` — Length of semi-minor axis of cylinder

positive scalar

Length of semi-minor axis of cylinder, specified as a positive scalar. Units are in meters.

Example: `3.0`

Data Types: `double`

### `height` — Height of cylinder

positive scalar

Height of cylinder, specified as a positive scalar. Units are in meters.

Example: `3.0`

Data Types: `double`

### `c` — Signal propagation speed

positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. For the SI value of the speed of light, use `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

### `fc` — Frequency for computing radar cross section

positive scalar | positive, real-valued, 1-by-*L* row vector

Frequency for computing radar cross section, specified as a positive scalar or positive, real-valued, 1-by-*L* row vector. Frequency units are in Hz.

Example: `[100e6 200e6]`

Data Types: `double`

### `az` — Azimuth angles

`-180:180` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°, inclusive.

The azimuth angle is the angle between the *x*-axis and the projection of a direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `-45:2:45`

Data Types: `double`

### `el` — Elevation angles

`-90:90` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a real-valued, 1-by-*N* row vector where *N* is the number of desired elevation directions. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive.

The elevation angle is the angle between a direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `-75:1:70`

Data Types: `double`

**Tip** To construct a circular cylinder, set `r2` equal to `r1`.

## Output Arguments

### `rcspat` — Radar cross section pattern

real-valued *N*-by-*M*-by-*L* array

Radar cross section pattern, returned as a real-valued *N*-by-*M*-by-*L* array. *N* is the length of the vector returned in the `elout` argument. *M* is the length of the vector returned in the `azout` argument. *L* is the length of the `fc` vector. Units are in meters-squared.

Data Types: `double`

**`azout` — Azimuth angles**
real-valued 1-by-*M* row vector

Azimuth angles for computing directivity and pattern, returned as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles specified by the `az` input argument. Angle units are in degrees.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Data Types: `double`

**`elout` — Elevation angles**
real-valued 1-by-*N* row vector

Elevation angles for computing directivity and pattern, returned as a real-valued 1-by-*N* row vector where *N* is the number of elevation angles specified in `el` output argument. Angle units are in degrees.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Data Types: `double`

# More About

## Azimuth and Elevation

This section describes the convention used to define azimuth and elevation angles.

The azimuth angle of a vector is the angle between the *x*-axis and its orthogonal projection onto the *xy*-plane. The angle is positive when going from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180° and 180° degrees, inclusive. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy*-plane. Elevation angles lie between –90° and 90° degrees, inclusive.

# rcssphere

Radar cross section of sphere

## Syntax

```
rcspat = rcssphere(r,c,fc)
rcspat = rcssphere(r,c,fc,az,el)
[rcspat,azout,elout] = rcssphere( ___ )
```

## Description

`rcspat = rcssphere(r,c,fc)` returns the radar cross section pattern of a sphere of radius `r` as a function of signal frequency, `fc`, and signal propagation speed, `c`. The center of the sphere is assumed to be located at the origin of the local coordinate system.

`rcspat = rcssphere(r,c,fc,az,el)` also specifies the azimuth angles, `az`, and elevation angles, `el`, at which to compute the radar cross section.

`[rcspat,azout,elout] = rcssphere( ___ )` also returns the azimuth angles, `azout`, and elevation angles, `elout`, at which the radar cross sections are computed. You can use these output arguments with any of the previous syntaxes.

## Examples

### Radar Cross Section of Sphere

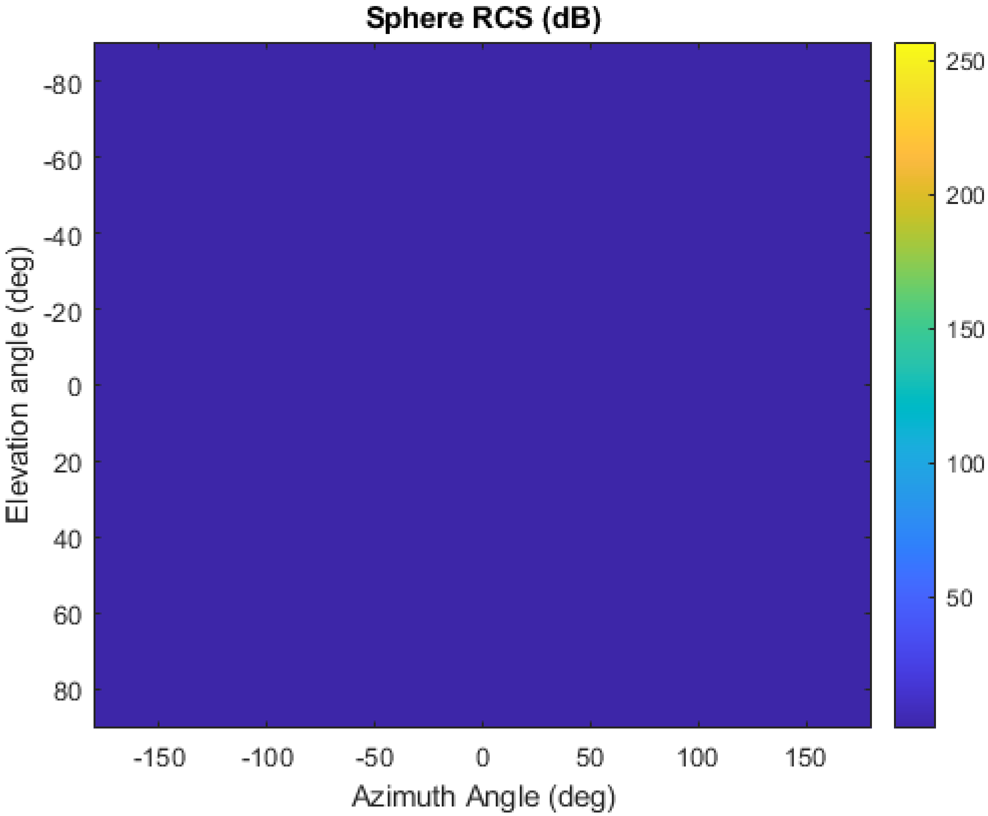
Display the radar cross section (RCS) pattern of a sphere as a function of azimuth and elevation. The sphere radius is 20.0 cm. The operating frequency is 4.5 GHz.

Define the sphere radius and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
rad = 0.20;
```

Compute the RCS over all angles. The image shows that the RCS is constant over all directions.

```
[rcspat,azresp,elresp] = rcssphere(rad,c,fc);
image(azresp,elresp,pow2db(rcspat))
colorbar
ylabel('Elevation angle (deg)')
xlabel('Azimuth Angle (deg)')
title('Sphere RCS (dB)')
```



### Radar Cross Section of Sphere as Function of Elevation

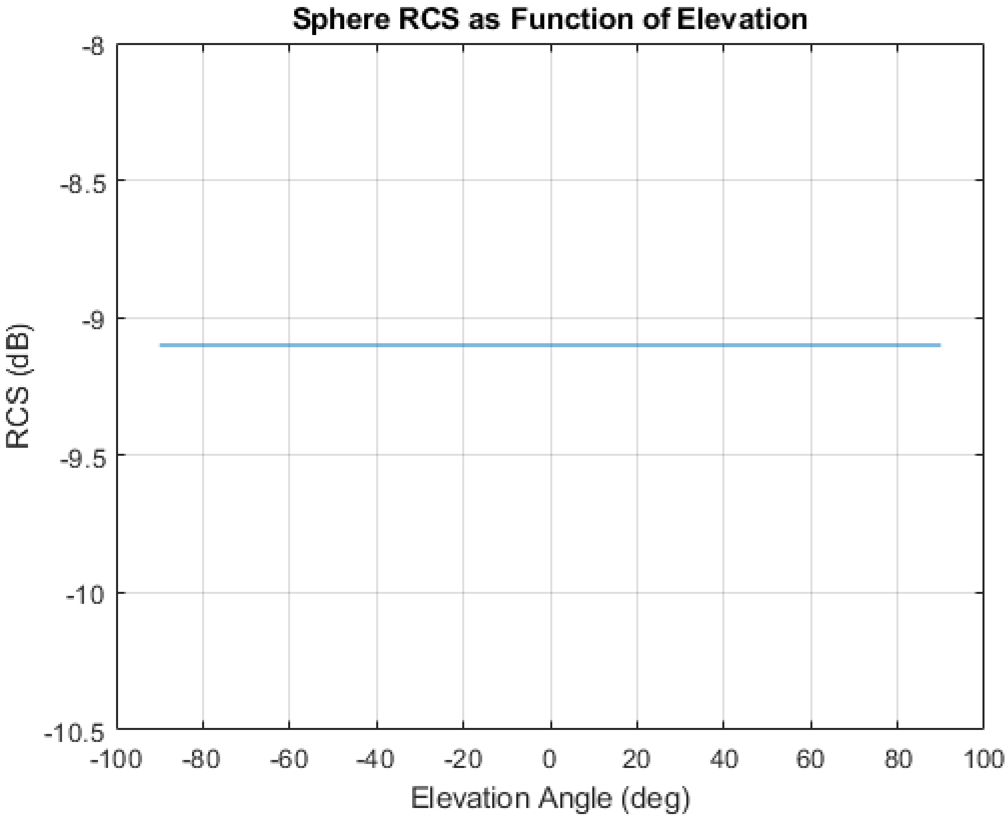
Plot the radar cross section (RCS) pattern of a sphere as a function of elevation angle for a fixed azimuth angle of 5 degrees. The sphere radius is 20.0 cm. The operating frequency is 4.5 GHz.

Specify the sphere radius and signal parameters.

```
c = physconst('LightSpeed');
rad = 0.20;
fc = 4.5e9;
```

Compute the RCS over a constant azimith slice. The plot shows that the RCS is constant.

```
az = 5.0;
el = -90:90;
[rcspat,azresp,elresp] = rcssphere(rad,c,fc,az,el);
plot(elresp,pow2db(rcspat))
xlabel('Elevation Angle (deg)')
ylabel('RCS (dB)')
title('Sphere RCS as Function of Elevation')
grid on
```



### Radar Cross Section of Sphere as Function of Frequency

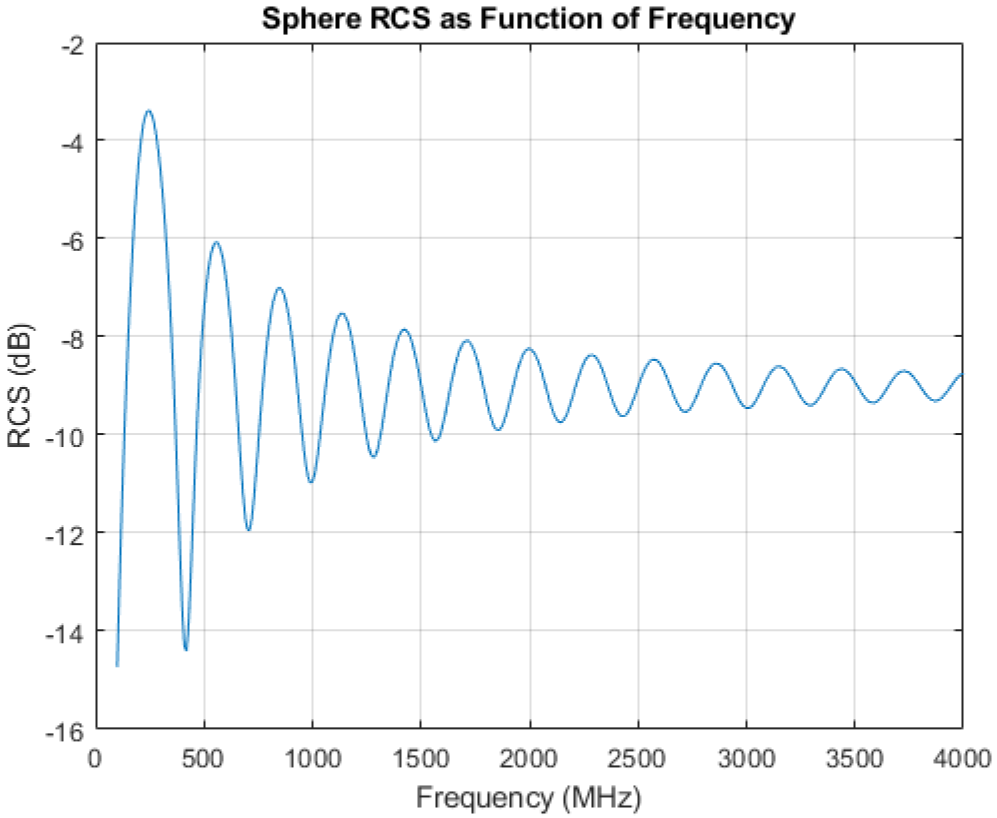
Plot the radar cross section (RCS) pattern of a sphere as a function of frequency for a single azimuth and elevation. The radius of the sphere is 20.0 cm

Define the sphere radius and signal parameters.

```
c = physconst('Lightspeed');
rad = 0.20;
```

Compute the RCS over a range of frequencies for a single direction.

```
az = 5.0;
el = 20.0;
fc = (100:10:4000)*1e6;
rcspat = rcssphere(rad,c,fc,az,el);
plot(fc/1e6,pow2db(squeeze(rcspat)))
xlabel('Frequency (MHz)')
ylabel('RCS (dB)')
title('Sphere RCS as Function of Frequency')
grid on
```



## Input Arguments

### `r` — Radius of sphere

positive scalar

Radius of sphere, specified as a positive scalar. Units are in meters.

Example: `5.5`

Data Types: `double`

### `c` — Signal propagation speed

positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. For the SI value of the speed of light, use `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

### `fc` — Frequency for computing radar cross section

positive scalar | positive, real-valued, 1-by-*L* row vector

Frequency for computing radar cross section, specified as a positive scalar or positive, real-valued, 1-by-*L* row vector. Frequency units are in Hz.

Example: `[100e6 200e6]`

Data Types: `double`

### `az` — Azimuth angles

`-180:180` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°, inclusive.

The azimuth angle is the angle between the *x*-axis and the projection of a direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `-45:2:45`

Data Types: `double`

### `el` — Elevation angles

`-90:90` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a real-valued, 1-by-*N* row vector where *N* is the number of desired elevation directions. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive.

The elevation angle is the angle between a direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `-75:1:70`

Data Types: `double`

## Output Arguments

### `rcspat` — Radar cross section pattern

real-valued *N*-by-*M*-by-*L* array

Radar cross section pattern, returned as a real-valued *N*-by-*M*-by-*L* array. *N* is the length of the vector returned in the `elout` argument. *M* is the length of the vector returned in the `azout` argument. *L* is the length of the `fc` vector. Units are in meters-squared.

Data Types: `double`

### `azout` — Azimuth angles

real-valued 1-by-*M* row vector

Azimuth angles for computing directivity and pattern, returned as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles specified by the `az` input argument. Angle units are in degrees.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Data Types: `double`

### `elout` — Elevation angles

real-valued 1-by-*N* row vector

Elevation angles for computing directivity and pattern, returned as a real-valued 1-by-*N* row vector where *N* is the number of elevation angles specified in `el` output argument. Angle units are in degrees.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Data Types: `double`

# rcsdisc

Radar cross section of flat circular plate

## Syntax

```
rcspat = rcsdisc(r,c,fc)
rcspat = rcsdisc(r,c,fc,az,el)
[rcspat,azout,elout] = rcsdisc( ___ )
```

## Description

`rcspat = rcsdisc(r,c,fc)` returns the radar cross section pattern of a flat circular plate of radius `r`. The radar cross section is a function of signal frequency, `fc`, and signal propagation speed, `c`. The plate is assumed to lie on the *xy*-plane. The center of the plate is located at the origin of the local coordinate system.

`rcspat = rcsdisc(r,c,fc,az,el)` also specifies the azimuth angles, `az`, and elevation angles, `el`, at which to compute the radar cross section.

`[rcspat,azout,elout] = rcsdisc( ___ )` also returns the azimuth angles, `azout`, and elevation angles, `elout`, at which the radar cross sections are computed. You can use these output arguments with any of the previous syntaxes.

## Examples

### Radar Cross Section of Circular Plate

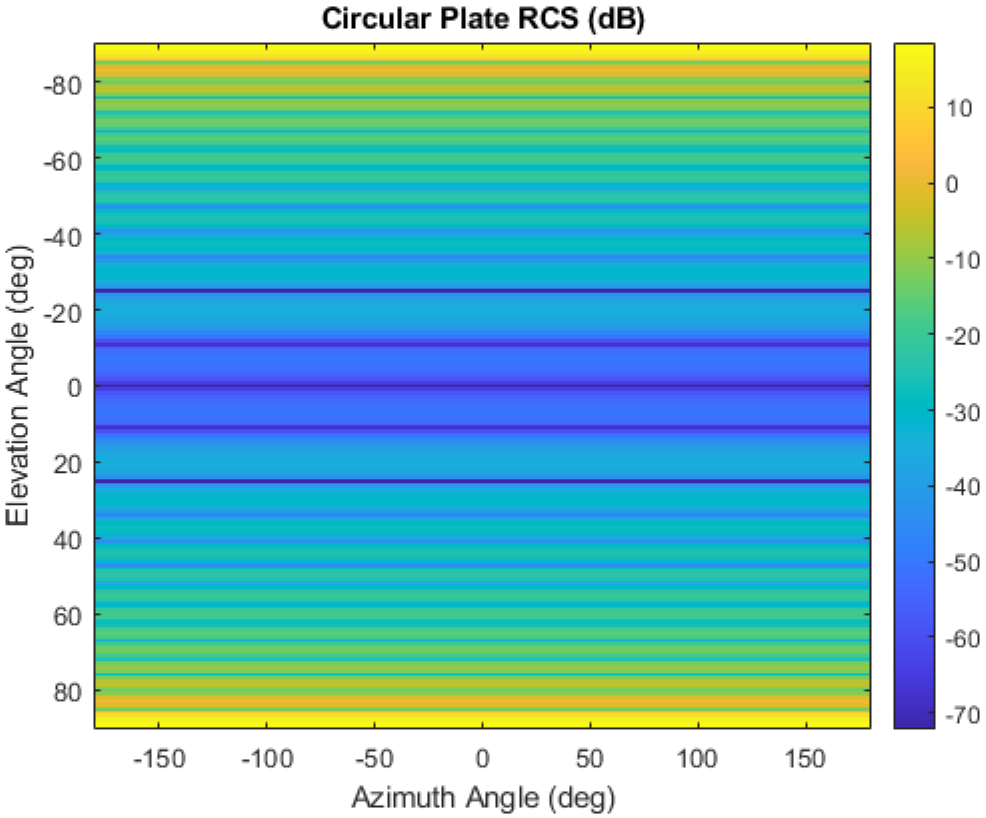
Display the radar cross section (RCS) pattern of a circular plate as a function of azimuth and elevation. The plate radius is 22.5 cm. The operating frequency is 4.5 GHz.

Specify the plate geometry and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
rad = 0.225;
```

Compute the RCS for all directions using the default direction values.

```
[rcspat,azresp,elresp] = rcsdisc(rad,c,fc);
imagesc(azresp,elresp,pow2db(rcspat))
colorbar
xlabel('Azimuth Angle (deg)')
ylabel('Elevation Angle (deg)')
title('Circular Plate RCS (dB)')
```



### Radar Cross Section of Circular Plate as Function of Elevation

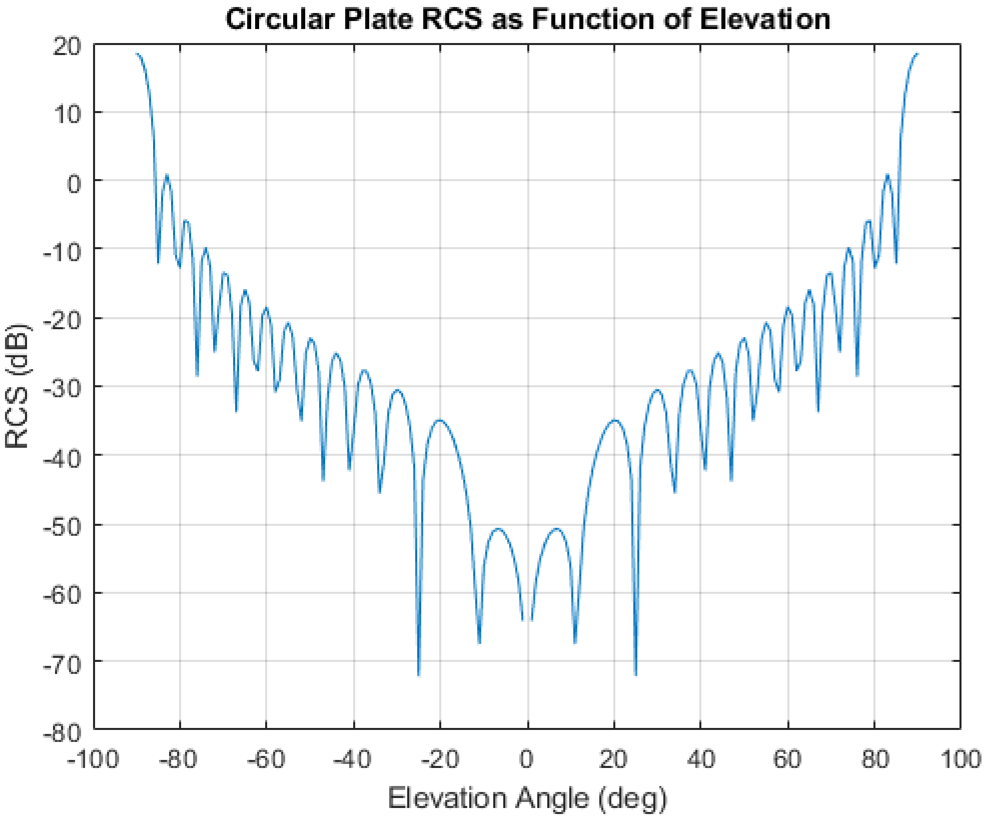
Plot the radar cross section (RCS) pattern of a circular plate as a function of elevation angle for a fixed azimuth angle of 5 degrees. The plate radius is 22.5 cm. The operating frequency is 4.5 GHz.

Define the plate radius and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
rad = 0.225;
```

Compute the RCS as a function of elevation.

```
az = 5;
el = -90:90;
[rcspat,azresp,elresp] = rcsdisc(rad,c,fc,az,el);
plot(elresp,pow2db(rcspat))
xlabel('Elevation Angle (deg)')
ylabel('RCS (dB)')
title('Circular Plate RCS as Function of Elevation')
grid on
```



### Radar Cross Section of Circular Plate as Function of Frequency

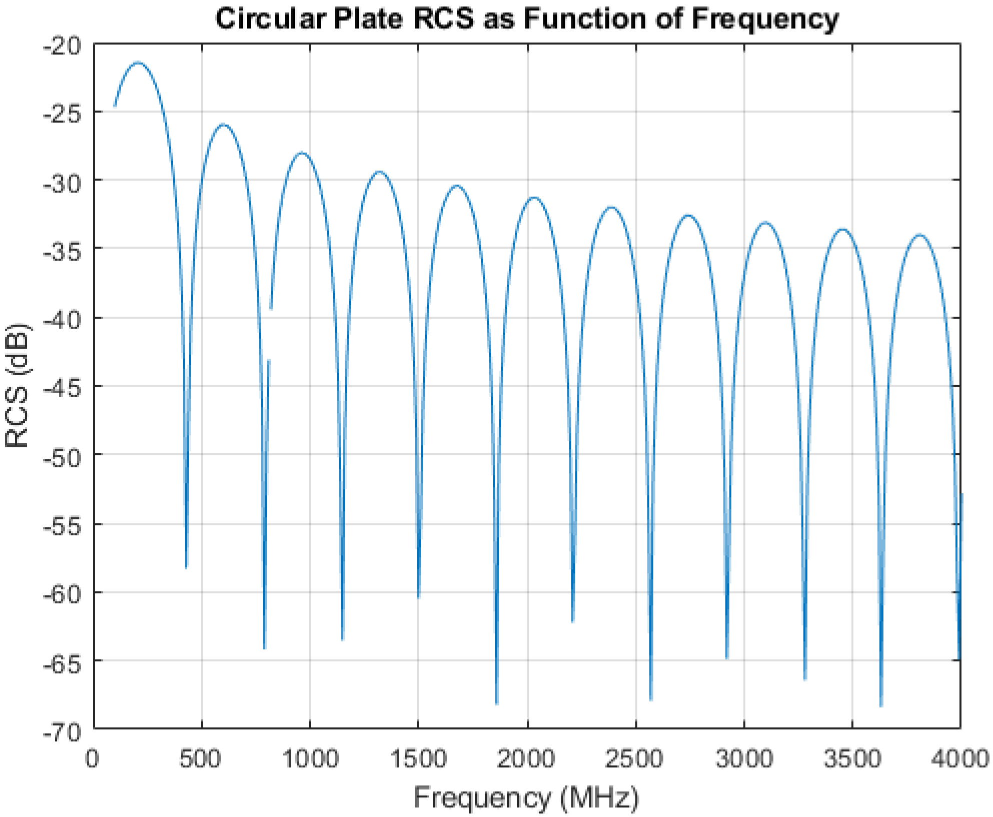
Plot the radar cross section (RCS) pattern of a circular plate as a function of frequency for a single azimuth and elevation. The plate radius 22.5 cm.

Define the plate radius and signal parameters.

```
c = physconst('Lightspeed');
rad = 0.225;
```

Compute the RCS over a range of frequencies for a single direction.

```
az = 5.0;
el = 20.0;
fc = (100:10:4000)*1e6;
rcspat = rcsdisc(rad,c,fc,az,el);
plot(fc/1e6,pow2db(squeeze(rcspat)))
xlabel('Frequency (MHz)')
ylabel('RCS (dB)')
title('Circular Plate RCS as Function of Frequency')
grid on
```



## Input Arguments

### `r` — Radius of circular plate

positive scalar

Radius of circular plate, specified as a positive scalar. Units are in meters.

Example: `5.5`

Data Types: `double`

### `c` — Signal propagation speed

positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. For the SI value of the speed of light, use `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

### `fc` — Frequency for computing radar cross section

positive scalar | positive, real-valued, 1-by-*L* row vector

Frequency for computing radar cross section, specified as a positive scalar or positive, real-valued, 1-by-*L* row vector. Frequency units are in Hz.

Example: `[100e6 200e6]`

Data Types: `double`

### `az` — Azimuth angles

`-180:180` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°, inclusive.

The azimuth angle is the angle between the *x*-axis and the projection of a direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `-45:2:45`

Data Types: `double`

### `el` — Elevation angles

`-90:90` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a real-valued, 1-by-*N* row vector where *N* is the number of desired elevation directions. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive.

The elevation angle is the angle between a direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `-75:1:70`

Data Types: `double`

## Output Arguments

### `rcspat` — Radar cross section pattern

real-valued *N*-by-*M*-by-*L* array

Radar cross section pattern, returned as a real-valued *N*-by-*M*-by-*L* array. *N* is the length of the vector returned in the `elout` argument. *M* is the length of the vector returned in the `azout` argument. *L* is the length of the `fc` vector. Units are in meters-squared.

Data Types: `double`

### `azout` — Azimuth angles

real-valued 1-by-*M* row vector

Azimuth angles for computing directivity and pattern, returned as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles specified by the `az` input argument. Angle units are in degrees.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Data Types: `double`

### `elout` — Elevation angles

real-valued 1-by-*N* row vector

Elevation angles for computing directivity and pattern, returned as a real-valued 1-by-*N* row vector where *N* is the number of elevation angles specified in `el` output argument. Angle units are in degrees.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Data Types: `double`

# More About

## Azimuth and Elevation

This section describes the convention used to define azimuth and elevation angles.

The azimuth angle of a vector is the angle between the *x*-axis and its orthogonal projection onto the *xy*-plane. The angle is positive when going from the *x*-axis toward the *y*-axis. Azimuth angles lie between –180° and 180° degrees, inclusive. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy*-plane. Elevation angles lie between –90° and 90° degrees, inclusive.

**Introduced in R2019a**

# rcstruncone

Radar cross section of truncated cone

## Syntax

```
rcspat = rcstruncone(r1,r2,height,c,fc)
rcspat = rcstruncone(r1,r2,height,c,fc,az,el)
[rcspat,azout,elout] = rcstruncone( ___ )
```

## Description

`rcspat = rcstruncone(r1,r2,height,c,fc)` returns the radar cross section pattern of a truncated cone. `r1` is the radius of the small end of the cone, `r2` is the radius of the large end, and `height` is the cone height. The radar cross section is a function of signal frequency, `fc`, and signal propagation speed, `c`. You can create a non-truncated cone by setting `r1` to zero. The cone points downward towards the *xy*-plane. The origin is located at the apex of a the non-truncated cone constructed by extending the truncated cone to an apex.

`rcspat = rcstruncone(r1,r2,height,c,fc,az,el)` also specifies the azimuth angles, `az`, and elevation angles, `el`, at which to compute the radar cross section.

`[rcspat,azout,elout] = rcstruncone( ___ )` also returns the azimuth angles, `azout`, and elevation angles, `elout`, at which the radar cross sections are computed. You can use these output arguments with any of the previous syntaxes.

## Examples

### Radar Cross Section of Truncated Cone

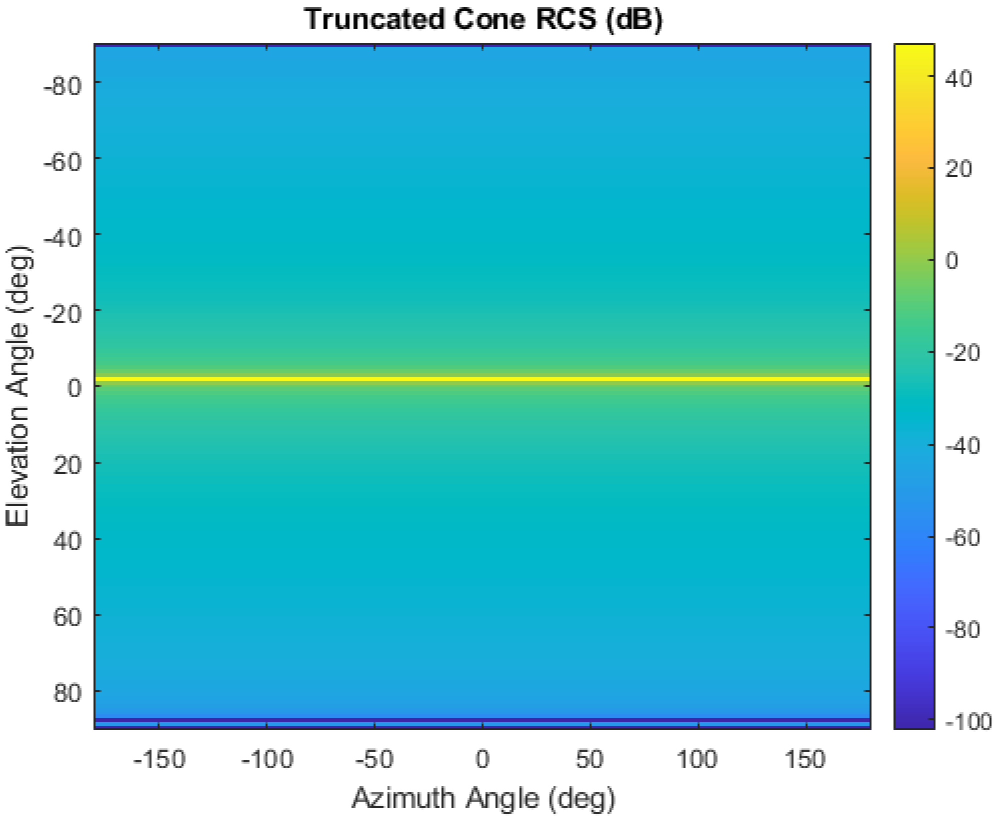
Display the radar cross section (RCS) pattern of a truncated cone as a function of azimuth angle and elevation. The truncated cone has a bottom radius of 9.0 cm and a top radius of 12.5 cm. The cone height is 1 m. The operating frequency is 4.5 GHz.

Define the truncated cone geometry and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
radbot = 0.090;
radtop = 0.125;
hgt = 1;
```

Compute the RCS for all directions using the default direction values.

```
[rcspat,azresp,elresp] = rcstruncone(radbot,radtop,hgt,c,fc);
imagesc(azresp,elresp,pow2db(rcspat))
xlabel('Azimuth Angle (deg)')
ylabel('Elevation Angle (deg)')
title('Truncated Cone RCS (dB)')
colorbar
```



### Radar Cross Section of Truncated Cone as Function of Elevation

Plot the radar cross section (RCS) pattern of a truncated cone as a function of elevation for a fixed azimuth angle of 5 degrees. The cone has a bottom radius of 9.0 cm and a top radius of 12.5 cm. The truncated cone height is 1 m. The operating frequency is 4.5.

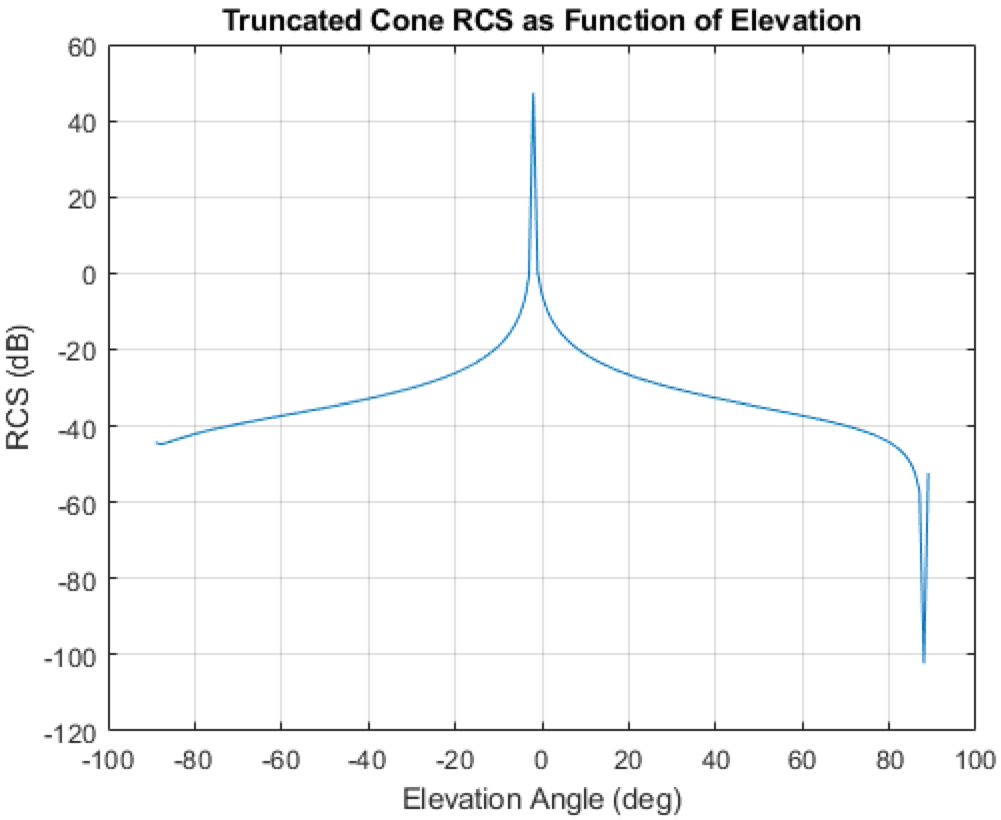
Define the truncated cone geometry and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
radbot = 0.090;
```

```
radtop = 0.125;
hgt = 1;
```

Compute the RCS at an azimuth angle of 5 degrees.

```
az = 5.0;
el = -90:90;
[rcspat,azresp,elresp] = rcstruncone(radbot,radtop,hgt,c,fc,az,el);
plot(elresp,pow2db(rcspat))
xlabel('Elevation Angle (deg)')
ylabel('RCS (dB)')
title('Truncated Cone RCS as Function of Elevation')
grid on
```



### Radar Cross Section of Truncated Cone as Function of Frequency

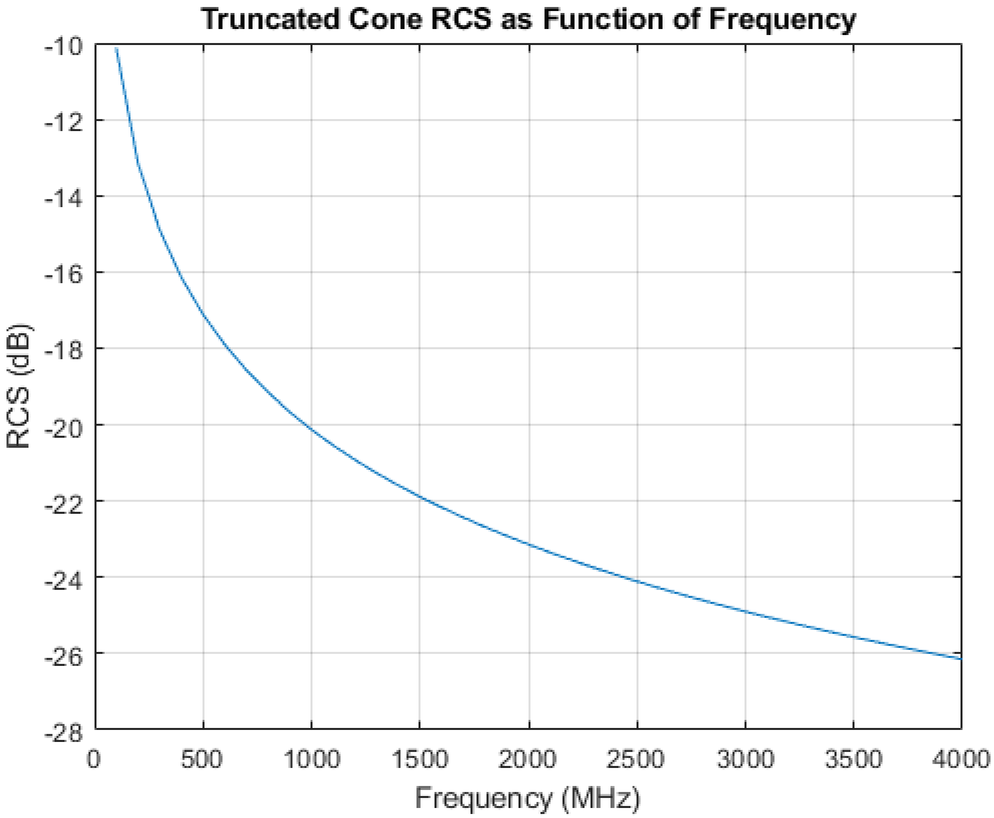
Plot the radar cross section (RCS) pattern of a truncated cone as a function of frequency for a single direction. The cone has a bottom radius of 9.0 cm and a top radius of 12.5 cm. The truncated cone height is 1 m.

Specify the truncated cone geometry and signal parameters.

```
c = physconst('Lightspeed');
radbot = 0.090;
radtop = 0.125;
hgt = 1;
```

Compute the RCS over a range of frequencies for a single direction.

```
az = 5.0;
el = 20.0;
fc = (100:100:4000)*1e6;
rcspat = rcstruncone(radbot,radtop,hgt,c,fc,az,el);
plot(fc/1e6,pow2db(squeeze(rcspat)))
xlabel('Frequency (MHz)')
ylabel('RCS (dB)')
title('Truncated Cone RCS as Function of Frequency')
grid on
```



### Radar Cross Section of Full Cone as Function of Elevation

Plot the radar cross section (RCS) pattern of a full cone as a function of elevation for a fixed azimuth angle. To define a full cone set the bottom radius to zero. Set the top radius to 20.0 cm and the cone height to 50 cm. Assume the operating frequency is 4.5 GHz and the azimuth angle is 5 degrees.

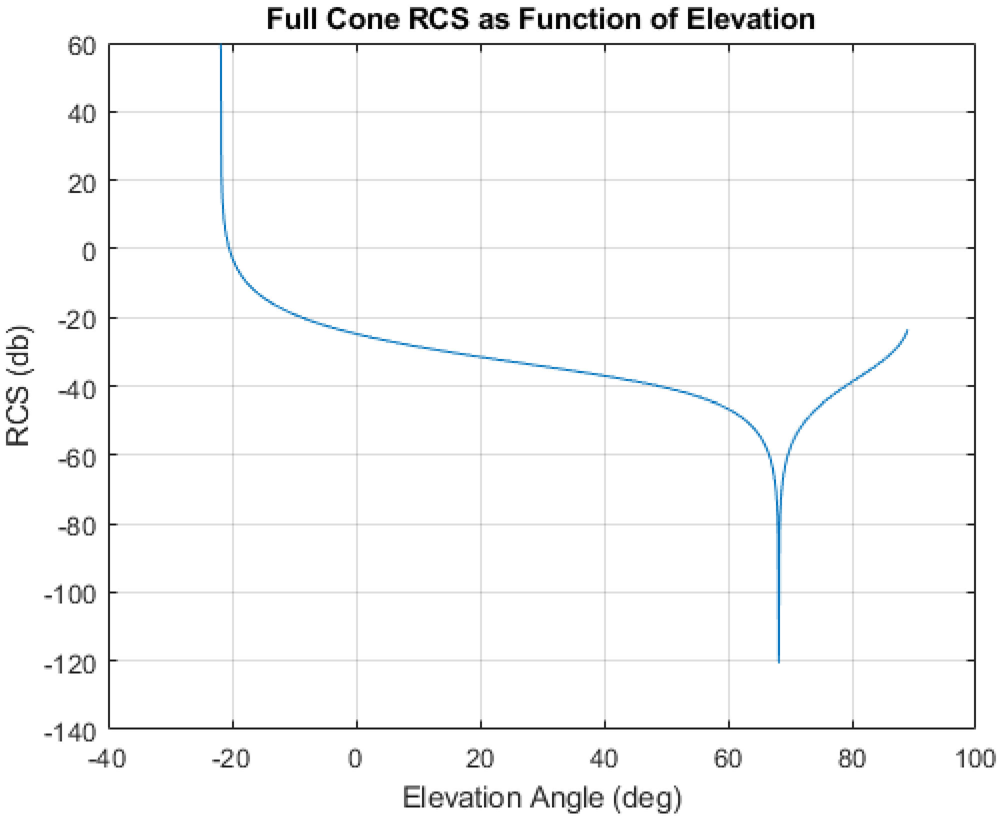
Define the cone geometry and signal parameters.

```
c = physconst('Lightspeed');
fc = 4.5e9;
```

```
radsmall = 0.0;
radlarge = 0.20;
hgt = 0.5;
```

Compute the RCS for a fixed azimuth angle of 5 degrees.

```
az = 5.0;
el = -89:0.1:89;
[rcspat,azresp,elresp] = rcstruncone(radsmall,radlarge,hgt,c,fc,az,el);
plot(elresp,pow2db(rcspat))
xlabel('Elevation Angle (deg)')
ylabel('RCS (db)')
title('Full Cone RCS as Function of Elevation')
grid on
```



# Input Arguments

### `r1` — Radius of small end of truncated cone

nonnegative scalar

Radius of small end of truncated cone, specified as a nonnegative scalar. Units are in meters.

Example: `5.5`

Data Types: `double`

### `r2` — Radius of large end of truncated cone

positive scalar

Radius of large end of truncated cone, specified as a positive scalar. Units are in meters.

Example: `5.5`

Data Types: `double`

### `height` — Height of truncated cone

positive scalar

Height of truncated cone, specified as a positive scalar. Units are in meters.

Example: `3.0`

Data Types: `double`

### `c` — Signal propagation speed

positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. For the SI value of the speed of light, use `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

### `fc` — Frequency for computing radar cross section

positive scalar | positive, real-valued, 1-by-*L* row vector

Frequency for computing radar cross section, specified as a positive scalar or positive, real-valued, 1-by-*L* row vector. Frequency units are in Hz.

Example: `[100e6 200e6]`

Data Types: `double`

**`az` — Azimuth angles**
`-180:180` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°, inclusive.

The azimuth angle is the angle between the *x*-axis and the projection of a direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `-45:2:45`

Data Types: `double`

**`el` — Elevation angles**
`-90:90` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a real-valued, 1-by-*N* row vector where *N* is the number of desired elevation directions. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive.

The elevation angle is the angle between a direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `-75:1:70`

Data Types: `double`

## Output Arguments

**`rcspat` — Radar cross section pattern**
real-valued *N*-by-*M*-by-*L* array

Radar cross section pattern, returned as a real-valued *N*-by-*M*-by-*L* array. *N* is the length of the vector returned in the `elout` argument. *M* is the length of the vector returned in the `azout` argument. *L* is the length of the `fc` vector. Units are in meters-squared.

Data Types: `double`

**`azout` — Azimuth angles**
real-valued 1-by-*M* row vector

Azimuth angles for computing directivity and pattern, returned as a real-valued 1-by-*M* row vector where *M* is the number of azimuth angles specified by the `az` input argument. Angle units are in degrees.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Data Types: `double`

**`elout` — Elevation angles**
real-valued 1-by-*N* row vector

Elevation angles for computing directivity and pattern, returned as a real-valued 1-by-*N* row vector where *N* is the number of elevation angles specified in `el` output argument. Angle units are in degrees.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Data Types: `double`

# rotpat

Rotate radiation pattern

## Syntax

```
rpat = rotpat(pat,az,el,rotax)
rpat = rotpat(pat,az,el,rotax,expval)
```

## Description

`rpat = rotpat(pat,az,el,rotax)` rotates a radiation pattern, `pat`, into a new pattern, `rpat`, whose boresight is aligned with the *x*-axis of a new local coordinate system defined by `rotax`. `az` and `el` specify the azimuth and elevation angles at which the original pattern is sampled.

`rpat = rotpat(pat,az,el,rotax,expval)` also specifies an extrapolated value to be used when `az` and `el` do not cover the entire 3-D space.

**Tip** You can use this function to rotate real and complex scalar radiation patterns as well as the orthogonal components of polarized fields. To rotate polarized fields, rotate the horizontal and vertical polarization components separately.

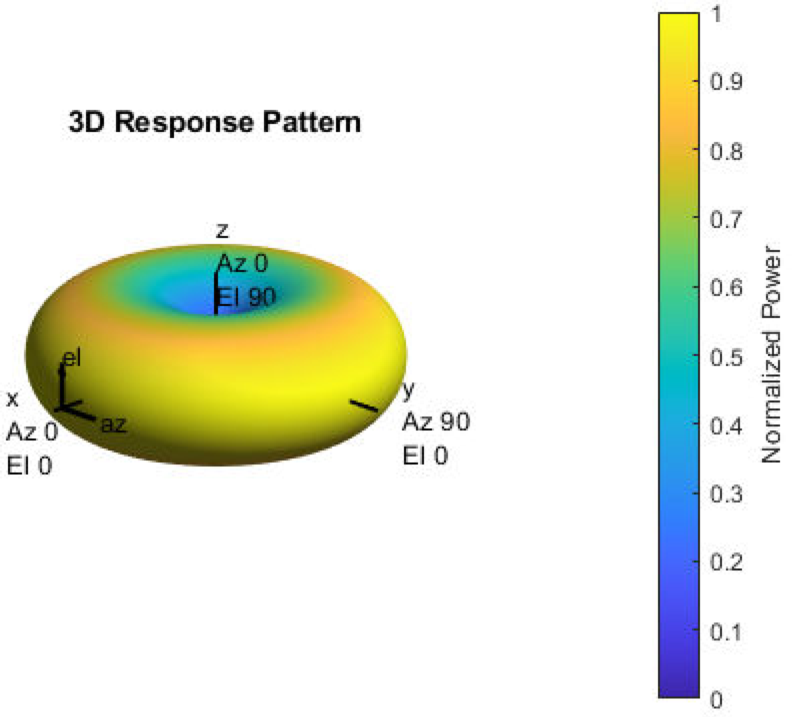
## Examples

### Rotate Pattern of Short-Dipole Antenna

Use a short-dipole antenna to create a polarized radiation pattern. Rotate the pattern and use the rotated pattern as the radiation pattern of a custom antenna.

Create a `phased.ShortDipoleAntennaElement` antenna object with default properties. The short-dipole antenna radiates polarized radiation. Obtain and display the radiation for all directions.

```
antenna1 = phased.ShortDipoleAntennaElement;
el = -90:90;
az = -180:180;
pat_h = zeros(numel(el),numel(az),'like',1+1i);
pat_v = pat_h;
fc = 3e8;
for m = 1:numel(el)
    temp = antenna1(fc,[az;el(m)*ones(1,numel(az))]);
    pat_h(m,:) = temp.H;
    pat_v(m,:) = temp.V;
end
pattern(antenna1,fc,'Type','Power')
```

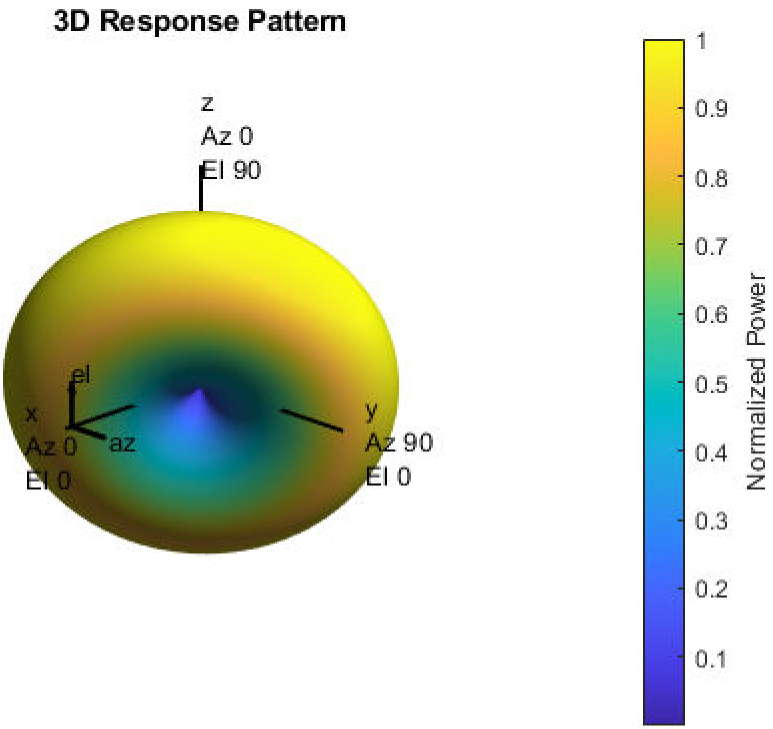


Rotate the antenna pattern around the *y*-axis by 135 degrees followed by a rotation around the *x*-axis by 65 degrees.

```
newax = rotx(65)*roty(135);
pat2_h = rotpat(pat_h,az,el,newax);
pat2_v = rotpat(pat_v,az,el,newax);
```

Insert the rotated pattern into a `phased.CustomAntennaElement` object. Set the antenna polarization properties so that the element radiates horizontal and vertical polarized fields. Then display the rotated pattern in three dimensions.

```
antenna2 = phased.CustomAntennaElement( ...
    'SpecifyPolarizationPattern',true, ...
    'HorizontalMagnitudePattern',mag2db(abs(pat2_h)), ...
    'HorizontalPhasePattern',rad2deg(angle(pat2_h)), ...
    'VerticalMagnitudePattern',mag2db(abs(pat2_v)), ...
    'VerticalPhasePattern',rad2deg(angle(pat2_v)));
pattern(antenna2,fc,'Type','Power')
```



### Rotate Pattern of Cosine Antenna

Create a radiation pattern for a cosine antenna using a `phased.CosineAntennaElement` object. Rotate the pattern to use in a `phased.CustomAntennaElement` antenna object.

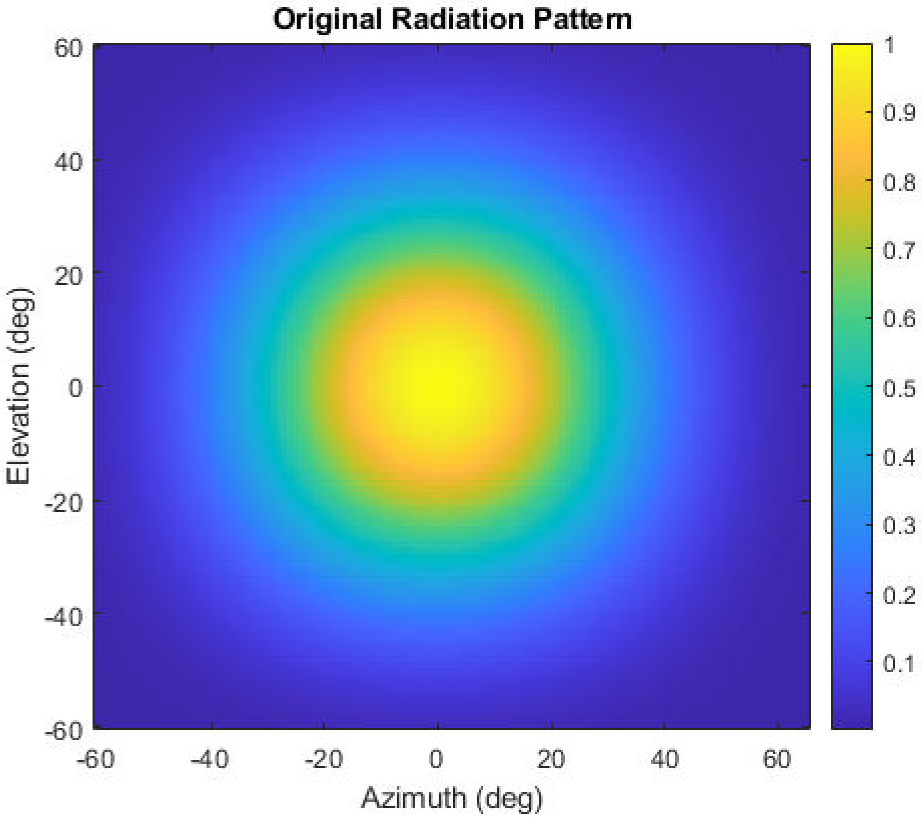
First obtain the radiation pattern for a `phased.CosineAntennaElement` object over a limited range of directions. The field is not polarized.

```
antenna1 = phased.CosineAntennaElement('CosinePower',[5,5]);
az = -60:65;
```

```
el = -60:60;
pat = zeros(numel(el),numel(az),'like',1);
fc = 300e6;
for m = 1:numel(el)
    temp = antenna1(fc,[az;el(m)*ones(1,numel(az))]);
    pat(m,:) = temp;
end
```

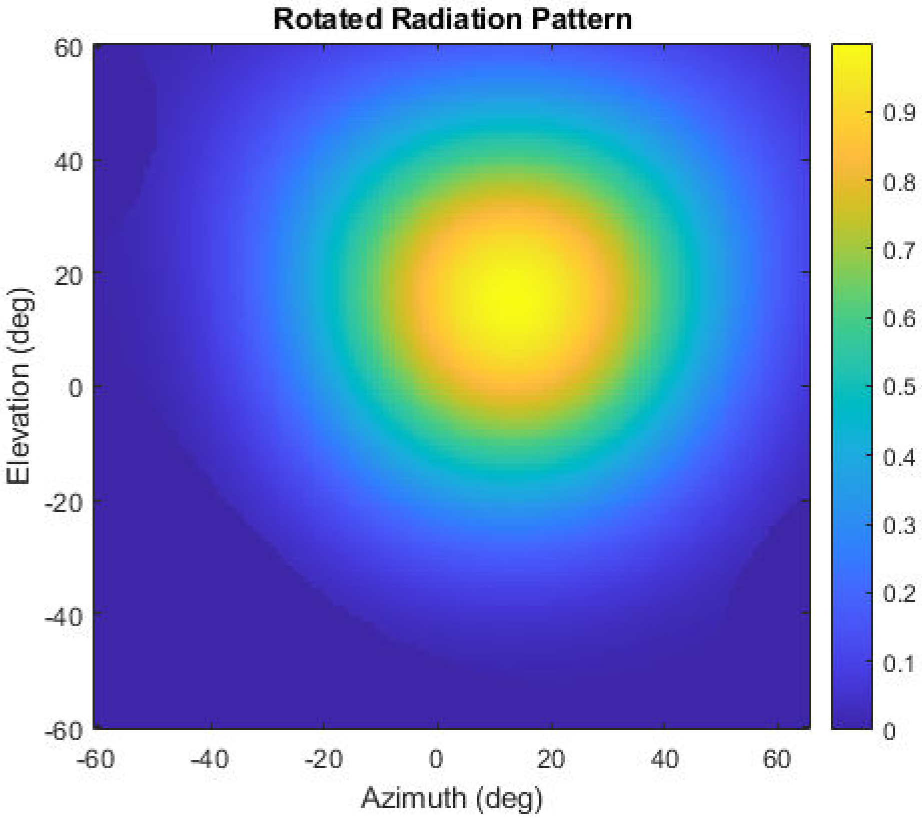
Display the original pattern.

```
imagesc(az,el,abs(pat))
axis xy
axis equal
axis tight
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
title('Original Radiation Pattern')
colorbar
```



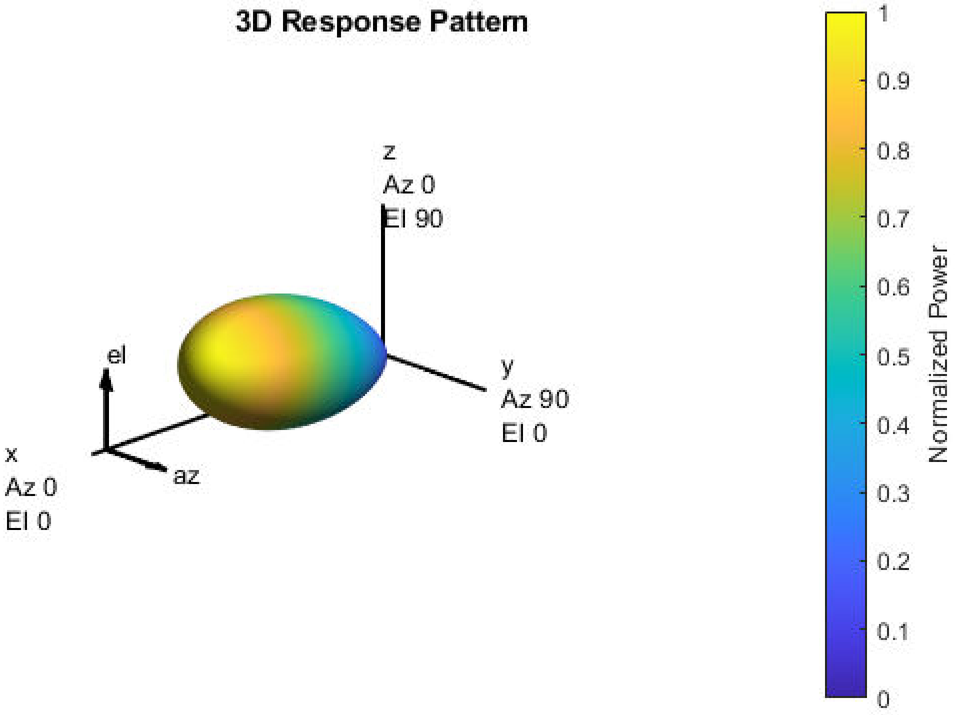
Rotate the antenna pattern by 20 degrees around the *z*-axis and 50 degrees around the *x*-axis. Then display the rotated pattern.

```
newax = rotx(50)*rotz(20);
rpat = rotpat(pat,az,el,newax);
imagesc(az,el,abs(rpat))
axis xy
axis equal
axis tight
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
title('Rotated Radiation Pattern')
colorbar
```



Use the rotated pattern in a custom antenna element and display the pattern in 3-D.

```
antenna2 = phased.CustomAntennaElement( ...
    'AzimuthAngles',az,'ElevationAngles',el,'SpecifyPolarizationPattern',false, ...
    'MagnitudePattern',mag2db(abs(rpat)), ...
    'PhasePattern',zeros(size(rpat)));
pattern(antenna2,fc,'Type','Power')
```



## Input Arguments

### `pat` — Radiation pattern

complex-valued *N*-by-*M* matrix | complex-valued *N*-by-*M*-by-*L* array

Radiation pattern, specified as a complex-valued *N*-by-*M* matrix or complex-valued *N*-by-*M*-by-*L* array. *N* is the length of the `el` vector and *M* is the length of the `az` vector. Each column corresponds to one of the azimuth angles specified in the `az` argument. Each row corresponds to one of the elevation angles specified in the `el` argument. You can specify multiple radiation patterns using *L* pages. For example, you can use pages to specify radiation patterns at different frequencies. The main lobe of each pattern is assumed to point along the *x*-axis. Units are in meters-squared.

Data Types: `double`

### `az` — Azimuth angles

`-180:180` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing 3-D radiation pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Each entry corresponds to one of the columns of the matrix specified in the `pat` argument. Angle units are in degrees. Azimuth angles must lie between –180° and 180°, inclusive.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy*-plane. The azimuth angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `-45:2:45`

Data Types: `double`

### `el` — Elevation angles

`-90:90` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of elevation angles. Each entry corresponds to one of the rows of the matrix specified in the `pat` argument. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured toward the *z*-axis.

Example: `-75:1:70`

Data Types: `double`

### `rotax` — Rotation matrix

real-valued orthonormal 3-by-3 matrix | real-valued orthonormal 3-by-3-by-*P* array of orthonormal matrices

Rotation matrix, specified as a real-valued orthonormal 3-by-3 matrix or a real-valued 3-by-3-by-*P* array. The columns represent the *x*, *y*, and *z* directions of the rotated coordinate system with respect to the original coordinate system. The *P* pages specify different rotation matrices.

This table describes how dimensions of the output pattern `rpat` depend on the dimensions of the `pat` and `rotax` arguments.

**Dimensions of `rpat`**

| Dimensions of `pat` | Dimensions of `rotax` | |
|---|---|---|
| | *3*-by-*3* | *3*-by-*3*-by-*P* |
| *M*-by-*N* | Rotate a single pattern by a single rotation matrix. Output dimensions of `rpat` are *M*-by-*N*. | Rotate a single pattern by *P* different rotation matrices. Output dimensions of `rpat` are *M*-by-*N*-by-*P*. |
| *M*-by-*N*-by-*L* | Rotate *L* patterns by the same rotation matrix. Output dimensions of `rpat` are *M*-by-*N*-by-*L*. | In this case, *P* must equal *L* and the function rotates each pattern by the corresponding rotation matrix. Output dimensions of `rpat` are *M*-by-*N*-by-*L*. |

Example: `rotx(45)*roty(30)`

Data Types: `double`

**`expval` — Extrapolation value**
`0` (default) | scalar

Extrapolation value, specified as a scalar. This scalar is the extrapolated value when the rotated patterns do not fill the entire 3-D space specified by `az` and `el`. In general, consider setting `expval` to 0 if the pattern is specified in a linear scale or `-inf` if the pattern is specified in a dB scale.

Example: `-inf`

Data Types: `double`

# Output Arguments

**`rpat` — Rotated radiation pattern**
complex-valued *N*-by-*M* matrix | complex-valued *N*-by-*M*-by-*P* array

Rotated radiation pattern, returned as a complex-valued *N*-by-*M* matrix or complex-valued *N*-by-*M*-by-*P* array. *N* is the length of the `el` vector. *M* is the length of the `az` vector. The dimensionality of `pat` and `rotax` determine the value of *P* as discussed in the `rotax` input argument. Units are in meters-squared.

Data Types: `double`

# Extended Capabilities

# tl2range

Compute range from underwater transmission loss

## Syntax

```
rng = tl2range(tl,freq,depth)
```

## Description

`rng = tl2range(tl,freq,depth)` returns the range, `rng`, to the source of a sound wave with frequency `freq` from the transmission loss, `tl`. The channel depth is `depth` and the sound frequency is `freq`. The transmission loss is due to geometrical spreading and frequency-dependent absorption. This function is the inverse of `range2tl` function.

## Examples

### Estimate Range from Transmission Loss

Find the distance traveled by a sound wave with a transmission loss of 50 dB. The sonar operates at 2 kHz in a channel 200 m deep.

```
tl = 50.0;
freq = 2000.0;
depth = 200.0;
rng = tl2range(tl,freq,depth)
```

```
rng = 972.1666
```

## Input Arguments

**`tl` — Transmission loss from source to receiver**
positive scalar

Transmission loss from source to receiver, specified as a positive scalar. Units are in dB.

Data Types: `double`

### `freq` — Frequency of sound

positive scalar less than or equal to 2 MHz

Frequency of sound, specified as a positive scalar less than or equal to 2 MHz. Units are in Hz.

Example: `1e3`

Data Types: `double`

### `depth` — Depth of sound channel

positive scalar

Depth of sound channel, specified as a positive scalar. Units are in meters.

Example: `200`

Data Types: `double`

## Output Arguments

### `rng` — Distance from source to receiver

positive scalar

Distance from source to receiver, returned as a positive scalar. Units are in meters.

Data Types: `double`

## Limitations

- The transmission loss model assumes that seawater salinity is 35 ppt, pH is 8, and temperature is 10°C.
- The transmission loss model is valid for frequencies less than or equal to 2.0 MHz.

# rangeangle

Range and angle calculation

## Syntax

```
[rng,ang] = rangeangle(pos)
[rng,ang] = rangeangle(pos,refpos)
[rng,ang] = rangeangle(pos,refpos,refaxes)
[rng,ang] = rangeangle( ___ ,model)
```

## Description

The function `rangeangle` determines the propagation path length and path direction of a signal from a source point or set of source points to a reference point. The function supports two propagation models – the *free space* model and the *two-ray* model. The *free space* model is a single line-of-sight path from a source point to a reference point. The *two-ray* multipath model generates two paths. The first path follows the free-space path. The second path is a reflected path off a boundary plane at $z = 0$. Path directions are defined with respect to either the global coordinate system at the reference point or a local coordinate system at the reference point. Distances and angles at the reference point do not depend upon which direction the signal is travelling along the path.

`[rng,ang] = rangeangle(pos)` returns the propagation path length, `rng`, and direction angles, `ang`, of a signal path from a source point or set of source points, `pos`, to the origin of the global coordinate system. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the origin. Signals follow a line-of-sight path from the source point to the origin. The line-of-sight path corresponds to the geometric straight line between the points.

`[rng,ang] = rangeangle(pos,refpos)` also specifies a reference point or set of reference points, `refpos`. `rng` now contains the propagation path length from the source points to the reference points. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the reference points. You can specify multiple points and multiple reference points.

`[rng,ang] = rangeangle(pos,refpos,refaxes)` also specifies local coordinate system axes, `refaxes`, at the reference points. Direction angles are the azimuth and elevation with respect to the local coordinate axes centered at `refpos`.

`[rng,ang] = rangeangle( ___ ,model)`, also specifies a propagation model. When `model` is set to `'freespace'`, the signal propagates along a line-of-sight path from source point to reception point. When `model` is set to `'two-ray'`, the signal propagates along two paths from source point to reception point. The first path is the line-of-sight path. The second path is the reflecting path. In this case, the function returns the distances and angles for two paths for each source point and corresponding reference point.

## Input Arguments

### `pos`

Source point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by-*N* matrix. A matrix represents multiple source points. The columns contain the Cartesian coordinates of *N* points in the form `[x;y;z]`.

When `pos` is a 3-by-*N* matrix, you must specify `refpos` as a 3-by-*N* matrix for *N* reference positions. If all the reference points are identical, you can specify `refpos` by a single 3-by-1 vector.

Position units are meters.

### `refpos`

Reference point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by-*N* matrix. A matrix represents multiple reference points. The columns contain the Cartesian coordinates of *N* points ins the form `[x;y;z]`.

When `refpos` is a 3-by-*N* matrix, you must specify `pos` as a 3-by-*N* matrix for *N* source positions. If all the source points are identical, you can specify `pos` by a single 3-by-1 vector.

Position units are meters.

**Default:** `[0;0;0]`

### `refaxes`

Local coordinate system axes, specified as a real-valued 3-by-3 matrix or a 3-by-3-by-*N* array. For an array, each page corresponds to a local coordinate axes at each reference point. The columns in `refaxes` specify the direction of the coordinate axes for the local coordinate system in Cartesian coordinates. *N* must match the number of columns in `pos` or `refpos` when these dimensions are greater than one.

**Default:** `[1 0 0;0 1 0;0 0 1]`

### `model`

Propagation model, specified as `'freespace'` or `'two-ray'`. Choosing `'freespace'` invokes the free space propagation model. Choosing `'two-ray'` invokes the two-ray propagation model.

**Default:** `'freespace'`

## Output Arguments

### `rng`

Propagation range, returned as a real-valued 1-by-*N* vector or real-valued 1-by-*2N* vector.

When `model` is set to `'freespace'`, the size of `rng` is 1-by-*N*. The propagation range is the length of the direct path from the position defined in `pos` to the corresponding reference position defined in `refpos`.

When `model` is set to `'two-ray'`, `rng` contains the ranges for the direct path and the reflected path. Alternate columns of `rng` refer to the line-of-sight path and reflected path, respectively for the same source-reference point pair. Position units are meters.

### `ang`

Azimuth and elevation angles, returned as a 2-by-*N* matrix or 2-by-*2N* matrix. Each column represents a direction angle in the form `[azimuth;elevation]`.

When `model` is set to `'freespace'`, `ang` is a 2-by-*N* matrix and represents the angle of the path from a source point to a reference point.

When `model` is set to `'two-ray'`, `ang` is a 2-by-2*N* matrix. Alternate columns of `ang` refer to the line-of-sight path and reflected path, respectively.

Angle units are in degrees.

# Examples

### Range and Angle Computation

Compute the range and angle of a target located at *(1000,2000,50)* meters from the origin.

```
TargetLoc = [1000;2000;50];
[tgtrng,tgtang] = rangeangle(TargetLoc)
```

```
tgtrng = 2.2366e+03

tgtang = 2×1

   63.4349
    1.2810
```

### Range and Angle With Respect to Local Origin

Compute the range and angle of a target located at *(1000,2000,50)* meters with respect to a local origin at *(100,100,10)* meters.

```
TargetLoc = [1000;2000;50];
Origin = [100;100;10];
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin)
```

```
tgtrng = 2.1028e+03

tgtang = 2×1

   64.6538
    1.0900
```

### Range and Angle With Respect to Local Coordinates

Compute the range and angle of a target located at *(1000,2000,50)* meters but with respect to a local coordinate system origin at *(100,100,10)* meters. Choose a local coordinate reference frame that is rotated about the z-axis by 45° from the global coordinate axes.

```
targetpos = [1000;2000;50];
origin = [100;100;10];
refaxes = [1/sqrt(2) -1/sqrt(2) 0; 1/sqrt(2) 1/sqrt(2) 0; 0 0 1];
[tgtrng,tgtang] = rangeangle(targetpos,origin,refaxes)
```

```
tgtrng = 2.1028e+03

tgtang = 2×1

   19.6538
    1.0900
```

### Two-Ray Range and Angle

Compute the two-ray propagation distances and arrival angles of rays from a source located at *(1000,1000,500)* meters from the origin. The receiver is located at *(100,100,200)* meters from the origin.

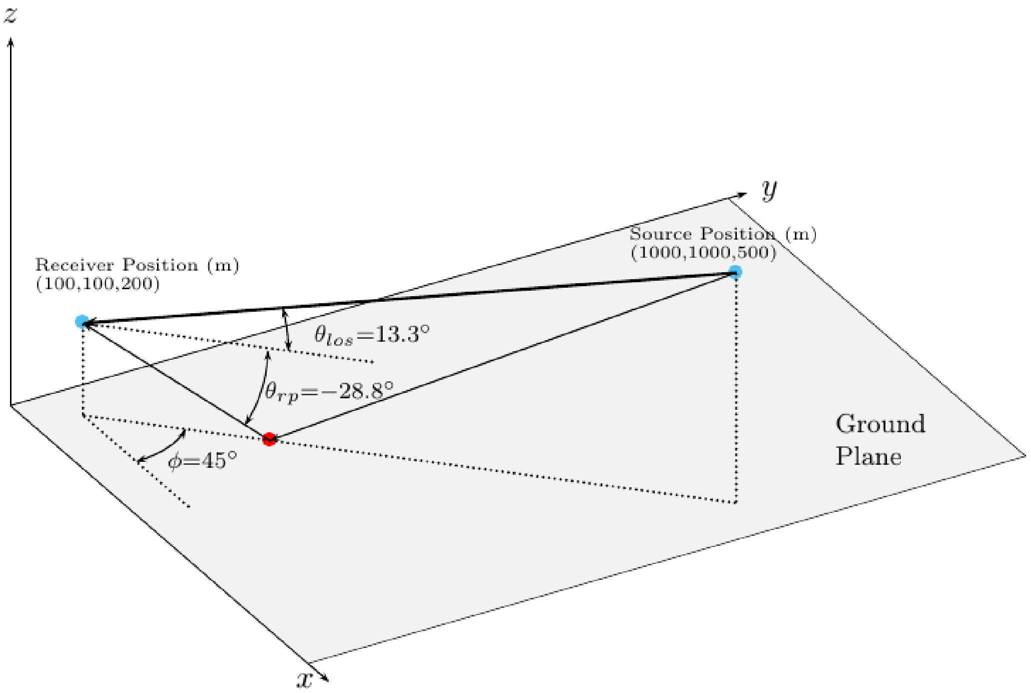
```
sourceLoc = [1000;1000;500];
receiverLoc = [100;100;200];
[sourcerngs,sourceangs] = rangeangle(sourceLoc,receiverLoc,'two-ray')
```

```
sourcerngs = 1×2
10^3 ×

    1.3077    1.4526

sourceangs = 2×2

   45.0000   45.0000
   13.2627   -28.8096
```



Find the range and angle of the same target with the same origin but with respect to a local coordinate axes. The local coordinate axes are rotated around the z-axis by 45 degrees from the global coordinate axes.

```
refaxes = rotz(45);
[sourcerngs,sourceangs] = rangeangle(sourceLoc,receiverLoc,refaxes,'two-ray')
```

```
sourcerngs = 1×2
10^3 ×
```

```
    1.3077    1.4526

sourceangs = 2×2

         0         0
   13.2627  -28.8096
```

### Range and Angle With Respect to Two Origins

Compute the ranges and angles of two targets located at (1000,200,500) and (2500,80,-100) meters with respect to two local origins at (100,300,-40) and (500,-60,10) meters. Specify two different sets of local axes.

```
targetPos = [1000,2500;200,80;500,-100];
origins = [100,500;300,-60;-40,10];
ax(:,:,1) = rotx(40)*rotz(10);
ax(:,:,2) = roty(5)*rotx(10);
[tgtrng,tgtang] = rangeangle(targetPos,origins,ax)
```

```
tgtrng = 1×2
10^3 ×

    1.0543    2.0079

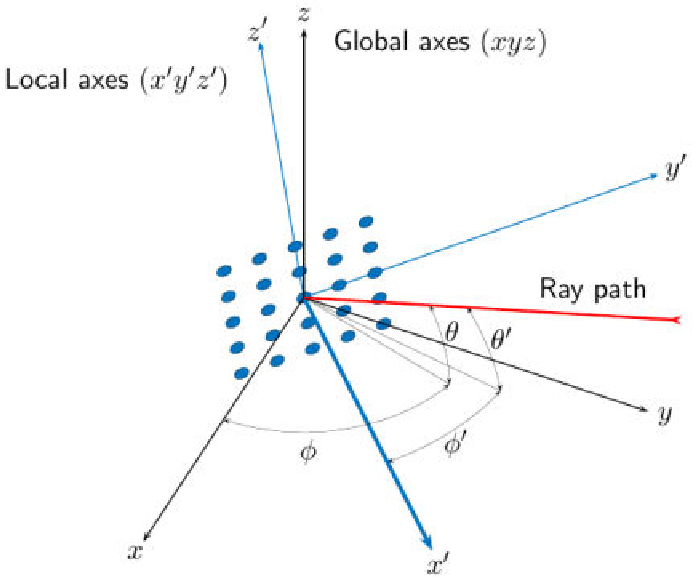
tgtang = 2×2

    6.7285    4.2597
   26.9567    1.1254
```

# More About

## Angles in Local and Global Coordinate Systems

The `rangeangle` function returns the path distance and path angles in either the global or local coordinate systems. Every antenna or microphone element and array has a gain pattern that is expressed in local angular coordinates of azimuth and elevation. As the element or array moves or rotates, the gain pattern is carried with it. To determine the strength of a signal', you must know the angle that the signal path makes with respect to the local angular coordinates of the element or array. By default, the `rangeangle` function determines the angle a signal path makes with respect to global coordinates. If you add the `refaxes` argument, you can compute the angles with respect to local coordinates. As an illustration, this figure shows a 5-by-5 uniform rectangular array (URA) rotated from the global coordinates *(xyz)* using `refaxes`. The *x*' axis of the local coordinate system *(x'y'z')* is aligned with the main axis of the array and moves as the array moves. The path length is independent of orientation. The global coordinate system defines the azimuth and elevations angles *(Φ,θ)* and the local coordinate system defines the azimuth and elevations angles *(Φ',θ')*.



**Local and Global Coordinate Axes**

## Free Space Propagation Model

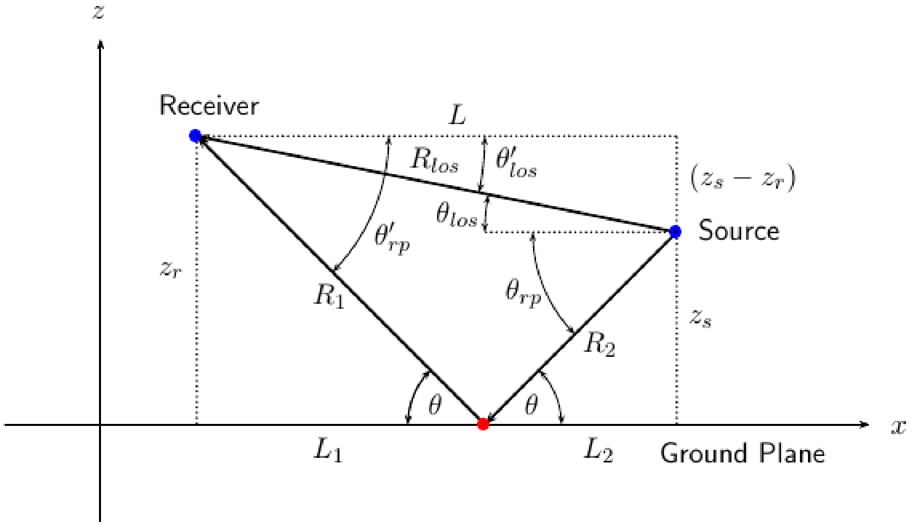
The free-space signal propagation model states that a signal propagating from one point to another in a homogeneous, isotropic medium travels in a straight line, called the *line-of-sight* or *direct path*. The straight line is defined by the geometric vector from the radiation source to the destination. Similar assumptions are made for sonar but the term *isovelocity* channel is used in place of free space.

## Two-Ray Propagation Model

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at $z = 0$. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel (see the `phased.FreeSpace` System object). The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The `phased.TwoRayChannel` and `phased.WidebandTwoRayChannel` System objects model propagation time delay, phase shift, Doppler shift, and loss effects for both paths. For the reflected path, loss effects include reflection loss at the boundary.

The figure illustrates two propagation paths. From the source position, $s_s$, and the receiver position, $s_r$, you can compute the arrival angles of both paths, $\theta'_{los}$ and $\theta'_{rp}$. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, $\theta_{los}$ and $\theta_{rp}$. In the global coordinates, the angle of reflection at the boundary is the same as the angles $\theta_{rp}$ and $\theta'_{rp}$. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by $R_{los}$ which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp}= R_1 + R_2$. The quantity $L$ is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{(z_r - z_s)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{(z_r + z_s)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{(z_r + z_s)^2 + L^2}$$

$$\tan\theta_{los} = \frac{(z_s - z_r)}{L}$$

$$\tan\theta_{rp} = -\frac{(z_s + z_r)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

**Introduced in R2011a**

# rdcoupling

Range Doppler coupling

## Syntax

```
dr = rdcoupling(fd,slope)
dr = rdcoupling(fd,slope,c)
```

## Description

`dr = rdcoupling(fd,slope)` returns the range offset on page 2-480 due to the Doppler shift in a linear frequency modulated signal. For example, the signal can be a linear FM pulse or an FMCW signal. `slope` is the slope of the linear frequency modulation.

`dr = rdcoupling(fd,slope,c)` specifies the signal propagation speed.

## Examples

### Target Range After Correcting for Doppler Shift

Calculate the true range of the target for an FMCW waveform that sweeps a band of 30 MHz in 2 ms. The dechirped target echo has a beat frequency of 1 kHz. The processing of the target return indicates a Doppler shift of 100 Hz.

```
slope = 30e6/2e-3;
fb = 1e3;
fd = 100;
r = beat2range(fb,slope) - rdcoupling(fd,slope)
```

```
r = 10.9924
```

# Input Arguments

**`fd` — Doppler shift**
array of real numbers

Doppler shift, specified as an array of real numbers.

Data Types: `double`

**`slope` — Slope of linear frequency modulation**
nonzero scalar

Slope of linear frequency modulation, specified as a nonzero scalar in hertz per second.

Data Types: `double`

**`c` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

# Output Arguments

**`dr` — Range offset due to Doppler shift**
real scalar

Range offset due to Doppler shift, returned as an array of real numbers. The dimensions of `dr` match the dimensions of `fd`.

# More About

## Range Offset

The range offset is the difference between the estimated range and the true range. The difference arises from coupling between the range and Doppler shift.

## Algorithms

The function computes `-c*fd/(2*slope)`.

# rocpfa

Receiver operating characteristic curves by false-alarm probability

## Syntax

```
[Pd,SNR] = rocpfa(Pfa)
[Pd,SNR] = rocpfa(Pfa,Name,Value)
rocpfa(...)
```

## Description

`[Pd,SNR] = rocpfa(Pfa)` returns the single-pulse detection probabilities, `Pd`, and required SNR values, `SNR`, for the false-alarm probabilities in the row or column vector `Pfa`. By default, for each false-alarm probability, the detection probabilities are computed for 101 equally spaced SNR values between 0 and 20 dB. The ROC curve is constructed assuming a single pulse in coherent receiver with a nonfluctuating target.

`[Pd,SNR] = rocpfa(Pfa,Name,Value)` returns detection probabilities and SNR values with additional options specified by one or more `Name,Value` pair arguments.

`rocpfa(...)` plots the ROC curves.

## Input Arguments

**`Pfa`**

False-alarm probabilities in a row or column vector.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`MaxSNR`**

Maximum SNR to include in the ROC calculation.

**Default:** `20`

**`MinSNR`**

Minimum SNR to include in the ROC calculation.

**Default:** `0`

**`NumPoints`**

Number of SNR values to use when calculating the ROC curves. The actual values are equally spaced between `MinSNR` and `MaxSNR`.

**Default:** `101`

**`NumPulses`**

Number of pulses to integrate when calculating the ROC curves. A value of `1` indicates no pulse integration.

**Default:** `1`

**`SignalType`**

This property specifies the type of received signal or, equivalently, the probability density functions (PDF) used to compute the ROC. Valid values are: `'Real'`, `'NonfluctuatingCoherent'`, `'NonfluctuatingNoncoherent'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, and `'Swerling4'`. Values are not case sensitive.

The `'NonfluctuatingCoherent'` signal type assumes that the noise in the received signal is a complex-valued, Gaussian random variable. This variable has independent zero-mean real and imaginary parts each with variance $\sigma^2/2$ under the null hypothesis. In the case of a single pulse in a coherent receiver with complex white Gaussian noise, the probability of detection, $P_D$, for a given false-alarm probability, $P_{FA}$ is:

$$P_D = \frac{1}{2}\operatorname{erfc}(\operatorname{erfc}^{-1}(2P_{FA}) - \sqrt{\chi})$$

where `erfc` and `erfc`$^{-1}$ are the complementary error function and that function’s inverse, and $\chi$ is the SNR not expressed in decibels.

For details about the other supported signal types, see [1] on page 2-485.

**Default:** 'NonfluctuatingCoherent'

# Output Arguments

### Pd

Detection probabilities corresponding to the false-alarm probabilities. For each false-alarm probability in Pfa, Pd contains one column of detection probabilities.

### SNR

Signal-to-noise ratios in a column vector. By default, the SNR values are 101 equally spaced values between 0 and 20. To change the range of SNR values, use the optional MinSNR or MaxSNR input argument. To change the number of SNR values, use the optional NumPoints input argument.

# Examples

### Plot ROC Curves For Different PFAs

Plot ROC curves for false-alarm probabilities of 1e-8, 1e-6, and 1e-3, assuming no pulse integration.

```
Pfa = [1e-8 1e-6 1e-3];
rocpfa(Pfa,'SignalType','NonfluctuatingCoherent')
```

# rocsnr

Receiver operating characteristic curves by SNR

## Syntax

```
[Pd,Pfa] = rocsnr(SNRdB)
[Pd,Pfa] = rocsnr(SNRdB,Name,Value)
rocsnr(...)
```

## Description

`[Pd,Pfa] = rocsnr(SNRdB)` returns the single-pulse detection probabilities, `Pd`, and false-alarm probabilities, `Pfa`, for the SNRs in the vector `SNRdB`. By default, for each SNR, the detection probabilities are computed for 101 false-alarm probabilities between 1e–10 and 1. The false-alarm probabilities are logarithmically equally spaced. The ROC curve is constructed assuming a coherent receiver with a nonfluctuating target.

`[Pd,Pfa] = rocsnr(SNRdB,Name,Value)` returns detection probabilities and false-alarm probabilities with additional options specified by one or more `Name,Value` pair arguments.

`rocsnr(...)` plots the ROC curves.

## Input Arguments

### SNRdB

Signal-to-noise ratios in decibels, in a row or column vector.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`MaxPfa`**

Maximum false-alarm probability to include in the ROC calculation.

**Default:** `1`

**`MinPfa`**

Minimum false-alarm probability to include in the ROC calculation.

**Default:** `1e-10`

**`NumPoints`**

Number of false-alarm probabilities to use when calculating the ROC curves. The actual probability values are logarithmically equally spaced between `MinPfa` and `MaxPfa`.

**Default:** `101`

**`NumPulses`**

Number of pulses to integrate when calculating the ROC curves. A value of `1` indicates no pulse integration.

**Default:** `1`

**`SignalType`**

This property specifies the type of received signal or, equivalently, the probability density functions (PDF) used to compute the ROC. Valid values are: `'Real'`, `'NonfluctuatingCoherent'`, `'NonfluctuatingNoncoherent'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, and `'Swerling4'`. Values are not case sensitive.

The `'NonfluctuatingCoherent'` signal type assumes that the noise in the received signal is a complex-valued, Gaussian random variable. This variable has independent zero-mean real and imaginary parts each with variance $\sigma^2/2$ under the null hypothesis. In the case of a single pulse in a coherent receiver with complex white Gaussian noise, the probability of detection, $P_D$, for a given false-alarm probability, $P_{FA}$ is:

$$P_D = \frac{1}{2}\mathrm{erfc}(\mathrm{erfc}^{-1}(2P_{FA}) - \sqrt{\chi})$$

where erfc and erfc$^{-1}$ are the complementary error function and that function’s inverse, and $\chi$ is the SNR not expressed in decibels.

For details about the other supported signal types, see [1].

**Default:** 'NonfluctuatingCoherent'

# Output Arguments

### Pd

Detection probabilities corresponding to the false-alarm probabilities. For each SNR in SNRdB, Pd contains one column of detection probabilities.

### Pfa

False-alarm probabilities in a column vector. By default, the false-alarm probabilities are 101 logarithmically equally spaced values between 1e–10 and 1. To change the range of probabilities, use the optional MinPfa or MaxPfa input argument. To change the number of probabilities, use the optional NumPoints input argument.

# Examples

### ROC Curves for Different SNRs

Plot ROC curves for different SNR's for a single pulse.

```
SNRdB = [3 6 9 12];
[Pd,Pfa] = rocsnr(SNRdB,'SignalType','NonfluctuatingCoherent');
semilogx(Pfa,Pd)
grid on
xlabel('P_{fa}')
ylabel('P_d')
legend('SNR 3 dB','SNR 6 dB','SNR 9 dB','SNR 12 dB',  'location','northwest')
title('Receiver Operating Characteristic (ROC) Curves')
```

**Introduced in R2011a**

# rootmusicdoa

Direction of arrival using Root MUSIC

## Syntax

```
ang = rootmusicdoa(R,nsig)
ang = rootmusicdoa( ___ ,'Name','Value')
```

## Description

`ang = rootmusicdoa(R,nsig)` estimates the directions of arrival, `ang`, of a set of plane waves received on a uniform line array (ULA). The estimation uses the root MUSIC algorithm. The input arguments are the estimated spatial covariance matrix between sensor elements, `R`, and the number of arriving signals, `nsig`. In this syntax, sensor elements are spaced one-half wavelength apart.

`ang = rootmusicdoa( ___ ,'Name','Value')` allows you to specify additional input parameters in the form of Name-Value pairs. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Three Signals Arriving at Half-Wavelength-Spaced ULA

Assume a half-wavelength spaced uniform line array with 10 elements. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white Gaussian noise.

Set the SNR for each signal to 5 dB. Find the arrival angles.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
```

```
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = rootmusicdoa(R,Nsig)
```

```
doa = 1×3

    0.0000   30.0000  -25.0000
```

These angles agree with the known input angles.

### Three Signals Arriving at 0.4-Wavelength-Spaced ULA

Assume a uniform line array 10 elements, as in the previous example. But now the element spacing is smaller than one-half wavelength. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white Gaussian noise. The SNR for each signal is 5 dB.

Set element spacing to 0.4 wavelengths using the `ElementSpacing` name-value pair. Then, find the arrival angles.

```
N = 10;
d = 0.4;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = rootmusicdoa(R,Nsig,'ElementSpacing',d)
```

```
doa = 1×3

  -25.0000   30.0000    0.0000
```

The solution agrees with the known angles.

## Input Arguments

**R — Spatial covariance matrix**
complex-valued positive-definite *N*-by-*N* matrix

Spatial covariance matrix, specified as a complex-valued, positive-definite, *N*-by-*N* matrix. In this matrix, *N* represents the number of elements in the ULA array. If `R` is not Hermitian, a Hermitian matrix is formed by averaging the matrix and its conjugate transpose, `(R+R')/2`.

Example: [ 4.3162, –0.2777 –0.2337i; –0.2777 + 0.2337i , 4.3162]

Data Types: `double`
Complex Number Support: Yes

**`nsig` — Number of arriving signals**
positive integer

Number of arriving signals, specified as a positive integer. The number of signals must be smaller than the number of elements in the ULA array.

Example: 2

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: ‘ElementSpacing’, 0.4

**`ElementSpacing` — ULA element spacing**
0.5 (default) | real-valued positive scalar

ULA element spacing, specified as a real-valued, positive scalar. Position units are measured in terms of signal wavelength.

Example: 0.4

Data Types: `double`

# Output Arguments

**ang — Directions of arrival angles**
real-valued 1-by-*M* row vector

Directions of arrival angle, returned as a real-valued, 1-by-*M* vector. The dimension *M* is the number of arriving signals specified in the argument `nsig`. Angle units are degrees and angle values lie between –90° and 90°.

# rotx

Rotation matrix for rotations around x-axis

## Syntax

```
R = rotx(ang)
```

## Description

`R = rotx(ang)` creates a 3-by-3 matrix for rotating a 3-by-1 vector or 3-by-N matrix of vectors around the x-axis by `ang` degrees. When acting on a matrix, each column of the matrix represents a different vector. For the rotation matrix `R` and vector `v`, the rotated vector is given by `R*v`.

## Examples

### Rotation Matrix for 30° Rotation

Construct the matrix for a rotation of a vector around the x-axis by 30°. Then let the matrix operate on a vector.

```
R = rotx(30)
```

```
R = 3×3

    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660
```

```
x = [2;-2;4];
y = R*x
```

```
y = 3×1
```

```
    2.0000
   -3.7321
    2.4641
```

Under a rotation around the *x*-axis, the x-component of a vector is invariant.

## Input Arguments

**ang — Rotation angle**
real-valued scalar

Rotation angle specified as a real-valued scalar. The rotation angle is positive if the rotation is in the counter-clockwise direction when viewed by an observer looking along the x-axis towards the origin. Angle units are in degrees.

Example: 30.0

Data Types: `double`

## Output Arguments

**R — Rotation matrix**
real-valued orthogonal matrix

3-by-3 rotation matrix returned as

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

for a rotation angle $\alpha$.

# More About

## Rotation Matrices

Rotation matrices are used to rotate a vector into a new direction.

In transforming vectors in three-dimensional space, rotation matrices are often encountered. Rotation matrices are used in two senses: they can be used to rotate a vector into a new position or they can be used to rotate a coordinate basis (or coordinate system) into a new one. In this case, the vector is left alone but its components in the new basis will be different from those in the original basis. In Euclidean space, there are three basic rotations: one each around the x, y and z axes. Each rotation is specified by an angle of rotation. The rotation angle is defined to be positive for a rotation that is counterclockwise when viewed by an observer looking along the rotation axis towards the origin. Any arbitrary rotation can be composed of a combination of these three *(Euler's rotation theorem)*. For example, you can rotate a vector in any direction using a sequence of three rotations: $\mathbf{v}' = A\mathbf{v} = R_z(\gamma)R_y(\beta)R_x(\alpha)\mathbf{v}$.

The rotation matrices that rotate a vector around the x, y, and z-axes are given by:

- Counterclockwise rotation around x-axis

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

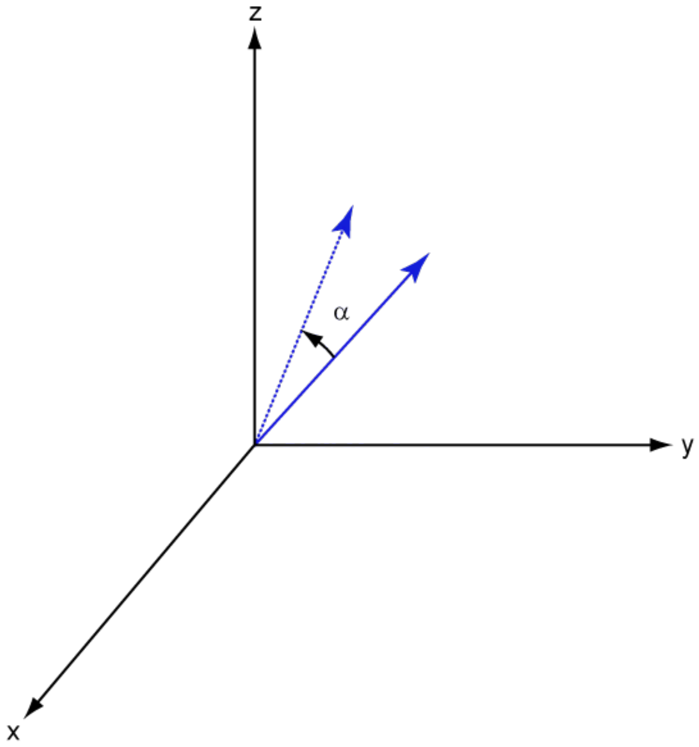
- Counterclockwise rotation around y-axis

$$R_y(\beta) = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix}$$

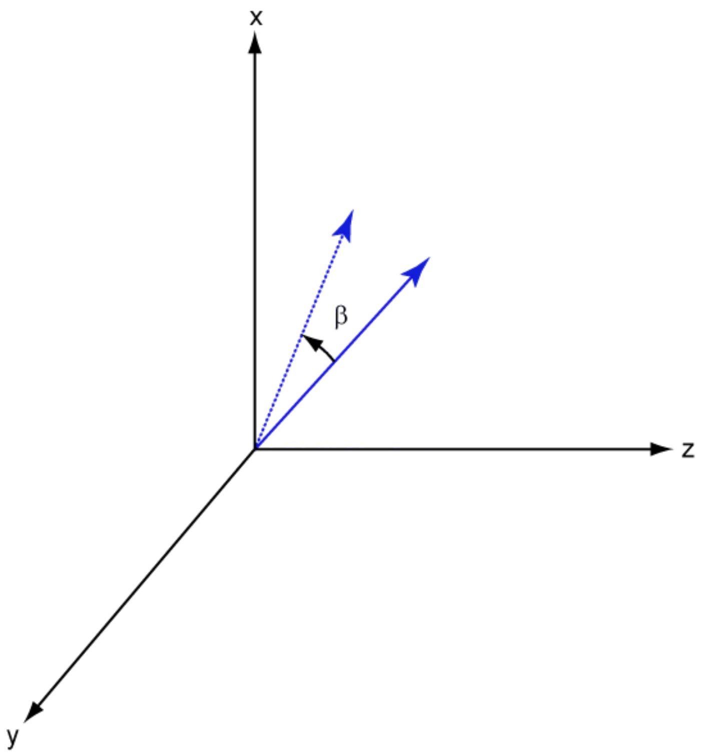
- Counterclockwise rotation around z-axis

$$R_z(\gamma) = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

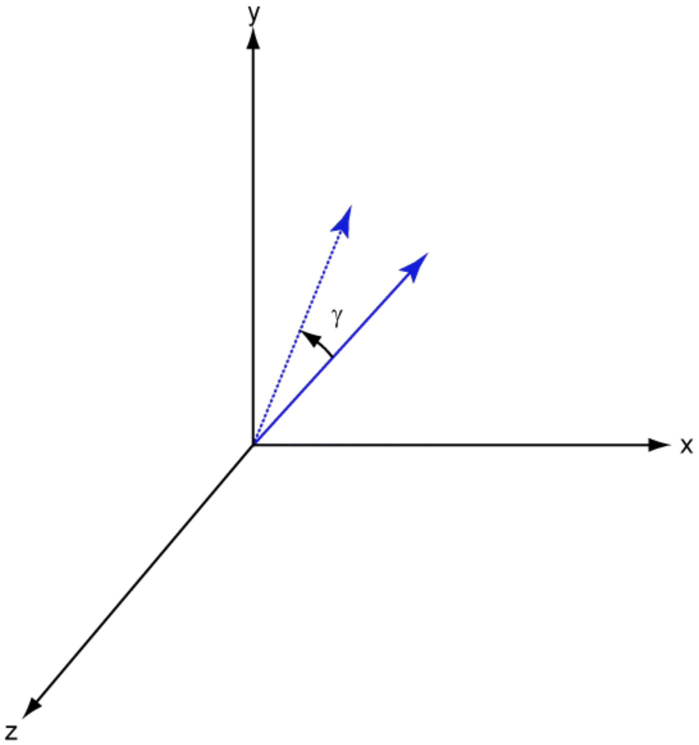
The following three figures show what positive rotations look like for each rotation axis:



z
α
y
x



x
β
z
y



For any rotation, there is an inverse rotation satisfying $A^{-1}A = 1$. For example, the inverse of the x-axis rotation matrix is obtained by changing the sign of the angle:

$$R_x^{-1}(\alpha) = R_x(-\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{bmatrix} = R_x'(\alpha)$$

This example illustrates a basic property: the inverse rotation matrix is the transpose of the original. Rotation matrices satisfy *A′A = 1*, and consequently *det(A) = 1*. Under rotations, vector lengths are preserved as well as the angles between vectors.

We can think of rotations in another way. Consider the original set of basis vectors, **i**, **j**, **k**, and rotate them all using the rotation matrix *A*. This produces a new set of basis vectors **i**′, **j**,′ **k**′ related to the original by:

$$\begin{aligned}\mathbf{i}' &= A\mathbf{i}\\ \mathbf{j}' &= A\mathbf{j}\\ \mathbf{k}' &= A\mathbf{k}\end{aligned}$$

Using the transpose, you can write the new basis vectors as a linear combinations of the old basis vectors:

$$\begin{bmatrix}\mathbf{i}'\\ \mathbf{j}'\\ \mathbf{k}'\end{bmatrix} = A'\begin{bmatrix}\mathbf{i}\\ \mathbf{j}\\ \mathbf{k}\end{bmatrix}$$

Now any vector can be written as a linear combination of either set of basis vectors:

$$\mathbf{v} = v_x\mathbf{i} + v_y\mathbf{j} + v_z\mathbf{k} = v'_x\mathbf{i}' + v'_y\mathbf{j}' + v'_z\mathbf{k}'$$

Using algebraic manipulation, you can derive the transformation of components for a fixed vector when the basis (or coordinate system) rotates. This transformation uses the transpose of the rotation matrix.

$$\begin{bmatrix}v'_x\\ v'_y\\ v'_z\end{bmatrix} = A^{-1}\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix} = A'\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix}$$

The next figure illustrates how a vector is transformed as the coordinate system rotates around the x-axis. The figure after shows how this transformation can be interpreted as a rotation *of the vector* in the opposite direction.

## Rotation Matrices

Rotation matrices are used to rotate a vector into a new direction.

In transforming vectors in three-dimensional space, rotation matrices are often encountered. Rotation matrices are used in two senses: they can be used to rotate a vector into a new position or they can be used to rotate a coordinate basis (or coordinate system) into a new one. In this case, the vector is left alone but its components in the new basis will be different from those in the original basis. In Euclidean space, there are three basic rotations: one each around the x, y and z axes. Each rotation is specified by an angle of rotation. The rotation angle is defined to be positive for a rotation that is counterclockwise when viewed by an observer looking along the rotation axis towards the origin. Any arbitrary rotation can be composed of a combination of these three *(Euler's rotation theorem)*. For example, you can rotate a vector in any direction using a sequence of three rotations: $\mathbf{v}' = A\mathbf{v} = R_z(\gamma)R_y(\beta)R_x(\alpha)\mathbf{v}$.

The rotation matrices that rotate a vector around the x, y, and z-axes are given by:

- Counterclockwise rotation around x-axis

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

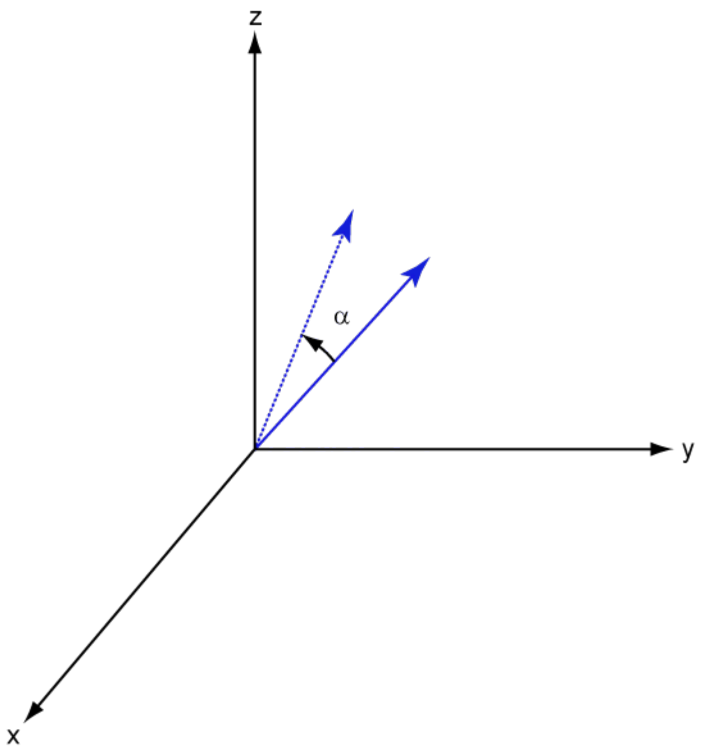
- Counterclockwise rotation around y-axis

$$R_y(\beta) = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix}$$

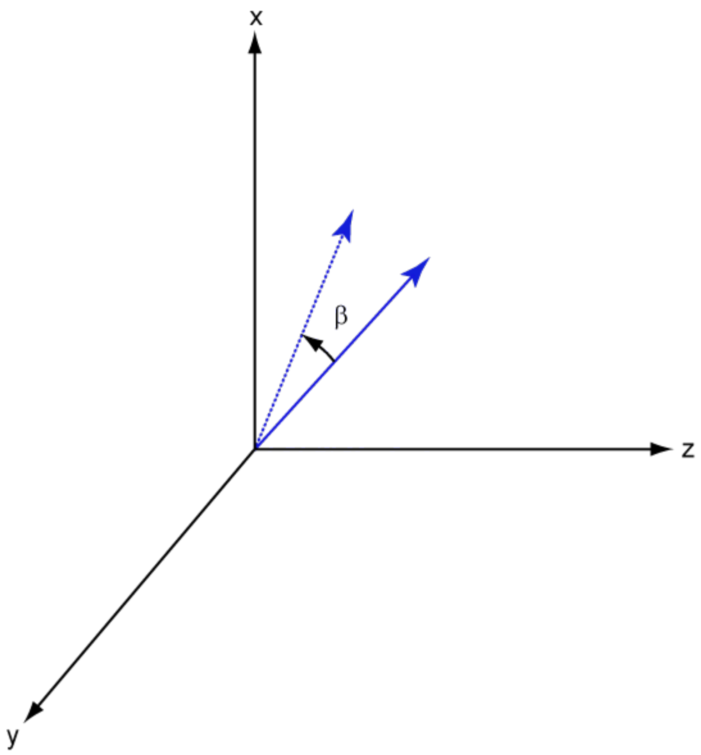
- Counterclockwise rotation around z-axis

$$R_z(\gamma) = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

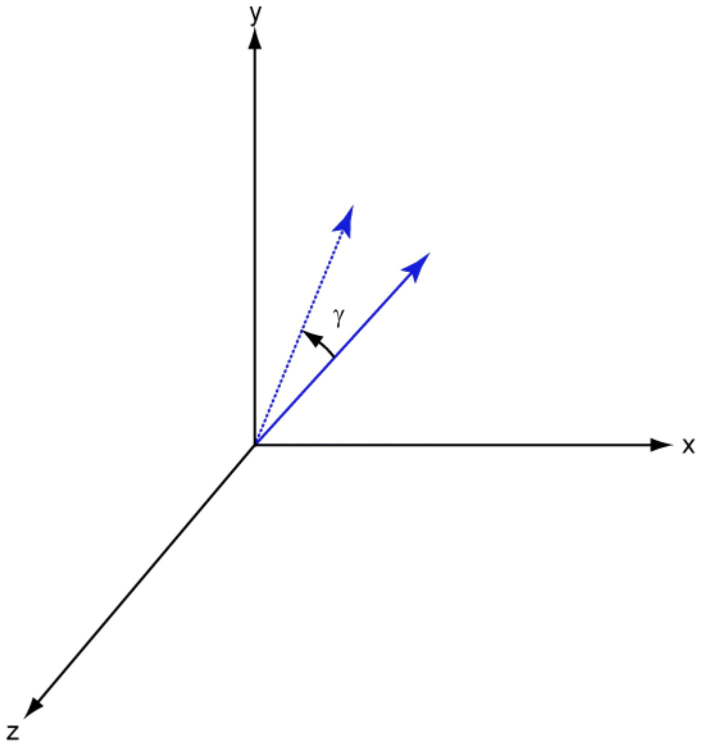
The following three figures show what positive rotations look like for each rotation axis:



z
α
y
x



x
β
z
y



For any rotation, there is an inverse rotation satisfying $A^{-1}A = 1$. For example, the inverse of the x-axis rotation matrix is obtained by changing the sign of the angle:

$$R_x^{-1}(\alpha) = R_x(-\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{bmatrix} = R_x'(\alpha)$$

This example illustrates a basic property: the inverse rotation matrix is the transpose of the original. Rotation matrices satisfy *A′A = 1*, and consequently *det(A) = 1*. Under rotations, vector lengths are preserved as well as the angles between vectors.

We can think of rotations in another way. Consider the original set of basis vectors, **i**, **j**, **k**, and rotate them all using the rotation matrix *A*. This produces a new set of basis vectors **i**′, **j**,′ **k**′ related to the original by:

$$\begin{aligned}\mathbf{i}' &= A\mathbf{i}\\ \mathbf{j}' &= A\mathbf{j}\\ \mathbf{k}' &= A\mathbf{k}\end{aligned}$$

Using the transpose, you can write the new basis vectors as a linear combinations of the old basis vectors:

$$\begin{bmatrix}\mathbf{i}'\\ \mathbf{j}'\\ \mathbf{k}'\end{bmatrix} = A'\begin{bmatrix}\mathbf{i}\\ \mathbf{j}\\ \mathbf{k}\end{bmatrix}$$

Now any vector can be written as a linear combination of either set of basis vectors:

$$\mathbf{v} = v_x\mathbf{i} + v_y\mathbf{j} + v_z\mathbf{k} = v'_x\mathbf{i}' + v'_y\mathbf{j}' + v'_z\mathbf{k}'$$

Using algebraic manipulation, you can derive the transformation of components for a fixed vector when the basis (or coordinate system) rotates. This transformation uses the transpose of the rotation matrix.

$$\begin{bmatrix}v'_x\\ v'_y\\ v'_z\end{bmatrix} = A^{-1}\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix} = A'\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix}$$

The next figure illustrates how a vector is transformed as the coordinate system rotates around the x-axis. The figure after shows how this transformation can be interpreted as a rotation *of the vector* in the opposite direction.

# More About

## Rotation Matrices

Rotation matrices are used to rotate a vector into a new direction.

In transforming vectors in three-dimensional space, rotation matrices are often encountered. Rotation matrices are used in two senses: they can be used to rotate a vector into a new position or they can be used to rotate a coordinate basis (or coordinate system) into a new one. In this case, the vector is left alone but its components in the new basis will be different from those in the original basis. In Euclidean space, there are three basic rotations: one each around the x, y and z axes. Each rotation is specified by an angle of rotation. The rotation angle is defined to be positive for a rotation that is counterclockwise when viewed by an observer looking along the rotation axis towards the origin. Any arbitrary rotation can be composed of a combination of these three *(Euler's rotation theorem)*. For example, you can rotate a vector in any direction using a sequence of three rotations: $\mathbf{v}' = A\mathbf{v} = R_z(\gamma)R_y(\beta)R_x(\alpha)\mathbf{v}$.

The rotation matrices that rotate a vector around the x, y, and z-axes are given by:

- Counterclockwise rotation around x-axis

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

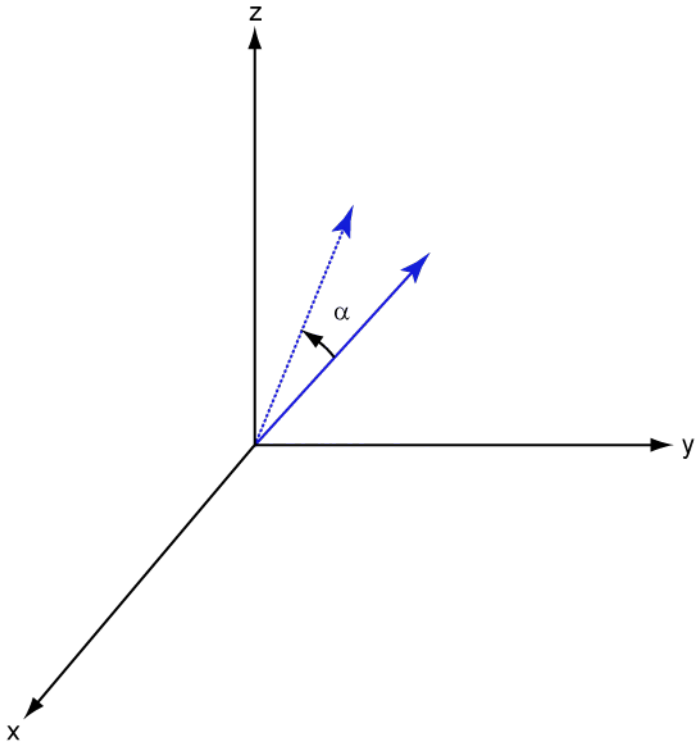
- Counterclockwise rotation around y-axis

$$R_y(\beta) = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix}$$

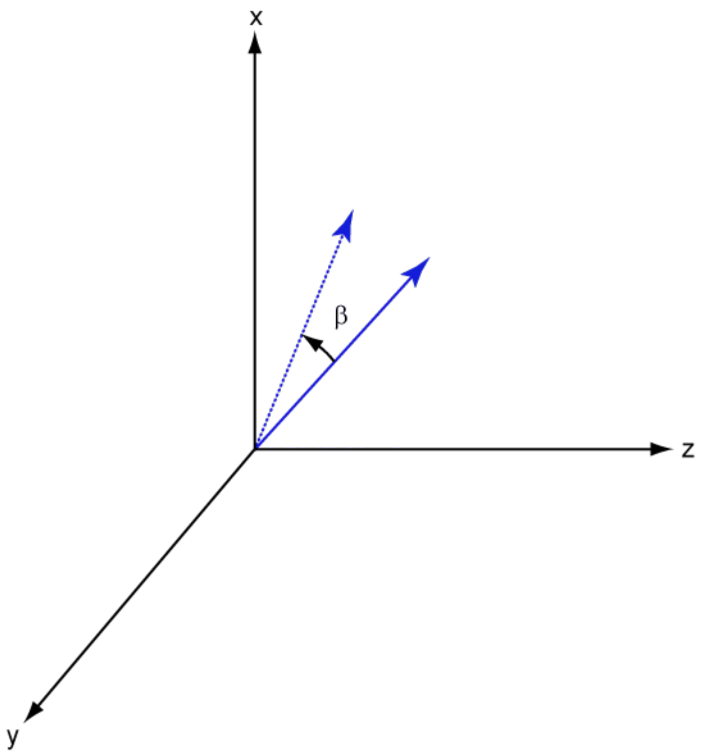
- Counterclockwise rotation around z-axis

$$R_z(\gamma) = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

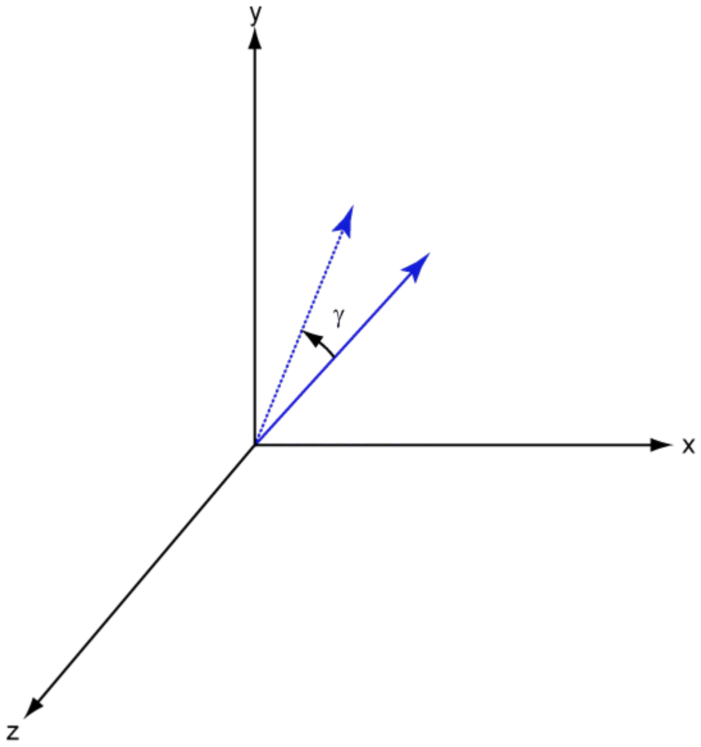
The following three figures show what positive rotations look like for each rotation axis:



z
α
y
x



x
β
z
y



For any rotation, there is an inverse rotation satisfying $A^{-1}A = 1$. For example, the inverse of the x-axis rotation matrix is obtained by changing the sign of the angle:

$$R_x^{-1}(\alpha) = R_x(-\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{bmatrix} = R_x'(\alpha)$$

This example illustrates a basic property: the inverse rotation matrix is the transpose of the original. Rotation matrices satisfy *A'A = 1*, and consequently *det(A) = 1*. Under rotations, vector lengths are preserved as well as the angles between vectors.

We can think of rotations in another way. Consider the original set of basis vectors, **i**, **j**, **k**, and rotate them all using the rotation matrix *A*. This produces a new set of basis vectors **i**′, **j**,′ **k**′ related to the original by:

$$\mathbf{i}' = A\mathbf{i}$$
$$\mathbf{j}' = A\mathbf{j}$$
$$\mathbf{k}' = A\mathbf{k}$$

Using the transpose, you can write the new basis vectors as a linear combinations of the old basis vectors:

$$\begin{bmatrix}\mathbf{i}'\\ \mathbf{j}'\\ \mathbf{k}'\end{bmatrix} = A'\begin{bmatrix}\mathbf{i}\\ \mathbf{j}\\ \mathbf{k}\end{bmatrix}$$

Now any vector can be written as a linear combination of either set of basis vectors:

$$\mathbf{v} = v_x\mathbf{i} + v_y\mathbf{j} + v_z\mathbf{k} = v'_x\mathbf{i}' + v'_y\mathbf{j}' + v'_z\mathbf{k}'$$

Using algebraic manipulation, you can derive the transformation of components for a fixed vector when the basis (or coordinate system) rotates. This transformation uses the transpose of the rotation matrix.

$$\begin{bmatrix}v'_x\\ v'_y\\ v'_z\end{bmatrix} = A^{-1}\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix} = A'\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix}$$

The next figure illustrates how a vector is transformed as the coordinate system rotates around the x-axis. The figure after shows how this transformation can be interpreted as a rotation *of the vector* in the opposite direction.

# sensorcov

Sensor spatial covariance matrix

## Syntax

```
xcov = sensorcov(pos,ang)
xcov = sensorcov(pos,ang,ncov)
xcov = sensorcov(pos,ang,ncov,scov)
```

## Description

`xcov = sensorcov(pos,ang)` returns the sensor spatial covariance matrix, `xcov`, for narrowband plane wave signals arriving at a sensor array. The sensor array is defined by the sensor positions specified in the `pos` argument. The signal arrival directions are specified by azimuth and elevation angles in the `ang` argument. In this syntax, the noise power is assumed to be zero at all sensors, and the signal power is assumed to be unity for all signals.

`xcov = sensorcov(pos,ang,ncov)` specifies, in addition, the spatial noise covariance matrix, `ncov`. This value represents the noise power on each sensor as well as the correlation of the noise between sensors. In this syntax, the signal power is assumed to be unity for all signals. This syntax can use any of the input arguments in the previous syntax.

`xcov = sensorcov(pos,ang,ncov,scov)` specifies, in addition, the signal covariance matrix, `scov`, which represents the power in each signal and the correlation between signals. This syntax can use any of the input arguments in the previous syntaxes.

## Examples

### Covariance Matrix for Two Signals without Noise

Create a covariance matrix for a 3-element, half-wavelength-spaced uniform line array. Use the default syntax, which assumes no noise power and unit signal power.

```
N = 3;
d = 0.5;
elementPos = (0:N-1)*d;
xcov = sensorcov(elementPos,[30 60])
```

```
xcov = 3×3 complex

   2.0000 + 0.0000i  -0.9127 - 1.4086i  -0.3339 + 0.7458i
  -0.9127 + 1.4086i   2.0000 + 0.0000i  -0.9127 - 1.4086i
  -0.3339 - 0.7458i  -0.9127 + 1.4086i   2.0000 + 0.0000i
```

The diagonal terms of the matrix represent the sum of the two signal powers.

### Covariance Matrix for Two Independent Signals with 10 dB SNR

Create a spatial covariance matrix for a 3-element, half-wavelength-spaced uniform line array. Assume there are two incoming signals with unit power and there is additive noise with –10 dB power.

```
N = 3;
d = 0.5;
elementPos = (0:N-1)*d;
xcov = sensorcov(elementPos,[30 35],db2pow(-10))
```

```
xcov = 3×3 complex

   2.1000 + 0.0000i  -0.2291 - 1.9734i  -1.8950 + 0.4460i
  -0.2291 + 1.9734i   2.1000 + 0.0000i  -0.2291 - 1.9734i
  -1.8950 - 0.4460i  -0.2291 + 1.9734i   2.1000 + 0.0000i
```

The diagonal terms represent the two signal powers plus noise power at each sensor.

### Covariance Matrix for Two Correlated Signals with 10 dB SNR

Compute the covariance matrix for a 3-element half-wavelength spaced line array when there is some correlation between two signals. The correlation can model, for example, multipath propagation caused by reflection from a surface. Assume an additive noise power value of –10 dB.

```
N = 3;
d = 0.5;
elementPos = (0:N-1)*d;
scov = [1, 0.8; 0.8, 1];
xcov = sensorcov(elementPos,[30 35],db2pow(-10),scov)
```

```
xcov = 3×3 complex

   3.7000 + 0.0000i  -0.4124 - 3.5521i  -3.4111 + 0.8028i
  -0.4124 + 3.5521i   3.6574 + 0.0000i  -0.4026 - 3.4682i
  -3.4111 - 0.8028i  -0.4026 + 3.4682i   3.5321 + 0.0000i
```

## Input Arguments

**pos — Positions of array sensor elements**
1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

**ang — Arrival directions of incoming signals**
1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Arrival directions of incoming signals specified as a 1-by-*M* vector or a 2-by-*M* matrix, where *M* is the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the incoming signal `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the arrival direction vector onto the *xy* plane. It is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the arrival direction vector and *xy*-plane. It is positive when measured towards the *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: [45;0]

Data Types: `double`

### `ncov` — Noise spatial covariance matrix

0 (default) | non-negative real-valued scalar | *1*-by-*N* non-negative real-valued vector | *N*-by-*N* positive definite, complex-valued matrix

Noise spatial covariance matrix specified as a non-negative, real-valued scalar, a non-negative, 1-by-*N* real-valued vector or an *N*-by-*N*, positive definite, complex-valued matrix. In this argument, *N* is the number of sensor elements. Using a non-negative scalar results in a noise spatial covariance matrix that has identical white noise power values (in watts) along its diagonal and has off-diagonal values of zero. Using a non-negative real-valued vector results in a noise spatial covariance that has diagonal values corresponding to the entries in `ncov` and has off-diagonal entries of zero. The diagonal entries represent the independent white noise power values (in watts) in each sensor. If `ncov` is *N*-by-*N* matrix, this value represents the full noise spatial covariance matrix between all sensor elements.

Example: [1,1,4,6]

Data Types: `double`
Complex Number Support: Yes

### `scov` — Signal covariance matrix

1 (default) | non-negative real-valued scalar | *1*-by-*M* non-negative real-valued vector | *N*-by-*M* positive semidefinite, complex-valued matrix

Signal covariance matrix specified as a non-negative, real-valued scalar, a *1*-by-*M* non-negative, real-valued vector or an *M*-by-*M* positive semidefinite, matrix representing the covariance matrix between *M* signals. The number of signals is specified in `ang`. If `scov` is a nonnegative scalar, it assigns the same power (in watts) to all incoming signals which are assumed to be uncorrelated. If `scov` is a 1-by-*M* vector, it assigns the separate power values (in watts) to each incoming signal which are also assumed to be uncorrelated. If `scov` is an *M*-by-*M* matrix, then it represents the full covariance matrix between all incoming signals.

Example: [1 0 ; 0 2]

Data Types: `double`
Complex Number Support: Yes

# Output Arguments

**`xcov` — Sensor spatial covariance matrix**
complex-valued *N*-by-*N* matrix

Sensor spatial covariance matrix returned as a complex-valued, *N*-by-*N* matrix. In this matrix, *N* represents the number of sensor elements of the array.

# sensorsig

Simulate received signal at sensor array

## Syntax

```
x = sensorsig(pos,ns,ang)
x = sensorsig(pos,ns,ang,ncov)
x = sensorsig(pos,ns,ang,ncov,scov)
x = sensorsig(pos,ns,ang,ncov,scov,'Taper',taper)
[x,rt] = sensorsig( ___ )
[x,rt,r] = sensorsig( ___ )
```

## Description

`x = sensorsig(pos,ns,ang)` simulates the received narrowband plane wave signals at a sensor array. `pos` represents the positions of the array elements, each of which is assumed to be isotropic. `ns` indicates the number of snapshots of the simulated signal. `ang` represents the incoming directions of each plane wave signal. The plane wave signals are assumed to be constant-modulus signals with random phases.

`x = sensorsig(pos,ns,ang,ncov)` describes the noise across all sensor elements. `ncov` specifies the noise power or covariance matrix. The noise is a Gaussian distributed signal.

`x = sensorsig(pos,ns,ang,ncov,scov)` specifies the power or covariance matrix for the incoming signals.

`x = sensorsig(pos,ns,ang,ncov,scov,'Taper',taper)` specifies the array taper as a comma-separated pair consisting of `'Taper'` and a scalar or column vector.

`[x,rt] = sensorsig( ___ )` also returns the theoretical covariance matrix of the received signal, using any of the input arguments in the previous syntaxes.

`[x,rt,r] = sensorsig( ___ )` also returns the sample covariance matrix of the received signal.

## Examples

### Received Signal and Direction-of-Arrival Estimation

Simulate the received signal at an array, and use the data to estimate the arrival directions.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create an 8-element uniform linear array whose elements are spaced half a wavelength apart.

```
fc = 3e8;
c = 3e8;
lambda = c/fc;
array = phased.ULA(8,lambda/2);
```

Simulate 100 snapshots of the received signal at the array. Assume there are two signals, coming from azimuth 30° and 60°, respectively. The noise is white across all array elements, and the SNR is 10 dB.

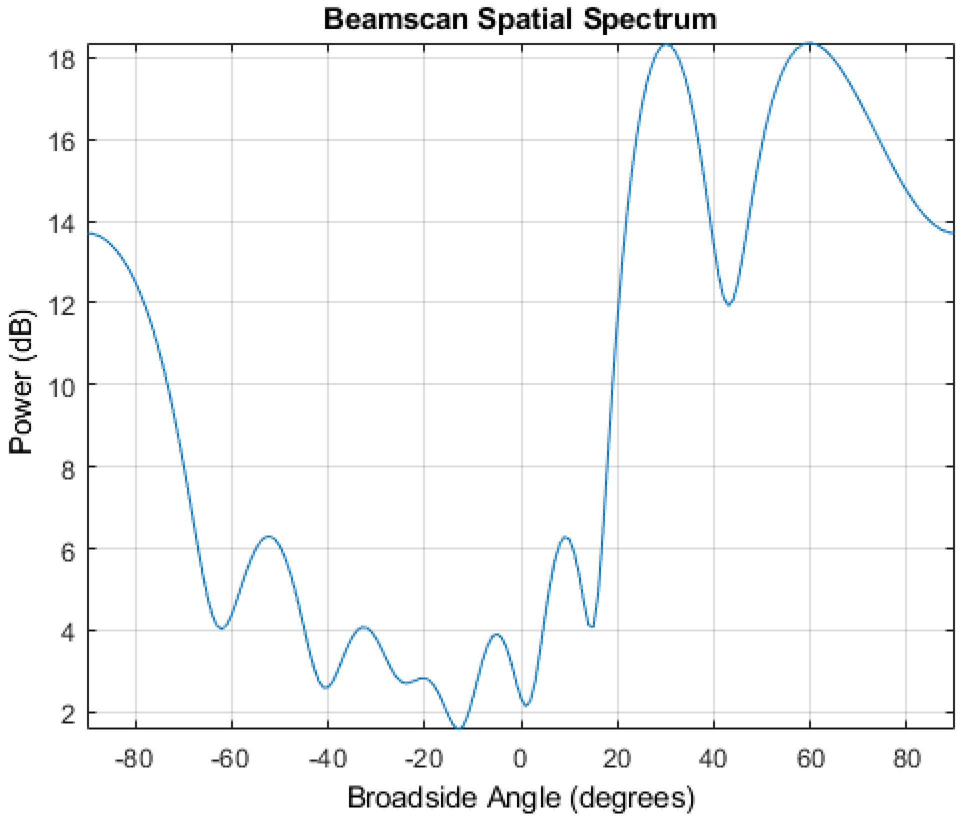
```
x = sensorsig(getElementPosition(array)/lambda,...
   100,[30 60],db2pow(-10));
```

Use a beamscan spatial spectrum estimator to estimate the arrival directions, based on the simulated data.

```
estimator = phased.BeamscanEstimator('SensorArray',array,...
   'PropagationSpeed',c,'OperatingFrequency',fc,...
   'DOAOutputPort',true,'NumSignals',2);
[~,ang_est] = estimator(x);
```

Plot the spatial spectrum resulting from the estimation process.

```
plotSpectrum(estimator)
```



The plot shows peaks at 30° and 60°.

### Signals With Different Power Levels

Simulate receiving two uncorrelated incoming signals that have different power levels. A vector named `scov` stores the power levels.

Create an 8-element uniform linear array whose elements are spaced half a wavelength apart.

```
fc = 3e8;
c = 3e8;
```

```
lambda = c/fc;
ha = phased.ULA(8,lambda/2);
```

Simulate 100 snapshots of the received signal at the array. Assume that one incoming signal originates from 30 degrees azimuth and has a power of 3 W. A second incoming signal originates from 60 degrees azimuth and has a power of 1 W. The two signals are not correlated with each other. The noise is white across all array elements, and the SNR is 10 dB.

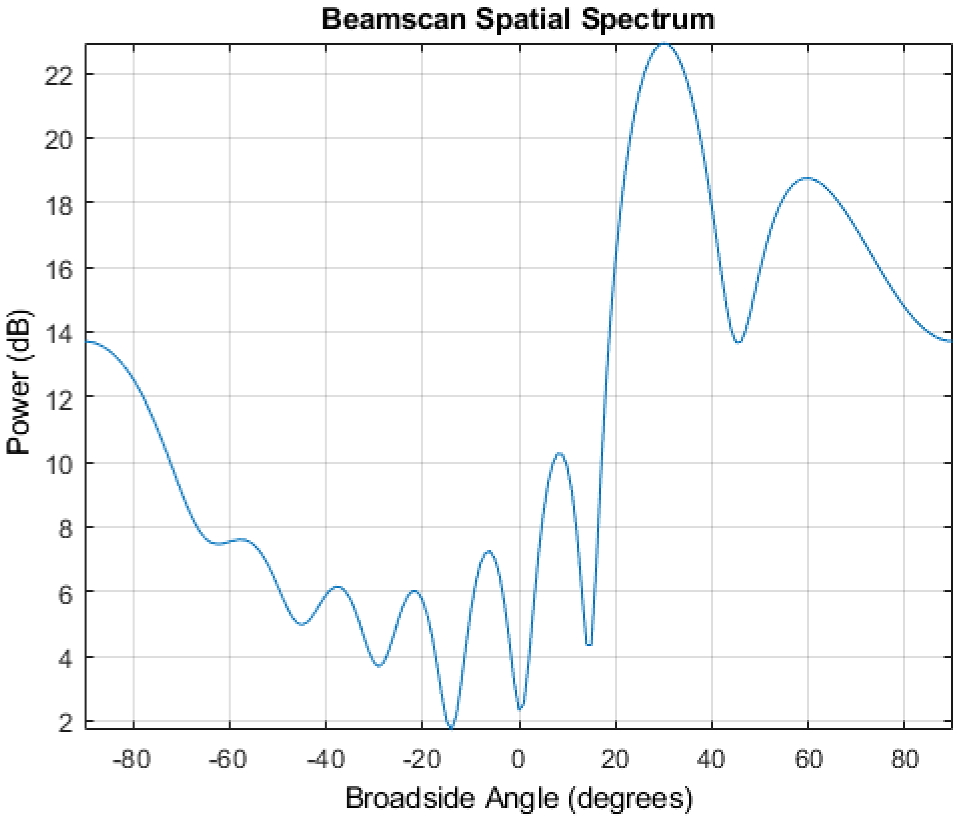
```
ang = [30 60];
scov = [3 1];
x = sensorsig(getElementPosition(ha)/lambda,...
   100,ang,db2pow(-10),scov);
```

Use a beamscan spatial spectrum estimator to estimate the arrival directions, based on the simulated data.

```
hdoa = phased.BeamscanEstimator('SensorArray',ha,...
   'PropagationSpeed',c,'OperatingFrequency',fc,...
   'DOAOutputPort',true,'NumSignals',2);
[~,ang_est] = step(hdoa,x);
```

Plot the spatial spectrum resulting from the estimation process.

```
plotSpectrum(hdoa);
```



The plot shows a high peak at 30 degrees and a lower peak at 60 degrees.

### Reception of Correlated Signals

Simulate the reception of three signals, two of which are correlated.

Create a signal covariance matrix in which the first and third of three signals are correlated with each other.

```
scov = [1 0 0.6;...
        0 2 0;...
        0.6 0 1];
```

Simulate receiving 100 snapshots of three incoming signals from 30°, 40°, and 60° azimuth, respectively. The array that receives the signals is an 8-element uniform linear array whose elements are spaced one-half wavelength apart. The noise is white across all array elements, and the SNR is 10 dB.

```
pos = (0:7)*0.5;
ns = 100;
ang = [30 40 60];
ncov = db2pow(-10);
x = sensorsig(pos,ns,ang,ncov,scov);
```

### Theoretical and Empirical Covariance of Received Signal

Simulate receiving a signal at a URA. Compare the signal theoretical covariance with its sample covariance.

Create a 2-by-2 uniform rectangular array having elements spaced 1/4-wavelength apart.

```
pos = 0.25 * [0 0 0 0; -1 1 -1 1; -1 -1 1 1];
```

Define the noise power independently for each of the four array elements. Each entry in `ncov` is the noise power of an array element. This element position is the corresponding column in `pos`. Assume the noise is uncorrelated across elements.

```
ncov = db2pow([-9 -10 -10 -11]);
```

Simulate 100 snapshots of the received signal at the array, and store the theoretical and empirical covariance matrices. Assume that one incoming signal originates from 30° azimuth and 10° elevation. A second incoming signal originates from 50° azimuth and 0° elevation. The signals have a power of 1 W and are uncorrelated.

```
ns = 100;
ang1 = [30; 10];
ang2 = [50; 0];
ang = [ang1, ang2];
rng default
[x,rt,r] = sensorsig(pos,ns,ang,ncov);
```

View the magnitudes of the theoretical covariance and sample covariance.

```
abs(rt)
```

```
ans = 4×4

    2.1259    1.8181    1.9261    1.9754
    1.8181    2.1000    1.5263    1.9261
    1.9261    1.5263    2.1000    1.8181
    1.9754    1.9261    1.8181    2.0794
```

```
abs(r)
```

```
ans = 4×4

    2.2107    1.7961    2.0205    1.9813
    1.7961    1.9858    1.5163    1.8384
    2.0205    1.5163    2.1762    1.8072
    1.9813    1.8384    1.8072    2.0000
```

### Correlation of Noise Between Sensors

Simulate receiving a signal at a ULA, where the noise between different sensors is correlated.

Create a 4-element uniform linear array whose elements are spaced one-half wavelength apart.

```
pos = 0.5 * (0:3);
```

Define the noise covariance matrix. The value in the ( *k*,_j_) position in the `ncov` matrix is the covariance between the *k* and *j* array elements listed in array.

```
ncov = 0.1 * [1 0.1 0 0; 0.1 1 0.1 0; 0 0.1 1 0.1; 0 0 0.1 1];
```

Simulate 100 snapshots of the received signal at the array. Assume that one incoming signal originates from 60° azimuth.

```
ns = 100;
ang = 60;
[x,rt,r] = sensorsig(pos,ns,ang,ncov);
```

View the theoretical and sample covariance matrices for the received signal.

```
rt,r
```

```

## Input Arguments

**pos — Positions of elements in sensor array**
1-by-N vector | 2-by-N matrix | 3-by-N matrix

Positions of elements in sensor array, specified as an N-column vector or matrix. The values in the matrix are in units of signal wavelength. For example, `[0 1 2]` describes three elements that are spaced one signal wavelength apart. N is the number of elements in the array.

Dimensions of `pos`:

- For a linear array along the y axis, specify the y coordinates of the elements in a 1-by-N vector.
- For a planar array in the yz plane, specify the y and z coordinates of the elements in columns of a 2-by-N matrix.
- For an array of arbitrary shape, specify the x, y, and z coordinates of the elements in columns of a 3-by-N matrix.

Data Types: `double`

**ns — Number of snapshots of simulated signal**
positive integer scalar

Number of snapshots of simulated signal, specified as a positive integer scalar. The function returns this number of samples per array element.

Data Types: `double`

**ang — Directions of incoming plane wave signals**
1-by-M vector | 2-by-M matrix

Directions of incoming plane wave signals, specified as an M-column vector or matrix in degrees. M is the number of incoming signals.

Dimensions of `ang`:

- If `ang` is a 2-by-M matrix, each column specifies a direction. Each column is in the form `[azimuth; elevation]`. The azimuth angle on page 2-542 must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.
- If `ang` is a 1-by-M vector, each entry specifies an azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Data Types: `double`

**ncov — Noise characteristics**
0 (default) | nonnegative scalar | 1-by-N vector of positive numbers | N-by-N positive definite matrix

Noise characteristics, specified as a nonnegative scalar, 1-by-N vector of positive numbers, or N-by-N positive definite matrix.

Dimensions of `ncov`:

- If `ncov` is a scalar, it represents the noise power of the white noise across all receiving sensor elements, in watts. In particular, a value of `0` indicates that there is no noise.
- If `ncov` is a 1-by-N vector, each entry represents the noise power of one of the sensor elements, in watts. The noise is uncorrelated across sensors.
- If `ncov` is an N-by-N matrix, it represents the covariance matrix for the noise across all sensor elements.

Data Types: `double`

### `scov` — Incoming signal characteristics

1 (default) | positive scalar | 1-by-M vector of positive numbers | M-by-M positive semidefinite matrix

Incoming signal characteristics, specified as a positive scalar, 1-by-M vector of positive numbers, or M-by-M positive semidefinite matrix.

Dimensions of `scov`:

- If `scov` is a scalar, it represents the power of all incoming signals, in watts. In this case, all incoming signals are uncorrelated and share the same power level.
- If `scov` is a 1-by-M vector, each entry represents the power of one of the incoming signals, in watts. In this case, all incoming signals are uncorrelated with each other.
- If `scov` is an M-by-M matrix, it represents the covariance matrix for all incoming signals. The matrix describes the correlation among the incoming signals. In this case, `scov` can be real or complex.

Data Types: `double`

### `taper` — Array element taper

1 (default) | scalar | *N*-by-1 column vector

Array element taper, specified as a scalar or complex-valued *N*-by-1 column vector. The dimension *N* is the number of array elements. If `taper` is a scalar, all elements in the array use the same value. If `taper` is a vector, each entry specifies the taper applied to the corresponding array element.

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `x` — Received signal

complex `ns`-by-N matrix

Received signal at sensor array, returned as a complex `ns`-by-N matrix. Each column represents the received signal at the corresponding element of the array. Each row represents a snapshot.

### `rt` — Theoretical covariance matrix

complex N-by-N matrix

Theoretical covariance matrix of the received signal, returned as a complex N-by-N matrix.

**r — Sample covariance matrix**
complex N-by-N matrix

Sample covariance matrix of the received signal, returned as a complex N-by-N matrix. N is the number of array elements. The function derives this matrix from x.

**Note** If you specify this output argument, consider making ns greater than or equal to N. Otherwise, r is rank deficient.

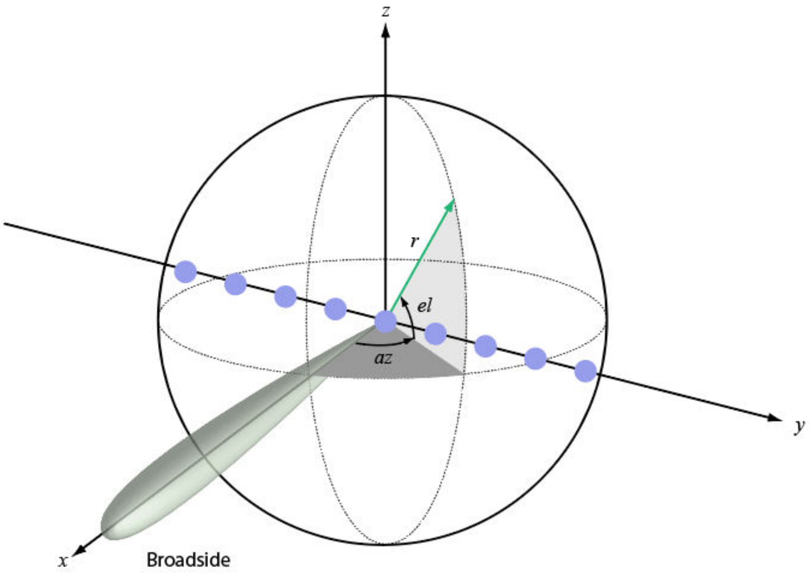
# More About

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.



# Extended Capabilities

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Does not support variable-size inputs.

# See Also

`phased.SteeringVector`

**Introduced in R2012b**

# shnidman

Required SNR using Shnidman’s equation

## Syntax

```
SNR = shnidman(Prob_Detect,Prob_FA)
SNR = shnidman(Prob_Detect,Prob_FA,N)
SNR = shnidman(Prob_Detect,Prob_FA,N, Swerling_Num)
```

## Description

`SNR = shnidman(Prob_Detect,Prob_FA)` returns the required signal-to-noise ratio in decibels for the specified detection and false-alarm probabilities using Shnidman's equation. The SNR is determined for a single pulse and a Swerling case number of 0, a nonfluctuating target.

`SNR = shnidman(Prob_Detect,Prob_FA,N)` returns the required SNR for a nonfluctuating target based on the noncoherent integration of *`N`* pulses.

`SNR = shnidman(Prob_Detect,Prob_FA,N, Swerling_Num)` returns the required SNR for the Swerling case number *`Swerling_Num`*.

## Examples

### Compute Single-Pulse SNR

Find and compare the required single-pulse SNR for Swerling cases I and III. The Swerling case I has no dominant scatterer while the Swerling case III has a dominant scatterer.

Specify the false-alarm and detection probabilities.

```
pfa = 1e-6:1e-5:.001;
Pd = 0.9;
```

Allocate arrays for plotting.

```
SNR_Sw1 = zeros(1,length(pfa));
SNR_Sw3 = zeros(1,length(pfa));
```

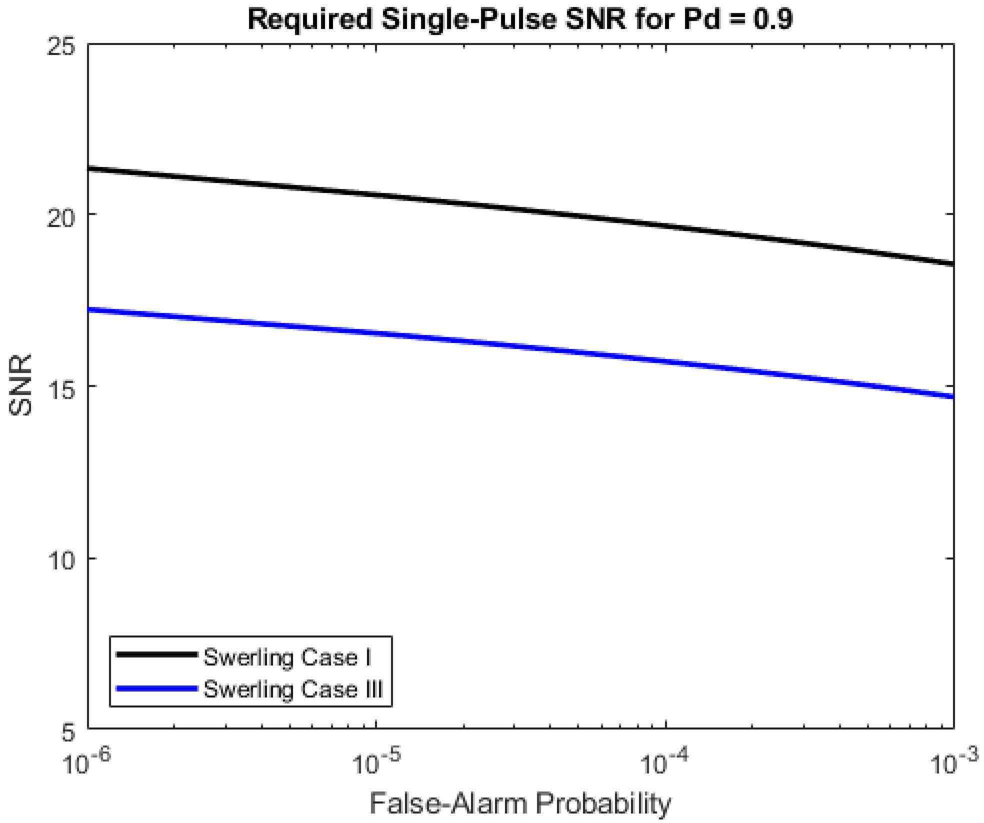
Loop over PFA's for both scatterer cases.

```
for j=1:length(pfa)

    SNR_Sw1(j) = shnidman(Pd,pfa(j),1,1);
    SNR_Sw3(j) = shnidman(Pd,pfa(j),1,3);
end
```

Plot the SNR vs PFA.

```
semilogx(pfa,SNR_Sw1,'k','linewidth',2)
hold on
semilogx(pfa,SNR_Sw3,'b','linewidth',2)
axis([1e-6 1e-3 5 25])
xlabel('False-Alarm Probability')
ylabel('SNR')
title('Required Single-Pulse SNR for Pd = 0.9')
legend('Swerling Case I','Swerling Case III',...
    'Location','SouthWest')
```



The presence of a dominant scatterer reduces the required SNR for the specified detection and false-alarm probabilities.

## More About

### Shnidman's Equation

Shnidman's equation is a series of equations that yield an estimate of the SNR required for a specified false-alarm and detection probability. Like Albersheim's equation, Shnidman's equation is applicable to a single pulse or the noncoherent integration of *N* pulses. Unlike Albersheim's equation, Shnidman's equation holds for square-law detectors and is applicable to fluctuating targets. An important parameter in Shnidman's equation is the Swerling case number.

## Swerling Case Number

The Swerling case numbers characterize the detection problem for fluctuating pulses in terms of:

- A decorrelation model for the received pulses
- The distribution of scatterers affecting the probability density function (PDF) of the target radar cross section (RCS).

The Swerling case numbers consider all combinations of two decorrelation models (scan-to-scan; pulse-to-pulse) and two RCS PDFs (based on the presence or absence of a dominant scatterer).

| Swerling Case Number | Description |
|---|---|
| 0 (alternatively designated as 5) | Nonfluctuating pulses. |
| I | Scan-to-scan decorrelation. Rayleigh/ exponential PDF–A number of randomly distributed scatterers with no dominant scatterer. |
| II | Pulse-to-pulse decorrelation. Rayleigh/ exponential PDF– A number of randomly distributed scatterers with no dominant scatterer. |
| III | Scan-to-scan decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant. |
| IV | Pulse-to-pulse decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant. |

# sonareqsl

Compute source level using the sonar equation

## Syntax

```
SL = sonareqsl(SNR,NL,DI,TL)
SL = sonareqsl(SNR,NL,DI,TL,TS)
```

## Description

`SL = sonareqsl(SNR,NL,DI,TL)` returns the source level of a signal, `SL`, required to achieve a specified received signal-to-noise ratio, `SNR`. Source level is computed using the "Sonar Equation". Specify the received noise level, `NL`, receiver directivity index, `DI`, and the transmission loss, `TL`. Use this syntax to evaluate passive sonar system performance.

`SL = sonareqsl(SNR,NL,DI,TL,TS)` returns the source level taking into account the target strength `TS`. Use this syntax to evaluate active sonar system performance, where the transmitted signal is reflected from a target. `TL` represents one-way transmission loss.

## Examples

### Estimate Source Level from Passive Sonar Equation

Estimate the source level of a signal arriving from a source with an SNR of 10 dB. The noise level is 75 dB, the receive array directivity index is 25 dB, and the transmission loss is 140 dB.

```
SNR = 10;
NL = 75.0;
DI = 25.0;
TL = 140.0;
SL = sonareqsl(SNR,NL,DI,TL)
```

```
SL = 200
```

### Estimate Source Level from Active Sonar Equation

Estimate the source level of a signal transmitted by a source with SNR of 15 dB and reflected from a target with 25 dB//1 $m^2$ target strength. The noise level is 45 dB//1 µPa, the receive array directivity index is 25 dB, and the one-way transmission loss is 60 dB.

```
SNR = 15.0;
NL = 45.0;
DI = 25.0;
TL = 60.0;
TS = 25.0;
SL = sonareqsl(SNR,NL,DI,TL,TS)
```

```
SL = 130
```

## Input Arguments

### SNR — Received signal-to-noise ratio

scalar

Received signal-to-noise ratio, specified as a scalar. Units are in dB.

Example: `10`

Data Types: `double`

### NL — Received noise level

scalar

Received noise level, specified as a scalar. Noise level is the ratio of the noise intensity to a reference intensity, converted to dB. The reference intensity is the intensity of a sound wave having a root-mean-square (rms) pressure of 1 µPa. Units are in dB//1 µPa.

Example: `70`

Data Types: `double`

### DI — Receiver directivity index

scalar

Receiver directivity index, specified as a scalar. Units are in dB.

Example: `30`

Data Types: `double`

### TL — Transmission loss

positive scalar

Transmission loss (*TL*), specified as a positive scalar. Transmission loss is the attenuation of sound intensity as the sound propagates through the underwater channel. Transmission loss is defined as the ratio of sound intensity at 1 m from a source to the sound intensity at distance *R*. For active sonar, `TL` represents one-way transmission loss.

$$TL = 10\log\frac{I_s}{I(R)}$$

Units are in dB.

Example: `120`

Data Types: `double`

### TS — Target strength

scalar

Target strength, specified as a scalar. Target strength is the ratio of the intensity of a reflected signal at 1 m from a target to the incident intensity. Target strength is the sonar analog to radar cross section. Units are in dB//1 m$^2$.

Example: `5`

Data Types: `double`

## Output Arguments

### SL — Sonar source level

scalar

Sonar source level, returned as a scalar. Source level is the ratio of the source intensity to a reference intensity, converted to dB. The reference intensity is the intensity of a sound wave having an rms pressure of 1 µPa. Units are in dB//1 µPa.

# sonareqsnr

Compute SNR using the sonar equation

## Syntax

```
SNR = sonareqsnr(SL,NL,DI,TL)
SNR = sonareqsnr(SL,NL,DI,TL,TS)
```

## Description

`SNR = sonareqsnr(SL,NL,DI,TL)` returns the received signal-to-noise ratio, `SNR`, from the source level, `SL`, received noise level, `NL`, receiver directivity index, `DI`, and transmission loss, `TL`. SNR is computed using the “Sonar Equation”. Use this syntax to evaluate passive sonar system performance.

`SNR = sonareqsnr(SL,NL,DI,TL,TS)` returns SNR taking into account the target strength `TS`. Use this syntax to evaluate active sonar system performance, where the transmitted signal is reflected from a target.

## Examples

### Estimate SNR from Passive Sonar Equation

Estimate the SNR of a signal arriving from a source with a source level of 200 dB. The noise level is 75 dB, the receive array directivity index is 25 dB, and the transmission loss is 140 dB.

```
SL = 200.0;
NL = 75.0;
DI = 25.0;
TL = 140.0;
SNR = sonareqsnr(SL,NL,DI,TL)
```

```
SNR = 10
```

### Estimate SNR from Active Sonar Equation

Estimate the SNR of a signal transmitted by a source with a source level of 130 dB//1 μPa and reflected from a target with 25 dB//1 $m^2$ target strength. The noise level is 45 dB//1 μPa, the receive array directivity is 25 dB, and the one-way transmission loss is 60 dB.

```
SL = 130.0;
NL = 45.0;
DI = 25.0;
TL = 60.0;
TS = 25.0;
SNR = sonareqsnr(SL,NL,DI,TL,TS)
```

```
SNR = 15
```

## Input Arguments

### SL — Sonar source level

scalar

Sonar source level, specified as a scalar. Source level is the ratio of the source intensity to a reference intensity, converted to dB. The reference intensity is the intensity of a sound wave having a root-mean-square (rms) pressure of 1 μPa. Units are in dB//1 μPa.

Example: `90`

Data Types: `double`

### NL — Received noise level

scalar

Received noise level, specified as a scalar. Noise level is the ratio of the noise intensity to a reference intensity, converted to dB. The reference intensity is the intensity of a sound wave having a root-mean-square (rms) pressure of 1 μPa. Units are in dB//1 μPa.

Example: `70`

Data Types: `double`

### `DI` — Receiver directivity index

scalar

Receiver directivity index, specified as a scalar. Units are in dB.

Example: `30`

Data Types: `double`

### `TL` — Transmission loss

positive scalar

Transmission loss (*TL*), specified as a positive scalar. Transmission loss is the attenuation of sound intensity as the sound propagates through the underwater channel. Transmission loss is defined as the ratio of sound intensity at 1 m from a source to the sound intensity at distance *R*. For active sonar, `TL` represents one-way transmission loss.

$$TL = 10\log\frac{I_s}{I(R)}$$

Units are in dB.

Example: `120`

Data Types: `double`

### `TS` — Target strength

scalar

Target strength, specified as a scalar. Target strength is the ratio of the intensity of a reflected signal at 1 m from a target to the incident intensity. Target strength is the sonar analog to radar cross section. Units are in dB//1 m$^2$.

Example: `5`

Data Types: `double`

## Output Arguments

### `SNR` — Received signal-to-noise ratio

real scalar

Received signal-to-noise ratio, returned as a scalar.

Data Types: `double`

# sonareqtl

Compute transmission loss using the sonar equation

## Syntax

```
TL = sonareqtl(SL,SNR,NL,DI)
TL = sonareqtl(SL,SNR,NL,DI,TS)
```

## Description

`TL = sonareqtl(SL,SNR,NL,DI)` returns the transmission loss of a signal from source to receiver that produces the signal-to-noise ratio, `SNR`. Transmission loss is computed using the "Sonar Equation". Required inputs are the source level, `SL`, received noise level, `NL`, and receiver directivity index, `DI`. Use this syntax to evaluate passive sonar system performance.

`TL = sonareqtl(SL,SNR,NL,DI,TS)` returns the one-way transmission loss. The signal is reflected from a target with a target strength, `TS`. Use this syntax to evaluate active sonar system performance, where the transmitted signal is reflected from a target.

## Examples

### Estimate Transmission Loss from Passive Sonar Equation

Estimate the transmission loss of a signal arriving from a source with source level of 200 dB. The received SNR is 10 dB, the noise level is 75 dB, and the receive array directivity index is 25 dB.

```
SNR = 10;
SL = 200.0;
NL = 75.0;
DI = 25.0;
TL = sonareqtl(SL,SNR,NL,DI)
TL = 140
```

### Estimate Transmission Loss from Active Sonar Equation

Estimate the one-way transmission loss of a signal transmitted by a source with source level of 130 dB//1 µPa and reflected from a target with 25 dB//1 $m^2$ target strength. The noise level is 45 dB//1 µPa, the receive array directivity is 25 dB.

```
SL = 130.0;
SNR = 15.0;
NL = 45.0;
DI = 25.0;
TS = 25.0;
TL = sonareqtl(SL,SNR,NL,DI,TS)
```

```
TL = 60
```

## Input Arguments

### SL — Sonar source level

scalar

Sonar source level, specified as a scalar. Source level is the ratio of the source intensity to a reference intensity, converted to dB. The reference intensity is the intensity of a sound wave having a root-mean-square (rms) pressure of 1 µPa. Units are in dB//1 µPa.

Example: `90`

Data Types: `double`

### SNR — Received signal-to-noise ratio

scalar

Received signal-to-noise ratio, specified as a scalar. Units are in dB.

Example: `10`

Data Types: `double`

### NL — Received noise level

scalar

Received noise level, specified as a scalar. Noise level is the ratio of the noise intensity to a reference intensity, converted to dB. The reference intensity is the intensity of a sound wave having a root-mean-square (rms) pressure of 1 μPa. Units are in dB//1 μPa.

Example: `70`

Data Types: `double`

### DI — Receiver directivity index

scalar

Receiver directivity index, specified as a scalar. Units are in dB.

Example: `30`

Data Types: `double`

### TS — Target strength

scalar

Target strength, specified as a scalar. Target strength is the ratio of the intensity of a reflected signal at 1 m from a target to the incident intensity. Target strength is the sonar analog to radar cross section. Units are in dB//1 $m^2$.

Example: `5`

Data Types: `double`

## Output Arguments

### TL — Transmission loss

positive scalar

Transmission loss, returned as a positive scalar. Transmission loss is the attenuation of sound intensity as the sound propagates through the underwater channel. Transmission loss is defined as the ratio of sound intensity at 1 m from a source to the sound intensity at distance *R*. When target strength, `TS`, is specified, transmission loss is two-way.

# scatteringchanmtx

Scattering channel matrix

## Syntax

```
chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat)
chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat,angrange)
chmat = scatteringchanmtx(txarraypos,rxarraypos,txang,rxang,G)
```

## Description

`chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat)` returns the channel matrix, `chmat`, for a MIMO channel consisting of a transmitting array, a receiver array, and multiple scatterers. The transmitting array is located at `txarraypos` and the receiving array at `rxarraypos`. `numscat` is the number of point scatterers.

The function generates `numscat` random transmission directions and `numscat` random receiving directions. The channel matrix describes multipath propagation through the `numscat` paths. By assumption, all paths arrive at the receiving array simultaneously implying that the channel is frequency flat. Flat frequency means that the spectrum of the signal is not changed. Path gains are derived from a zero-mean, unit-variance, complex-valued normal distribution.

`chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat,angrange)` also specifies the angular range for transmitting and receiving angles.

`chmat = scatteringchanmtx(txarraypos,rxarraypos,txang,rxang,G)` specifies transmitting angles, receiving angles, and path gains.

## Examples

### Compute Channel Matrix for Random Signal Paths

Compute the channel matrix for a 13-element transmitting array and a 15-element receiving array. Assume that there are 17 randomly located scatterers. The arrays are uniform linear arrays with 0.45-wavelength spacing. The receiving array is 300 wavelengths away from the transmitting array. Use the channel matrix to compute a propagated signal from the transmitting array to the receiving array.

Specify the arrays. Element spacing is in units of wavelength.

```
numtx = 13;
sp = 0.45;
txpos = (0:numtx-1)*sp;
numrx = 15;
rxpos = 300 + (0:numrx-1)*sp;
```

Specify the number of scatterers and create the channel matrix.

```
numscat = 17;
chmat = scatteringchanmtx(txpos,rxpos,numscat);
```

Create a signal consisting of zeros and ones. Then, propagate the signal from the transmitter to receiver.

```
x = randi(2,[100 numtx])-1;
y = x*chmat;
```

### Compute Channel Matrix for Constrained Random Signal Paths

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume that 17 scatterers are randomly located within a specified angular range. The element spacing for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Use the channel matrix to compute a propagated signal from the transmitting array to the receiving array. Constrain the angular span for the transmitting and receiving directions.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Set the angular limits for transmitting and receiving.

- The azimuth angle limits for the transmitter are −45° to +45°.
- The azimuth angle limits for the receiver are −75° to +50°.
- The elevation angle limits for the transmitter are −12° to +12°.
- The elevation angle limits for the receiver are −30° to +30°.

```
angrange = [-45 45 -75 50; -12 12 -30 30];
```

Specify the number of scatterers and create the channel matrix.

```
numscat = 6;
chmat = scatteringchanmtx(txpos,rxpos,numscat,angrange);
```

Create a 100-sample signal consisting of zeros and ones. Then, propagate the signal from the transmitting array to the receiving array.

```
x = randi(2,[100 Nt*Nt])-1;
y = x*chmat;
```

### Compute Channel Matrix for Specified Signal Paths

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume there are 3 scatterers with known directions. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Use the channel matrix to compute a propagated signal from the transmitting array to the receiving array. Specify the transmitting and receiving directions. The number of directions determines the number of scatterers.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
```

```
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Specify the transmitting and receiving angles and the gains. Then, create the channel matrix.

```
txang = [20 -10 40; 0 12 -12];
rxang = [70 -5.5 27.2; 4 1 -10];
gains = [1 1+1i 2-3*1i];
chmat = scatteringchanmtx(txpos,rxpos,txang,rxang,gains);
```

Create a 100-sample signal consisting of zeros and ones. Then, propagate the signal from the transmitting array to the receiving array.

```
x = randi(2,[100 Nt*Nt])-1;
y = x*chmat;
```

# Input Arguments

### `txarraypos` — Positions of elements in transmitting array

real-valued 1-by-$N_t$ row vector | real-valued 2-by-$N_t$matrix | real-valued 3-by-$N_t$ matrix

Transmitting array element positions, specified as a real-valued 1-by-$N_t$ row vector, 2-by-$N_t$matrix, or 3-by-$N_t$ matrix. $N_t$ is the number of elements in the transmitting array.

| `txarraypos` | Dimensions of Transmitting Array |
|---|---|
| 1-by-$N_t$ row vector | All transmitting array elements lie along the *y*-axis. The vector specifies the *y*-coordinates of the array elements. |

| `txarraypos` | Dimensions of Transmitting Array |
|---|---|
| 2-by-$N_t$ matrix | All transmitting array elements lie in the *yz*-plane. Each column of the matrix specifies the *y* and *z* coordinates of an array element. |
| 3-by-$N_t$ matrix | The transmitting array elements have arbitrary 3-D coordinates. Each column of the matrix specifies the *x*, *y*, and *z* coordinates of an array element. |

Units are in wavelengths.

Example: `[-2.0,-1.0,0.0,1.0,2.0]`

Data Types: `double`

**`rxarraypos` — Positions of elements in receiving array**

real-valued 1-by-$N_r$ row vector | real-valued 2-by-$N_r$matrix | real-valued 3-by-$N_r$ matrix

Receiving array element positions, specified as a real-valued 1-by-$N_r$ row vector, 2-by-vmatrix, or 3-by-$N_r$ matrix. $N_t$ is the number of elements in the transmitting array.

| `rxarraypos` | Dimensions of Receiving Array |
|---|---|
| 1-by-$N_r$ row vector | All receiving array elements lie along the *y*-axis. The vector specifies the *y*-coordinates of the array elements. |
| 2-by-$N_r$ matrix | All receiving array elements lie in the *yz*-plane. Each column of the matrix specifies the *y* and *z* coordinates of an array element. |
| 3-by-$N_r$ matrix | The receiving array elements have arbitrary 3-D coordinates. Each column of the matrix specifies the *x*, *y*, and *z* coordinates of an array element. |

Units are in wavelengths.

Example: `[-2.0,-1.0,0.0,1.0,2.0]`

Data Types: `double`

**`numscat` — Number of scatterers**

positive integer

Number of scatters, specified as a positive integer

Example: 7

Data Types: `double`

**angrange — Angular range of transmission and reception directions**
real-valued 1-by-2 row vector | real-valued row 1-by-4 vector | real-valued 2-by-2 matrix | real-valued 2-by-4 matrix

Angular range of transmitting and receiving directions, specified as one of the values in this table.

| Size of angrange | Angular range |
|---|---|
| real-valued 1-by-2 row vector | Specify the same azimuth angle direction span for the transmitting and receiving arrays by using the minimum and maximum azimuth angles, `[az_min az_max]`. The elevation direction span is –90° to +90°. |
| real-valued 1-by-4 row vector | Specify the azimuth angle direction range for the transmitting and receiving arrays by using `[tx_az_min tx_az_max rx_az_min rx_az_max]`. The first two values are the minimum and maximum of the transmitting array directions. The last two values are the minimum and maximum of the receiving array directions. The range of the elevation angles is –90° to +90°. |
| real-valued 2-by-2 matrix | Specify the same azimuth and elevation angle direction spans for the transmitting and receiving arrays by using the minimum and maximum azimuth and elevation angles, `[az_min az_max; el_min el_max]`. |

| Size of angrange | Angular range |
|---|---|
| real-valued 2-by-4 matrix | Specify separate azimuth and elevation angle direction spans by using `[tx_az_min tx_az_max rx_az_min rx_az_max; tx_el_min tx_el_max rx_el_min rx_el_max]`. The first and second columns form the transmitting array direction span. The last two columns form the receiving array direction span. |

Units are in degrees.

Example: `[-45 45 -30 30; -10 20 -5 30]`

Data Types: `double`

**`txang` — Transmission path angles**
real-valued 1-by-$N_s$ row vector | real-valued 2-by-$N_s$ matrix

Transmission path angles, specified as a real-valued 1-by-$N_s$ row vector or a 2-by-$N_s$ matrix. $N_s$ is the number of scatterers specified by `numscat`.

- When `txang` is a vector, each element specifies the azimuth angle of a path. The elevation angle of the path is zero degrees.
- When `txang` is a matrix, each column specifies the azimuth and elevation angles of a path in the form `[az;el]`.

Example: `[4 -2; 0 35]`

Data Types: `double`

**`rxang` — Receiving path angles**
real-valued 1-by-$N_s$ row vector | real-valued 2-by-$N_s$ matrix

Receiving path angles, specified as a real-valued 1-by-$N_s$ row vector or a 2-by-$N_s$ matrix. $N_s$ is the number of scatterers specified by `numscat`.

- When `rxang` is a vector, each element specifies the azimuth angle of a path. The elevation angle of the path is zero degrees.
- When `rxang` is a matrix, each column specifies the azimuth and elevation angles of a path in the form `[az;el]`.

Example: `[4 -2; 0 35]`

Data Types: `double`

**`G` — Path gains**
1-by-$N_s$ complex-valued row vector

Path gains, specified as a 1-by-$N_s$ complex-valued row vector. $N_s$ is the number of scatterers specified by `numscat`. The gains apply to the corresponding paths. Units are dimensionless.

Example: `exp(1i*pi/3)`

Data Types: `double`

## Output Arguments

**`chmat` — MIMO channel matrix**
$N_t$-by-$N_r$ complex-valued matrix

MIMO channel matrix, returned as an $N_t$-by-$N_r$ complex-valued matrix. $N_t$ is the number of elements in the transmitting array. $N_r$ is the number of elements in the receiving array.

Data Types: `double`

# speed2dop

Convert speed to Doppler shift

## Syntax

```
Doppler_shift = speed2dop(radvel,lambda)
```

## Description

`Doppler_shift = speed2dop(radvel,lambda)` returns the one-way Doppler shift in hertz corresponding to the radial velocity, `radvel`, for the wavelength `lambda`.

## Examples

### Calculate Doppler Shift from Speed

Calculate the Doppler shift in hertz for a given carrier wavelength and source speed. The radar frequency is 24.15 GHz. Assume a radial speed of 35.76 m/s.

```
radvel = 35.76;
f0 = 24.15e9;
lambda = physconst('LightSpeed')/f0;
doppler_shift = speed2dop(radvel,lambda)
```

```
doppler_shift = 2.8807e+03
```

## More About

### Doppler-Radial Velocity Relation

The Doppler shift of a source relative to a receiver can be computed from the relative radial velocity between the source and receiver:

$$\Delta f = \frac{V_{s,r}}{\lambda}$$

where $\Delta f$ is the Doppler shift in hertz, $V_{s,r}$ denotes the radial velocity of the source relative to the receiver, and $\lambda$ is the carrier frequency wavelength in meters.

# sph2cartvec

Convert vector from spherical basis components to Cartesian components

## Syntax

```
vr = sph2cartvec(vs,az,el)
```

## Description

`vr = sph2cartvec(vs,az,el)` converts the components of a vector or set of vectors, `vs`, from their spherical basis representation to their representation in a local Cartesian coordinate system. A spherical basis representation is the set of components of a vector projected into the right-handed spherical basis given by $(\hat{\mathbf{e}}_{az}, \hat{\mathbf{e}}_{el}, \hat{\mathbf{e}}_{R})$. The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

## Examples

### Cartesian Representation of Azimuthal Vector

Start with a vector in a spherical basis located at 45° azimuth, 45° elevation. The vector points along the azimuth direction. Compute the vector components with respect to Cartesian coordinates.

```
vs = [1;0;0];
vr = sph2cartvec(vs,45,45)
```

```
vr = 3×1

   -0.7071
    0.7071
         0
```

## Input Arguments

### vs — Vector in spherical basis representation

3-by-1 column vector | 3-by-N matrix

Vector in spherical basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of `vs` contains the three components of a vector in the right-handed spherical basis ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$).

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

### az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

### el — Elevation angle

scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

# Output Arguments

**vr — Vector in Cartesian representation**

3-by-1 column vector | 3-by-N matrix

Cartesian vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as vs. Each column of vr contains the three components of the vector in the right-handed *x*,*y*,*z* basis.

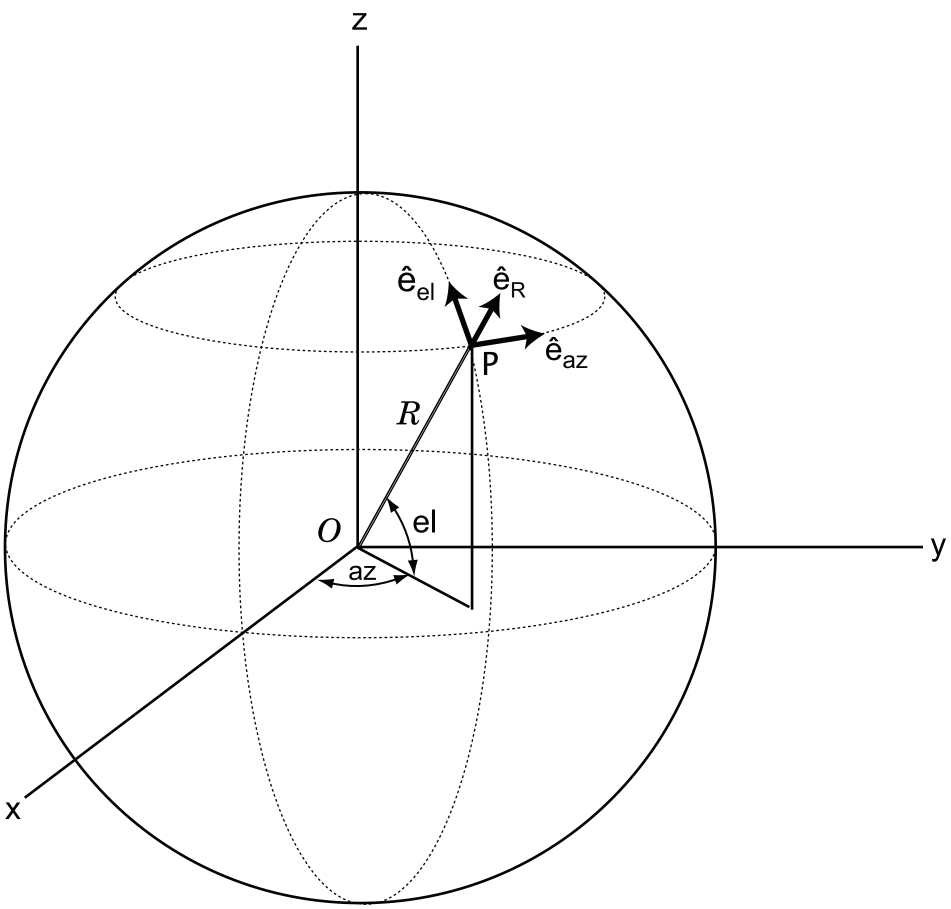
# More About

## Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ($\widehat{\mathbf{e}}_{az}$, $\widehat{\mathbf{e}}_{el}$, $\widehat{\mathbf{e}}_{R}$) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of *R* so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\widehat{\mathbf{e}}_{\mathbf{az}} = -\sin(az)\widehat{\mathbf{i}} + \cos(az)\widehat{\mathbf{j}}$$

$$\widehat{\mathbf{e}}_{\mathbf{el}} = -\sin(el)\cos(az)\widehat{\mathbf{i}} - \sin(el)\sin(az)\widehat{\mathbf{j}} + \cos(el)\widehat{\mathbf{k}}$$

$$\widehat{\mathbf{e}}_{\mathbf{R}} = \cos(el)\cos(az)\widehat{\mathbf{i}} + \cos(el)\sin(az)\widehat{\mathbf{j}} + \sin(el)\widehat{\mathbf{k}} \quad .$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\widehat{\mathbf{e}}_{\mathbf{az}} + v_{el}\widehat{\mathbf{e}}_{\mathbf{el}} + v_R\widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

# Extended Capabilities

`azelaxes` | `cart2sphvec`

**Introduced in R2013a**

# spsmooth

Spatial smoothing

## Syntax

```
RSM = spsmooth(R,L)
RSM = spsmooth(R,L,'fb')
```

## Description

`RSM = spsmooth(R,L)` computes an averaged spatial covariance matrix, `RSM`, from the full spatial covariance matrix, `R`, using spatial smoothing (see Van Trees [1], p. 605). Spatial smoothing creates a smaller averaged covariance matrix over $L$ maximum overlapped subarrays. $L$ is a positive integer less than $N$. The resulting covariance matrix, `RSM`, has dimensions ($N$–$L$+1)-by-($N$–$L$+1). Spatial smoothing is useful when two or more signals are correlated.

`RSM = spsmooth(R,L,'fb')` computes an averaged covariance matrix and at the same time performing forward-backward averaging. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Comparison of Smoothed and Nonsmoothed Covariance Matrices

Construct a 10-element half-wavelength-spaced uniform line array receiving two plane waves arriving from 0° and -25° azimuth. Both elevation angles are 0°. Assume the two signals are partially correlated. The SNR for each signal is 5 dB. The noise is spatially and temporally Gaussian white noise. First, create the spatial covariance matrix from the signal and noise. Then, solve for the number of signals, using `rootmusicdoa`. Next, perform spatial smoothing on the covariance matrix, using `spsmooth`, and solve for the signal arrival angles again using `rootmusicdoa`.

Set up the array and signals. Then, generate the spatial covariance matrix for the array from the signals and noise.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 -25];
ac = [1 1/5];
scov = ac'*ac;
R = sensorcov(elementPos,angles,db2pow(-5),scov);
```

Solve for the arrival angles using the original covariance matrix.

```
Nsig = 2;
doa =  rootmusicdoa(R,Nsig)
```

```
doa = 1×2

    0.3603   79.2382
```

The solved-for arrival angles are wrong - they do not agree with the known angles of arrival used to create the covariance matrix.

Next, solve for the arrival angles using a smoothed covariance matrix. Perform spatial smoothing to detect L-1 coherent signals. Choose L = 3.

```
Nsig = 2;
L = 2;
RSM = spsmooth(R,L);
doasm = rootmusicdoa(RSM,Nsig)
```

```
doasm = 1×2

  -25.0000    0.0000
```

In this case, computed angles do agree with the known angles of arrival.

## Input Arguments

**R — Spatial covariance matrix**
complex-valued positive-definite *N*-by-*N* matrix.

Spatial covariance matrix, specified as a complex-valued, positive-definite *N*-by-*N* matrix. In this matrix, *N* represents the number of sensor elements.

Example: [ 4.3162, –0.2777 –0.2337i; –0.2777 + 0.2337i , 4.3162]

Data Types: `double`
Complex Number Support: Yes

**L — Maximum number of overlapped subarrays**
positive integer

Maximum number of overlapped subarrays, specified as a positive integer. The value *L* must be less than the number of sensors, *N*.

Example: 2

Data Types: `double`

## Output Arguments

**`RSM` — Smoothed covariance matrix**
complex-valued *M*-by-*M* matrix

Smoothed covariance matrix, returned as a complex-valued, *M*-by-*M* matrix. The dimension *M* is given by $M = N–L+1$.

# steervec

Steering vector

## Syntax

```
sv = steervec(pos,ang)
sv = steervec(pos,ang,nqbits)
```

## Description

`sv = steervec(pos,ang)` returns the steering vector `sv` for each incoming plane wave or set of plane waves impinging on a sensor array. The steering vector represents the set of phase-delays for an incoming wave at each sensor element. The `pos` argument specifies the positions of the sensor array elements. The `ang` argument specifies the incoming wave arrival directions in terms of azimuth and elevation angles. The steering vector, `sv`, is an *N*-by-*M* complex-valued matrix. In this matrix, *N* represents the number of element positions in the sensor array while *M* represents the number of incoming waves. Each column of `sv` contains the steering vector for the corresponding direction specified in `ang`. All elements in the sensor array are assumed to be isotropic.

`sv = steervec(pos,ang,nqbits)` returns quantized narrowband steering vector when the number of phase shifter bits is set to `nqbits`.

## Examples

### Line Array Steering Vector

Specify a uniform line array of five elements spaced 10 cm apart. Then, specify an incoming plane wave with a frequency of 1 GHz and an arrival direction of 45° azimuth and 0° elevation. Compute the steering vector of this wave.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
```

```
lam = c/fc;
ang = [45;0];
sv = steervec(elementPos/lam,ang)
```

```
sv = 5×1 complex

   1.0000 + 0.0000i
   0.0887 + 0.9961i
  -0.9843 + 0.1767i
  -0.2633 - 0.9647i
   0.9376 - 0.3478i
```

### Quantized Line Array Steering Vector

Specify a uniform line array (ULA) containing five isotropic elements spaced 10 cm apart. Then, specify an incoming plane wave having a frequency of 1 GHz and an arrival direction of 45° azimuth and 0° elevation. Compute the steering vector of this wave. Quantize the steering vector to three bits.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
lam = c/fc;
ang = [45;0];
sv = steervec(elementPos/lam,ang,3)
```

```
sv = 5×1 complex

   1.0000 + 0.0000i
   0.0000 + 1.0000i
  -1.0000 + 0.0000i
  -0.0000 - 1.0000i
   1.0000 + 0.0000i
```

## Input Arguments

**pos — Positions of array sensor elements**
1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

**ang — Arrival directions of incoming signals**
1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Arrival directions of incoming signals specified as a 1-by-*M* vector or a 2-by-*M* matrix, where *M* is the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the incoming signal `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the arrival direction vector onto the *xy* plane. It is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the arrival direction vector and *xy*-plane. It is positive when measured towards the *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: [45;0]

Data Types: `double`

**`nqbits` — Number of phase shifter quantization bits**
0 (default) | non-negative integer

Number of bits used to quantize the phase shift in beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: `5`

# Output Arguments

### sv — Steering vector

*N*-by-*M* complex-valued matrix

Steering vector returned as an *N*-by-*M* complex-valued matrix. In this matrix, *N* represents the number of sensor elements of the array and *M* represents the number of incoming plane waves. Each column of `sv` corresponds to the same column in `ang`.

# stokes

Stokes parameters of polarized field

## Syntax

```
G = stokes(fv)
stokes(fv)
```

## Description

`G = stokes(fv)` returns the four Stokes parameters `G` of a polarized field or set of fields specified in `fv`. The field should be expressed in terms of linear polarization components. The expression of a field in terms of a two-row vector of linear polarization components is called the Jones vector formalism.

`stokes(fv)` displays the Stokes parameters corresponding to `fv` as points on the Poincare sphere.

## Examples

### Stokes Vector

Create a left circularly-polarized field. Convert it to a linear representation and compute the Stokes vector.

```
cfv = [2;0];
fv = circpol2pol(cfv);
G = stokes(fv)
```

```
G = 4×1

    4.0000
         0
         0
    4.0000
```

### Poincare Sphere

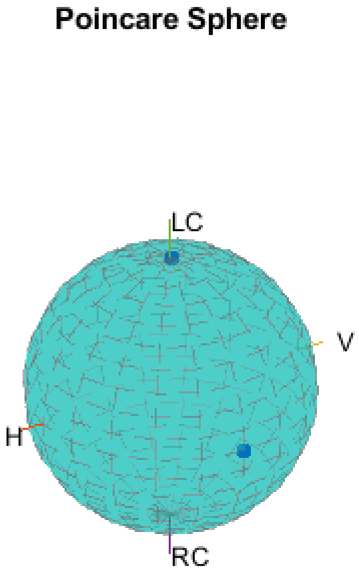
Display points on the Poincare sphere for a left circularly-polarized field and a 45° linear polarized field.

```
fv = [sqrt(2)/2, 1; sqrt(2)/2*1i, 1];
G = stokes(fv)
```

```
G = 4×2

    1.0000    2.0000
         0         0
         0    2.0000
    1.0000         0
```

```
stokes(fv);
```



The point at the north pole represents the left circularly-polarized field. The point on the equator represents the 45° linear polarized field.

## Input Arguments

**`fv` — Field vector in linear polarization representation or linear polarization ratio**

1-by-*N* complex-value row vector or 2-by-*N* complex-value matrix

Field vector in its linear polarization representation specified as a 2-by-*N* complex-valued matrix or in its linear polarization ratio representation specified as a 1-by-*N* complex-valued row vector. If `fv` is a matrix, each column of `fv` represents a field in the form

`[Eh;Ev]`, where `Eh` and `Ev` are its horizontal and vertical linear polarization components. The expression of a field in terms of a two-row vector of linear polarization components is called the Jones vector formalism. If `fv` is a vector, each entry in `fv` is contains the polarization ratio, `Ev/Eh`.

Example: [sqrt(2)/2*1i; 1]

Data Types: `double`
Complex Number Support: Yes

# Output Arguments

### G — Stokes parameters

4-by-*N* matrix of Stokes parameters.

`G` contains the four Stokes parameters for each polarized field specified in `fv`. The Stokes parameters are computed from combinations of intensities of the field:

- $G_0$ describes the total intensity of the field.
- $G_1$ describes the preponderance of horizontal linear polarization intensity over vertical linear polarization intensity.
- $G_2$ describes the preponderance of +45° linear polarization intensity over -45° linear polarization intensity.
- $G_3$ describes the preponderance of right circular polarization intensity over left circular polarization intensity.

# stretchfreq2rng

Convert frequency offset to range

## Syntax

```
R = stretchfreq2rng(FREQ,SLOPE,REFRNG)
R = stretchfreq2rng(FREQ,SLOPE,REFRNG,V)
```

## Description

`R = stretchfreq2rng(FREQ,SLOPE,REFRNG)` returns the range corresponding to the frequency offset `FREQ`. The computation assumes you obtained `FREQ` through stretch processing with a reference range of `REFRNG`. The sweeping slope of the linear FM waveform is `SLOPE`.

`R = stretchfreq2rng(FREQ,SLOPE,REFRNG,V)` specifies the propagation speed `V`.

## Input Arguments

### FREQ

Frequency offset in hertz, specified as a scalar or vector.

### SLOPE

Sweeping slope of the linear FM waveform, in hertz per second, specified as a nonzero scalar.

### REFRNG

Reference range, in meters, specified as a scalar.

### V

Propagation speed, in meters per second, specified as a positive scalar.

**Default:** Speed of light

## Output Arguments

**R**

Range in meters. R has the same dimensions as FREQ .

## Examples

### Range Corresponding to Frequency Offset

Calculate the range corresponding to a frequency offset of 2 kHz obtained from stretch processing. Assume the reference range is 5000 m and the linear FM waveform has a sweeping slope of 2 GHz/s.

```
r = stretchfreq2rng(2e3,2e9,5000)
```

```
r = 4.8501e+03
```

# surfacegamma

Gamma value for different terrains

## Syntax

```
G = surfacegamma(TerrainType)
G = surfacegamma(TerrainType,FREQ)
surfacegamma
```

## Description

`G = surfacegamma(TerrainType)` returns the $\gamma$ value for the specified terrain. The $\gamma$ value is for an operating frequency of 10 GHz.

`G = surfacegamma(TerrainType,FREQ)` specifies the operating frequency of the system.

`surfacegamma` displays several terrain types and their corresponding $\gamma$ values. These $\gamma$ values are for an operating frequency of 10 GHz.

## Input Arguments

### TerrainType

Character vectors that describe the terrain type. Valid values are:

- `'sea state 3'`
- `'sea state 5'`
- `'woods'`
- `'metropolitan'`
- `'rugged mountain'`
- `'farmland'`

- `'wooded hill'`
- `'flatland'`

**FREQ**

Operating frequency of radar system in hertz. This value can be a scalar or vector.

**Default:** `10e9`

## Output Arguments

**G**

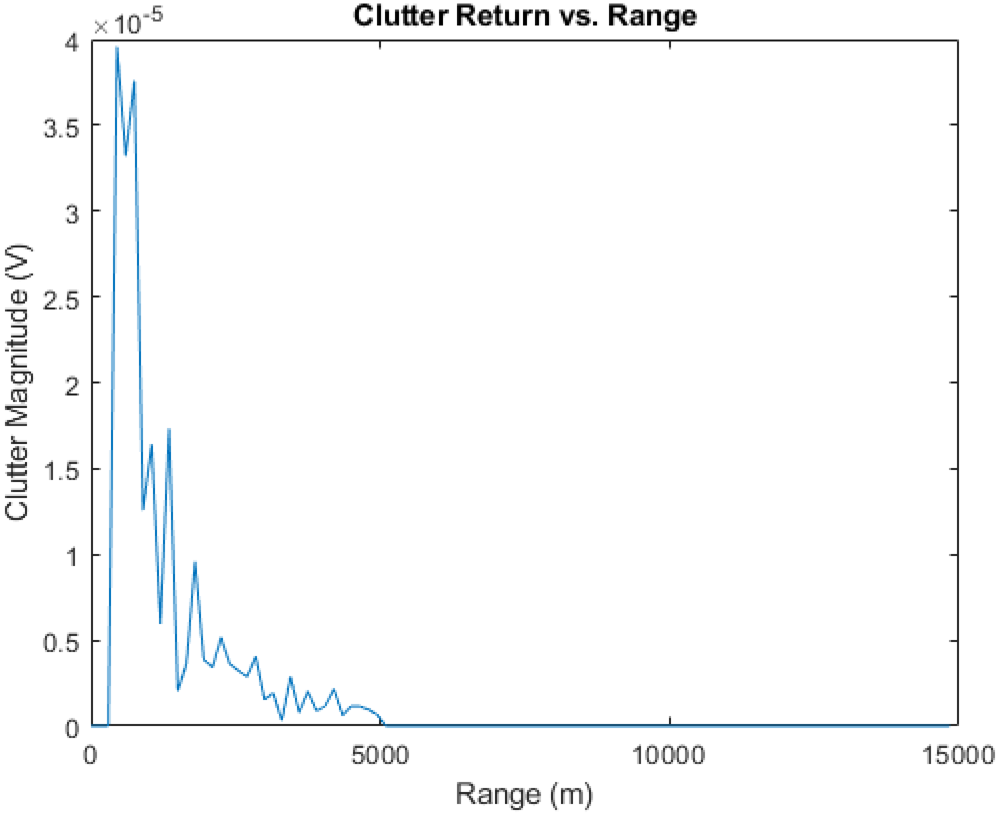
Value of $\gamma$ in decibels, for constant $\gamma$ clutter model.

## Examples

### Simulate Constant Gamma Clutter

Determine the γ value for a wooded area, and then simulate the clutter return from that area. Assume the radar system uses a single cosine pattern antenna element and has an operating frequency of 300 MHz.

```
fc = 300e6;
g = surfacegamma('woods',fc);
clutter = phased.ConstantGammaClutter('Gamma',g,...
    'Sensor',phased.CosineAntennaElement,...
    'OperatingFrequency',fc);
x = clutter();
r = (0:numel(x)-1)/(2*clutter.SampleRate) * ...
    clutter.PropagationSpeed;
plot(r,abs(x))
xlabel('Range (m)')
ylabel('Clutter Magnitude (V)')
title('Clutter Return vs. Range')
```



## More About

### Gamma

A frequently used model for clutter simulation is the constant gamma model. This model uses a parameter, $\gamma$, to describe clutter characteristics of different types of terrain. Values of $\gamma$ are derived from measurements.

## Algorithms

The $\gamma$ values for the terrain types `'sea state 3'`, `'sea state 5'`, `'woods'`, `'metropolitan'`, and `'rugged mountain'` are from [2].

The $\gamma$ values for the terrain types `'farmland'`, `'wooded hill'`, and `'flatland'` are from [3].

Measurements provide values of $\gamma$ for a system operating at 10 GHz. The $\gamma$ value for a system operating at frequency $f$ is:

$$\gamma = \gamma_0 + 5\log\left(\frac{f}{f_0}\right)$$

where $\gamma_0$ is the value at frequency $f_0$ = 10 GHz.

# surfclutterrcs

Surface clutter radar cross section (RCS)

## Syntax

```
RCS = surfclutterrcs(NRCS,R,az,el,graz,tau)
RCS = surfclutterrcs(NRCS,R,az,el,graz,tau,c)
```

## Description

`RCS = surfclutterrcs(NRCS,R,az,el,graz,tau)` returns the radar cross section (RCS) of a clutter patch that is of range `R` meters away from the radar system. `az` and `el` are the radar system azimuth and elevation beamwidths, respectively, corresponding to the clutter patch. `graz` is the grazing angle of the clutter patch relative to the radar. `tau` is the pulse width of the transmitted signal. The calculation automatically determines whether the surface clutter area is beam limited or pulse limited, based on the values of the input arguments.

`RCS = surfclutterrcs(NRCS,R,az,el,graz,tau,c)` specifies the propagation speed in meters per second.

## Input Arguments

### NRCS

Normalized radar cross section of clutter patch in units of square meters/square meters.

### R

Range of clutter patch from radar system, in meters.

### az

Azimuth beamwidth of radar system corresponding to clutter patch, in degrees.

**el**

Elevation beamwidth of radar system corresponding to clutter patch, in degrees.

**graz**

Grazing angle of clutter patch relative to radar system, in degrees.

**tau**

Pulse width of transmitted signal, in seconds.

**c**

Propagation speed, in meters per second.

**Default:** Speed of light

## Output Arguments

**RCS**

Radar cross section of clutter patch.

## Examples

### Compute Surface Clutter RCS

Calculate the RCS of a clutter patch and estimate the clutter-to-noise ratio (CNR) at the receiver. Assume that the patch has a normalized radar cross section (NRCS) of 1 $m^2/m^2$ and is 1.0 km away from the radar system. The azimuth and elevation beamwidths are 1° and 3°, respectively. The grazing angle is 10°. The pulse width is 10μs. The radar operates at a wavelength of 1 cm with a peak power of 5 kW.

```
nrcs = 1;
rng = 1.0e3;
az = 1;
el = 3;
graz = 10;
```

```
tau = 10e-6;
lambda = 0.01;
ppow = 5000;
rcs = surfclutterrcs(nrcs,rng,az,el,graz,tau)

rcs = 5.2627e+03

cnr = radareqsnr(lambda,rng,ppow,tau,'rcs',rcs)

cnr = 75.2006
```

## Tips

- You can calculate the clutter-to-noise ratio using the output of this function as the `RCS` input argument value in `radareqsnr`.

# systemp

Receiver system-noise temperature

## Syntax

```
STEMP = systemp(NF)
STEMP = systemp(NF,REFTEMP)
```

## Description

`STEMP = systemp(NF)` calculates the effective system-noise temperature, `STEMP`, in kelvin, based on the noise figure, `NF`. The reference temperature is 290 K.

`STEMP = systemp(NF,REFTEMP)` specifies the reference temperature.

## Input Arguments

### NF

Noise figure in decibels. The noise figure is the ratio of the actual output noise power in a receiver to the noise power output of an ideal receiver.

### REFTEMP

Reference temperature in kelvin, specified as a nonnegative scalar. The output of an ideal receiver has a white noise power spectral density that is approximately the Boltzmann constant times the reference temperature in kelvin.

**Default:** `290`

## Output Arguments

**`STEMP`**

Effective system-noise temperature in kelvin. The effective system-noise temperature is `REFTEMP*10^(NF/10)`.

## Examples

### Compute System Noise Temperature

Calculate the system noise temperature of a receiver with a 300 K reference temperature and a 5 dB noise figure.

```
T = systemp(5,300)
```

```
T = 948.6833
```

# taylortaperc

Taylor nbar taper for arrays

## Syntax

```
W = taylortaperc(pos,diam)
W = taylortaperc(pos,diam,nbar)
W = taylortaperc(pos,diam,nbar,sll)
W = taylortaperc(pos,diam,nbar,sll,cpos)
```

## Description

`W = taylortaperc(pos,diam)` returns the value of a Taylor n-bar taper, `W`, at sensor element positions specified by `pos` in a circular aperture having diameter `diam`.

`W = taylortaperc(pos,diam,nbar)` also specifies, `nbar`, the number of approximately constant-level sidelobes next to the mainlobe.

`W = taylortaperc(pos,diam,nbar,sll)` also specifies the maximum sidelobe level, `sll`, relative to the mainlobe peak.

`W = taylortaperc(pos,diam,nbar,sll,cpos)` also specifies the center of the array, `cpos`. Without this argument, the function sets the array center to the computed centroid of the array.

## Examples

### Default Taylor Taper Circular Array

Apply a Taylor nbar taper to a circular aperture array. Obtain the circular aperture by cropping a square uniform rectangular array into a circle. Let all the parameters remain at their default values: nbar is 4 and the sidelobe level is –30. Let the center of the array be the centroid of the array elements. Plot the array power pattern at 300 MHz.

Create a square URA with a side length of 10 m. Set the element spacing to 1/2 m. The spacing is equal to one-half wavelength at this frequency.

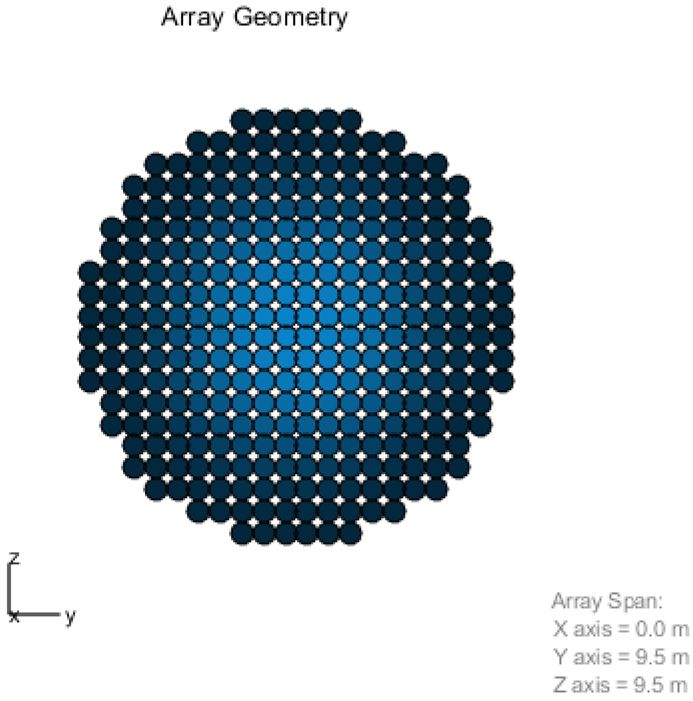
```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam);
```

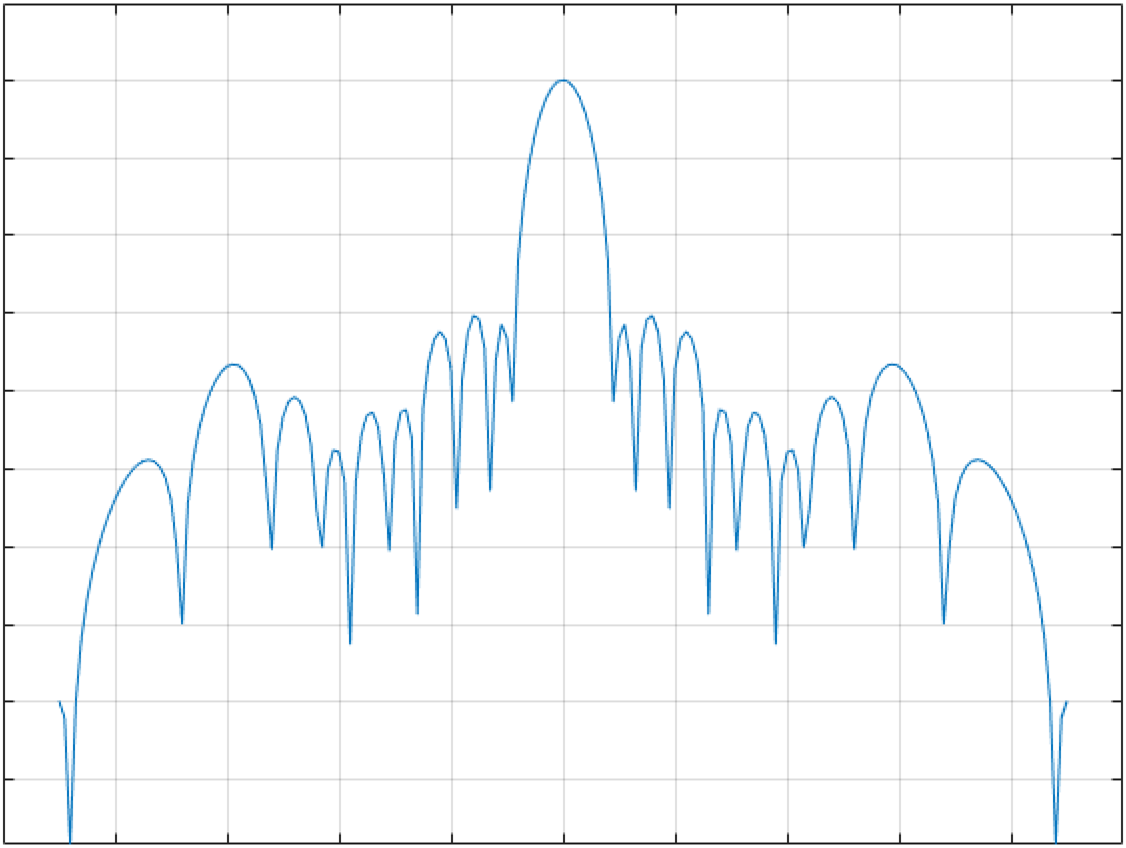
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



### Taylor Taper Circular Array Specifying Nbar

Apply a Taylor nbar taper to a circular aperture array. Create the circular aperture by cropping a square uniform rectangular array into a circle. Set the value of nbar to 2. Let the sidelobe level assume a default value of –30. Let the center of the array be the centroid of the array elements. Plot the array power pattern at 300 MHz.

Create a square URA with a side length of 10 m. Set the element spacing to 0.5 m. The spacing is equal to one-half wavelength at this frequency.

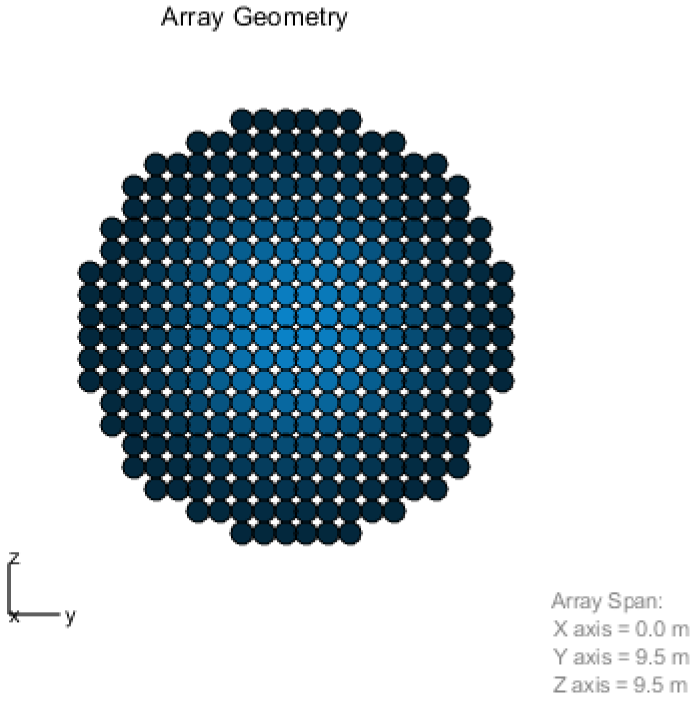
```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
nbar = 2;
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam,nbar);
```

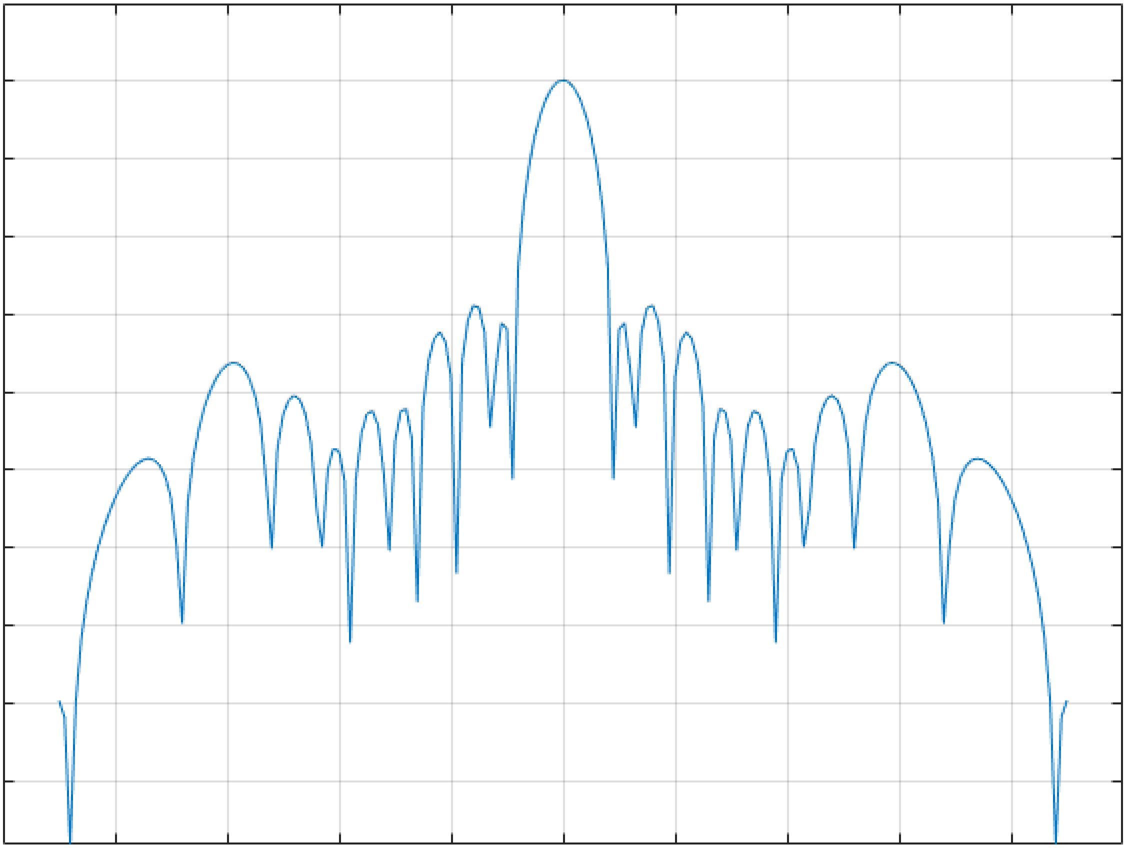
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



### Taylor Taper Circular Array Specifying Sidelobe Level

Apply a Taylor nbar taper to a circular aperture array. Create the circular aperture by cropping a square uniform rectangular array into a circle. Set the value of nbar to 4. Set the sidelobe level to –25. Let the center of the array be the centroid of the array elements. Plot the array power pattern at 300 MHz.

First, create a square URA with a side length of 10 m. Set the element spacing to 0.5 m. The spacing is equal to one-half wavelength at this frequency.

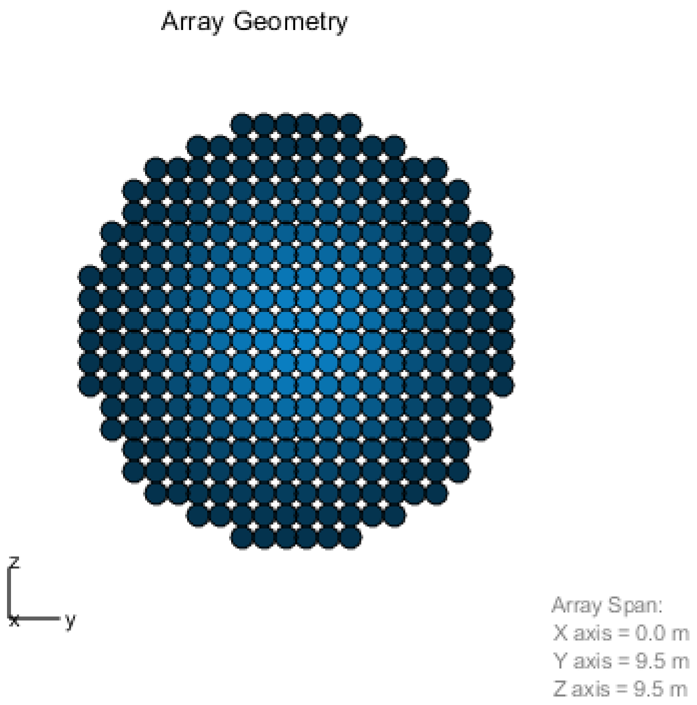
```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
nbar = 2;
sll = -25;
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam,nbar,sll);
```

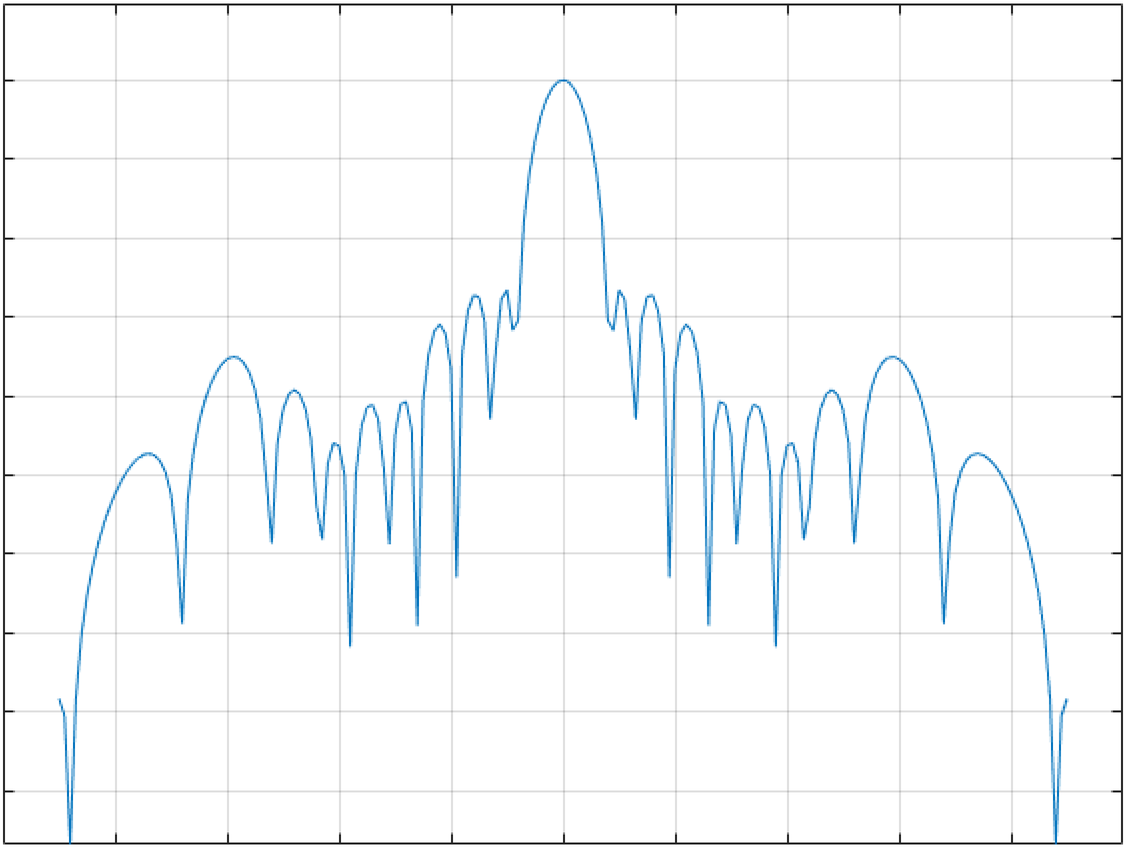
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



### Taylor Taper Circular Array Specifying Array Center

Apply a Taylor nbar taper to a circular aperture array. Create the circular aperture by cropping a square uniform rectangular array into a circle. Set the sidelobe level to –25. Set the center of the array to the origin. Plot the array power pattern at 300 MHz.

Create a square URA with a side length of 10 m. Set the element spacing to 0.5 m. The spacing is equal to one-half wavelength at this frequency.

```
fc = 300.0e6;
diam = 10.0;
```

```
d = 0.5;
sll = -25;
```

Compute nbar from the sidelobe level.

```
A = acosh(10^(-sll/20))/pi;
nbar = ceil(2*A^2 + 0.5)
```

```
nbar = 4
```

Create the URA element positions.

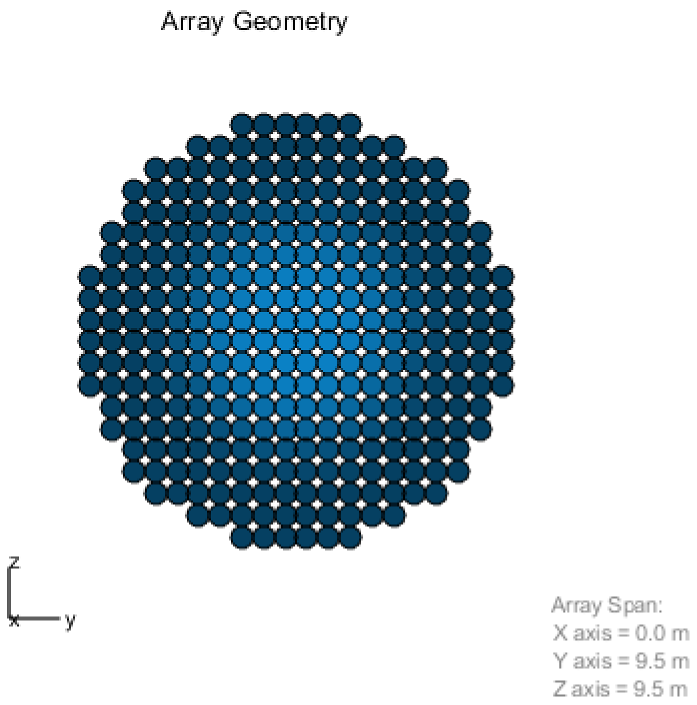
```
cpos = [0;0;0];
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam,nbar,sll,cpos);
```

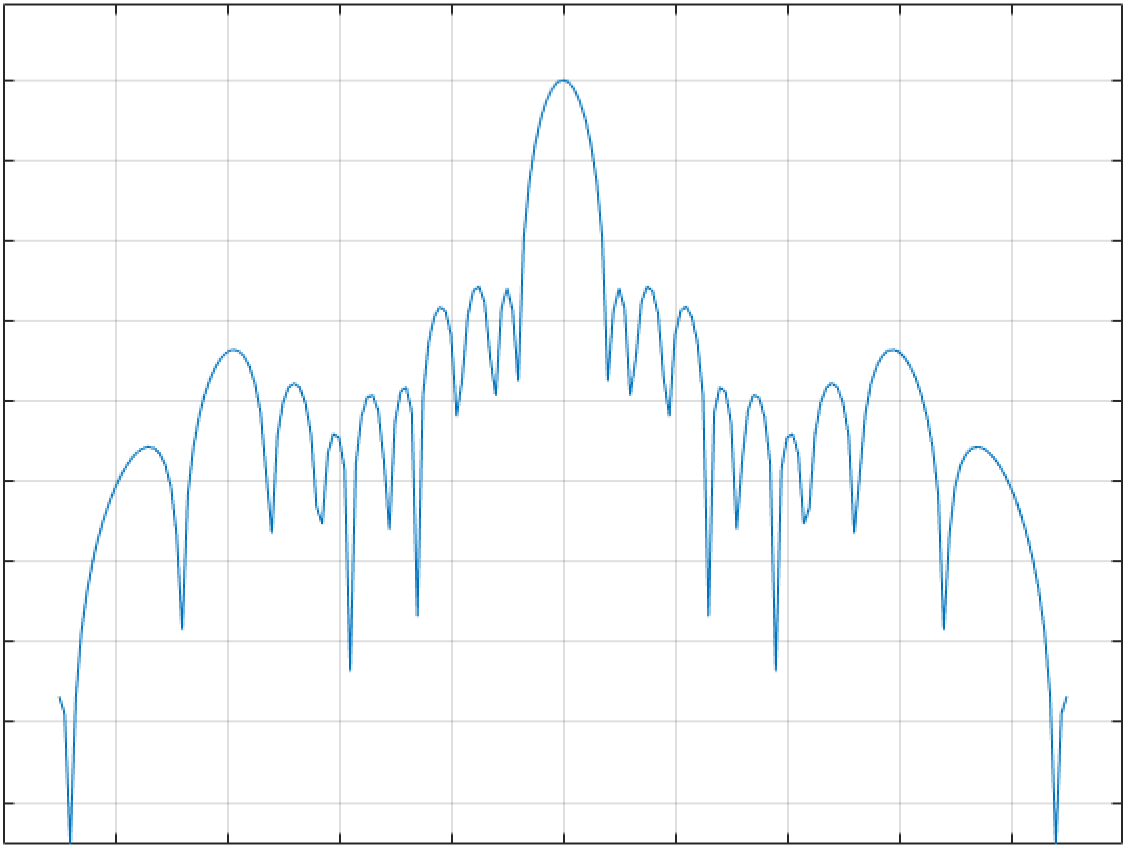
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



## Input Arguments

### pos — Position of array elements

2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Position of array elements, specified as a 2-by-*N* or 3-by-*N* real-valued matrix where *N* is the number of elements. If `pos` is a 2-by-*N* matrix, then all elements lie in the *z = 0* plane. Each column specifies the position, `[x;y]`, of the element. If `pos` is a 3-by-*N* matrix, its columns represent the positions of array elements in `[x;y;z]` format. `W` is an *N*-by-1 column vector containing the Taylor tapers. The 2-by-*N* form is designed for planar arrays although you can use the 3-by-*N* form and set the third row to zero. Position units are in meters.

Example: `[–5,–5,5,5;-5,5,5,-5]`

Data Types: `double`

### `diam` — Array diameter

positive scalar

Array diameter, specified as a positive scalar. Diameter units are in meters.

Example: `15.5`

Data Types: `double`

### `nbar` — Number of nearly equal sidelobes

4 (default) | positive integer

Number of nearly equal sidelobes on each side of the mainlobe, specified as a positive integer. Units are dimensionless.

Example: `3`

Data Types: `double`

### `sll` — Maximum sidelobe level

`-30.0` (default) | negative scalar

Maximum sidelobe, specified as a negative scalar. Sidelobe levels are referenced to the mainlobe. Units are in dB.

Example: `-10.0`

Data Types: `double`

### `cpos` — Array center

array centroid (default) | real-valued 2-by-1 vector | real-valued 3-by-1 vector

Array center, specified as a real-valued 2-by-1 or 3-by-1 vector. Units are in meters. Use a 2-by-1 vector when the element positions are specified as a 2-by-*N* matrix. The default value is the computed centroid of all the array elements.

Example: `[5;-10;3]`

Data Types: `double`

# Output Arguments

**`W` — Taylor weights**

real-valued *N*-by-1 column vector

Taylor weights, returned as a real-valued *N*-by-1 column vector. *N* is the number of array elements. Units are dimensionless.

# Algorithms

## Compute Minimum Value of N-bar

A useful guideline for choosing a value of `nbar` that meets the required sidelobe level (sll), as specified in the `sll` argument, is to satisfy the inequality

$$\bar{n} \geq \frac{2}{\pi^2}\left(\cosh^{-1}\left(10^{-\frac{sll}{20}}\right)\right)^2 + 0.5$$

This is a recommendation and you may be able to use a smaller value.

# time2range

Convert propagation time to propagation distance

## Syntax

```
r = time2range(t)
r = time2range(t,c)
```

## Description

`r = time2range(t)` returns the distance a signal propagates during `t` seconds. The propagation is assumed to be two-way, as in a monostatic radar system.

`r = time2range(t,c)` specifies the signal propagation speed.

## Examples

### Minimum Detectable Range for Specified Pulse Width

Calculate the minimum detectable range for a monostatic radar system where the pulse width is 2 ms.

```
t = 2e-3;
r = time2range(t)
```

```
r = 2.9979e+05
```

## Input Arguments

**t — Propagation time**
array of positive numbers

Propagation time in seconds, specified as an array of positive numbers.

**c — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

## Output Arguments

**r — Propagation distance**
array of positive numbers

Propagation distance in meters, returned as an array of positive numbers. The dimensions of `r` are the same as those of `t`.

Data Types: `double`

## Algorithms

The function computes `c*t/2`.

# unigrid

Uniform grid

## Syntax

```
Grid = unigrid(StartValue,Step,EndValue)
Grid = unigrid(StartValue,Step,EndValue,IntervalType)
```

## Description

`Grid = unigrid(StartValue,Step,EndValue)` returns a uniformly sampled grid from the closed interval `[StartValue,EndValue]`, starting from `StartValue`. `Step` specifies the step size. This syntax is the same as calling `StartValue:Step:EndValue`.

`Grid = unigrid(StartValue,Step,EndValue,IntervalType)` specifies whether the interval is closed, or semi-open. Valid values of `IntervalType` are `'[]'` (default), and `'[)'`. Specifying a closed interval does not always cause `Grid` to contain the value `EndValue`. The inclusion of `EndValue` in a closed interval also depends on the step size `Step`.

## Examples

### Create Uniform Grids

Create a uniform closed interval grid with a positive increment.

```
grid = unigrid(0,0.1,1);
grid(1)
```

```
ans = 0
```

```
grid(end)
```

```
ans = 1
```

Note that `grid(1) = 0` and `grid(end) = 1`.

Create a uniform grid with a semi-open interval.

```
grid = unigrid(0,0.1,1,'[)');
grid(1)
```

```
ans = 0
```

```
grid(end)
```

```
ans = 0.9000
```

In this case, `grid(end) = 0.9`

Create a decreasing grid with a semi-open interval.

```
grid = unigrid(1,-0.2,0,'[)')
```

```
grid = 1×5

    1.0000    0.8000    0.6000    0.4000    0.2000
```

# uv2azel

Convert u/v coordinates to azimuth/elevation angles

## Syntax

```
AzEl = uv2azel(UV)
```

## Description

`AzEl = uv2azel(UV)` converts the *u*/*v* space on page 2-628 coordinates to their corresponding azimuth/elevation angle on page 2-630 pairs.

## Examples

### Conversion of U/V Coordinates to AzEl

Find the corresponding azimuth/elevation representation for $u = 0.5$ and $v = 0$.

```
azel = uv2azel([0.5; 0])
```

```
azel = 2×1

   30.0000
         0
```

## Input Arguments

**UV — Angle in u/v space**
two-row matrix

Angle in *u*/*v* space, specified as a two-row matrix. Each column of the matrix represents a pair of coordinates in the form [*u*; *v*]. Each coordinate is between –1 and 1, inclusive. Also, each pair must satisfy $u^2 + v^2 \leq 1$.

Data Types: `double`

# Output Arguments

**`AzEl` — Azimuth/elevation angle pairs**

two-row matrix

Azimuth and elevation angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation]. The matrix dimensions of `AzEl` are the same as those of `UV`.

# More About

## U/V Space

The *u*/*v* coordinates for the positive hemisphere $x \geq 0$ can be derived from the phi and theta angles on page 2-629.

The relation between the two coordinates is

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$

$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of *u* and *v*

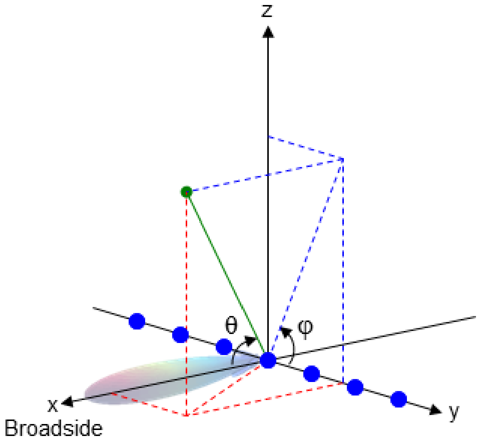
$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector’s orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector shown as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue disks.

# uv2azelpat

Convert radiation pattern from u/v form to azimuth/elevation form

## Syntax

```
pat_azel = uv2azelpat(pat_uv,u,v)
pat_azel = uv2azelpat(pat_uv,u,v,az,el)
[pat_azel,az_pat,el_pat] = uv2azelpat( ___ )
```

## Description

`pat_azel = uv2azelpat(pat_uv,u,v)` expresses the antenna radiation pattern `pat_azel` in azimuth/elevation angle on page 2-640 coordinates instead of u/v space on page 2-638 coordinates. `pat_uv` samples the pattern at *u* angles in `u` and *v* angles in `v`. The `pat_azel` matrix uses a default grid that covers azimuth values from –90 to 90 degrees and elevation values from –90 to 90 degrees. In this grid, `pat_azel` is uniformly sampled with a step size of 1 for azimuth and elevation. The function interpolates to estimate the response of the antenna at a given direction.

`pat_azel = uv2azelpat(pat_uv,u,v,az,el)` uses vectors `az` and `el` to specify the grid at which to sample `pat_azel`. To avoid interpolation errors, `az` should cover the range [–90, 90] and `el` should cover the range [–90, 90].

`[pat_azel,az_pat,el_pat] = uv2azelpat( ___ )` returns vectors containing the azimuth and elevation angles at which `pat_azel` samples the pattern, using any of the input arguments in the previous syntaxes.

## Examples

### Convert Radiation Pattern

Convert a radiation pattern to azimuth/elevation form with the angles spaced 1° apart.

Define the pattern in terms of *u* and *v*. Because *u* and *v* values outside the unit circle are not physical, set the pattern values in this region to zero.

```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to azimuth/elevation space.

```
pat_azel = uv2azelpat(pat_uv,u,v);
```

### Plot Converted Radiation Pattern

Convert a radiation pattern to azimuth/elevation form with the angles spaced 1° apart.

Define the pattern in terms of *u* and *v*. Because *u* and *v* values outside the unit circle are not physical, set the pattern values in this region to zero.

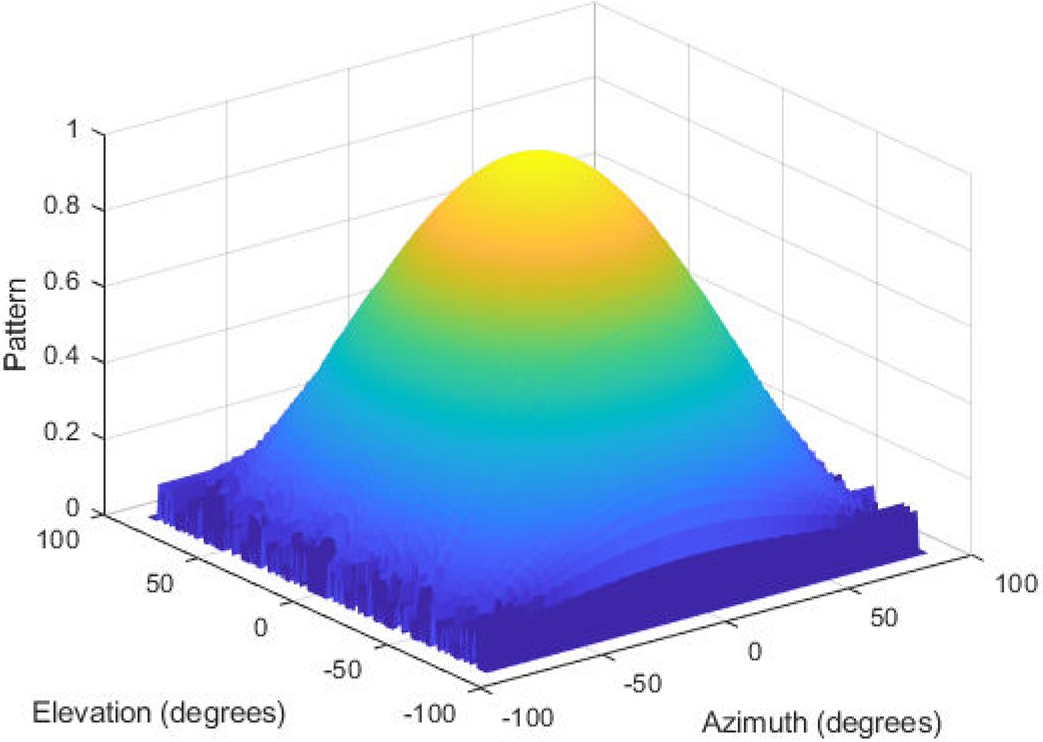
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to azimuth/elevation space. Store the azimuth and elevation angles for plotting.

```
[pat_azel,az,el] = uv2azelpat(pat_uv,u,v);
```

Plot the pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)')
ylabel('Elevation (degrees)')
zlabel('Pattern')
```



### Convert Radiation Pattern Using Specific Azimuth/Elevation Values

Convert a radiation pattern to azimuth/elevation form, with the angles spaced 5° apart.

Define the pattern in terms of *u* and *v*. Because *u* and *v* values outside the unit circle are not physical, set the pattern values in this region to zero.

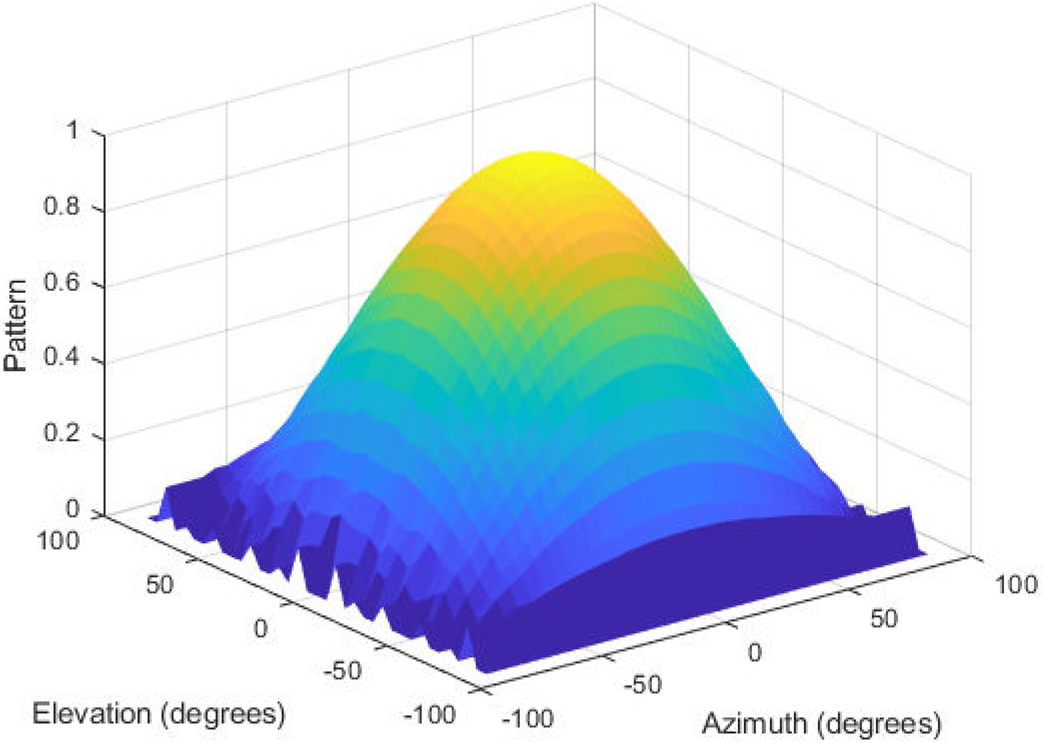
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Define the set of azimuth and elevation angles at which to sample the pattern. Then convert the pattern.

```
az = -90:5:90;
el = -90:5:90;
pat_azel = uv2azelpat(pat_uv,u,v,az,el);
```

Plot the pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)')
ylabel('Elevation (degrees)')
zlabel('Pattern')
```



## Input Arguments

### pat_uv — Antenna radiation pattern in *u*/*v* form

Q-by-P matrix

Antenna radiation pattern in *u*/*v* form, specified as a Q-by-P matrix. `pat_uv` samples the 3-D magnitude pattern in decibels in terms of *u* and *v* coordinates. P is the length of the `u` vector and Q is the length of the `v` vector.

Data Types: `double`

### u — *u* coordinates

vector of length P

*u* coordinates at which `pat_uv` samples the pattern, specified as a vector of length P. Each coordinate is between –1 and 1.

Data Types: `double`

### v — *v* coordinates

vector of length Q

*v* coordinates at which `pat_uv` samples the pattern, specified as a vector of length Q. Each coordinate is between –1 and 1.

Data Types: `double`

### az — Azimuth angles

`[-90:90]` (default) | vector of length L

Azimuth angles at which `pat_azel` samples the pattern, specified as a vector of length L. Each azimuth angle is in degrees, between –90 and 90. Such azimuth angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

### el — Elevation angles

`[-90:90]` (default) | vector of length M

Elevation angles at which `pat_azel` samples the pattern, specified as a vector of length M. Each elevation angle is in degrees, between –90 and 90.

Data Types: `double`

## Output Arguments

**`pat_azel` — Antenna radiation pattern in azimuth/elevation form**
M-by-L matrix

Antenna radiation pattern in azimuth/elevation form, returned as an M-by-L matrix. `pat_azel` samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. L is the length of the `az` vector, and M is the length of the `el` vector.

**`az_pat` — Azimuth angles**
vector of length L

Azimuth angles at which `pat_azel` samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

**`el_pat` — Elevation angles**
vector of length M

Elevation angles at which `pat_azel` samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

## More About

### U/V Space

The *u* and *v* coordinates are the direction cosines of a vector with respect to the *y*-axis and *z*-axis, respectively.

The *u*/*v* coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles on page 2-639, as follows:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \le u \le 1$$
$$-1 \le v \le 1$$
$$u^2 + v^2 \le 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

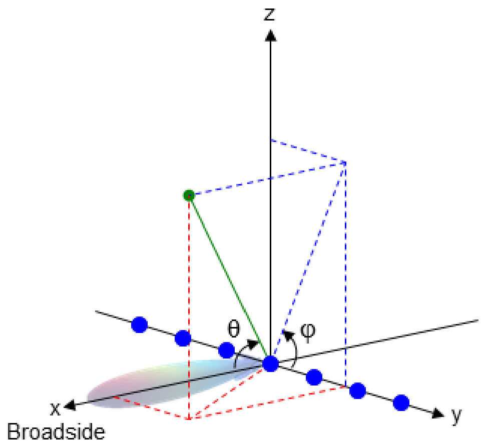
The azimuth and elevation angles can also be written in terms of *u* and *v*

$$\sin el = v$$
$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector’s orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

## Azimuth Angle, Elevation Angle

The azimuth angle of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

**Note** The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

# uv2phithetapat

Convert radiation pattern from u/v form to phi/theta form

## Syntax

```
pat_phitheta = uv2phithetapat(pat_uv,u,v)
pat_phitheta = uv2phithetapat(pat_uv,u,v,phi,theta)
[pat_phitheta,phi_pat,theta_pat] = uv2phithetapat( ___ )
```

## Description

`pat_phitheta = uv2phithetapat(pat_uv,u,v)` expresses the antenna radiation pattern `pat_phitheta` in φ/θ angle on page 2-653 coordinates instead of u/v space on page 2-652 coordinates. `pat_uv` samples the pattern at *u* angles in `u` and *v* angles in `v`. The `pat_phitheta` matrix uses a default grid that covers φ values from 0 to 360 degrees and θ values from 0 to 90 degrees. In this grid, `pat_phitheta` is uniformly sampled with a step size of 1 for φ and θ. The function interpolates to estimate the response of the antenna at a given direction.

`pat_phitheta = uv2phithetapat(pat_uv,u,v,phi,theta)` uses vectors `phi` and `theta` to specify the grid at which to sample `pat_phitheta`. To avoid interpolation errors, `phi` should cover the range [0, 360], and `theta` should cover the range [0, 90].

`[pat_phitheta,phi_pat,theta_pat] = uv2phithetapat( ___ )` returns vectors containing the φ and θ angles at which `pat_phitheta` samples the pattern, using any of the input arguments in the previous syntaxes.

## Examples

### Convert Radiation Pattern to φ-θ

Convert a radiation pattern to φ-θ space with the angles spaced 1° apart.

Define the pattern in terms of *u* and *v*. Because *u* and *v* values outside the unit circle are not physical, set the pattern values in this region to zero.

```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to φ-θ space.

```
[pat_phitheta,phi,theta] = uv2phithetapat(pat_uv,u,v);
```

### Plot Converted Radiation Pattern

Convert a radiation pattern to $\phi-\theta$ space with the angles spaced one degree apart.

Define the pattern in terms of *u* and *v*. For values outside the unit circle, *u* and *v* are undefined, and the pattern value is 0.

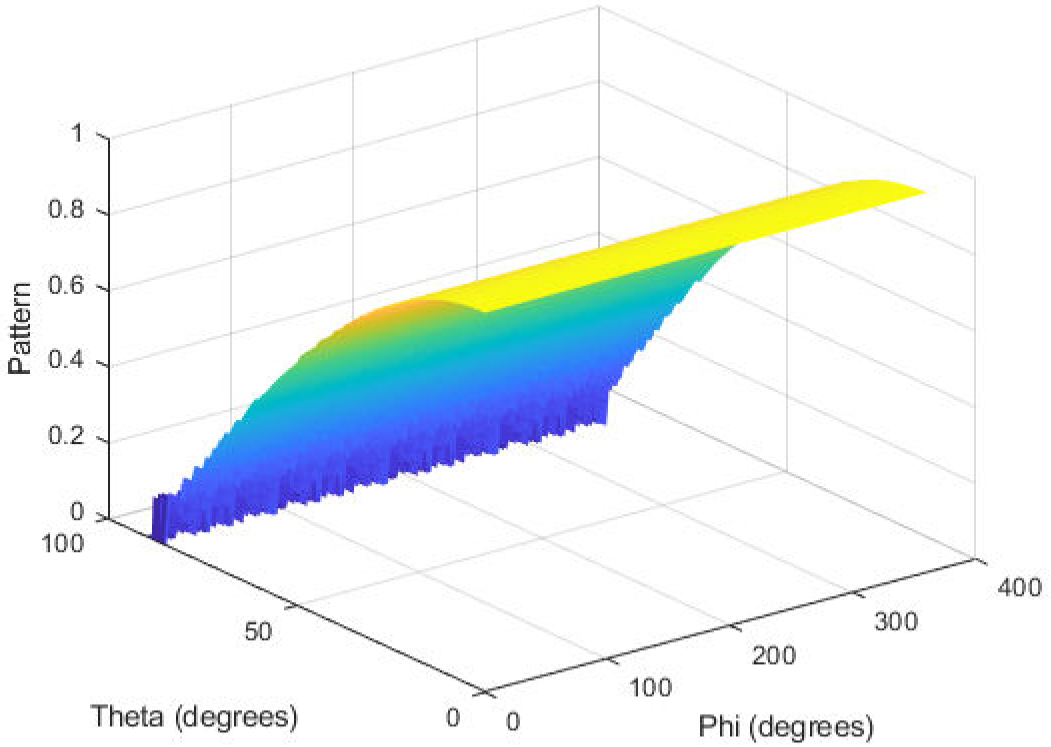
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to $\phi-\theta$ space. Store the $\phi$ and $\theta$ angles for use in plotting.

```
[pat_phitheta,phi,theta] = uv2phithetapat(pat_uv,u,v);
```

Plot the result.

```
H = surf(phi,theta,pat_phitheta);
H.LineStyle = 'none';
xlabel('Phi (degrees)');
ylabel('Theta (degrees)');
zlabel('Pattern');
```



### Convert Radiation Pattern Using Specific Phi/Theta Values

Convert a radiation pattern to $\phi - \theta$ space with the angles spaced five degrees apart.

Define the pattern in terms of *u* and *v*. For values outside the unit circle, *u* and *v* are undefined, and the pattern value is 0.

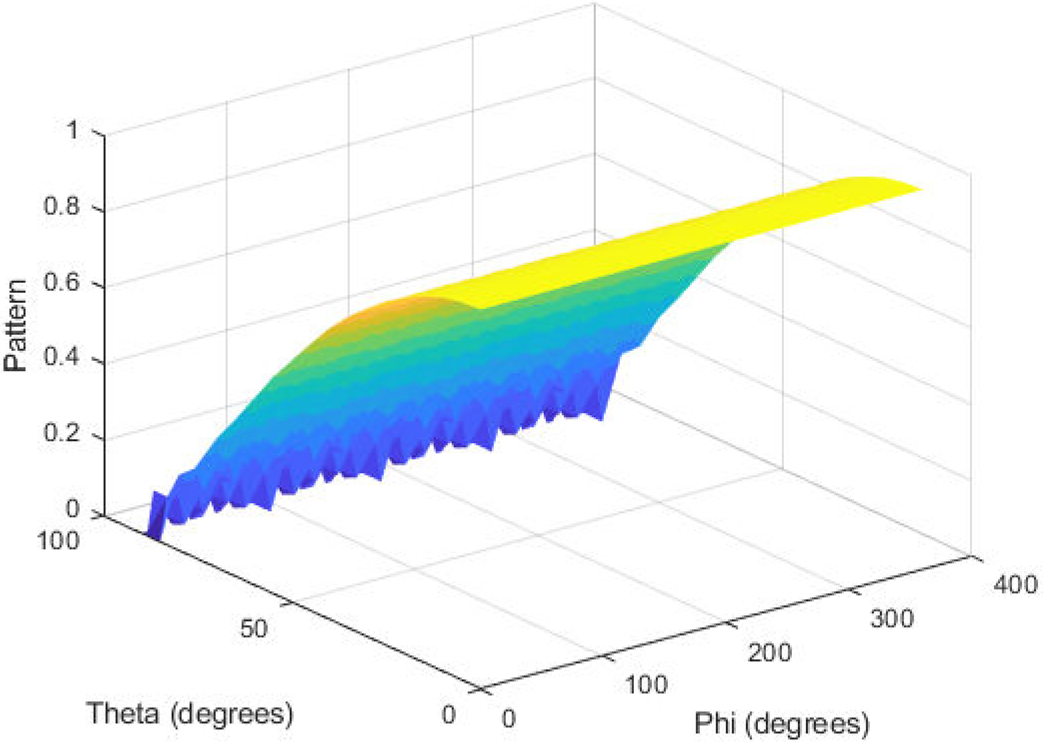
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Define the set of $\phi$ and $\theta$ angles at which to sample the pattern. Then, convert the pattern.

```
phi = 0:5:360;
theta = 0:5:90;
pat_phitheta = uv2phithetapat(pat_uv,u,v,phi,theta);
```

Plot the result.

```
H = surf(phi,theta,pat_phitheta);
H.LineStyle = 'none';
xlabel('Phi (degrees)');
ylabel('Theta (degrees)');
zlabel('Pattern');
```



## Input Arguments

### `pat_uv` — Antenna radiation pattern in *u*/*v* form

Q-by-P matrix

Antenna radiation pattern in *u*/*v* form, specified as a Q-by-P matrix. `pat_uv` samples the 3-D magnitude pattern in decibels, in terms of *u* and *v* coordinates. P is the length of the `u` vector, and Q is the length of the `v` vector.

Data Types: `double`

### `u` — *u* coordinates

vector of length P

*u* coordinates at which `pat_uv` samples the pattern, specified as a vector of length P. Each coordinate is between –1 and 1.

Data Types: `double`

### `v` — *v* coordinates

vector of length Q

*v* coordinates at which `pat_uv` samples the pattern, specified as a vector of length Q. Each coordinate is between –1 and 1.

Data Types: `double`

### `phi` — Phi angles

`[0:360]` (default) | vector of length L

Phi angles at which `pat_phitheta` samples the pattern, specified as a vector of length L. Each φ angle is in degrees, between 0 and 360.

Data Types: `double`

### `theta` — Theta angles

`[0:90]` (default) | vector of length M

Theta angles at which `pat_phitheta` samples the pattern, specified as a vector of length M. Each θ angle is in degrees, between 0 and 90. Such θ angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

## Output Arguments

**`pat_phitheta` — Antenna radiation pattern in phi/theta form**
M-by-L matrix

Antenna radiation pattern in phi/theta form, returned as an M-by-L matrix. `pat_phitheta` samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. L is the length of the `phi_pat` vector, and M is the length of the `theta` vector.

**`phi_pat` — Phi angles**
vector of length L

Phi angles at which `pat_phitheta` samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

**`theta_pat` — Theta angles**
vector of length M

Theta angles at which `pat_phitheta` samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

## More About

### U/V Space

The *u* and *v* coordinates are the direction cosines of a vector with respect to the *y*-axis and *z*-axis, respectively.

The *u*/*v* coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles on page 2-653, as follows:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \le u \le 1$$
$$-1 \le v \le 1$$
$$u^2 + v^2 \le 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u/v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

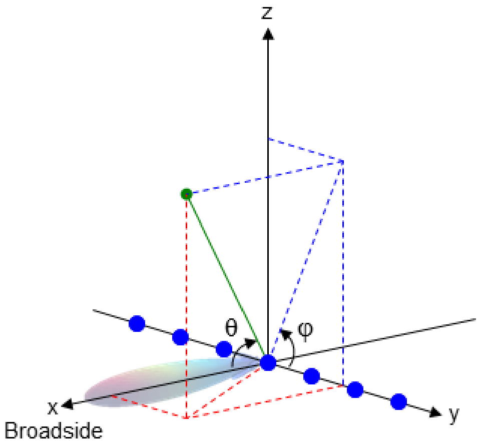
The azimuth and elevation angles can also be written in terms of *u* and *v*

$$\sin el = v$$
$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

## Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector’s orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az/el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el})/\sin(\mathrm{az})$$

### Introduced in R2012a

# val2ind

Uniform grid index

## Syntax

```
Ind = val2ind(Value,Delta)
Ind = val2ind(Value,Delta,GridStartValue)
```

## Description

`Ind = val2ind(Value,Delta)` returns the index of the value `Value` in a uniform grid with a spacing between elements of `Delta`. The first element of the uniform grid is zero. If `Value` does not correspond exactly to an element of the grid, the next element is returned. If `Value` is a row vector, `Ind` is a row vector of the same size.

`Ind = val2ind(Value,Delta,GridStartValue)` specifies the starting value of the uniform grid as `GridStartValue`.

## Examples

### Compute Index of Value in Grid

Find the index corresponding to 0.0001 in a uniform grid with 1 MHz sampling rate.

```
fs = 1e6;
indx = val2ind(0.0001,1/fs)
```

```
indx = 101
```

### Compute Indices of Values in Grid

Find the indices corresponding to a vector of values in a uniform grid with 1 kHz sampling rate. Values are not divisible by 1/fs.

```
fs = 1.0e3;
values =[0.0095 0.0125 0.0225];
indx = val2ind(values,1/fs)
```

```
indx = 1×3

    11    14    24
```

# Extended Capabilities

**Introduced in R2011a**

# waterfill

Waterfill MIMO power distribution

## Syntax

```
P = waterfill(Pt,Pn)
waterfill(Pt,Pn)
```

## Description

`P = waterfill(Pt,Pn)` optimally distributes the total transmitted power, `Pt`, among multiple channels to maximize channel capacity. The argument `Pn` represents the noise in each channel. The function can optimize independent subcarriers simultaneously.

`waterfill(Pt,Pn)` displays a waterfill diagram.

## Examples

### Compute Distributed Power Using Waterfill

Using the waterfill algorithm, compute the distributed power per channel for two subcarriers. There are four channels per subcarrier.

Specify the same total power for both subcarriers using a scalar value.

```
Pt = 10;
```

Specify the noise power. The rows correspond to the subcarriers and the columns to the channels.

```
Pn = [1 4 6 3; 5 4 3 6];
P = waterfill(Pt,Pn)
```

```
P = 2×4
```

```
     5     2     0     3
     2     3     4     1
```

Now, specify a different total power for each subcarrier.

```
Pt = [10,5];
P = waterfill(Pt,Pn)
```

```
P = 2×4

    5.0000    2.0000         0    3.0000
    0.6667    1.6667    2.6667         0
```

### Plot Distributed Power Using Waterfill

Using the waterfill algorithm, plot the distributed power per channel for two subcarriers. There are four channels per subcarrier.

Specify a different total power for each subcarrier.

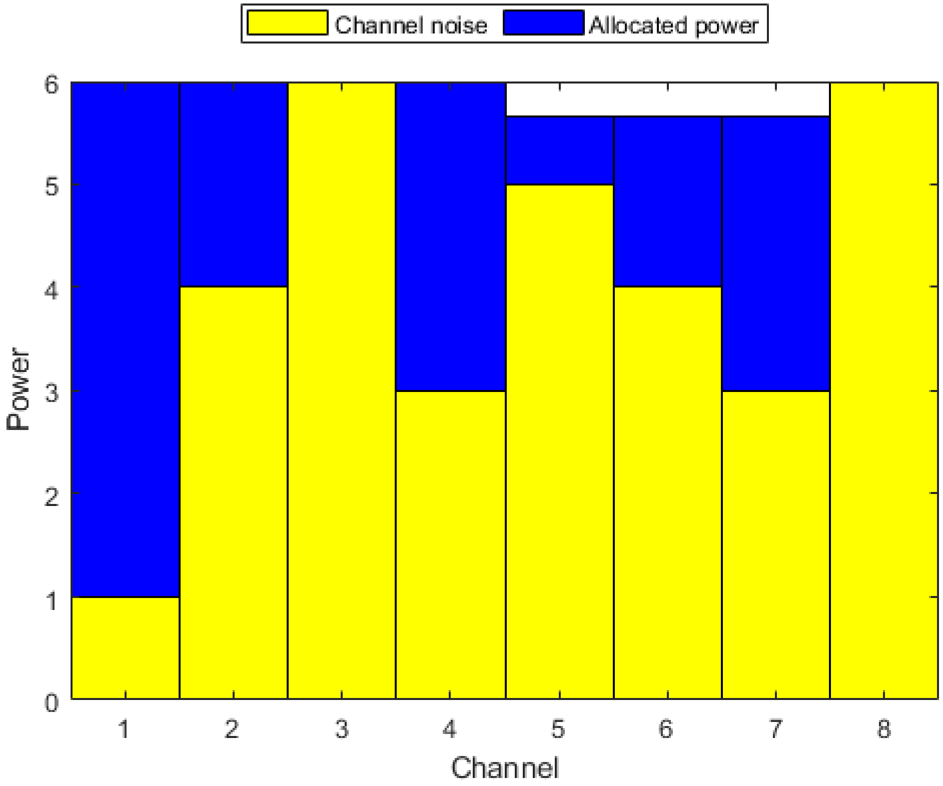
```
Pt = [10,5];
```

Specify the noise power. The rows correspond to the subcarriers and the columns to the channels.

```
Pn = [1 4 6 3; 5 4 3 6];
```

Display the waterfill plot.

```
waterfill(Pt,Pn)
```



## Input Arguments

### Pt — Total transmitted power

positive scalar | positive-valued *L*-element row or column vector

Total transmitted power per subcarrier, specified as a positive-valued *L*-element row or column vector where *L* is the number of subcarriers. When `Pt` is a scalar, all subcarriers have the same power. When `Pt` is a vector, the total power in a subcarriers is given by the corresponding element in `Pt`. Units are arbitrary.

Example: `[20 30]`

Data Types: `double`

### Pn — Channel noise power

positive-valued *N*-element row or column vector | positive-valued *L*-by-*N*-element matrix

Channel noise powers, specified as a positive-valued *N*-element row or column vector or a positive-valued *L*-by-*N*-element matrix. *N* is the number of channels and *L* is the number of subcarriers. If `Pn` is a vector, each element represents the noise power in the corresponding channel. The noise powers for each channel is the same for all subcarriers. If `Pn` is a matrix, an element in the matrix represents the noise power in the corresponding channel at the corresponding subcarrier. Units are arbitrary but must match the units for `Pt`.

Example: `[10 20 15]`

Data Types: `double`

## Output Arguments

### P — Allocated power per channel

positive-valued *L*-by-*N*-element matrix

Allocated power per channel, specified as a positive-valued *L*-by-*N*-element matrix. *N* is the number of channels and *L* is the number of subcarriers. Units are the same as the transmitted power, `Pt`. Each row corresponds to a subcarrier and specifies the distributed power for the channels in the subcarrier. Units are the same as for `Pt` and `Pn`.

Data Types: `double`

## Algorithms

The number of subcarriers is determined by either the dimensions of `Pt` or `Pn`.

- When you specify `Pt` as an *L*-element vector, there are *L* subcarriers with different total powers. If you specify `Pn` as *N*-element vector, this noise power vector is the same for all subcarriers. If you specify `Pn` as an *L*-by-*N* matrix, each row applies to the corresponding subcarrier.
- When you specify `Pt` as a scalar, `Pn` determines the number of subcarriers. If you specify `Pn` as an *N*-element vector, each element is the noise power in a channel and

there is only one subcarrier. If you specify `Pn` as an *L*-by-*N* matrix, there are *L* subcarriers all having the same transmitted power.

# tirempl

Path loss using Terrain Integrated Rough Earth Model (TIREM)

## Syntax

```
pl = tirempl(r,z,f)
pl = tirempl(r,z,f,Name,Value)
[pl,output] = tirempl( ___ )
```

## Description

`pl = tirempl(r,z,f)` returns the path loss in dB for a signal with frequency `f` when it is propagated over terrain. You can specify terrain using numeric vectors for distance `r` and elevation `z` along the great circle path between the transmitter and the receiver. The Terrain Integrated Rough Earth Model™ (TIREM™) model combines physics with empirical data to provide path loss estimates. The TIREM model is valid from 1 MHz to 1000 GHz.

**Note** `tirempl` requires access to the external TIREM library. Use `tiremSetup` to set up access.

`pl = tirempl(r,z,f,Name,Value)` returns the path loss in dB with additional options specified by name-value pairs.

`[pl,output] = tirempl( ___ )` returns the path loss, `pl`, and the output structure containing the information on the TIREM analysis.

# Examples

## Path Loss Over Flat Terrain

Calculate the path loss over flat terrain. Define the terrain profile for distances up to 10 km with step size of 100 m.

```
freq = 28e9;
r = 0:100:10000;
z = zeros(1,numel(r));
    Lterrain1 = tirempl(r,z,freq,...
       'TransmitterAntennaHeight',5, ...
       'ReceiverAntennaHeight',5)
```

```
Lterrain1 =

  142.6089
```

# Input Arguments

**r — Distances**
numeric vector

Distances along the great circle path between the transmitter and the receiver, specified as a numeric vector with each value in meters. The number of distance values must be equal to the number of elevation values.

Data Types: `double`

**z — Elevation**
numeric vector

Elevation values corresponding to the distance values along the great circle path between the transmitter and the receiver, specified as a numeric vector with each value in meters. The number of elevation values must be equal to the number of distance values.

Data Types: `double`

**f — Frequency of propagated signal**
scalar | numeric vector

Frequency of the propagated signal, specified as a scalar or numeric vector with each element unit in Hz.

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'TransmitterAntennaHeight',50`

### `TransmitterAntennaHeight` — Transmitter antenna height above ground

`10` (default) | numeric scalar

Transmitter antenna height above the ground, specified as a numeric scalar in the range of 0 to 30000. The height is measured from ground elevation to the center of the antenna.

Data Types: `double`

### `ReceiverAntennaHeight` — Receiver antenna height above ground

`1` (default) | numeric scalar

Receiver antenna height above the ground, specified as a numeric scalar in the range of 0 to 30000. The height is measured from ground elevation to the center of the antenna.

Data Types: `double`

### `AntennaPolarization` — Polarization of transmitter and receiver antennas

`'horizontal'` (default) | `'vertical'`

Polarization of the transmitter and the receiver antennas, specified as `'horizontal'` or `'vertical'`.

Data Types: `string` | `char`

### `GroundConductivity` — Conductivity of ground

`0.005` (default) | numeric scalar

Conductivity of the ground, specified as a numeric scalar in the range of 0.00005 to 100 in Siemens per meter. This value is used to calculate the path loss due to ground reflection. The default value corresponds to the average ground conductivity.

Data Types: `double`

**`GroundPermittivity` — Relative permittivity of ground**
`15` (default) | numeric scalar

Relative permittivity of the ground, specified as a numeric scalar in the range of 1 to100. Relative permittivity is the ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to the average ground permittivity.

Data Types: `double`

**`AtmosphericRefractivity` — Atmospheric refractivity near ground**
`301` (default) | numeric scalar

Atmospheric refractivity near the ground, specified as a numeric scalar in N-units in the range of 250 to 400. This value is used to calculate the path loss due to atmospheric refraction and tropospheric scatter. The default value corresponds to average atmospheric conditions.

Data Types: `double`

**`Humidity` — Absolute air humidity near ground**
`9` (default) | numeric scalar

Absolute air humidity near the ground, specified as a numeric scalar in g/m^$^3$ in the range of 50 to 110. This value is used to calculate path loss due to atmospheric absorption. The default value corresponds to the absolute humidity of air at 15 degrees Celsius and 70 percent relative humidity.

Data Types: `double`

## Output Arguments

**`pl` — Path loss**
scalar | 1-by-*N* vector

Path loss, returned as a scalar or 1-by-*N* vector with each element unit in decibels. *N* is the number of frequencies defined in the input `f`.

Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through the atmosphere, tropospheric scatter, and atmospheric absorption.

**`output` — Information of TIREM analysis**

structure

Information of TIREM analysis, returned as a structure. Each field of the structure represents an output from TIREM analysis.

## Topics

"Access TIREM Software"

**Introduced in R2019a**

# tiremSetup

Set up access to Terrain Integrated Rough Earth Model (TIREM)

## Syntax

```
tiremSetup
tiremSetup(libfolder)
libfolder = tiremSetup
```

## Description

`tiremSetup` opens a dialog to select the Terrain Integrated Rough Earth Model (TIREM) library folder. The TIREM library folder must contain the `tirem3` shared library, where the full library name is platform dependent. For more information, see .“Platform dependent library names” on page 2-669

`tiremSetup(libfolder)` sets the TIREM library folder to `libfolder`.

`libfolder = tiremSetup` returns the current TIREM library folder.

## Input Arguments

### `libfolder` — Name of TIREM library folder

character vector

Name of the TIREM library folder, specified as a character vector.

Data Types: `char` | `string`

## Output Arguments

### `libfolder` — Current TIREM library folder

character vector | string scalar

Current TIREM library folder, returned as a character vector or a string scalar. If TIREM access has not been setup, `libfolder` is empty.

# More About

## Platform dependent library names

| Platform | Shared library name |
|---|---|
| `Windows` | `libtirem3.dll` or `tirem3.dll` |
| `Linux` | `libtirem3.so` |

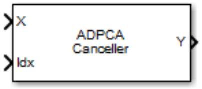
# ADPCA Canceller

Adaptive displaced phase center array (ADPCA) pulse canceller for a uniform linear array

**Library:** Phased Array System Toolbox / Space-Time Adaptive Processing



## Description

The ADPCA Canceller block filters clutter impinging on a uniform linear array using a displaced phase center array pulse canceller.

## Ports

### Input

**X — Input signal**

*M*-by-*N*-by-*P* complex-valued matrix

Input signal, specified as an *M*-by-*N*-by-*P* complex-valued array. *M* is the number of range samples, *N* is the number of channels, and *P* is the number of pulses.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**`Idx` — Index of range cells**

positive integer

Index of range cells to compute processing weights.

Example: `1`

Data Types: `double`

### PRF — Pulse repetition frequency

positive scalar

Pulse repetition frequency of current pulse, specified as a positive scalar.

#### Dependencies

To enable this port, set the **Specify PRF as** parameter to `Input port`.

Data Types: `double`

### Ang — Targeting direction

2-by-1 real-valued vector

Targeting direction, specified as a 2-by-*1* real-valued vector. The vector takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Specify direction as** parameter to `Input port`.

Data Types: `double`

### Dop — Targeting Doppler frequency

scalar

Targeting Doppler frequency of current pulse, specified as a scalar.

#### Dependencies

This port appears when the **Output pre-Doppler result** check box is cleared and the **Specify targeting Doppler as** parameter is set to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-1 complex-valued vector

Processing output, returned as an *M*-by-*1* complex-valued vector. The quantity *M* is the number of range samples in the input port X.

Data Types: `double`

### `W` — Processing weights

length *N***P* complex-valued vector

Processing weights, returned as Length *N***P* complex-valued vector. The quantity *N* is the number of channels and *P* is the number of pulses. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` input port or by the **Beamforming direction (deg)** parameter. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** check box.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Specify PRF as` — Source of PRF value

`Property` (default) | `Input port`

Source of PRF value, specified as `Property` or `Input port`. When set to `Property`, the **Pulse repetition frequency (Hz)** parameter sets the PRF. When set to `Input port`, pass in the PRF using the `PRF` input port.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1` (default) | positive scalar

Pulse repetition frequency, PRF, specified as a positive scalar. Units are in Hertz. Set this parameter to the same value set in any `Waveform` library block used in the simulation.

#### Dependencies

To enable this parameter, set the **Specify PRF as** parameter to `Property`.

### `Specify direction as` — Specify source of targeting directions

`Property` (default) | `Input port`

Specify whether the targeting direction for the STAP processor block comes from a block parameter or from the `ANG` input port. Values of this parameter are

| | |
|---|---|
| `Property` | • For the ADPCA Canceller and DPCA Canceller blocks, targeting direction is specified using **Receiving mainlobe direction (deg)**.<br>• For the SMI Beamformer block, targeting direction is specified using **Targeting direction**.<br>These parameters appear only when the **Specify direction as** parameter is set to `Property`. |
| `Input port` | Enter the targeting directions using the `Ang` input port. This port appears only when **Specify direction as** is set to `Input port`. |

### `Receiving mainlobe direction (deg)` — Pointing direction of main lobe of array

`[0;0]` (default) | real-valued 2-by-1 vector

Specify the direction of the main lobe of the receiving sensor array as a real-valued 2-by-1 vector. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]`. The azimuth angle should be between –180° and 180° and the elevation angle should be between –90° and 90°.

Example: `[100;-45]`

#### Dependencies

To enable this parameter, set **Specify direction as** to `Property`.

### `Number of bits in phase shifters` — Number of phase shift quantization bits

`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### `Specify targeting Doppler as` — Source of targeting Doppler

`Property` (default) | `Input port`

Specify whether targeting Doppler values for the STAP processor comes from the **Targeting Doppler (Hz)** parameter of this block or using the `DOP` input port. For the ADPCA Canceller and DPCA Canceller blocks, the **Specify targeting Doppler as** parameter appears only when the **Output pre-Doppler result** check box is cleared. Values of this parameter are

| | |
|---|---|
| `Property` | Specify targeting Doppler values using the **Targeting Doppler** parameter of the block. The **Targeting Doppler** parameter appears only when **Specify targeting Doppler as** is set to `Property`. |
| `Input port` | Specify targeting Doppler values using the `Dop` input port. This port appears only when **Specify targeting Doppler as** is set to `Input port`. |

### `Targeting Doppler (Hz)` — Targeting Doppler of STAP processor

`0` (default) | scalar

Targeting Doppler of STAP processor, specified as a scalar.

#### Dependencies

- To enable this parameter for the SMI Beamformer block, set **Specify targeting Doppler as** to `Property`.
- To enable this parameter for the ADPCA Canceller and DPCA Canceller blocks, first clear the **Output pre-Doppler result** check box. Then set the **Specify targeting Doppler as** parameter to `Property`.

### `Number of guard cells` — Number of guard cells using for training

2 (default) | positive even integer

Number of guard cells used for training, specified as a positive, even integer. Whenever possible, the set of guard cells is equally divided into regions before and after the test cell.

### `Number of training cells` — Number of cells used for training

2 (default) | positive even integer

Number of cells used for training, specified as a positive even integer. Whenever possible, the set of training cells is equally divided into regions before and after the test cell.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Output pre-Doppler result` — Output results before Doppler filtering

on (default) | off

Select this check box to output the results before Doppler filtering. Clear this check box to output the processing result after Doppler filtering. Selecting this check box will remove the **Specify targeting Doppler as** and **Targeting Doppler (Hz)** parameters.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

**Dependencies**

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Microphone`.

## Array Parameters

### `Specify sensor array as` — Type of array

`Array (no subarrays)` (default) | `MATLAB expression`

Specify a ULA sensor array directly or by using a MATLAB expression.

#### Types

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

### `Number of elements` — Number of array elements in U

2 (default) | positive integer greater than or equal to two

The number of array elements for ULA arrays, specified as an integer greater than or equal to two.

Example: `11`

Data Types: `double`

### `Element spacing` — Distance between ULA elements

`0.5` (default) | positive scalar

Distance between adjacent ULA elements, specified as a positive scalar. Units are in meters.

Example: `1.5`

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Taper` — ULA array taper

`1` (default) | complex-valued vector

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Example: [0.5;1;0.5]

Data Types: `double`

#### **Expression — MATLAB expression used to create an array**

Phased Array System Toolbox array System object

MATLAB expression used to create a ULA array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.ULA('NumElements',13)`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

# Angle Doppler Response

Angle-Doppler response

**Library:** Phased Array System Toolbox / Space-Time Adaptive Processing

X
Angle Doppler Response
Resp
Ang
Dop

## Description

The Angle Doppler Response block computes the angle-Doppler response of the input signal. The output response is a matrix whose rows represent Doppler bins and whose columns represent angle bins.

## Ports

### Input

**X — Input data**

*M*-by-*N* complex-valued matrix | *M*N*-element complex-valued vector

Input signal, specified as an *M*-by-*N* complex-valued matrix or an *M*N* complex-valued vector. *M* is the number of array elements or the number of subarrays, if the array supports subarrays, specified in the **Sensor Array** panel. *N* is the number of data samples. *N* must be greater than or equal to two.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**PRF — Pulse repetition frequency**

positive scalar

Pulse repetition frequency of current pulse, specified as a positive scalar.

#### Dependencies

To enable this port, set the **Specify PRF as** parameter to `Input port`.

Data Types: `double`

### `El` — Elevation angle

scalar

Elevation angle, specified as a scalar. Angle units are in degrees. The elevation angle must lie between –90° and 90°, inclusive.

#### Dependencies

To enable this port, set **Source of elevation angle** to `Input port`.

Data Types: `double`

## Output

### `Resp` — Angle-Doppler response

*P*-by-*Q* complex-valued matrix

Angle Doppler response, returned as a *P*-by-*Q* matrix. *P* is specified by the **Number of Doppler bins** parameter and *Q* is specified by the **Number of angle bins** parameter.

Data Types: `double`

### `Ang` — Response-matrix angle values

*Q*-by-1 real-valued vector

Response-matrix angle values, returned as a *Q*-by-1 real-valued vector. The angle values correspond to the columns of the angle-Doppler response matrix. *Q* is specified by the **Number of angle bins** parameter.

Data Types: `double`

### `Dop` — Response-matrix Doppler values

*P*-by-1 real-valued vector

Response-matrix Doppler values, returned as a *P*-by-1 real-valued vector. The Doppler values correspond to the rows of the angle-Doppler response matrix. *P* is specified by the **Number of Doppler bins** parameter.

Data Types: `double`

# Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Specify PRF as` — Source of PRF value

`Property` (default) | `Input port`

Source of PRF value, specified as `Property` or `Input port`. When specifier as `Property`, the **Pulse repetition frequency (Hz)** parameter sets the PRF. When set to `Input port`, pass in the PRF using the PRF input port.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1` (default) | positive scalar

Pulse repetition frequency, PRF, specified as a positive scalar. Units are in Hertz. Set this parameter to the same value set in any `Waveform` library block used in the simulation.

#### Dependencies

To enable this parameter, set the **Specify PRF as** parameter to `Property`.

### `Source of elevation angle` — Elevation angle source

`Property` (default) | `Input port`

Elevation angle source, specified as `Property` or `Input port`. Values of this parameter are

| | |
|---|---|
| Property | The **Elevation angle (deg)** parameter of this block specifies the elevation angle. |
| Input port | The elevation angle is set using the El input port. |

### Elevation angle (deg) — Elevation angle used to calculate the angle-Doppler response

0 (default) | scalar

Elevation angle used to calculate the angle-Doppler response, specified as a scalar. Units are degrees. The angle must be between –90° and 90°.

Example: -45

**Dependencies**

To enable this parameter, set **Source of elevation angle** to Property

Data Types: double

### Number of angle bins — Number of angle samples

256 (default) | positive integer greater than two

The number of samples in the angular domain used to calculate the angle-Doppler response, specified as a positive integer greater than two.

Example: 600

Data Types: double

### Number of Doppler bins — Number of angle samples

256 (default) | positive integer greater than two

The number of samples in the Doppler domain used to calculate the angle-Doppler response, specified as a positive integer greater than two.

Example: 128

Data Types: double

### Simulate using — Block simulation method

Interpreted Execution (default) | Code Generation

Block simulation, specified as Interpreted Execution or Code Generation. If you want your block to use the MATLAB interpreter, choose Interpreted Execution. If

you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.

- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.

- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

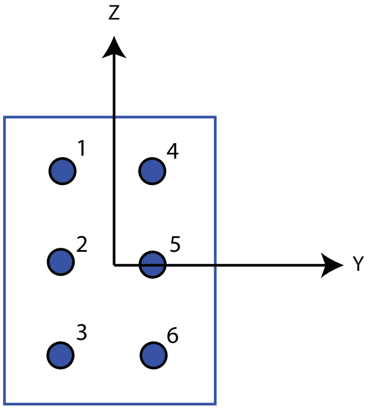
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.

- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

**`Element positions (m)` — Positions of conformal array elements**
`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter set **Geometry** to `Conformal Array`.

**`Element normals (deg)` — Direction of conformal array element normal vectors**
`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

**Dependencies**

To enable this parameter, set **Geometry** to `Conformal Array`.

**`Taper` — Array element tapers**
1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.

- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

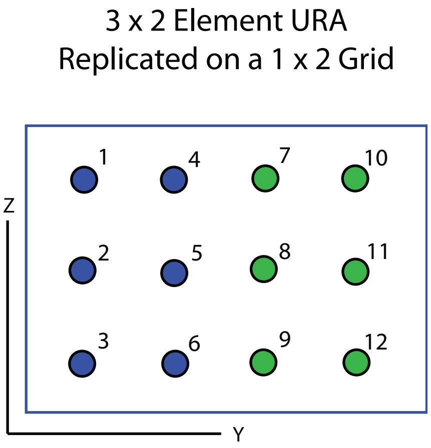
To enable this parameter, set **Sensor array** to `Replicated subarray`

### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The

transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

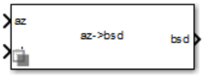
# Azimuth Broadside Converter

Convert azimuth angle to broadside angle or broadside angle to azimuth angle

**Library:** Phased Array System Toolbox / Environment and Target



## Description

The Azimuth Broadside Converter block converts an angle direction expressed in terms of "Broadside Angles" into the equivalent azimuth angle or converts from azimuth angle into the equivalent broadside angle. In both cases, you must specify the elevation angle.

## Ports

### Input

**az — Azimuth angle**
scalar | vector of real-values

Azimuth angle of direction, specified as a scalar or vector of real-values. Units are in degrees. When `az` is a vector, the dimensions of `az` and `el` must match.

**Dependencies**

To enable this port, set **Conversion Mode** to **azimuth -> broadside**.

Data Types: `double`

**bsd — Broadside angle**
scalar | vector of real-values

Broadside angle of direction, specified as a scalar or vector of real-values. Units are in degrees. When `bsd` is a vector, the dimensions of `bsd` and `el` must match.

**Dependencies**

To enable this port, set **Conversion Mode** to **broadside -> azimuth**.

Data Types: `double`

### `el` — Elevation angle

scalar | vector of real-values

Elevation angle of direction, specified as a scalar or vector of real-values. Units are in degrees. The dimensions of `el` must match the dimensions of `az` and `bsd`.

Data Types: `double`

## Output

### `az` — Azimuth angle

scalar | vector of real-values

Azimuth angle of direction, returned as a scalar or vector of real-values. Units are in degrees.

#### Dependencies

To enable this port, set **Conversion Mode** to **broadside -> azimuth**.

Data Types: `double`

### `bsd` — Broadside angle

scalar | vector of real-values

Broadside angle of direction, returned as a scalar or vector of real-values. Units are in degrees.

#### Dependencies

To enable this port, set **Conversion Mode** to **azimuth -> broadside**.

Data Types: `double`

# Parameters

### `Conversion mode` — Angle conversion type

**broadside -> azimuth** (default) | **azimuth -> broadside**

Angle conversion type, specified as

|  |  |
|---|---|
| **broadside -> azimuth** | Convert direction expressed in broadside and elevation angles to azimuth and elevation angles. |
| **azimuth -> broadside** | Convert direction expressed in azimuth and elevation angles to broadside and elevation angles. |

# Backscatter Bicyclist

Backscatter signals from bicyclist

**Library:** Phased Array System Toolbox / Environment and Target

X
Ang
AngH
Speed
Coast
Backscatter
Bicyclist
Y
Pos
Vel
Ax

## Description

The Backscatter Bicyclist block simulates backscattered radar signals reflected from a moving bicyclist. The bicyclist consists of the bicycle and its rider. The object models the motion of the bicyclist and computes the sum of all reflected signals from multiple discrete scatterers on the bicyclist. The model ignores internal occlusions within the bicyclist. The reflected signals are computed using a multi-scatterer model developed from a 77-GHz radar system.

Scatterers are located on five major bicyclist components:

- bicycle frame and rider
- bicycle pedals
- upper and lower legs of the rider
- front wheel
- back wheel

Excluding the wheels, there are 114 scatterers on the bicyclist. The wheels contain scatterers on the rim and spokes. The number of scatterers on the wheels depends on the number of spokes per wheel, which can be specified using the `NumWheelSpokes` property.

## Ports

### Input

**X — Incident radar signals**
complex-valued *M*-by-*N* matrix

Incident radar signals on each bicyclist scatterer, specified as a complex-valued *M*-by-*N* matrix. *M* is the number of samples in the signal. *N* is the number of point scatterers on the bicyclist and is determined partly from the number of spokes in each wheel, $N_{ws}$. See “Bicyclist Scatterer Indices” on page 3-43 for the column representing the incident signal at each scatterer.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

**AngH — Bicyclist heading**
`0.0` | scalar

Heading of the bicyclist, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards the *y*-axis. Units are in degrees.

Example: `-34`

Data Types: `double`

**Ang — Directions of incident signals**
real-valued 2-by-*N* vector

Directions of incident signals on the scatterers, specified as a real-valued 2-by-*N* matrix. Each column of `Ang` specifies the incident direction of the signal to the corresponding scatterer. Each column takes the form of an *[AzimuthAngle;ElevationAngle]* pair. Units are in degrees. See “Bicyclist Scatterer Indices” on page 3-43 for the column representing the incident arrival angle at each scatterer.

Data Types: `double`

**Speed — Bicyclist speed**
nonnegative scalar

Speed of bicyclist, specified as a nonnegative scalar. The motion model limits the speed to 60 m/s. Units are in meters per second.

Example: 8

Data Types: `double`

### `Coast` — Bicyclist coasting state

`false` (default) | `true`

Bicyclist coasting state, specified as `false` or `true`. This property controls the coasting of the bicyclist. If set to `true`, the bicyclist does not pedal but the wheels are still rotating (freewheeling). If set to `false`, the bicyclist is pedaling and the `Gear transmission ratio` parameter determines the ratio of wheel rotations to pedal rotations.

**Tunable:** Yes

Data Types: `Boolean`

## Output

### Y — Combined reflected radar signals

complex-valued *M*-by-1 column vector

Combined reflected radar signals, returned as a complex-valued *M*-by-1 column vector. *M* equals the number of samples in the input signal, `X`.

Data Types: `double`
Complex Number Support: Yes

### `Pos` — Positions of scatterers

real-valued 3-by-*N* matrix

Positions of scatterers, returned as a real-valued 3-by-*N* matrix. *N* is the number of scatterers on the bicyclist. Each column represents the Cartesian position, [*x*;*y*;*z*], of one of the scatterers. Units are in meters. See “Bicyclist Scatterer Indices” on page 3-43 for the column representing the position of each scatterer.

Data Types: `double`

### `Vel` — Velocity scatterers

real-valued 3-by-*N* matrix

Velocity of scatterers, returned as a real-valued 3-by-*N* matrix. *N* is the number of scatterers on the bicyclist. Each column represents the Cartesian velocity, [*vx*;*vy*;*vz*], of one of the scatterers. Units are in meters per second. See “Bicyclist Scatterer Indices” on page 3-43 for the column representing the velocity of each scatterer.

Data Types: `double`

### `Ax` — Orientation of scatterers

real-valued 3-by-3 matrix

Orientation axes of scatterers, returned as a real-valued 3-by-3 matrix.

Data Types: `double`

## Parameters

### `Number of wheel spokes` — Number of spokes per wheel

`20` (default) | positive integer

Number of spokes per wheel of the bicycle, specified as a positive integer from 3 through 50, inclusive. Units are dimensionless.

Data Types: `double`

### `Gear transmission ratio` — Ratio of wheel rotations to pedal rotations

`1.5` (default) | positive scalar

Ratio of wheel rotations to pedal rotations, specified as a positive scalar. The gear ratio must be in the range 0.5 through 6. Units are dimensionless.

Data Types: `double`

### `Signal carrier frequency (Hz)` — Carrier frequency

`77e9` (default) | positive scalar

Carrier frequency of narrowband incident signals, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `Initial position (m)` — Initial position of bicyclist

`[0;0;0]` (default) | 3-by-1 real-valued vector

Initial position of the bicyclist, specified as a 3-by-1 real-valued vector in the form of [*x*;*y*;*z*]. Units are in meters.

Data Types: `double`

**`Initial heading direction (deg)` — Initial heading of bicyclist**
`0` (default) | scalar

Initial heading of the bicyclist, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards *y*-axis. Units are in degrees.

Data Types: `double`

**`Initial bicyclist speed (m/s)` — Initial speed of bicyclist**
`4` (default) | nonnegative scalar

Initial speed of bicyclist, specified as a nonnegative scalar. The motion model limits the speed to a maximum of 60 m/s (216 kph). Units are in meters per second.

**Tunable:** Yes

Data Types: `double`

**`Propagation speed (m/s)` — Signal propagation speed**
`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

**`RCS pattern` — Source of RCS pattern**
`Auto` (default) | `Property`

Source of the RCS pattern, specified as either `Auto` or `Property`. When you specify `Auto`, the pattern is a 1-by-361 matrix containing values derived from radar measurements taken at 77 GHz.

**`Azimuth angles (deg)` — Azimuth angles**
`[-180:180]` (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrix specified by the **Radar cross section pattern (square meters)** parameter. Specify the azimuth angles as a length *P* vector. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

#### Dependencies

To enable this parameter, set the **RCS pattern** parameter to `Property`.

Data Types: `double`

### `Elevation angles (deg)` — Elevation angles

`[-90:90]` (default) | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrix specified by the **Radar cross section pattern (square meters)** parameter. Specify the elevation angles as a length *Q* vector. *Q* must be greater than two. Angle units are in degrees.

#### Dependencies

To enable this parameter, set the **RCS pattern** parameter to `Property`.

Data Types: `double`

### `Radar cross section pattern (square meters)` — Radar cross-section pattern

1-by-361 real-valued matrix (default) | *Q*-by-*P* real-valued matrix | 1-by-*P* real-valued vector

Radar cross-section (RCS) pattern as a function of elevation and azimuth angle, specified as a *Q*-by-*P* real-valued matrix or a 1-by-*P* real-valued vector. *Q* is the length of the vector defined by the `ElevationAngles` property. *P* is the length of the vector defined by the `AzimuthAngles` property. Units are in square meters.

You can also specify the pattern as a 1-by-*P* real-valued vector of azimuth angles for one elevation.

The default value of this property is a 1-by-361 matrix containing values derived from radar measurements taken at 77 GHz found in `backscatterBicyclist.defaultRCSPattern`.

#### Dependencies

To enable this parameter, set the **RCS pattern** parameter to `Property`.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations usually run faster as compiled code than interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| **Block Simulation** | **Simulation Behavior** | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# More About

## Bicyclist Scatterer Indices

Bicyclist scatterer indices define which columns in the scatterer position or velocity matrices contain the position and velocity data for a specific scatterer. For example, column 92 of `bpos` specifies the 3-D position of one of the scatterers on a pedal.

The wheel scatterers are equally divided between the wheels. You can determine the total number of wheel scatterers, $N$, by subtracting 113 from the output of the `getNumScatterers` function. The number of scatterers per wheel is $N_{sw} = N/2$.

**Bicyclist Scatterer Indices**

| Bicyclist Component | Bicyclist Scatterer Index |
|---|---|
| Frame and rider | 1 … 90 |
| Pedals | 91 … 99 |
| Rider legs | 100 … 113 |
| Front wheel | 114 … 114 + $N_{sw}$ - 1 |
| Rear wheel | 114 + $N_{sw}$ … 114 + $N$ - 1 |

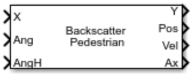
# Backscatter Pedestrian

Backscatter signals from pedestrian
**Library:** Phased Array System Toolbox / Environment and Target



## Description

The Backscatter Pedestrian block models the monostatic reflection of non-polarized electromagnetic signals from a walking pedestrian. The pedestrian walking model coordinates the motion of 16 body segments to simulate natural motion. The model also simulates the radar reflectivity of each body segment. From this model, you can obtain the position and velocity of each segment and the total backscattered radiation as the body moves.

## Ports

### Input

**X — Incident radar signals**
complex-valued *M*-by-16 matrix

Incident radar signals on each body segment, specified as a complex-valued *M*-by-16 matrix. *M* is the number of samples in the signal. See “Body Segment Indices” on page 3-49 for the column representing the incident signal at each body segment.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

**Ang — Incident signal directions**
real-valued 2-by-16 matrix

Incident signal directions on the body segments, specified as a real-valued 2-by-16 matrix. Each column of ANG specifies the incident direction of the signal to the corresponding body part. Each column takes the form of an [AzimuthAngle;ElevationAngle] pair. Units are in degrees. See "Body Segment Indices" on page 3-49 for the column representing the incident direction at each body segment.

Data Types: double

### AngH — Pedestrian heading

scalar

Heading of the pedestrian, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards the *y*-axis. Units are in degrees.

Example: -34

Data Types: double

## Output

### Y — Combined reflected radar signals

complex-valued *M*-by-1 column vector

Combined reflected radar signals, returned as a complex-valued *M*-by-1 column vector. *M* equals the same number of samples as in the input signal, X.

Data Types: double
Complex Number Support: Yes

### Pos — Positions of body segments

real-valued 3-by-16 matrix

Positions of body segments, returned as a real-valued 3-by-16 matrix. Each column represents the Cartesian position, [x;y;z], of one of 16 body segments. Units are in meters. See "Body Segment Indices" on page 3-49 for the column representing the position of each body segment.

Data Types: double

### Vel — Velocity of body segments

real-valued 3-by-16 matrix

Velocity of body segments, returned as a real-valued 3-by-16 matrix. Each column represents the Cartesian velocity, [vx;vy;vz], of one of 16 body segments. Units are in meters per second. See “Body Segment Indices” on page 3-49 for the column representing the velocity of each body segment.

Data Types: `double`

### `Ax` — Orientation of body segments

real-valued 3-by-3-by-16 array

Orientation axes of body segments, returned as a real-valued 3-by-3-by-16 array. Each page represents the 3-by-3 orientation axes of one of 16 body segments. Units are dimensionless. See “Body Segment Indices” on page 3-49 for the page representing the orientation of each body segment.

Data Types: `double`

## Parameters

### `Height (m)` — Height of pedestrian

`1.65` (default) | positive scalar

Height of pedestrian, specified as a positive scalar. Units are in meters.

Data Types: `double`

### `Walking Speed (m/s)` — Walking speed of pedestrian

`1.4` times pedestrian height (default) | nonnegative scalar

Walking speed of the pedestrian, specified as a nonnegative scalar. The motion model limits the walking speed to 1.4 times the pedestrian height set in the **Height (m)** parameter. Units are in meters per second.

Data Types: `double`

### `Propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

### `Operating Frequency (Hz)` — Carrier frequency

`300e6` (default) | positive scalar

Carrier frequency of narrowband incident signals, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `Initial Position (m)` — Initial position of pedestrian

`[0;0;0]` (default) | 3-by-1 real-valued vector

Initial position of the pedestrian, specified as a 3-by-1 real-valued vector in the form of `[x;y;z]`. Units are in meters.

Data Types: `double`

### `Initial Heading (deg)` — Initial heading of pedestrian

`0` (default) | scalar

Initial heading of the pedestrian, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards *y*-axis. Units are in degrees.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# More About

## Body Segment Indices

Body segment indices define which columns in the **X**, **Ang**, **BPPOS**, and **BPVEL** ports contain the data for a specific body segment. Body segment indices define which page in the **Ax** port contains the data for a specific body segments. For example, column 3 of **X** contains sample data for the left lower leg. Column 3 of **Ang** contains the arrival angle of the signal at the left lower leg.

**Body Segment Indices**

| Body segment | Body segment index |
|---|---|
| left foot | 1 |
| right foot | 2 |
| left lower leg | 3 |
| right lower leg | 4 |
| left upper leg | 5 |
| right upper leg | 6 |
| left hip | 7 |
| right hip | 8 |
| left lower arm | 9 |
| right lower arm | 10 |
| left upper arm | 11 |
| right upper arm | 12 |
| left shoulder | 13 |
| right shoulder | 14 |
| neck | 15 |
| head | 16 |

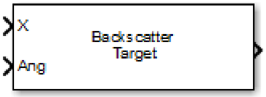
**Introduced in R2019a**

# Backscatter Radar Target

Backscatter radar target



## Library

Environment and Target

`phasedenvlib`

## Description

The Backscatter Radar Target block models the monostatic case of reflection of nonpolarized electromagnetic signals from a radar target. Target model includes all four Swerling target fluctuation models and non-fluctuating model. You can model several targets simultaneously by specifying multiple radar cross-section matrices.

## Parameters

**Azimuth angles (deg)**

Azimuth angles used to define the angular coordinates of the **RCS pattern (m^2)** parameter. Specify azimuth angles as a length *P* vector. Units are degrees. *P* must be greater than two. This parameter determines the incident azimuthal arrival angle of any element of the cross-section patterns.

**Elevation angles (deg)**

Elevation angles used to define the angular coordinates of the **RCS pattern (m^2)** parameter. Specify elevation angles as a length *Q* vector. Units are degrees. *Q* must be greater than two. This parameter determines the incident elevation arrival angle of any element of the cross-section patterns.

**RCS pattern (m^2)**

Radar cross-section pattern, specified as a *Q*-by-*P* real-valued matrix or a *Q*-by-*P*-by-*M* real-valued array.

- *Q* is the length of the vector in the **Elevation angles (deg)** parameter.
- *P* is the length of the vector in the **Azimuth angles (deg)** parameter.
- *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the input port `X`. You can, however, use a single pattern to model multiple signals reflecting from a single target.

You can, however, use a single pattern to model multiple signals reflecting from a single target. Pattern units are square-meters.

Pattern units are square-meters.

**Fluctuation model**

Specify the statistical model of the target as either `Nonfluctuating`, `Swerling1`, `Swerling2`, `Swerling3`, or `Swerling4`. When you set this parameter to a value other than `Nonfluctuating`, you then set radar cross-sections parameters using the `Update` input port.

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the carrier frequency of the signal that reflects from the target, as a positive scalar in hertz.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| X | Input signals.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| Ang | Incident angle | Double-precision floating point |
| Update | Update RCS at block execution. | Double-precision floating point |
| Out | Scattered signal | Double-precision floating point |

## See Also

`phased.BackscatterRadarTarget`

**Introduced in R2016a**

# Barrage Jammer

Barrage jammer interference source

## Library

Environment and Target

`phasedenvlib`

## Description

The Barrage Jammer block generates a wideband noise-like jamming signal.

## Parameters

**Effective radiated power (W)**

Specify the effective radiated power (ERP) in watts of the jamming signal as a positive scalar.

**Source of number of samples per frame**

Specify the source for number of samples per frame as `Property` or `Derive from reference input port`. When you choose `Property`, the block obtains the number of samples from the **Number of samples per frame** parameter. When you choose `Derive from reference input port` the block uses the number of samples from a reference signal passed into the `Ref` input port.

**Number of samples per frame**

Specify the number of samples in the jamming signal output as a positive integer. The number of samples must match the number of samples produced by a signal source. This parameter appears only when **Source of number of samples per frame** is set to `Property`. As an example, if you use the Rectangular Waveform block as a signal source and set its **Output signal format** to `Samples`, the value of **Number of samples per frame** should match the Rectangular Waveform block's **Number of samples in output** parameter. If you set the **Output signal format** to `Pulses`, the **Number of samples per frame** should match the product of **Sample rate** and **Number of pulses in output** divided by the **Pulse repetition frequency**.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |

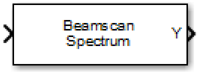
# Beamscan Spectrum

Beamscan spatial spectrum estimator
**Library:** Phased Array System Toolbox / Direction of Arrival



## Description

The Beamscan Spectrum block estimates the 2-D spatial spectrum of incoming narrowband signals by scanning a range of azimuth and elevation angles using a narrowband conventional beamformer. The block optionally calculates the direction of arrival of a specified number of signals by locating peaks of the spectrum.

## Ports

### Input

**X — Received signal**
*M*-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the length of the signal, the number of sample values contained in the signal. The quantity *N* is the number of sensor elements in the array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

### Output

**Y — Beamscan 2-D spatial spectrum**
non-negative real-valued *P*-by-*Q* matrix

2Magnitude of the estimated 2-D spatial spectrum, returned as a non-negative, returned as a real-valued *P*-by-*Q* matrix. Each entry represents the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the **Azimuth scan angles (deg)** and **Elevation scan angles (deg)** parameters. *P* equals the length of the vector specified in **Azimuth scan angles (deg)** and *Q* equals the length of the vector specified in **Elevation scan angles (deg)**.

Data Types: `double`

### `Ang` — Directions of arrival

non-negative, real-valued 2-by-*L* matrix

Directions of arrival of the signals, returned as a real-valued 2-by-*L* matrix. *L* is the number of signals specified by the **Number of signals** parameter. The direction of arrival angle is defined by the azimuth and elevation angles of the source with respect to the array local coordinate system. The first row of the matrix contains the azimuth angles and the second row contains the elevation angles. If the object cannot identify peaks in the spectrum, it will return `NaN`. Angle units are in degrees.

#### Dependencies

To enable this output port, select the **Enable DOA output** check box.

Data Types: `double`

## Parameters

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

**`Number of bits in phase shifters` — Number of phase shift quantization bits**
`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**`Forward-backward averaging` — Enable forward-backward averaging**
off (default) | on

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold structure.

**`Azimuth scan angles (deg)` — Scan angles in azimuth direction**
`-180:180` (default) | real-valued vector

Scan angles in azimuthal direction, specified as a real-valued vector. The angles must lie be between –180° and 180°, inclusive. You must specify the angles in ascending order. Units are in degrees.

Data Types: `double`

**`Elevation scan angles (deg)` — Scan angles in elevation direction**
`-90:90` (default) | real-valued vector

Scan angles in elevation direction, specified as a real-valued vector. The angles must lie be between –90° and 90°, inclusive. You must specify the angles in ascending order. Units are in degrees.

Data Types: `double`

**`Enable DOA output` — Output directions of arrival through output port**
off (default) | on

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port.

**`Number of signals` — Expected number of arriving signals**
`1` (default) | positive integer

Specify the expected number of signals for DOA estimation as a positive scalar integer.

#### Dependencies

To enable this parameter, select the **Enable DOA output** check box.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

#### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Array Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array

- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

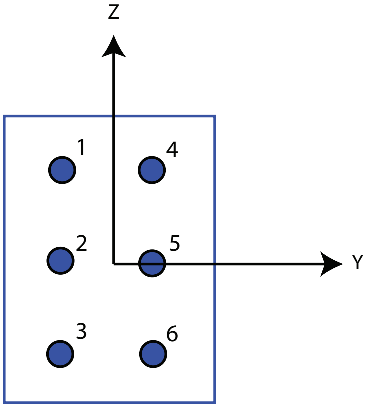
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Dependencies**

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

## See Also

`phased.BeamscanEstimator2D` | `phased.ConformalArray` | `phased.UCA` | `phased.ULA` | `phased.URA`

**Introduced in R2014b**

# Beamspace ESPRIT DOA

Beamspace ESPRIT direction of arrival (DOA) estimator for ULA

## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The Beamspace ESPRIT DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the estimation of signal parameters via rotational invariance technique (ESPRIT) algorithm in beamspace.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of signals**

Specify the number of signals as a positive integer scalar.

**Spatial smoothing**

Specify the amount of averaging, $L$, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N – 2$, where $N$ is the number of sensors.

**Type of least squares method**

Specify the least squares method used for ESPRIT as one of `TLS` or `LS` where `TLS` refers to total least squares and `LS`refers to least squares.

**Beam fan center direction (deg)**

Specify the direction of the center of the beam fan, in degrees, as a real scalar value between –90° and 90°.

**Source of number of beams**

Specify the source of the number of beams as one of `Auto` or `Property`. If you set this parameter to `Auto`, the number of beams equals $N - L$, where $N$ is the number of array elements and $L$ is the value of **Spatial smoothing**.

**Number of beams**

Specify the number of beams as a positive scalar integer. The lower the number of beams, the greater the reduction in computational cost. This parameter appears when you set **Source of number of beams** to `Property`.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

**Specify sensor array as**

Specify a ULA sensor array directly or by using a MATLAB expression.

### Types

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Number of elements**

Specifies the number of elements in the array as an integer.

**Element spacing**

Specify the spacing, in meters, between two adjacent elements in the array.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

### Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

### Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

### Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone’s response pattern in 3-D space from the polar pattern.

### Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Estimated DOA angles. | Double-precision floating point |

**Introduced in R2014b**

# CFAR Detector

Constant false alarm rate (CFAR) detector

X
Idx
CA CFAR
Y

## Library

Detection

`phaseddetectlib`

## Description

The CA CFAR block implements a constant false-alarm rate detector using an estimate of the noise power. The CFAR detector estimates noise power from neighboring cells surrounding the cell under test. There are four methods for estimating noise: cell-averaging (CA), greatest-of cell averaging (GOCA), smallest-of cell averaging (SOCA), and order statistics (OS).

## Parameters

### CFAR algorithm

Specify the CFAR detection algorithm using one of the values

| | |
|---|---|
| `CA` | Cell-averaging |
| `GOCA` | Greatest-of cell averaging |
| `OS` | Order statistic |
| `SOCA` | Smallest-of cell averaging |

**Number of guard cells**

Specify the number of guard cells used in training as an even integer. This parameter specifies the total number of cells on both sides of the cell under test.

**Number of training cells**

Specify the number of training cells used in training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test.

**Rank of order statistic**

This parameter appears when **CFAR algorithm** is set to `OS`. Specify the rank of the order statistic as a positive integer scalar. The value must be less than or equal to the value of **Number of training cells**.

**Threshold factor method**

Specify whether the threshold factor comes from an automatic calculation, the **Custom threshold factor** parameter, or an input argument. Values of this parameter are:

| | |
|---|---|
| `Auto` | The application calculates the threshold factor automatically based on the desired probability of false alarm specified in the **Probability of false alarm** parameter. The calculation assumes each independent signal in the input is a single pulse coming out of a square law detector with no pulse integration. The calculation also assumes the noise is white Gaussian. |
| `Custom` | The **Custom threshold factor** parameter specifies the threshold factor. |
| `Input port` | Threshold factor is set using the input port `K`. This port appears only when **Threshold factor method** is set to `Input port`. |

**Probability of false alarm**

This parameter appears only when you set **Threshold factor method** to `Auto`. Specify the desired probability of false alarm as a scalar between 0 and 1 (not inclusive).

**Custom threshold factor**

This parameter appears only when you set **Threshold factor method** to `Custom`. Specify the custom threshold factor as a positive scalar.

**Output format**

Format of detection results returned in output port `Y`, by the specified as `'CUT result'` or `'Detection index'`.

- When set to `'CUT result'`, the results are logical detection values (`1` or `0`) for each tested cell. `1` indicates that the value of the tested cell exceeds a detection threshold.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells which exceed a detection threshold.

**Output detection threshold**

Select this check box to create an output port `Th` containing the detection threshold.

**Output estimated noise power**

Select this check box to create an output port `N` containing the estimated noise.

**Source of the number of detections**

Source of the number of detections, specified as `Auto` or `Property`. When you select `Auto`, the number of detection indices reported is the total number of cells under test that have detections. If you select `Property`, the number of reported detections is determined by the value of the **Maximum number of detections** parameter.

To enable this parameter, set the **Output format** parameter to `Detection index`.

**Maximum number of detections**

Maximum number of detection indices to report, specified as a positive integer.

To enable this parameter, set the **Output format** parameter to `Detection index` and the **Source of the number of detections** parameter to `Property`.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling.

However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| X | Input cell matrix.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| Idx | Cells under test. | Double-precision floating point |
| K | Threshold factor. | Double-precision floating point |
| N | Noise power. | Double-precision floating point |
|  |  |  |
| Y | Detection results. | Double-precision floating point |

# 2-D CFAR Detector

Two-dimensional constant false alarm rate (CFAR) detector
**Library:** Phased Array System Toolbox / Detection

X
Idx
CA CFAR 2-D
Y

## Description

The 2-D CFAR Detector block implements a constant false-alarm rate detector for two dimensional image data. A detection is declared when an image cell value exceeds a threshold. To maintain a constant false alarm-rate, the threshold is set to a multiple of the image noise power. The detector estimates noise power from neighboring cells surrounding the cell-under-test (CUT) using one of three cell averaging methods, or an order statistics method. The cell-averaging methods are cell-averaging (CA), greatest-of cell averaging (GOCA), or smallest-of cell averaging (SOCA).

For each test cell, the detector:

1. estimates the noise statistic from the cell values in the training band surrounding the CUT cell.
2. computes the threshold by multiplying the noise estimate by the threshold factor.
3. compares the CUT cell value to the threshold to determine whether a target is present or absent. If the value is greater than the threshold, a target is present.

## Ports

### Input

**X — Input image**
real *M*-by-*N* matrix | real *M*-by-*N*-by-*P* array

Input image, specified as a real *M*-by-*N* matrix or real *M*-by-*N*-by-*P* array. *M* and *N* represent the rows and columns of the matrix. Each page is a different 2-D signal.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

### `idx` — Location of test cells

*2*-by-*L* matrix of positive integers

Location of test cells, specified as a *2*-by-*L* matrix of positive integers, where *L* is the number of test cells. Each column of `idx` specifies the row and column index of a CUT cell. The locations of CUT cells are restricted so that their training regions lie completely within the input images.

Data Types: `double`

### K — Detection threshold factor

positive scalar

Threshold factor used to calculate the detection threshold, specified as a positive scalar.

#### Dependencies

To enable this port, set the **Threshold factor method** parameter to `'Input port'`

Data Types: `double`

## Output

### Y — Detection results

logical matrix (default) | real-valued matrix

Detection results, whose format depends on the `Output Format` property

- When `OutputFormat` is `'Cut result'`, `Y` is a *D*-by-*P* matrix containing logical detection results for cells under test. *D* is the length of `cutidx` and *P* is the number of pages of `X`. The rows of `Y` correspond to the rows of `cutidx`. For each row, `Y` contains `1` in a column if there is a detection in the corresponding cell in `X`. Otherwise, `Y` contains a `0`.

- When OutputFormat is Detection index, Y is a *K*-by-*L* matrix containing detections indices. *K* is the number of dimensions of X. *L* is the number of detections found in the input data. When X is a matrix, Y contains the row and column indices of each detection in X in the form [detrow;detcol]. When X is an array, Y contains the row, column, and page indices of each detection in X in the form [detrow;detcol;detpage]. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

Data Types: double

### Th — Computed detection threshold

real-valued matrix

Computed detection threshold for each detected cell, returned as a real-valued matrix. Th has the same dimensions as Y.

- When OutputFormat is 'CUT result', Th returns the detection threshold whenever an element of Y is 1 and NaN whenever an element of Y is 0.
- When OutputFormat is Detection index, th returns a detection threshold for each corresponding detection in Y. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

#### Dependencies

To enable this port, select the **Output detection threshold** checkbox.

Data Types: double

### N — Estimated noise power

real-valued matrix

Estimated noise power for each detected cell, returned as a real-valued matrix. noise has the same dimensions as Y.

- When OutputFormat is 'CUT result', noise returns the noise power whenever an element of Y is 1 and NaN whenever an element of Y is 0.
- When OutputFormat is 'Detection index', noise returns a noise power for each corresponding detection in Y. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

#### Dependencies

To enable this port, select the **Output estimated noise power** checkbox.

Data Types: `double`

## Parameters

### `CFAR algorithm` — Noise power estimation algorithm

`CA` (default) | `GOCA` | `SOCA` | `OS`

Noise power estimation algorithm, specified as `CA`, `GOCA`, `SOCA`, or `OS`. For `CA`, `GOCA`, `SOCA`, the noise power is the sample mean derived from the training band. For `OS`, the noise power is the *k*th cell value obtained from a numerical ordering of all training cell values. Set *k* by the **Rank of order statistic** parameter. See “Training cells” on page 3-90.

| Averaging Method | Description |
|---|---|
| `CA` — Cell-averaging algorithm | Computes the sample mean of all training cells surrounding the CUT cell. |
| `GOCA` — Greatest-of cell-averaging algorithm | Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the largest mean. |
| `SOCA` — Smallest-of cell-averaging algorithm | Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the smallest mean. |
| `OS` — Order statistic algorithm | Sorts training cells in ascending order of numeric values. Then the algorithm selects the *k*th value from the list. *k* is the rank specified by the `Rank` parameter. |

### `Rank of order statistic` — Rank of order statistic

`1` (default) | positive integer

Specify the rank of the order statistic used in the 2-D CFAR algorithm as a positive integer. The value of this parameter must lie between 1 and $N_{train}$, where $N_{train}$ is the number of training cells. A value of 1 selects the smallest value in the training region.

**Dependencies**

To enable this parameter, set the **CFAR Algorithm** parameter to `OS`.

### `Size in cells of the guard region band` — Widths of guard band

`[1,1]` (default) | nonnegative integer scalar | 2-element vector of positive integers

The number of row and column guard cells on each side of the cell under test as nonnegative integers. The first element specifies the guard band size along the row dimension. The second element specifies the guard band size along the row dimension. Specifying **Size in cells of the guard region band** as a scalar is equivalent to specifying a vector with the same value for both dimensions. For example, a value of `[1 1]`, indicates that there is a one-guard-cell-wide region surrounding each CUT cell.

### `Size in cells of the training region band` — Widths of training band

`[1,1]` (default) | nonnegative integer scalar | 2-element vector of positive integers

Size in cells of the training region band, specified as a nonnegative integer or 1-by-2 matrix of nonnegative integers. The first element specifies the training band size along the row dimension, and the second along the column dimension. Specifying **Size in cells of the training region band** as a scalar is equivalent to specifying a vector with the same value for both dimensions. For example, a value of `[1 1]` indicates that there is a one-training-cell-wide region surrounding the guard region for each cell under test.

### `Threshold factor method` — Method to determine threshold factor

`Auto` (default) | `Input port` | `Custom`

Method to determine threshold factor, specified as `Auto`, `Input port`, or `Custom`.

- When you choose `Auto`, the threshold factor is determined from the estimated noise statistic and the probability of false alarm.
- When you choose `Input Port`, set the threshold factor using the `K` input port.
- When you choose `Custom`, set the threshold factor using the **Custom threshold factor** parameter.

### `Custom threshold factor` — Custom threshold factor

`1` (default) | positive scalar

Custom threshold factor, specified as a positive scalar.

#### Dependencies

To enable this parameter, set the **Threshold factor method** parameter to `Custom`.

### `Probability of false alarm` — Probability of false alarm

`0.1` (default) | real scalar between 0 and 1

Probability of false alarm, specified as a real scalar between 0 and 1. You can calculate the threshold factor from the required probability of false alarm.

#### Dependencies

To enable this parameter, set the **Threshold factor method** property to `Auto`.

### `OutputFormat` — Format of detection results

`CUT result` (default) | `Detection index`

Format of detection results, specified as `CUT result` or `Detection index`.

- When set to `'CUT result'`, the detection results are logical detection values (`1` or `0`) for each tested cell.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells that exceed a detection threshold.

### `Output threshold detection` — Enable detection threshold output

off (default) | on

Select this check box to enable the output of detection thresholds via the `Th` output port.

### `Output estimated noise power` — Enable detection threshold output

off (default) | on

Select this check box to enable the output of estimated noise power via the `N` output port.

### `Source of the number of detections` — Source of the number of detections to report

`Auto` (default) | `Property`

Source of the number of detections, specified as `Auto` or `Property`. When you select `Auto`, the number of detection indices reported is the total number of cells under test that have detections. If you select `Property`, the number of reported detections is determined by the value of the **Maximum number of detections** parameter.

**Dependencies**

To enable this parameter, set the **Output format** parameter to `Detection index`.

Data Types: `char`

### `Maximum number of detections` — Maximum number of detection indices to report

`1` (default) | positive integer

Maximum number of detection indices to report, specified as a positive integer.

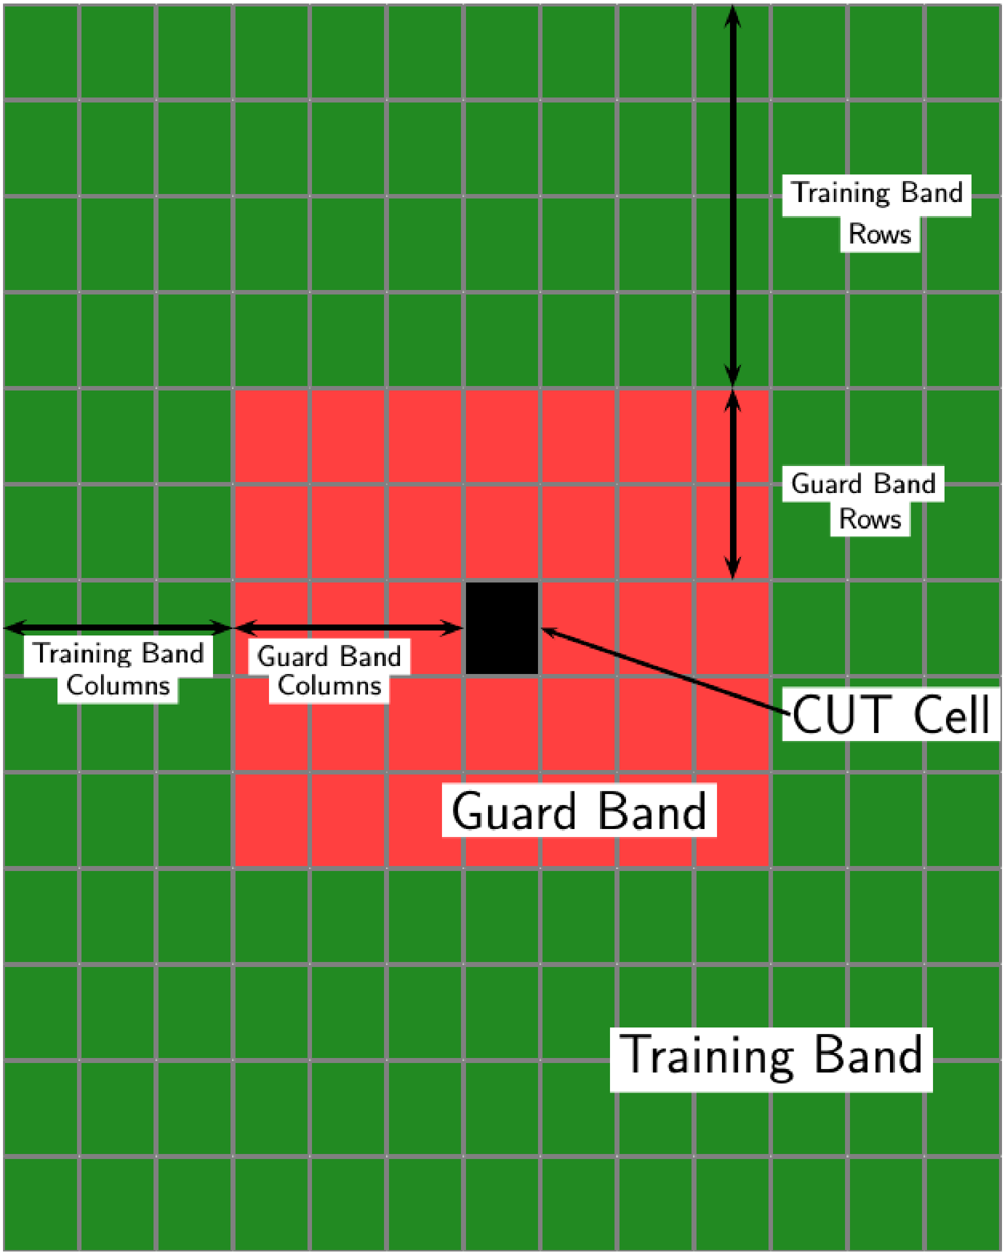
**Dependencies**

To enable this parameter, set the **Output format** parameter to `Detection index` and the **Source of the number of detections** parameter to `Property`.

Data Types: `double`

## Algorithms

CFAR 2-D requires an estimate of the noise power. Noise power is computed from cells that are assumed not to contain any target signal. These cells are the training cells. Training cells form a band around the cell-under-test (CUT) cell but may be separated from the CUT cell by a guard band. The detection threshold is computed by multiplying the noise power by the threshold factor.



Training Band
Rows
Guard Band
Rows
Training Band
Columns
Guard Band
Columns
CUT Cell
Guard Band
Training Band

For GOCA and SOCA averaging, the noise power is derived from the mean value of one of the left or right halves of the training cell region.

Because the number of columns in the training region is odd, the cells in the middle column are assigned equally to either the left or right half.

When using the order-statistic method, the rank cannot be larger than the number of cells in the training cell region, $N_{train}$. You can compute $N_{train}$.

- $N_{TC}$ is the number of training band columns.
- $N_{TR}$ is the number of training band rows.
- $N_{GC}$ is the number of guard band columns.
- $N_{GR}$ is the number of guard band rows.

The total number of cells in the combined training region, guard region, and CUT cell is $N_{total} = (2N_{TC} + 2N_{GC} + 1)(2N_{TR}+ 2N_{GR} + 1)$.

The total number of cells in the combined guard region and CUT cell is $N_{guard} = (2N_{GC} + 1)(2N_{GR} + 1)$.

The number of training cells is $N_{train} = N_{total} - N_{guard}$.

By construction, the number of training cells is always even. Therefore, to implement a median filter, you can choose a rank of $N_{train}/2$ or $N_{train}/2 + 1$.

Clusters

## Description

Cluster data using the density-based spatial clustering of applications with noise (DBSCAN) algorithm. The DBSCAN Clusterer block can cluster any type of data. The block can also solve for the threshold parameter (epsilon) and can perform data disambiguation in two dimensions.

## Ports

### Input

**X — Input data**
*N*-by-*P* real-valued matrix

Input data, specified as a real-valued *N*-by-*P* matrix, where *N* is the number of data points to cluster. *P* is the number of feature dimensions. The DBSCAN algorithm can cluster any type of data with appropriate **Minimum number of points in a cluster** and **Cluster threshold epsilon** settings.

Data Types: `double`

**`Update` — Enable automatic update of epsilon**
`false` (default) | `true`

Enable automatic update of the epsilon estimate, specified as `false` or `true`.

- When `true`, the epsilon threshold is first estimated as the average of the knees of the *k*-*NN* search curves. The estimate is then added to a buffer of size *L*, set by the **Length of cluster threshold epsilon history** parameter. The final value of epsilon is calculated as the average of the *L*-length epsilon history buffer. If **Length of cluster**

**threshold epsilon history** is set to one, the estimate is memory-less. Memory-less means that each epsilon estimate is immediately used and no moving-average smoothing occurs.

- When `false`, a previous epsilon estimate is used. Estimating epsilon is computationally intensive and not recommended for large data sets.

#### Dependencies

To enable this port, set the **Source of cluster threshold epsilon** parameter to `Auto` and set the **Maximum number of points for 'Auto' epsilon** parameter.

Data Types: `Boolean`

### `AmbLims` — Ambiguity limits

1-by-2 real-valued vector (default) | 2-by-2 real-valued matrix

Ambiguity limits, specified as a 1-by-2 real-valued vector or 2-by-2 real-valued matrix. For a single ambiguity dimension, specify the limits as a 1-by-2 vector *[MinAmbiguityLimitDimension1,MaxAmbiguityLimitDimension1]*. For two ambiguity dimensions, specify the limits as a 2-by-2 matrix *[MinAmbiguityLimitDimension1, MaxAmbiguityLimitDimension1; MinAmbiguityLimitDimension2,MaxAmbiguityLimitDimension2]*.

Clustering can occur across boundaries to ensure that ambiguous detections are appropriately clustered for up to two dimensions. The ambiguous columns of the input port data X are defined using the **Indices of ambiguous dimensions** parameter. The **AmbLims** parameter defines the minimum and maximum ambiguity limits in the same units as used in the **Indices of ambiguous dimensions** columns of the input data X.

#### Dependencies

To enable this port, select the **Enable disambiguation of dimensions** check box.

Data Types: `double`

## Output

### `Idx` — Cluster indices

*N*-by-1 integer-valued column vector

Cluster indices, returned as an *N*-by-1 integer-valued column vector. Cluster IDs represent the clustering results of the DBSCAN algorithm. A value equal to '-1' implies a

DBSCAN noise point. Positive `Idx` values correspond to clusters that satisfy the DBSCAN clustering criteria.

**Dependencies**

To enable this port, set the **Define outputs for Simulink block** parameter to `Index` or `Index and ID`.

Data Types: `double`

### `Clusters` — Alternative cluster IDs

1-by-*N* integer-valued row vector

Alternative cluster IDs, returned as a 1-by-*N* row vector of positive integers. Each value is a unique identifier indicating a hypothetical target cluster. This argument contains unique positive cluster IDs for all points including noise. In contrast, the `Idx` output argument labels noise points with '–1'. Use this output as input to Phased Array System Toolbox blocks such as Range Estimator and Doppler Estimator.

**Dependencies**

To enable this port, set the **Define outputs for Simulink block** parameter to `Cluster ID` or `Index and ID`.

Data Types: `double`

## Parameters

### `Define outputs for Simulink block` — Type of cluster data output

`Index and ID` (default) | `Cluster ID` | `Index`

Type of cluster data output, specified as:.

- `Index and ID` -- Enables the `Idx` and `Clusters` output ports.
- `Cluster ID` -- Enables the `Clusters` output port only.
- `Index` -- Enables the `Idx` output port only.

### `Source of cluster threshold epsilon` — Epsilon source

`Property` (default) | `Auto`

Epsilon source for cluster threshold:

- `Property` — Epsilon is obtained from the **Cluster threshold epsilon** parameter.
- `Auto` — Epsilon is estimated automatically using a k-nearest neighbor (*k*-NN) search. The search is calculated with *k* ranging from one less than the value of **Minimum number of points in a cluster** to one less than the value of **Maximum number of points for 'Auto' epsilon**. The subtraction of one is needed because the neighborhood of a point includes the point itself.

### `Cluster threshold epsilon` — Cluster neighborhood size

`10.0` (default) | positive scalar | positive real-valued 1-by-*P* row vector

Cluster neighborhood size for a search query, specified as a positive scalar or real-valued 1-by-*P* row vector. *P* is the number of clustering dimensions in the input data `X`.

Epsilon defines the radius around a point inside which to count the number of detections. When epsilon is a scalar, the same value applies to all clustering feature dimensions. You can specify different epsilon values for different clustering dimensions by specifying a real-valued 1-by-*P* row vector. Using a row vector creates a multi-dimensional ellipse search area, which is useful when the data columns have different physical meanings such as range and Doppler.

### `Minimum number of points in a cluster` — Minimum number of points required for cluster

`3` (default) | positive integer

Minimum number of points required for a cluster, specified as a positive integer. This parameter defines the minimum number of points in a cluster when determining whether a point is a core point.

### `Maximum number of points for 'Auto' epsilon` — Maximum number of points required for cluster

`10` (default) | positive integer

Maximum number of points in a cluster, specified as a positive integer. This property is used to estimate epsilon when the object performs a *k*-NN search.

#### Dependencies

To enable this parameter, set the **Source of cluster threshold epsilon** parameter to `Auto`.

### `Length of cluster threshold epsilon history` — Length of cluster threshold epsilon history

`10` (default) | positive integer

Length of the stored cluster threshold epsilon history, specified as a positive integer. When set to one, the history is memory-less. Then, each epsilon estimate is immediately used and no moving-average smoothing occurs. When greater than one, the epsilon value is averaged over the history length specified.

Example: `5`

Data Types: `double`

### `Enable disambiguation of dimensions` — Turn on disambiguation

`off` (default) | `on`

Check box to enable disambiguation of dimensions, specified as `false` or `true`. When checked, clustering occurs across boundaries defined by the values in the input port `AmbLims` at execution. Ambiguous detections are appropriately clustered. Use the **Indices of ambiguous dimensions** parameter to specify those column indices of `X` in which ambiguities can occur. Up to two ambiguous dimensions are permitted. Turning on disambiguation is not recommended for large data sets.

Data Types: `Boolean`

### `Indices of ambiguous dimensions` — Indices of ambiguous dimensions

`1` (default) | positive integer | 1-by-2 vector of positive integers

Indices of ambiguous dimensions, specified as a positive integer or 1-by-2 vector of positive integers. This property specifies the column indices of the input port data `X` in which disambiguation can occur. A positive integer corresponds to a single ambiguous dimension in the input data matrix `X`. A 1-by-2 length row vector of indices corresponds to two ambiguous dimensions. The size and order of **Indices of ambiguous dimensions** must be consistent with the `AmbLims` input port value.

Example: `[3 4]`

#### Dependencies

To enable this parameter, select the **Enable disambiguation of dimensions** check box.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

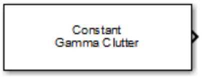
**Introduced in R2019b**

# Constant Gamma Clutter

Constant gamma clutter simulation

**Library:** Phased Array System Toolbox / Environment and Target



## Description

The Constant Gamma Clutter block generates constant gamma clutter reflected from homogeneous terrain for a monostatic radar transmitting a narrowband signal into free space. The radar is assumed to be at constant altitude moving at constant speed.

## Ports

### Input

**PRFIdx — PRF Index**

positive integer

Index to select the pulse repetition frequency (PRF), specified as a positive integer. The index selects the PRF from the predefined vector of values specified by the **Pulse repetition frequency (Hz)** parameter.

Example: 4

**Dependencies**

To enable this port, select **Enable PRF selection input**.

Data Types: `double`

**WS — Subarray element weights**

$N_E$-by-$N_S$ complex-valued matrix

Weights applied to each element in a subarray, specified as an $N_E$-by-$N_S$ complex-valued matrix.

- When you set **Specify sensor array** to `Replicated Subarray`, all subarrays have the same dimensions. Then, you can specify the subarray element weights as a complex-valued $N_{\mathrm{E}}$-by-$N_{\mathrm{S}}$ matrix. $N_E$ is the number of elements in each subarray and $N_{\mathrm{S}}$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray.
- When you set **Specify sensor array** to `Partitioned array`, subarrays are not required to have identical dimensions and sizes. You can specify subarray element weights as a complex-valued $N_{\mathrm{E}}$-by-$N_{\mathrm{S}}$ matrix, where $N_{\mathrm{E}}$ now is the number of elements in the largest subarray. The first $K$ entries in each column are the element weights for the corresponding subarray where $K$ is the number of elements in the subarray.

#### Dependencies

To enable this port, set **Specify sensor array** to `Partitioned array` or `Replicated Subarray`. Then, set **Subarray steering method** to `Custom`.

Data Types: `double`

### `Steer` — Steering angle input

scalar | 2-by-1 real-valued vector

Steering angle, specified as a scalar or a 2-by-1 real-valued vector. As a vector, the steering angle takes the form of `[AzimuthAngle; ElevationAngle]`. As a scalar, the steering angle represents the azimuth angle only. Then the elevation angle is assumed to be zero degrees. Units are in degrees

#### Dependencies

To enable this port, set **Specify sensor array** to `Partitioned array` or `Replicated Subarray`. Then, set **Subarray steering method** to `Phase` or `Time`.

Data Types: `double`

## Output

### `Out` — Simulated clutter

$N$-by-$M$ complex-valued matrix

Simulated clutter, returned as an $N$-by-$M$ complex-valued matrix.

$N$ is the number of samples output from the block. When you set the **Output signal format** parameter to `Samples`, specify $N$ using the **Number of samples in output** parameter. When you set the **Output signal format** parameter to `Pulses`, *N* is the total number of samples in the next *P* pulses where *P* is specified in the **Number of pulse in output** parameter.

*M* is either

- the number of subarrays in the sensor array if sensor array contains subarrays.
- the number of radiating or collecting elements if the sensor array does not contain subarrays.

Data Types: `double`

# Parameters

## Main Tab

### `Terrain gamma value (dB)` — Clutter model parameter

`0` (default) | scalar

Clutter model parameter, specified as a scalar. This parameter contains the $\gamma$ value used in the constant $\gamma$ clutter model. The $\gamma$ value depends on both terrain type and the operating frequency. Units are in dB.

Example: `-5.0`

Data Types: `double`

### `Earth model` — Earth shape

`Flat` (default) | `Curved`

Specify the earth model used in clutter simulation as `Flat` or `Curved`. When you set this parameter to `Flat`, the earth is assumed to be a plane. When you set this parameter to `Curved`, the earth is assumed to be spherical.

### `Maximum range (m)` — Maximum range of transmitted clutter

`5000` (default) | positive scalar

Specify the maximum range for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the **Radar height (m)** parameter in the **Radar** panel. Units are in meters.

Example: `1000.0`

Data Types: `double`

**`Azimuth coverage (deg)` — Angular clutter coverage**
`60` (default) | positive scalar

Azimuth coverage, specified as a positive scalar. The clutter simulation covers a region having the specified azimuth span centered on zero-degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but by setting the **Clutter patch azimuth span (deg)** value, you can cause some patches to extend beyond the region. Units are in degrees.

Example: `40`

Data Types: `double`

**`Clutter patch azimuth span (deg)` — Azimuth span of clutter patches**
`60` (default) | positive scalar

Azimuth span of each clutter patch, specified as a positive scalar. Units are in degrees.

Example: `10`

Data Types: `double`

**`Clutter coherence time (s)` — Coherence time of clutter simulation**
`Inf` (default) | positive scalar

Coherence time for the clutter simulation, specified as a positive scalar. After the coherence time elapses, the block updates the random numbers it uses for the clutter simulation at the next pulse. When you use the default value of `Inf`, the random numbers are never updated. Units are in seconds.

Example: `4`

Data Types: `double`

**`Signal propagation speed (m/s)` — Signal propagation speed**
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Sample rate (Hz)` — Clutter sample rate

`1e6` (default) | positive scalar

Clutter sample rate, specified as a positive scalar. Units are in Hertz.

Example: `10e6`

Data Types: `double`

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar | row vector of positive values

Pulse repetition frequency, PRF, specified as a positive scalar or a row vector of positive values. Units are in Hertz.

Example: `[1e4,2e4]`

Data Types: `double`

### `Enable PRF selection input` — Select predefined PRF

off (default) | on

Select this parameter to enable the `PRFIdx` port.

- When enabled, pass in an index into a vector of predefined PRFs. Set predefined PRFs using the **Pulse repetition frequency (Hz)** parameter.
- When not enabled, the block cycles through the vector of PRFs specified by the **Pulse repetition frequency (Hz)** parameter. If **Pulse repetition frequency (Hz)** is a scalar, the PRF is constant.

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### `Number of pulses in output` — Number of pulses in output

`1` (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: `2`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Pulses`.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Radar Tab

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Effective transmitted power (W)` — radar system effective transmitted power

`5000` (default) | positive scalar

Effective radiated power (ERP) of the radar system, specified as a positive scalar. Units are in watts.

Example: `3500`

Data Types: `double`

**`Radar height (m)` — Height of radar above surface**
`0` (default) | nonnegative scalar

Height of radar above surface, specified as a nonnegative scalar. Units are in meters.

Example: `50`

Data Types: `double`

**`Radar speed (m/s)` — Radar platform speed**
`0` (default) | nonnegative scalar

Radar platform speed, specified as a nonnegative scalar. Units are in meters per second.

Example: `5`

Data Types: `double`

**`Radar motion direction (deg)` — Direction of motion of radar platform**
`[90;0]` (default) | 2-by-1 real vector

Specify the direction of radar platform motion as a 2-by-1 real vector in the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees. Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180° and 180°. Elevation angle must be between –90° and 90°.

The default value of this parameter indicates that the radar platform is moving perpendicular to the radar antenna array broadside direction.

Example: `[25;30]`

Data Types: `double`

**`Broadside depression angle (deg)` — Depression angle of antenna array**
`0` (default) | scalar

Depression angle of the radar antenna array with respect to broadside, specified as a scalar. Broadside is defined as zero-degrees azimuth and zero-degrees elevation. The depression angle is measured downward from the horizontal. Units are in degrees.

Example: `-10`

Data Types: `double`

## Sensor Array Tab

### Specify sensor array as — Method to specify array

Array (no subarrays) (default) | Partitioned array | Replicated subarray | MATLAB expression

Method to specify array, specified as Array (no subarrays) or MATLAB expression.

- Array (no subarrays) — use the block parameters to specify the array.
- Partitioned array — use the block parameters to specify the array.
- Replicated subarray — use the block parameters to specify the array.
- MATLAB expression — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: phased.URA('Size',[5,3])

#### Dependencies

To enable this parameter, set **Specify sensor array as** to MATLAB expression.

#### Element Parameters

### Element type — Array element types

Isotropic Antenna (default) | Cosine Antenna | Custom Antenna | Omni Microphone | Custom Microphone

Antenna or microphone type, specified as one of the following:

- Isotropic Antenna
- Cosine Antenna
- Custom Antenna
- Omni Microphone
- Custom Microphone

### Operating frequency range (Hz) — Operating frequency range of the antenna or microphone element

[0,1.0e20] (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form [LowerBound,UpperBound]. The element has no response outside this frequency range. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to Isotropic Antenna, Cosine Antenna, or Omni Microphone.

### Operating frequency vector (Hz) — Operating frequency range of custom antenna or microphone elements

[0,1.0e20] (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to Custom Antenna or Custom Microphone. Use **Frequency responses (dB)** to set the responses at these frequencies.

### Baffle the back of the element — Set back response of an Isotropic Antenna element or an Omni Microphone element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

**Dependencies**

To enable this check box, set **Element type** to Isotropic Antenna or Omni Microphone.

### Exponent of cosine pattern — Exponents of azimuth and elevation cosine patterns

[1.5 1.5] (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- ULA — Uniform linear array
- URA — Uniform rectangular array
- UCA — Uniform circular array
- Conformal Array — arbitrary element positions

### Number of elements — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to ULA or UCA.

### Element spacing (m) — Spacing between array elements

0.5 for ULA arrays and [0.5,0.5] for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form [SpacingBetweenArrayRows,SpacingBetweenArrayColumns].
- When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

### Array axis — Linear axis direction of ULA

y (default) | x | z

Linear axis direction of ULA, specified as y, x, or z. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

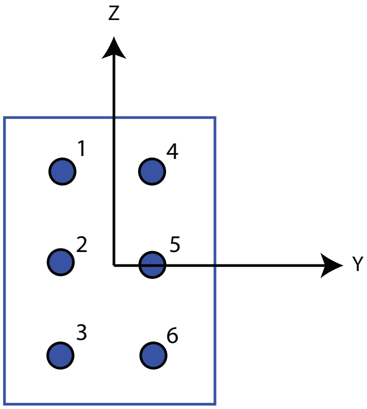
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

**Dependencies**

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

**Dependencies**

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

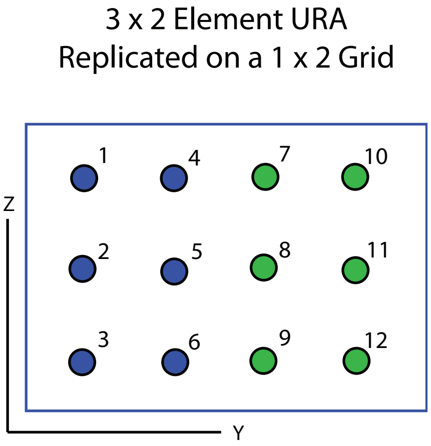
To enable this parameter, set **Sensor array** to `Replicated subarray`

### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

## See Also

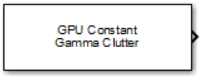
`phased.ConstantGammaClutter`

**Introduced in R2014b**

# GPU Constant Gamma Clutter

Constant gamma clutter simulation using gpu

**Library:** Phased Array System Toolbox / Environment and Target



## Description

The GPU Constant Gamma Clutter block generates, using a graphical processing unit (GPU), constant gamma clutter reflected from a homogeneous terrain for a monostatic radar transmitting a narrowband signal into free space. The radar is assumed to be at a constant altitude moving at a constant speed.

## Ports

### Input

**`PRFIdx` — PRF Index**
positive integer

Index to select the pulse repetition frequency (PRF), specified as a positive integer. The index selects the PRF from the predefined vector of values specified by the **Pulse repetition frequency (Hz)** parameter.

Example: 4

**Dependencies**

To enable this port, select **Enable PRF selection input**.

Data Types: `double`

**`WS` — Subarray element weights**
$N_E$-by-$N_S$ complex-valued matrix

Weights applied to each element in a subarray, specified as an $N_E$-by-$N_S$ complex-valued matrix.

- When you set **Specify sensor array** to `Replicated Subarray`, all subarrays have the same dimensions. Then, you can specify the subarray element weights as a complex-valued $N_E$-by-$N_S$ matrix. $N_E$ is the number of elements in each subarray and $N_S$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray.
- When you set **Specify sensor array** to `Partitioned array`, subarrays are not required to have identical dimensions and sizes. You can specify subarray element weights as a complex-valued $N_E$-by-$N_S$ matrix, where $N_E$ now is the number of elements in the largest subarray. The first *K* entries in each column are the element weights for the corresponding subarray where *K* is the number of elements in the subarray.

#### Dependencies

To enable this port, set **Specify sensor array** to `Partitioned array` or `Replicated Subarray`. Then, set **Subarray steering method** to `Custom`.

Data Types: `double`

### `Steer` — Steering angle input

scalar | 2-by-1 real-valued vector

Steering angle, specified as a scalar or a 2-by-1 real-valued vector. As a vector, the steering angle takes the form of `[AzimuthAngle; ElevationAngle]`. As a scalar, the steering angle represents the azimuth angle only. Then the elevation angle is assumed to be zero degrees. Units are in degrees

#### Dependencies

To enable this port, set **Specify sensor array** to `Partitioned array` or `Replicated Subarray`. Then, set **Subarray steering method** to `Phase` or `Time`.

Data Types: `double`

## Output

### `Out` — Simulated clutter

*N*-by-*M* complex-valued matrix

Simulated clutter, returned as an *N*-by-*M* complex-valued matrix.

*N* is the number of samples output from the block. When you set the **Output signal format** parameter to `Samples`, specify *N* using the **Number of samples in output** parameter. When you set the **Output signal format** parameter to `Pulses`, *N* is the total number of samples in the next *P* pulses where *P* is specified in the **Number of pulse in output** parameter.

*M* is either

- the number of subarrays in the sensor array if sensor array contains subarrays.
- the number of radiating or collecting elements if the sensor array does not contain subarrays.

Data Types: `double`

# Parameters

## Main Tab

### `Terrain gamma value (dB)` — Clutter model parameter

`0` (default) | scalar

Clutter model parameter, specified as a scalar. This parameter contains the $\gamma$ value used in the constant $\gamma$ clutter model. The $\gamma$ value depends on both terrain type and the operating frequency. Units are in dB.

Example: `-5.0`

Data Types: `double`

### `Earth model` — Earth shape

`Flat` (default) | `Curved`

Specify the earth model used in clutter simulation as `Flat` or `Curved`. When you set this parameter to `Flat`, the earth is assumed to be a plane. When you set this parameter to `Curved`, the earth is assumed to be spherical.

### `Maximum range (m)` — Maximum range of transmitted clutter

`5000` (default) | positive scalar

Specify the maximum range for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the **Radar height (m)** parameter in the **Radar** panel. Units are in meters.

Example: `1000.0`

Data Types: `double`

### `Azimuth coverage (deg)` — Angular clutter coverage

`60` (default) | positive scalar

Azimuth coverage, specified as a positive scalar. The clutter simulation covers a region having the specified azimuth span centered on zero-degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but by setting the **Clutter patch azimuth span (deg)** value, you can cause some patches to extend beyond the region. Units are in degrees.

Example: `40`

Data Types: `double`

### `Clutter patch azimuth span (deg)` — Azimuth span of clutter patches

`60` (default) | positive scalar

Azimuth span of each clutter patch, specified as a positive scalar. Units are in degrees.

Example: `10`

Data Types: `double`

### `Clutter coherence time (s)` — Coherence time of clutter simulation

`Inf` (default) | positive scalar

Coherence time for the clutter simulation, specified as a positive scalar. After the coherence time elapses, the block updates the random numbers it uses for the clutter simulation at the next pulse. When you use the default value of `Inf`, the random numbers are never updated. Units are in seconds.

Example: `4`

Data Types: `double`

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Sample rate (Hz)` — Clutter sample rate

`1e6` (default) | positive scalar

Clutter sample rate, specified as a positive scalar. Units are in Hertz.

Example: `10e6`

Data Types: `double`

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar | row vector of positive values

Pulse repetition frequency, PRF, specified as a positive scalar or a row vector of positive values. Units are in Hertz.

Example: `[1e4,2e4]`

Data Types: `double`

### `Enable PRF selection input` — Select predefined PRF

off (default) | on

Select this parameter to enable the `PRFIdx` port.

- When enabled, pass in an index into a vector of predefined PRFs. Set predefined PRFs using the **Pulse repetition frequency (Hz)** parameter.
- When not enabled, the block cycles through the vector of PRFs specified by the **Pulse repetition frequency (Hz)** parameter. If **Pulse repetition frequency (Hz)** is a scalar, the PRF is constant.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### `Number of pulses in output` — Number of pulses in output

`1` (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: 2

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Pulses`.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

### Radar Tab

#### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

#### `Effective transmitted power (W)` — radar system effective transmitted power

`5000` (default) | positive scalar

Effective radiated power (ERP) of the radar system, specified as a positive scalar. Units are in watts.

Example: `3500`

Data Types: `double`

#### `Radar height (m)` — Height of radar above surface

`0` (default) | nonnegative scalar

Height of radar above surface, specified as a nonnegative scalar. Units are in meters.

Example: `50`

Data Types: `double`

### `Radar speed (m/s)` — Radar platform speed

`0` (default) | nonnegative scalar

Radar platform speed, specified as a nonnegative scalar. Units are in meters per second.

Example: `5`

Data Types: `double`

### `Radar motion direction (deg)` — Direction of motion of radar platform

`[90;0]` (default) | 2-by-1 real vector

Specify the direction of radar platform motion as a 2-by-1 real vector in the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees. Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180° and 180°. Elevation angle must be between –90° and 90°.

The default value of this parameter indicates that the radar platform is moving perpendicular to the radar antenna array broadside direction.

Example: `[25;30]`

Data Types: `double`

### `Broadside depression angle (deg)` — Depression angle of antenna array

`0` (default) | scalar

Depression angle of the radar antenna array with respect to broadside, specified as a scalar. Broadside is defined as zero-degrees azimuth and zero-degrees elevation. The depression angle is measured downward from the horizontal. Units are in degrees.

Example: `-10`

Data Types: `double`

## Sensor Array Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### Element type — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### Operating frequency range (Hz) — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

**Dependencies**

To enable this parameter, set **Element type** to `Cosine Antenna`.

**`Frequency responses (dB)` — Antenna and microphone frequency response**
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

**`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern**
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

**`Elevation angles (deg)` — Elevation angles of antenna radiation pattern**
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

**`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern**
`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation**

**angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Dependencies**

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

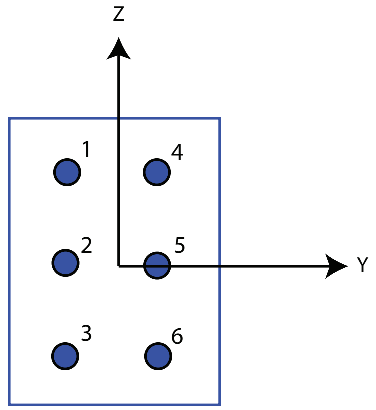
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Dependencies**

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.

- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

**Dependencies**

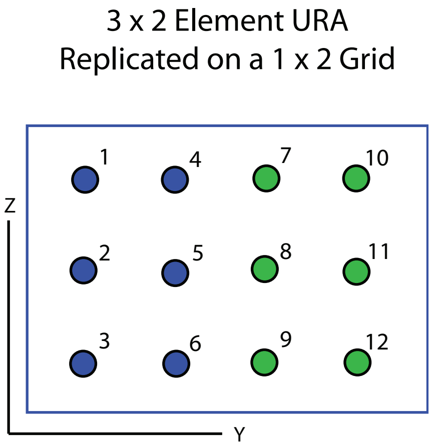
To enable this parameter, set **Sensor array** to `Replicated subarray`

### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The

transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

# Data Cube Slicer

Slice a data cube along specified dimensions

X
Angle-Doppler Slicer
Idx

## Library

Space-Time Adaptive Processing

`phasedstaplib`

## Description

The Data Cube Slicer block slices a data cube along the specified dimensions. The input is a data cube of dimensions *M*-by-*Q*-by-*N*. The first dimension is range, or fast time. The second dimension is angle, or channels. The third dimension is Doppler, or slow time. If you set **Output Slice** to `Angle-Doppler`, the output has dimension *Q*-by-*N*. If you set **Output Slice** to `Range-Doppler`, the output has dimension *M*-by-*N*. If you set **Output Slice** to `Range-angle`, the output has dimension *M*-by-*Q*.

## Parameters

**Output slice**

Select desired output for a *M*-by-*Q*-by-*N* data cube. Parameter values are

| Value | Dimension |
|---|---|
| `Angle-Doppler` | *Q*-by-*N* |
| `Range-Doppler` | *M*-by-*N* |
| `Range-angle` | *M*-by-*Q* |

## Ports

| Port | Supported Data Types |
|---|---|
| `X` | Double-precision floating point |
| `Idx` | Double-precision floating point |
| `Out` | Double-precision floating point |

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

**Introduced in R2014b**

# Dechirp Mixer

Dechirping operation on input signal

RefX
Dechirp
X

## Library

Detection

`phaseddetectlib`

## Description

The Dechirp Mixer block mixes the incoming signal with a reference signal incoming through the `Ref` port. The signals can be complex baseband signals. The input signal can be a matrix where each column is an independent channel. The reference signal is a vector. The reference signal is complex conjugated and then multiplied with each signal column to compute the output.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Supported Data Types |
|---|---|
| `X` | Double-precision floating point |
| `RefX` | Double-precision floating point |

| Port | Supported Data Types |
|---|---|
| `Out` | Double-precision floating point |

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

Does not support variable-size inputs.

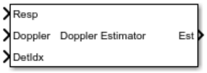
# Doppler Estimator

Doppler estimation
**Library:** Phased Array System Toolbox / Detection



## Description

The Doppler Estimator block estimates the Doppler (radial speed) of target detections obtained from the radar response data.

## Ports

### Input

**`Resp` — Doppler-processed response data cube**
complex-valued *P*-by-1 column vector | complex-valued *M*-by-*P* matrix | complex-valued *M*-by-*N*-by-*P* array

Doppler-processed response data cube, specified as a complex-valued *P*-by-1 column vector, a complex-valued *M*-by-*P* matrix, or a complex-valued *M*-by-*N*-by-*P* array.*M* represents the number of range samples, *N* is the number of sensor elements or beams, and *P* is the number of Doppler bins.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**`Doppler` — Doppler grid values along Doppler dimension**
real-valued *P*-by-1 column vector

Doppler grid values along the Doppler dimension, specified as a real-valued *P*-by-1 column vector. `Doppler` defines the Doppler values corresponding to the Doppler dimension of data input to the **Resp** port. Doppler values must be monotonically increasing and equally spaced. Units are in hertz or meters/sec.

Example: `[-0.3,-0.2,-0.1,0,0.1,0.2,0.3]`

Data Types: `double`

### `DetIdx` — Detection indices

real-valued $N_d$-by-$Q$ matrix

Detection indices, specified as a real-valued $N_d$-by-$Q$ matrix. $Q$ is the number of detections and $N_d$ is the number of dimensions in the response data cube, **Resp**. Each column of **DetIdx** contains the indices of a detection in the response data cube.

### `NoisePower` — Noise power at detection locations

positive scalar | real-valued 1-by-$Q$ row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-$Q$ row vector positive values. $Q$ is the number of detections specified in the **DetIdx** input port.

#### Dependencies

To enable this port, select the **Output variance for parameter estimates** parameter, and then set **Source of noise power parameter** to `Input port`.

### `Clusters` — Cluster IDs

real-valued 1-by-$Q$ row vector of positive values

Cluster IDs, specified as a real-valued 1-by-$Q$ row vector, where $Q$ is the number of detections specified in the **DetIdx** input port. Each element of **Clusters** corresponds to an element of **DetIdx**.

#### Dependencies

To enable this input port, select the **Enable cluster ID input** checkbox.

## Output

### `Est` — Doppler estimate

real-valued $K$-by-1 column vector

Doppler estimates, returned as a real-valued $K$-by-1 column vector.

- When **Enable cluster ID input** is not selected, each Doppler estimate corresponds to one of the columns in the **DetIdx** input port. Then *K* equals the number of elements, *Q*, of **DetIdx**.
- When **Enable cluster ID input** is selected, each Doppler estimate corresponds to one of the cluster IDs in the **Clusters**input port. Then *K* equals the number of unique cluster IDs.

#### `Var` — Doppler estimation variance

positive, real-valued *K*-by-1 column vector

Doppler estimation variance, returned as a positive, real-valued *K*-by-1 column vector, where *K* is the dimension of **Est**. Each element of **Var** corresponds to an element of **Est**. The estimator variance is computed using the Ziv-Zakai bound.

##### Dependencies

To enable this port, select the **Output variance for parameter estimates** parameter.

## Parameters

#### `Maximum number of estimates` — Maximum number of estimates to report

`1` (default) | positive integer

The maximum number of estimates to report, specified as a positive integer. When the number of requested estimates is greater than the number elements in **DetIdx**, the remainder is filled with `NaN`.

Data Types: `double`

#### `Enable cluster ID input` — Enable cluster ID input

`off` (default) | `on`

Enable the **Cluster** input port to pass in cluster association information.

Data Types: `Boolean`

#### `Output variance for parameter estimates` — Enable output variance port

`off` (default) | `on`

Enables the output of the parameter estimate variances via the **Var** port.

Data Types: `Boolean`

### Number of pulses in Doppler processed waveform — Number of pulses

2 (default) | positive integer

Number of pulses in Doppler processed waveform, specified as a positive integer.

#### Dependencies

To enable this parameter, select the **Output variance for parameter estimates** `Output variance for parameter estimates` parameter.

Data Types: `double`

### Source of noise power — Source of noise power values

`Property` (default) | `Input port`

Source of the noise power, specified as `Property` or `Input port`. If you set this parameter to `Property`, use the **Noise power** parameter to set the noise power at the detection locations. When set the parameter to `Input port`, specify noise power via the `NoisePower` input port.

### Noise power — Noise power values

`1.0` (default) | positive scalar

Noise power for detections, specified as a positive scalar. The same noise power value is applied to all detections. Noise power is in linear units.

#### Dependencies

To enable this parameter, select the **Output variance for parameter estimates** checkbox and set the **Source of noise power** parameter to `Property`.

Data Types: `double`

### Simulate using — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code`

`Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

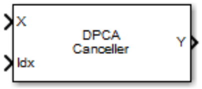
# DPCA Canceller

Displaced phase center array (DPCA) pulse canceller for a uniform linear array

**Library:** Phased Array System Toolbox / Space-Time Adaptive Processing



## Description

The DPCA Canceller block filters clutter impinging on a uniform linear array using a displaced phase center array pulse canceller.

## Ports

### Input

**X — Input signal**

*M*-by-*N*-by-*P* complex-valued matrix

Input signal, specified as an *M*-by-*N*-by-*P* complex-valued array. *M* is the number of range samples, *N* is the number of channels, and *P* is the number of pulses.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**`Idx` — Index of range cells**

positive integer

Index of range cells to compute processing weights.

Example: `1`

Data Types: `double`

### PRF — Pulse repetition frequency

positive scalar

Pulse repetition frequency of current pulse, specified as a positive scalar.

#### Dependencies

To enable this port, set the **Specify PRF as** parameter to `Input port`.

Data Types: `double`

### Ang — Targeting direction

2-by-1 real-valued vector

Targeting direction, specified as a 2-by-*1* real-valued vector. The vector takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Specify direction as** parameter to `Input port`.

Data Types: `double`

### Dop — Targeting Doppler frequency

scalar

Targeting Doppler frequency of current pulse, specified as a scalar.

#### Dependencies

This port appears when the **Output pre-Doppler result** check box is cleared and the **Specify targeting Doppler as** parameter is set to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-1 complex-valued vector

Processing output, returned as an *M*-by-*1* complex-valued vector. The quantity *M* is the number of range samples in the input port X.

Data Types: `double`

### `W` — Processing weights

length *N**P* complex-valued vector

Processing weights, returned as Length *N**P* complex-valued vector. The quantity *N* is the number of channels and *P* is the number of pulses. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` input port or by the **Beamforming direction (deg)** parameter. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** check box.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Specify PRF as` — Source of PRF value

`Property` (default) | `Input port`

Source of PRF value, specified as `Property` or `Input port`. When set to `Property`, the **Pulse repetition frequency (Hz)** parameter sets the PRF. When set to `Input port`, pass in the PRF using the `PRF` input port.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1` (default) | positive scalar

Pulse repetition frequency, PRF, specified as a positive scalar. Units are in Hertz. Set this parameter to the same value set in any `Waveform` library block used in the simulation.

#### Dependencies

To enable this parameter, set the **Specify PRF as** parameter to `Property`.

### `Specify direction as` — Specify source of targeting directions

`Property` (default) | `Input port`

Specify whether the targeting direction for the STAP processor block comes from a block parameter or from the `ANG` input port. Values of this parameter are

| | |
|---|---|
| `Property` | • For the ADPCA Canceller and DPCA Canceller blocks, targeting direction is specified using **Receiving mainlobe direction (deg)**.<br>• For the SMI Beamformer block, targeting direction is specified using **Targeting direction**.<br>These parameters appear only when the **Specify direction as** parameter is set to `Property`. |
| `Input port` | Enter the targeting directions using the `Ang` input port. This port appears only when **Specify direction as** is set to `Input port`. |

### `Receiving mainlobe direction (deg)` — Pointing direction of main lobe of array

`[0;0]` (default) | real-valued 2-by-1 vector

Specify the direction of the main lobe of the receiving sensor array as a real-valued 2-by-1 vector. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]`. The azimuth angle should be between –180° and 180° and the elevation angle should be between –90° and 90°.

Example: `[100;-45]`

#### Dependencies

To enable this parameter, set **Specify direction as** to `Property`.

### `Number of bits in phase shifters` — Number of phase shift quantization bits

`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### `Specify targeting Doppler as` — Source of targeting Doppler

`Property` (default) | `Input port`

Specify whether targeting Doppler values for the STAP processor comes from the **Targeting Doppler (Hz)** parameter of this block or using the `DOP` input port. For the ADPCA Canceller and DPCA Canceller blocks, the **Specify targeting Doppler as** parameter appears only when the **Output pre-Doppler result** check box is cleared. Values of this parameter are

| | |
|---|---|
| `Property` | Specify targeting Doppler values using the **Targeting Doppler** parameter of the block. The **Targeting Doppler** parameter appears only when **Specify targeting Doppler as** is set to `Property`. |
| `Input port` | Specify targeting Doppler values using the `Dop` input port. This port appears only when **Specify targeting Doppler as** is set to `Input port`. |

### `Targeting Doppler (Hz)` — Targeting Doppler of STAP processor

`0` (default) | scalar

Targeting Doppler of STAP processor, specified as a scalar.

#### Dependencies

- To enable this parameter for the SMI Beamformer block, set **Specify targeting Doppler as** to `Property`.
- To enable this parameter for the ADPCA Canceller and DPCA Canceller blocks, first clear the **Output pre-Doppler result** check box. Then set the **Specify targeting Doppler as** parameter to `Property`.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Output pre-Doppler result` — Output results before Doppler filtering

on (default) | off

Select this check box to output the results before Doppler filtering. Clear this check box to output the processing result after Doppler filtering. Selecting this check box will remove the **Specify targeting Doppler as** and **Targeting Doppler (Hz)** parameters.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

## Array Parameters

### `Specify sensor array as` — Type of array

`Array (no subarrays)` (default) | `MATLAB expression`

Specify a ULA sensor array directly or by using a MATLAB expression.

**Types**

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

### `Number of elements` — Number of array elements in U

2 (default) | positive integer greater than or equal to two

The number of array elements for ULA arrays, specified as an integer greater than or equal to two.

Example: `11`

Data Types: `double`

### `Element spacing` — Distance between ULA elements

`0.5` (default) | positive scalar

Distance between adjacent ULA elements, specified as a positive scalar. Units are in meters.

Example: `1.5`

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Dependencies**

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### Taper — ULA array taper

`1` (default) | complex-valued vector

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Example: [0.5;1;0.5]

Data Types: `double`

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create a ULA array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.ULA('NumElements',13)`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

## See Also

`phased.DPCACanceller`

**Introduced in R2014b**

# ESPRIT DOA

ESPRIT direction of arrival (DOA) estimator for ULA

## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The ESPRIT DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the ESPRIT algorithm.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of signals**

Specify the number of signals as a positive integer scalar.

**Spatial smoothing**

Specify the amount of averaging, *L*, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N – 2$, where *N* is the number of sensors.

**Type of least squares method**

Specify the least squares method used for ESPRIT as one of `TLS` or `LS` where `TLS` refers to total least squares and `LS`refers to least squares.

**Forward-backward averaging**

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

**Row weighting factor**

Specify the row weighting factor for signal subspace eigenvectors as a positive integer scalar. This parameter controls the weights applied to the selection matrices. In most cases higher value are better. However, the value can never be greater than *(N-1)/2* where *N* is the number of elements of the array.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

**Specify sensor array as**

Specify a ULA sensor array directly or by using a MATLAB expression.

### Types

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Number of elements**

Specifies the number of elements in the array as an integer.

**Element spacing**

Specify the spacing, in meters, between two adjacent elements in the array.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

### Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

### Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

### Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

### Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signals.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Estimated broadside DOA angles. | Double-precision floating point |

# FMCW Waveform

Frequency-modulated continuous (FMCW) waveform source

## Library

Waveforms

`phasedwavlib`

## Description

The FMCW Waveform block generates a frequency modulated continuous wave (FMCW) waveform with a specified sweep time and sweep bandwidth. The block output can be either an integer number of pulses or samples.

## Parameters

**Sample rate**

Specify the sample rate of the signal as a positive scalar. Units are hertz. The product of **Sample rate** and **Sweep time** must be integers.

**Sweep time**

Specify the duration, in seconds, of the upsweep or the downsweep of the signal as a scalar or row vector of positive, real numbers. The product of the **Sample rate** value and each **Sweep time** entry must be an integer.

To implement a varying sweep time, specify **Sweep time** as a row vector. The waveform uses successive entries of the vector as the sweep time for successive periods of the waveform. If the last element of the vector is reached, the process continues cyclically with the first entry of the vector.

If **Sweep time** and **Sweep bandwidth** are both row vectors, the vectors must have the same length.

If **Sweep direction** is `Up` or `Down`, the sweep period equals the sweep time. If **Sweep direction** is `Triangle`, the sweep period is twice the sweep time because each period consists of an upsweep segment and a downsweep segment.

**Sweep bandwidth**

Specify the bandwidth of the linear FM sweeping, in hertz, as a scalar or row vector of positive, real numbers.

To implement a varying bandwidth, specify **Sweep bandwidth** as a row vector. The waveform uses successive entries of the vector as the sweep bandwidth for successive periods of the waveform. If the waveform reaches the last element of the **Sweep bandwidth** vector, the process continues cyclically with the first entry of the vector.

If **Sweep time** and **Sweep bandwidth** are both row vectors, the vectors must have the same length.

**Sweep direction**

Specify the direction of the linear FM sweep as one of `Up`, `Down`, or `Triangle`.

**Sweep interval**

If you set this parameter value to `Positive`, the waveform sweeps in the interval between 0 and *B*, where *B* is the value of the **Sweep bandwidth** parameter. If you set this parameter to `Symmetric`, the waveform sweeps in the interval between *–B/2* and *B/2*.

**Output signal format**

Specify the format of the output signal as `Sweeps` or `Samples`.

If you set this parameter to `Sweeps`, the output of the block is in the form of multiple sweeps. The number of sweeps is the value of the **Number of sweeps in output** parameter.

If you set this parameter to `Samples`, the output of the block is in the form of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If the **Sweep direction** parameter is set to `Triangle`, each sweep is one-half of a period.

**Number of sweeps in output**

Specify the number of sweeps in the block output as a positive integer. This parameter appears only when you set **Output signal format** to `Sweeps`.

**Number of samples in output**

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Supported Data Types |
|---|---|
| `Out` | Double-precision floating point |

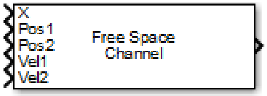
# Free Space

Free space environment



## Library

Environment and Target

`phasedenvlib`

## Description

The Free Space Channel block propagates the signal from one point to another in space. The block models propagation time, free space propagation loss and Doppler shift. The block assumes that the propagation speed is much greater than the target or array speed in which case the stop-and-hop model is valid.

When propagating a signal in free-space to an object and back, you have the choice of either using a single block to compute a two-way free space propagation delay or two blocks to perform one-way propagation delays in each direction. Because the free-space propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Signal carrier frequency (Hz)**

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

**Perform two-way propagation**

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Maximum one-way propagation distance (m)**

The maximum distance, in meters, between the origin and the destination as a positive scalar. Amplitudes of any signals that propagate beyond this distance will be set to zero.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| X | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| Pos1 | Signal origin position. | Double-precision floating point |

| Port | Description | Supported Data Types |
|---|---|---|
| `Pos2` | Signal destination position. | Double-precision floating point |
| `Vel1` | Signal origin velocity. | Double-precision floating point |
| `Vel2` | Signal destination velocity. | Double-precision floating point |
| `Out` | Output signal. | Double-precision floating point |

## Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t – \tau)/L$. The quantity $\tau$ is the delay and $L$ is the propagation loss. The delay is computed from $\tau = R/c$ where $R$ is the propagation distance and $c$ is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter $v$ is the relative speed of the destination with respect to the origin.

# Frost Beamformer

Frost beamformer
**Library:** Phased Array System Toolbox / Beamforming

## Description

The Frost Beamformer block implements a Frost beamformer. The Frost beamformer consists of a time-domain MVDR beamformer followed by a bank of FIR filters. The MVDR beamformer steers the beam towards a given direction while the FIR filters preserve the input signal power.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**XT — Training signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`

### `Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### `Y` — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to

Partitioned array or Replicated subarray, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the Ang port or by the Beamforming direction (deg) property. There is one set of weights for each beamforming direction.

**Dependencies**

To enable this port, select the **Enable weights output** checkbox.

Data Types: double

## Parameters

**Main Tab**

### Signal propagation speed (m/s) — Signal propagation speed

physconst('LightSpeed') (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by physconst('LightSpeed'). Units are in meters per second.

Example: 3e8

Data Types: double

### Inherit sample rate — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: Boolean

### Sample rate (Hz) — Sampling rate of signal

1e6 (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

**Dependencies**

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: double

### `FIR filter length` — FIR filter length

`1` (default) | positive integer

The length of the FIR filter used to process each sensor element data, specified as a positive integer.

Data Types: `double`

### `Diagonal loading factor` — Diagonal loading factor for stability

nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

### `Enable training data input` — Enable the use of training data

off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

### `Source of beamforming direction` — Source of beamforming direction

`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

### `Beamforming direction (deg)` — Beamforming directions

*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

**`Specify sensor array as` — Method to specify array**
`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

**`Expression` — MATLAB expression used to create an array**
Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

**`Element type` — Array element types**
`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element**
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation**

**angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

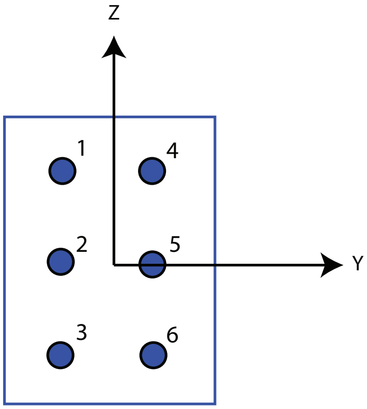
Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.

- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Array normal — Array normal direction

x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as x, y, or z.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| x | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| y | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| z | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to URA or UCA.

### Radius of UCA (m) — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to UCA.

### Element positions (m) — Positions of conformal array elements

[0;0;0] (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

**Dependencies**

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

## See Also

`phased.FrostBeamformer`

**Introduced in R2014b**

# GCC DOA and TOA

Generalized crosscorrelator with phase transform

## Library

Direction of arrival

`phaseddoalib`

## Description

The GCC DOA and TOA block estimates direction of arrival and time of arrival of a signal at an array. The block uses a generalized crosscorrelation with phased transform *(GCC-PHAT)* algorithm.

## Parameters

**Signal propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Source of sensor pairs**

Source

| | |
|---|---|
| `Property` | When you set this parameter to `Property`, specify the sensor pairs for computing correlation using the **Sensor pairs** parameter. |
| `Auto` | When you set this parameter to `Auto`, correlations are computed between the first element and all other elements. The first element serves as the reference channel. |

**Sensor pairs**

Sensor pairs, specified as a 2-by-*M* matrix of strictly positive integers. This parameter appears only when you set the **Source of sensor pairs** parameter to `Property`.

**Enable correlation output**

Check this box to output the correlations computed using the GCC-PHAT algorithm as well as the corresponding lags between sensor pairs. Correlation values are output via the `Rxy` port. Lag values are output via the `Lags` port. These ports appear only when you check the **Enable correlation output** box. Clear this check box to disable output of correlations.

**Enable delay output**

Select this check box to output the delay corresponding to the arrival angle of a signal between each sensor pair. The delay is output in the `Tau` port. This port appears only when you check the **Enable delay output** box. Clear this check box to disable output of delays.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

### Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

**Types**

| |
|---|
| `Array (no subarrays)` |
| `Partitioned array` |
| `Replicated subarray` |
| `MATLAB expression` |

### Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

**Number of elements**

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the subarray.

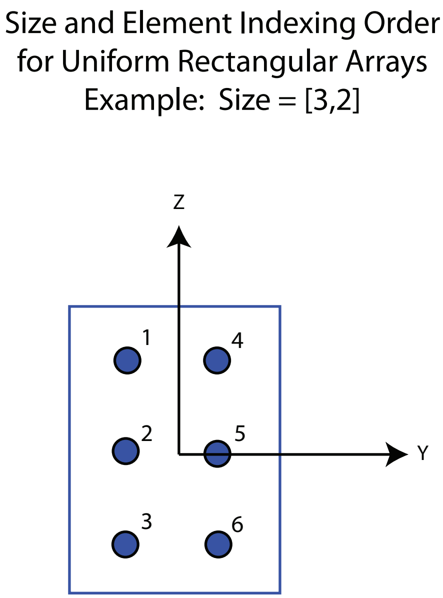
**Array size**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Element spacing (m)**

This parameter appears when **Geometry** is set to `ULA` or `URA`. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a `ULA`, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a `URA`, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see `phased.URA`. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Element lattice**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

**Element positions (m)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

**Element normals (deg)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

**Subarray definition matrix**

This parameter appears when **Specify sensor array as** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix corresponds to

a subarray and each entry in the row indicates whether or not an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

**Subarray steering method**

This parameter appears when the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as either

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Phase shifter frequency (Hz)**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

**Number of bits in phase shifters**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

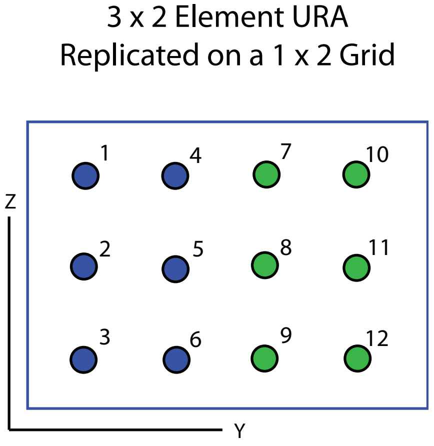
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

### Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



### Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

**Subarray positions (m)**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

**Subarray normals**

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Expression**

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Estimated DOA angles. | Double-precision floating point |
| `Rxy` | Estimated crosscorrelation. | Double-precision floating point |
| `Lag` | Time lags. | Double-precision floating point |
| `Tau` | Time delays of arrival. | Double-precision floating point |

**Introduced in R2015b**

# GSC Beamformer

Generalized sidelobe canceller
**Library:** Phased Array System Toolbox / Beamforming

## Description

The GSC Beamformerblock implements a generalized sidelobe cancellation (GSC) beamformer. A GSC beamformer splits an arrays incoming signals and sends them through a conventional beamformer path and a sidelobe canceling path. The algorithm first presteers the array to the beamforming direction and then adaptively chooses filter weights to minimize power at the output of the sidelobe canceling path. The algorithm uses least mean squares (LMS) to compute the adaptive weights. The final beamformed signal is the difference between the outputs of the two paths.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**Ang — Beamforming direction**
*2*-by-*L* real-valued matrix

Beamforming direction, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified in the `Ang` port.

# Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Signal path FIR filter length` — Length of the FIR filter along the signal path

`1` (default) | positive integer

Length of the signal path FIR filter, specified as a positive integer. The FIR filter is a delta function.

### `Adaptive filter step size` — LMS adaptive filter step size factor

`0.1` (default) | positive scalar

The adaptive filter step size factor, specified as a positive scalar. This quantity, when divided by the total power in the sidelobe canceling path, determines the actual adaptive filter step size used by the LMS algorithm.

### `Beamforming direction (deg)` — Beamforming directions

*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

### Source of beamforming direction — Source of beamforming direction

Property (default) | Input port

Source of beamforming direction, specified as Property or Input port. When you set **Source of beamforming direction** to Property, you then set the direction using the **Beamforming direction (deg)** parameter. When you select Input port, the direction is determined by the input to the Ang port.

### Simulate using — Block simulation method

Interpreted Execution (default) | Code Generation

Block simulation, specified as Interpreted Execution or Code Generation. If you want your block to use the MATLAB interpreter, choose Interpreted Execution. If you want your block to run as compiled code, choose Code Generation. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using Code Generation. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in Accelerator mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array

- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

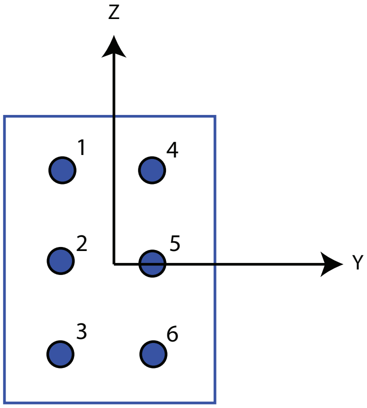
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

**Dependencies**

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

# More About

## Generalized Sidelobe Cancellation

The generalized sidelobe canceller (GSC) is an efficient implementation of a linear constraint minimum variance (LCMV) beamformer. LCMV beamforming minimizes the output power of an array while preserving the power in one or more specified directions. This type of beamformer is called a *constrained beamformer*. You can compute exact weights for the constrained beamformer but the computation is costly when the number of elements is large. The computation requires the inversion of a large spatial covariance matrix. The GSC formulation converts the adaptive constrained optimization LCMV problem into an adaptive unconstrained problem, which simplifies the implementation.

In the GSC algorithm, incoming sensor data is split into two signal paths as shown in the block diagram. The upper path is a conventional beamformer. The lower path is an adaptive unconstrained beamformer whose purpose is to minimize the GSC output power. The GSC algorithm consists of these steps:

1. Presteer the element sensor data by time-shifting the incoming signals. Presteering time-aligns all sensor element signals. The time shifts depend on the arrival angle of the signal.
2. Pass the presteered signals through the upper path into a conventional beamformer with fixed weights, $\mathbf{w}_{conv}$.
3. Also pass the presteered signals through the lower path into the blocking matrix, **B**. The blocking matrix is orthogonal to the signal and removes the signal from the lower path.
4. Filter the lower path signals through a bank of FIR filters. The `FilterLength` property sets the length of the filters. The filter coefficients are the adaptive filter weights, $\mathbf{w}_{ad}$.
5. Compute the difference between the upper and lower signal paths. This difference is the beamformed GSC output.

**6** Feed the beamformed output back into the filter. Adapt the filter weights using a least mean-square (LMS) algorithm. The adaptive LMS step size is the quantity set by the `LMSStepSizeFactor` property, divided by the total signal power.

`phased.GSCBeamformer`

**Introduced in R2016b**

# LCMV Beamformer

Narrowband linear constraint minimum variance (LCMV) beamformer
**Library:** Phased Array System Toolbox / Beamforming

## Description

The LCMV Beamformer block performs narrowband linear-constraint minimum-variance (LCMV) beamforming. The number of constraints must be less than the number of elements or subarrays in the array.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signals to beamformer, specified as an *M*-by-*N* complex-valued matrix. *M* is the number of signal samples. *N* is the number of sensor array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**XT — Training signal**
*P*-by-*N* complex-valued matrix

Training input signal, specified as a *P*-by-*N* complex-valued matrix. *P* is the number of samples in the training input signal. *N* is the number of elements of the sensor array. *P* must be greater than *N*.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this port, select the **Enable training data input** checkbox.

Data Types: `double`

## Output

### `Y` — Beamformed output

*M*-by-1 complex-valued column vector

Beamformed output, specified as an *M*-by-1 complex-valued column vector. *M* is the number of signal samples.

Data Types: `double`

### `W` — Beamformer weights output

*N*-by-1 complex-valued column vector

Beamformer weights output, specified as an *N*-by-1 complex-valued column vector. *N* is the number of array elements.

#### Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

# Parameters

### `Constraint matrix` — LCMV beamformer constraint matrix

`complex([1;1])` (default) | *N*-by-*K* complex-valued matrix

LCMV beamformer constraint matrix specified as an *N*-by-*K* complex-valued matrix. Each column of the matrix is a constraint. *N* is the number of elements in the sensor array and *K* is the number of constraints. *K* must be less than or equal to the number of sensors, $N, K \leq N$

### `Desired response vector` — Desired response for LCMV beamforming

`1` (default) | real-valued *K*-by-1 column vector

Desired response of the LCMV beamformer, specified as a real-valued *K*-by-1 column vector. *K* is the number of constraints in the **Constraint matrix**. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the **Constraint matrix** parameter.

### `Diagonal loading factor` — Diagonal loading factor

positive scalar

Diagonal loading factor, specified as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

### `Enable training data input` — Enable training data input port

`off` (default) | `on`

Enable training data input port, specified as `off` or `on`. To enable the training data input port, `XT`, select this checkbox.

### `Enable weights output` — Enable output of beamformer weights

`off` (default) | `on`

Enable beamforming weights output port, specified as `off` or `on`. To enable the beamforming weights output port, `W`, select this checkbox.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

#### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Linear FM Waveform

Linear FM (LFM) pulse waveform
**Library:** Phased Array System Toolbox / Waveforms

## Description

The Linear FM Waveform block generates a linear FM pulse waveform with specified pulse width, pulse repetition frequency (PRF), and sweep bandwidth. The block outputs an integer number of pulses or samples.

## Ports

### Input

**`PRFIdx` — PRF Index**
positive integer

Index to select the pulse repetition frequency (PRF), specified as a positive integer. The index selects the PRF from the predefined vector of values specified by the **Pulse repetition frequency (Hz)** parameter.

Example: 4

**Dependencies**

To enable this port, select **Enable PRF selection input**.

Data Types: `double`

### Output

**Y — Pulse waveform**
complex-valued vector

Pulse waveform samples, returned as a complex-valued vector.

Data Types: `double`

### PRF — Pulse repetition frequency

positive scalar

Pulse repetition frequency of current pulse, returned as a positive scalar.

#### Dependencies

To enable this port, set the **Output signal format** parameter to `Pulses` and then select the **Enable PRF output** parameter.

Data Types: `double`

## Parameters

### `Sample rate (Hz)` — Sample rate of the output waveform

`1e6` (default) | positive scalar

Sample rate of the output waveform, specified as a positive scalar. The ratio of **Sample rate (Hz)** to each element in the **Pulse repetition frequency (Hz)** vector must be an integer. This restriction is equivalent to requiring that the pulse repetition interval is an integral multiple of the sample interval.

### `Method to specify pulse duration` — Pulse duration as time or duty cycle

`Pulse width` (default) | `Duty cycle`

Method to set the pulse duration, specified as `Pulse width` or `Duty cycle`. When you set this parameter to `Pulse width`, the pulse duration is set using the **Pulse width (s)** parameter. When you set this parameter to `Duty cycle`, the pulse duration is computed from the values of the **Pulse repetition frequency (Hz)** and **Duty Cycle** parameters.

### `Pulse width (s)` — Time duration of pulse

`50e-6` (default) | positive scalar

The duration of each pulse, specified as a positive scalar. Set the product of **Pulse width (s)** and **Pulse repetition frequency** to be less than or equal to one. This restriction ensures that the pulse width is smaller than the pulse repetition interval. Units are in seconds.

Example: `300e-6`

#### Dependencies

To enable this parameter, set the **Method to specify pulse duration** parameter to `Pulse width`.

### `Duty cycle` — Waveform duty cycle

`0.5` (default) | scalar in the range *[0,1]*

Waveform duty cycle, specified as a scalar in the range *[0,1]*.

Example: `0.7`

#### Dependencies

To enable this parameter, set the **Method to specify pulse duration** parameter to `Duty cycle`.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* by using block parameter settings alone or in conjunction with the input port, `PRFIdx`.

- When the **Enable PRF selection input** parameter is not selected, set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.

  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses cycles through the successive values of the *PRF* vector.
- When the **Enable PRF selection input** parameter is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute the block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, the number of output samples is fixed when you set the **Output signal format** to `Samples`. When you use a varying *PRF* and set **Output signal format** to `Pulses`, the number of output samples can vary.

### `Enable PRF selection input` — Select predefined PRF

off (default) | on

Select this parameter to enable the `PRFIdx` port.

- When enabled, pass in an index into a vector of predefined PRFs. Set predefined PRFs using the **Pulse repetition frequency (Hz)** parameter.
- When not enabled, the block cycles through the vector of PRFs specified by the **Pulse repetition frequency (Hz)** parameter. If **Pulse repetition frequency (Hz)** is a scalar, the PRF is constant.

### `Sweep bandwidth (Hz)` — Bandwidth of FM sweep

`1e5` (default) | positive scalar

Bandwidth of the linear FM sweep, specified as a positive scalar. Units are in Hertz.

Example: `1e3`

### `Sweep direction` — Direction of FM sweep

`Up` (default) | `Down`

Specify the direction of the linear FM sweep as `Up` (increasing frequency) or `Down` (decreasing frequency).

### `Sweep interval` — FM frequency sweep interval

`Positive` (default) | `Symmetric`

FM frequency sweep interval, specified as `Positive` or `Symmetric`. If you set this parameter to `Positive`, the waveform sweeps the frequency interval between *0* and *B*, where *B* is the value of the **Sweep bandwidth** parameter. If you set this parameter value to `Symmetric`, the waveform sweeps the interval between *–B/2* and *B/2*.

### `Envelope function` — FM signal amplitude envelope

`Rectangular` (default) | `Gaussian`

FM signal amplitude envelope, specified as `Rectangular` or `Gaussian`.

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### `Number of pulses in output` — Number of pulses in output

`1` (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: `2`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Pulses`.

Data Types: `double`

### `Enable PRF Output` — Enable output of PRF

off (default) | on

Select this parameter to enable the PRF output port.

#### Dependencies

To enable this parameter, set **Output signal format** to `Pulses`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

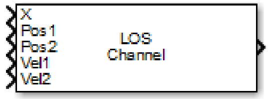
`phased.LinearFMWaveform`

**Introduced in R2014b**

# LOS Channel

Narrowband line-of-sight propagation channel



## Library

Environment and Target

`phasedenvlib`

## Description

The LOS Channel block propagates signals from one point in space to multiple points or from multiple points back to one point via line-of-sight (LOS) channels. The block models propagation time, free-space propagation loss, Doppler shift, and atmospheric as well as weather loss. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

When propagating a signal in an LOS channel to an object and back, you have the choice of either using a single block to compute two-way LOS channel propagation delay or two blocks to perform one-way propagation delays in each direction. Because the LOS channel propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Signal carrier frequency (Hz)**

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

**Specify atmospheric parameters**

Select this check box to enable atmospheric attenuation modeling.

**Temperature (degrees Celsius)**

Ambient atmospheric temperature, specified as a real-valued scalar. Units are degrees Celsius. This parameter appears when you select the **Specify atmospheric parameters** check box. Units are degrees Celsius.

**Dry air pressure (Pa)**

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are Pascals (Pa). The value 101325 for this property corresponds to one standard atmosphere. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Water vapour density (g/m^3)**

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are gm/m$^3$. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Liquid water density (g/m^3)**

Liquid water density of fog or clouds, specified as a non-negative real-valued scalar. Units are gm/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Rain rate (mm/hr)**

Rainfall rate, specified as a non-negative real-valued scalar. Units are in mm/hour. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Perform two-way propagation**

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Maximum one-way propagation distance (m)**

The maximum distance between the signal origin and the destination, specified as a positive scalar. Units are in meters. Amplitudes of any signals that propagate beyond this distance will be set to zero.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| X | Input signal. | Double-precision floating point |
| Pos1 | Signal source position. | Double-precision floating point |
| Pos2 | Signal destination position. | Double-precision floating point |
| Vel1 | Signal source velocity. | Double-precision floating point |
| Vel2 | Signal destination velocity. | Double-precision floating point |
| Out | Propagated signal. | Double-precision floating point |

# More About

## Attenuation and Loss Factors

Attenuation or path loss in the Wideband LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- $L_{fsp}$ is the free-space path attenuation
- $L_g$ is the atmospheric path attenuation
- $L_c$ is the fog and cloud path attenuation
- $L_r$ is the rain path attenuation

Each component is in magnitude units, not in dB.

## Propagation Delay, Doppler, and Free-Space Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_i$, multiplied by a spectral line strength, *S*$_i$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right]W\,.$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is $P + W$.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, $R$. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = k r^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

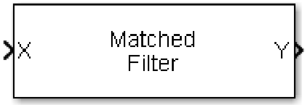
# Matched Filter

Matched filter



## Library

Detection

`phaseddetectlib`

## Description

The Matched Filter block implements matched filtering of an input signal. Matched filtering is an FIR filtering operation with the coefficients equal to the time reversed samples of the transmitted signal. The filter can improve SNR before detection.

## Parameters

**Source of coefficients**

Specify whether the matched filter coefficients come from **Coefficients** or from an input port.

| | |
|---|---|
| `Property` | Matched filter coefficients are specified by **Coefficients**. |
| `Input port` | Matched filter coefficients are specified via the input port `Coeff`. |

**Coefficients**

Specify the matched filter coefficients as a column vector. This parameter appears when you set **Source of coefficients** to `Property`.

**Spectrum window**

Specify the window used for spectrum weighting using one of

| |
|---|
| `None` |
| `Hamming` |
| `Chebyshev` |
| `Hann` |
| `Kaiser` |
| `Taylor` |

Spectrum weighting is often used with linear FM waveforms to reduce sidelobe levels in the time domain. The block computes the window length internally to match the FFT length.

**Spectrum window range**

This parameter appears when you set the **Spectrum window** parameter to any value other than `None`. Specify the spectrum region, in hertz, on which the spectrum window is applied as a 1-by-2 vector in the form of `[StartFrequency,EndFrequency]`.

Note that both `StartFrequency` and `EndFrequency` are measured in baseband. That is, they are within `[-Fs/2,Fs/2]`, where `Fs` is the sample rate specified in any of the waveform library blocks. The parameter `StartFrequency` must be less than `EndFrequency`.

**Sidelobe attenuation level**

This parameter appears when you set **Spectrum window** to `Chebyshev` or `Taylor`. Specify the sidelobe attenuation level, in dB, of a Chebyshev or Taylor window as a positive scalar.

**Kaiser shape parameter**

This parameter appears when you set the **Spectrum window** parameter to `Kaiser`. Specify the parameter that affects the Kaiser window sidelobe attenuation as a nonnegative scalar. Please refer to the function `kaiser` for more details.

**Number of constant level sidelobes**

This parameter appears when you set the **Spectrum window** parameter to `Taylor`. Specify the number of nearly-constant-level sidelobes adjacent to the mainlobe in a Taylor window as a positive integer.

**Enable SNR gain output**

Select this check this box to obtain the matched filter SNR gain via the output port `G`. The output port appears only when this box is selected.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | | Supported Data Types |
|---|---|---|
| `X` | Input signal matrix.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Coeff` | Matched filter coefficients. | Double-precision floating point |
| `Y` | Filter output. | Double-precision floating point |
| `G` | Matched-filter gain. | Double-precision floating point |

# MFSK waveform

Multiple frequency shift keying (MFSK) continuous waveform

## Library

Waveforms

`phasedwavlib`

## Description

The MFSK Waveform block generates a multiple frequency- shift keying (MFSK) continuous waveform with a specified step time, sweep bandwidth, frequency offset, and number of steps. The block outputs an integer number of samples, steps, or sweeps. For details on the structure of an MFSK waveform, see `phased.MFSKWaveform`.

## Parameters

**Sample rate (Hz)**

Sample rate of the signal, specified as a positive scalar. Units are in hertz.

**Sweep bandwidth (Hz)**

Bandwidth of the MFSK sweep, specified as a positive scalar. Units are in hertz.

**Frequency step burst time (s)**

Time duration of each frequency step, specified as a positive scalar. Units are in seconds.

**Number of steps per sweep**

Total number of steps in each sweep, specified as an even positive integer.

**Chirp offset frequency (Hz)**

Chirp offset frequency, specified as a real scalar. Units are in hertz. The offset determines the frequency translation between the two sequences.

**Output signal format**

Format of the output signal, specified as one of the following:

- `'Steps'` — The block outputs the number of samples contained in an integer number of frequency steps, **Number of steps in output**.
- `'Samples'` — The block outputs the number of samples specified in **Number of samples in output**.
- `'Sweeps'` — The block outputs the number of samples contained in an integer number of sweeps, **Number of sweeps in output**.

**Number of sweeps in output**

Number of sweeps in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Sweeps`.

**Number of samples in output**

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

**Number of steps in output**

Number of steps in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Steps`.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Supported Data Types |
|---|---|
| `Out` | Double-precision floating point |

DeltaEl

## Description

The Monopulse Feed block forms the sum and difference channels used for amplitude monopulse directing finding. Sum and difference channels are derived from signals received by an array. You can feed these channels into the Monopulse Estimator block.

## Ports

### Input

**X — Input signal**
complex-valued *M*-by-*N* matrix

Input signal, specified as a complex-valued *M*-by-*N* matrix, where *M* is the number of samples or snapshots of data, and *N* is the number of array elements. If the array contains subarrays, then *N* is the number of subarrays.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**STEER — Array steering direction**
scalar | real-valued 2-by-1 column vector

Array steering direction, specified as a scalar or real-valued 2-by-1 column vector.

- When you set the **Monopulse coverage** parameter to `Azimuth`, the steering direction is a scalar and represents the azimuth steering angle.

- When you set the **Monopulse coverage** parameter to `3D`, the steering direction vector has the form `[azimuthAngle; elevationAngle]`, where `azimuthAngle` is the azimuth steering angle, and `elevationAngle` is the elevation steering angle.

Units are in degrees. Azimuth angles lie between –180° and 180°, inclusive, and elevation angles lie between –90° and 90°, inclusive.

Example: `[40;10]`

Data Types: `double`

## Output

### `SIGMA` — Sum-channel signal

complex-valued *M*-by-1 column vector

Sum-channel signal, returned as a complex-valued *M*-by-1 column vector, where *M* is the number of rows of `X`.

Data Types: `double`
Complex Number Support: Yes

### `DeltaAz` — Azimuth-difference channel signal

complex-valued *M*-by-1 column vector

Azimuth-difference channel signal, returned as a complex-valued *M*-by-1 column vector, where *M* is the number of rows of `X`.

Data Types: `double`
Complex Number Support: Yes

### `DeltaEl` — Elevation-difference channel signal

complex-valued *M*-by-1 vector

Elevation difference-channel signal, returned as a complex-valued *M*-by-1 column vector, where *M* is the number of rows of `X`.

#### Dependencies

To enable this output port, set the **Monopulse coverage** parameter to `3D`.

Data Types: `double`
Complex Number Support: Yes

### `ANG` — Estimated direction of target

real-valued 2-by-1 vector

Estimated direction of target, returned as a real-valued 2-by-1 vector in the form `[azimuth,elevation]`. Units are in degrees.

#### Dependencies

To enable this output port, select the **Output angle estimate** check box.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Monopulse coverage` — Monopulse coverage directions

`3D` (default) | `Azimuth`

Coverage directions of monopulse feed, specified as `3D` or `Azimuth`. When you set this parameter to `3D`, the monopulse feed forms the sum channel and both azimuth and elevation difference channels. When you set this parameter to `Azimuth`, the monopulse feed forms the sum channel and the azimuth difference channel.

### `Squint angle (degrees)` — Squint angle

`10` (default) | scalar | real-valued 2-by-1 vector

Squint angle, specified as a scalar or real-valued 2-by-1 vector. The squint angle is the separation angle between the sum beam and the beams along the azimuth and elevation directions.

- When you set the `Monopulse coverage` parameter to `Azimuth`, set the `Squint angle` parameter to a scalar.
- When you set the `Monopulse coverage` parameter to `3D`, you can specify the squint angle as either a scalar or vector. If you set the `Squint angle` parameter to a scalar, the squint angle is the same along both the azimuth and elevation directions. If you set the `Squint angle` parameter to a 2-by-1 vector, its elements specify the squint angle along the azimuth and elevation directions.

Example: `[20;5]`

### `Output angle estimate` — Enable angle estimate output

`off` (default) | `on`

Select this check box to output an estimate of the target direction angle using the `ANG` output port.

### `Generate Monopulse Tracker` — Create Monopulse estimator block

button

Click this button to create a Monopulse Estimate block based on the parameters in this block.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

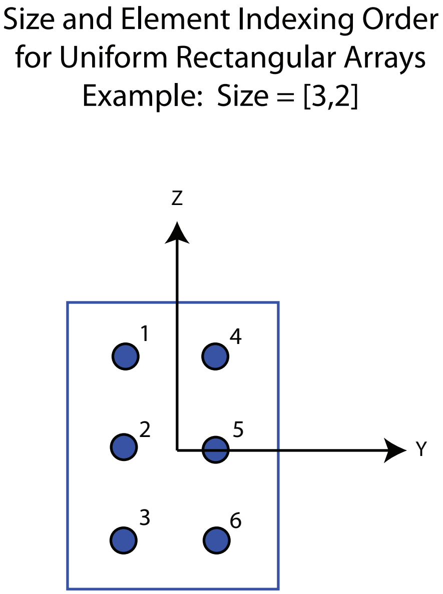
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| x | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| y | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| z | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Dependencies**

To enable this parameter, set **Geometry** to URA or UCA.

### Radius of UCA (m) — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Geometry** to UCA.

### Element positions (m) — Positions of conformal array elements

[0;0;0] (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position [x;y;z]of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

**Dependencies**

To enable this parameter set **Geometry** to Conformal Array.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

**`Subarray steering method` — Specify subarray steering method**

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

**`Phase shifter frequency (Hz)` — Subarray phase shifting frequency**

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

**Dependencies**

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

**Dependencies**

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray`

### `Grid size` — Dimensions of rectangular subarray grid

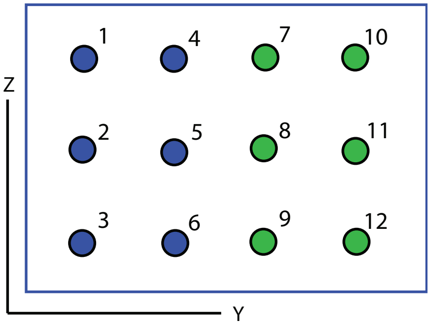
`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The

second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

3 x 2 Element URA
Replicated on a 1 x 2 Grid



**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

## See Also

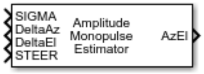
`phased.MonopulseFeed`

**Introduced in R2018b**

# Monopulse Estimator

Estimate target direction from sum and difference channels

**Library:** Phased Array System Toolbox / Direction of Arrival



## Description

The Monopulse Estimator estimates the direction of arrival of a narrowband signal based on an initial guess by applying amplitude monopulse processing on sum and difference channel signals received by an array. You can create these channels using the Monopulse Feed block.

## Ports

### Input

**`SIGMA` — Sum-channel signal**
complex-valued *N*-by-1 column vector

Sum-channel signal, specified as a complex-valued *N*-by-1 column vector. *N* is the number of snapshots in the signal.

Data Types: `double`
Complex Number Support: Yes

**`DeltaAz` — Azimuth difference-channel signal**
complex-valued *N*-by-1 column vector

Azimuth difference-channel signal, specified as a complex-valued *N*-by-1 column vector. *N* is the number of snapshots in the signal.

Data Types: `double`
Complex Number Support: Yes

### `DeltaEl` — Elevation difference-channel signal

complex-valued *M*-by-1

Elevation difference-channel signal, specified as a complex-valued *N*-by-1 column vector. *N* is the number of snapshots in the signal.

#### Dependencies

To enable this output port, set the **Monopulse coverage** parameter to `3D`.

Data Types: `double`
Complex Number Support: Yes

### `STEER` — Array steering direction

scalar | real-valued 2-by-1 column vector

Array steering direction, specified as a scalar or real-valued 2-by-1 column vector.

- When you set the **Monopulse coverage** parameter to `Azimuth`, the steering direction is a scalar and represents the azimuth steering angle.
- When you set the **Monopulse coverage** parameter to `3D`, the steering direction vector has the form `[azimuthAngle; elevationAngle]`, where `azimuthAngle` is the azimuth steering angle, and `elevationAngle` is the elevation steering angle.

Units are in degrees. Azimuth angles lie between –180° and 180°, inclusive, and elevation angles lie between –90° and 90°, inclusive.

Example: `[40;10]`

Data Types: `double`

## Output

### `Az` — Estimated azimuth direction of target

real-valued 1-by-*N* vector

Estimated azimuth direction of target, returned as a real-valued 1-by-*N*. The vector elements contain the estimated target direction azimuth angle at each signal snapshot. Units are in degrees.

#### Dependencies

To enable this output port, set the **Monopulse coverage** to `Azimuth` and the **OutputFormat** to `Angle`.

Data Types: `double`

### `dAz` — Estimated offset of azimuth direction of target

real-valued 1-by-*N* vector

Estimated offset of azimuth direction of target, returned as a real-valued 1-by-*N* vector. The vector elements contain the offset of the estimated target direction azimuth angle from the azimuth steering direction at each signal snapshot. Units are in degrees.

#### Dependencies

To enable this output port, set the **Monopulse coverage** to `Azimuth` and the **OutputFormat** to `Angle offset`.

Data Types: `double`

### `AzEl` — Estimated direction of target

real-valued 2-by-*N* matrix

Estimated direction of target, returned as a real-valued 2-by-*N* matrix. Each column contains the estimated target direction in the form `[azimuthAngle; elevationAngle]` ,where `azimuthAngle` is the estimated azimuth angle, and `elevationAngle` is estimated elevation angle. Units are in degrees.

#### Dependencies

To enable this output port, set the **Monopulse coverage** to `3D` and the **OutputFormat** to `Angle`.

Data Types: `double`

### `dAzEl` — Estimated offset of direction of target

real-valued 2-by-*N* matrix

Estimated offset of direction of target, returned as a real-valued 2-by-*N* matrix. The offset is the difference between the target direction and the steering vector. Each column contains the estimated offset of the target direction in the form `[dazimuthAngle; delevationAngle]`, where `dazimuthAngle` is the estimated azimuth angle offset, and `delevationAngle` is estimated elevation angle offset. Units are in degrees.

#### Dependencies

To enable this output port, set the **Monopulse coverage** to `3D` and the **OutputFormat** to `Angle offset`.

Data Types: `double`

### `AzRatio` — Ratio of sum and azimuth difference channels

real-valued 1-by-*N* vector

Ratio of sum and azimuth difference channels, returned as a real-valued 1-by-*N* vector. The elements contain the ratio of the sum to azimuth difference channel at each signal snapshot.

#### Dependencies

To enable this output port, set the **Monopulse coverage** to `Azimuth` and select the **Output sum difference ratio** check box.

Data Types: `double`

### `AzElRatio` — Ratio of sum channel to azimuth and elevation difference channels

real-valued 2-by-*N* matrix

Ratio of sum and azimuth and elevation difference channels, returned as a real-valued 2-by-*N* matrix. The elements of the first row contain the ratio of the sum to azimuth difference channel at each signal snapshot. The elements of the second row contain the ratio of the sum to elevation difference channel at each signal snapshot.

#### Dependencies

To enable this output port, set the **Monopulse coverage** to `3D` and select the **Output sum difference ratio** check box.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Monopulse coverage` — Monopulse coverage directions

`3D` (default) | `Azimuth`

Monopulse coverage directions, specified as `3D` or `Azimuth`. When you set this parameter to `3D`, the monopulse estimator uses the sum channel and both azimuth and elevation difference channels. When you set this parameter to `Azimuth`, the monopulse estimator uses the sum channel and the azimuth difference channel.

### `Squint angle (degrees)` — Squint angle

`10` (default) | scalar | real-valued 2-by-1 vector

Squint angle, specified as a scalar or real-valued 2-by-1 vector. The squint angle is the separation angle between the sum beam and the beams along the azimuth and elevation directions.

- When you set the `Monopulse coverage` parameter to `Azimuth`, set the `Squint angle` parameter to a scalar.
- When you set the `Monopulse coverage` parameter to `3D`, you can specify the squint angle as either a scalar or vector. If you set the `Squint angle` parameter to a scalar, the squint angle is the same along both the azimuth and elevation directions. If you set the `Squint angle` parameter to a 2-by-1 vector, its elements specify the squint angle along the azimuth and elevation directions.

Example: `[20;5]`

### `Output format` — Output direction format

`Angle` (default) | `Angle offset`

Format of direction output, specified `Angle` or `Angle offset`. When you set this parameter to `Angle`, the output port is labeled `AzEl` or `Az` and is the actual direction of the target. When you set this property to `Angle offset`, the output port is labeled `dAzEl` or `dAz` and is the angle offset of the target from the array steering direction.

### `Output sum difference ratio` — Enable sum-difference ratio output port

`off` (default) | `on`

Select this check box to output the ratio of the sum and difference channels in the azimuth and elevation directions. When you set the **Monopulse coverage** to `Azimuth`, the block outputs the sum-azimuth difference ratio using the `AzRatio` port. When you set the **Monopulse coverage** to `3D`, the block outputs the sum-azimuth difference and sum-elevation difference channels ratio using the `AzElRatio` port.

**`Generate Monopulse Feed` — Create monopulse feed block**
button

Click this button to create a Monopulse Feed block based on the parameters in this block.

**`Simulate using` — Block simulation method**
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### Element type — Array element types

Isotropic Antenna (default) | Cosine Antenna | Custom Antenna | Omni Microphone | Custom Microphone

Antenna or microphone type, specified as one of the following:

- Isotropic Antenna
- Cosine Antenna
- Custom Antenna
- Omni Microphone
- Custom Microphone

### Operating frequency range (Hz) — Operating frequency range of the antenna or microphone element

[0,1.0e20] (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form [LowerBound,UpperBound]. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to Isotropic Antenna, Cosine Antenna, or Omni Microphone.

### Operating frequency vector (Hz) — Operating frequency range of custom antenna or microphone elements

[0,1.0e20] (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to Custom Antenna or Custom Microphone. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation**

**angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency

specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Microphone`.

**Array Parameters**

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.

- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

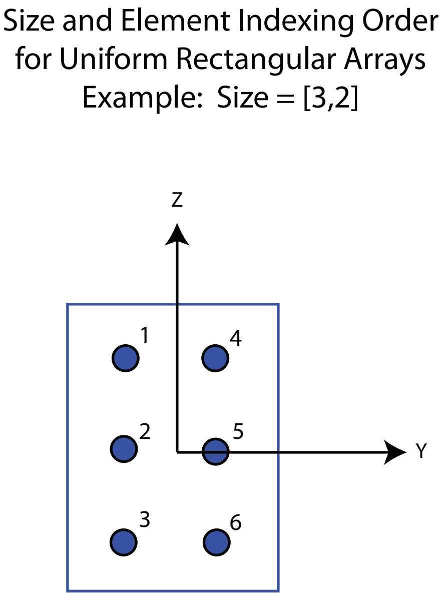
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

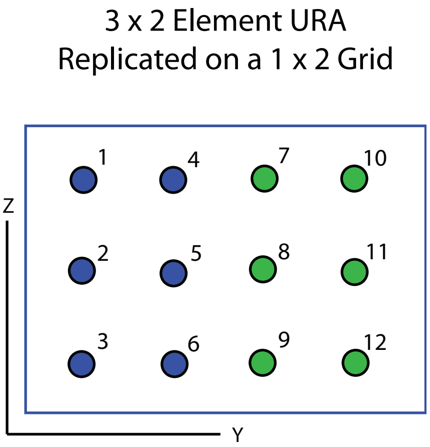
### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The

second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

## See Also

`phased.MonopulseEstimator`

**Introduced in R2018b**

# MVDR Beamformer

Narrowband MVDR (Capon) beamformer
**Library:** Phased Array System Toolbox / Beamforming

## Description

The MVDR Beamformer block performs minimum variance distortionless response (MVDR) beamforming. The block preserves the signal power in the given direction while suppressing interference and noise from other directions. The MVDR beamformer is also called the Capon beamformer.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**XT — Training signal**
*M*-by-*N* complex-valued matrix

Training signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`

### `Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to

`Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

**Dependencies**

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

## Parameters

**Main tab**

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Diagonal loading factor` — Diagonal loading factor for stability

nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

### `Enable training data input` — Enable the use of training data

off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

### `Source of beamforming direction` — Source of beamforming direction

`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

### `Beamforming direction (deg)` — Beamforming directions

*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

### `Number of bits in phase shifters` — Number of phase shift quantization bits

`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

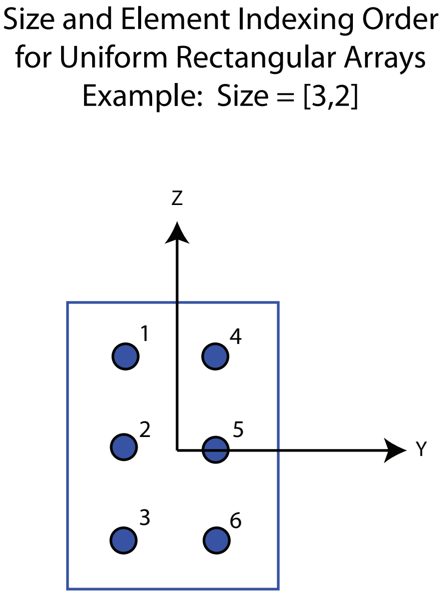
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

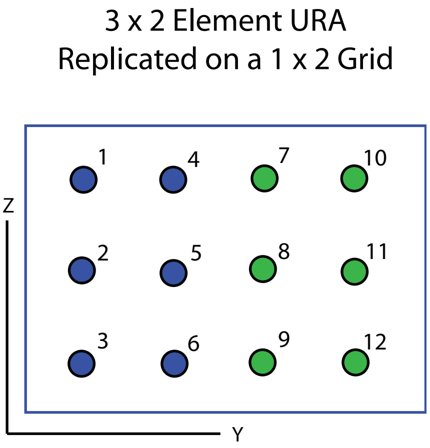
### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The

second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Dependencies**

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

## See Also

`phased.MVDRBeamformer`

**Introduced in R2014b**

# MUSIC Spectrum

MUSIC 2D spatial spectrum estimator
**Library:** Phased Array System Toolbox / Direction of Arrival

## Description

The MUSIC Spectrum block uses the MUltiple SIgnal Classification (MUSIC) algorithm to estimate the spatial spectrum of incoming narrowband signals. The block optionally calculates the direction of arrival of a specified number of signals by finding the peaks of the spectrum.

## Ports

### Input

**`Port 1` — Received signal**
*M*-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the length of the signal, the number of sample values contained in the signal. The quantity *N* is the number of sensor elements in the array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

### Output

**Y — MUSIC 2-D spatial spectrum**
non-negative real-valued *P*-by-*Q* matrix

2-D MUSIC spatial spectrum, returned as a non-negative, returned as a real-valued *P*-by-*Q* matrix. Each entry represents the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the **Azimuth scan angles (deg)** and **Elevation scan angles (deg)** parameters. *P* equals the length of the vector specified in **Azimuth scan angles (deg)** and *Q* equals the length of the vector specified in **Elevation scan angles (deg)**.

Data Types: `double`

### Ang — Directions of arrival

non-negative, real-valued 2-by-*L* matrix

Directions of arrival of the signals, returned as a real-valued 2-by-*L* matrix. *L* is the number of signals specified by the **Number of signals** parameter. The direction of arrival angle is defined by the azimuth and elevation angles of the source with respect to the array local coordinate system. The first row of the matrix contains the azimuth angles and the second row contains the elevation angles. If the object cannot identify peaks in the spectrum, it will return `NaN`. Angle units are in degrees.

#### Dependencies

Select the **Enable DOA output** parameter to enable this output port.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Forward-backward averaging` — Enable forward-backward averaging

off (default) | on

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold structure.

### `Azimuth scan angles (deg)` — Azimuth scan angles

`-90:90` (default) | real-valued scalar | real-valued row vector

Azimuth scan angles, specified as a real-valued row vector. The angle values must lie between –180° and 180°, inclusive, and specified in ascending order. Angle units are in degrees.

### `Elevation scan angles (deg)` — Elevation scan angles

`0` (default) | real-valued scalar | real-valued row vector

Elevation scan angles, specified as a scalar or real-valued row vector. The angle values must lie between –90° and 90°, inclusive, and specified in ascending order. Angle units are in degrees.

### `Enable DOA output` — Output directions of arrival through output port

off (default) | on

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port.

### `Number of signals` — Expected number of arriving signals

`1` (default) | positive integer

Specify the expected number of signals for DOA estimation as a positive scalar integer.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Array Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

**Dependencies**

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

**Dependencies**

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

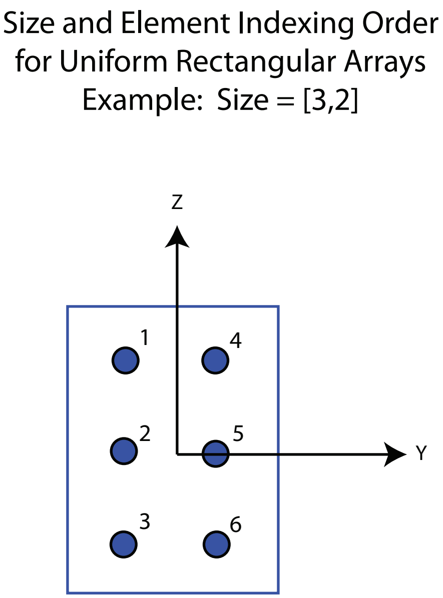
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Dependencies**

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

**Dependencies**

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

**`Element normals (deg)` — Direction of conformal array element normal vectors**
`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

**`Taper` — Array element tapers**
1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

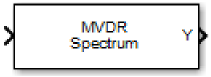
## Topics

“MUSIC Super-Resolution DOA Estimation”

**Introduced in R2016b**

# MVDR Spectrum

Minimum variation distortionless response (MVDR) spatial spectrum estimator



## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The narrowband MVDR Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a range of azimuth and elevation angles using an MVDR conventional beamformer. The block optionally calculate the direction of arrival of a specified number of signals by estimating the peaks of the spectrum. This estimator is also referred to as a Capon estimator.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of bits in phase shifters**

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Forward-backward averaging**

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

**Azimuth scan angles (deg)**

Specify the azimuth scan angles, in degrees, as a real vector. The angles must be between –180° and 180°, inclusive. You must specify the angles in ascending order.

**Elevation scan angles (deg)**

Specify the elevation scan angles, in degrees, as a real vector or scalar. The angles must be between –90° and 90°, inclusive. You must specify the angles in an ascending order.

**Enable DOA output**

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port. Selecting this parameter enables the **Number of signals** parameter.

**Number of signals**

Specify the number of signals for DOA estimation as a positive scalar integer. This parameter appears when you select the **Enable DOA output** check box.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

**Specify sensor array as**

Specify a sensor array directly or by using a MATLAB expression.

### Types

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Geometry**

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

**Number of elements**

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the subarray.

### Array size

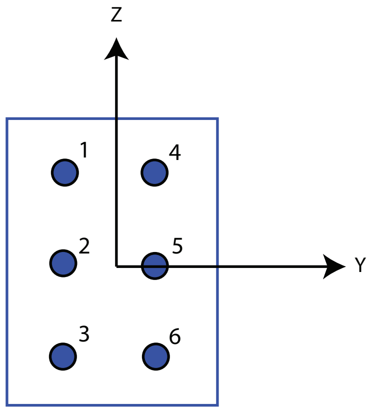
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



### Element spacing (m)

This parameter appears when **Geometry** is set to `ULA` or `URA`. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a `ULA`, specify the spacing, in meters, between two adjacent elements in the array as a scalar.

- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see `phased.URA`. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix,

a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Element lattice**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

**Element positions (m)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

**Element normals (deg)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

**Expression**

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P*

specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone’s response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Y` | Spatial spectrum. | Double-precision floating point |
| `Ang` | Estimated DOA angle. | Double-precision floating point |

`phasedtxrxlib`

## Description

The Narrowband Receive Array block implements a narrowband receive array. The array processes narrowband plane waves incident on the sensor elements of the array. The delay at each element is approximated using a corresponding phase shift in the time domain.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Sensor gain measure**

Sensor gain measure, specified as `dB` or `dBi`.

- When you set this parameter to `dB`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.

- When you set this parameter to `dBi`, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values computed by the radar equation that uses dBi to specify the antenna gain. The computation using the `dBi` option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor. The default value is `dB`.

**Enable weights input**

Select this check box to specify array weights via the input port `W`. The input port appears only when this box is selected.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see "Choosing a Simulation Mode" (Simulink).

Clicking the **Analyze** button launches the **Sensor Array Analyzer** app. This app lets you examine important array properties such as array response and array geometry.

## Array Parameters

**Specify sensor array as**

Specify sensor element or sensor array. A sensor array can also contain subarrays or be a partitioned array. This parameter can also be expressed as a MATLAB expression.

**Types**

| |
|---|
| `Single element` |
| `Array (no subarrays)` |
| `Partitioned array` |
| `Replicated subarray` |
| `MATLAB expression` |

**Geometry**

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array

- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

**Number of elements**

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the subarray.

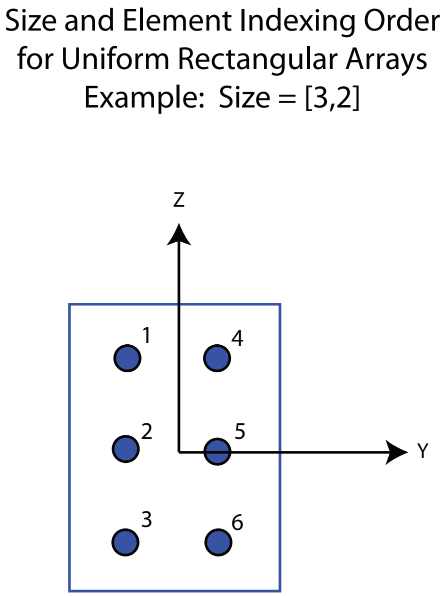
**Array size**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Element spacing (m)**

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the Replicated subarray option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form [SpacingBetweenRows,SpacingBetweenColumns]. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

**Array axis**

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as x, y, or z. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Element lattice**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

**Element positions (m)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

**Element normals (deg)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

**Subarray definition matrix**

This parameter appears when **Specify sensor array as** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix corresponds to

a subarray and each entry in the row indicates whether or not an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

**Subarray steering method**

This parameter appears when the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as either

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Phase shifter frequency (Hz)**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

**Number of bits in phase shifters**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Subarrays layout**

This parameter appears when you set **Sensor array** to `Replicated subarray`.

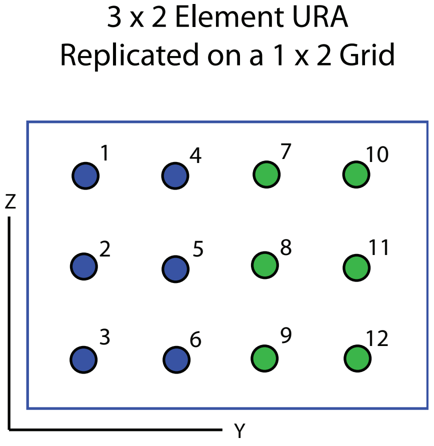
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

**Grid size**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



**Grid spacing**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

**Subarray positions (m)**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

**Subarray normals**

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Expression**

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone’s response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Arriving signals input port<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Incident directions of signals input port. | Double-precision floating point |
| `W` | Array or subarray weights input port. To enable this port, select the **Enable weights input** check box. | Double-precision floating point |
| `WS` | Subarray element weights input port. To enable this port select `Custom` from the **Subarray steering method** pull down menu. | |
| `Steer` | Steering angle input port. To enable this port, select `Phase` or `Time` from the **Subarray steering method** pull down menu. | Double-precision floating point |
| `Out` | Collected signals | Double-precision floating point |

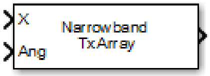
# Narrowband Transmit Array

Narrowband transmit array



## Library

Transmitters and Receivers

`phasedtxrxlib`

## Description

The Narrowband Transmit Array block generates narrowband plane waves in the far field of the array by adding the far-field radiated signals of each element. Think of the block output as the field at a reference distance from the element or from the center of the array.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Sensor gain measure**

Sensor gain measure, specified as `dB` or `dBi`.

- When you set this parameter to `dB`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.

- When you set this parameter to dBi, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values computed by the radar equation that uses dBi to specify the antenna gain. The computation using the dBi option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor. The default value is dB.

**Enable weights input**

Select this check box to specify array weights using the input port W. The input port appears only when this box is checked.

**Simulate using**

Block simulation method, specified as Interpreted Execution or Code Generation. If you want your block to use the MATLAB interpreter, choose Interpreted Execution. If you want your block to run as compiled code, choose Code Generation. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using Code Generation. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in Accelerator mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

Clicking the **Analyze** button launches the **Sensor Array Analyzer** app. The app lets you examine important array properties such as array response and array geometry.

## Array Parameters

**Specify sensor array as**

Specify sensor element or sensor array. A sensor array can also contain subarrays or be a partitioned array. This parameter can also be expressed as a MATLAB expression.

**Types**

| |
|---|
| `Single element` |
| `Array (no subarrays)` |
| `Partitioned array` |
| `Replicated subarray` |
| `MATLAB expression` |

**Geometry**

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array

- UCA — Uniform circular array
- Conformal Array — arbitrary element positions

**Number of elements**

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to ULA or UCA. If **Sensor Array** has a Replicated subarray option, this parameter applies to the subarray.

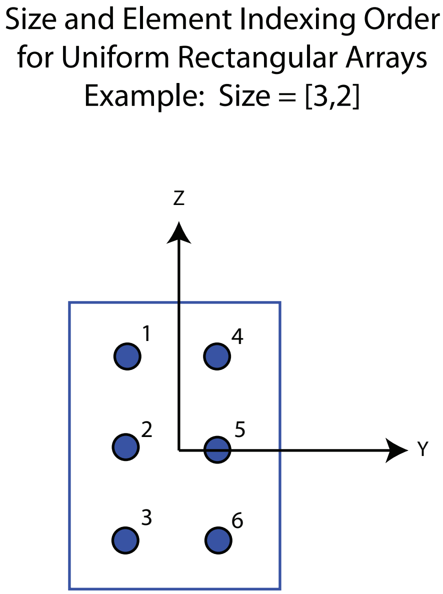
**Array size**

This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to Replicated subarray, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form [NumberOfArrayRows,NumberOfArrayColumns].
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of [3,2] produces an array of three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

### Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see `phased.URA`. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

### Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Element lattice**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

**Element positions (m)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

**Element normals (deg)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

**Subarray definition matrix**

This parameter appears when **Specify sensor array as** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix corresponds to

a subarray and each entry in the row indicates whether or not an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

**Subarray steering method**

This parameter appears when the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as either

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Phase shifter frequency (Hz)**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

**Number of bits in phase shifters**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Subarrays layout**

This parameter appears when you set **Sensor array** to `Replicated subarray`.

Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

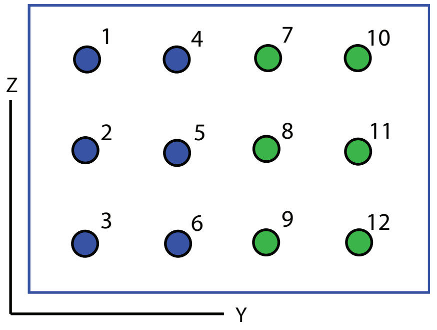
**Grid size**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

3 x 2 Element URA
Replicated on a 1 x 2 Grid



**Grid spacing**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

**Subarray positions (m)**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

**Subarray normals**

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Expression**

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Radiated signals input port<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Radiating directions of signals input port. | Double-precision floating point |
| `W` | Array or subarray weights input port. To enable this port, select the **Enable weights input** check box. | Double-precision floating point |
| `WS` | Subarray element weights input port. To enable this port select `Custom` from the **Subarray steering method** pull down menu. | |
| `Steer` | Steering angle input port. To enable this port, select `Phase` or `Time` from the **Subarray steering method** pull down menu. | Double-precision floating point |
| `Out` | Radiated signals. | Double-precision floating point |

# Phase Coded Waveform

Phase-coded pulse waveform

**Library:** Phased Array System Toolbox / Waveforms

## Description

The Phase-Coded Waveform block generates samples of a phase-coded pulse waveform with specified chip width, pulse repetition frequency (PRF), and phase code. The block outputs an integer number of pulses or samples.

## Ports

### Input

**`PRFIdx` — PRF Index**
positive integer

Index to select the pulse repetition frequency (PRF), specified as a positive integer. The index selects the PRF from the predefined vector of values specified by the **Pulse repetition frequency (Hz)** parameter.

Example: 4

**Dependencies**

To enable this port, select **Enable PRF selection input**.

Data Types: `double`

### Output

**Y — Pulse waveform**
complex-valued vector

Pulse waveform samples, returned as a complex-valued vector.

Data Types: `double`

**PRF — Pulse repetition frequency**
positive scalar

Pulse repetition frequency of current pulse, returned as a positive scalar.

**Dependencies**

To enable this port, set the **Output signal format** parameter to `Pulses` and then select the **Enable PRF output** parameter.

Data Types: `double`

## Parameters

**`Sample rate (Hz)` — Sample rate of the output waveform**
`1e6` (default) | positive scalar

Sample rate of the output waveform, specified as a positive scalar. Set the ratio of the **Sample rate (Hz)** parameter to the **Pulse repetition frequency (Hz)** parameter to an integer.

- The ratio of **Sample rate (Hz)** to each element in the **Pulse repetition frequency (Hz)** vector must be an integer. This restriction is equivalent to requiring that the pulse repetition interval is an integral multiple of the sample interval.
- The product of **Sample rate (Hz)** and **Chip width (s)** must be an integer. This restriction is equivalent to requiring that the chip width is an integer multiple of the sample interval.

Units are in Hz.

Example: `5e3`

**`Phase code` — Code type used for phase modulation**
`Frank` (default)

Code type used for phase modulation, specified as one of

- `Barker`

- `Frank`
- `P1`
- `P2`
- `P3`
- `P4`
- `Px`
- `Zadoff-Chu`

Example: `P2`

### `Chip width (s)` — Chip time duration

`1e-5` (default) | positive scalar

Duration of every chip in a phase-coded waveform, specified as a positive scalar. The value of this parameter must satisfy these constraints:

- The product of **Chip width (s)**, **Number of chips**, and **Pulse repetition frequency (Hz)** must be less than or equal to one. This restriction is equivalent to requiring that the pulse length is less than the pulse repetition interval.
- The product of **Sample rate (Hz)** and **Chip width (s)** must be an integer. This restriction is equivalent to requiring that the chip width is an integer multiple of the sample interval.

Units are in seconds.

Example: `2e-4`

### `Number of chips` — Number of chips in waveform

`4` (default) | positive integer

Number of chips in a phase-coded waveform, specified as a positive integer. The product of the **Chip width (s)**, **Number of chips**, and **Pulse repetition frequency (Hz)** parameters must be less than or equal to one. This restriction is equivalent to requiring that the chip width is an integer multiple of the sample interval.

The table shows additional constraints on the number of chips for different code types.

| If the Phase code parameter is... | Then the Number of chips parameter must be... |
|---|---|
| `Frank`, `P1`, or `Px` | A perfect square |
| `P2` | An even number that is a perfect square |
| `Barker` | 2, 3, 4, 5, 7, 11, or 13 |

Example: 9

### `Zadoff-Chu sequence index` — Sequence index for Zadoff-Chu code type

`1` (default) | positive integer

Sequence index for Zadoff-Chu code type, specified as a positive integer. The values of the **Zadoff-Chu sequence index** and the **Number of chips** parameters must be relatively prime.

Example: 2

#### Dependencies

To enable this parameter, set **Phase Code** to `Zadoff-Chu`.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* by using block parameter settings alone or in conjunction with the input port, `PRFIdx`.

- When the **Enable PRF selection input** parameter is not selected, set the *PRF* using block parameters.

  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.
  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses cycles through the successive values of the *PRF* vector.
- When the **Enable PRF selection input** parameter is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute the block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, the number of output samples is fixed when you set the **Output signal format** to `Samples`. When you use a varying *PRF* and set **Output signal format** to `Pulses`, the number of output samples can vary.

### `Enable PRF selection input` — Select predefined PRF

off (default) | on

Select this parameter to enable the `PRFIdx` port.

- When enabled, pass in an index into a vector of predefined PRFs. Set predefined PRFs using the **Pulse repetition frequency (Hz)** parameter.
- When not enabled, the block cycles through the vector of PRFs specified by the **Pulse repetition frequency (Hz)** parameter. If **Pulse repetition frequency (Hz)** is a scalar, the PRF is constant.

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### `Number of pulses in output` — Number of pulses in output

`1` (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: `2`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Pulses`.

Data Types: `double`

### `Enable PRF Output` — Enable output of PRF

off (default) | on

Select this parameter to enable the PRF output port.

#### Dependencies

To enable this parameter, set **Output signal format** to `Pulses`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## See Also

`phased.PhaseCodedWaveform`

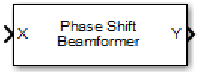
# Phase Shift Beamformer

Narrowband phase-shift beamformer
**Library:** Phased Array System Toolbox / Beamforming



## Description

The Phase Shift Beamformer block performs delay-and-sum beamforming. The delay is approximated using the phase-shift approximation in the time domain.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**Ang — Beamforming direction**
2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### `Y` — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

# Parameters

#### Main tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

**`Operating frequency (Hz)` — System operating frequency**
`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

**`Source of beamforming direction` — Source of beamforming direction**
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

**`Beamforming direction (deg)` — Beamforming directions**
*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

**Dependencies**

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

**`Number of bits in phase shifters` — Number of phase shift quantization bits**
`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**`Weights normalizing method` — Specify weights normalization method**
`Distortionless` (default) | `Preserve power`

Specify this parameter to set the weights normalizing method. Choose `Distortionless` to set the gain in the beamforming direction to zero dB. Choose `Preserve power` to set the norm of the weights to one.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

#### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### Specify sensor array as — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### Element type — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- ULA — Uniform linear array
- URA — Uniform rectangular array
- UCA — Uniform circular array
- Conformal Array — arbitrary element positions

### Number of elements — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to ULA or UCA.

### Element spacing (m) — Spacing between array elements

0.5 for ULA arrays and [0.5,0.5] for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form [SpacingBetweenArrayRows,SpacingBetweenArrayColumns].
- When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to ULA or URA.

### Array axis — Linear axis direction of ULA

y (default) | x | z

Linear axis direction of ULA, specified as y, x, or z. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

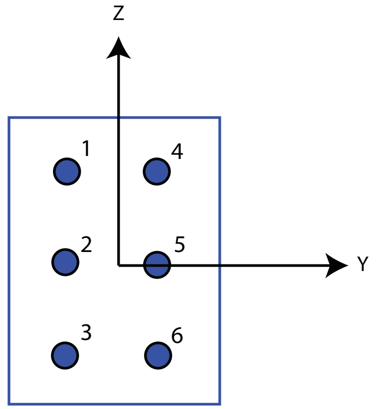
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Element lattice — Lattice of URA element positions

Rectangular (default) | Triangular

Lattice of URA element positions, specified as Rectangular or Triangular.

- Rectangular — Aligns all the elements in row and column directions.
- Triangular — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Array normal — Array normal direction

x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as x, y, or z.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| x | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| y | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| z | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to URA or UCA.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

**Dependencies**

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

**Dependencies**

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

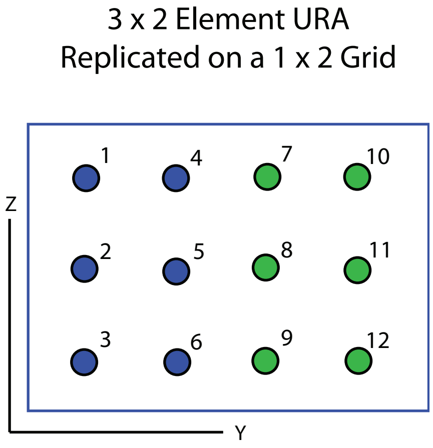
To enable this parameter, set **Sensor array** to `Replicated subarray`

### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

# Motion Platform

Motion platform

Platform
Pos
Vel

## Library

Environment and Target

`phasedenvlib`

## Description

The Motion Platform block models the motion of multiple platforms such as airplanes, ground vehicles, and/or receiving and transmitting sensors arrays, determining their positions and velocities. The platforms move along trajectories determined by initial positions and velocities, according to which motion model you choose — the velocity or acceleration model. The platform positions and velocities are updated at each simulation step. In addition, you can specify initial orientations for the platforms and obtain orientation updates.

## Parameters

### Model of object motion

Object motion model, specified as `Velocity`, `Acceleration`, or `Custom`. When you set this parameter to `Velocity`, the platform follows a constant velocity trajectory during each simulation step. When you set this parameter to `Acceleration`, the platform follows a constant acceleration trajectory during each simulation step. When you set the parameter to `Custom`, the platform motion follows a sequence of waypoints specified by the **Custom trajectory waypoints** parameter. The object performs a piecewise cubic interpolation on the waypoints to derive the position and velocity at each time step.

### Initial position (m)

Specify the initial position of the platform in meters as a 3-by-*N* matrix where each column represents the initial position of a platform in the form `[x;y;z]`. The quantity *N* is the number of platforms.

### Initial velocity (m/s)

Specify the initial velocity of the platform in m/s as a 3-by-*N* matrix where each column represents the initial velocity of a platform in the form `[vx;vy;vz]`. The quantity *N* is the number of platforms. This parameter appears only when you set the **Source of velocity** or the **Source of acceleration** parameters to `Input port`.

### Source of velocity

This parameter appears only when you set the **Model of object motion** parameter to `Velocity`. Then, you must supply velocity data for the model. Specify the **Source of velocity** data as either coming from a `Property` or an `Input port`.

| Source of velocity | Use these model parameters or ports |
|---|---|
| `Property` | **Initial position (m)** parameter<br>**Velocity (m/s)** parameter |
| `Input port` | **Initial position (m)** parameter<br>**Initial velocity (m/s)** parameter<br>`Vel` input port |

### Velocity (m/s)

Specify the current velocity of the platforms in m/s as a 3-by-*N* matrix where each column represents the current velocity of a platform in the form `[vx;vy;vz]`. This parameter appears only when you set the **Model of object motion** parameter to `Velocity` and set the **Source of velocity** parameter to `Property`.

### Source of acceleration

This parameter appears only when you set the **Model of object motion** parameter to `Acceleration`. Then, you must supply acceleration values for the model. Specify the **Source of acceleration** data as either coming from a `Property` or an `Input port`.

| Source of acceleration | Use these model parameters or ports |
|---|---|
| `Property` | **Initial Position (m)** parameter<br>**Initial Velocity (m/s)** parameter<br>**Acceleration (m/s^2)** parameter |
| `Input port` | **Initial Position (m)** parameter<br>**Initial Velocity (m/s)** parameter<br>`Acl` input port |

**Acceleration (m/s^2)**

Specify the current acceleration of the platforms in m/s^2 as a 3-by-*N* matrix where each column represents the current acceleration of a platform in the form `[ax;ay;az]`. This parameter appears when you set the **Model of object motion** parameter to `Acceleration` and set the **Source of acceleration** parameter to `Property`.

**Custom trajectory waypoints**

Custom trajectory waypoints, specified as a real-valued *M*-by-*L* matrix, or *M*-by-*L*-by-*N* array. *M* is the number of waypoints. *L* is either 4 or 7.

- When *L* is 4, the first column indicates the times at which the platform position is measured. The 2$^{nd}$ through 4$^{th}$ columns are position measurements in x, y, and z coordinates. The velocity is derived from the position measurements.
- When L is 7, the 5th through seven$^{th}$ columns in the matrix are velocity measurements in x, y, and z coordinates.

When you set the **Custom trajectory waypoints** parameter to a three-dimensional array, the number of pages, *N*, represent the number of platforms. Time units are in seconds, position units are in meters, and velocity units are in meters per second.

To enable this property, set the **Model of object motion** property to `Custom`.

**Mechanical scanning mode**

Mechanical scan mode for platform, specified as `None`, `Circular`, or `Sector`, where `None` is the default. When you set the **Mechanical scanning mode** parameter to `Circular`, the platform scan clockwise 360 degrees continuously in the azimuthal direction of the platform orientation axes. When you set the **Mechanical scanning**

**mode** parameter to `Sector`, the platform scans clockwise in the azimuthal direction in the platform orientation axes within a range specified by the **Azimuth scan angle span (deg)** parameter. When the platform scan reaches the span limits, the scan reverses direction and scans back to the other scan limit. Scanning happens within the orientation axes of the platform.

**Initial scan angle (deg)**

Initial scan angle of platform, specified as a 1-by-*N* vector where *N* is the number of platforms. The scanning occurs in the local coordinate system of the platform. The **Initial orientation axes** parameter specifies the original local coordinate system. At the start of the simulation, the orientation axes specified by the **Initial orientation axes** are rotated by the angle specified in the `InitialScanAngle` **Initial scan angle (deg)** parameter. The default value is zero. Units are in degrees. This parameter applies when you set the **Mechanical scanning mode** parameter to `Circular` or `Sector`.

**Azimuth scan angle span (deg)**

The azimuth angle span, specified as an *N*-by-2 matrix where *N* is the number of platforms. Each row of the matrix specifies the scan range of the corresponding platform in the form `[ScanAngleLowerBound ScanAngleHigherBound]`. The default value is `[-60 60]`. Units are in degrees. To enable this parameter, set the **Mechanical scanning mode** parameter to `Sector`.

**Azimuth scan rate (deg/s)**

Azimuth scan rate, specified as a 1-by-*N* vector where *N* is the number of platforms. Each entry in the vector is the azimuth scan rate for the corresponding platform. The default value is 10 degrees/second. Units are in degrees/second. To enable this parameter, set the **Mechanical scanning mode** parameter to `Circular` or `Sector`.

**Initial orientation axes**

Specify the three axes that define the initial local *(x,y,z)* coordinate system at the platform as a 3-by-3-by-*N* matrix. Each column of the matrix represents an axis of the local coordinate system. The three axes must be orthonormal.

**Enable orientation axes output**

Select this check box to obtain the instantaneous orientation axes of the platform via the output port `LAxes`. The port appears only when the check box is selected.

**Source of elapsed simulation time**

Specify the source for elapsed simulation time as `Auto` or `Derive from reference input port`. When you choose `Auto`, the block computes the elapsed time. When you choose `Derive from reference input port`, the block uses the time duration of a reference signal passed into the `Ref` input port.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `Vel` | Platform velocity input | Double-precision floating point |
| `Acl` | Platform acceleration input | Double-precision floating point |
| `Ref` | Reference signal input | Double-precision floating point |
| `Pos` | Platform position output | Double-precision floating point |
| `Vel` | Platform velocity output | Double-precision floating point |
| `LAxes` | Platform orientation output | Double-precision floating point |

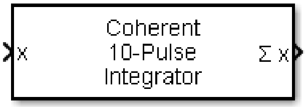
# Pulse Integrator

Coherent or noncoherent pulse integration



## Library

Detection

`phaseddetectlib`

## Description

The Pulse Integrator block performs coherent or noncoherent integration of successive pulses of a signal and puts out an integrated output. You can specify how many pulses to integrate and the number of overlapped pulses in successive integrations.

## Parameters

**Integration method**

Specify the integration method as `Coherent` or `Noncoherent`.

**Number of pulses to integrate**

Specify the number of pulses to integrate as an integer.

**Integration overlap (in pulses)**

Specify the number of overlapped pulses in successive integrations as an integer. This number must be less than the value specified in **Number of pulses to integrate**.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Supported Data Types |
|---|---|
| X | Double-precision floating point |
| ∑ X | Double-precision floating point |

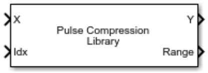
## See Also

`pulsint`

**Introduced in R2014b**

# Pulse Compression Library

Library of pulse compression specifications
**Library:** Phased Array System Toolbox / Detection



## Description

The Pulse Compression Library block performs range processing using pulse compression. Pulse compression techniques include matched filtering and stretch processing. The block lets you create a library of different pulse compression specifications. The output is the filter response consisting of a matrix or a three-dimensional array with rows representing range gates.

## Ports

### Input

**X — Input signal**
complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Input signal, specified as a complex-valued *K*-by-*L* matrix, complex-valued *K*-by-*N* matrix, or a complex-valued *K*-by-*N*-by-*L* array. *K* denotes the number of fast time samples, *L* the number of pulses, and *N* is the number of channels. Channels can be array elements or beams.

Data Types: `double`

**`Idx` — Index of processing specification**
positive integer

Index of the processing specification in the pulse compression library, specified as a positive integer.

Data Types: `double`

## Output

### Y — Output signal

complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Output signal, returned as a complex-valued *M*-by-*L* matrix, complex-valued *M*-by-*N* matrix, or a complex-valued *M*-by-*N*-by-*L* array. *M* denotes the number of fast time samples, *L* the number of pulses, and *N* is the number of channels. Channels can be array elements or beams. The number of dimensions of `Y` matches the number of dimensions of `X`.

When matched filtering is performed, *M* is equal to the number of rows in `X`. When stretch processing is performed and you specify a value for the `RangeFFTLength` name-value pair, *M* is set to the value of `RangeFFTLength`. When you do not specify `RangeFFTLength`, *M* is equal to the number of rows in `X`.

Data Types: `double`

### Range — Sample range

real-valued length-*M* vector

Sample ranges, returned as a real-valued length-*M* vector where *M* is the number of rows of `Y`. Elements of this vector denote the ranges corresponding to the rows of `Y`.

Data Types: `double`

## Parameters

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Specification of each waveform in the library` — Specification of pulse waveforms in the library

`{{'Rectangular','PRF',1e4,'PulseWidth',50e-6}, {'LinearFM','PRF',1e4,'PulseWidth',50e-6,'SweepBandwidth',1e5,'SweepDirection','Up','SweepInterval','Positive'}}` (default) | cell array

Pulse waveforms, specified as a cell array. Each cell of the array contains the specification of one waveform. Each waveform specification is also a cell array containing the parameters of the waveform.

```
{{Waveform 1 Specification},{Waveform 2 Specification},{Waveform 3 Specification}, ...}
```

This block supports four built-in waveforms and also lets you specify custom waveforms. Each built-in waveform specifier consists of a waveform identifier followed by several name-value pairs that set the properties of the waveform.

#### Built-in Waveforms

| Waveform type | Waveform identifier | Waveform name-value pair arguments |
|---|---|---|
| Linear FM | `'LinearFM'` | See "Linear FM Waveform Arguments" on page 1-1647 |
| Phase coded | `'PhaseCoded'` | See "Phase-Coded Waveform Arguments" on page 1-1649 |
| Rectangular | `'Rectangular'` | See "Rectangular Waveform Arguments" on page 1-1651 |
| Stepped FM | `'SteppedFM'` | See "Stepped FM Waveform Arguments" on page 1-1674 |

You can create a custom waveform with a user-defined function. The first input argument of the function must be the sample rate. Use a function handle instead of the waveform identifier in the first cell of a waveform specification. The remaining cells contain all function input arguments except the sample rate. Specify all input arguments in the order they are passed into the function. The function must have at least one output argument to return the samples of each pulse in a column vector. You can only create custom waveforms when you set **Simulate using** to `Interpreted Execution`.

**Pulse compression specifications — Specify type of pulse compression**
{{'MatchedFilter','SpectrumWindow','None'}, {'StretchProcessor','RangeSpan',200,'ReferenceRange',5e3,'RangeWindow','None'}} (default) | cell array

Waveform processing type and parameters, specified as a cell array of processing specifications. Each processing specification is itself a cell array containing the processing type and processing arguments.

```
{{Processing 1 Specification},{Processing 2 Specification},{Processing 3 Specification}, ...}
```

Each processing specification indicates which type of processing to apply to a waveform and the arguments needed for processing.

```
{processtype,Name,Value,...}
```

The value of `processtype` is either `'MatchedFilter'` or `'StretchProcessor'`.

- `'MatchedFilter'` – The name-value pair arguments are
  - `'Coefficients'`,`coeff` – specifies the matched filter coefficients, `coeff`, as a column vector. When not specified, the coefficients are calculated from the `WaveformSpecification` property. For the Stepped FM waveform containing multiple pulses, `coeff` corresponds to each pulse until the pulse index, `idx` changes.
  - `'SpectrumWindow'`,`sw` – specifies the spectrum weighting window, `sw`, applied to the waveform. Window values are one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, and `'Taylor'`. The default value is `'None'`.
  - `'SidelobeAttenuation'`,`slb` – specifies the sidelobe attenuation window, `slb`, of the Chebyshev or Taylor window as a positive scalar. The default value is 30. This parameter applies when you set `'SpectrumWindow'` to `'Chebyshev'` or `'Taylor'`.
  - `'Beta'`,`beta` – specifies the parameter, `beta`, that determines the Kaiser window sidelobe attenuation as a nonnegative scalar. The default value is 0.5. This parameter applies when you set `'SpectrumWindow'` to `'Kaiser'`.
  - `'Nbar'`,`nbar` – specifies the number of nearly constant level sidelobes, `nbar`, adjacent to the main lobe in a Taylor window as a positive integer. The default value is 4. This parameter applies when you set `'SpectrumWindow'` to `'Taylor'`.
  - `'SpectrumRange'`,`sr` – specifies the spectrum region, `sr`, on which the spectrum window is applied as a 1-by-2 vector having the form `[StartFrequency EndFrequency]`. The default value is [0 1.0e5]. This parameter applies when you set the `'SpectrumWindow'` to any value other than 'None'. Units are in Hz.

Both `StartFrequency` and `EndFrequency` are measured in the baseband region [-*Fs*/2 *Fs*/2]. *Fs* is the sample rate specified by the `SampleRate` property. `StartFrequency` cannot be larger than `EndFrequency`.

- `'StretchProcessor'` – The name-value pair arguments are

  - `'ReferenceRange'`,`refrng` – specifies the center of ranges of interest, `refrng`, as a positive scalar. The `refrng` must be within the unambiguous range of one pulse. The default value is 5000. Units are in meters.
  - `'RangeSpan'`,`rngspan` – specifies the span of the ranges of interest. `rngspan`, as a positive scalar. The range span is centered at the range value specified in the `'ReferenceRange'` parameter. The default value is 500. Units are in meters.
  - `'RangeFFTLength'`,`len` – specifies the FFT length in the range domain, `len`, as a positive integer. If not specified, the default value is same as the input data length.
  - `'RangeWindow'`,`rw` specifies the window used for range processing, `rw`, as one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, and `'Taylor'`. The default value is `'None'`.

Data Types: `cell`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If

you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

`phased.PulseCompressionLibrary`

**Introduced in R2018b**

# Pulse Waveform Library

Library of pulse waveforms

**Library:** Phased Array System Toolbox / Waveforms

## Description

The Pulse Waveform Library generates different types of pulse waveforms from a library of waveforms.

## Ports

### Input

**`Idx` — Waveform index**

positive integer

Index to select the waveform, specified as a positive integer. The index selects the waveform from the set of waveforms defined by the **Specification of each waveform in the library** parameter.

Data Types: `double`

### Output

**Y — Pulse waveform samples**

complex-valued column vector | complex-valued matrix

Pulse waveform samples, returned as a complex-valued vector or complex-valued matrix.

Data Types: `double`

## Parameters

### `Sample rate (Hz)` — Sample rate of the output waveform

`1e6` (default) | positive scalar

Sample rate of the output waveform, specified as a positive scalar. The ratio of **Sample rate (Hz)** to each element in the **Pulse repetition frequency (Hz)** vector must be an integer. This restriction is equivalent to requiring that the pulse repetition interval is an integral multiple of the sample interval.

### `Specification of each waveform in the library` — Pulse waveforms in the library

`{{'Rectangular','PRF',1e4,'PulseWidth',50e-6}, {'LinearFM','PRF',1e4,'PulseWidth',50e-6,'SweepBandwidth',1e5,'SweepDirection','Up','SweepInterval','Positive'}}` (default) | cell array

Pulse waveforms, specified as a cell array. Each cell of the array contains the specification of one waveform. Each waveform is also a cell array containing the parameters of the waveform.

```
{{Waveform 1 Specification},{Waveform 2 Specification},{Waveform 3 Specification}, ...}
```

This block supports four built-in waveforms and also lets you specify custom waveforms. Each built-in waveform specifier consists of a waveform identifier followed by several name-value pairs that set the properties of the waveform.

#### Built-in Waveforms

| Waveform type | Waveform identifier | Waveform name-value pair arguments |
|---|---|---|
| Linear FM | `'LinearFM'` | See “Linear FM Waveform Arguments” on page 1-1669 |
| Phase coded | `'PhaseCoded'` | See “Phase-Coded Waveform Arguments” on page 1-1671 |
| Rectangular | `'Rectangular'` | See “Rectangular Waveform Arguments” on page 1-1673 |
| Stepped FM | `'SteppedFM'` | See “Stepped FM Waveform Arguments” on page 1-1674 |

You can create a custom waveform with a user-defined function. The first input argument of the function must be the sample rate. Use a function handle instead of the waveform identifier in the first cell of a waveform specification. The remaining cells contain all function input arguments except the sample rate. Specify all input arguments in the order they are passed into the function. The function must have at least one output argument to return the samples of each pulse in a column vector. You can only create custom waveforms when you set **Simulate using** to `Interpreted Execution`.

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Radar Target

Radar target

## Library

Environment and Target

`phasedenvlib`

## Description

The Radar Target block models a radar target that reflects the signal according to the specified radar cross section (RCS). The block supports all four Swerling models.

## Parameters

**Source of mean radar cross section**

Specify whether the target’s mean radar cross-section (RCS) value comes from the **Mean radar cross section** parameter of this block or from an input port. Values of this parameter are

| | |
|---|---|
| `Property` | The **Mean radar cross section** parameter for this block specifies the mean RCS value. |
| `Input port` | Choosing this value creates the RCS input port to specify the mean radar cross-section. |

**Mean radar cross section (m^2)**

Specify the mean value of the target's radar cross section, in square meters, as a nonnegative scalar. This parameter appears only when the **Source of mean radar cross section** parameter is set to `Property`.

**Fluctuation model**

Specify the statistical model of the target as one of `Nonfluctuating`, `Swerling1`, `Swerling2`, `Swerling3`, or `Swerling4`. Setting this parameter to a value other than `Nonfluctuating`, allows setting cross-sections parameters via an input port, `Update`.

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the carrier frequency of the signal that reflects from the target, as a positive scalar in hertz.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Incident signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `RCS` | Mean radar cross-section. | Double-precision floating point |

| Port | Description | Supported Data Types |
|---|---|---|
| `Update` | Update RCS at block execution. | Double-precision floating point |
| `Out` | Scattered signal. | Double-precision floating point |

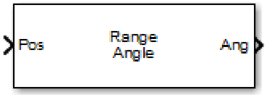
# Range Angle Calculator

Range and angle calculations



## Library

Environment and Target

`phasedenvlib`

## Description

The Range Angle Calculator block calculates the ranges and/or the azimuth and elevation angles of several positions with respect to a reference position and with respect to a reference axes orientation. The reference position and reference axes can be specified in the block dialog or using input ports.

## Parameters

**Propagation model**

Specify the propagation model by setting this parameter to `Free space` or `Two-ray`.

**Reference position source**

Specify the reference position source by setting this parameter to `Property` or `Input port`. If **Reference position source** is set to `Property`, set the position using the **Reference position** parameter. If **Reference position source** is set to `Input port`, use the input port labeled `RefPos`.

**Reference position**

Specify the reference position as a 3-by-1 vector of rectangular coordinates in meters in the form `[x;y;z]`. The reference position serves as the origin of the local coordinate system. Ranges and angles of the input positions are measured with respect to the reference position. This parameter appears only when **Reference position source** is set to `Property`.

**Reference axes source**

Specify the reference axes source by setting this parameter to `Property` or `Input port`. If **Reference axes source** is set to `Property`, set the axes using the **Reference axes** parameter. If **Reference axes source** is set to `Input port`, use the input port labeled `RefAxes`.

**Reference axes**

Specify the reference axes of the local coordinate system with which to calculate range and angles in the form of a 3-by-3 orthonormal matrix. Each column of the matrix specifies the direction of an axis for the local coordinate system in the form of `[x; y; z]` with origin at the reference position. This parameter appears only when **Reference axes source** is set to `Property`.

**Output(s)**

Specify the desired output(s) of the block. Each type of output is sent to a different port depending on the parameter value.

| Value | Port |
|---|---|
| `Angle` | `Ang` |
| `Range` | `Range` |
| `Range and Angle` | `Ang` and `Range` |

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Supported Data Types |
|---|---|
| `Pos` | Double-precision floating point |
| `RefPos` | Double-precision floating point |
| `RefAxes` | Double-precision floating point |
| `Range` | Double-precision floating point |
| `Ang` | Double-precision floating point |

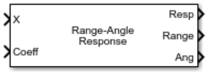
# Range-Angle Response

Obtain range-angle response map for array

**Library:** Phased Array System Toolbox / Detection



## Description

The Range-Angle Response block computes the range-angle map of an input signal. The output response is a matrix or a three-dimensional array whose rows represent range gates and columns represent angles. Pages represent

## Ports

### Input

**X — Input signal data cube**

complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Input signal cube, specified as a complex-valued *K*-by-*N* matrix or complex-valued *K*-by-*N*-by-*L* array. The contents of the data cube depend on the type of range-angle processing specified by the different syntaxes.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or directions.
- *L* is the slow-time dimension that corresponds to the number of pulses or sweeps in the input signal.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**PRF — Pulse repetition frequency**

positive scalar

Pulse repetition frequency

#### Dependencies

To enable this input argument, set the value of **Range processing method** to `FFT` and do not select the **Dechirp input signal** check box.

Data Types: `double`

### `Xref` — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the fast-time dimension of `X`.

#### Dependencies

To enable this input argument, set the value of **Range processing method** to `FFT` and select the **Dechirp input signal** check box.

Data Types: `double`

### `Coeff` — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*. *K* is the number of fast-time or range sample.

#### Dependencies

To enable this input argument, set the value of **Range processing method** to `Matched filter`.

Data Types: `double`

### `El` — Elevation angle

scalar

Elevation angle of response, specified as a scalar between –90° and +90°. The range-angle response is computed for this elevation. Units are in degrees.

#### Dependencies

To enable this argument, set the **Source of elevation angle** parameter to `Input port`.

Data Types: `double`

## Output

### Resp — Range response data cube

complex-valued *M*-element column vector | complex-valued *M*-by-*L* matrix | complex-valued *M*-by-*N* by-*L* array

Range response data cube, returned as one of the following:

- Complex-valued *M*-element column vector
- Complex-valued *M*-by-*L* matrix
- Complex-valued *M*-by-*N* by-*L* array

The value of *M* depends on the type of processing

| Range Processing Method | Value of *M* |
|---|---|
| `FFT` | If you set the **Source of FFT length in range processing** parameter to `Auto`, then *M* = *K*, the length of the fast-time dimension of `X`. Otherwise, *M* equals the value of the FFT length in range processing parameter. |
| `Matched filter` | *M* = *K*, the length of the fast-time dimension of `X`. |

Data Types: `double`

### Range — Range values along range dimension

real-valued *M*-by-1 column vector

Range values along range dimension, returned as a real-valued *M*-by-1 column vector. This vector defines the ranges that correspond to the fast-time dimension of the `RESP` output data cube. *M* is the length of the fast-time dimension of `RESP`. Range values are monotonically increasing and equally spaced. Units are in meters.

Data Types: `double`

### Ang — Angle values along angle direction

*P*-by-1 real-valued vector

Angle values corresponding to the samples along angle direction, returned as a *P*-by-1 real-valued vector. Units are in degrees.

Data Types: `double`

# Parameters

**Main Tab**

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Range processing method` — Range processing method

`Matched filter` (default) | `FFT`

Range processing method, specified as `Matched filter` or `FFT`.

- `Matched filter` — The object match-filters the incoming signal. This approach is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal.
- `FFT` — The object applies an FFT to the input signal. This approach is commonly used for chirped signals such as FMCW and linear FM pulsed signals.

Data Types: `char`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

**Dependencies**

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `FM sweep slope (Hz/s)` — Linear FM sweep slope

`1.0e9` (default) | scalar

Linear FM sweep slope, specified as a scalar. The fast-time dimension of the `X` input port must correspond to sweeps having this slope.

Example: `1.5e9`

**Dependencies**

To enable this parameter, set the **Range processing method** parameter to `FFT`.

Data Types: `double`

### `Dechirp input signal` — Enable dechirping of input signals

`on` (default) | `off`

Option to enable dechirping of input signals, specified as `on` or `off`. Not selecting this check box indicates that the input signal is already dechirped and no dechirp operation is necessary. Select this check box when the input signal requires dechirping.

**Dependencies**

To enable this parameter, set the **Range processing method** parameter to `FFT`.

Data Types: `Boolean`

### `Source of FFT length in range` — Source of FFT length for range processing of dechirped signals

`Auto` (default) | `Property`

Source of the FFT length used for the range processing of dechirped signals, specified as `Auto` or `Property`.

- `Auto` — The FFT length equals the length of the fast-time dimension of the input data cube.
- `Property` — Specify the FFT length by using the **FFT length in range processing** parameter.

#### Dependencies

To enable this parameter, set the **Range processing method** parameter to `FFT`.

Data Types: `char`

### `FFT length in range processing` — FFT length used for range processing

`1024` (default) | positive integer

FFT length used for range processing, specified as a positive integer.

#### Dependencies

To enable this parameter, set the **Range processing method** parameter to `FFT` and the **Source of FFT length in range processing** parameter to `Property`.

Data Types: `double`

### `Range processing window` — FFT weighting window for range processing

`None` (default) | `Hamming` | `Chebyshev` | `Hann` | `Kaiser` | `Taylor`

FFT weighting window for range processing, specified as `None`, `Hamming`, `Chebyshev`, `Hann`, `Kaiser`, or `Taylor`.

If you set this parameter to `Taylor`, the generated Taylor window has four nearly constant sidelobes next to the mainlobe.

#### Dependencies

To enable this parameter, set the **Range processing method** parameter to `FFT`.

Data Types: `char`

### `Range sidelobe attenuation level` — Sidelobe attenuation for range processing

`30` (default) | scalar

Sidelobe attenuation for range processing, specified as a positive scalar. This attenuation applies only to Kaiser, Chebyshev, or Taylor windows. Units are in dB.

#### Dependencies

To enable this parameter, set the **Range processing method** parameter to FFT and the **Range processing window** parameter to Kaiser, Chebyshev, or Kaiser.

### Set reference range at center — Set reference range at center of range grid

on (default) | off

Set reference range at center of range grid, specified as on or off. Selecting this check box enables you to set the reference range at the center of the range grid. Otherwise, the reference range corresponds to the beginning of the range grid.

#### Dependencies

To enable this parameter, set the **Range processing method** to FFT.

Data Types: Boolean

### Reference range (m) — Reference range of range grid

0.0 (default) | nonnegative scalar

Reference range of the range grid, specified as a nonnegative scalar.

- If you set the **Range processing method** parameter to 'Matched filter', the reference range is set to the start of the range grid.
- If you set the **Range processing method** parameter to FFT, the reference range is determined by the **Set reference range at center** parameter.

  - When you select the **Set reference range at center** check box, the reference range is set to the center of the range grid.
  - Otherwise, the reference range is set to the start of the range grid.

  Units are in meters.

Example: 1000.0

Data Types: double

### Source of elevation angle — Source of elevation angle

Property (default) | **Input port**

Source of elevation angle, specified as Property or **Input port**.

| | |
|---|---|
| `Property` | The elevation angle comes from the **Elevation angle (deg)** parameter. |
| `Input port` | The elevation angle comes from an input port. |

### `Elevation angle (deg)` — Elevation angle used to calculate range-angle response

`0` (default) | scalar

Elevation angle used to calculate range-angle response, specified as a scalar. The angle must be between --90 and 90 degrees. This property applies when you set the ElevationAngleSource property to `'Property'`. The default value of this property is 0.

### `Angle span (deg)` — Angle response span

`[-90 90]` (default) | real-valued 1-by-2 vector

Angle response span, specified as a real-valued 2-by-1 vector. The object calculates the range-angle response within the angle range, `[min_angle max_angle]`.

Example: `[-45 45]`

Data Types: `12wqqqq`` | `qdouble`

### `Number of angle bins` — Number of samples in angle span

positive integer greater than two

Number of samples in angle span used to calculate range-angle response, specified as a positive integer greater than two.

Example: `[256]`

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code`

Generation. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in Accelerator mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### Specify sensor array as — Method to specify array

Array (no subarrays) (default) | Partitioned array | Replicated subarray | MATLAB expression

Method to specify array, specified as Array (no subarrays) or MATLAB expression.

- Array (no subarrays) — use the block parameters to specify the array.
- Partitioned array — use the block parameters to specify the array.
- Replicated subarray — use the block parameters to specify the array.
- MATLAB expression — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

**Dependencies**

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

**Dependencies**

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### Phase pattern (deg) — Custom antenna radiation phase pattern

zeros(181,361) (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### Polar pattern frequencies (Hz) — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### Polar pattern angles (deg) — Polar pattern response angles

[-180:180] (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### Polar pattern (dB) — Custom microphone polar response

zeros(1,361) (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

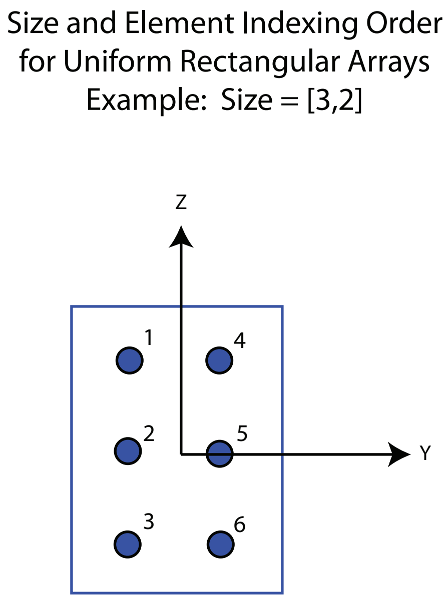
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### Element lattice — Lattice of URA element positions

Rectangular (default) | Triangular

Lattice of URA element positions, specified as Rectangular or Triangular.

- Rectangular — Aligns all the elements in row and column directions.
- Triangular — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### Array normal — Array normal direction

x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as x, y, or z.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

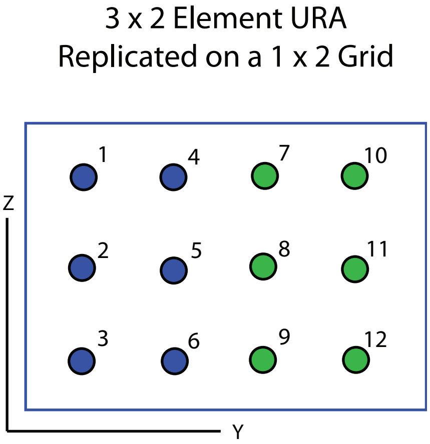
### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The

second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

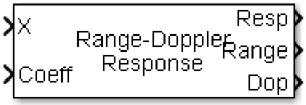
## See Also

`phased.RangeAngleResponse`

**Introduced in R2018b**

# Range Doppler Response

Range-Doppler response



## Library

Detection

`phaseddetectlib`

## Description

The Range-Doppler Response block computes the range-Doppler map of an input signal. The output response is a matrix whose rows represent range gates and whose columns represent Doppler bins.

## Parameters

**Range processing method**

Specify the method of range processing as `Matched filter` or `FFT`

| | |
|---|---|
| `Matched filter` | Applies a matched filter to the incoming signal. This technique is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal. Choosing this option creates the `Coeff` input port. |
| `FFT` | Performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW and linear FM pulsed signals. |

**Signal propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Source of pulse repetition frequency**

Source of pulse repetition frequency, specified as

- `Auto` — automatically compute the pulse repetition frequency (PRF). The PRF is the sample rate of the signal divided by the number of rows in the input port signal, `X`.
- `Property`— specify the pulse repetition frequency using the `PRF` parameter.
- `Input port`— specify the PRF using the `PRF` input port.

Use the `Property` or `Input port` option when the pulse repetition frequency cannot be determined by the signal duration, as is the case with range-gated data.

**Pulse repetition frequency of the input signal (Hz)**

Pulse repetition frequency of the input signal, specified as a positive scalar. `PRF` must be less than or equal to the sample rate divided by the number of rows of the input signal. When the signal length is variable, use the maximum possible number of rows of the input signal instead.

To enable this parameter, set the **Source of pulse repetition frequency** parameter to `Property`.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Source of FFT length in Doppler processing**

Specify how the block determines the length of the FFT used in Doppler processing. Values of this parameter are

| | |
|---|---|
| `Auto` | The FFT length equals the number of rows of the input signal. |
| `Property` | The **FFT length in Doppler processing** parameter of this block specifies the FFT length. |

### FFT length in Doppler processing

This parameter appears only when you set **Source of FFT length in Doppler processing** to `Property`. Specify the length of the FFT used in Doppler processing as a positive integer.

### Doppler processing window

Specify the window used for Doppler processing using one of

```
None
Hamming
Chebyshev
Hann
Kaiser
Taylor
```

If you set this parameter to `Taylor`, the generated Taylor window has four nearly-constant sidelobes adjacent to the mainlobe.

### Doppler sidelobe attenuation level

This parameter appears only when **Doppler processing window** is set to `Kaiser`, `Chebyshev`, or `Taylor`. Specify the sidelobe attenuation level as a positive scalar, in decibels.

### Doppler output

Specify the Doppler domain output as `Frequency` or `Speed`

| | |
|---|---|
| `Frequency` | Doppler shift, in hertz. |
| `Speed` | Radial speed corresponding to Doppler shift, in meters per second. |

### Signal carrier frequency (Hz)

This parameter appears only when you set **Doppler output** to `Speed`. Specify the carrier frequency, in hertz, as a scalar.

### FM sweep slope (Hz/s)

This parameter appears only when you set **Range processing method** to `FFT`. Specify the slope of the linear FM sweeping, in hertz per second, as a scalar.

**Dechirp input signal**

This check box appears only when you set **Range processing method** to FFT. Select this check box to make the block perform the dechirp operation on the input signal. Clear this check box to indicate that the input signal is already dechirped and no dechirp operation is necessary.

**Source of FFT length in range processing**

Specify how the block determines the FFT length in range processing. Values of this parameter are

| | |
|---|---|
| Auto | The FFT length equals the number of rows of the input signal. |
| Property | The FFT length is specified by **FFT length in range processing**. |

This parameter appears only when you set **Range processing method** to FFT.

**FFT length in range processing**

This parameter appears only when you set **Range processing method** to FFT and **Source of FFT length in range processing** to Property. Specify the FFT length in the range domain as a positive integer.

**Range processing window**

This parameter appears only when you set **Range processing method** to FFT. Specify the window used for range processing using one of

None

Hamming

Chebyshev

Hann

Kaiser

Taylor

If you set this parameter to Taylor, the generated Taylor window has four nearly-constant sidelobes adjacent to the mainlobe.

**Set reference range at center**

Set reference range at the center of range grid, specified as on or off. Selecting this check box, enables you to set the reference range at the center of the range grid. Otherwise, the reference range is set to the beginning of the range grid.

**Reference range (m)**

Reference range of the range grid, specified as a nonnegative scalar.

- If you set the **Range processing method** parameter to `Matched filter`, the reference range is set to the start of the range grid.
- If you set the **Range processing method** property to `FFT`, the reference range depends on the **Set reference range at center** check box.
  - When you select the **Set reference range at center** check box, the reference range is set to the center of the range grid.
  - If you do not select the **Set reference range at center** check box, the reference range is set to the start of the range grid.

  Units are in meters.

**Range sidelobe attenuation level**

This parameter appears only when you set **Range processing method** to `FFT` and **Range processing window** to `Kaiser`, `Chebyshev`, or `Taylor`. Specify the sidelobe attenuation level as a positive scalar, in decibels.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.<br>Signal lengths can vary when you use pulse waveforms. Then you can only apply the `Matched filter` option of the **Range processing method** parameter. | Double-precision floating point |
| `Coeff` | Matched-filter coefficients. | Double-precision floating point |
| `XRef` | Reference signal | Double-precision floating point |
| `PRF` | Pulse repetition frequency | Double-precision floating point |
| `Resp` | Range-Doppler response. | Double-precision floating point |
| `Range` | Range grid. | Double-precision floating point |
| `Dop` | Doppler grid. | Double-precision floating point |

## Description

The Range Estimator block estimates the range of target detections obtained from the radar response data.

## Ports

### Input

**Resp — Range-processed response data cube**
complex-valued *P*-by-1 column vector | complex-valued *M*-by-*P* matrix | complex-valued *M*-by-*N*-by-*P* matrix

Range-processed response data cube, specified as a complex-valued *P*-by-1 column vector, a complex-valued *M*-by-*P* matrix, or a complex-valued *M*-by-*N*-by-*P* array. *M* represents the number of range samples, *N* is the number of sensor elements or beams, and *P* is the number of Doppler bins.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**Range — Range grid values along range dimension**
real-valued *M*-by-1 column vector

Range grid values along the range dimension of the data cube input, **Resp**, specified as a real-valued *M*-by-1 column vector. Range values must be monotonically increasing and equally spaced. Units are in meters.

Example: `[-0.3,-0.2,-0.1,0,0.1,0.2,0.3]`

Data Types: `double`

### `DetIdx` — Detection indices

real-valued $N_d$-by-$Q$ matrix

Detection indices, specified as a real-valued $N_d$-by-$Q$ matrix. $Q$ is the number of detections and $N_d$ is the number of dimensions in the response data cube, **Resp**. Each column of **DetIdx** contains the indices of a detection in the response data cube.

### `NoisePower` — Noise power at detection locations

positive scalar | real-valued 1-by-$Q$ row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-$Q$ row vector positive values. $Q$ is the number of detections specified in the **DetIdx** input port.

#### Dependencies

To enable this port, select the **Output variance for parameter estimates** parameter, and then set **Source of noise power parameter** to `Input port`.

### `Clusters` — Cluster IDs

real-valued 1-by-$Q$ row vector of positive values

Cluster IDs, specified as a real-valued 1-by-$Q$ row vector, where $Q$ is the number of detections specified in the **DetIdx** input port. Each element of **Clusters** corresponds to an element of **DetIdx**.

#### Dependencies

To enable this input port, select the **Enable cluster ID input** checkbox.

## Output

### `Est` — Range estimate

real-valued $K$-by-1 column vector

Range estimates, specified as a real-valued $K$-by-1 column vector.

- When **Enable cluster ID input** is not selected, each range estimate corresponds to one of the columns of the **DetIdx** input port. Then $K$ equals the column dimension, $Q$, of **DetIdx**.

- When **Enable cluster ID input** is selected, each range estimate corresponds to one of the cluster IDs in the **Clusters** input port. Then *K* equals the number of unique cluster IDs.

### `Var` — Range estimation variance

positive, real-valued *K*-by-1 column vector

Range estimation variance, returned as a positive, real-valued *K*-by-1 column vector, where *K* is the dimension of **Est**. Each element of **Var** corresponds to an element of **Est**. The estimator variance is computed using the Ziv-Zakai bound.

#### Dependencies

To enable this output port, select the **Output variance for parameter estimates** parameter.

## Parameters

### `Maximum number of estimates` — Maximum number of estimates to report

`1` (default) | positive integer

The maximum number of estimates to report, specified as a positive integer. When the number of requested estimates is greater than the number elements in **DetIdx**, the remainder is filled with `NaN`.

Data Types: `double`

### `Enable cluster ID input` — Enable cluster ID input

`off` (default) | `on`

Enable the **Cluster** input port to pass in cluster association information.

Data Types: `Boolean`

### `Output variance for parameter estimates` — Enable output variance port

`off` (default) | `on`

Enables the output of the parameter estimate variances via the **Var** port.

Data Types: `Boolean`

### `Root-mean-square range resolution` — Range resolution

`2` (default) | positive scalar

Root-mean-square range resolution of the detection, specified as a positive scalar. This parameter must have the same units as the **Range** input port.

#### Dependencies

To enable this parameter, select the `Output variance for parameter estimates` parameter.

Data Types: `double`

### `Source of noise power` — Source of noise power values

`Property` (default) | `Input port`

Source of the noise power, specified as `Property` or `Input port`. If you set this parameter to `Property`, use the **Noise power** parameter to set the noise power at the detection locations. When set the parameter to `Input port`, specify noise power via the `NoisePower` input port.

### `Noise power` — Noise power values

`1.0` (default) | positive scalar

Noise power for detections, specified as a positive scalar. The same noise power value is applied to all detections. Noise power is in linear units.

#### Dependencies

To enable this parameter, select the **Output variance for parameter estimates** checkbox and set the **Source of noise power** parameter to `Property`.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Range Response

Range response
**Library:** Phased Array System Toolbox / Detection

X
Coeff
Range Response
Resp
Range

## Description

The Range Response block performs range filtering on fast-time (range) data, using either a matched filter or an FFT-based algorithm. The output is typically used as input to a detector. Matched filtering improves the SNR of pulsed waveforms. For continuous FM signals, FFT processing extracts the beat frequency of FMCW waveforms. Beat frequency is directly related to range.

The input to the block is a radar data cube. The organization of the data cube follows the Phased Array System Toolbox convention. The first dimension of the cube represents the fast time samples or ranges of the received signals. The second dimension represents multiple spatial channels such as different sensors or beams. The third dimension, slow time, represent pulses. Range filtering operates along the fast-time dimension of the cube. Processing along the other dimensions is not performed. If the data contains only one channel or pulse, the data cube can contain fewer than three dimensions. Because this object performs no Doppler processing, you can use it to process noncoherent radar pulses.

The output of the block is also a data cube with the same number of dimensions as the input. Its first dimension contains range-processed data but its length can differ from the first dimension of the input data cube.

## Ports

### Input

**X — Input data cube**
complex-valued *K*-by-1 column vector | complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N*-by-*L* array

Input data cube, specified as a complex-valued *K*-by-1 column vector, a complex-valued *K*-by-*L* matrix, or a complex-valued *K*-by-*N*-by-*L* array.

- *K* is the number of range or time samples.
- *N* is the number of independent channels such as sensors or directions.
- *L* is the number of pulses or sweeps in the input signal.

See “Radar Data Cube Concept”.

Each *K*-element column vector is processed independently.

For an FMCW waveform, with a triangle sweep, the sweeps alternate between positive and negative slopes. However, Range Response is designed to process consecutive sweeps of the same slope. To apply the Range Response block for a triangle-sweep system, use one of the following approaches:

- Specify a positive **Sweep slope** parameter value, with X corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative **Sweep slope** parameter value, with X corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

### `Coeff` — Matched filter coefficients

complex-valued column vector

Matched filter coefficients, specified as a complex-valued column vector. The length of the vector must be less than or equal to the number of rows in the input data, *K*.

#### Dependencies

To enable this port, set **Range processing method** to `Matched filter`.

Data Types: `double`

### `XRef` — Reference signal

complex-valued *K*-by-1 column vector

Reference signal used for dechirping the input signal, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the first dimension of `X`.

#### Dependencies

To enable this port, set **Range processing method** to `FFT` and select the **Dechirp input signal** parameter.

Data Types: `double`

## Output

### Resp — Range response data cube

complex-valued *M*-element column vector | complex-valued *M*-by-*L* matrix | complex-valued *M*-by-*N* by-*L* array

Range response data cube, returned as a

- Complex-valued *M*-element column vector
- Complex-valued *M*-by-*L* matrix
- Complex-valued *M*-by-*N* by-*L* array

See “Radar Data Cube Concept”. The value of *M* depends on the type of processing

| Range processing method | Dechirp input signal | Value of *M* |
|---|---|---|
| `FFT` | `off` | If you set the **Source of FFT length in range processing** to `Auto`,*M* = *K*, the length of the first dimension of `x`. Otherwise, *M* equals the value of the **FFT length in range processing** parameter. |
| | `on` | *M* equals the number of rows, *K*, of the input signal. |
| `Matched filter` | N/A | *M* equals the number of rows, *K*, of the input signal. |

Data Types: `double`

### Range — Range values along range dimension

real-valued *M*-by-1 column vector

Range values along the first dimension of the **Resp** output data port, specified as a real-valued *M*-by-1 column vector. This quantity defines the range values along the first dimension of the `Resp` output port data. Units are in meters.

Data Types: `double`

## Parameters

### `Range processing method` — Range processing method

`Matched filter` (default) | `FFT`

Range processing method, specified as `Matched filter` or `FFT`.

| | |
|---|---|
| `Matched filter` | The block applies a matched filter to the incoming signal. This approach is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal. |
| `FFT` | The block applies an FFT to the input signal. This approach is commonly used for FMCW and linear FM pulsed signals. |

Data Types: `char`

### `Propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### Sample rate (Hz) — Sampling rate of signal

1e6 (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: double

### FM sweep slope (Hz/s) — FM sweep slope

1e9 (default) | scalar

Specify the slope of the linear FM sweep as a scalar. This parameter must match the actual sweep of the input data in port X.

#### Dependencies

To enable this parameter, set **Range processing method** to FFT.

Data Types: double

### Dechirp input signal — Enable dechirping of input signal

on (default) | off

Select this parameter to enable dechirping of input signal.

#### Dependencies

To enable this parameter, set **Range processing method** to FFT.

Data Types: Boolean

### Source of FFT length in range processing — Source of FFT length for range processing

Auto (default) | Property

Source of FFT length for range processing, specified as Auto or Property

| | |
|---|---|
| Auto | The FFT length equals the number of rows of the input data cube. |
| Property | Specify FFT length in the **FFT length in range processing** parameter. |

#### Dependencies

To enable this parameter, set **Range processing method** to `FFT`.

Data Types: `char`

### `FFT length in range processing` — Range processing FFT length

`1024` (default) | positive integer

FFT length for range processing, specified as a positive integer.

#### Dependencies

To enable this parameter, set **Range processing method** to `FFT` and **Source of FFT length in range processing** to `Property`.

Data Types: `double`

### `Range processing window` — Range FFT weighting window

`None` (default) | `Hamming` | `Chebyshev` | `Hann` | `Kaiser` | `Taylor`

Range FFT weighting window, specified as `None`, `Hamming`, `Chebyshev`, `Hann`, `Kaiser`, or `Taylor`.

If you set this property to `Taylor`, the generated Taylor window has four nearly constant sidelobes next to the mainlobe.

#### Dependencies

To enable this parameter, set **Range processing method** to `FFT`.

Data Types: `char`

### `Range sidelobe attenuation level` — Sidelobe attenuation for range processing

`30` (default) | positive scalar

Sidelobe attenuation for range processing, specified as a positive scalar. Units are in dB.

#### Dependencies

To enable this parameter, set **Range processing method** to `FFT` and **Range processing window** to `Kaiser`, `Chebyshev`, or `Taylor`.

Data Types: `double`

### `Set reference range at center` — Set reference range at center of range grid

`on` (default) | `off`

Set reference range at the center of range grid, specified as `on` or `off`. Selecting this check box, enables you to set the reference range at the center of the range grid. Otherwise, the reference range is set to the beginning of the range grid.

#### Dependencies

To enable this property, set the **Range processing method** to `FFT`.

### `Reference range (m)` — Reference range of range grid

`0.0` (default) | nonnegative scalar

Reference range of the range grid, specified as a nonnegative scalar.

- If you set the **Range processing method** parameter to `Matched filter`, the reference range is set to the start of the range grid.
- If you set the **Range processing method** property to `FFT`, the reference range depends on the **Set reference range at center** check box.

  - When you select the **Set reference range at center** check box, the reference range is set to the center of the range grid.
  - If you do not select the **Set reference range at center** check box, the reference range is set to the start of the range grid.

  Units are in meters.

Example: `1000.0`

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code`

`Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Receiver Preamp

Receiver preamplifier

X
Receiver
Preamp

## Library

Transmitters and Receivers

`phasedtxrxlib`

## Description

The Receiver Preamp block implements a receiver preamplifier that amplifies an input signal and adds thermal noise. In addition, you can add phase noise using an input port.

## Parameters

**Gain (dB)**

Specify a scalar containing the gain in dB of the receiver preamplifier.

**Loss factor (dB)**

Specify a scalar containing the loss factor in dB of the receiver preamplifier.

**Noise specification method**

Specify the receiver noise as `Noise power` or `Noise temperature`.

**Noise power**

Specify a scalar containing the noise power in watts at the receiver preamplifier. If the receiver has multiple channels or sensors, the noise bandwidth applies to each channel or sensor. This parameter appears only when you set **Noise specification method** to `Noise power`.

**Noise figure (dB)**

Specify a scalar containing the noise figure of the receiver preamplifier. Units are in dB. If the receiver has multiple channels or sensors, the noise figure applies to each channel or sensor. This parameter appears only when you set **Noise specification method** to `Noise temperature`.

**Reference temperature (K)**

A scalar containing the reference temperature in degrees kelvin of the receiver preamplifier. If the receiver has multiple channels or sensors, the reference temperature applies to each channel or sensor. This parameter appears only when you set **Noise specification method** to `Noise temperature`.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter. This parameter appears only when **Noise specification method** is set to `Noise temperature`.

**Sample rate**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Enable enabling signal input**

Select this check box to allow input of the receiver-enabling signal via the input port `TR`. This parameter appears only when **Noise specification method** is set to `Noise temperature`.

**Enable phase noise input**

Select this check box to allow input of phase noise for each incoming sample using the input port `Ph`. You can use this information to emulate coherent-on-receive systems. This parameter appears only when you set **Noise specification method** to `Noise temperature`.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| X | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| TR | Enabling signal input<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.<br>. | Double-precision floating point |

# Rectangular Waveform

Rectangular pulse waveform
**Library:** Phased Array System Toolbox / Detection

## Description

The Rectangular Waveform block generates a rectangular pulse waveform with a specified pulse width and pulse repetition frequency (PRF). The block outputs an integral number of pulses or samples.

## Ports

### Input

**`PRFIdx` — PRF Index**
positive integer

Index to select the pulse repetition frequency (PRF), specified as a positive integer. The index selects the PRF from the predefined vector of values specified by the **Pulse repetition frequency (Hz)** parameter.

Example: 4

**Dependencies**

To enable this port, select **Enable PRF selection input**.

Data Types: `double`

### Output

**Y — Pulse waveform**
complex-valued vector

Pulse waveform samples, returned as a complex-valued vector.

Data Types: `double`

### PRF — Pulse repetition frequency

positive scalar

Pulse repetition frequency of current pulse, returned as a positive scalar.

#### Dependencies

To enable this port, set the **Output signal format** parameter to `Pulses` and then select the **Enable PRF output** parameter.

Data Types: `double`

## Parameters

### `Sample rate (Hz)` — Sample rate of the output waveform

`1e6` (default) | positive scalar

Sample rate of the output waveform, specified as a positive scalar. The ratio of **Sample rate (Hz)** to each element in the **Pulse repetition frequency (Hz)** vector must be an integer. This restriction is equivalent to requiring that the pulse repetition interval is an integral multiple of the sample interval.

### `Method to specify pulse duration` — Pulse duration as time or duty cycle

`Pulse width` (default) | `Duty cycle`

Method to set the pulse duration, specified as `Pulse width` or `Duty cycle`. When you set this parameter to `Pulse width`, the pulse duration is set using the **Pulse width (s)** parameter. When you set this parameter to `Duty cycle`, the pulse duration is computed from the values of the **Pulse repetition frequency (Hz)** and **Duty Cycle** parameters.

### `Pulse width (s)` — Time duration of pulse

`50e-6` (default) | positive scalar

The duration of each pulse, specified as a positive scalar. Set the product of **Pulse width (s)** and **Pulse repetition frequency** to be less than or equal to one. This restriction ensures that the pulse width is smaller than the pulse repetition interval. Units are in seconds.

Example: `300e-6`

#### Dependencies

To enable this parameter, set the **Method to specify pulse duration** parameter to `Pulse width`.

### `Duty cycle` — Waveform duty cycle

`0.5` (default) | scalar in the range *[0,1]*

Waveform duty cycle, specified as a scalar in the range *[0,1]*.

Example: `0.7`

#### Dependencies

To enable this parameter, set the **Method to specify pulse duration** parameter to `Duty cycle`.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* by using block parameter settings alone or in conjunction with the input port, `PRFIdx`.

- When the **Enable PRF selection input** parameter is not selected, set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.

  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses cycles through the successive values of the *PRF* vector.
- When the **Enable PRF selection input** parameter is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute the block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, the number of output samples is fixed when you set the **Output signal format** to `Samples`. When you use a varying *PRF* and set **Output signal format** to `Pulses`, the number of output samples can vary.

### `Enable PRF selection input` — Select predefined PRF

off (default) | on

Select this parameter to enable the `PRFIdx` port.

- When enabled, pass in an index into a vector of predefined PRFs. Set predefined PRFs using the **Pulse repetition frequency (Hz)** parameter.
- When not enabled, the block cycles through the vector of PRFs specified by the **Pulse repetition frequency (Hz)** parameter. If **Pulse repetition frequency (Hz)** is a scalar, the PRF is constant.

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### `Number of pulses in output` — Number of pulses in output

`1` (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: 2

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Pulses`.

Data Types: `double`

### `Enable PRF Output` — Enable output of PRF

off (default) | on

Select this parameter to enable the PRF output port.

#### Dependencies

To enable this parameter, set **Output signal format** to `Pulses`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If

you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

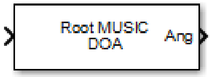
# Root MUSIC DOA

Root multiple signal classification (MUSIC) direction of arrival (DOA) estimator for ULA



## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The Root MUSIC DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the root multiple signal classification (Root MUSIC) algorithm.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of signals**

Specify the number of signals as a positive integer scalar.

**Forward-backward averaging**

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

**Spatial smoothing**

Specify the amount of averaging, *L*, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is *N* – *2*, where *N* is the number of sensors.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

**Specify sensor array as**

Specify a ULA sensor array directly or by using a MATLAB expression.

**Types**

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Geometry**

Specify the array geometry as one of the following

- `ULA` — Uniform Line Array
- `UCA` — Uniform Circular Array

**Number of elements**

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the subarray.

**Element spacing**

Specify the spacing, in meters, between two adjacent elements in the array.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P*

specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone’s response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Estimated broadside DOA angles. | Double-precision floating point |

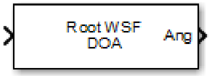
## See Also

`phased.RootMUSICEstimator`

**Introduced in R2014b**

# Root WSF DOA

Root weighted subspace fitting (WSF) direction of arrival (DOA) estimator for ULA



## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The Root WSF DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the Root weighted subspace fitting (RootWSF) algorithm.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of signals**

Specify the number of signals as a positive integer.

**Iterative method**

Specify the iterative method as one of `IMODE` or `IQML`.

**Maximum number of iterations**

Specify the maximum number of iterations as a positive integer or `Inf`.

### Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

### Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

**Types**

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Number of elements**

Specifies the number of elements in the array as an integer.

**Element spacing**

Specify the spacing, in meters, between two adjacent elements in the array.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`

- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**.

Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Estimated broadside DOA angles. | Double-precision floating point |

`phased.RootWSFEstimator`

**Introduced in R2014b**

# SMI Beamformer

Sample matrix inversion (SMI) beamformer

**Library:** Phased Array System Toolbox / Space-Time Adaptive Processing

X
Idx
SMI
Beamformer
Y

## Description

The SMI Beamformer block implements a sample matrix inversion (SMI) space-time adaptive beamformer employing the sample space-time covariance matrix.

## Ports

### Input

**X — Input signal**

*M*-by-*N*-by-*P* complex-valued matrix

Input signal, specified as an *M*-by-*N*-by-*P* complex-valued array. *M* is the number of range samples, *N* is the number of channels, and *P* is the number of pulses.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**`Idx` — Index of range cells**

positive integer

Index of range cells to compute processing weights.

Example: 1

Data Types: `double`

### PRF — Pulse repetition frequency

positive scalar

Pulse repetition frequency of current pulse, specified as a positive scalar.

#### Dependencies

To enable this port, set the **Specify PRF as** parameter to `Input port`.

Data Types: `double`

### Ang — Targeting direction

2-by-1 real-valued vector

Targeting direction, specified as a 2-by-*1* real-valued vector. The vector takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Specify direction as** parameter to `Input port`.

Data Types: `double`

### Dop — Targeting Doppler frequency

scalar

Targeting Doppler frequency of current pulse, specified as a scalar.

#### Dependencies

To enable this port, set the **Specify targeting Doppler as** parameter to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-1 complex-valued vector

Processing output, returned as an *M*-by-*1* complex-valued vector. The quantity *M* is the number of range samples in the input port X.

Data Types: `double`

### `W` — Processing weights

length *N***P* complex-valued vector

Processing weights, returned as Length *N***P* complex-valued vector. The quantity *N* is the number of channels and *P* is the number of pulses. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` input port or by the **Beamforming direction (deg)** parameter. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** check box.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Specify PRF as` — Source of PRF value

`Property` (default) | `Input port`

Source of PRF value, specified as `Property` or `Input port`. When set to `Property`, the **Pulse repetition frequency (Hz)** parameter sets the PRF. When set to `Input port`, pass in the PRF using the `PRF` input port.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1` (default) | positive scalar

Pulse repetition frequency, PRF, specified as a positive scalar. Units are in Hertz. Set this parameter to the same value set in any `Waveform` library block used in the simulation.

#### Dependencies

To enable this parameter, set the **Specify PRF as** parameter to `Property`.

### `Specify direction as` — Specify source of targeting directions

`Property` (default) | `Input port`

Specify whether the targeting direction for the STAP processor block comes from a block parameter or from the `ANG` input port. Values of this parameter are

| | |
|---|---|
| `Property` | - For the ADPCA Canceller and DPCA Canceller blocks, targeting direction is specified using **Receiving mainlobe direction (deg)**.<br>- For the SMI Beamformer block, targeting direction is specified using **Targeting direction**.<br>These parameters appear only when the **Specify direction as** parameter is set to `Property`. |
| `Input port` | Enter the targeting directions using the `Ang` input port. This port appears only when **Specify direction as** is set to `Input port`. |

### `Targeting direction (deg)` — Processor targeting direction

`[0;0]` (default) | real-valued length-2 column vector

Processor targeting direction, specified as a real-valued length-2 column vector of azimuth and elevation angles, `[AzimuthAngle;ElevationAngle]`. The azimuth angle is between –180° and 180° and the elevation angle is between –90° and 90°. Units are in degrees.

#### Dependencies

To enable this parameter, set **Specify direction as** to `Property`.

### `Number of bits in phase shifters` — Number of phase shift quantization bits

`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### `Specify targeting Doppler as` — Source of targeting Doppler

`Property` (default) | `Input port`

Specify whether targeting Doppler values for the STAP processor comes from the **Targeting Doppler (Hz)** parameter of this block or using the `DOP` input port. For the ADPCA Canceller and DPCA Canceller blocks, the **Specify targeting Doppler as** parameter appears only when the **Output pre-Doppler result** check box is cleared. Values of this parameter are

| | |
|---|---|
| `Property` | Specify targeting Doppler values using the **Targeting Doppler** parameter of the block. The **Targeting Doppler** parameter appears only when **Specify targeting Doppler as** is set to `Property`. |
| `Input port` | Specify targeting Doppler values using the `Dop` input port. This port appears only when **Specify targeting Doppler as** is set to `Input port`. |

### `Targeting Doppler (Hz)` — Targeting Doppler of STAP processor

`0` (default) | scalar

Targeting Doppler of STAP processor, specified as a scalar.

#### Dependencies

- To enable this parameter for the SMI Beamformer block, set **Specify targeting Doppler as** to `Property`.
- To enable this parameter for the ADPCA Canceller and DPCA Canceller blocks, first clear the **Output pre-Doppler result** check box. Then set the **Specify targeting Doppler as** parameter to `Property`.

### `Number of guard cells` — Number of guard cells using for training

2 (default) | positive even integer

Number of guard cells used for training, specified as a positive, even integer. Whenever possible, the set of guard cells is equally divided into regions before and after the test cell.

### `Number of training cells` — Number of cells used for training

2 (default) | positive even integer

Number of cells used for training, specified as a positive even integer. Whenever possible, the set of training cells is equally divided into regions before and after the test cell.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

### Element Parameters

**Element type — Array element types**
Isotropic Antenna (default) | Cosine Antenna | Custom Antenna | Omni Microphone | Custom Microphone

Antenna or microphone type, specified as one of the following:

- Isotropic Antenna
- Cosine Antenna
- Custom Antenna
- Omni Microphone
- Custom Microphone

**Operating frequency range (Hz) — Operating frequency range of the antenna or microphone element**
[0,1.0e20] (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form [LowerBound,UpperBound]. The element has no response outside this frequency range. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to Isotropic Antenna, Cosine Antenna, or Omni Microphone.

**Operating frequency vector (Hz) — Operating frequency range of custom antenna or microphone elements**
[0,1.0e20] (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to Custom Antenna or Custom Microphone. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation**

**angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency

specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### Array Parameters

#### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

#### `Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

#### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.

- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

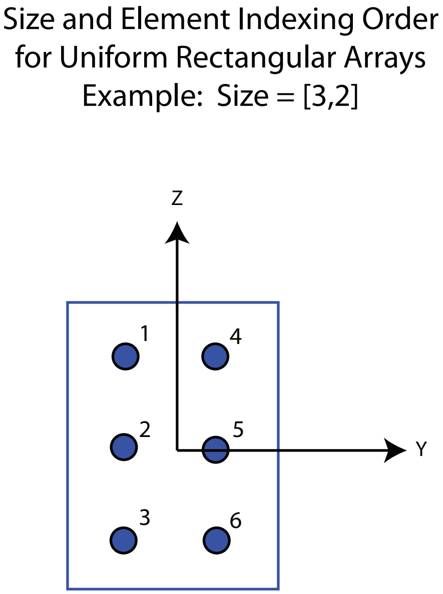
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to URA.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| x | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| y | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| z | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to URA or UCA.

### Radius of UCA (m) — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to UCA.

### Element positions (m) — Positions of conformal array elements

[0;0;0] (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position [x;y;z]of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to Conformal Array.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

### `Grid size` — Dimensions of rectangular subarray grid

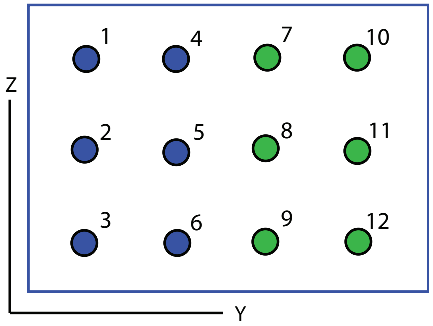
`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The

second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

3 x 2 Element URA
Replicated on a 1 x 2 Grid



**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

# Scattering MIMO Channel

Scattering MIMO propagation channel

**Library:** Phased Array System Toolbox / Environment and Target

## Description

The Scattering MIMO Channel models a 3-D multipath propagation channel in which radiated signals from a transmitting array are reflected from multiple scatters back towards a receiving array. In this channel, propagation paths are direct paths (line-of-sight) from point to point. The block models range-dependent time delay, gain, Doppler shift, phase change, and atmospheric loss due to gases, rain, fog, and clouds. You can optionally propagate a signal via a direct path from transmitter to receiver.

The attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz but the attenuation model for fog and clouds is valid for only 10–1000 GHz. Outside these frequency ranges, the object uses the nearest valid value.

## Ports

### Input

**X — Transmitted narrowband signal**

$M$-by-$N_t$ complex-valued matrix

The transmitted narrowband signal, specified as an $M$-by-$N_t$ complex-valued matrix. The quantity $M$ is the number of samples in the signal, and $N_t$ is the number of transmitting array elements. Each column represents the signal transmitted by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

### TxPos — Position of transmitting antenna array

3-by-1 real-valued column vector

Position of transmitting antenna array, specified as a 3-by-1 real-valued column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

#### Dependencies

To enable this port, set the **Source of transmit array motion** parameter to `Input port`.

Data Types: `double`

### TxVel — Velocity of transmitting antenna array

3-by-1 real-valued column vector

Velocity of transmitting antenna array, specified as a 3-by-1 real-valued column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

#### Dependencies

To enable this port, set the **Source of transmit array motion** parameter to `Input port`.

Data Types: `double`

### TxAxes — Axes orientation of transmitting antenna array

3-by-3 real orthonormal matrix

Axes orientation of transmitting antenna array, specified as a 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

#### Dependencies

To enable this port, set the **Source of transmit array motion** parameter to `Input port`.

Data Types: `double`

### RxPos — Position of receiving antenna array

3-by-1 real-valued column vector

Position of receiving antenna array, specified as a 3-by-1 real-valued column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

#### Dependencies

To enable this port, set the **Source of receive array motion** parameter to `Input port`.

Data Types: `double`

### `RxVel` — Velocity of receiving antenna array

3-by-1 real-valued column vector

Velocity of receiving antenna array, specified as a 3-by-1 real-valued column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

#### Dependencies

To enable this port, set the **Source of receive array motion** parameter to `Input port`.

Data Types: `double`

### `RxAxes` — Axes orientation of receiving antenna array

3-by-3 real orthonormal matrix

Axes orientation of receiving antenna array, specified as a 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

#### Dependencies

To enable this port, set the **Source of receive array motion** parameter to `Input port`.

Data Types: `double`

### `ScatPos` — Positions of scatterers

3-by-$N_s$ real-valued matrix

Position of scatterers, specified as a 3-by-$N_s$ real-valued matrix. Each column of the matrix takes the form `[x;y;z]`, containing the *x*, *y*, and *z* positions of a scatterer. Units are in meters.

#### Dependencies

To enable this port, set the **Scatterer specification** parameter to `Input port`.

Data Types: `double`

### `ScatVel` — Velocities of scatterers

3-by-$N_s$ real-valued matrix

Velocities of scatterers, specified as a 3-by-$N_s$ real-valued matrix. Each matrix column has the form `[vx;vy;vz]`, containing the *x*, *y*, and *z* velocities of a scatterer. Units are in meters per second.

#### Dependencies

To enable this port, set the **Scatterer specification** parameter to `Input port`.

Data Types: `double`

### `ScatCoef` — Scattering coefficients

1-by-$N_s$ complex-valued row vector

Scattering coefficients, specified as a 1-by-$N_s$ complex-valued row vector. Each vector element specifies the scattering coefficient of the corresponding scatterer. Units are dimensionless.

#### Dependencies

To enable this port, set the **Scatterer specification** parameter to `Input port`.

Data Types: `double`

## Output

### Y — Received narrowband signal

$M$-by-$N_r$ complex-valued matrix

Received narrowband signal, returned as an $M$-by-$N_r$ complex-valued matrix. The quantity $M$ is the number of samples in the signal, and $N_r$ is the number of receiving array elements. Each column represents the signal received by the corresponding array element.

Data Types: `double`
Complex Number Support: Yes

### `CS` — Channel response

$N_t$-by-$N_r$-by-$N_s$ complex-valued MATLAB array

Channel response, returned as an $N_t$-by-$N_r$-by-$N_s$ complex-valued MATLAB array. $N_t$ is the number of transmitting array elements. $N_r$ is the number of receiving array elements. $N_s$ is the number of scatterers. Each page of the array corresponds to the channel response matrix for a specific scatterer.

#### Dependencies

To enable this port, select the **Output channel response** checkbox.

Data Types: `double`
Complex Number Support: Yes

### `Tau` — Path delays

1-by-$N_s$ real-valued vector

Path delays, returned as a 1-by-$N_s$ real-valued vector. $N_s$ is the number of scatterers. Each element corresponds to the path time delay from the transmitting array phase center to the scatterer and then to the receiving array phase center.

#### Dependencies

To enable this port, select the **Output channel response** checkbox.

Data Types: `double`

## Parameters

#### Main Tab

### `Propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

### `Signal carrier frequency (Hz)` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Data Types: `double`

### `Specify atmospheric parameters` — Enable atmospheric attenuation model

off (default) | on

Select this parameter to enable to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. When you select this parameter, the **Temperature (degrees Celsius)**, **Dry air pressure (Pa)**, **Water vapour density (g/m^3)**, **Liquid water density (g/m^3)**, and **Rain rate (mm/hr)** parameters appear in the dialog box.

Data Types: `Boolean`

### `Temperature (degrees Celsius)` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Dry air pressure (Pa)` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this parameter corresponds to one standard atmosphere.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Water vapour density (g/m^3)` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `datetime`

### `Liquid water density (g/m^3)` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Rain rate (mm/hr)` — Rainfall rate

`0.0` (default) | non-negative real-valued scalar

Rainfall rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Simulate direct path propagation` — Enable propagation along direct path

off (default) | on

Select this check box to enable signal propagation along the line-of-sight direct path from the transmitting array to the receiving array with no scattering.

Data Types: `Boolean`

### `Maximum delay (s)` — Maximum signal delay

`10e-6` (default) | positive scalar

The maximum signal delay, specified as a positive scalar. Delays greater than this value are ignored.

Data Types: `double`

### `Output channel response` — Enable output of channel response

off (default) | on

Select this checkbox to output the channel response and time delay via the output ports `CS` and `Tau`.

Data Types: `Boolean`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Transmit and Receive Array Tabs

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

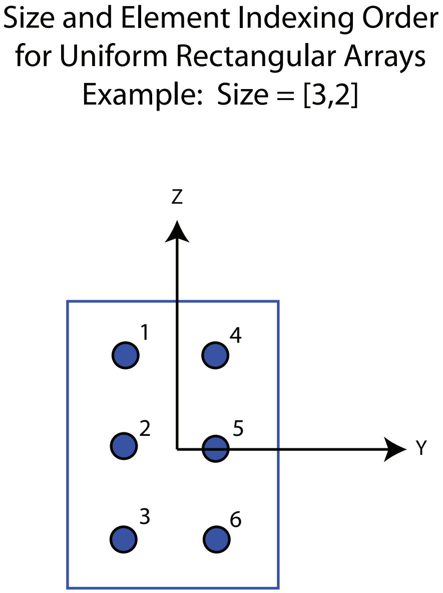
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Element lattice — Lattice of URA element positions

Rectangular (default) | Triangular

Lattice of URA element positions, specified as Rectangular or Triangular.

- Rectangular — Aligns all the elements in row and column directions.
- Triangular — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Array normal — Array normal direction

x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as x, y, or z.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| x | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| y | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| z | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to URA or UCA.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

#### Motion Tab

### `Source of transmit array motion` — Specify the source of the transmitting array motion parameters

`Property` (default) | `Input port`

Source of transmitting array motion parameters, specified as `Property` or `Input port`.

- When you select `Property`, specify the array location and orientation using the **Position of the transmit array (m)** and **Orientation of the transmit array** parameters. The array is stationary.
- When you select `Input port`, specify the array location, velocity, and orientation using the `TxPos`, `TxVel`, and `TxAxes` input ports of the block.

Data Types: `char`

### `Position of the transmit array (m)` — Position of transmitting array

`[0;0;0]` (default) | real-valued 3-by-1 vector

The position of the transmitting array phase center, specified as a real-valued, 3-by-1 vector in Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

#### Dependencies

To enable this parameter, set the **Source of transmit array motion** parameter to `Property`.

Data Types: `double`

### `Orientation of the transmit array` — Set the orientation of transmitting array axes

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

The orientation of transmitting array, specified as a real-valued, 3-by-3 orthonormal matrix. The matrix specifies the directions of the three axes that define the local coordinate system of the array with respect to the global coordinate system. The columns of the array correspond to the *x*, *y*, and *z* axes, respectively.

#### Dependencies

To enable this parameter, set the **Source of transmit array motion** parameter to `Property`.

Data Types: `double`

### `Source of receive array motion` — Specify the source of the receiving array motion parameters

`Property` (default) | `Input port`

Source of receiving array motion parameters, specified as `Property` or `Input port`.

- When you select `Property`, specify the array location and orientation using the **Position of the receive array (m)** and **Orientation of the receive array** parameters. The array is stationary.
- When you select `Input port`, specify the array location, velocity, and orientation using the `RxPos`, `RxVel`, and `RxAxes` input ports of the block.

Data Types: `char`

### `Position of the receive array (m)` — Position of receiving array

`[physconst('LightSpeed' )/1e5; 0;0]` (default) | real-valued 3-by-1 vector

The position of the receiving array phase center, specified as a real-valued, 3-by-1 vector in Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

#### Dependencies

To enable this parameter, set the **Source of receive array motion** parameter to `Property`.

Data Types: `double`

### `Orientation of the receive array` — Set the orientation of receiving array axes

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

The orientation of receiving array, specified as a real-valued, 3-by-3 orthonormal matrix. The matrix specifies the directions of the three axes that define the local coordinate system of the array with respect to the global coordinate system. The columns of the array correspond to the *x*, *y*, and *z* axes, respectively.

#### Dependencies

To enable this parameter, set the **Source of receive array motion** parameter to `Property`.

Data Types: `double`

### `Scatterer specification` — Specify source of scatterer parameters

`Auto` (default) | `Property` | `Input port`

The source of scatterer parameters, specified as `Auto`, `Property`, or `Input port`.

- When you set this parameter to `Auto`, all scatterer positions and coefficients are randomly generated. Scatterer velocities are zero. The generated positions are contained within the region set by the **Boundary of scatterer positions** parameter. Set the number of scatterers using the **Number of scatterers** parameter.
- When you set this property to `Property`, set the scatterer positions using the **Positions of scatterers (m)** parameter. Set the scattering coefficients using the **Scattering coefficients** parameter. Scatterer velocities are zero.
- When you set this parameter to `Input port`, you specify the scatterer positions, velocities, and scattering coefficients using the `ScatPos`, `ScatVel`, and `ScatCoef` block input ports.

Data Types: `char`

### `Number of scatterers` — Number of scatterers

`1` (default) | nonnegative integer

The number of scatterers, specified as a nonnegative integer.

#### Dependencies

To enable this property, set the **Scatterer specification** parameter to `Auto`.

Data Types: `double`

### `Boundary of scatterer positions` — Constrain scatterer positions within a boundary

`[0,1000]` (default) | 1-by-2 real-valued vector | 3-by-2 real-valued matrix

The boundary scatterer positions, specified as a 1-by-2 real-valued row vector or a 3-by-2 real-valued matrix. If the boundary is a 1-by-2 row vector, the vector contains the minimum and maximum, `[minbdry maxbdry]`, for all three dimensions. If the boundary is a 3-by-2 matrix, the matrix specifies boundaries in all three dimensions in the form `[x_minbdry x_maxbdry;y_minbdry y_maxbdry; z_minbdry z_maxbdry]`.

#### Dependencies

To enable this property, set the **Scatterer specification** parameter to `Auto`.

Data Types: `double`

### `Positions of scatterers (m)` — Positions of scatterers

`[physconst('LightSpeed' )*5e-6;0;0]` (default) | real-valued 3-by-$N_s$ matrix

The positions of the scatterers, specified as real-valued 3-by-$N_s$ matrix. $N_s$ is the number of scatterers. Each column represents a different scatterer and has the Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

#### Dependencies

To enable this property, set the **Scatterer specification** parameter to `Property`.

Data Types: `double`

### `ScattererCoefficient` — Scattering coefficients

`1` (default) | complex-valued 1-by-$N_s$ matrix

Scattering coefficients, specified as a complex-valued 1-by-$N_s$ vector. $N_s$ is the number of scatterers. Units are dimensionless.

#### Dependencies

To enable this property, set the **Scatterer specification** parameter to `Property`.

Data Types: `double`

**Introduced in R2017a**

# Stepped FM Waveform

Stepped FM pulse waveform
**Library:** Phased Array System Toolbox / Waveforms

## Description

The Stepped FM Waveform block generates a stepped FM pulse waveform with a specified pulse width, pulse repetition frequency (PRF), and number of frequency steps. The transmitted frequency is incremented in constant steps over the duration of the pulse. The block outputs an integral number of pulses or samples.

## Ports

### Input

**`PRFIdx` — PRF Index**
positive integer

Index to select the pulse repetition frequency (PRF), specified as a positive integer. The index selects the PRF from the predefined vector of values specified by the **Pulse repetition frequency (Hz)** parameter.

Example: 4

**Dependencies**

To enable this port, select **Enable PRF selection input**.

Data Types: `double`

### Output

**Y — Pulse waveform**
complex-valued vector

Pulse waveform samples, returned as a complex-valued vector.

Data Types: `double`

### PRF — Pulse repetition frequency

positive scalar

Pulse repetition frequency of current pulse, returned as a positive scalar.

#### Dependencies

To enable this port, set the **Output signal format** parameter to `Pulses` and then select the **Enable PRF output** parameter.

Data Types: `double`

## Parameters

### `Sample rate (Hz)` — Sample rate of the output waveform

`1e6` (default) | positive scalar

Sample rate of the output waveform, specified as a positive scalar. The ratio of **Sample rate (Hz)** to each element in the **Pulse repetition frequency (Hz)** vector must be an integer. This restriction is equivalent to requiring that the pulse repetition interval is an integral multiple of the sample interval.

### `Method to specify pulse duration` — Pulse duration as time or duty cycle

`Pulse width` (default) | `Duty cycle`

Method to set the pulse duration, specified as `Pulse width` or `Duty cycle`. When you set this parameter to `Pulse width`, the pulse duration is set using the **Pulse width (s)** parameter. When you set this parameter to `Duty cycle`, the pulse duration is computed from the values of the **Pulse repetition frequency (Hz)** and **Duty Cycle** parameters.

### `Pulse width (s)` — Time duration of pulse

`50e-6` (default) | positive scalar

The duration of each pulse, specified as a positive scalar. Set the product of **Pulse width (s)** and **Pulse repetition frequency** to be less than or equal to one. This restriction ensures that the pulse width is smaller than the pulse repetition interval. Units are in seconds.

Example: `300e-6`

**Dependencies**

To enable this parameter, set the **Method to specify pulse duration** parameter to `Pulse width`.

### `Duty cycle` — Waveform duty cycle

`0.5` (default) | scalar in the range *[0,1]*

Waveform duty cycle, specified as a scalar in the range *[0,1]*.

Example: `0.7`

**Dependencies**

To enable this parameter, set the **Method to specify pulse duration** parameter to `Duty cycle`.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* by using block parameter settings alone or in conjunction with the input port, `PRFIdx`.

- When the **Enable PRF selection input** parameter is not selected, set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.

  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses cycles through the successive values of the *PRF* vector.
- When the **Enable PRF selection input** parameter is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute the block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, the number of output samples is fixed when you set the **Output signal format** to `Samples`. When you use a varying *PRF* and set **Output signal format** to `Pulses`, the number of output samples can vary.

### `Enable PRF selection input` — Select predefined PRF

off (default) | on

Select this parameter to enable the `PRFIdx` port.

- When enabled, pass in an index into a vector of predefined PRFs. Set predefined PRFs using the **Pulse repetition frequency (Hz)** parameter.
- When not enabled, the block cycles through the vector of PRFs specified by the **Pulse repetition frequency (Hz)** parameter. If **Pulse repetition frequency (Hz)** is a scalar, the PRF is constant.

### `Frequency step (Hz)` — Linear frequency step size

`2e4` (default) | positive scalar

Specify the linear frequency step size as a positive scalar. Units are in Hertz.

Example: `1e3`

### `Number of frequency steps` — Number of frequency steps in pulse

`5` (default) | positive integer

Specify the number of frequency steps as a positive integer. When the **Number of frequency steps** is 1, the stepped FM waveform reduces to a rectangular waveform.

Example: `8`

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### `Number of pulses in output` — Number of pulses in output

`1` (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: `2`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Pulses`.

Data Types: `double`

### `Enable PRF Output` — Enable output of PRF

off (default) | on

Select this parameter to enable the PRF output port.

#### Dependencies

To enable this parameter, set **Output signal format** to `Pulses`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Stretch Processor

Stretch processor for linear FM waveforms

**Library:** Phased Array System Toolbox / Detection

## Description

The Stretch Processor block applies stretch processing on a linear FM waveform. Also known as dechirping, stretch processing is an alternative to matched filtering for linear FM waveforms.

## Ports

### Input

**X — Input signal**

*M*-by-*P* complex-valued matrix

Input signal, specified as an *M*-by-*P* complex-valued array. *M* is the number of samples and *P* is the number of pulses.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**PRF — Pulse repetition frequency**

positive scalar

Pulse repetition frequency of current pulse, specified as a positive scalar.

**Dependencies**

To enable this port, set the **Specify PRF as** parameter to `Input port`.

Data Types: `double`

## Output

**Y — Stretch processed signal**
*M*-by-*P* complex-valued matrix

Stretch processed signal, returned as an *M*-by-*P* complex-valued array. *M* is the number of samples and *P* is the number of pulses.

Data Types: `double`

# Parameters

**`Sample rate (Hz)` — Sample rate of the output waveform**
`1e6` (default) | positive scalar

Sample rate of the output waveform, specified as a positive scalar. The ratio of **Sample rate (Hz)** to each element in the **Pulse repetition frequency (Hz)** vector must be an integer. This restriction is equivalent to requiring that the pulse repetition interval is an integral multiple of the sample interval.

**`Pulse width (s)` — Time duration of pulse**
`50e-6` (default) | positive scalar

The duration of each pulse, specified as a positive scalar. Set the product of **Pulse width (s)** and **Pulse repetition frequency** to be less than or equal to one. This restriction ensures that the pulse width is smaller than the pulse repetition interval. Units are in seconds.

Example: `300e-6`

**`Specify PRF as` — Source of PRF value**
`Property` (default) | `Auto` | `Input port`

Source of PRF value for the stretch processor, specified as `Property`, `Auto`, or `Input port`. When set to `Property`, the **Pulse repetition frequency (Hz)** parameter sets the PRF. When set to `Input port`, pass in the PRF using the `PRF` input port. When set to `Auto`, PRF is computed from the number of rows in the input signal.

.

### `Pulse repetition frequency (Hz)` — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency, PRF, specified as a positive scalar. Units are in Hertz. Set this parameter to the same value set in any `Waveform` library block used in the simulation.

#### Dependencies

To enable this parameter, set the **Specify PRF as** parameter to `Property`.

### `FM sweep slope (Hz/s)` — Slope of linear FM sweep

`2e9` (default) | scalar

Slope of the linear FM sweeping as a scalar, specified as a scalar. Units are in Hertz per second.

Example: `1e3`

### `FM sweep interval` — Direction of FM sweep

`Positive` (default) | `Symmetric`

FM sweep interval, specified as `Positive` or `Symmetric`. If you set this parameter value to `Positive`, the waveform sweeps the frequency bandwidth between *0* and *B*, where *B* is the frequency bandwidth. If you set this parameter value to `Symmetric`, the waveform sweeps in the interval between –*B/2* and *B/2*.

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Reference range (m)` — Center of ranges of interest

`5000` (default) | positive scalar

Center of ranges of interest, specified as a positive scalar. The reference range must be within the unambiguous range of one pulse. Units are in meters.

Example: `10e3`

### `Reference span (m)` — Span of ranges of interest

`500` (default) | positive scalar

Span of ranges of interest, specified as a positive scalar. The span of ranges is centered on the range specified by the **Reference range (m)** parameter. Units are in meters.

Example: `1e3`

### `Source of simulation sample time` — Source of simulation sample time

`Derive from waveform parameters` (default) | `Inherit from Simulink engine`

Source of simulation sample time, specified as `Derive from waveform parameters` or `Inherit from Simulink engine`. When set to `Derive from waveform parameters`, the block runs at a variable rate determined by the PRF of the selected waveform. The elapsed time is variable. When set to `Inherit from Simulink engine`, the block runs at a fixed rate so the elapsed time is a constant.

#### Dependencies

To enable this parameter, select the **Enable PRF selection input** parameter.

### `Output signal format` — Format of the output signal

`Pulses` (default) | `Samples`

The format of the output signal, specified as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block consists of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block consists of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

### `Number of samples in output` — Number of samples in output

`100` (default) | positive integer

Number of samples in the block output, specified as a positive integer.

Example: `1000`

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to `Samples`.

Data Types: `double`

### Number of pulses in output — Number of pulses in output

1 (default) | positive integer

Number of pulses in the block output, specified as a positive integer.

Example: 2

#### Dependencies

To enable this parameter, set the **Output signal format** parameter to Pulses.

Data Types: double

### Enable PRF Output — Enable output of PRF

off (default) | on

Select this parameter to enable the PRF output port.

#### Dependencies

To enable this parameter, set **Output signal format** to Pulses.

### Simulate using — Block simulation method

Interpreted Execution (default) | Code Generation

Block simulation, specified as Interpreted Execution or Code Generation. If you want your block to use the MATLAB interpreter, choose Interpreted Execution. If you want your block to run as compiled code, choose Code Generation. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using Code Generation. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in Accelerator mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

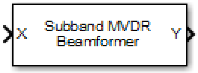
# Subband MVDR Beamformer

Subband MVDR (Capon) beamformer
**Library:** Phased Array System Toolbox / Beamforming



## Description

The Subband MVDR Beamformer block performs minimum variance distortionless response (MVDR) beamforming on wideband signals. Signals are decomposed into frequency subbands and narrowband MVDR beamforming is performed in each band. The resulting subband signals are summed to form the output signal. MVDR beamforming preserves signal power in a given direction while suppressing interference and noise from other directions. The MVDR beamformer is also called the Capon beamformer.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**XT — Training signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`

### `Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `Freq` — Subband center frequencies

*K*-by-1 real-valued column vector

Subband center frequencies, returned as *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the `Number of subbands` property.

#### Dependencies

To enable this port, select the **Enable subband center frequencies output** checkbox.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

## Parameters

#### Main tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Number of subbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

### `Diagonal loading factor` — Diagonal loading factor for stability

nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

### `Enable training data input` — Enable the use of training data

off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

### `Source of beamforming direction` — Source of beamforming direction

`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

### Beamforming direction (deg) — Beamforming directions

2-by-*L* real-valued matrix

Beamforming directions, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

**Dependencies**

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

### Enable weights output — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### Enable subband center frequencies output — Enable the output of subband center frequencies

off (default) | on

Select this check box to obtain the center frequencies of each subband via the output port, `Freq`.

### Simulate using — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation**

**angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency

specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Microphone`.

**Array Parameters**

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.

- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

#### Dependencies

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

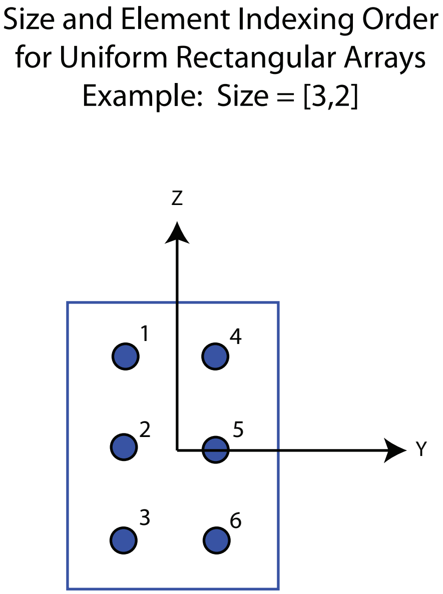
### `Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

### `Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array` or `Replicated subarray`.

### `Phase shifter frequency (Hz)` — Subarray phase shifting frequency

`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Number of bits in phase shifters` — Subarray steering phase shift quantization bits

`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

### `Subarrays layout` — Subarray position specification

`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

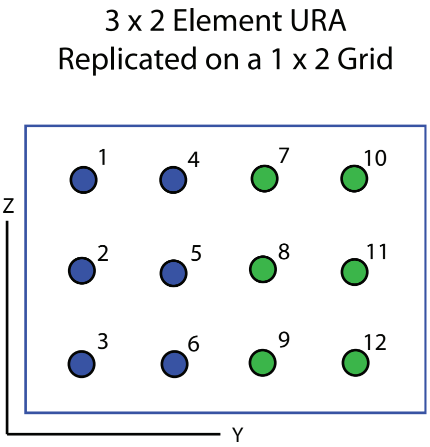
### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The

second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

## See Also

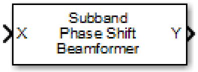
`phased.SubbandMVDRBeamformer`

**Introduced in R2015b**

# Subband Phase Shift Beamformer

Subband phase shift beamformer

**Library:** Phased Array System Toolbox / Beamforming



## Description

The Subband Phase Shift Beamformer block performs delay-and-sum beamforming in the frequency domain. The signal is divided into frequency subbands. In each subband, a phase shift at the subband center frequency approximates the time delay. The resulting subband signals are summed to form the frequency-domain output signal and then converted to the time domain.

## Ports

### Input

**X — Input signal**

*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**Ang — Beamforming direction**

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of

`[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### `Y` — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `Freq` — Subband center frequencies

*K*-by-1 real-valued column vector

Subband center frequencies, returned as *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the `Number of subbands` property.

#### Dependencies

To enable this port, select the **Enable subband center frequencies output** checkbox.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

## Parameters

#### Main tab

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

#### `Number of subbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

#### `Source of beamforming direction` — Source of beamforming direction

`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

#### `Beamforming direction (deg)` — Beamforming directions

*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

##### Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

#### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

#### `Enable subband center frequencies output` — Enable the output of subband center frequencies

off (default) | on

Select this check box to obtain the center frequencies of each subband via the output port, `Freq`.

#### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.

- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

**Dependencies**

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

**Element Parameters**

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between – 90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.

- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

### `Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

### `Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

**Dependencies**

To enable this parameter, set **Geometry** to `ULA` or `URA`.

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Dependencies**

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

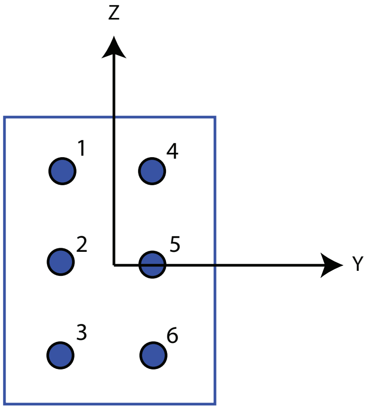
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along the leftmost column, and then continue to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.

- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

**Dependencies**

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Dependencies**

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Geometry** to `UCA`.

### Element positions (m) — Positions of conformal array elements

[0;0;0] (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position [x;y;z]of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

#### Dependencies

To enable this parameter set **Geometry** to Conformal Array.

### Element normals (deg) — Direction of conformal array element normal vectors

[0;0] | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. For a matrix, each column specifies the normal direction of the corresponding element in the form [azimuth;elevation] with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to Replicated subarray, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

#### Dependencies

To enable this parameter, set **Geometry** to Conformal Array.

### Taper — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

### `Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix represents a subarray and each entry in the row indicates when an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray lies at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `Partitioned array`.

### `Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting Phase or Time opens the Steer input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting Custom opens the WS input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

#### Dependencies

To enable this parameter, set **Specify sensor array as** to Partitioned array or Replicated subarray.

### Phase shifter frequency (Hz) — Subarray phase shifting frequency

3.0e8 (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

#### Dependencies

To enable this parameter, set **Sensor array** to Partitioned array or Replicated subarray and set **Subarray steering method** to Phase.

### Number of bits in phase shifters — Subarray steering phase shift quantization bits

0 (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

#### Dependencies

To enable this parameter, set **Sensor array** to Partitioned array or Replicated subarray and set **Subarray steering method** to Phase.

### Subarrays layout — Subarray position specification

Rectangular (default) | Custom

Specify the layout of replicated subarrays as Rectangular or Custom.

- When you set this parameter to Rectangular, use the **Grid size** and **Grid spacing** parameters to place the subarrays.

- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray`

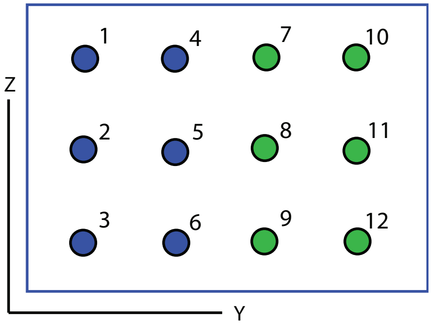
### `Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer, or a 1-by-2 row vector of positive integers.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

3 x 2 Element URA
Replicated on a 1 x 2 Grid



**Dependencies**

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Grid spacing (m)` — Spacing between subarrays on rectangular grid

`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

### `Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

#### Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

### `Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The

transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

#### Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

## See Also

`phased.SubbandPhaseShiftBeamformer`

**Introduced in R2014b**

# Time Delay Beamformer

Time-delay beamformer
**Library:** Phased Array System Toolbox / Beamforming

## Description

The Time Delay Beamformer block performs delay-and-sum beamforming. Plane-wave signals arriving at the array elements are time-aligned and then summed. Time alignment is achieved by transforming the signals into the frequency domain and applying linear phase shifts corresponding to a time delay. The individual signals are then added and converted back to the time domain.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**Ang — Beamforming direction**
`2`-by-`1` real-valued vector

Beamforming direction, specified as a `2`-by-`1` real-valued vector. The vector takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### Y — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

# Parameters

**Main tab**

### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

**Dependencies**

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Source of beamforming direction` — Source of beamforming direction

`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the Ang port.

### `Beamforming direction (deg)` — Beamforming directions

*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element**

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

**`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements**

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

**Dependencies**

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

**`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero**

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### Geometry — Array geometry

ULA (default) | URA | UCA | Conformal Array

Array geometry, specified as one of

- ULA — Uniform linear array
- URA — Uniform rectangular array
- UCA — Uniform circular array
- Conformal Array — arbitrary element positions

### Number of elements — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to ULA or UCA.

### Element spacing (m) — Spacing between array elements

0.5 for ULA arrays and [0.5,0.5] for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form [SpacingBetweenArrayRows,SpacingBetweenArrayColumns].

#### Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

### Array axis — Linear axis direction of ULA

y (default) | x | z

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Dependencies**

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

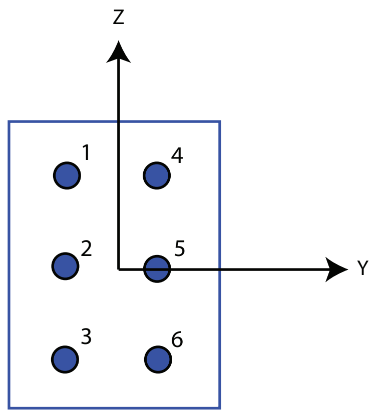
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to `URA`.

### `Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| `x` | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `y` | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `z` | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to `URA` or `UCA`.

### Radius of UCA (m) — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

#### Dependencies

To enable this parameter, set **Geometry** to `UCA`.

### Element positions (m) — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

#### Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

### Element normals (deg) — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

## See Also

`phased.TimeDelayBeamformer`

**Introduced in R2014b**

# Time Delay LCMV Beamformer

Time delay LCMV beamformer
**Library:** Phased Array System Toolbox / Beamforming

## Description

The Time Delay LCMV Beamformer block performs time-delay linear constraint minimum variance (LCMV) beamforming.

## Ports

### Input

**X — Input signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**XT — Training signal**
*M*-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`

### `Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

## Output

### `Y` — Beamformed output

*M*-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`

### `W` — Beamforming weights

*N*-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

#### Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`

## Parameters

#### Main tab

### `Signal propagation speed (m/s)` — Signal propagation speed
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `FIR filter length` — FIR filter length
`1` (default) | positive integer

The length of the FIR filter used to process each sensor element data, specified as a positive integer.

Data Types: `double`

**`Constraint matrix` — Constraint matrix used for time-delay LCMV beamformer**
`[1;1]` | complex-valued *M*-by-*K* matrix

The constraint matrix used for time-delay LCMV beamformer, specified as a complex-valued*M*-by-*K* matrix. Each column of the matrix is a constraint and *M* is the degrees of freedom of the beamformer. For a time delay LCMV beamformer, *M* is given by the product of the number of elements of the array and the value of the **FIR filter length** parameter.

Data Types: `double`

**`Desired response vector` — Desired response of time-delay LCMV beamformer**
`1` (default) | *K* column vector

Desired response used for time-delay LCMV beamformer, specified as a length-*K* column vector. *K* is the number of constraints in the **Constraint matrix** parameter. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the **Constraint matrix** parameter matrix.

**`Diagonal loading factor` — Diagonal loading factor for stability**
nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

**`Enable training data input` — Enable the use of training data**
off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

**`Source of beamforming direction` — Source of beamforming direction**
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the

**Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

### `Beamforming direction (deg)` — Beamforming directions

*2*-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

#### Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

### `Enable weights output` — Option to output beamformer weights

off (default) | on

Select this check box to obtain the beamformer weights from the output port, `W`.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Arrays Tab

### Specify sensor array as — Method to specify array

Array (no subarrays) (default) | MATLAB expression

Method to specify array, specified as Array (no subarrays) or MATLAB expression.

- Array (no subarrays) — use the block parameters to specify the array.
- MATLAB expression — create the array using a MATLAB expression.

### Expression — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: phased.URA('Size',[5,3])

#### Dependencies

To enable this parameter, set **Specify sensor array as** to MATLAB expression.

#### Element Parameters

### Element type — Array element types

Isotropic Antenna (default) | Cosine Antenna | Custom Antenna | Omni Microphone | Custom Microphone

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equals the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### Geometry — Array geometry

ULA (default) | URA | UCA | Conformal Array

Array geometry, specified as one of

- ULA — Uniform linear array
- URA — Uniform rectangular array
- UCA — Uniform circular array
- Conformal Array — arbitrary element positions

### Number of elements — Number of array elements

2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

#### Dependencies

To enable this parameter, set **Geometry** to ULA or UCA.

### Element spacing (m) — Spacing between array elements

0.5 for ULA arrays and [0.5,0.5] for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form [SpacingBetweenArrayRows,SpacingBetweenArrayColumns].

#### Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

### Array axis — Linear axis direction of ULA

y (default) | x | z

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Dependencies**

- To enable this parameter, set **Geometry** to `ULA`.
- This parameter is also enabled when the block only supports ULA arrays.

### `Array size` — Dimensions of URA array

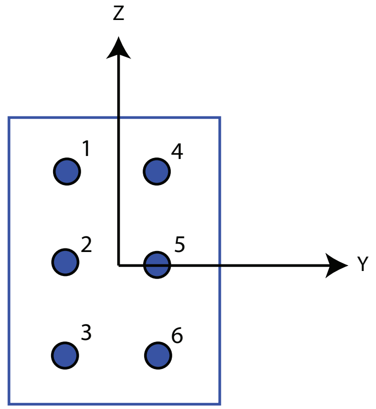
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along the leftmost array column, and continued to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Element lattice — Lattice of URA element positions

Rectangular (default) | Triangular

Lattice of URA element positions, specified as Rectangular or Triangular.

- Rectangular — Aligns all the elements in row and column directions.
- Triangular — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

#### Dependencies

To enable this parameter, set **Geometry** to URA.

### Array normal — Array normal direction

x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as x, y, or z.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

| Array Normal Parameter Value | Element Positions and Boresight Directions |
|---|---|
| x | Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| y | Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| z | Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis. |

#### Dependencies

To enable this parameter, set **Geometry** to URA or UCA.

### `Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

**Dependencies**

To enable this parameter, set **Geometry** to `UCA`.

### `Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

**Dependencies**

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

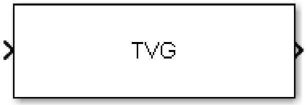
`phased.TimeDelayLCMVBeamformer`

**Introduced in R2014b**

# Time Varying Gain

Time varying gain (TVG) control



## Library

Detection

`phaseddetectlib`

## Description

The Time Varying Gain block applies a time varying gain to input signals to compensate for range loss at each range gate. Time varying gain (TVG) is sometimes called automatic gain control (AGC).

## Parameters

**Source of range losses**

Specify the range loss source as either `Property` or `Input Port`

| | |
|---|---|
| `Property` | Range losses are specified by the **Range loss (dB)** parameter. |
| `Input port` | Range losses are specified using the input port `L`. |

**Range loss (dB)**

Specify the loss due to range as a vector — elements correspond to the samples in the input signal. Units are in dB

**Reference range loss (dB)**

Specify the loss, in dB, at a given reference range as a scalar.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `L` | Range loss.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | |
| `Out` | Compensated signal. | Double-precision floating point |

# Transmitter

Amplify and transmit a signal

Transmitter
Y

## Library

Transmitters and Receivers

`phasedtxrxlib`

## Description

The Transmitter block amplifies and transmits waveform pulses. The transmitter can either maintain coherence between pulses or insert phase noise.

## Parameters

**Peak power (W)**

Specify the transmit peak power in watts as a positive scalar.

**Gain (dB)**

Specify the transmit gain in dB as a real scalar.

**Loss factor (dB)**

Specify the transmit loss factor in dB as a nonnegative scalar.

**Enable transmitter status output**

Select this check box to send the transmitter-in-use status for each output sample from the output port TR. From the output port, a 1 indicates that the transmitter is on, and a 0 indicates that the transmitter is off.

**Preserve coherence among pulses**

Select this check box to preserve coherence among transmitted pulses. When you select this box, the transmitter does not introduce any random phases to the output pulses. When you clear this box, the transmitter adds a random phase noise to each transmitted pulse. The random phase noise is introduced by multiplying the pulse value by $e^{j\phi}$ where $\phi$ is a uniform random variable on the interval *[0,2π]*.

**Enable pulse phase noise output**

This check box appears only when **Preserve coherence among pulses** is cleared.

Select this check box to create an output port, `Ph`, with the output sample's random phase noise introduced if **Preserve coherence among pulses** is cleared. The output port can be directed to a receiver to simulate coherent-on-receive systems.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ph` | Added phase noise. | Double-precision floating point |

| Port | Description | Supported Data Types |
|---|---|---|
| TR | Transmitter status. | Double-precision floating point |
| Y | Transmitted signal. | Double-precision floating point |

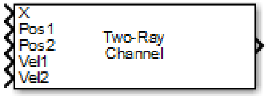
## See Also

`phased.Transmitter`

**Introduced in R2014b**

# Two-Ray Channel

Two-ray channel environment



## Library

Environment and Target

`phasedenvlib`

## Description

The Two-Ray Channel block propagates narrowband signals from one point in space to multiple points or from multiple points back to one point via both the direct path and the ground reflection path. The block models propagation time, free-space propagation loss, and Doppler shift. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Signal carrier frequency (Hz)**

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

**Specify atmospheric parameters**

Select this check box to enable atmospheric attenuation modeling.

**Temperature (degrees Celsius)**

Ambient atmospheric temperature, specified as a real-valued scalar. Units are degrees Celsius. This parameter appears when you select the **Specify atmospheric parameters** check box. Units are degrees Celsius.

**Dry air pressure (Pa)**

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are Pascals (Pa). The value 101325 for this property corresponds to one standard atmosphere. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Water vapour density (g/m^3)**

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are gm/m$^3$. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Liquid water density (g/m^3)**

Liquid water density of fog or clouds, specified as a non-negative real-valued scalar. Units are gm/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Rain rate (mm/hr)**

Rainfall rate, specified as a non-negative real-valued scalar. Units are in mm/hour. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Ground reflection coefficient**

Fraction of incident signal amplitude reflected towards receiver.

**Combine two rays at output**

Select this checkbox to coherently sum the direct-path and reflected-path signals at output. Clear the checkbox to keep the two rays separate.

### Maximum one-way propagation distance (m)

The maximum distance between the signal origin and the destination, specified as a positive scalar. Units are in meters. Amplitudes of any signals that propagate beyond this distance will be set to zero.

### Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Input signal. | Double-precision floating point |
| `Pos1` | Signal source position. | Double-precision floating point |
| `Pos2` | Signal destination position. | Double-precision floating point |
| `Vel1` | Signal source velocity. | Double-precision floating point |
| `Vel2` | Signal destination velocity. | Double-precision floating point |
| `Out` | Propagated signal. | Double-precision floating point |

## Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity $\tau$ is the delay and $L$ is the propagation loss. The delay is computed from $\tau = R/c$ where $R$ is the propagation distance and $c$ is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter $v$ is the relative speed of the destination with respect to the origin.

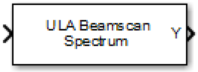
# ULA Beamscan Spectrum

Beamscan spatial spectrum estimator for ULA
**Library:** Phased Array System Toolbox / Direction of Arrival



## Description

The ULA Beamscan Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a region of broadside angles using a narrowband conventional beamformer applied to a uniform linear array. The block optionally calculates the direction of arrival of a specified number of signals by estimating peaks of the spectrum.

## Ports

### Input

**`Port 1` — Received signal**
$M$-by-$N$ complex-valued matrix

Received signal, specified as an $M$-by-$N$ complex-valued matrix. The quantity $M$ is the number of sample values (snapshots) contained in the signal and $N$ is the number of sensor elements in the array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

### Output

**Y — Beamscan spatial spectrum**
non-negative, real-valued column vector

Beamscan spatial spectrum, returned as a non-negative, real-valued column vector representing the magnitude of the estimated beamscan spatial spectrum. Each entry corresponds to an angle specified by the **Scan angles (deg)** parameter.

Data Types: `double`

#### `Ang` — Directions of arrival

non-negative, real-valued column vector

Directions of arrival of the signals, returned as a real-valued row vector. The direction of arrival angle is the broadside angle between the source direction and the array axis. Angle units are in degrees. The length of the vector is the number of signals specified by the **Number of signals** parameter. If the object cannot identify peaks in the spectrum, it will return `NaN`.

##### Dependencies

To enable this output port, select the **Enable DOA output** check box.

Data Types: `double`

## Parameters

#### `Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

#### `Operating frequency (Hz)` — System operating frequency

`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

#### `Number of bits in phase shifters` — Number of phase shift quantization bits

`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### `Forward-backward averaging` — Enable forward-backward averaging

off (default) | on

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold structure.

### `Spatial smoothing` — Enable spatial smoothing

`0` (default) | non-negative integer

Specify the amount of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is *N* – *2*, where *N* is the number of sensors in the ULA.

### `Scan angles (deg)` — Search angles for spectrum peaks

`-90:90` (default) | real-valued row vector

Specify the scan angles in degrees as a real-valued row vector. The angles are array broadside angles and must lie between –90° and 90°, inclusive. You must specify the angles in increasing order.

### `Enable DOA output` — Output directions of arrival through output port

off (default) | on

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port.

### `Number of signals` — Expected number of arriving signals

`1` (default) | positive integer

Specify the expected number of signals for DOA estimation as a positive scalar integer.

#### Dependencies

To enable this parameter, select the **Enable DOA output** check box.

Data Types: `double`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Array Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### `Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

### `Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

### `Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of

**Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`.

### `Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Radiation pattern (dB)` — Custom antenna radiation pattern

`zeros(181,361)` | complex-valued matrix | complex-valued MATLAB array

Magnitude of the combined polarized antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must equal the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must equal the value of *P* specified by **Azimuth angles (deg)**. The value of *L* must equal the value of *L* specified by **Operating frequency vector (Hz)**.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Number of elements` — Number of array elements in U

2 (default) | positive integer greater than or equal to two

The number of array elements for ULA arrays, specified as an integer greater than or equal to two.

Example: `11`

Data Types: `double`

**`Element spacing` — Distance between ULA elements**
`0.5` (default) | positive scalar

Distance between adjacent ULA elements, specified as a positive scalar. Units are in meters.

Example: `1.5`

**`Array axis` — Linear axis direction of ULA**
`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. Then, all ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**`Taper` — Array element tapers**
1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

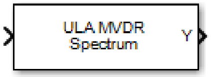
# See Also

`phased.BeamscanEstimator`

**Introduced in R2014b**

# ULA MVDR Spectrum

MVDR spatial spectrum estimator for ULA



## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The ULA MVDR Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a region of broadside angles using a narrowband minimum variance distortionless response (MVDR) beamformer for a uniform linear array. The block optionally calculates the direction of arrival (DOA) of a specified number of signals by estimating peaks of the spectrum. The MVDR DOA estimator is also called the Capon DOA estimator.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of bits in phase shifters**

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Forward-backward averaging**

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

**Spatial smoothing**

Specify the amount of averaging, *L*, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is *N – 2*, where *N* is the number of sensors.

**Scan angles (deg)**

Specify the scan angles in degrees as a real vector. The angles are broadside angles and must be between –90° and 90°, inclusive. You must specify the angles in increasing order.

**Enable DOA output**

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port. Selecting this parameter enables the **Number of signals** parameter.

**Number of signals**

Specify the number of signals for DOA estimation as a positive scalar integer. This parameter appears when you select the **Enable DOA output** check box.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

**Specify sensor array as**

Specify a ULA sensor array directly or by using a MATLAB expression.

**Types**

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Number of elements**

Specifies the number of elements in the array as an integer.

**Element spacing**

Specify the spacing, in meters, between two adjacent elements in the array.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P*

specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone’s response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `In` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Estimated broadside DOA angles. | Double-precision floating point |
| `Y` | Estimated spatial spectrum. | Double-precision floating point |

## See Also

`phased.MVDREstimator`

**Introduced in R2014b**

# ULA MUSIC Spectrum

MUSIC spatial spectrum estimator for ULA
**Library:** Phased Array System Toolbox / Direction of Arrival

## Description

The ULA MUSIC Spectrum block estimates the spatial spectrum of incoming narrowband signals using the MUSIC algorithm. The algorithm computes the MUSIC pseudo-spectrum of a ULA by scanning a region of broadside angles. The block optionally calculates the direction of arrival (DOA) of a specified number of signals by estimating peaks of the spectrum.

## Ports

### Input

**`Port 1` — Received signal**
*M*-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) contained in the signal and *N* is the number of sensor elements in the array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

### Output

**Y — MUSIC spatial spectrum**
non-negative, real-valued column vector

MUSIC spatial spectrum, returned as a non-negative, real-valued column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the **Scan angles (deg)** parameter.

Data Types: `double`

### `Ang` — Directions of arrival
non-negative, real-valued column vector

Directions of arrival of the signals, returned as a real-valued row vector. The direction of arrival angle is the broadside angle between the source direction and the array axis. The length of the vector is the number of signals specified by the `Number of signals` parameter. If the object cannot identify peaks in the spectrum, it will return `NaN`. Angle units are in degrees.

#### Dependencies

Select the **Enable DOA output** parameter to enable this output port.

Data Types: `double`

## Parameters

#### Main Tab

### `Signal propagation speed (m/s)` — Signal propagation speed
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

### `Operating frequency (Hz)` — System operating frequency
`3.0e8` (default) | positive real scalar

System operating frequency, specified as a positive scalar. Units are in Hz.

### `Forward-backward averaging` — Enable forward-backward averaging
off (default) | on

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold structure.

### `Spatial smoothing` — Enable spatial smoothing

`0` (default) | non-negative integer

Specify the amount of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is *N* – *2*, where *N* is the number of sensors in the ULA.

### `Scan angles (deg)` — Search angles for spectrum peaks

`-90:90` (default) | real-valued row vector

Specify the scan angles in degrees as a real-valued row vector. The angles are array broadside angles and must lie between –90° and 90°, inclusive. You must specify the angles in increasing order.

### `Enable DOA output` — Output directions of arrival through output port

off (default) | on

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port.

### `Number of signals` — Expected number of arriving signals

`1` (default) | positive integer

Specify the expected number of signals for DOA estimation as a positive scalar integer.

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

#### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

#### Sensor Array Tab

### `Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

### `Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

#### Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

#### Element Parameters

### `Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

### `Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

### `Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

### Baffle the back of the element — Set back response of an Isotropic Antenna element or an Omni Microphone element to zero

off (default) | on

Select this check box to baffle the back response of the element. When back baffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is defined as 0° azimuth angle and 0° elevation angle.

#### Dependencies

To enable this check box, set **Element type** to Isotropic Antenna or Omni Microphone.

### Exponent of cosine pattern — Exponents of azimuth and elevation cosine patterns

[1.5 1.5] (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When **Exponent of cosine pattern** is a 1-by-2 vector, the first element is the exponent in the azimuth direction and the second element is the exponent in the elevation direction. When you set this parameter to a scalar, both the azimuth direction and elevation direction cosine patterns are raised to the same power.

#### Dependencies

To enable this parameter, set **Element type** to Cosine Antenna.

### Frequency responses (dB) — Antenna and microphone frequency response

[0,0] (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

#### Dependencies

To enable this parameter, set **Element type** to Custom Antenna or Custom Microphone.

### Azimuth angles (deg) — Azimuth angles of antenna radiation pattern

[-180:180] (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Radiation pattern (dB)` — Custom antenna radiation pattern

`zeros(181,361)` | complex-valued matrix | complex-valued MATLAB array

Magnitude of the combined polarized antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must equal the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must equal the value of *P* specified by **Azimuth angles (deg)**. The value of *L* must equal the value of *L* specified by **Operating frequency vector (Hz)**.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

### `Polar pattern frequencies (Hz)` — Polar pattern microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Polar pattern microphone response frequencies, specified as a real scalar, or a real-valued, 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

#### Dependencies

To enable this parameter, set **Element type** set to `Custom Microphone`.

### `Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

### `Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. The pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. The polar pattern is symmetric around the central axis. You can construct the microphone response pattern in 3-D space from the polar pattern.

#### Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

#### Array Parameters

### `Number of elements` — Number of array elements in U

`2` (default) | positive integer greater than or equal to two

The number of array elements for ULA arrays, specified as an integer greater than or equal to two.

Example: `11`

Data Types: `double`

### `Element spacing` — Distance between ULA elements

`0.5` (default) | positive scalar

Distance between adjacent ULA elements, specified as a positive scalar. Units are in meters.

Example: `1.5`

### `Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. Then, all ULA array elements are uniformly spaced along this axis in the local array coordinate system.

### `Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as element weights, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce side lobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

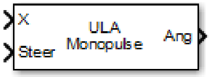
**Introduced in R2016b**

# ULA Sum and Difference Monopulse

Sum-and-difference monopulse tracker for ULA



## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The ULA Sum-and-Difference Monopulse block estimates the direction of arrival of a narrowband signal on a uniform linear array based on an initial guess using a sum-and-difference monopulse algorithm. The block obtains the difference steering vector by phase-reversing the latter half of the sum steering vector.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of bits in phase shifters**

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose

`Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

### Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

**Types**

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

**Number of elements**

Specifies the number of elements in the array as an integer.

**Element spacing**

Specify the spacing, in meters, between two adjacent elements in the array.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`

- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**.

Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Steer` | Initial estimate of broadside DOA angles. | Double-precision floating point |

| Port | Description | Supported Data Types |
|---|---|---|
| `Ang` | Estimated broadside DOA angles. | Double-precision floating point |

## See Also

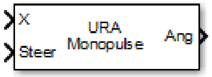
**Introduced in R2014b**

# URA Sum and Difference Monopulse

Sum-and-difference monopulse for URA



## Library

Direction of Arrival (DOA)

`phaseddoalib`

## Description

The URA Sum-and-Difference Monopulse block estimates the direction of arrival of a narrowband signal on a uniform rectangular array (URA) based on an initial guess using a sum-and-difference monopulse algorithm. The block obtains the difference steering vector by phase-reversing the latter half of the sum steering vector.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Operating frequency (Hz)**

Specify the operating frequency of the system, in hertz, as a positive scalar.

**Number of bits in phase shifters**

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose

`Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

### Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

### Types

| |
|---|
| `Array (no subarrays)` |
| `MATLAB expression` |

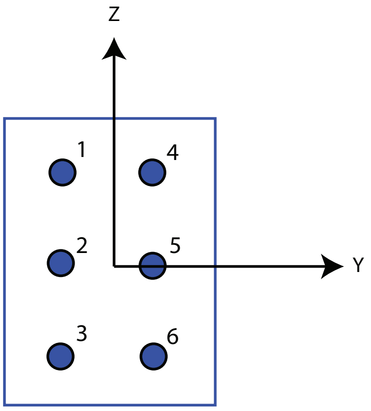
**Array size**

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

Elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array has three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



**Element spacing**

Specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

**Element lattice**

Specify the element lattice as one of Rectangular or Triangular.

- Rectangular — Aligns all the elements in row and column directions.
- Triangular — Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The elements are shifted a distance of half the element spacing along the row.

**Array normal**

This parameter appears when you set **Geometry** to URA or UCA. Specify the **Array normal** as x, y, or z. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of [NumberofRows, NumberOfColumns] in the **Array size** matrix. If Taper is a scalar, the same weight is applied to each element. If the value of **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Expression**

A valid MATLAB expression containing a constructor for a uniform rectangular array, for example, phased.URA.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- Isotropic Antenna
- Cosine Antenna

- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**.

Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Input signal.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Steer` | Initial estimate of arrival directions. | Double-precision floating point |

| Port | Description | Supported Data Types |
|---|---|---|
| `Ang` | Estimate of arrival directions. | Double-precision floating point |

# Wideband Backscatter Radar Target

Backscatter wideband signals from radar target

**Library:** Phased Array System Toolbox / Environment and Target

X
Ang
Wideband
Backscatter
Target

## Description

The Wideband Backscatter Radar Target block models the monostatic reflection of nonpolarized wideband electromagnetic signals from a radar target. The target radar cross-section (RCS) model includes all four Swerling target fluctuation models and a nonfluctuating model. You can model several targets simultaneously by specifying multiple RCS matrices.

## Ports

### Input

**X — Wideband incident nonpolarized signal**
*N*-by-*M* complex-valued matrix

Wideband incident nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples, and *M* is the number of independent signals reflecting off the target. Each column contains an independent signal to be reflected from the target.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**Ang — Incident signal direction**
2-by-1 real-valued column vector of positive values | 2-by-*M* real-valued column vector of positive values

Incident signal direction, specified as a 2-by-1 or 2-by-*M* real-valued column matrix of positive values. Each column of Ang specifies the incident direction of the corresponding signal. The number of columns in Ang must match the number of independent signals in X. The columns take the form [AzimuthAngle;ElevationAngle]. Units are in degrees.

Data Types: double

### Update — Enable update of RCS

false (default) | true

Option to enable updating of RCS values for fluctuation models, specified as false or true. When Update is true, a new RCS value is generated each time you run the block. If Update is false, the RCS remains unchanged.

#### Dependencies

To enable this port, set the **Fluctuation model** parameter to one of the Swerling models.

Data Types: Boolean

## Output

### Out — Wideband reflected nonpolarized signal

*N*-by-*M* complex-valued matrix

Wideband reflected nonpolarized signal, returned as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples, and *M* is the number of independent signals reflected from the target. Each column contains an independent signal reflected from the target.

Data Types: double

# Parameters

### Backscatter pattern frequency vector (Hz) — Wideband backscatter pattern frequencies

[0,1e20] (default) | real-valued row vector of positive values in strictly increasing order

Specify the frequencies used in the RCS matrix. The elements of this vector must be in strictly increasing order. The target has no response outside this frequency range. Frequencies are defined with respect to the physical frequency band, not the baseband. Frequency units are in Hz.

### `Azimuth angles (deg)` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrices specified by the **RCS pattern (m^2)** parameter. Specify the azimuth angles as a length *P* vector. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

### `Elevation angles (deg)` — Elevation angles

`[-90:90]` (default) | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrices specified by the **RCS pattern (m^2)** parameter. Specify the elevation angles as a length *Q* vector. *Q* must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

### `RCS pattern (m^2)` — Radar cross-section pattern

`ones(181,361)` (default) | *Q*-by-*P* real-valued matrix | *Q*-by-*P*-by-*K* real-valued array | 1-by-*P*-by-*K* real-valued array | *K*-by-*P* real-valued matrix

Radar cross-section pattern, specified as a real-valued matrix or array.

| Dimensions | Application |
|---|---|
| *Q*-by-*P* matrix | Specifies a matrix of RCS values as a function of *Q* elevation angles and *P* azimuth angles. The same RCS matrix is used for all frequencies. |
| *Q*-by-*P*-by-*K* array | Specifies an array of RCS patterns as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If K = 1, the RCS pattern is equivalent to a *Q*-by-*P* matrix. |
| 1-by-*P*-by-*K* array | Specifies a matrix of RCS values as a function of *P* azimuth angles and *K* |

| Dimensions | Application |
|---|---|
| *K*-by-*P* matrix | frequencies. These dimension formats apply when there is only one elevation angle. |

- *Q* is the length of the vector specified by the **Elevation angles (deg)** parameter.
- *P* is the length of the vector specified by the **Azimuth angles (deg)** parameter.
- *K* is the number of frequencies specified by the **Backscatter pattern frequency vector (Hz)** parameter.

You can specify patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the block. You can, however, use one pattern to model *L* multiple targets.

RCS units are in square meters.

Example: `[1,2;2,1]`

Data Types: `double`

### `Fluctuation model` — Target fluctuation model

`Nonfluctuating` (default) | `Swerling1` | `Swerling2` | `Swerling3` | `Swerling4`

Target fluctuation model, specified as `Nonfluctuating`, `Swerling1`, `Swerling2`, `Swerling3`, or `Swerling4`. If you set this parameter to a value other than `Nonfluctuating`, you must pass either `true` or `false` into the **Update** `Update` port.

### `Propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

### `Operating frequency (Hz)` — Signal carrier frequency

`300.0e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Number of subbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

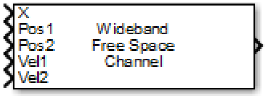
**Introduced in R2016b**

# Wideband Free Space

Wideband free space environment



## Library

Environment and Target

`phasedenvlib`

## Description

The Wideband Free Space Channel block propagates the signal from one point to another in space. The block models propagation time, free space propagation loss and Doppler shift. The block assumes that the propagation speed is much greater than the target or array speed in which case the stop-and-hop model is valid.

When propagating a signal in free-space to an object and back, you have the choice of either using a single block to compute a two-way free space propagation delay or two blocks to perform one-way propagation delays in each direction. Because the free-space propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Signal carrier frequency (Hz)**

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

**Number of subbands**

The number of subbands used for subband processing, specified as a positive integer.

**Perform two-way propagation**

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Maximum one-way propagation distance (m)**

The maximum distance , in meters, between the origin and the destination as a positive scalar. Amplitudes of any signals that propagate beyond this distance will be set to zero.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Input signal. | Double-precision floating point |
| `Pos1` | Signal source position. | Double-precision floating point |
| `Pos2` | Signal destination position. | Double-precision floating point |
| `Vel1` | Signal source velocity. | Double-precision floating point |
| `Vel2` | Signal destination velocity. | Double-precision floating point |

| Port | Description | Supported Data Types |
|---|---|---|
| `Out` | Propagated signal. | Double-precision floating point |

## Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity $\tau$ is the delay and $L$ is the propagation loss. The delay is computed from $\tau = R/c$ where $R$ is the propagation distance and $c$ is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter $v$ is the relative speed of the destination with respect to the origin.

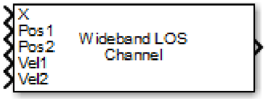
**Introduced in R2015b**

# Wideband LOS Channel

Wideband line-of-sight propagation channel



## Library

Environment and Target

`phasedenvlib`

## Description

The Wideband LOS Channel block propagates signals from one point in space to multiple points or from multiple points back to one point via line-of-sight (LOS) channels. The block models propagation time, free-space propagation loss, Doppler shift, and atmospheric as well as weather loss. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

When propagating a signal in an LOS channel to an object and back, you have the choice of either using a single block to compute two-way LOS channel propagation delay or two blocks to perform one-way propagation delays in each direction. Because the LOS channel propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

# Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Signal carrier frequency (Hz)**

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

**Number of subbands**

The number of subbands used for subband processing, specified as a positive integer.

**Specify atmospheric parameters**

Select this check box to enable atmospheric attenuation modeling.

**Temperature (degrees Celsius)**

Ambient atmospheric temperature, specified as a real-valued scalar. Units are degrees Celsius. This parameter appears when you select the **Specify atmospheric parameters** check box. Units are degrees Celsius.

**Dry air pressure (Pa)**

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are Pascals (Pa). The value 101325 for this property corresponds to one standard atmosphere. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Water vapour density (g/m^3)**

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are gm/m$^3$. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Liquid water density (g/m^3)**

Liquid water density of fog or clouds, specified as a non-negative real-valued scalar. Units are gm/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Rain rate (mm/hr)**

Rainfall rate, specified as a non-negative real-valued scalar. Units are in mm/hour. This parameter appears when you select the **Specify atmospheric parameters** check box.

**Perform two-way propagation**

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Maximum one-way propagation distance (m)**

The maximum distance between the signal origin and the destination, specified as a positive scalar. Units are in meters. Amplitudes of any signals that propagate beyond this distance will be set to zero.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | Normal | Accelerator | Rapid Accelerator |
| Interpreted Execution | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| Code Generation | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| X | Input signal. | Double-precision floating point |
| Pos1 | Signal source position. | Double-precision floating point |
| Pos2 | Signal destination position. | Double-precision floating point |
| Vel1 | Signal source velocity. | Double-precision floating point |
| Vel2 | Signal destination velocity. | Double-precision floating point |
| Out | Propagated signal. | Double-precision floating point |

# More About

## Attenuation and Loss Factors

Attenuation or path loss in the Wideband LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- $L_{fsp}$ is the free-space path attenuation
- $L_g$ is the atmospheric path attenuation
- $L_c$ is the fog and cloud path attenuation
- $L_r$ is the rain path attenuation

Each component is in magnitude units, not in dB.

## Propagation Delay, Doppler, and Free-Space Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t\text{-}\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_{\mathrm{i}}$, multiplied by a spectral line strength, *S*$_{\mathrm{i}}$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right]W\,.$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is $P + W$.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, $R$. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, $N_\mathrm{B}$, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, $f_c$. The overall bandwidth is given by the sample rate, $f_s$. Frequency subband widths are $\Delta f = f_\mathrm{s}/N_\mathrm{B}$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N_B-1)f_s}{2N_B} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, \quad m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output when you run the object. The returned subband frequencies are ordered consistently with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

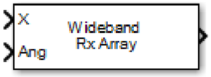
**Introduced in R2016a**

# Wideband Receive Array

Wideband receive array



## Library

Transmitters and Receivers

`phasedtxrxlib`

## Description

The Wideband Receive Array block receives wideband plane waves incident on the elements of a sensor array. The block divides the input signal into subbands and then applies a phase shift in each subband according to the incident direction. The resulting subband signals are then combined to form the output.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Assume modulated input**

Select this check this box to indicate that the input signal is demodulated at a carrier frequency.

**Carrier frequency**

This parameter appears when the **Assume modulated input** check box is selected. The parameter specifies the carrier frequency, in hertz, as a positive scalar.

**Number of subbands**

Number of processing subbands, specified as a positive integer.

**Sensor gain measure**

Sensor gain measure, specified as `dB` or `dBi`.

- When you set this parameter to `dB`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.
- When you set this parameter to `dBi`, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values computed by the radar equation that uses dBi to specify the antenna gain. The computation using the `dBi` option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor. The default value is `dB`.

**Enable weights input**

Select this check box to specify array weights using the input port `W`. The input port appears only when this box is checked.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

### Specify sensor array as

Specify sensor element or sensor array. A sensor array can also contain subarrays or be a partitioned array. This parameter can also be expressed as a MATLAB expression.

**Types**

| |
|---|
| `Single element` |
| `Array (no subarrays)` |
| `Partitioned array` |
| `Replicated subarray` |
| `MATLAB expression` |

### Geometry

Specify the array geometry as one of the following:

- ULA — Uniform linear array
- URA — Uniform rectangular array
- UCA — Uniform circular array
- Conformal Array — arbitrary element positions

### Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to ULA or UCA. If **Sensor Array** has a Replicated subarray option, this parameter applies to the subarray.

### Array size

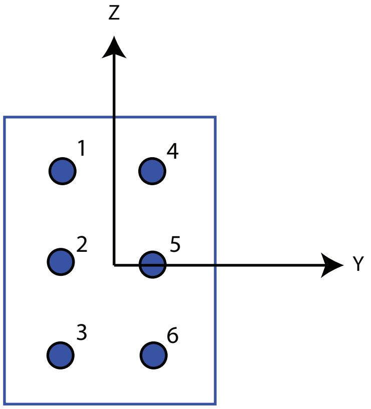
This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to Replicated subarray, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form [NumberOfArrayRows,NumberOfArrayColumns].
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of [3,2] produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



**Element spacing (m)**

This parameter appears when **Geometry** is set to `ULA` or `URA`. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a `ULA`, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a `URA`, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see `phased.URA`. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Element lattice**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

**Element positions (m)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

**Element normals (deg)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

**Subarray definition matrix**

This parameter appears when **Specify sensor array as** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix corresponds to

a subarray and each entry in the row indicates whether or not an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

**Subarray steering method**

This parameter appears when the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as either

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Phase shifter frequency (Hz)**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

**Number of bits in phase shifters**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

### Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

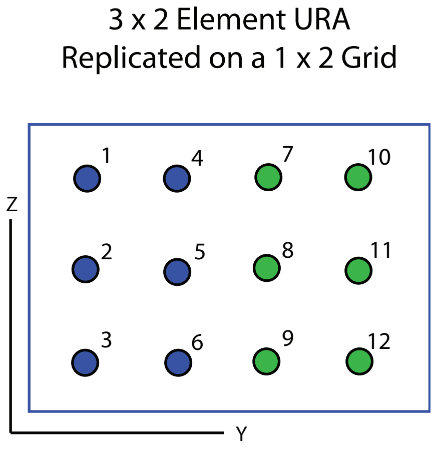
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

### Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



### Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

**Subarray positions (m)**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

**Subarray normals**

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Expression**

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Arriving signals input port<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Incident directions of signals input port. | Double-precision floating point |
| `W` | Array or subarray weights input port. To enable this port, select the **Enable weights input** check box. | Double-precision floating point |
| `WS` | Subarray element weights input port. To enable this port select `Custom` from the **Subarray steering method** pull down menu. | |
| `Steer` | Steering angle input port. To enable this port, select `Phase` or `Time` from the **Subarray steering method** pull down menu. | Double-precision floating point |
| `Out` | Collected signals | Double-precision floating point |

Wideband Two-Ray Channel

## Description

The Wideband Two-Ray Channel block propagates wideband signals from one point in space to multiple points or from multiple points back to one point via both the direct path and the ground reflection path. The block propagates wideband signals by (1) decomposing them into subbands, (2) propagating subbands independently, and (3) recombining the propagated subbands. The block models propagation time, propagation loss, and Doppler shift. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

## Ports

### Input

**X — Wideband input signal**

*M*-by-*N* complex-valued matrix | *M*-by-2*N* complex-valued matrix

- Wideband nonpolarized scalar signal, specified as an
  - *M*-by-*N* complex-valued matrix. The quantity *M* is the number of samples in the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair. Each column contains an identical signal that is propagated along the line-of-sight and reflected paths.
  - *M*-by-2*N* complex-valued matrix. The quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair. Each adjacent pair of columns represents a different channel. Within each pair, the first column represents the signal propagated along the line-of-sight path and the second column represents the signal propagated along the reflected path.

The quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

### `Pos1` — Position of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If **Pos1** is a column vector, it takes the form `[x;y;z]`. If **Pos1** is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are in meters.

**Pos1** and **Pos2** cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

### `Pos2` — Position of signal destination

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If **Pos2** is a column vector, it takes the form `[x;y;z]`. If **Pos2** is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are in meters.

**Pos1** and **Pos2** cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

Example: `[-100;300;50]`

Data Types: `double`

### `Vel1` — Velocity of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of **Vel1** must match the dimensions of **Pos1**. If **Vel1** is a column vector, it takes the form `[Vx;Vy;Vz]`. If **Vel1** is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[-10;3;5]`

Data Types: `double`

### `Vel2` — Velocity of signal destination

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of **Vel2** must match the dimensions of **Pos2**. If **Vel2** is a column vector, it takes the form `[Vx;Vy;Vz]`. If **Vel2** is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[-1000;300;550]`

Data Types: `double`

## Output

### `Out` — Propagated signal

*M*-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix

- *M*-by-*N* complex-valued matrix. To return this format, set the `CombinedRaysOutput` property to `true`. Each matrix column contains the coherently combined signals from the line-of-sight path and the reflected path.
- *M*-by-*2N* complex-valued matrix. To return this format set the `CombinedRaysOutput` property to `false`. Alternate columns of the matrix contain the signals from the line-of-sight path and the reflected path.

The output **Out** contains signal samples arriving at the signal destination within the current input time frame. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contributions from the input of the current time frame. The remaining output will appear in the next execution of the block.

## Parameters

**`Signal propagation speed (m/s)` — Signal propagation speed**
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`. Units are in meters per second.

Example: `3e8`

Data Types: `double`

**`Signal carrier frequency (Hz)` — Signal carrier frequency**
`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Data Types: `double`

**`Number of subbands` — Number of processing subbands**
`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

**`Specify atmospheric parameters` — Enable atmospheric attenuation model**
off (default) | on

Select this parameter to enable to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. When you select this parameter, the **Temperature (degrees Celsius)**, **Dry air pressure (Pa)**, **Water vapour density (g/m^3)**, **Liquid water density (g/m^3)**, and **Rain rate (mm/hr)** parameters appear in the dialog box.

Data Types: `Boolean`

**`Temperature (degrees Celsius)` — Ambient temperature**
`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Dry air pressure (Pa)` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this parameter corresponds to one standard atmosphere.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Water vapour density (g/m^3)` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `datetime`

### `Liquid water density (g/m^3)` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Rain rate (mm/hr)` — Rainfall rate

`0.0` (default) | non-negative real-valued scalar

Rainfall rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

#### Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

### `Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

### `Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate** check box.

Data Types: `double`

### `Ground reflection coefficient` — Ground reflection coefficient

-1 (default) | complex-valued scalar | complex-valued 1-by-*N* row vector

Ground reflection coefficient for the field at the reflection point, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. Coefficients have an absolute value less than or equal to one. The quantity *N* is the number of two-ray channels. Units are dimensionless.

Example: `-0.5`

### `Combine two rays at output` — Option to combine two rays at output

on (default) | off

Select this parameter to combine the two rays at channel output. Combining the two rays coherently adds the line-of-sight propagated signal and the reflected path signal to form the output signal. You can use this mode when you do not need to include the directional gain of an antenna or array in your simulation.

Example: on

### `Maximum one-way propagation distance (m)` — Maximum one-way propagation distance

`10.0e3` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a real-valued positive scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000.0`

### `Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster with generated code than in interpreted execution. You can run repeated executions without recompiling, but if you change any block parameters, then the block automatically recompiles before execution.

This table shows how the **Simulate using** parameter affects the overall simulation behavior.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

### Acceleration Modes

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity $\tau$ is the delay and $L$ is the propagation loss. The delay is computed from $\tau = R/c$ where $R$ is the propagation distance and $c$ is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter $v$ is the relative speed of the destination with respect to the origin.

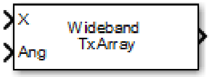
# Wideband Transmit Array

Wideband transmit array



## Library

Transmitters and Receivers

`phasedtxrxlib`

## Description

The Wideband Transmit Array block transmits wideband plane waves from the elements of a sensor array. The block divides the transmitted signals into subbands and then applies a phase shift for each subband according to the radiating direction. The resulting subband signals are then combined to form the output.

## Parameters

**Signal Propagation speed (m/s)**

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

**Inherit sample rate**

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

**Sample rate (Hz)**

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

**Assume modulated input**

Select this check this box to indicate that the input signal is demodulated at a carrier frequency.

**Carrier frequency**

This parameter appears when the **Assume modulated input** check box is selected. The parameter specifies the carrier frequency, in hertz, as a positive scalar.

**Number of subbands**

The number of subbands used for subband processing, specified as a positive integer.

**Sensor gain measure**

Sensor gain measure, specified as `dB` or `dBi`.

- When you set this parameter to `dB`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.
- When you set this parameter to `dBi`, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values computed by the radar equation that uses dBi to specify the antenna gain. The computation using the `dBi` option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor. The default value is `dB`.

**Enable weights input**

Select this check box to specify array weights using the input port `W`. The input port appears only when this box is checked.

**Simulate using**

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

**Acceleration Modes**

| Block Simulation | Simulation Behavior | | |
|---|---|---|---|
| | `Normal` | `Accelerator` | `Rapid Accelerator` |
| `Interpreted Execution` | The block executes using the MATLAB interpreter. | The block executes using the MATLAB interpreter. | Creates a standalone executable from the model. |
| `Code Generation` | The block is compiled. | All blocks in the model are compiled. | |

For more information, see “Choosing a Simulation Mode” (Simulink).

## Array Parameters

### Specify sensor array as

Specify sensor element or sensor array. A sensor array can also contain subarrays or be a partitioned array. This parameter can also be expressed as a MATLAB expression.

**Types**

| |
|---|
| `Single element` |
| `Array (no subarrays)` |
| `Partitioned array` |
| `Replicated subarray` |
| `MATLAB expression` |

### Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

**Number of elements**

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the subarray.

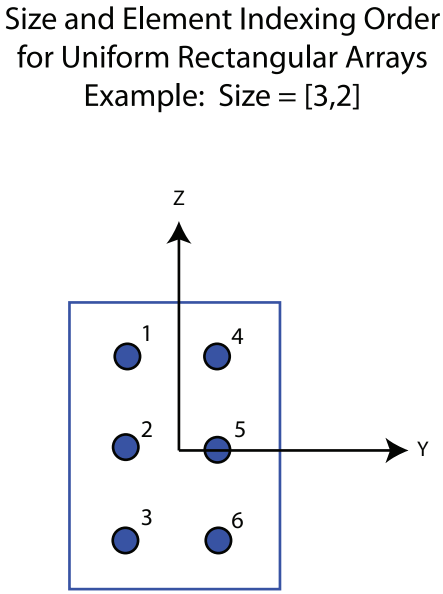
**Array size**

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.



Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]
Z
Y
1
2
3
4
5
6

**Element spacing (m)**

This parameter appears when **Geometry** is set to `ULA` or `URA`. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a `ULA`, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a `URA`, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see `phased.URA`. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

**Array axis**

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

**Array normal**

This parameter appears when you set **Geometry** to URA or UCA. Specify the **Array normal** as x, y, or z. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*-planes, respectively, of the array coordinate system.

**Radius of UCA (m)**

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

**Taper**

Tapers, also known as element weights, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to Replicated subarray, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of [NumberofArrayRows,NumberOfArrayColumns] in the **Array size** matrix. If Taper is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a Conformal Array, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

**Element lattice**

This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to Replicated subarray, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

**Element positions (m)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

**Element normals (deg)**

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

**Subarray definition matrix**

This parameter appears when **Specify sensor array as** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix corresponds to

a subarray and each entry in the row indicates whether or not an element belongs to the subarray. When the entry is zero, the element does not belong the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

**Subarray steering method**

This parameter appears when the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as either

- `None`
- `Phase`
- `Time`
- `Custom`

Selecting `Phase` or `Time` opens the `Steer` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

Selecting `Custom` opens the `WS` input port on the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, Wideband Transmit Array blocks, Constant Gamma Clutter, and GPU Constant Gamma Clutter blocks.

**Phase shifter frequency (Hz)**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

**Number of bits in phase shifters**

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Subarrays layout**

This parameter appears when you set **Sensor array** to `Replicated subarray`.

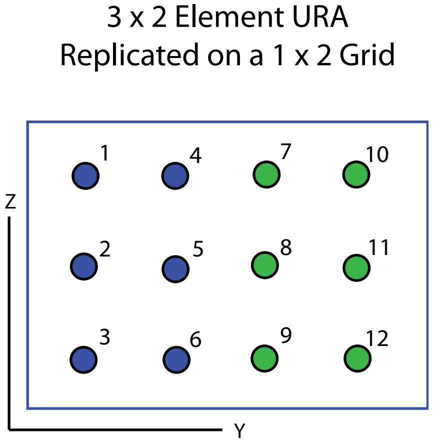
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

**Grid size**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



**Grid spacing**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

**Subarray positions (m)**

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

**Subarray normals**

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Expression**

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

## Sensor Array Tab: Element Parameters

**Element type**

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

**Exponent of cosine pattern**

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

**Operating frequency range (Hz)**

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

**Operating frequency vector (Hz)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

**Frequency responses (dB)**

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

**Azimuth angles (deg)**

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Elevation angles (deg)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Radiation pattern (dB)**

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

**Polar pattern frequencies (Hz)**

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

**Polar pattern angles (deg)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

**Polar pattern (dB)**

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone’s response pattern in 3-D space from the polar pattern.

**Baffle the back of the element**

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from broadside are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

# Ports

**Note** The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

| Port | Description | Supported Data Types |
|---|---|---|
| `X` | Radiated signals input port<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. | Double-precision floating point |
| `Ang` | Radiating directions of signals input port. | Double-precision floating point |
| `W` | Array or subarray weights input port. To enable this port, select the **Enable weights input** check box. | Double-precision floating point |
| `WS` | Subarray element weights input port. To enable this port select `Custom` from the **Subarray steering method** pull down menu. | |
| `Steer` | Steering angle input port. To enable this port, select `Phase` or `Time` from the **Subarray steering method** pull down menu. | |
| `Out` | Radiated signals. | Double-precision floating point |

# App Reference

# Radar Equation Calculator

Estimate maximum range, peak power, and SNR of a radar system

## Description

The **Radar Equation Calculator** app solves the basic radar equation for monostatic or bistatic radar systems. The radar equation relates target range, transmitted power, and received signal SNR. Using this app, you can:

- Solve for maximum target range based on the transmit power of the radar and specified received SNR
- Calculate required transmit power based on known target range and specified received SNR
- Calculate the received SNR value based on known range and transmit power

## Open the Radar Equation Calculator App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `radarEquationCalculator`.

## Examples

### Maximum Detection Range of a Monostatic Radar

This example shows how to compute the maximum detection range of a 10 GHz, 1 kW, monostatic radar with a 40 dB antenna gain and a detection threshold of 10 dB.

From the **Calculation Type** drop-down list, choose **Target Range** as the solution.

Choose **Configuration** as `monostatic`.

Enter 40 dB for the antenna **Gain**.

Set the **Wavelength** to 3 cm.

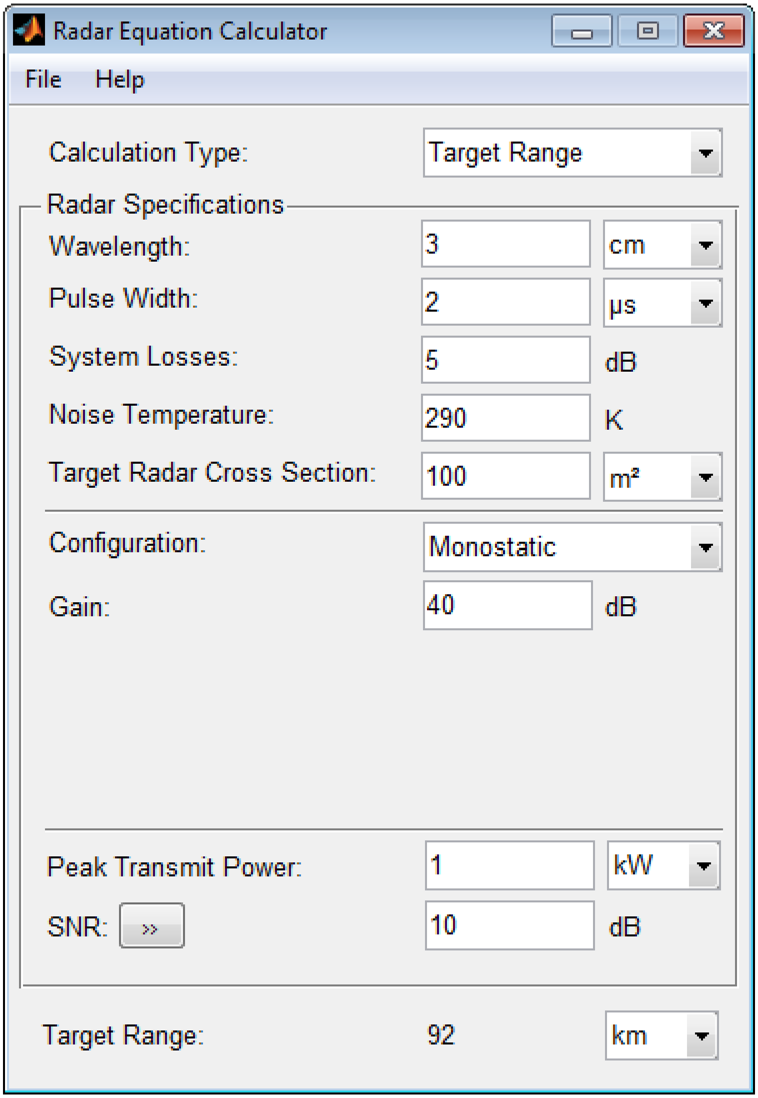
Set the **SNR** detection threshold parameter to 10 dB.

Assuming the target is a large airplane, set the **Target Radar Cross Section** value to 100 m$^2$.

Specify the **Peak Transmit Power** as 1 kW

Specify the **Pulse Width** as 2 μs.

Assume a total of 5 dB **System Losses**.



Calculation Type: Target Range

Radar Specifications

Wavelength: 3 cm

Pulse Width: 2 μs

System Losses: 5 dB

Noise Temperature: 290 K

Target Radar Cross Section: 100 m²

Configuration: Monostatic

Gain: 40 dB

Peak Transmit Power: 1 kW

SNR: 10 dB

Target Range: 92 km

The maximum target detection range is 92 km.

### Maximum Detection Range of a Monostatic Radar Using Multiple Pulses

This example shows how to use multiple pulses to reduce the transmitted power while maintaining the same maximum target range.

Continue with the results from the previous example.

Click the arrows to the right of the **SNR** label.

The **Detection Specifications for SNR** menu opens.

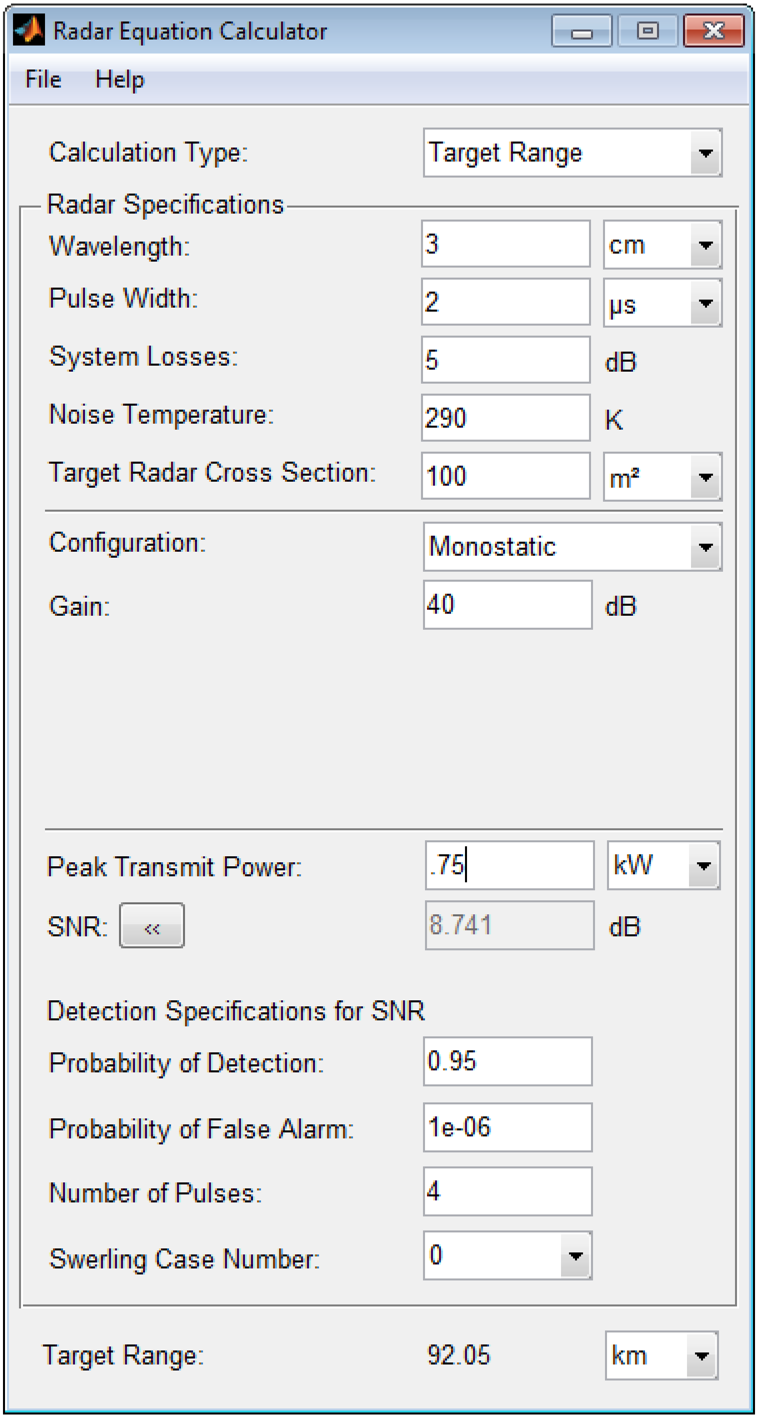
Set **Probability of Detection** to 0.95.

Set **Probability of False Alarm** to $10^{-6}$.

Set **Number of Pulses** to 4.

Reduce **Peak Transmit Power** to 0.75 kW.

Assume a nonfluctuating target model, and set the **Swerling Case Number** is 0.



Calculation Type: Target Range

Radar Specifications

Wavelength: 3 cm

Pulse Width: 2 μs

System Losses: 5 dB

Noise Temperature: 290 K

Target Radar Cross Section: 100 m²

Configuration: Monostatic

Gain: 40 dB

Peak Transmit Power: .75 kW

SNR: 8.741 dB

Detection Specifications for SNR

Probability of Detection: 0.95

Probability of False Alarm: 1e-06

Number of Pulses: 4

Swerling Case Number: 0

Target Range: 92.05 km

The maximum detection range is approximately the same as in the previous example, but the transmitted power is reduced by 25%.

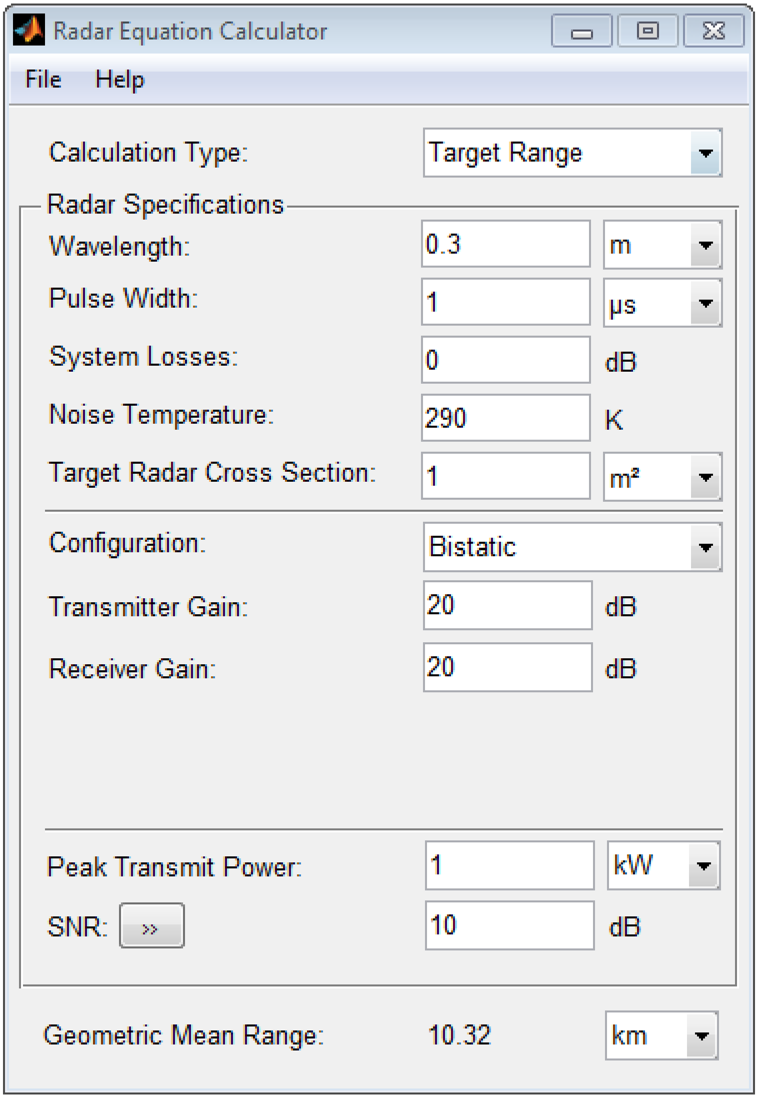
### Maximum Detection Range of Bistatic Radar System

This example shows how to solve for the geometric mean range of a target for a bistatic radar system.

Specify the **Calculation Type** as `Target Range`.

Specify the **Configuration** as `bistatic`.

Provide a **Transmitter Gain** and a **Receiver Gain** parameter, instead of the single gain needed in the monostatic case.



Calculation Type: Target Range

Radar Specifications

Wavelength: 0.3 m

Pulse Width: 1 μs

System Losses: 0 dB

Noise Temperature: 290 K

Target Radar Cross Section: 1 m²

Configuration: Bistatic

Transmitter Gain: 20 dB

Receiver Gain: 20 dB

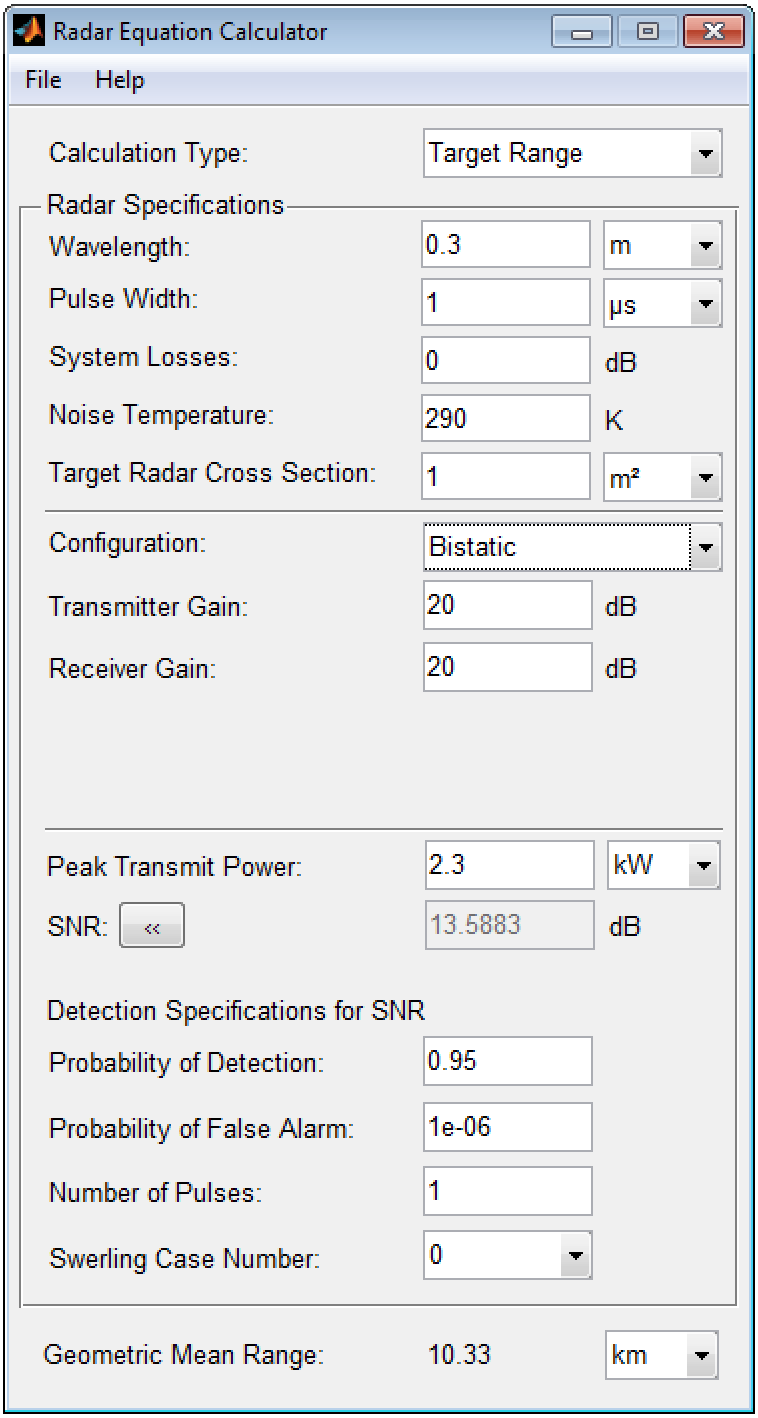
Peak Transmit Power: 1 kW

SNR: 10 dB

Geometric Mean Range: 10.32 km

Alternatively, to achieve a particular probability of detection and probability of false alarm, open the **Detection Specifications for SNR** menu.

Enter values for **Probability of Detection** and **Probability of False Alarm**, **Number of Pulses**, and **Swerling Case Number**.



Calculation Type: Target Range

Radar Specifications

Wavelength: 0.3 m

Pulse Width: 1 μs

System Losses: 0 dB

Noise Temperature: 290 K

Target Radar Cross Section: 1 m²

Configuration: Bistatic

Transmitter Gain: 20 dB

Receiver Gain: 20 dB

Peak Transmit Power: 2.3 kW

SNR: 13.5883 dB

Detection Specifications for SNR

Probability of Detection: 0.95

Probability of False Alarm: 1e-06

Number of Pulses: 1

Swerling Case Number: 0

Geometric Mean Range: 10.33 km

### Required Transmit Power for a Bistatic Radar

This example shows how to compute the required peak transmit power of a 10 GHz, bistatic X-band radar for a 80 km total bistatic range, and 10 dB received SNR.

The system has a 40 dB transmitter gain and a 20 dB receiver gain. The required receiver SNR is 10 dB.

From the **Calculation Type** drop-down list, choose **Peak Transmit Power** as the solution type.

Choose **Configuration** as `bistatic`.

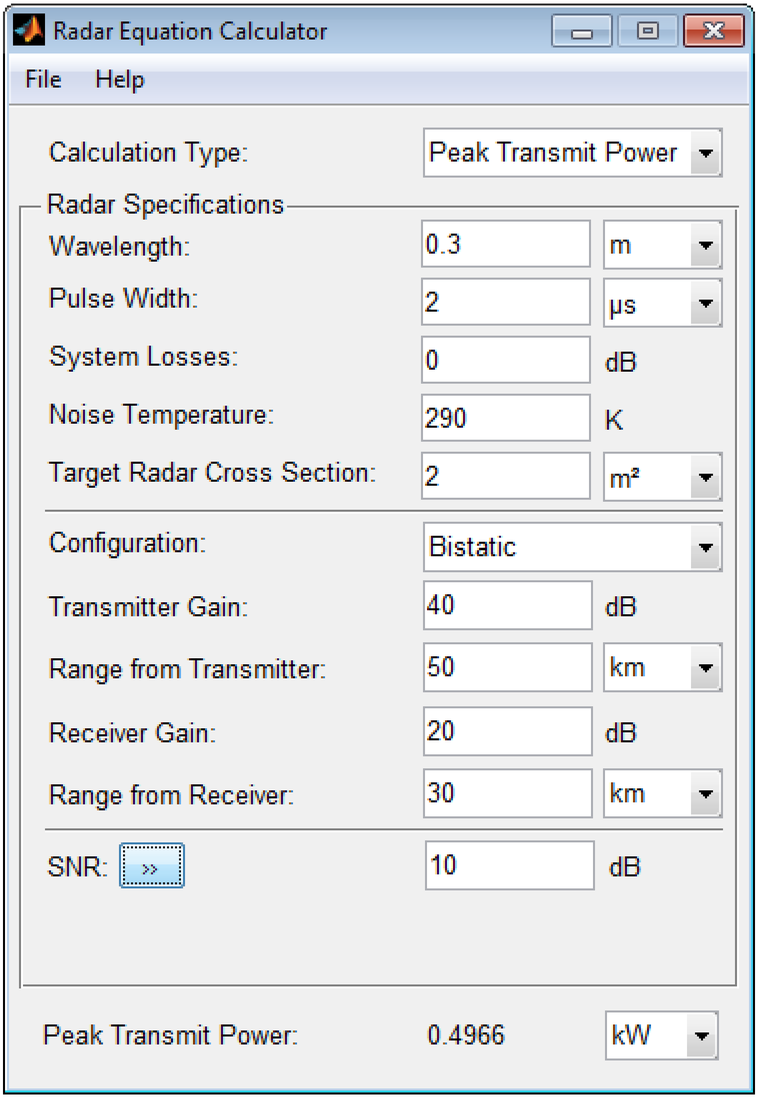
From the system specifications, set **Transmitter Gain** to 40 dB and **Receiver Gain** to 20 dB.

Set the **SNR** detection threshold to 10 dB and the **Wavelength** to 0.3 m.

Assume the target is a fighter aircraft having a **Target Radar Cross Section** value of 2 $m^2$.

Choose **Range from Transmitter** as 50 km, and **Range from Receiver** as 30 km.

Set the **Pulse Width** to 2 μs and the **System Losses** to 0 dB.



Calculation Type: Peak Transmit Power

Wavelength: 0.3 m

Pulse Width: 2 μs

System Losses: 0 dB

Noise Temperature: 290 K

Target Radar Cross Section: 2 m²

Configuration: Bistatic

Transmitter Gain: 40 dB

Range from Transmitter: 50 km

Receiver Gain: 20 dB

Range from Receiver: 30 km

SNR: 10 dB

Peak Transmit Power: 0.4966 kW

The required Peak Transmit Power is about 0.5 kW.

### Receiver SNR for a Monostatic Radar

This example shows how to compute the received SNR for a monostatic radar with 1 kW peak transmit power with a target at a range of 2 km.

Assume a 2 GHz radar frequency and 20 dB antenna gain.

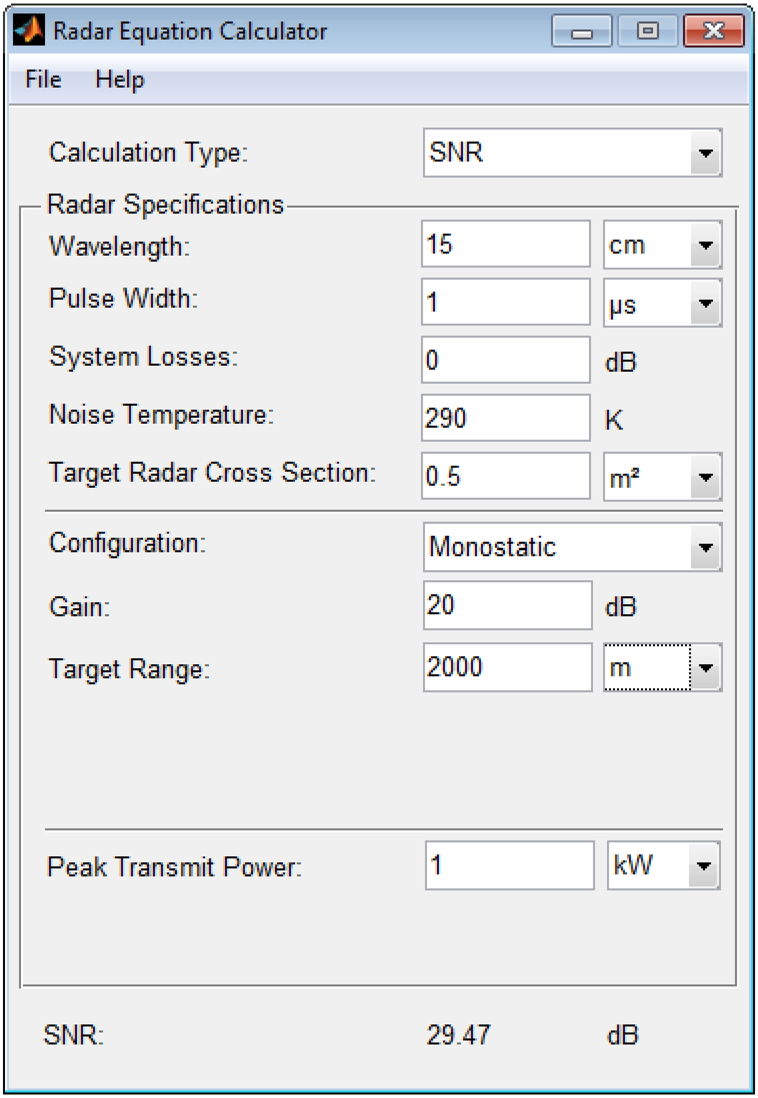
From the **Calculation Type** drop-down list, choose **SNR** as the solution type and set the **Configuration** as `monostatic`.

Set the **Gain** to 20, the **Peak Transmit Power** to 1 kW, and the **Target Range** to 2000 m.

Set the **Wavelength** to 15 cm.

Find the received SNR of a small boat having a **Target Radar Cross Section** value of 0.5 $m^2$.

The **Pulse Width** is 1 µs and **System Losses** are 0 dB.



Calculation Type: SNR

Wavelength: 15 cm

Pulse Width: 1 μs

System Losses: 0 dB

Noise Temperature: 290 K

Target Radar Cross Section: 0.5 m²

Configuration: Monostatic

Gain: 20 dB

Target Range: 2000 m

Peak Transmit Power: 1 kW

SNR: 29.47 dB

- "Detection, Range and Doppler Estimation"

## Parameters

### `Calculation Type` — Type of calculation to perform

`Target Range` (default) | `Peak Transmit Power` | `SNR`

`Target Range` – solves for maximum target range based on transmit power of the radar and desired received SNR.

`Peak Transmit – Power` computes power needed to transmit based on known target range and desired received SNR.

`SNR` – calculates the received SNR value based on known range and transmit power.

### `Wavelength` — Wavelength of radar operating frequency

0.3 m (default) | `m` | `cm` | `mm`

Specify the wavelength of radar operating frequency in `m`, `cm`, or `mm`.

The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light.

Denoting the speed of light by *c* and the frequency (in hertz) of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

### `Pulse Width` — Single pulse duration

1 µs (default) | `µs` | `ms` | `s`

Specify the single pulse duration in `µs`, `ms`, or `s`.

### `System Losses` — System loss in decibels (dB)

0 dB (default)

System Losses represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

### `Noise Temperature` — System noise temperature in kelvins

290 K (default)

The system noise temperature is the product of the system temperature and the noise figure.

### Target Radar Cross Section — Radar cross section (RCS)

1 m² (default) | m² | dBsm

Specify the target radar cross section in m², or dBsm.

The target radar cross section is nonfluctuating.

### Configuration — Type of radar system

Monostatic (default) | Bistatic

Monostatic – Transmitter and receiver are colocated (monostatic radar).

Bistatic – Transmitter and receiver are not colocated (bistatic radar).

### Gain — Transmitter and receiver gain in decibels (dB)

20 dB (default)

When the transmitter and receiver are colocated (monostatic radar), the transmit and receive gains are equal.

This parameter is enabled only if the **Configuration** is set to Monostatic.

### Peak Transmit Power — Transmitter peak power

1 kw (default) | kW | mW | W | dBW

Specify the transmitter peak power in kW, mW, W, or dBW.

This parameter is enabled only if the **Calculation Type** is set to Target Range or SNR.

### SNR — Minimum output signal-to-noise ratio at the receiver in decibels

10 dB (default)

Specify an SNR value, or calculate an SNR value using Detection Specifications for SNR.

You can calculate the SNR required to achieve a particular probability of detection and probability of false alarm using Shnidman's equation. To calculate the SNR value:

1. Click the arrows to the right of the **SNR** label to open the Detection Specifications for SNR menu.
2. Enter values for Probability of Detection, Probability of False Alarm, Number of Pulses, and Swerling Case Number.

This parameter is enabled only if the **Calculation Type** is set to `Target Range` or `Peak Transmit Power`.

### `Probability of Detection` — Detection probability used to estimate SNR

0.81029 (default)

Specify the detection probability used to estimate SNR using Shnidman's equation.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

### `Probability of False Alarm` — False alarm probability used to estimate SNR

0.001 (default)

Specify the false-alarm probability used to estimate SNR using Shnidman's equation.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

### `Number of Pulses` — Number of pulses used to estimate SNR

1 (default)

Specify a single pulse, or the number of pulses used for noncoherent integration in Shnidman's equation.

Use multiple pulses to reduce the transmitted power while maintaining the same maximum target range.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

### `Swerling Case Number` — Swerling case number used to estimate SNR

`0` (default) | `1` | `2` | `3` | `4`

Specify the Swerling case number used to estimate SNR using Shnidman's equation:

- **`0`** – Nonfluctuating pulses.
- **`1`** – Scan-to-scan decorrelation. Rayleigh/exponential PDF–A number of randomly distributed scatterers with no dominant scatterer.

- **2** – Pulse-to-pulse decorrelation. Rayleigh/exponential PDF– A number of randomly distributed scatterers with no dominant scatterer.
- **3** – Scan-to-scan decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant.
- **4** – Pulse-to-pulse decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant.

Swerling case numbers characterize the detection problem for fluctuating pulses in terms of:

- A decorrelation model for the received pulses.
- The distribution of scatterers affecting the probability density function (PDF) of the target radar cross section (RCS).

The Swerling case numbers consider all combinations of two decorrelation models (scan-to-scan; pulse-to-pulse) and two RCS PDFs (based on the presence or absence of a dominant scatterer).

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

### `Target Range` — Range to target

10 km (default) | `km` | `m` | `mi` | `nmi`

Specify target range in `m`, `km`, `mi`, or `nmi`.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `SNR`, and the **Configuration** is set to `Monostatic`.

### `Transmitter Gain` — Transmitter gain in decibels (dB)

20 dB (default)

When the transmitter and receiver are not colocated (bistatic radar), specify the transmitter gain separately from the receiver gain.

This parameter is enabled only if the **Configuration** is set to `Bistatic`.

### `Range from Transmitter` — Range from the transmitter to the target

10 km (default) | `km` | `m` | `mi` | `nmi`

When the transmitter and receiver are not colocated (bistatic radar), specify the transmitter range separately from the receiver range.

You can specify range in `m`, `km`, `mi`, or `nmi`.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `SNR`, and the **Configuration** is set to `Bistatic`.

**`Receiver Gain` — Receiver gain in decibels (dB)**
20 dB (default)

When the transmitter and receiver are not colocated (bistatic radar), specify the receiver gain separately from the transmitter gain.

This parameter is enabled only if the **Configuration** is set to `Bistatic`.

**`Range from Receiver` — Range from the target to the receiver**
10 km (default) | `km` | `m` | `mi` | `nmi`

When the transmitter and receiver are not colocated (bistatic radar), specify the receiver range separately from the transmitter range.

You can specify range in `m`, `km`, `mi`, or `nmi`.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `SNR`, and the **Configuration** is set to `Bistatic`.

# Radar Waveform Analyzer

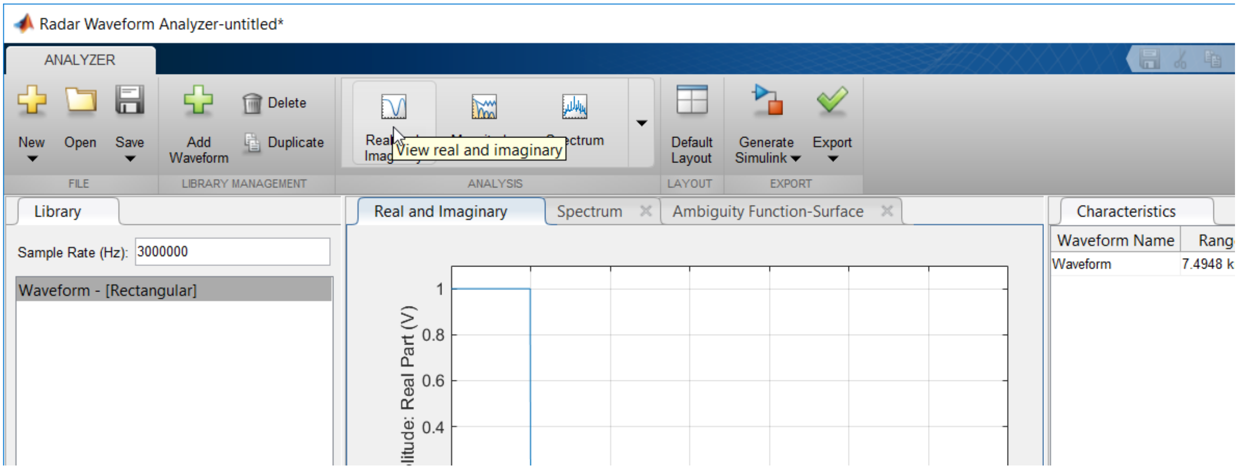
Analyze performance characteristics of pulsed, frequency-modulated, and phase-coded waveforms

## Description

The **Radar Waveform Analyzer** app lets you explore the properties of signals commonly used in radar. You can display 2-D plots and 3-D images that let you visualize waveform time series and spectra.

The app lets you change waveform parameters and see how different parameter values affect the appearance and properties of the waveform. Waveform parameters include pulse repetition frequency (PRF), pulse duration, and bandwidth. The app displays basic waveform characteristics such as range resolution, Doppler resolution, and maximum range. When you launch the app, the **Real and Imaginary** and **Spectrum** tabs are shown by default. You can simultaneously overlay plots of multiple waveforms.

You can select different types of displays using this pull-down menu.



Sample Rate (Hz): 3000000

Waveform - [Rectangular]

| Waveform Name | Rang |
|---|---|
| Waveform | 7.4948 k |

The app lets you analyze these types of waveforms:

- Rectangular

- Linear frequency modulation (LFM)
- Stepped FM
- Phase-coded waveforms
- Frequency modulation constant waveform (FMCW)

You can export waveforms as workspace variables or files containing:

- Phased Array System Toolbox waveform objects such as `phased.LinearFMWaveform`.
- Phased Array System Toolbox `phased.PulseWaveformLibrary` objects.

You can also create waveform blocks and Pulse Waveform Library blocks for use in Simulink.

You can also use this app for sonar applications by choosing the appropriate propagation speed.

## Open the Radar Waveform Analyzer App

- MATLAB toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, select the app icon, or
- MATLAB command prompt: Enter `radarWaveformAnalyzer`. For ways to use the app programmatically, see “Programmatic Use” on page 4-30.

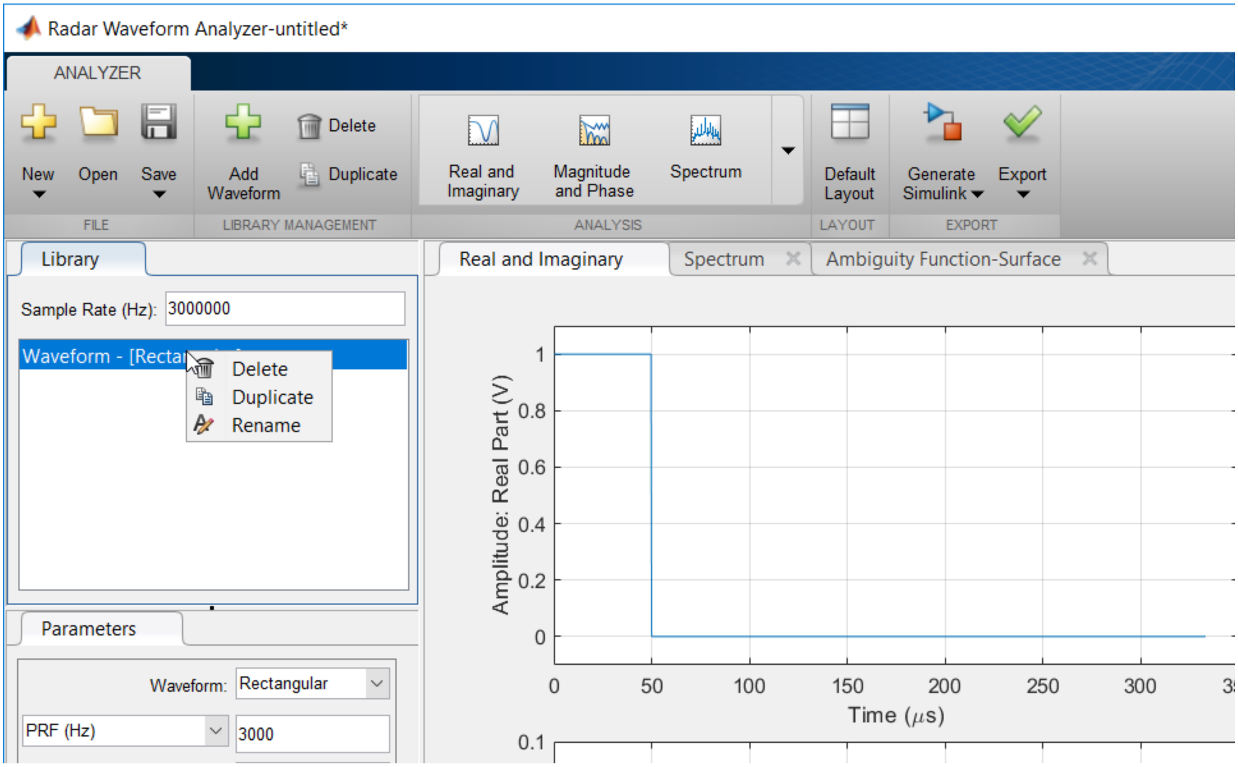
## Examples

### Rectangular Waveform

This example shows how to analyze a rectangular waveform. An ideal rectangular waveform jumps instantaneously to a constant value and stays there for some duration.

When you open the app, the **Library** tab shows the default rectangular waveform and the center panel displays the waveform shape or spectrum. First, set the **Sample Rate (Hz)** to 3 MHz. The same sample rate applies to all waveforms that you analyze.

You can rename the waveform by right-clicking its name. For example, change the name to `RectangularPulse`.



Sample Rate (Hz): 3000000

Waveform: Rectangular

PRF (Hz): 3000

Design the pulse for a maximum range of 50 km. For this range, the time for a signal to propagate and return is 333 µs. Therefore, allow 333 µsec between pulses, equivalent to a pulse repetition frequency (**PRF**) of 3000 Hz.

Set the **Pulse Width** to 50 µs.

Change the value of the speed of light in the **Propagation Speed** field to a more precise value by entering `physconst('Lightspeed')`. You can use workspace variables and MATLAB functions in any editable field.

After you select the green check mark, the app displays a range resolution of approximately 7.5 km in the **Characteristics** tab on the right hand panel. In this panel, you can scroll right to see other properties. The range resolution of a rectangular pulse is roughly 1/2 the pulse-width multiplied by the speed of light. The Doppler resolution is approximately the width of the Fourier transform of the pulse.

In the center panel of the window select the **Real and Imaginary** tab to plot the waveform.

Waveform - [Rectangular]

Waveform: Rectangular

PRF (Hz): 3000

Number of Pulses: 1

Pulse Width (s): 5e-05

Propagation Speed (m/s): 299792458

Frequency Offset (Hz): 0

| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| Waveform | 7.4948 km | 3 kHz |

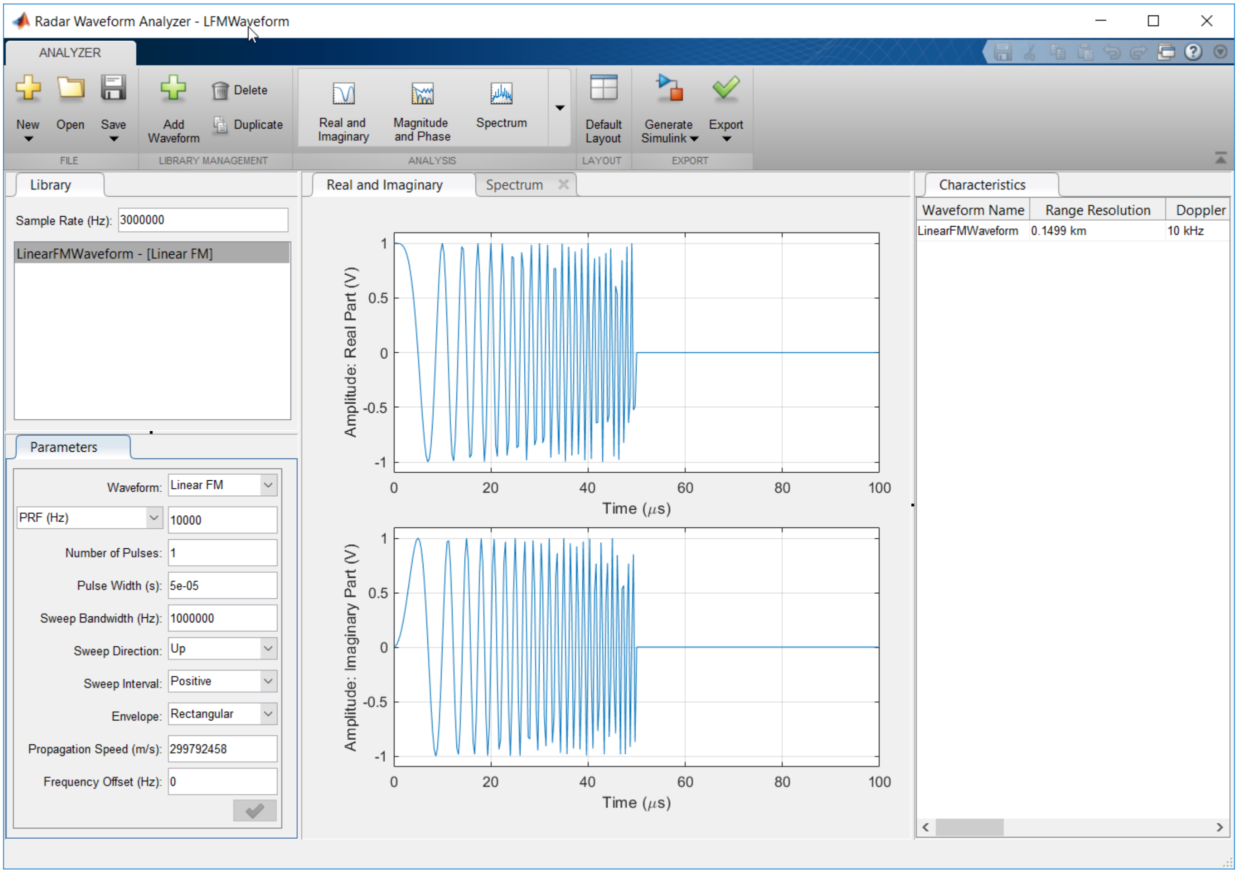
### Linear FM Waveform

This example shows how to improve range resolution using a linear FM waveform. In the previous example, the range resolution of the rectangular pulse was poor, approximately 7.5 km. You can improve the range resolution by choosing a signal with a larger bandwidth. A good choice is a linear FM pulse.

In the **Parameter** tab, change the **Waveform** to `Linear FM`. Then, for example, change the waveform name to `LinearFMWaveform`. This type of pulse has a varying frequency which can either increase or decrease as a linear function of time. Keep the sample rate at 3 MHz.

Choose the **Sweep Direction** as Up, and the **Sweep Bandwidth** as 1 MHz.

You can see that keeping the same pulse width as in the previous example, improves the range resolution to 150 m, as shown in the **Characteristics** tab.



Sample Rate (Hz): 3000000

LinearFMWaveform - [Linear FM]

Waveform: Linear FM

PRF (Hz): 10000

Number of Pulses: 1

Pulse Width (s): 5e-05

Sweep Bandwidth (Hz): 1000000

Sweep Direction: Up

Sweep Interval: Positive

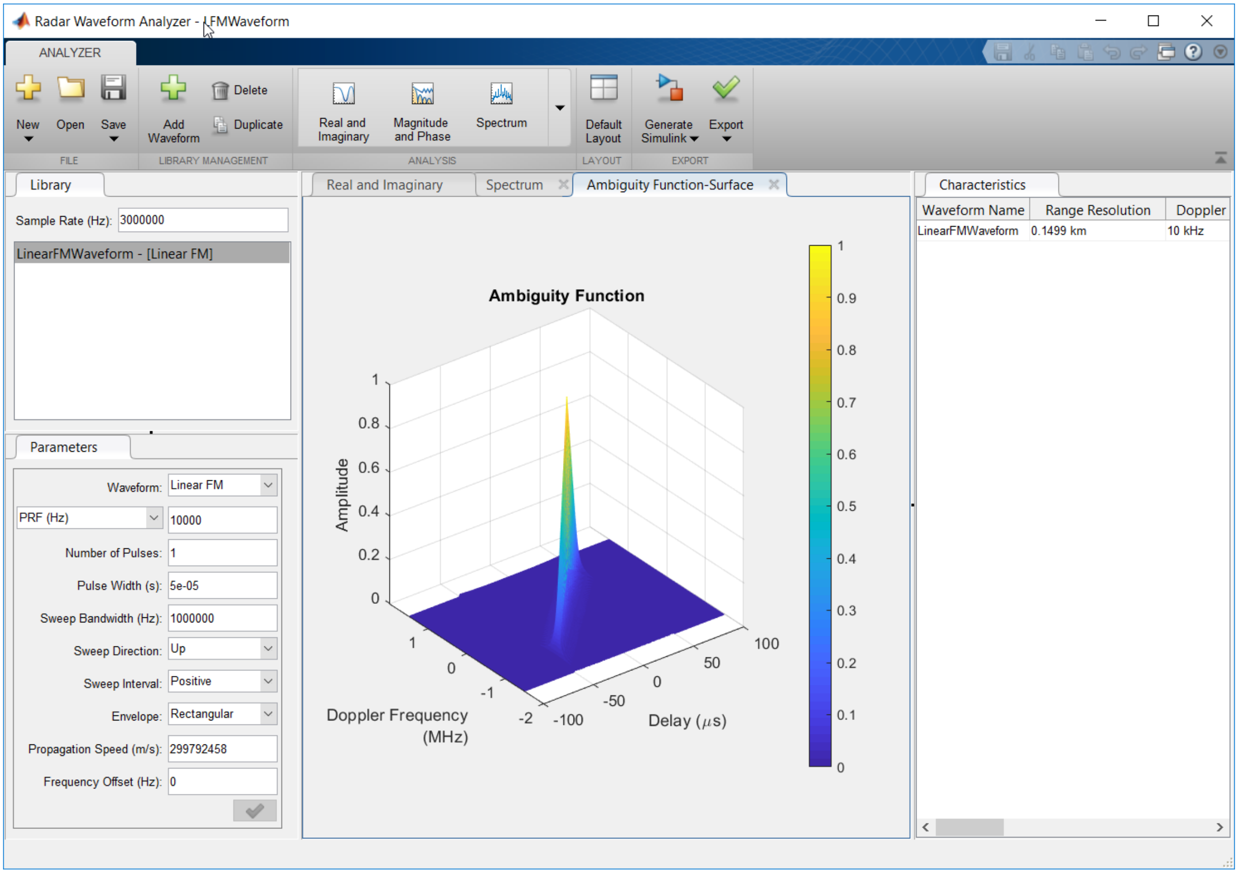
Envelope: Rectangular

Propagation Speed (m/s): 299792458

Frequency Offset (Hz): 0

| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| LinearFMWaveform | 0.1499 km | 10 kHz |

While the range resolution becomes better, the Doppler resolution is worse than the resolution of a rectangular waveform. You can see this by selecting the **Surface** ambiguity plot. The **Ambiguity Function-Surface** tab shows this tradeoff between Doppler resolution and range resolution.



Sample Rate (Hz): 3000000

LinearFMWaveform - [Linear FM]

Waveform: Linear FM

PRF (Hz): 10000

Number of Pulses: 1

Pulse Width (s): 5e-05

Sweep Bandwidth (Hz): 1000000

Sweep Direction: Up

Sweep Interval: Positive

Envelope: Rectangular

Propagation Speed (m/s): 299792458

Frequency Offset (Hz): 0

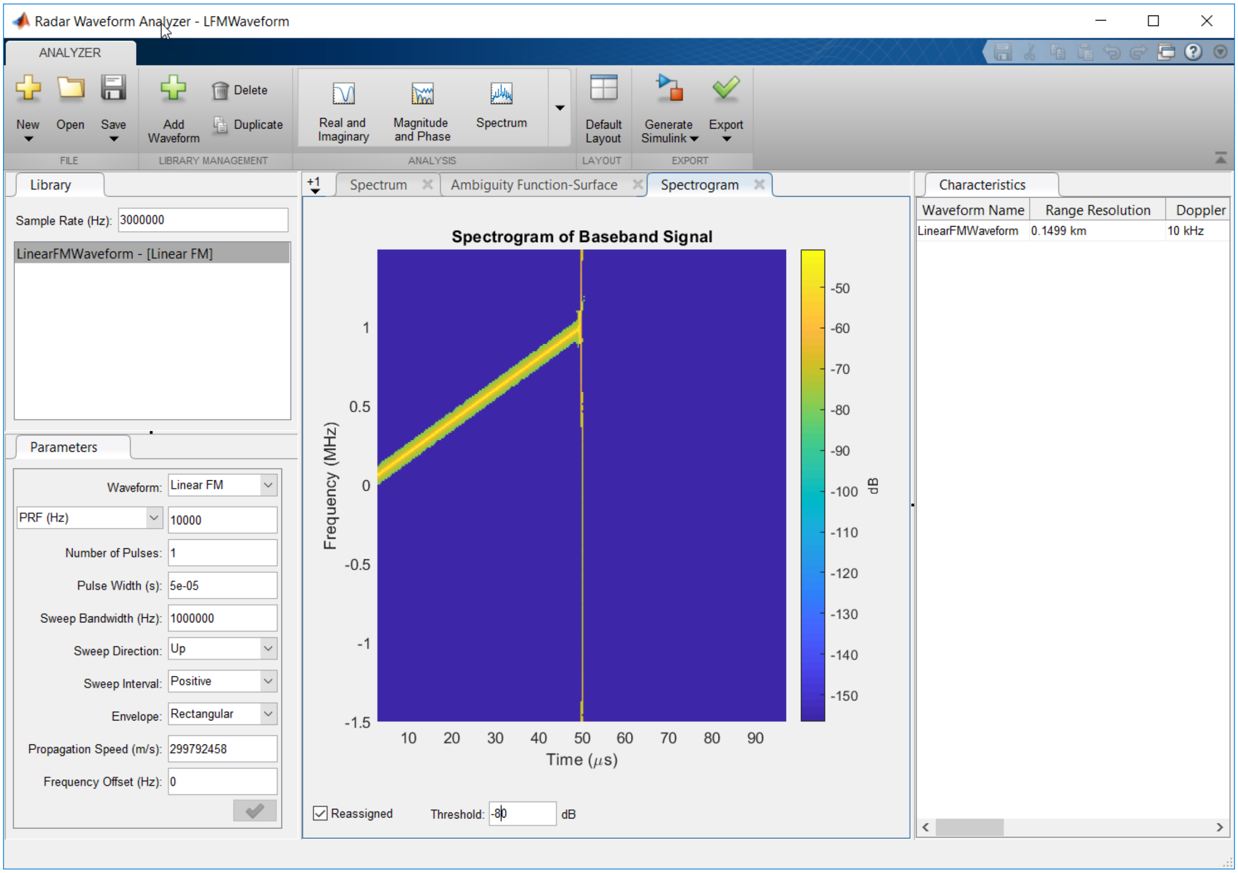
| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| LinearFMWaveform | 0.1499 km | 10 kHz |

### Linear FM Waveform Spectrogram

This example shows how to display the spectrogram of a linear FM waveform with and without frequency reassignment.

Use the same signal parameters as in the previous example.

Select **Spectrogram** from the **Signal Plots** drop-down menu. Then, select the **Reassigned** check box to show the frequency reassigned spectrogram (reassignment is turned on by default). Set the **Threshold** to -100 dB. Frequency reassignment is a technique for sharpening the magnitude spectrogram of a signal using information from its phase spectrum. For more information on frequency reassignment, see Fulop and Kelly (2006) [1].



Sample Rate (Hz): 3000000

LinearFMWaveform - [Linear FM]

Waveform: Linear FM

PRF (Hz): 10000

Number of Pulses: 1

Pulse Width (s): 5e-05

Sweep Bandwidth (Hz): 1000000

Sweep Direction: Up

Sweep Interval: Positive

Envelope: Rectangular

Propagation Speed (m/s): 299792458

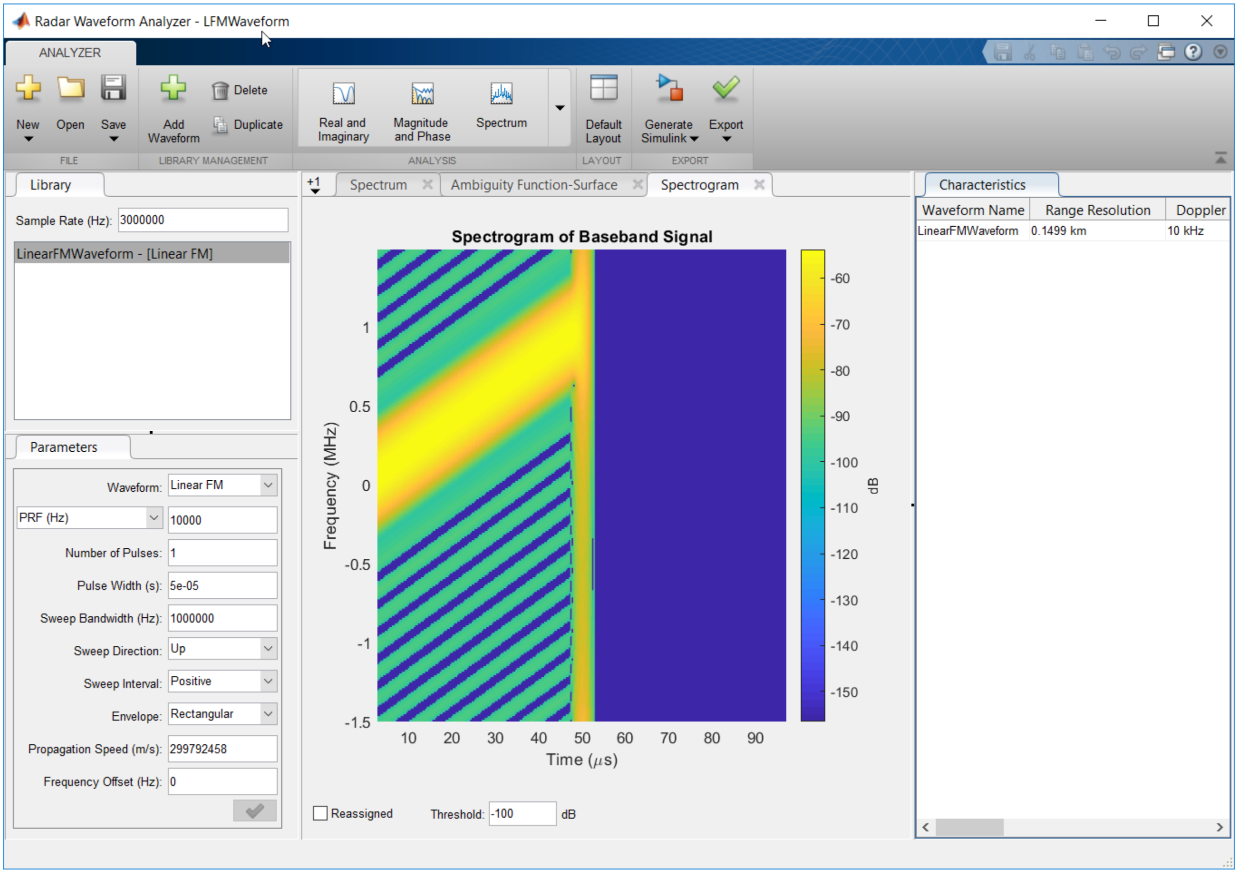
Frequency Offset (Hz): 0

☑ Reassigned    Threshold: -80 dB

| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| LinearFMWaveform | 0.1499 km | 10 kHz |

You can vary the **Threshold** setting to show or hide weaker spectrum components.

To view the conventional spectrogram, clear the **Reassigned** check box.



Radar Waveform Analyzer - LFMWaveform

Sample Rate (Hz): 3000000

LinearFMWaveform - [Linear FM]

Waveform: Linear FM
PRF (Hz): 10000
Number of Pulses: 1
Pulse Width (s): 5e-05
Sweep Bandwidth (Hz): 1000000
Sweep Direction: Up
Sweep Interval: Positive
Envelope: Rectangular
Propagation Speed (m/s): 299792458
Frequency Offset (Hz): 0

□ Reassigned Threshold: -100 dB

| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| LinearFMWaveform | 0.1499 km | 10 kHz |

Again, you can vary the **Threshold Value** setting to show or hide weaker spectrum components.

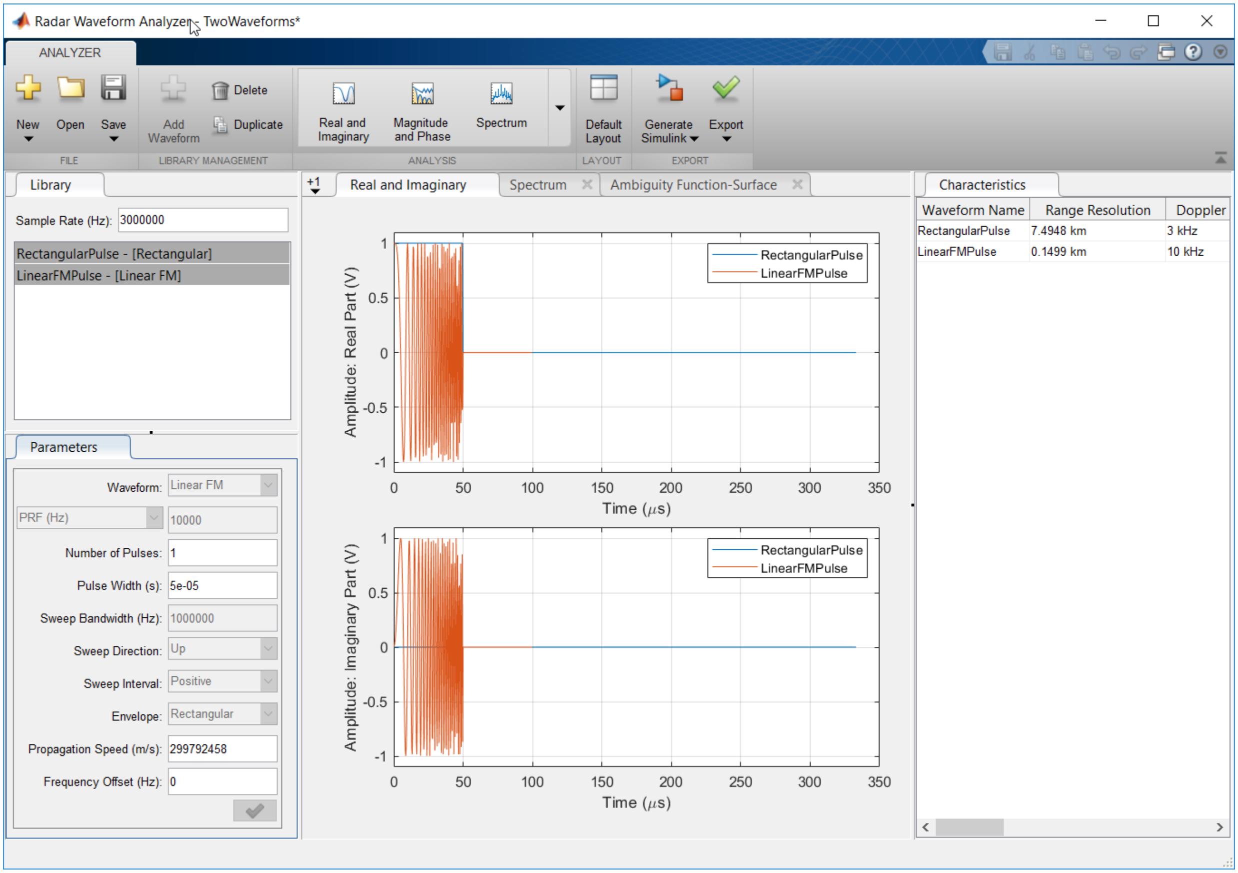
### Display and Analyze Two Signals

This example shows how to display the two signals simultaneously.

First, create a rectangular waveform having the same parameters as used in the first example. Then, rename the waveform to `RectangularPulse`.

Next, create an LFM waveform. Click the **Add Waveform** button. Rename the second waveform to `LinearFMPulse`. Set the waveform parameters to the same values as in the second example.

Select both waveforms in the **Library** panel. The displays now shows the waveforms, spectra, and characteristics for both waveforms.

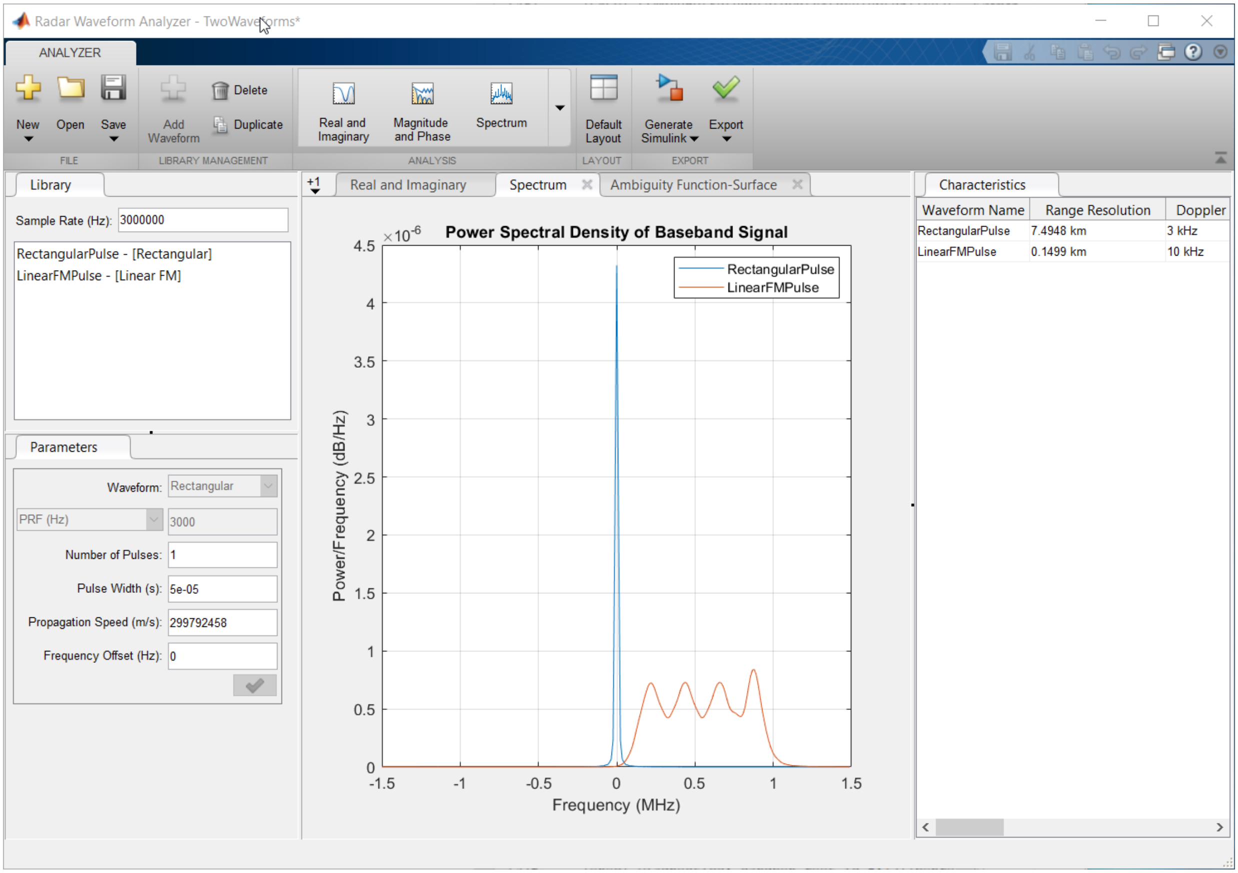


Sample Rate (Hz): 3000000

RectangularPulse - [Rectangular]
LinearFMPulse - [Linear FM]

Waveform: Linear FM
PRF (Hz): 10000
Number of Pulses: 1
Pulse Width (s): 5e-05
Sweep Bandwidth (Hz): 1000000
Sweep Direction: Up
Sweep Interval: Positive
Envelope: Rectangular
Propagation Speed (m/s): 299792458
Frequency Offset (Hz): 0

| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| RectangularPulse | 7.4948 km | 3 kHz |
| LinearFMPulse | 0.1499 km | 10 kHz |



Radar Waveform Analyzer - TwoWaveforms*

Sample Rate (Hz): 3000000

RectangularPulse - [Rectangular]
LinearFMPulse - [Linear FM]

Waveform: Rectangular
PRF (Hz): 3000
Number of Pulses: 1
Pulse Width (s): 5e-05
Propagation Speed (m/s): 299792458
Frequency Offset (Hz): 0

| Waveform Name | Range Resolution | Doppler |
|---|---|---|
| RectangularPulse | 7.4948 km | 3 kHz |
| LinearFMPulse | 0.1499 km | 10 kHz |

## Programmatic Use

You can run **radarWaveformAnalyzer** from the command line.

`radarWaveformAnalyzer(wav)` opens the **Radar Waveform Analyzer** app and imports and plots the waveform `wav`. `wav` can be a variable in the workspace representing a waveform object such as:

```
wav = phased.LinearFMWaveform('SampleRate',fs, ...
    'SweepBandwidth',200e3,...
    'PulseWidth',1e-3,'PRF',1e3);
radarWaveformAnalyzer(wav)
```

or you can enter the object directly:

```
radarWaveformAnalyzer(phased.LinearFMWaveform( ...
    'SampleRate',fs, ...
    'SweepBandwidth',200e3,...
    'PulseWidth',1e-3,'PRF',1e3))
```

`radarWaveformAnalyzer(wavlib)` opens the **Radar Waveform Analyzer** app and imports a `phased.PulseWaveformLibrary` object, `wavlib`. For example, construct the waveform library object from three waveforms with a common sample rate of 1 MHz. Then run from the command line:

```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth', 50e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',50e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'PhaseCoded','PRF',1e4,'Code','Zadoff-Chu', ...
    'SequenceIndex',3,'ChipWidth',5e-6,'NumChips',8};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
radarWaveformAnalyzer(wavlib)
```

# Sensor Array Analyzer

Analyze beam pattern of linear, planar, and conformal sensor arrays

## Description

The **Sensor Array Analyzer** app enables you to construct and analyze common sensor array configurations. These configurations range from 1-D to 3-D arrays of antennas and microphones.

After you specify array parameters, the app displays basic performance characteristics such as array directivity and array dimensions. You can then create various plots and images.

You can use this app to generate the directivity of the following arrays:

- Uniform Linear Array (ULA)
- Uniform Rectangular Array (URA)
- Uniform Circular Array
- Uniform Hexagonal Array
- Circular Plane Array
- Concentric Array
- Spherical Array
- Cylindrical Array
- Arbitrary Geometry

### Element Types

These elements are available to populate an array:

- Isotropic Antenna
- Cosine Antenna
- Omnidirectional Microphone
- Cardioid Microphone

- Custom Antenna
- Isotropic Hydrophone
- Isotropic Projector

### Plot Options

The **Sensor Array Analyzer** app can create the following plots:

- Array Geometry
- 2-D Array Pattern
- 3-D Array Pattern
- Grating Lobes

## Open the Sensor Array Analyzer App

- MATLAB toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `sensorArrayAnalyzer`.

## Examples

#### Uniform Linear Array

This example analyzes a 10-element uniform linear array (ULA) in a sonar application. The array consists of isotropic hydrophones. Design the array for a 10-kHz signal.

A uniform linear array has sensor elements that are equally spaced along a line.

Under the **Analyzer** tab, in the **Array** section of the toolstrip, select **ULA**. In the **Element** section of the toolstrip, select **Hydrophone**.

Select the Parameters tab and set the **Number of Elements** to 10. Set the **Element Spacing** to 0.5 wavelengths. Then click the **Apply** button. You can change many menu items and apply the changes at any time. The parameters that appear in this tab depend on your choice of array and element.

Design the array for a 10-kHz signal by setting **Signal Frequencies (Hz)** to `10000`.

When you choose a sonar element, the app automatically sets the signal propagation speed in water to `1500`. You can set the signal **Propagation Speed** to any value by setting the **Propagation Speed (m/s)**.

In the **Plots** section of the **Analyzer** tab, select **Array Geometry** button to draw the array. Clicking on the **Array Geometry** center panel in the display causes the **Array Geometry** tab to appear. In this tab, use the check boxes to display element normals (**Show Normals**), element indices (**Show Index**), and element tapers (**Show Tapers**).

| HPBW | 12.00° Az / 360.00° El |
| FNBW | 24.00° Az / -° El |
| SLL | 0.00 dB Az / - dB El |

In the rightmost **Array Characteristics** panel, you can view the array directivity, half-power beam width (HPBW), first-null beam-width (FNBW), and side lobe level (SLL).

To display a directivity plot, go to the **Plots** section of the **Analyzer** tab. Select Azimuth Pattern from the 2-D Pattern menu. The azimuth directivity pattern is now displayed in the center panel of the app. Select the Azimuth Pattern tab, and set the Coordinate to line.

| FNBW | 24.00° Az / -° El |
| SLL | 0.00 dB Az / - dB El |

You can see the main lobe of the array directivity function (also called the main beam) at 0° and another main lobe at ±180°. Two main lobes appear because of the cylindrical symmetry of the ULA array.

A beam scanner works by successively pointing the array main lobe in different directions. In the Steering Angle section of the toolstrip, changing the **Steering Angles (deg)** values to `[30;0]` steers the main lobe to 30° in azimuth and 0° elevation. The next figure shows two main lobes, one at 30° as expected, and another at 150°. Two main lobes appear because of the cylindrical symmetry of the array.

One disadvantage of a ULA is its large side lobes. An examination of the array directivity shows two side lobes close to each main lobe, each down by about only 13 dB. A strong side lobe inhibits the ability of the array to detect a weaker signal in the presence of a larger nearby signal. By using array tapering, you can reduce the side lobes.

Use the **Taper** option to specify the array taper as a `Taylor` window with **Sidelobe Attenuation** set to `30` dB and **nbar** set to `4`. The next figure shows how the Taylor window reduces all side lobes to –30 dB—but at the expense of broadening the main lobe.

### Uniform Rectangular Array

This example shows how to construct a 6-by-6 uniform rectangular array (URA) designed to detect and localize a 100-MHz signal.

Under the **Analyzer** tab, in the **Array** section of the toolstrip, select **URA**. In the **Element** section of the toolstrip, select **Isotropic**.

Design the array for a 100-MHz signal by setting **Signal Frequencies** to `100e+6` and the row and column **Element Spacing** to 0.5 wavelength.

Select the Parameters tab and set the **Number of Elements** to [6,6]. Set the **Element Spacing** to 0.5 wavelengths. Then click the **Apply** button. You can change many menu items and apply the changes at any time. The parameters that appear in this tab depend on your choice of array and element.

From the **Row and Column** pull-down menu, choose `Row and Column`. Set **Row Taper** and **Column Taper** to a `Taylor` window using default taper parameters.

The shape of the array is shown in this figure.

□ Back Baffled

| | @ 100 MHz |
|---|---|
| Array Directivity | 16.03 dBi at 0 Az; 0 El |
| Array Span | x=0 m y=7.49 m z=7.49 m |
| Number of Elements | 36 |
| HPBW | 22.00° Az / 22.00° El |
| FNBW | 60.00° Az / 60.00° El |
| SLL | 0.00 dB Az / 0.00 dB El |

A significant performance measure for any array is directivity. You can use the app to examine the effects of tapering on array directivity. Without tapering, the array directivity for this URA is 17.2 dB. With tapering, the array directivity loses 1 dB to yield 16.0 dB.

## Grating Lobes for a Rectangular Array

This example shows the grating lobe diagram of a 4-by-4 uniform rectangular array (URA) designed to detect and localize a 300-MHz signal.

Under the **Analyzer** tab, in the **Array** section of the toolstrip, select **URA**. In the **Element** section of the toolstrip, select **Isotropic**. Set the **Size** to `[4,4]`. Steer the array to `[20;0]`.

Design the array for a 300-MHz signal by setting **Signal Frequencies** to `300e+6` and the row and column **Element Spacing** to 0.7 wavelength.

By setting the row and column **Element Spacing** to 0.7 wavelengths, you create a spatially under sampled array.

This figure shows the grating lobe diagram produced when you beamform the array towards the angle [20,0]. The main lobe is designated by the small black-filled circle. The multiple grating lobes are designated by the small unfilled black circles. The larger black circle is called the physical region, for which $u^2 + v^2 \leq 1$. The main lobe always lies in the physical region. The grating lobes can sometimes lie outside the physical region. Any grating lobe in the physical region leads to an ambiguity in the direction of the incoming wave. The green region shows where the main lobe can be pointed without any grating lobes appearing in the physical region. If the main lobe is set to point outside the green region, a grating lobe can move into the physical region.

## Specify Arbitrary Array Geometry

This example shows how to construct a triangular array of three isotropic antenna elements.

You can specify an array which has an arbitrary placement of sensors. In this example, the elements are placed at (0,0,0), (0,1,0), and (0,0.5,0.866). All elements have the same normal direction (0,20), pointing to 0° azimuth and 20° elevation.

## Specify Arbitrary Array Geometry Using Variables

This example illustrates an array with arbitrary geometry specified by MATLAB variables set at the command line. Use them in the appropriate `sensorArrayAnalyzer` fields.

At the MATLAB command line, create an element position array, `pos`, an element normal array, `nrm`, and a taper value array, `tpr`.

```
pos = [0,0,0;0,1,0.5;0,0,0.866];
nrm = [0,0,0;20,20,20];
tpr = [1,1,1];
```

Enter these variables in the appropriate `sensorArrayAnalyzer` fields.

# Sonar Equation Calculator

Estimate maximum range, SNR, transmission loss and source level of a sonar system

## Description

The **Sonar Equation Calculator** app solves the basic sonar equation for monostatic sonar systems. The sonar equation relates transmission loss (or target range), source level, directivity, noise level, target strength, and signal SNR. You can solve for one of these quantities in terms of the others. Using this app, you can:

- Calculate the received SNR value from transmission loss (or equivalently, target range), source level, and noise level.
- Solve for transmission loss from sonar source level of the sonar, specified received SNR, and array directivity.
- Solve for target range from sonar source level of the sonar, specified received SNR, and array directivity.
- Calculate required source level from target range, source level, and received SNR.

## Open the Sonar Equation Calculator App

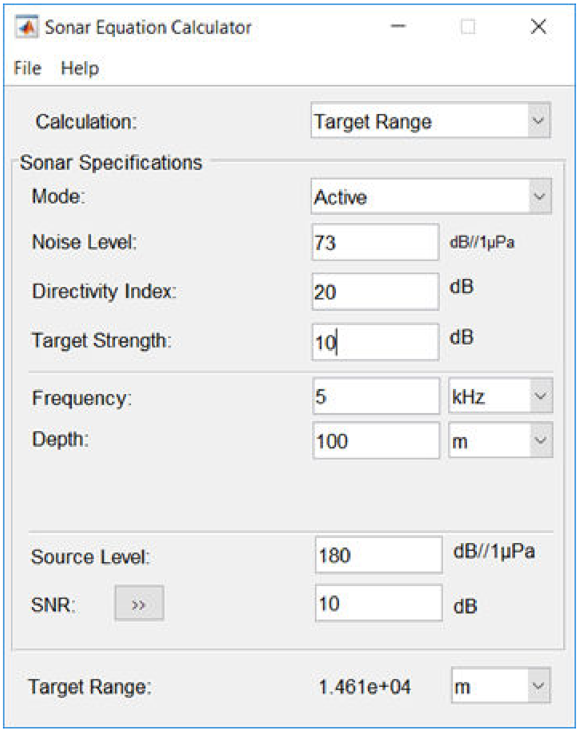
- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command line: Enter `sonarEquationCalculator`.

## Examples

### Maximum Detection Range of Active Sonar

Compute the maximum detection range of an active monostatic sonar designed to achieve an SNR of at least 10 dB. The operating frequency is 5 kHz, and the source level is 180 dB. Assume that the noise level is 73 dB, the receiver directivity is 20 dB, and the target strength is 10 dB.

- Set **Calculation** to Target Range.
- Set **Mode** to Active.
- Set **Noise Level** to 73 dB//1µPa.
- Set receiver **Directivity index** to 20 dB.
- Set **Target Strength** to 10 dB.
- Set **Frequency** to 5 kHz.
- Set channel **Depth** to 100 m.
- Set **Source Level** to 180 dB//1µPa.
- Set required **SNR** to 10 dB.



Calculation: Target Range

Mode: Active

Noise Level: 73 dB//1µPa

Directivity Index: 20 dB

Target Strength: 10 dB

Frequency: 5 kHz

Depth: 100 m

Source Level: 180 dB//1µPa

SNR: 10 dB

Target Range: 1.461e+04 m

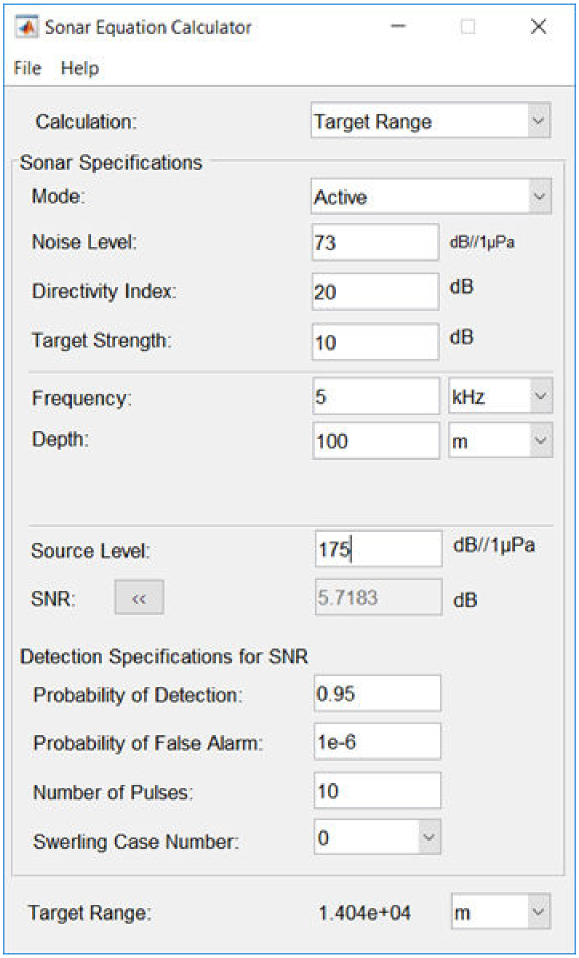
The maximum target range is 14.61 km.

## Maximum Detection Range for Multiple Pulses

Use multiple pulses to reduce the source level while maintaining the same maximum target range.

Start with the values set in the “Maximum Detection Range of Active Sonar” on page 4-46 example.

- Click the arrows to the right of the **SNR** label to access the **Detection Specifications for SNR** options.
- Set **Probability of Detection** to `0.95`.
- Set **Probability of False Alarm** to `1e-6`.
- Set **Number of Pulses** to `10`.
- Reduce **Source Level** to `175`.
- Set the **Swerling Case Number** to `0` assuming a nonfluctuating target.



Calculation: Target Range

Sonar Specifications

Mode: Active

Noise Level: 73 dB//1μPa

Directivity Index: 20 dB

Target Strength: 10 dB

Frequency: 5 kHz

Depth: 100 m

Source Level: 175 dB//1μPa

SNR: 5.7183 dB

Detection Specifications for SNR

Probability of Detection: 0.95

Probability of False Alarm: 1e-6

Number of Pulses: 10

Swerling Case Number: 0

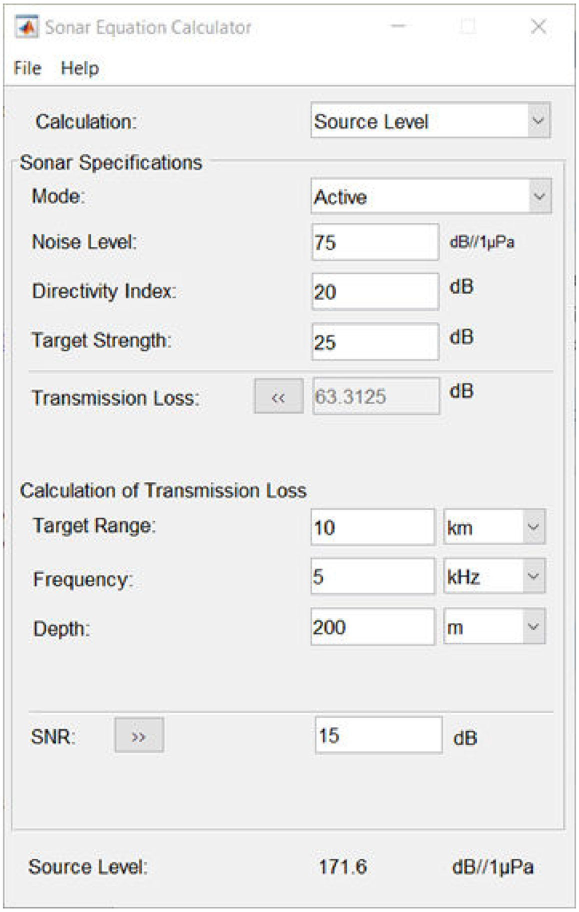
Target Range: 1.404e+04 m

The maximum detection range is 14.81 km, approximately the same as in the previous example, but the source level is reduced by 5 dB.

## Required Source Level for Monostatic Sonar

Compute the source level for an active monostatic sonar with a received SNR of 15 dB. The target range is 5 km and the target strength is 25 dB. Assume a 5-kHz sonar frequency.

- Set **Calculation** to `Source Level`.
- Set **Mode** to `Active`.
- Set **Noise Level** to `75`.
- Set receiver **Directivity index** to `20` dB.
- Set **Target Strength** to `25`.
- Click the arrows to the right of the **Transmission Loss** label to access the **Calculation of Transmission Loss** options.
- Set the **Range** to `10.0` km.
- Set the **Frequency** to `5` kHz.
- Set the **Depth** to `200` m.
- Set **SNR** to `15` dB.



Calculation: Source Level

Sonar Specifications

Mode: Active

Noise Level: 75 dB//1µPa

Directivity Index: 20 dB

Target Strength: 25 dB

Transmission Loss: 63.3125 dB

Calculation of Transmission Loss

Target Range: 10 km

Frequency: 5 kHz

Depth: 200 m

SNR: 15 dB

Source Level: 171.6 dB//1µPa

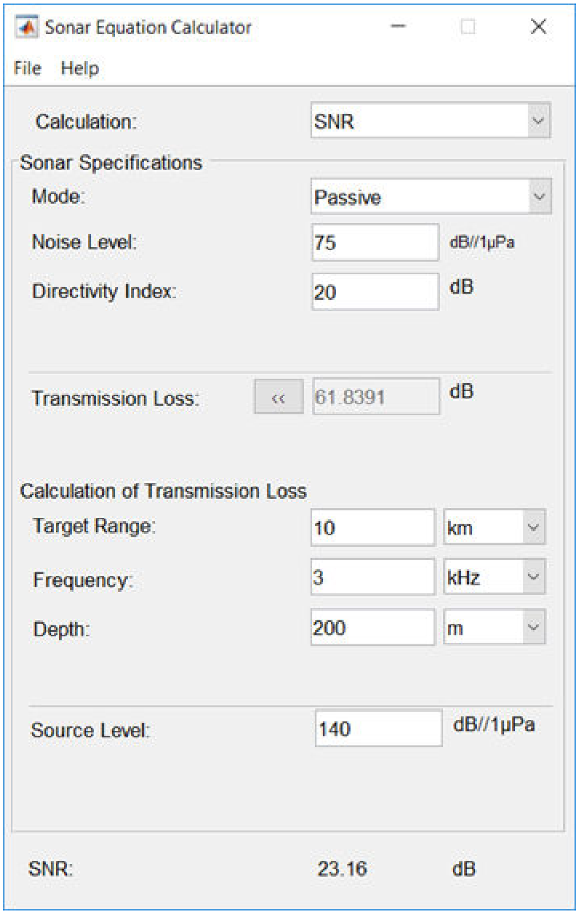
The required source level is 171.6 dB//1 µPa.

## Received SNR for Monostatic Sonar

Compute the received SNR for a passive sonar with a source level of 140 db//1 µPa for a source 10.0 km away. Assume a 3-kHz sonar frequency.

- Set **Calculation** to SNR.
- Set **Mode** to `Passive`.

- Set **Noise Level** to 75.
- Set receiver **Directivity index** to 20 dB.
- Click the arrows to the right of the **Transmission Loss** label to access the **Calculation of Transmission Loss** options.
- Set **Range** to 10.0 km.
- Set **Frequency** to 3 kHz.
- Set **Depth** to 200 m.
- Set **Source Level** to 140 dB//1 µPa.



Calculation: SNR

Sonar Specifications

Mode: Passive

Noise Level: 75 dB//1µPa

Directivity Index: 20 dB

Transmission Loss: 61.8391 dB

Calculation of Transmission Loss

Target Range: 10 km

Frequency: 3 kHz

Depth: 200 m

Source Level: 140 dB//1µPa

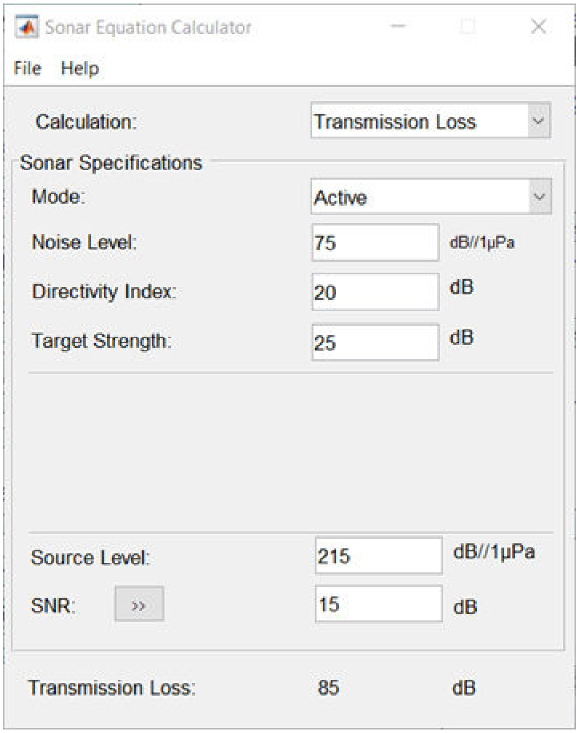
SNR: 23.16 dB

The received SNR is 23.16 dB.

## Transmission Loss of Monostatic Active Sonar

Compute the transmission loss for an active sonar that results in an SNR of 15 dB. The source level is 215 dB//1 µPa. Assume that the noise level is 75 dB//1 µPa, the receiver directivity is 20 dB, and the target strength is 10 dB.

- Set **Calculation** to `Transmission Loss`.
- Set **Mode** to `Active`.
- Set **Noise Level** to `75` dB.
- Set receiver **Directivity index** to `20` dB.
- Set **Target Strength** to `25` dB.
- Set **Source Level** to `215` dB.
- Set required **SNR** to `15` dB.



Calculation: Transmission Loss

Mode: Active

Noise Level: 75 dB//1µPa

Directivity Index: 20 dB

Target Strength: 25 dB

Source Level: 215 dB//1µPa

SNR: 15 dB

Transmission Loss: 85 dB

The transmission loss is 85 dB.

## Parameters

### `Calculation` — Select type of calculation

`Target Range` (default) | `Transmission Loss` | `Source Level` | `SNR`

Select the type of calculation:

- `Target Range` -— solves for the maximum target range based on source level of the sonar and required received SNR.
- `Transmission Loss` -— computes the required transmit power from known target range and required received SNR.
- `Source Level` -— computes the source level from the range or transmission loss, and received SNR.
- `SNR` -— calculates the received SNR value based on known range and transmit power.

### `Mode` — Type of sonar

`Active` (default) | `Passive`

Specify whether the sonar is operating in active mode or passive mode. Active mode means that a signal is transmitted from a source, reflects off a target, and returns to the receiver which is collocated with the source. Active mode requires the specification of the reflector target strength. Passive mode means that the signal is transmitted from a source to a receiver along a direct path.

### `Noise Level` — Noise Level

`70` (default) | scalar

Noise level at sonar receiver, specified as a scalar. Units are dB//1μP.

### `Directivity Index` — Directivity index of receive array or element

`20` (default) | scalar

Directivity index of receive array or element, specified as a scalar. Units are dB.

### `Target Strength` — Target strength of reflector

`25` (default) | scalar

Target strength of reflector, specified as a scalar. Units are dB//1m$^2$.

#### Dependencies

To enable this parameter, set the **Mode** parameter to `Active`.

### `Frequency` — Sound frequency

`2` (default) | positive scalar

Sound frequency, specified as a positive scalar. Default units are in kHz. You can also select `Hz`, `kHz`, or `MHz`.

### `Depth` — Water channel depth

`10000` (default) | positive scalar

Water channel depth. Default units are meters. You can select units in `m`, `km`, `mi`, or `nmi`.

### `Source Level` — Source level of sonar transmitter

`220` (default) | scalar

Source level of sonar transmitter, specified as a scalar. Units are dB//1 μP.

### `SNR` — Output signal-to-noise ratio at receiver

`10` (default)

Specify an SNR value, or calculate an SNR value using the **Detection Specifications for SNR** options. You can calculate the SNR required to achieve a particular probability of detection and probability of false alarm using the Shnidman equation. To calculate the SNR value:

1. Click the arrows to the right of the **SNR** label to access the **Detection Specifications for SNR** options.
2. Enter values for **Probability of Detection**, **Probability of False Alarm**, **Number of Pulses**, and **Swerling Case Number**.

#### Dependencies

To enable this parameter, set **Calculation** to `Target Range`, `Transmission Loss`, or `Source Level`.

### `Probability of Detection` — Detection probability used to estimate SNR

`0.81029` (default)

Specify the detection probability used to estimate SNR using the Shnidman equation.

#### Dependencies

To enable this parameter, set **Calculation** to `Target Range`, `Transmission Loss`, or `Source Level`, and select the Detection Specifications for SNR options for the **SNR** parameter.

### `Probability of False Alarm` — False alarm probability used to estimate SNR

`0.001` (default)

Specify the false alarm probability used to estimate SNR using the Shnidman equation.

#### Dependencies

To enable this parameter, set **Calculation** to `Target Range`, `Transmission Loss`, or `Source Level`, and access the **Detection Specifications for SNR** options for the **SNR** parameter.

### `Number of Pulses` — Number of pulses used to estimate SNR

`1` (default)

Specify the number of pulses. You can specify multiple pulses for noncoherent integration in the Shnidman equation.

#### Dependencies

To enable this parameter, set **Calculation** to `Target Range`, `Transmission Loss`, or `Source Level`, and select the **Detection Specifications for SNR** options for the **SNR** parameter.

### `Swerling Case Number` — Swerling case number used estimate SNR

`0` (default) | `1` | `2` | `3` | `4`

Specify the Swerling case number used to estimate SNR using the Shnidman equation. Swerling numbers characterize the detection problem for fluctuating pulses in terms of:

- a decorrelation model for the received pulses.
- the distribution of scatterers affecting the probability density function (pdf) of the target radar cross section (RCS).

The Swerling cases include two decorrelation models (scan-to-scan or pulse-to-pulse) and two radar cross section pdfs (based on the presence or absence of a dominant scatterer):

- **`0`** – Nonfluctuating pulses.

- **1** – Scan-to-scan decorrelation: Several randomly distributed scatterers with no dominant scatterer described by a Rayleigh/exponential PDF.
- **2** – Pulse-to-pulse decorrelation: Several randomly distributed scatterers with no dominant scatterer described by a Rayleigh/exponential PDF.
- **3** – Scan-to-scan decorrelation: Several scatterers with one dominant scatterer described by a chi-square PDF with 4 degrees of freedom.
- **4** – Pulse-to-pulse decorrelation: Several scatterers with one dominant scatterer described by a chi-square PDF with 4 degrees of freedom.

#### Dependencies

To enable this parameter, set **Calculation** to `Target Range`, `Transmission Loss`, or `Source Level`, and select the **Detection Specifications for SNR** options for the **SNR** parameter.

### `Transmission Loss` — Transmission loss in channel

`78.0614` (default) | scalar

Transmission loss in channel, specified as a scalar. Units are dB. For passive sonar modeling, specify a one-way transmission loss. For active sonar modeling, specify a two-way transmission loss. You can specify a transmission loss value, or calculate transmission loss using the **Calculation of Transmission Loss** options.

To calculate transmission loss:

1. Click the arrows to the right of the **Transmission Loss** label to access the **Calculation of Transmission Loss** menu.
2. Enter values for **Target Range**, **Frequency**, and **Depth**.

#### Dependencies

To enable this parameter, set **Calculation** to `Source Level` or `SNR`.

### `Target Range` — Target range

`10000` (default) | positive scalar

Target range, specified as a positive scalar. When **Mode** is `Passive`, target range is from source to receiver. When **Mode** is `Active`, target range is from source to reflecting target. Default units are in meters. You can also select `km`, `mi`, or `nmi`.

**Dependencies**

To enable this parameter, set the **Calculation** parameter to `Source Level` or `SNR` and click the arrow next to **Calculation of Transmission Loss**.

### `Frequency` — Signal frequency

`2` (default) | positive scalar

Signal frequency, specified as a positive scalar. Default units are in kHz. You can also select `Hz`, `kHz`, and `MHz`.

**Dependencies**

To enable this parameter, set **Calculation** to `Source Level` or `SNR` and click the arrow next to **Calculation of Transmission Loss**.

### `Depth` — Channel depth

`10000` (default) | positive scalar

Channel depth, specified as a positive scalar. Default units are in meters. You can also select `km`, `mi`, and `nmi`.

**Dependencies**

To enable this parameter, set the **Calculation** parameter to `Source Level` or `SNR` and click the arrow next to **Calculation of Transmission Loss**.
