# Alphabetical List

# phased.ADPCACanceller

**Package:** phased

Adaptive DPCA (ADPCA) pulse canceller

## Description

The ADPCACanceller object implements an adaptive displaced phase center array pulse canceller for a uniform linear array (ULA).

To compute the output signal of the space time pulse canceller:

1. Define and set up your ADPCA pulse canceller. See "Construction" on page 1-2.
2. Call step to execute the ADPCA algorithm according to the properties of phased.ADPCACanceller. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object™, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.ADPCACanceller creates an adaptive displaced phase center array (ADPCA) canceller System object, H. This object performs two-pulse ADPCA processing on the input data.

H = phased.ADPCACanceller(Name,Value) creates an ADPCA object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN). See "Properties" on page 1-3 for the list of available property names.

## Properties

### `SensorArray`

Uniform linear array

Uniform linear array, specified as a `phased.ULA` System object.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `PRFSource`

Source of pulse repetition frequency

Source of the PRF values for the STAP processor, specified as `'Property'` or `'Input port'`. When you set this property to `'Property''`, the PRF is determined by the value of the `PRF` property. When you set this property to `'Input port'`, the PRF is determined by an input argument to the `step` method at execution time.

**Default:** `'Property'`

### `PRF`

Pulse repetition frequency

Pulse repetition frequency (PRF) of the received signal, specified as a positive scalar. Units are in Hertz. This property can be specified as single or double precision.

**Dependencies**

To enable this property, set the `PRFSource` property to `'Property'`.

**Default:** `1`

### `DirectionSource`

Source of receiving main lobe direction

Specify whether the targeting direction for the STAP processor comes from the `Direction` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Direction` property of this object specifies the targeting direction. |
| `'Input port'` | An input argument in each invocation of `step` specifies the targeting direction. |

**Default:** `'Property'`

### `Direction`

Receiving mainlobe direction (degrees)

Specify the receiving mainlobe direction of the receiving sensor array as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). Azimuth angle should be between –180 and 180. Elevation angle should be between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`. This property can be specified as single or double precision.

**Default:** `[0; 0]`

### `NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed. You can specify this property as single or double precision.

**Default:** `0`

### `DopplerSource`

Source of targeting Doppler

Specify whether the targeting Doppler for the STAP processor comes from the `Doppler` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Doppler` property of this object specifies the Doppler. |
| `'Input port'` | An input argument in each invocation of `step` specifies the Doppler. |

**Default:** `'Property'`

### `Doppler`

Targeting Doppler frequency (Hz)

Specify the targeting Doppler of the STAP processor as a scalar. This property applies when you set the `DopplerSource` property to `'Property'`. This property can be specified as single or double precision.

**Default:** `0`

### `WeightsOutputPort`

Output processing weights

To obtain the weights used in the STAP processor, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the weights, set this property to `false`.

**Default:** `false`

### `PreDopplerOutput`

Output pre-Doppler result

Set this property to `true` to output the processing result before applying the Doppler filtering. Set this property to `false` to output the processing result after the Doppler filtering.

**Default:** `false`

**`NumGuardCells`**

Number of guard cells

Specify the number of guard cells used in the training as an even integer. This property specifies the total number of cells on both sides of the cell under test. This property can be specified as single or double precision.

**Default:** `2`, indicating that there is one guard cell at both the front and back of the cell under test

**`NumTrainingCells`**

Number of training cells

Specify the number of training cells used in the training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test. This property can be specified as single or double precision.

**Default:** `2`, indicating that there is one training cell at both the front and back of the cell under test

## Methods

| | |
|---|---|
| step | Perform ADPCA processing on input data |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Process Radar Data Cube Using ADPCA Processor

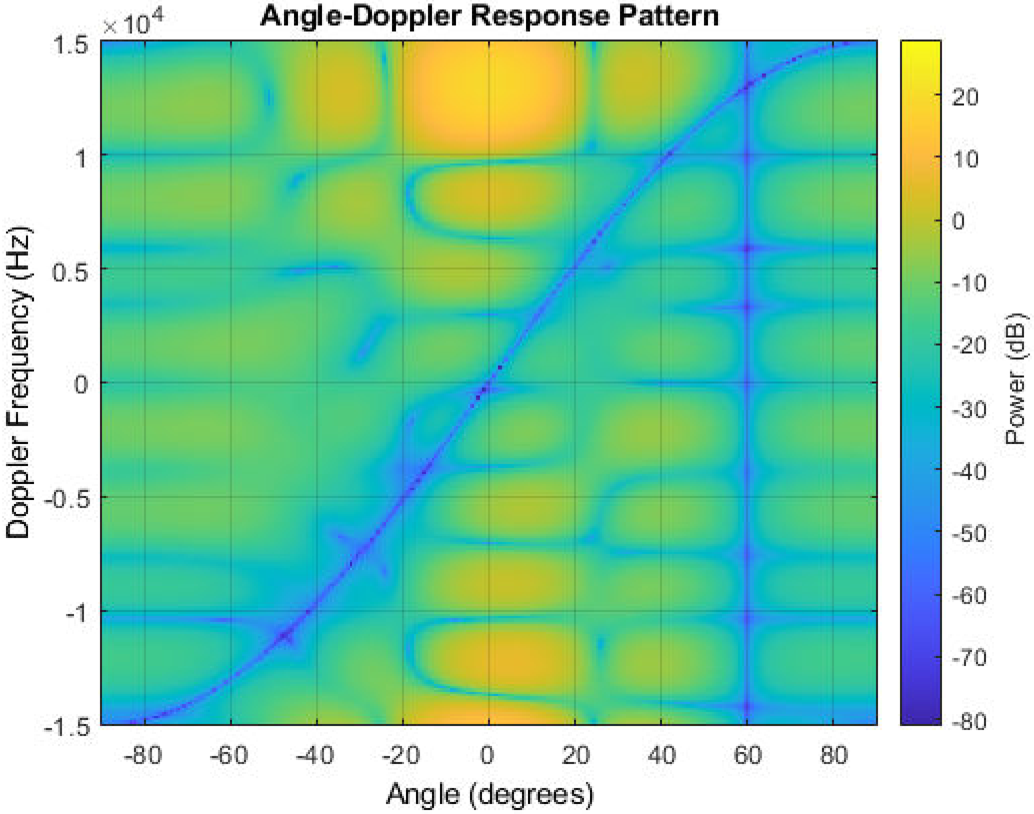
Process a radar data cube using an ADPCA processor. Weights are calculated for the 71st cell of the data cube. Set the look direction to (0,0) degrees and the Doppler shift to 12.980 kHz.

#### Load radar data file and compute weights

```
load STAPExampleData;
canceller = phased.ADPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'NumTrainingCells',100,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port');
[y,w] = canceller(STAPEx_ReceivePulse,71,[0; 0],12.980e3);
```

#### Create AnglerDoppler System object and plot response

```
sAngeDop = phased.AngleDopplerResponse(...
    'SensorArray',canceller.SensorArray,...
    'OperatingFrequency',canceller.OperatingFrequency,...
    'PRF',canceller.PRF,...
    'PropagationSpeed',canceller.PropagationSpeed);
plotResponse(sAngeDop,w)
```



## Algorithms

### Single Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2012a**

# step

**System object:** phased.ADPCACanceller
**Package:** phased

Perform ADPCA processing on input data

## Syntax

```
Y = step(H,X,CUTIDX)
Y = step(H,X,CUTIDX,ANG)
Y = step(H,X,CUTIDX,DOP)
Y = step(H,X,CUTIDX,PRF)
[Y,W] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X,CUTIDX) applies the ADPCA pulse cancellation algorithm to the input data X. The algorithm calculates the processing weights according to the range cell specified by CUTIDX. This syntax is available when the DirectionSource property is 'Property' and the DopplerSource property is 'Property'. The receiving mainlobe direction is the Direction property value. The output Y contains the result of pulse cancellation either before or after Doppler filtering, depending on the PreDopplerOutput property value.

Y = step(H,X,CUTIDX,ANG) uses ANG as the receiving main lobe direction. This syntax is available when the DirectionSource property is 'Input port' and the DopplerSource property is 'Property'.

Y = step(H,X,CUTIDX,DOP) uses DOP as the targeting Doppler frequency. This syntax is available when the DopplerSource property is 'Input port'.

Y = step(H,X,CUTIDX,PRF) uses PRF as the pulse repetition frequency. This syntax is available when the PRFSource property is 'Input port'.

[Y,W] = step(___) also returns the processing weights, W. This syntax is available when the WeightsOutputPort property is true.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

**H**

Pulse canceller object.

**X**

Input data. X must be a 3-dimensional M-by-N-by-P numeric array whose dimensions are (range, channels, pulses). You can specify this argument as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**CUTIDX**

Range cell. You can specify this argument as single or double precision.

**PRF**

Pulse repetition frequency specified as a positive scalar. To enable this argument, set the PRFSource property to 'Input port'. You can specify this argument as single or double precision. Units are in Hertz.

### ANG

Receiving main lobe direction. ANG must be a 2-by-1 vector in the form [AzimuthAngle; ElevationAngle], in degrees. The azimuth angle must be between –180 and 180. The elevation angle must be between –90 and 90. You can specify this argument as single or double precision.

**Default:** Direction property of H

### DOP

Targeting Doppler frequency in hertz. DOP must be a scalar. You can specify this argument as single or double precision.

**Default:** Doppler property of H

## Output Arguments

### Y

Result of applying pulse cancelling to the input data. The meaning and dimensions of Y depend on the PreDopplerOutput property of H:

- If PreDopplerOutput is true, Y contains the pre-Doppler data. Y is an M-by-(P–1) matrix. Each column in Y represents the result obtained by cancelling the two successive pulses.
- If PreDopplerOutput is false, Y contains the result of applying an FFT-based Doppler filter to the pre-Doppler data. The targeting Doppler is the Doppler property value. Y is a column vector of length M.

### W

Processing weights the pulse canceller used to obtain the pre-Doppler data. The dimensions of W depend on the PreDopplerOutput property of H:

- If PreDopplerOutput is true, W is a 2N-by-(P-1) matrix. The columns in W correspond to successive pulses in X.
- If PreDopplerOutput is false, W is a column vector of length (N*P).

## Examples

### Plot Response of ADPCA Processor with Quantized Weights

Process a radar data cube using an ADPCA processor. Weights are calculated for the 71st cell of the data cube. Load the data cube from `STAPExampleData.mat`. Quantize the weights to 4 bits. Set the look direction to (0,0) degrees and the Doppler shift to 12.980 kHz.

```
load STAPExampleData;
sADPCA = phased.ADPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'NumTrainingCells',100,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port',...
    'NumPhaseShifterBits',4);
[y,w] = step(sADPCA,STAPEx_ReceivePulse,71,[0; 0],12.980e3);
sAngDop = phased.AngleDopplerResponse(...
    'SensorArray',sADPCA.SensorArray,...
    'OperatingFrequency',sADPCA.OperatingFrequency,...
    'PRF',sADPCA.PRF,...
    'PropagationSpeed',sADPCA.PropagationSpeed);
plotResponse(sAngDop,w);
```

# phased.AngleDopplerResponse

**Package:** `phased`

Angle-Doppler response

## Description

The `AngleDopplerResponse` object calculates the angle-Doppler response of input data.

To compute the angle-Doppler response:

1. Define and set up your angle-Doppler response calculator. See “Construction” on page 1-15.
2. Call `step` to compute the angle-Doppler response of the input signal according to the properties of `phased.AngleDopplerResponse`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.AngleDopplerResponse` creates an angle-Doppler response System object, `H`. This object calculates the angle-Doppler response of the input data.

`H = phased.AngleDopplerResponse(Name,Value)` creates angle-Doppler object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `PRFSource`

Source of PRF values

Source of the PRF values for the STAP processor, specified as `'Property'` or `'Input port'`. When you set this property to `'Property'`, the PRF is determined by the value of the `PRF` property. When you set this property to `'Input port'`, the PRF is determined by an input argument to the `step` method at execution time.

**Default:** `'Property'`

### PRF

Pulse repetition frequency

Specify the pulse repetition frequency (PRF) in hertz of the input signal as a positive scalar. This property applies when you set the `PRFSource` property to `'Property'`. You can specify this property as single or double precision.

**Default:** `1`

### ElevationAngleSource

Source of elevation angle

Specify whether the elevation angle comes from the `ElevationAngle` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `ElevationAngle` property of this object specifies the elevation angle. |
| `'Input port'` | An input argument in each invocation of `step` specifies the elevation angle. |

**Default:** `'Property'`

### ElevationAngle

Elevation angle

Specify the elevation angle in degrees used to calculate the angle-Doppler response as a scalar. The angle must be between –90 and 90. This property applies when you set the `ElevationAngleSource` property to `'Property'`. You can specify this property as single or double precision.

**Default:** `0`

### NumAngleSamples

Number of samples in angular domain

Specify the number of samples in the angular domain used to calculate the angle-Doppler response as a positive integer. This value must be greater than 2. You can specify this property as single or double precision.

**Default:** 256

**`NumDopplerSamples`**

Number of samples in Doppler domain

Specify the number of samples in the Doppler domain used to calculate the angle-Doppler response as a positive integer. This value must be greater than 2. You can specify this property as single or double precision.

**Default:** 256

## Methods

| | |
|---|---|
| plotResponse | Plot angle-Doppler response |
| step | Calculate angle-Doppler response |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Calculate Angle-Doppler Response

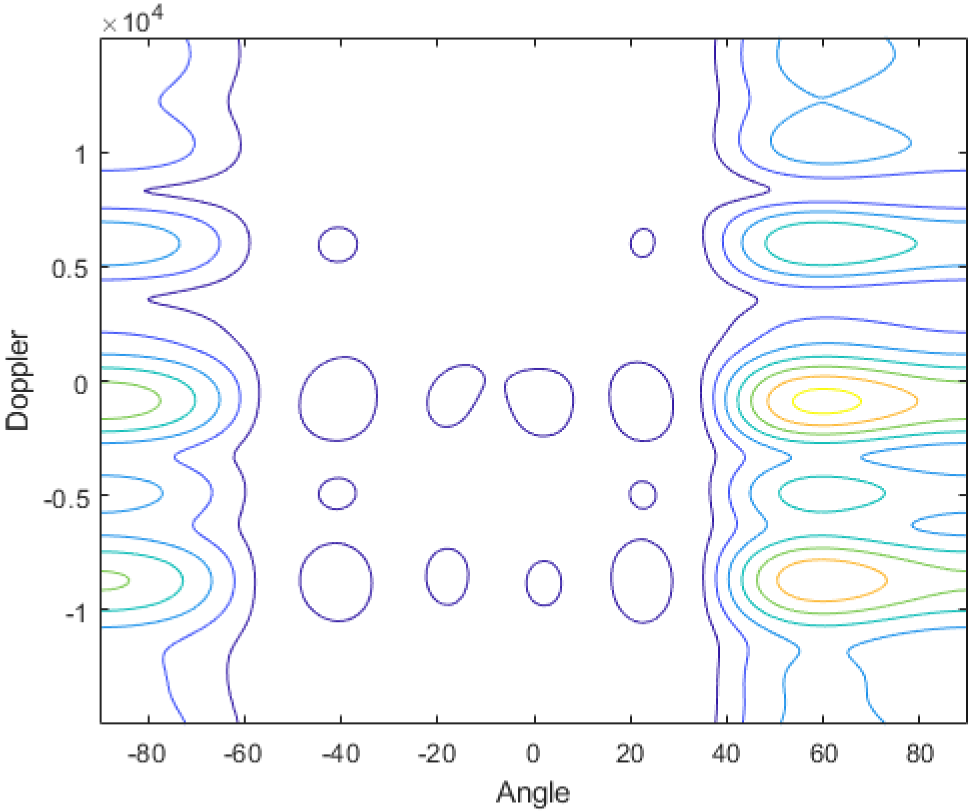
Calculate the angle-Doppler response of the 190th cell of a collected data cube.

Load data cube and construct a `phased.AngleDopplerResponse` System object™.

```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(190,:,:));
response = phased.AngleDopplerResponse(...
    'SensorArray',STAPEx_HArray,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'PRF',STAPEx_PRF);
```

Plot angle-Doppler response.

```
[resp,ang_grid,dop_grid] = response(x);
contour(ang_grid,dop_grid,abs(resp))
xlabel('Angle')
ylabel('Doppler')
```



# Algorithms

## Response Computation

`phased.AngleDopplerResponse` generates the response using a conventional beamformer and an FFT-based Doppler filter. For further details, see [1].

### Single Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# plotResponse

**System object:** phased.AngleDopplerResponse
**Package:** phased

Plot angle-Doppler response

## Syntax

```
plotResponse(H,X)
plotResponse(H,X,ELANG)
plotResponse(H,X,PRF)
plotResponse( ___ ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,X)` plots the angle-Doppler response of the data in `X` in decibels. This syntax is available when the `ElevationAngleSource` property is `'Property'`.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`plotResponse(H,X,ELANG)` plots the angle-Doppler response calculated using the specified elevation angle `ELANG`. This syntax is available when the `ElevationAngleSource` property is `'Input port'`.

`plotResponse(H,X,PRF)` plots the angle-Doppler response calculated using the specified pulse repetition frequency `PRF`. This syntax is available when the `PRFSource` property is `'Input port'`.

`plotResponse( ___ ,Name,Value)` plots the angle-Doppler response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns the handle of the image in the figure window, using any of the input arguments in the previous syntaxes.

# Input Arguments

**H**

Angle-Doppler response object.

**X**

Input data.

**ELANG**

Elevation angle in degrees.

**Default:** Value of `Elevation` property of `H`

**PRF**

Pulse repetition frequency specified as a positive scalar. To enable this argument, set the `PRFSource` property to `'Input port'`. Units are in Hertz.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**NormalizeDoppler**

Set this value to `true` to normalize the Doppler frequency. Set this value to `false` to plot the angle-Doppler response without normalizing the Doppler frequency.

**Default:** `false`

**Unit**

The unit of the plot. Valid values are `'db'`, `'mag'`, and `'pow'`.

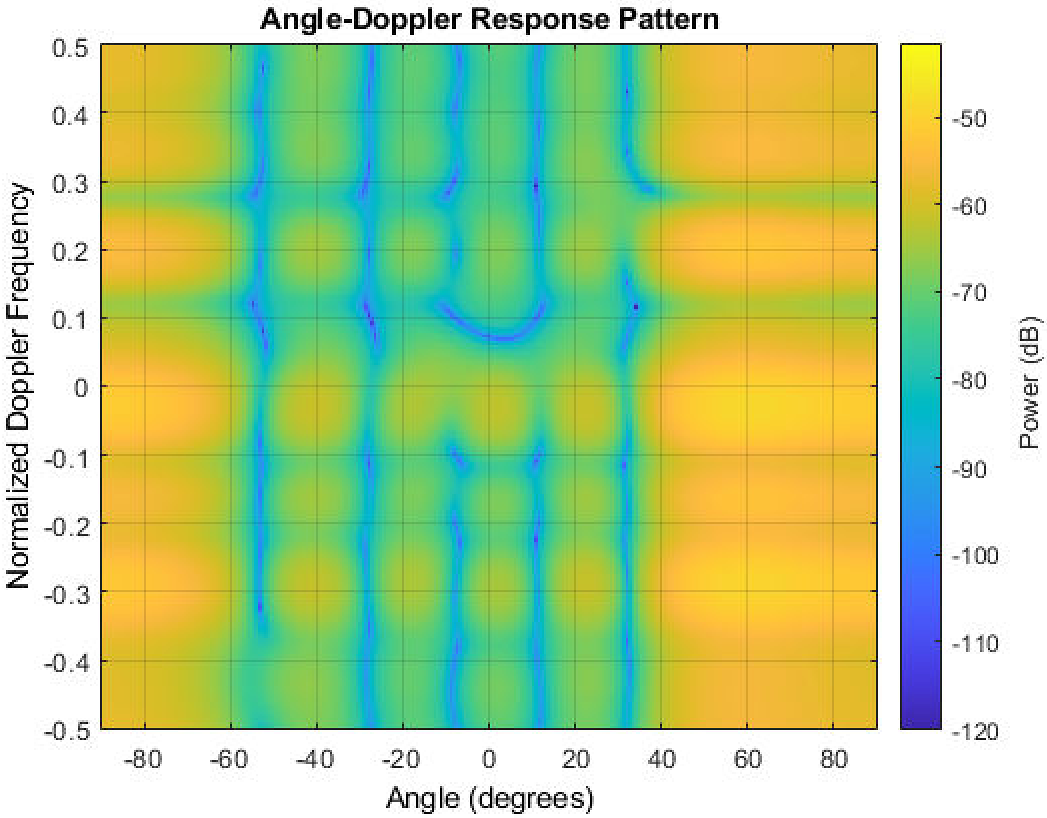
**Default:** `'db'`

## Examples

### Plot Angle-Doppler Response

Plot the angle-Doppler response of the 190th cell of a collected data cube.

```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(190,:,:));
hadresp = phased.AngleDopplerResponse(...
    'SensorArray',STAPEx_HArray,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'PRF',STAPEx_PRF);
plotResponse(hadresp,x,'NormalizeDoppler',true);
```



## See Also

`phitheta2azel` | `uv2azel`

# step

**System object:** phased.AngleDopplerResponse
**Package:** phased

Calculate angle-Doppler response

## Syntax

```
[RESP,ANG_GRID,DOP_GRID] = step(H,X)
[RESP,ANG_GRID,DOP_GRID] = step(H,X,ELANG)
RESP,ANG_GRID,DOP_GRID = step(H,X,PRF)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

[RESP,ANG_GRID,DOP_GRID] = step(H,X) calculates the angle-Doppler response of the data X. RESP is the complex angle-Doppler response. ANG_GRID and DOP_GRID provide the angle samples and Doppler samples, respectively, at which the angle-Doppler response is evaluated. This syntax is available when the ElevationAngleSource property is 'Property'.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

[RESP,ANG_GRID,DOP_GRID] = step(H,X,ELANG) calculates the angle-Doppler response using the specified elevation angle ELANG. This syntax is available when the ElevationAngleSource property is 'Input port'.

RESP,ANG_GRID,DOP_GRID = step(H,X,PRF) uses PRF as the pulse repetition frequency. This syntax is available when the PRFSource property is 'Input port'.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Angle-Doppler response object.

**`X`**

Input data as a matrix or column vector.

If `X` is a matrix, the number of rows in the matrix must equal the number of elements of the array specified in the `SensorArray` property of `H`.

If `X` is a vector, the number of rows must be an integer multiple of the number of elements of the array specified in the `SensorArray` property of `H`. In addition, the multiple must be at least 2.

**`ELANG`**

Elevation angle in degrees. You can specify this argument as single or double precision.

**Default:** Value of `Elevation` property of `H`

**`PRF`**

Pulse repetition frequency specified as a positive scalar. To enable this argument, set the `PRFSource` property to `'Input port'`. Units are in Hertz. You can specify this argument as single or double precision.

## Output Arguments

### RESP

Complex angle-Doppler response of X. RESP is a P-by-Q matrix. P is determined by the NumDopplerSamples property of H and Q is determined by the NumAngleSamples property.

### ANG_GRID

Angle samples at which the angle-Doppler response is evaluated. ANG_GRID is a column vector of length Q.

### DOP_GRID

Doppler samples at which the angle-Doppler response is evaluated. DOP_GRID is a column vector of length P.

## Examples

### Calculate Angle-Doppler Response

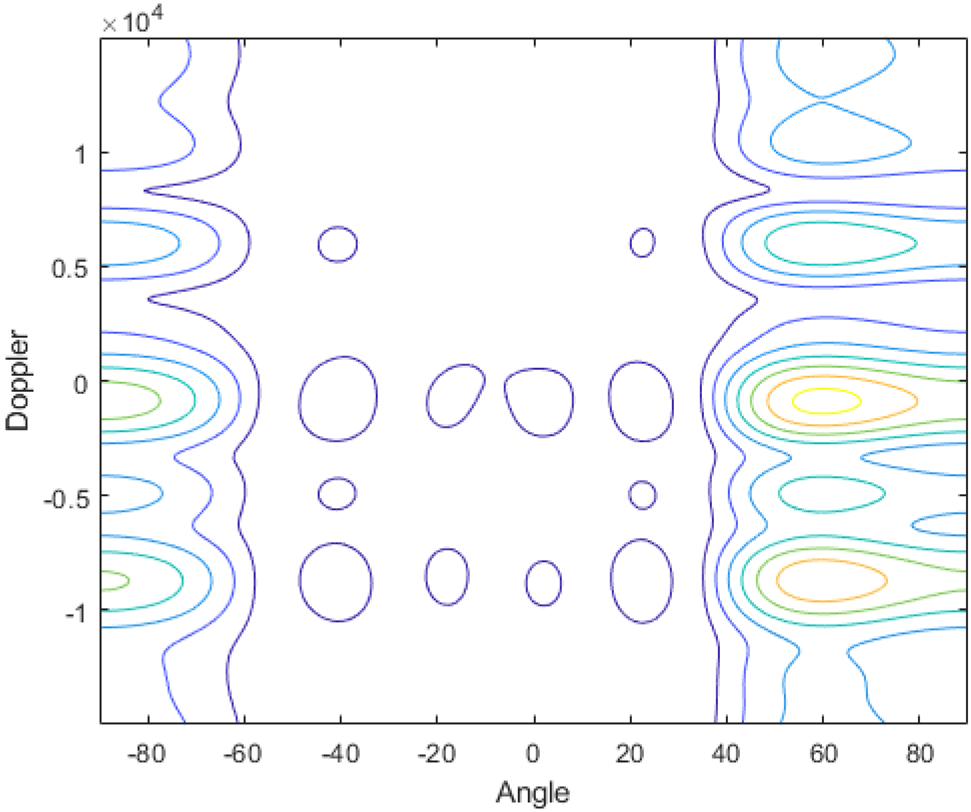
Calculate the angle-Doppler response of the 190th cell of a collected data cube.

Load data cube and construct a phased.AngleDopplerResponse System object™.

```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(190,:,:));
response = phased.AngleDopplerResponse(...
    'SensorArray',STAPEx_HArray,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'PRF',STAPEx_PRF);
```

Plot angle-Doppler response.

```
[resp,ang_grid,dop_grid] = response(x);
contour(ang_grid,dop_grid,abs(resp))
xlabel('Angle')
ylabel('Doppler')
```



## Algorithms

`phased.AngleDopplerResponse` generates the response using a conventional beamformer and an FFT-based Doppler filter. For further details, see [1].

# phased.ArrayGain

**Package:** `phased`

Sensor array gain

## Description

The `ArrayGain` object calculates the array gain for a sensor array. The array gain on page 1-32 is defined as the signal to noise ratio (SNR) improvement between the array output and the individual channel input, assuming the noise is spatially white. It is related to the array response but is not the same.

To compute the SNR gain of the antenna for specified directions:

1. Define and set up your array gain calculator. See “Construction” on page 1-30.
2. Call `step` to estimate the gain according to the properties of `phased.ArrayGain`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ArrayGain` creates an array gain System object, `H`. This object calculates the array gain of a 2-element uniform linear array for specified directions.

`H = phased.ArrayGain(Name,Value)` creates and array-gain object, `H`, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

**`SensorArray`**

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

**Default:** `phased.ULA` with default property values

**`PropagationSpeed`**

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Default:** Speed of light

**`WeightsInputPort`**

Add input to specify weights

To specify weights, set this property to `true` and use the corresponding input argument when you invoke `step`. If you do not want to specify weights, set this property to `false`.

**Default:** `false`

## Methods

| | |
|---|---|
| step | Calculate array gain of sensor array |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Array Gain of 4-Element ULA

Calculate the array gain for a 4-element uniform linear array (ULA) in the direction 30° azimuth and 20° elevation. The array operating frequency is 300 MHz.

```
fc = 300e6;
array = phased.ULA(4);
gain = phased.ArrayGain('SensorArray',array);
g = gain(fc,[30;20])
```

```
g = -17.1783
```

# More About

## Array Gain

The array gain is defined as the signal to noise ratio (SNR) improvement between the array output and the individual channel input, assuming the noise is spatially white. You can express the array gain as follows:

$$\frac{SNR_{\text{out}}}{SNR_{\text{in}}} = \frac{\left(\frac{w^H v s v^H w}{w^H N w}\right)}{\left(\frac{s}{N}\right)} = \frac{w^H v v^H w}{w^H w}$$

In this equation:

- $w$ is the vector of weights applied on the sensor array. When you use `phased.ArrayGain`, you can optionally specify weights by setting the `WeightsInputPort` property to `true` and specifying the `W` argument in the `step` method syntax.
- $v$ is the steering vector representing the array response toward a given direction. When you call the `step` method, the `ANG` argument specifies the direction.
- $s$ is the input signal power.
- $N$ is the noise power.
- $H$ denotes the complex conjugate transpose.

For example, if a rectangular taper is used in the array, the array gain is the square of the array response normalized by the number of elements in the array.

**Package:** phased

Calculate array gain of sensor array

## Syntax

```
G = step(H,FREQ,ANG)
G = step(H,FREQ,ANG,WEIGHTS)
G = step(H,FREQ,ANG,STEERANGLE)
G = step(H,FREQ,ANG,WEIGHTS,STEERANGLE)
G = step(H,FREQ,ANG,WS)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`G = step(H,FREQ,ANG)` returns the array gain on page 1-38 `G` of the array for the operating frequencies specified in `FREQ` and directions specified in `ANG`.

`G = step(H,FREQ,ANG,WEIGHTS)` applies weights `WEIGHTS` on the sensor array. This syntax is available when you set the `WeightsInputPort` property to `true`.

`G = step(H,FREQ,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`G = step(H,FREQ,ANG,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`G = step(H,FREQ,ANG,WS)` uses `WS` as weights applied to each element within each subarray. To use this syntax, set the `SensorArray` property to an array that supports subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Array gain object.

### FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of the sensor element. The element is `H.SensorArray.Element`, `H.SensorArray.Array.Element`, or `H.SensorArray.Subarray.Element`, depending on the type of array. The frequency range property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

### ANG

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction’s azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

### WEIGHTS

Weights on the sensor array. WEIGHTS can be either an N-by-L matrix or a column vector of length N. N is the number of subarrays if H.SensorArray contains subarrays, or the number of elements otherwise. L is the number of frequencies specified in FREQ.

If WEIGHTS is a matrix, each column of the matrix represents the weights at the corresponding frequency in FREQ.

If WEIGHTS is a vector, the weights apply at all frequencies in FREQ.

### STEERANGLE

Subarray steering angle in degrees. STEERANGLE can be a length-2 column vector or a scalar.

If STEERANGLE is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If STEERANGLE is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

### WS

Subarray element weights

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

**Dependencies**

To enable this argument, set the `SensorArray` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

# Output Arguments

### `G`

Gain of sensor array, in decibels. `G` is an M-by-L matrix. `G` contains the gain at the M angles specified in `ANG` and the L frequencies specified in `FREQ`.

# Examples

### Array Gain of 6-Element ULA

Construct a uniform linear array (ULA) having six elements and operating at 1 GHz. The array elements are spaced at one-half the operating wavelength. Find the array gain in dB in the direction 45° azimuth and 10° elevation.

Create the phased.ArrayGain System object™.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
array = phased.ULA('NumElements',6,'ElementSpacing',lambda/2);
gain = phased.ArrayGain('SensorArray',array);
```

Determine array gain at the specified operating frequency and angle.

```
arraygain = gain(fc,[45;10])
```

```
arraygain = -17.9275
```

# More About

## Array Gain

The array gain is defined as the signal to noise ratio (SNR) improvement between the array output and the individual channel input, assuming the noise is spatially white. You can express the array gain as follows:

$$\frac{SNR_{\mathrm{out}}}{SNR_{\mathrm{in}}} = \frac{\left(\frac{w^H v s v^H w}{w^H N w}\right)}{\left(\frac{s}{N}\right)} = \frac{w^H v v^H w}{w^H w}$$

In this equation:

- $w$ is the vector of weights applied on the sensor array. When you use `phased.ArrayGain`, you can optionally specify weights by setting the

WeightsInputPort property to true and specifying the W argument in the step method syntax.

- *v* is the steering vector representing the array response toward a given direction. When you call the step method, the ANG argument specifies the direction.
- *s* is the input signal power.
- *N* is the noise power.
- *H* denotes the complex conjugate transpose.

For example, if a rectangular taper is used in the array, the array gain is the square of the array response normalized by the number of elements in the array.

# phased.ArrayResponse

**Package:** `phased`

Sensor array response

## Description

The `ArrayResponse` object calculates the complex-valued response of a sensor array.

To compute the response of the array for specified directions:

1. Define and set up your array response calculator. See “Construction” on page 1-40.
2. Call `step` to estimate the response according to the properties of `phased.ArrayResponse`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ArrayResponse` creates an array response System object, `H`. This object calculates the response of a sensor array for the specified directions. By default, a 2-element uniform linear array (ULA) is used.

`H = phased.ArrayResponse(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Handle to sensor array used to calculate response

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array can contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Default:** Speed of light

### `WeightsInputPort`

Add input to specify weights

To specify weights, set this property to `true` and use the corresponding input argument when you invoke `step`. If you do not want to specify weights, set this property to `false`.

**Default:** `false`

### `EnablePolarization`

Enable polarization simulation

Set this property to `true` to let the array response simulate polarization. Set this property to `false` to ignore polarization. This property applies only when the array specified in the `SensorArray` property is capable of simulating polarization.

**Default:** `false`

## Methods

| | |
|---|---|
| step | Calculate array response of sensor array |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Plot Array Response

Calculate array response for a 4-element uniform linear array (ULA) in the direction of 30 degrees azimuth and 20 degrees elevation. Assume the array's operating frequency is 300 MHz.

### Construct ULA and ArrayResponse System objects

```
fc = 300e6;
c = physconst('LightSpeed');
array = phased.ULA(4);
response = phased.ArrayResponse('SensorArray',array);
resp = response(fc,[30;20])
```

```
resp = 0.2768 + 0.0000i
```

### Plot the array response in dB

Plot the normalized power in db as an azimuth cut at 0 degrees elevation.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','rectangular','Ty
```

RESP = step(H,FREQ,ANG,WS)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

RESP = step(H,FREQ,ANG) returns the array response RESP at operating frequencies specified in FREQ and directions specified in ANG.

RESP = step(H,FREQ,ANG,WEIGHTS) applies weights WEIGHTS on the sensor array. This syntax is available when you set the WeightsInputPort property to true.

RESP = step(H,FREQ,ANG,STEERANGLE) uses STEERANGLE as the subarray steering angle. This syntax is available when you configure H so that H.Sensor is an array that contains subarrays, and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

RESP = step(H,FREQ,ANG,WEIGHTS,STEERANGLE) combines all input arguments. This syntax is available when you configure H so that H.WeightsInputPort is true, H.Sensor is an array that contains subarrays, and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

RESP = step(H,FREQ,ANG,WS) uses WS as weights applied to each element within each subarray. To use this syntax, set the SensorArray property to an array that supports subarrays and set the SubarraySteering property of the array to 'Custom'.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

**H**

Array response object.

**FREQ**

Operating frequencies of array in hertz. FREQ is a row vector of length L. Typical values are within the range specified by a property of the sensor element. The element is H.SensorArray.Element, H.SensorArray.Array.Element, or H.SensorArray.Subarray.Element, depending on the type of array. The frequency range property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range. The element has zero response at frequencies outside that range.

**ANG**

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction’s azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

### WEIGHTS

Weights on the sensor array. WEIGHTS can be either an N-by-L matrix or a column vector of length N. N is the number of subarrays if H.SensorArray contains subarrays, or the number of elements otherwise. L is the number of frequencies specified in FREQ.

If WEIGHTS is a matrix, each column of the matrix represents the weights at the corresponding frequency in FREQ.

If WEIGHTS is a vector, the weights apply at all frequencies in FREQ.

### STEERANGLE

Subarray steering angle in degrees. STEERANGLE can be a length-2 column vector or a scalar.

If STEERANGLE is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If STEERANGLE is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

### WS

Subarray element weights

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

**Dependencies**

To enable this argument, set the `SensorArray` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

## Output Arguments

### RESP

Voltage response of the sensor array. The response depends on whether the `EnablePolarization` property is set to `true` or `false`.

- If the EnablePolarization property is set to false, the voltage response, RESP, has the dimensions *M*-by-*L*. *M* represents the number of angles specified in the input argument ANG while *L* represents the number of frequencies specified in FREQ.
- If the EnablePolarization property is set to true, the voltage response, RESP, is a MATLAB® struct containing two fields, RESP.H and RESP.V. The RESP.H field represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. Each field has the dimensions *M*-by-*L*. *M* represents the number of angles specified in the input argument, ANG, while *L* represents the number of frequencies specified in FREQ.

# Examples

### Array Response of ULA

Find the response of a 6-element uniform linear array operating at 1 GHz. The array elements are spaced one-half wavelength apart. The incident signal direction is 45° azimuth and 10° elevation. Obtain the response at this direction.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
```

Create the ULA array.

```
array = phased.ULA('NumElements',6,'ElementSpacing',lambda/2);
```

Create the array response System object™.

```
response = phased.ArrayResponse('SensorArray',array);
resp = response(fc,[45;10]);

# backscatterBicyclist

Backscatter radar signals from bicyclist

## Description

The backscatterBicyclist object simulates backscattered radar signals reflected from a moving bicyclist. The bicyclist consists of both the bicycle and its rider. The object models the motion of the bicyclist and computes the sum of all reflected signals from multiple discrete scatterers on the bicyclist. The model ignores internal occlusions within the bicyclist. The reflected signals are based on a multi-scatterer model developed from a 77 GHz radar system.

Scatterers are located on five major bicyclist components:

- Bicycle frame and rider
- Bicycle pedals
- Upper and lower legs of the rider
- Front wheel
- Back wheel

Excluding the wheels, there are 114 scatterers on the bicyclist. The wheels contain scatterers on the rim and spokes. The number of scatterers on the wheels depends on the number of spokes per wheel. The number of spokes is specified using the NumWheelSpokes property.

You can obtain the current bicyclist position and velocity by calling the move object function. Calling this function also updates the position and velocity for the next time epoch. To obtain the reflected signal, call the reflect object function. You can plot the instantaneous position of the bicyclist using the plot object function.

# Creation

## Syntax

```
bicyclist = backscatterBicyclist
bicyclist = backscatterBicyclist(Name,Value,...)
```

### Description

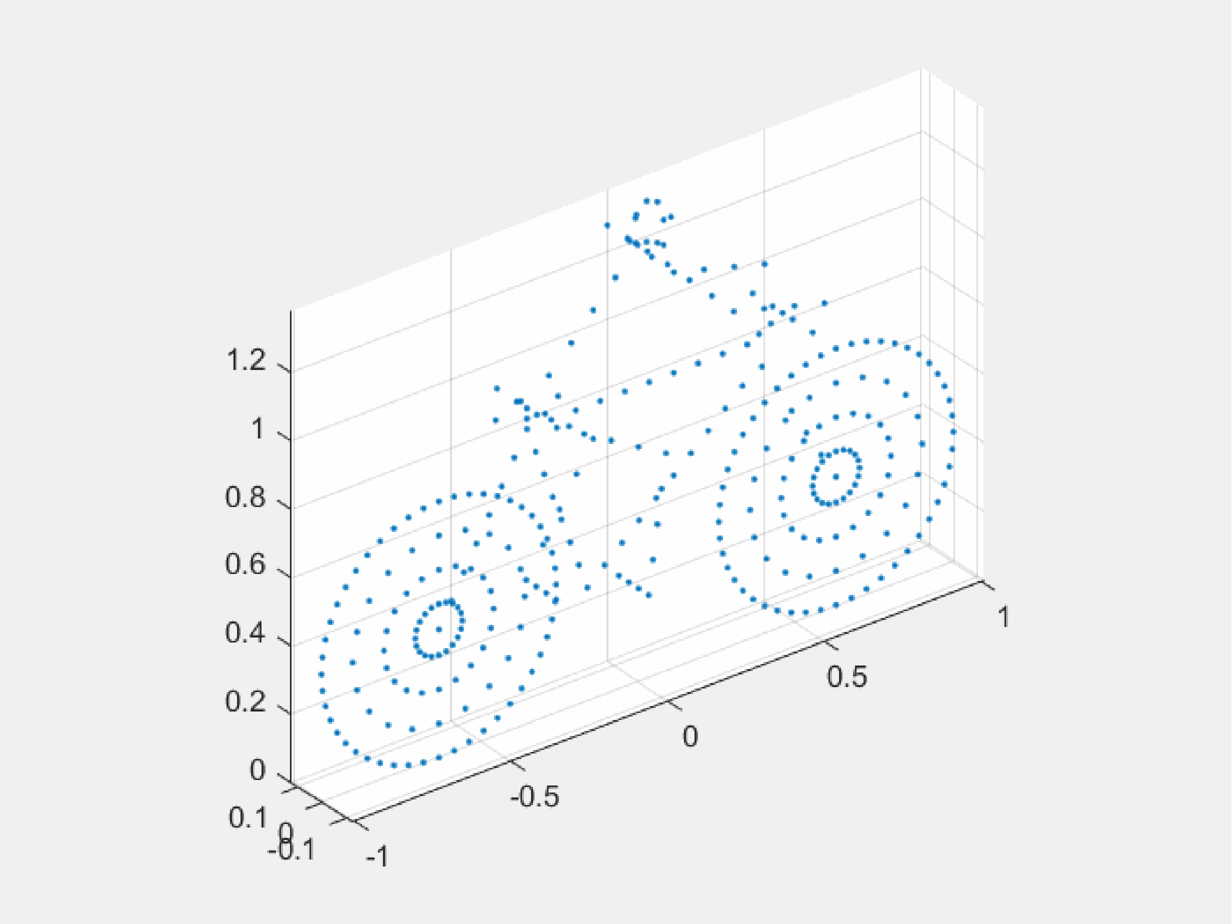
`bicyclist = backscatterBicyclist` creates a `backscatterBicyclist` object, `bicyclist`, having default property values.

`bicyclist = backscatterBicyclist(Name,Value,...)` creates a `backscatterBicyclist` object, `bicyclist`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Any unspecified properties take default values. For example,

```
bicyclist = backscatterBicyclist( ...
              'NumWheelSpokes',18,'Speed',10.0, ...
              'InitialPosition',[0;0;0],'InitialHeading',90, ...
              'GearTransmissionRatio',5.5);
```

models a bicycle with 18 spokes on each wheel that is moving along the positive *y*-axis at 10 meters per second. The gear transmission ratio of 5.5 indicates that there are 5.5 wheel rotations for each pedal rotation. The bicyclist is heading along the *y*-axis.

This figure illustrates a bicyclist starting to turn left.



## Properties

### `NumWheelSpokes` — Number of spokes per wheel

`20` (default) | positive integer

Number of spokes per wheel of the bicycle, specified as a positive integer from 3 to 50, inclusive.

Data Types: `double`

### `GearTransmissionRatio` — Ratio of wheel rotations to pedal rotations

`1.5` (default) | positive scalar

Ratio of wheel rotations to pedal rotations, specified as a positive scalar. The gear ratio must be in the range from 0.5 through 6. Units are dimensionless.

Data Types: `double`

### `OperatingFrequency` — Carrier frequency of narrowband signals

`77e9` (default) | positive scalar

Carrier frequency of the narrowband incident signals, specified as a positive scalar. Units are in Hz.

Example: `900e6`

Data Types: `double`

### `InitialPosition` — Initial position of bicyclist

`[0;0;0]` (default) | 3-by-1 real-valued vector

Initial position of the bicyclist, specified as a 3-by-1 real-valued vector in the form of [*x*;*y*;*z*] in global coordinates. Units are in meters. The initial position corresponds to the location of the origin of the bicycle coordinates. The origin is at the center of mass of the scatterers of the default bicyclist configuration projected onto the ground.

Data Types: `double`

### `InitialHeading` — Initial heading of bicyclist

`0` (default) | scalar

Initial heading of bicyclist, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards the *y*-axis. Heading is with respect to global coordinates. Units are in degrees.

Data Types: `double`

### `Speed` — Speed of bicyclist

`4` (default) | nonnegative scalar

Speed of bicyclist, specified as a nonnegative scalar. The motion model limits the speed to a maximum of 60 m/s (216 kph). Speed is defined with respect to global coordinates. Units are in meters per second.

Data Types: `double`

### Coast — Set bicycle coasting state

false (default) | true

Set bicycle coasting state, specified as false or true. If set to true, the bicyclist is not pedaling, but the wheels are still rotating (freewheeling). If set to false, the bicyclist is pedaling, and the GearTransmissionRatio determines the wheel rotations to pedal rotations.

Data Types: logical

### PropagationSpeed — Signal propagation speed

physconst('LightSpeed') (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by physconst('LightSpeed'). See physconst for more information.

Example: 3e8

Data Types: double

### AzimuthAngles — Radar cross-section azimuth angles

[-180:180] (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Radar cross-section azimuth angles, specified as a 1-by-*P* or *P*-by-1 real-valued vector. This property defines the azimuth coordinates of each column of the radar cross-section matrix specified by the RCSPattern property. *P* must be greater than two. Angle units are in degrees.

Example: [-45:0.1:45]

Data Types: double

### ElevationAngles — Radar cross-section elevation angles

0 (default) | scalar | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Radar cross-section elevation angles, specified as a 1-by-*Q* or *Q*-by-1 real-valued vector. This property defines the elevation coordinates of each row of the radar cross-section matrix specified by the RCSPattern property. *Q* must be greater than two. Angle units are in degrees.

Example: [-30:0.1:30]

Data Types: double

**`RCSPattern` — Radar cross-section pattern**

1-by-361 real-valued matrix (default) | *Q*-by-*P* real-valued vector | 1-by-*P* real-valued vector

Radar cross-section (RCS) pattern, specified as a *Q*-by-*P* real-valued matrix or a 1-by-*P* real-valued vector. Matrix rows represent constant elevation, and columns represent constant azimuth. *Q* is the length of the vector defined by the `ElevationAngles` property. *P* is the length of the vector defined by the `AzimuthAngles` property. Units are in square meters.

You can also specify the pattern as a 1-by-*P* real-valued vector of azimuth angles for a single elevation.

The default value of this property is a 1-by-361 matrix containing values derived from 77 GHz radar measurements of a bicyclist. The default values of `AzimuthAngles` and `ElevationAngles` correspond to the default RCS matrix.

Example: `[1,.5;.5,1]`

Data Types: `double`

# Object Functions

## Specific to This Object

| | |
|---|---|
| getNumScatterers | Number of scatterers on bicyclist |
| move | Position, velocity, and orientation of moving bicyclist |
| plot | Display locations of scatterers on bicyclist |
| reflect | Reflected signal from moving bicyclist |

## Common to All Objects

| | |
|---|---|
| clone | Create identical object |
| release | Release resources and allow changes to object property values and input characteristics |
| reset | Reset object state and property values |

# Examples

### Radar Signal Backscattered by Bicyclist

Compute the backscattered radar signal from a bicyclist moving along the *x*-axis at 5 m/s away from a radar. Assume that the radar is located at the origin. The radar transmits an LFM signal at 24 GHz with a 300-MHz bandwidth. A signal is reflected at the moment the bicyclist starts to move and then one second later.

### Initialize Bicyclist, Waveform, and Propagation Channel Objects

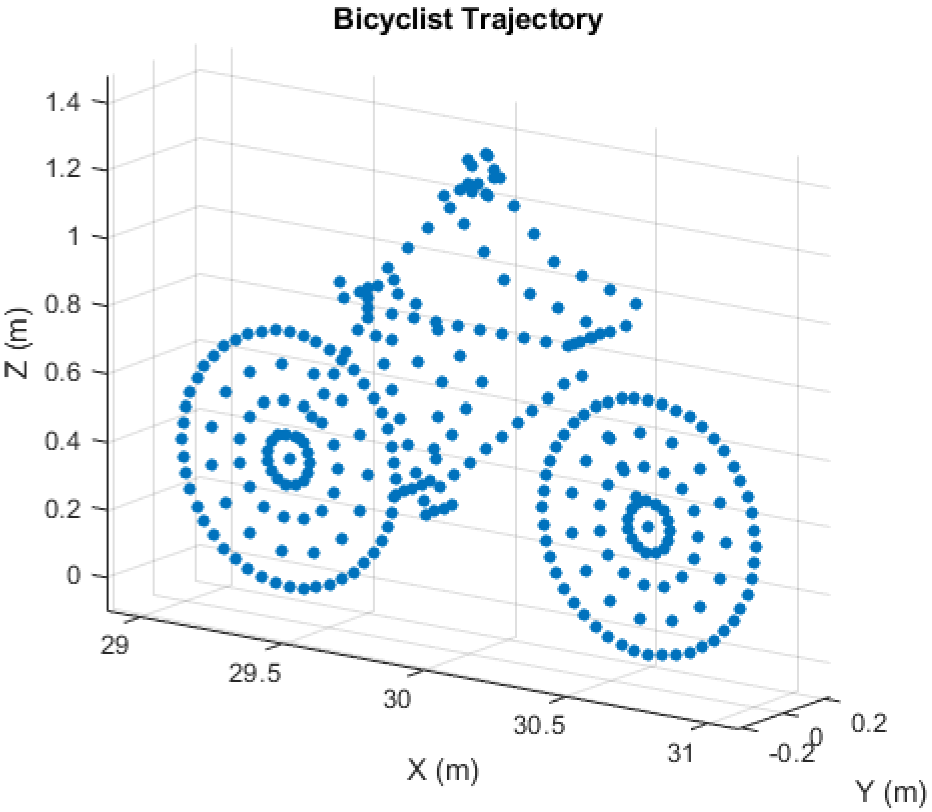
Initialize the `backscatterBicyclist`, `phased.LinearFMWaveform`, and `phased.FreeSpace` objects. Assume a 300 MHz sampling frequency. The initial position of the bicyclist lies on the *x*-axis 30 meters from the radar.

```
bw = 300e6;
fs = bw;
fc = 24e9;
radarpos = [0;0;0];
bpos = [30;0;0];
bicyclist = backscatterBicyclist( ...
    'OperatingFrequency',fc,'NumWheelSpokes',15, ...
    'InitialPosition',bpos,'Speed',5.0, ...
    'InitialHeading',0.0);
lfmwav = phased.LinearFMWaveform( ...
    'SampleRate',fs, ...
    'SweepBandwidth',bw);
sig = lfmwav();
chan = phased.FreeSpace(...
    'OperatingFrequency',fc,...
    'SampleRate',fs,...
    'TwoWayPropagation',true);
```

### Plot Initial Bicyclist Position

Using the `move` object function, obtain the initial scatterer positions, velocities and the orientation of the bicyclist. Plot the initial position of the bicyclist. The `dt` argument of the `move` object function determines that the next call to `move` returns the bicyclist state of motion `dt` seconds later.

```
dt = 1.0;
[bpos,bvel,bax] = move(bicyclist,dt,0);
plot(bicyclist)
```



### Obtain First Reflected Signal

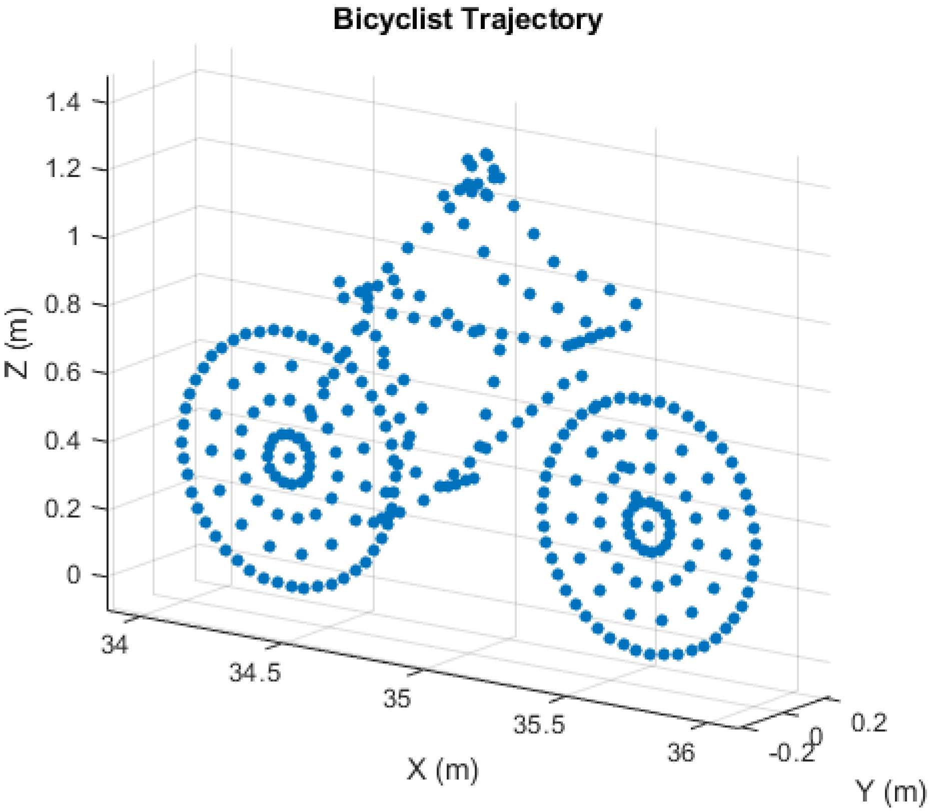
Propagate the signal to all scatterers and obtain the cumulative reflected return signal.

```
N = getNumScatterers(bicyclist);
sigtrns = chan(repmat(sig,1,N),radarpos,bpos,[0;0;0],bvel);
[rngs,ang] = rangeangle(radarpos,bpos,bax);
y0 = reflect(bicyclist,sigtrns,ang);
```

### Plot Bicyclist Position After Position Update

After the bicyclist has moved, obtain the scatterer positions and velocities and then move the bicycle along its trajectory for another second.

```
[bpos,bvel,bax] = move(bicyclist,dt,0);
plot(bicyclist)
```



### Obtain Second Reflected Signal

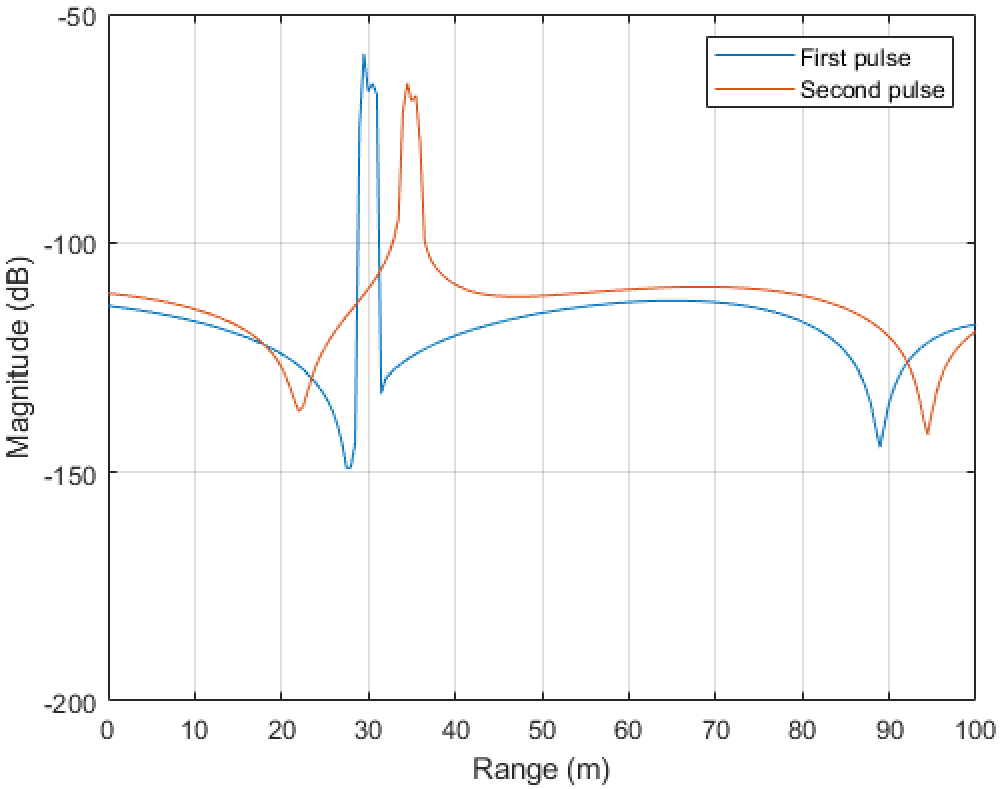
Propagate the signal to all scatterers at their new positions and obtain the cumulative reflected return signal.

```
sigtrns = chan(repmat(sig,1,N),radarpos,bpos,[0;0;0],bvel);
[~,ang] = rangeangle(radarpos,bpos,bax);
y1 = reflect(bicyclist,sigtrns,ang);
```

### Match Filter Reflected Signals

Match filter the reflected signals and plot them together.

```
mfsig = getMatchedFilter(lfmwav);
nsamp = length(mfsig);
mf = phased.MatchedFilter('Coefficients',mfsig);
ymf = mf([y0 y1]);
fdelay = (nsamp-1)/fs;
t = (0:size(ymf,1)-1)/fs - fdelay;
c = physconst('LightSpeed');
plot(c*t/2,mag2db(abs(ymf)))
ylim([-200 -50])
xlabel('Range (m)')
ylabel('Magnitude (dB)')
ax = axis;
axis([0,100,ax(3),ax(4)])
grid
legend('First pulse','Second pulse')
```



Compute the difference in range between the maxima of the two pulses.

```
[maxy,idx] = max(abs(ymf));
dpeaks = t(1,idx(2)) - t(1,idx(1));
drng = c*dpeaks/2
```

```
drng = 4.9965
```

The range difference is 5 m, as expected given the bicyclist speed.

### Display Micro-Doppler Shift from Moving Bicyclist

Display a spectrogram showing the micro-Doppler effect on radar signals reflected from the scatterers on a moving bicyclist target. A stationary radar transmits 1000 pulses of an FMCW radar wave with a bandwith of 250 MHz and of 1 $\mu$sec duration. The radar operates at 24 GHz. The bicyclist starts 5 m from the radar and moves away at 4 m/s.

Set up the waveform, channel, transmitter, receiver, and platform System objects.

```
bw = 250e6;
fs = 2*bw;
fc = 24e9;
c = physconst('Lightspeed');
tm = 1e-6;
wav = phased.FMCWWaveform('SampleRate',fs,'SweepTime',tm, ...
    'SweepBandwidth',bw);
chan = phased.FreeSpace('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'TwoWayPropagation',true,'SampleRate',fs);
radarplt = phased.Platform('InitialPosition',[0;0;0], ...
    'OrientationAxesOutputPort',true);
trx = phased.Transmitter('PeakPower',1,'Gain',25);
rcvx = phased.ReceiverPreamp('Gain',25,'NoiseFigure',10);
```

Create a `bicyclist` object moving at 4 meters/second.

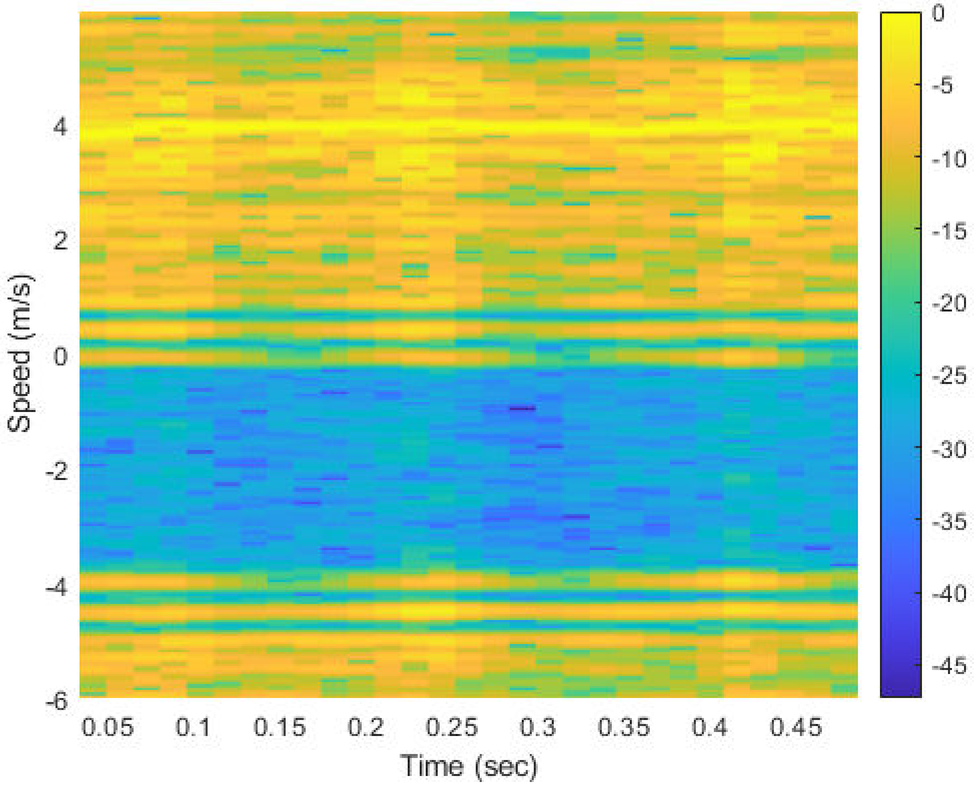
```
bicyclistSpeed = 4;
bicyclist = backscatterBicyclist('InitialPosition',[5;0;0],'Speed',bicyclistSpeed, ...
    'PropagationSpeed',c,'OperatingFrequency',fc,'InitialHeading',0.0);
lambda = c/fc;
fmax = 2*bicyclist.GearTransmissionRatio*bicyclistSpeed/lambda;
tsamp = 1/(2*fmax);
```

Loop over 1000 pulses. Find the angle of incidence of the radar. Propagate the wave to each scatterer, and then reflect the wave from the scatterers back to the radar.

```
npulse = 1000;
xr = complex(zeros(round(fs*tm),npulse));
for m = 1:npulse
    [posr,velr,axr] = radarplt(tsamp);
    [post,velt,axt] = move(bicyclist,tsamp,0);
    [~,angrt] = rangeangle(posr,post,axt);
    x = trx(wav());
    xt = chan(repmat(x,1,size(post,2)),posr,post,velr,velt);
    xr(:,m) = rcvx(reflect(bicyclist,xt,angrt));
end
```

Process the arriving signals. First, dechirp the signal and then pass the signal into a Kaiser-windowed short-tme Fourier transform.

```
xd = conj(dechirp(xr,x));
M = 128;
beta = 6;
w = kaiser(M,beta);
R = floor(1.7*(M-1)/(beta+1));
noverlap = M - R;
[S,F,T] = stft(sum(xd),1/tsamp,'Window',w,'FFTLength',M*2, ...
    'OverlapLength',noverlap);
maxval = max(10*log10(abs(S)));
pcolor(T,-F*lambda/2,10*log10(abs(S))-maxval);
shading flat;
colorbar
xlabel('Time (sec)')
ylabel('Speed (m/s)')
```



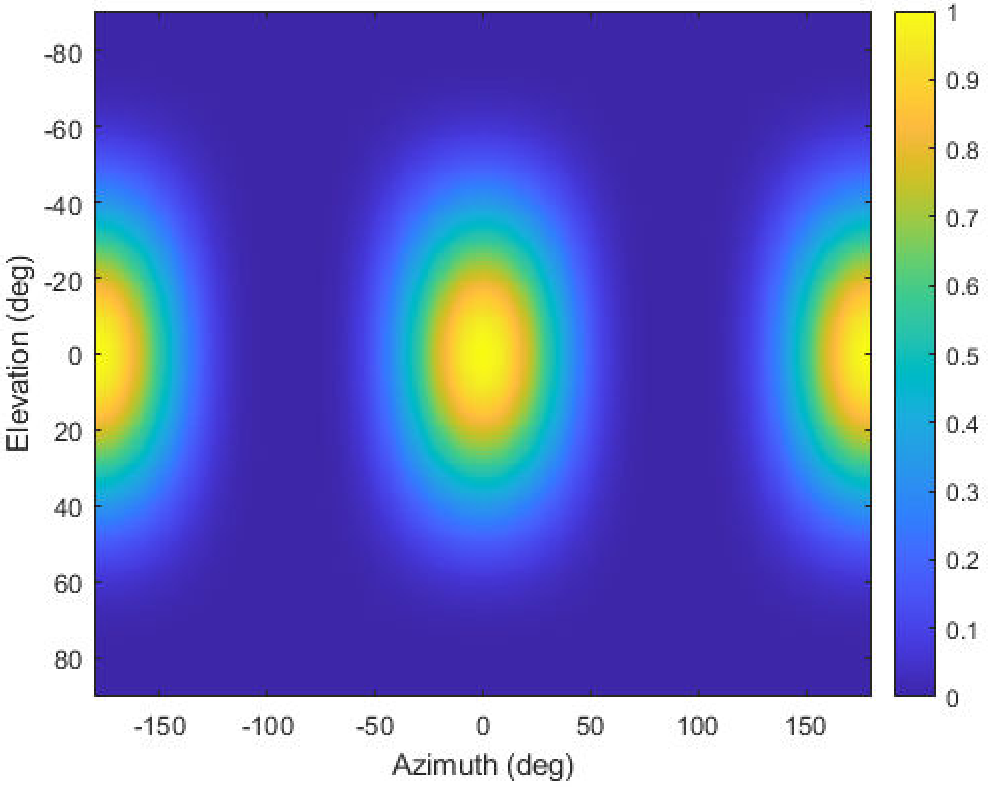
### Backscatter Bicyclist With Custom RCS Pattern

Create a custom RCS pattern to use with the `backscatterBicyclist` object.

The RCS pattern is computed from cosines raised to the fourth power.

```
az = [-180:180];
el = [-90:90];
caz = cosd(az').^4;
cel = cosd(el).^4;
rcs = (caz*cel)';
```

```
imagesc(az,el,rcs)
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
colorbar
```



```
bicyclist = backscatterBicyclist( ...
    'NumWheelSpokes',18,'Speed',10.0, ...
    'InitialPosition',[0;0;0],'InitialHeading',90, ...
    'GearTransmissionRatio',5.5,'AzimuthAngles',az, ...
    'ElevationAngles',el,'RCSPattern',rcs);
```

# Algorithms

## Bicycle Model

The bicyclist consists of five primary components: bicycle frame and rider, pedals, rider legs, front wheel, and rear wheel. Each component contains many scatterers. All components move with a velocity determined by the specified speed and heading properties. In addition, the legs, pedals, and wheels undergo cyclical motion determined by the speed.

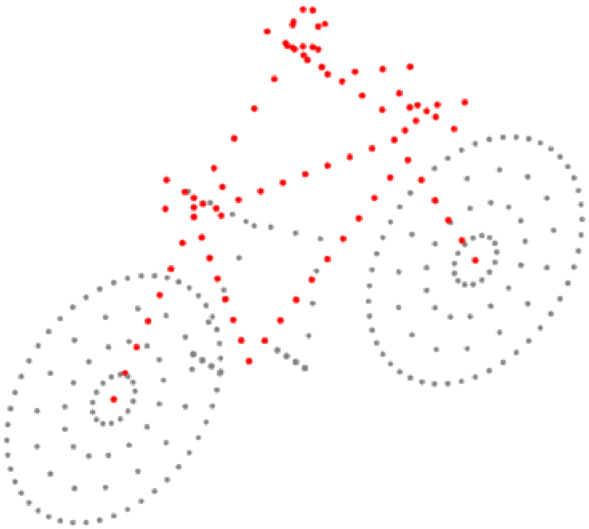
### Motion of Scatterers on Frame and Rider

Scatterers on the frame and rider are fixed with respect to the bicyclist and move with the ego velocity

$$\overrightarrow{v}_{\text{ego}} = v\cos H\widehat{i} + v\sin H\widehat{j}$$

where *v* is the speed of the bicyclist specified by the `Speed` property and *H* is the heading specified by the `InitialHeading` property. These properties can be changed by calling the `move` function.

This figure shows the location of the scatterers on the bicycle frame and rider.



### Motion of Scatterers on Pedals

Scatterers on the pedals move with the bicyclist but can also revolve around the crank spindle with a radius of rotation $R_{\text{ped}}$. There are two possible motions of the pedals depending upon whether the bicycle is coasting (freewheeling) or not coasting:

- When the bicycle is coasting, the pedals do not revolve around the crank spindle and the velocity of the pedal scatterers equals the bicyclist velocity. Their positions relative to the bicyclist are fixed. Coasting is turned on by setting the `Coast` property to `true` or by setting the `coast` argument of the `move` object function to `true`. The speed of the pedal is

  $$\overrightarrow{v}_{\text{ped,tot}} = \overrightarrow{v}_{\text{ego}}$$

- When the bicycle is not coasting, the rider is pedaling. The angular velocity of the pedals is related to the angular velocity of the wheels by

  $$\vec{\omega}_{\mathrm{wh}} = G\vec{\omega}_{\mathrm{ped}}$$

  where $G$ is the gear ratio defined by the `GearTransmissionRatio` property. The speed of a pedal scatterer equals the rotational speed of the pedal multiplied by the distance from pedal to crank spindle. The vector form of this relationship is:

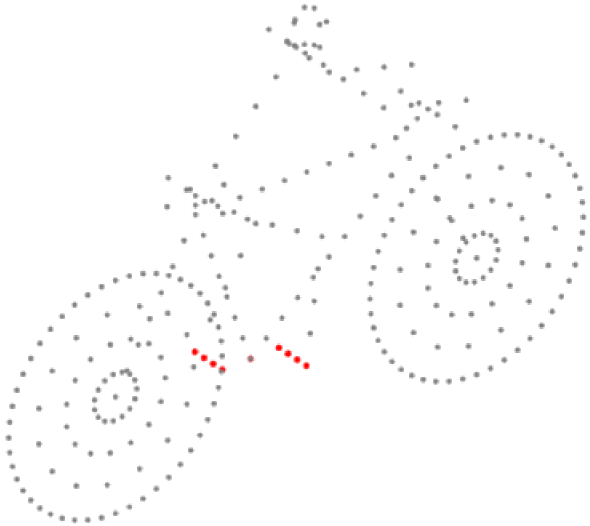
  $$\vec{v}_{\mathrm{ped}} = \vec{\omega}_{\mathrm{ped}} \times \vec{r}_{\mathrm{ped}}$$

  The velocity of the pedal with respect to the bicyclist is then

  $$\vec{v}_{\mathrm{ped,tot}} = \vec{\omega}_{\mathrm{ped}} \times \vec{r}_{\mathrm{ped}} + \vec{v}_{\mathrm{ego}} = G\vec{\omega}_{\mathrm{wh}} \times \vec{r}_{\mathrm{ped}} + \vec{v}_{\mathrm{ego}}$$

  Coasting is turned off by setting the `Coast` property to `false` or by setting the `coast` argument of the `move` object function to `false`.

This figure shows the locations of the pedal scatterers.



### Motion of Scatterers on Riders Legs

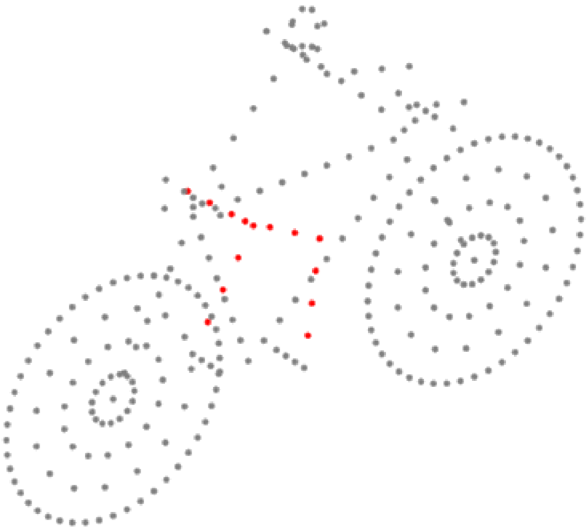
Scatterers on the upper and lower legs of the rider move with the bicycle with an added cyclical motion. There are two possible motions of the legs depending upon whether the bicycle is coasting or not coasting:

- When the bicycle is coasting, the legs are not moving with the respect to the bicycle and the scatterers move with the velocity of the bicyclist. Coasting is turned on by setting the `Coast` property to `true` or by setting the `coast` argument of the `move` object function to `true`.
- When the bicycle is not coasting, the upper and lower legs execute reciprocating motion. The upper legs partially rotate around the hip of the rider. The foot is attached to the pedal and rotates with the pedal. The knee connects the lower and upper legs.

The locations of the foot and hips of the rider determine the locations of the knees and the motion of the scatterers on the legs.

Coasting is turned off by setting the `Coast` property to `false` or by setting the `coast` argument of the `move` object function to `false`.

This figure shows the locations of the scatterers on the upper and lower legs of the rider.



### Motion of Scatterers on Bicycle Wheels

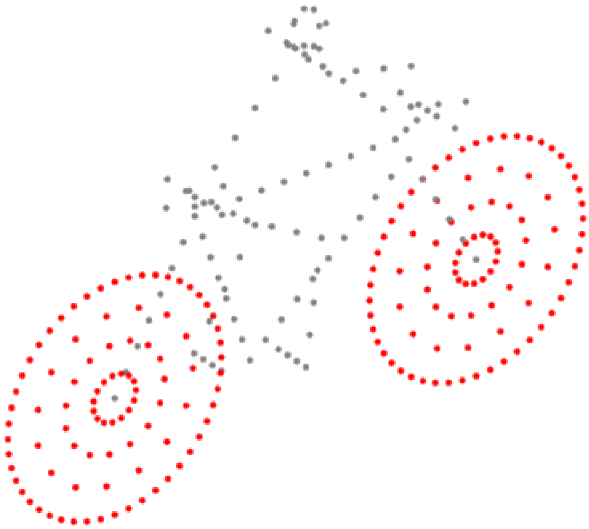
Scatterers are on the spokes and rims of the wheels and revolve around the wheel axle at varying distances, $r_{\mathrm{spk}}$, from the axle. The velocity of the scatterers in the bicyclist frame of reference is

$$\vec{v}_{\mathrm{spk}} = \vec{\omega}_{\mathrm{wh}} \times \vec{r}_{\mathrm{spk}}$$

The absolute velocity of a spoke or rim scatterer is

$$\vec{v}_{\mathrm{spk}} = \vec{\omega}_{\mathrm{wh}} \times \vec{r}_{\mathrm{spk}} + \vec{v}_{\mathrm{ego}}$$

This figure shows the locations of the scatterers on the wheel rims and spokes.



## Radar Cross-Section

The value of the radar cross-section (RCS) of a scatterer generally depends upon the incident angle of the reflected radiation. The `backscatterBicyclist` object uses a simplified RCS model: the RCS pattern of an individual scatterer equals the total bicyclist pattern divided by the number of scatterers. The value of the RCS is computed from the RCS pattern evaluated at an average over all scatterers of the azimuth and elevation incident angles. Therefore, the RCS value is the same for all scatterers. You can specify the RCS pattern using the `RCSPattern` property of the `backscatterBicyclist` object or use the default value.

# getNumScatterers

Number of scatterers on bicyclist

## Syntax

```
N = getNumscatterers(bicyclist)
```

## Description

`N = getNumscatterers(bicyclist)` returns the number of scatterers, `N`, on the `bicyclist`.

## Examples

### Find Number of Bicyclist Scatterers

Use the `getNumScatterers` object function to find the number of scatterers on a bicyclist with 25 spokes. Create the `backscatterBicyclist` object and then call `getNumScatterers`.

```
fc = 77e9;
bicyclist = backscatterBicyclist( ...
    'OperatingFrequency',fc,'NumWheelSpokes',25, ...
    'InitialPosition',[5;0;0]);
N = getNumScatterers(bicyclist)
```

```
N = 359
```

## Input Arguments

**bicyclist — Bicyclist target**
`backscatterBicyclist` object

Bicyclist, specified as a `backscatterBicyclist` object.

## Output Arguments

**`N` — Number of scatterers**
positive integer

Number of scatterers on bicyclist, returned as a positive integer.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

## See Also

`move` | `plot` | `reflect`

**Introduced in R2019b**

# move

Position, velocity, and orientation of moving bicyclist

## Syntax

```
[bpos,bvel,bax] = move(bicyclist,T,angh)
[bpos,bvel,bax] = move(bicyclist,T,angh,speed)
[bpos,bvel,bax] = move(bicyclist,T,angh,speed,coast)
```

## Description

`[bpos,bvel,bax] = move(bicyclist,T,angh)` returns the current positions, `bpos`, and current velocities, `bvel`, of the scatterers and the current orientation axes, `bax`, of the bicyclist. The positions, velocities, and axes are then updated for the next time interval `T`. `angh` specifies the heading angle of the bicyclist.

`[bpos,bvel,bax] = move(bicyclist,T,angh,speed)` also specifies the `speed` of the bicyclist.

`[bpos,bvel,bax] = move(bicyclist,T,angh,speed,coast)` also specifies the coasting state, `coast`, of the bicyclist.

## Examples

### Display Bicyclist Scatterer Positions

Plot the positions of all bicyclist scatterers. Assume there are 15 spokes per wheel.

Create a `backscatterBicyclist` object for a radar system operating at 77 GHz and having a bandwidth of 300 MHz. The sampling rate is twice the bandwidth. The bicyclist is initally 5 meters away from the radar.

```
bw = 300e6;
fs = 2*bw;
```

```
fc = 77e9;
rpos = [0;0;0];
bpos = [5;0;0];
bicyclist = backscatterBicyclist( ...
    'OperatingFrequency',fc,'NumWheelSpokes',15, ...
    'InitialPosition',bpos);
```

Obtain the initial position of the scatterers and advance the motion by 1 second.

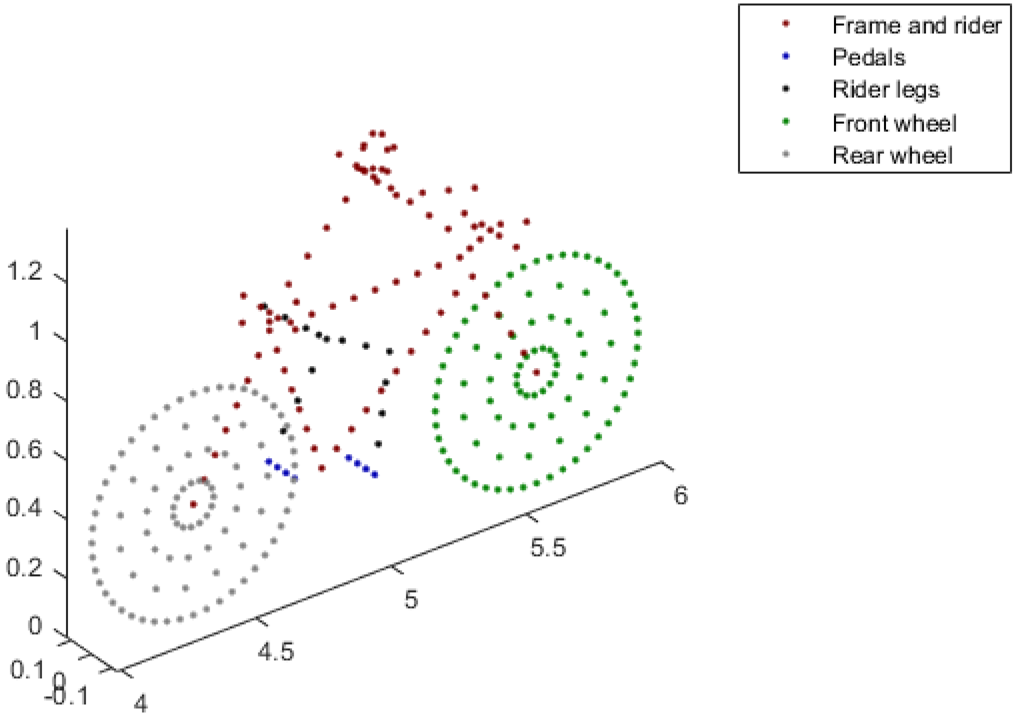
```
[bpos,bvel,bax] = move(bicyclist,1,0);
```

Obtain the number of scatterers and the indices of the wheel scatterers.

```
N = getNumScatterers(bicyclist);
Nsw = (N-114+1)/2;
idxfrontwheel = (114:(114 + Nsw - 1));
idxrearwheel = (114 + Nsw):N;
```

Plot the locations of the scatterers.

```
plot3(bpos(1,1:90),bpos(2,1:90),bpos(3,1:90), ...
    'LineStyle','none','Color',[0.5,0,0],'Marker','.')
axis equal
hold on
plot3(bpos(1,91:99),bpos(2,91:99),bpos(3,91:99), ...
    'LineStyle','none','Color',[0,0,0.7],'Marker','.')
plot3(bpos(1,100:113),bpos(2,100:113),bpos(3,100:113), ...
    'LineStyle','none','Color',[0,0,0],'Marker','.')
plot3(bpos(1,idxfrontwheel),bpos(2,idxfrontwheel),bpos(3,idxfrontwheel), ...
    'LineStyle','none','Color',[0,0.5,0],'Marker','.')
plot3(bpos(1,idxrearwheel),bpos(2,idxrearwheel),bpos(3,idxrearwheel), ...
    'LineStyle','none','Color',[0.5,0.5,0.5],'Marker','.')
hold off
legend('Frame and rider','Pedals','Rider legs','Front wheel','Rear wheel')
```

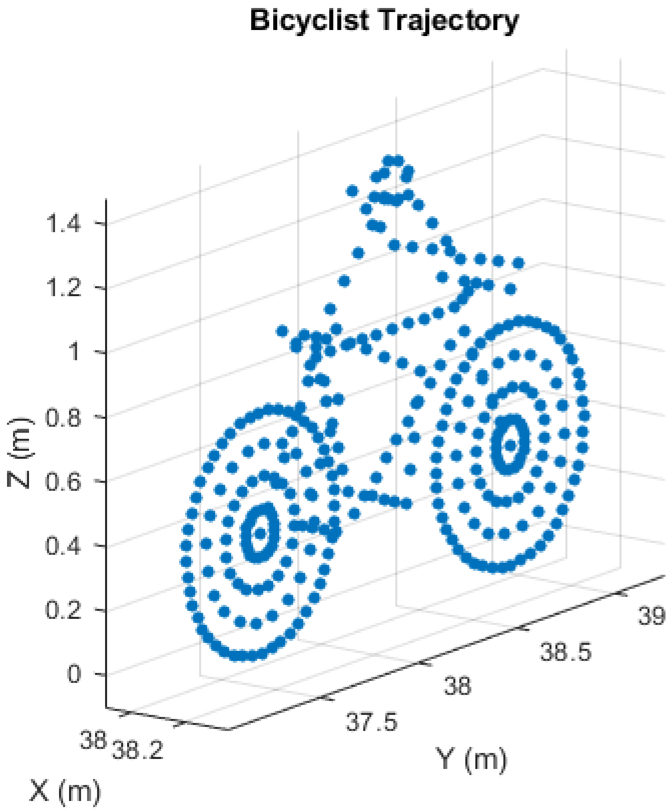


### Model Bicyclist Moving along Arc

Display an animation of a bicyclist riding in a quarter circle. Use the default property values of the `backscatterBicyclist` object. The motion is updated at 30 millisecond intervals for 500 steps.

```
dt = 0.03;
M = 500;
angstep = 90/M;
bicycle = backscatterBicyclist;
```

```
for m = 1:M
    [bpos,bvel,bang] = move(bicycle,dt,angstep*m);
    plot(bicycle)
end
```



## Input Arguments

### bicyclist — Bicyclist target

backscatterBicyclist object

Bicyclist, specified as a `backscatterBicyclist` object.

### T — Duration of next motion interval

scalar

Duration of next motion interval, specified as a positive scalar. The scatterer positions and velocities and bicyclist orientation are updated over this time duration. Units are in seconds.

Example: `0.75`

Data Types: `double`

### angh — Bicyclist heading

`0.0` | scalar

Heading of the bicyclist, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards the *y*-axis. Units are in degrees.

Example: `-34`

Data Types: `double`

### speed — Bicyclist speed

value `Speed` property (default) | nonnegative scalar

Bicyclist speed, specified as a nonnegative scalar. The motion model limits the speed to 60 m/s. Units are in meters per second. Alternatively, you can specify the bicyclist speed using the `Speed` property of the `backscatterBicyclist` object.

Example: 8

Data Types: `double`

### `coast` — Set bicyclist coasting state

value of `Coast` property (default) | `false` | `true`

Set bicyclist coasting state, specified as `false` or `true`. If set to `true`, the bicyclist is not pedaling, but the wheels are still rotating (freewheeling). If set to `false`, the bicyclist is pedaling, and the `GearTransmissionRatio` determines the ratio of wheel rotations to pedal rotations. Alternatively, you can specify the bicyclist coasting state using the `Coast` property of the `backscatterBicyclist` object.

Data Types: `logical`

# Output Arguments

### `bpos` — Positions of bicyclist scatterers

real-valued 3-by-*N* matrix

Positions of bicyclist scatterers, returned as a real-valued 3-by-*N* matrix. Each column represents the Cartesian position, [*x*;*y*;*z*], of one of the bicyclist scatterers. *N* represents the number of scatterers and can be obtained using the `getNumScatterers` object function. Units are in meters. See "Bicycle Scatterer Indices" on page 1-79 for the column representing the position of each scatterer.

Data Types: `double`

### `bvel` — Velocities of bicyclist scatterers

real-valued 3-by-*N* matrix

Velocities of bicyclist scatterers, returned as a real-valued 3-by-*N* matrix. Each column represents the Cartesian velocity, [*vx*;*vy*;*vz*], of one of the bicyclist scatterers. *N* represents the number of scatterers and can be obtained using the `getNumScatterers` object function. Units are in meters per second. See "Bicycle Scatterer Indices" on page 1-79 for the column representing the velocity of each scatterer.

Data Types: `double`

### `bax` — Orientation axes of bicyclist

real-valued 3-by-3 matrix

Orientation axes of bicyclist, returned as a real-valued 3-by-3 matrix. Units are dimensionless.

Data Types: `double`

# More About

## Bicycle Scatterer Indices

Bicyclist scatterer indices define which columns in the scatterer position or velocity matrices contain the position and velocity data for a specific scatterer. For example, column 92 of `bpos` specifies the 3-D position of one of the scatterers on a pedal.

The wheel scatterers are equally divided between the wheels. You can determine the total number of wheel scatterers, $N$, by subtracting 113 from the output of the `getNumScatterers` function. The number of scatterers per wheel is $N_{sw} = N/2$.

**Bicyclist Scatterer Indices**

| Bicyclist Component | Bicyclist Scatterer Index |
|---|---|
| Frame and rider | 1 … 90 |
| Pedals | 91 … 99 |
| Rider legs | 100 … 113 |
| Front wheel | 114 … 114 + $N_{sw}$ - 1 |
| Rear wheel | 114 + $N_{sw}$ … 114 + $N$ - 1 |

# Extended Capabilities

# plot

Display locations of scatterers on bicyclist

## Syntax

```
plot(bicyclist)
fhndl = plot(bicyclist)
fhndl = plot(bicyclist,'Parent',ax)
```

## Description

`plot(bicyclist)` displays the positions of all scatterers on a `bicyclist` at the current time. To display the current position of the bicyclist, call the `plot` object function after calling the `move` object function. Calling `plot` before any call to `move` displays the bicyclist at the origin.

`fhndl = plot(bicyclist)` returns the figure handle of the display window.

`fhndl = plot(bicyclist,'Parent',ax)` also specifies the plot axes for the bicyclist plot.

## Examples

### Radar Signal Backscattered by Bicyclist

Compute the backscattered radar signal from a bicyclist moving along the *x*-axis at 5 m/s away from a radar. Assume that the radar is located at the origin. The radar transmits an LFM signal at 24 GHz with a 300-MHz bandwidth. A signal is reflected at the moment the bicyclist starts to move and then one second later.

### Initialize Bicyclist, Waveform, and Propagation Channel Objects

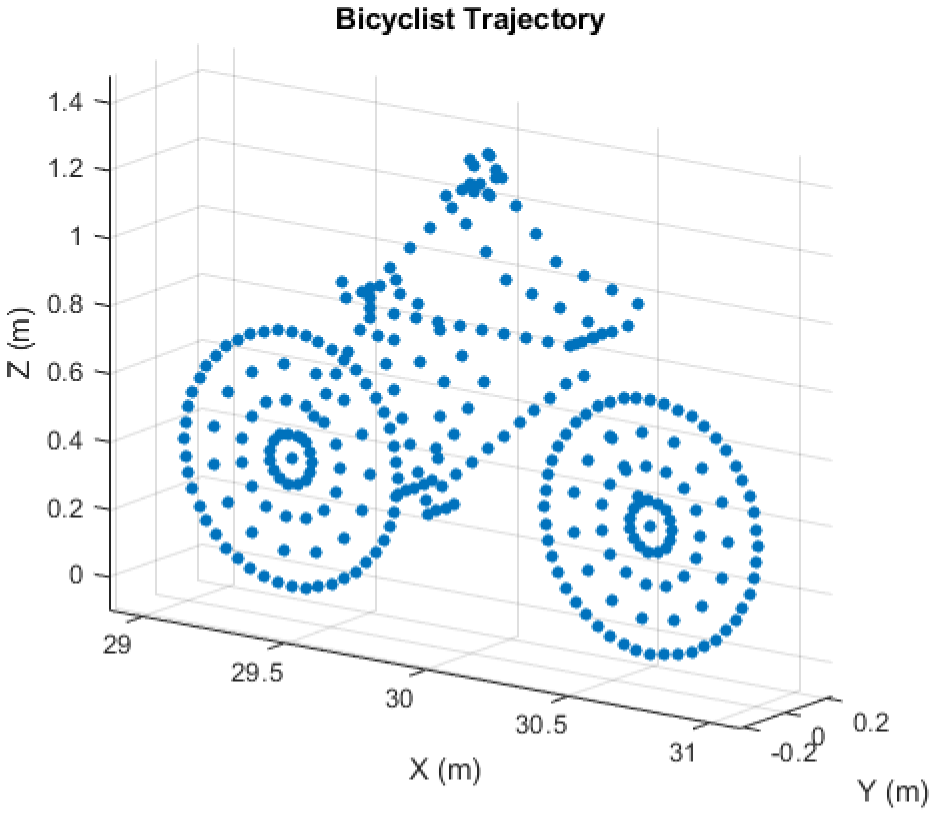
Initialize the `backscatterBicyclist`, `phased.LinearFMWaveform`, and `phased.FreeSpace` objects. Assume a 300 MHz sampling frequency. The initial position of the bicyclist lies on the *x*-axis 30 meters from the radar.

```
bw = 300e6;
fs = bw;
fc = 24e9;
radarpos = [0;0;0];
bpos = [30;0;0];
bicyclist = backscatterBicyclist( ...
    'OperatingFrequency',fc,'NumWheelSpokes',15, ...
    'InitialPosition',bpos,'Speed',5.0, ...
    'InitialHeading',0.0);
lfmwav = phased.LinearFMWaveform( ...
    'SampleRate',fs, ...
    'SweepBandwidth',bw);
sig = lfmwav();
chan = phased.FreeSpace(...
    'OperatingFrequency',fc,...
    'SampleRate',fs,...
    'TwoWayPropagation',true);
```

### Plot Initial Bicyclist Position

Using the `move` object function, obtain the initial scatterer positions, velocities and the orientation of the bicyclist. Plot the initial position of the bicyclist. The `dt` argument of the `move` object function determines that the next call to `move` returns the bicyclist state of motion `dt` seconds later.

```
dt = 1.0;
[bpos,bvel,bax] = move(bicyclist,dt,0);
plot(bicyclist)
```



### Obtain First Reflected Signal

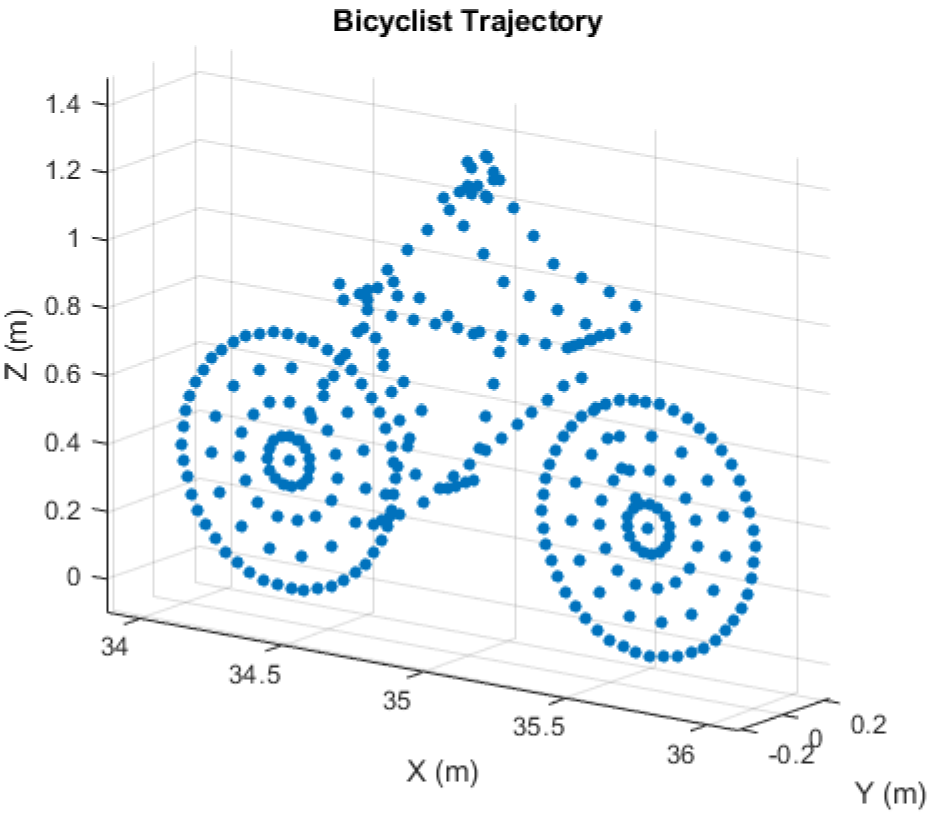
Propagate the signal to all scatterers and obtain the cumulative reflected return signal.

```
N = getNumScatterers(bicyclist);
sigtrns = chan(repmat(sig,1,N),radarpos,bpos,[0;0;0],bvel);
[rngs,ang] = rangeangle(radarpos,bpos,bax);
y0 = reflect(bicyclist,sigtrns,ang);
```

### Plot Bicyclist Position After Position Update

After the bicyclist has moved, obtain the scatterer positions and velocities and then move the bicycle along its trajectory for another second.

```
[bpos,bvel,bax] = move(bicyclist,dt,0);
plot(bicyclist)
```



### Obtain Second Reflected Signal

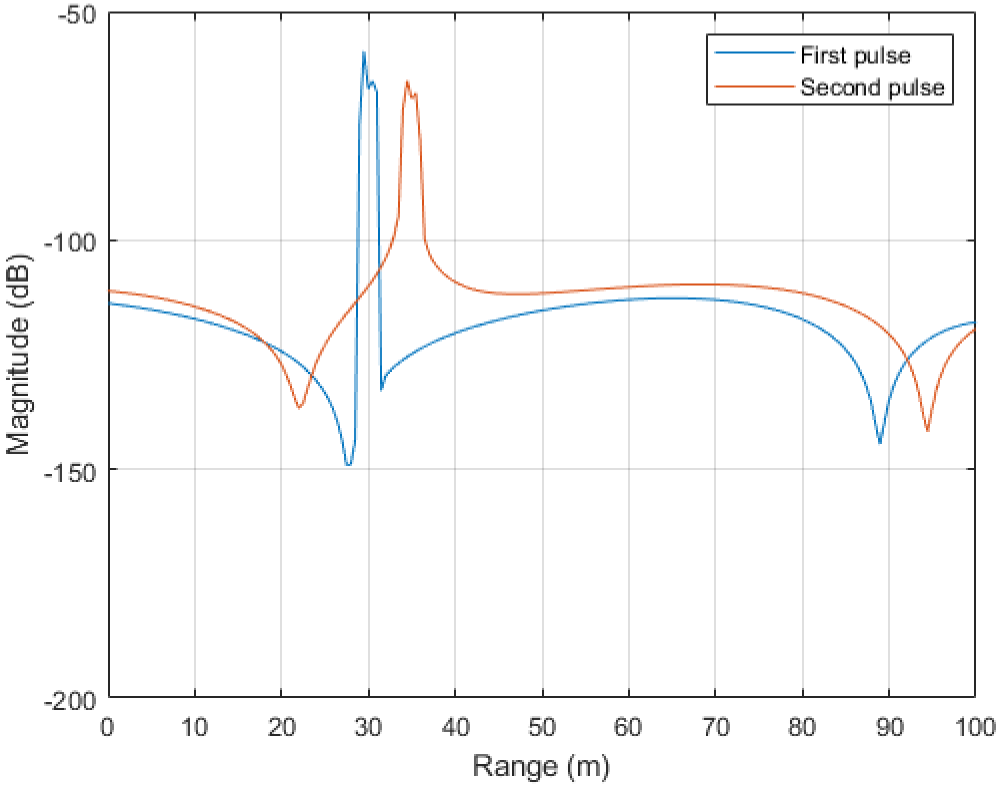
Propagate the signal to all scatterers at their new positions and obtain the cumulative reflected return signal.

```
sigtrns = chan(repmat(sig,1,N),radarpos,bpos,[0;0;0],bvel);
[~,ang] = rangeangle(radarpos,bpos,bax);
y1 = reflect(bicyclist,sigtrns,ang);
```

### Match Filter Reflected Signals

Match filter the reflected signals and plot them together.

```
mfsig = getMatchedFilter(lfmwav);
nsamp = length(mfsig);
mf = phased.MatchedFilter('Coefficients',mfsig);
ymf = mf([y0 y1]);
fdelay = (nsamp-1)/fs;
t = (0:size(ymf,1)-1)/fs - fdelay;
c = physconst('LightSpeed');
plot(c*t/2,mag2db(abs(ymf)))
ylim([-200 -50])
xlabel('Range (m)')
ylabel('Magnitude (dB)')
ax = axis;
axis([0,100,ax(3),ax(4)])
grid
legend('First pulse','Second pulse')
```



Compute the difference in range between the maxima of the two pulses.

```
[maxy,idx] = max(abs(ymf));
dpeaks = t(1,idx(2)) - t(1,idx(1));
drng = c*dpeaks/2
```

```
drng = 4.9965
```

The range difference is 5 m, as expected given the bicyclist speed.

## Input Arguments

**`bicyclist` — Bicyclist target**
`backscatterBicyclist` object

Bicyclist, specified as a `backscatterBicyclist` object.

**ax — Plot axes**
axes handle

Plot axes, specified as an axes handle.

Data Types: `double`

## Output Arguments

**`fhndl` — figure handle**
figure handle

Figure handle of plot window.

## See Also

`getNumScatterers` | `move` | `reflect`

**Introduced in R2019b**

# reflect

Reflected signal from moving bicyclist

## Syntax

```
Y = reflect(bicyclist,X,ang)
```

## Description

`Y = reflect(bicyclist,X,ang)` returns the total reflected signal, `Y`, from a bicyclist. The total reflected signal is the sum of all reflected signals from the bicyclist scatterers. `X` represents the incident signals at each scatterer. `ang` defines the directions of the incident and reflected signals with respect to the each scatterers.

The reflected signal strength depends on the value of the radar cross-section at the incident angle. This simplified model uses the same value for all scatterers.

## Examples

### Radar Signal Backscattered by Bicyclist

Compute the backscattered radar signal from a bicyclist moving along the *x*-axis at 5 m/s away from a radar. Assume that the radar is located at the origin. The radar transmits an LFM signal at 24 GHz with a 300-MHz bandwidth. A signal is reflected at the moment the bicyclist starts to move and then one second later.

**Initialize Bicyclist, Waveform, and Propagation Channel Objects**

Initialize the `backscatterBicyclist`, `phased.LinearFMWaveform`, and `phased.FreeSpace` objects. Assume a 300 MHz sampling frequency. The initial position of the bicyclist lies on the *x*-axis 30 meters from the radar.

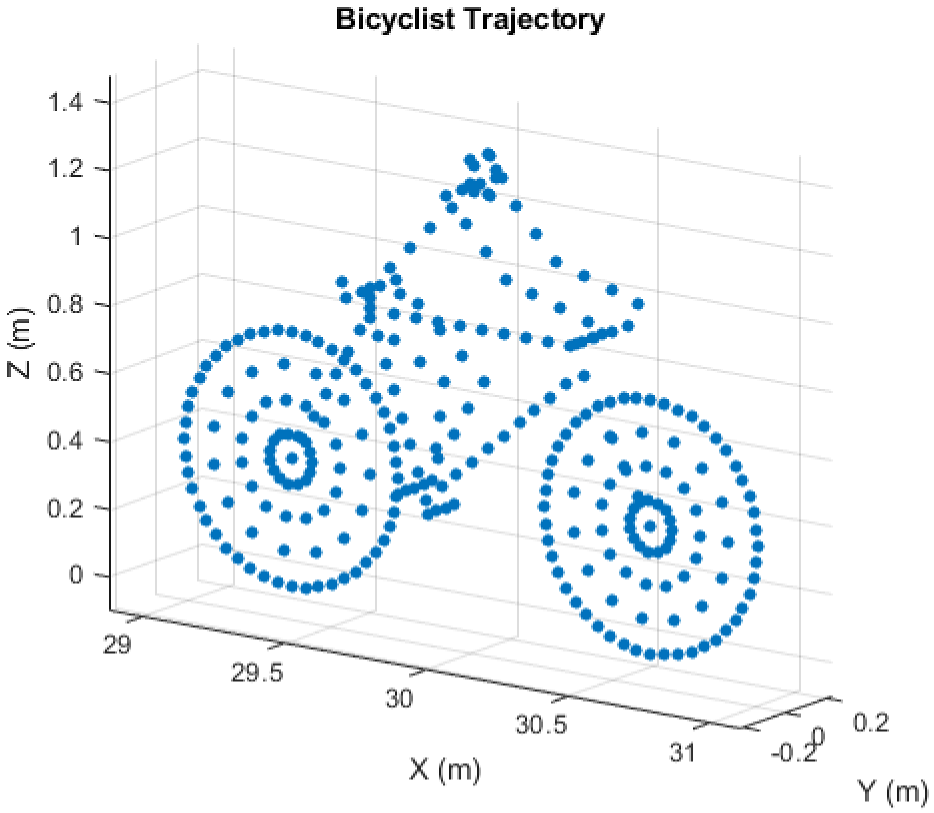
```
bw = 300e6;
fs = bw;
```

```
fc = 24e9;
radarpos = [0;0;0];
bpos = [30;0;0];
bicyclist = backscatterBicyclist( ...
    'OperatingFrequency',fc,'NumWheelSpokes',15, ...
    'InitialPosition',bpos,'Speed',5.0, ...
    'InitialHeading',0.0);
lfmwav = phased.LinearFMWaveform( ...
    'SampleRate',fs, ...
    'SweepBandwidth',bw);
sig = lfmwav();
chan = phased.FreeSpace(...
    'OperatingFrequency',fc,...
    'SampleRate',fs,...
    'TwoWayPropagation',true);
```

### Plot Initial Bicyclist Position

Using the `move` object function, obtain the initial scatterer positions, velocities and the orientation of the bicyclist. Plot the initial position of the bicyclist. The `dt` argument of the `move` object function determines that the next call to `move` returns the bicyclist state of motion `dt` seconds later.

```
dt = 1.0;
[bpos,bvel,bax] = move(bicyclist,dt,0);
plot(bicyclist)
```



### Obtain First Reflected Signal

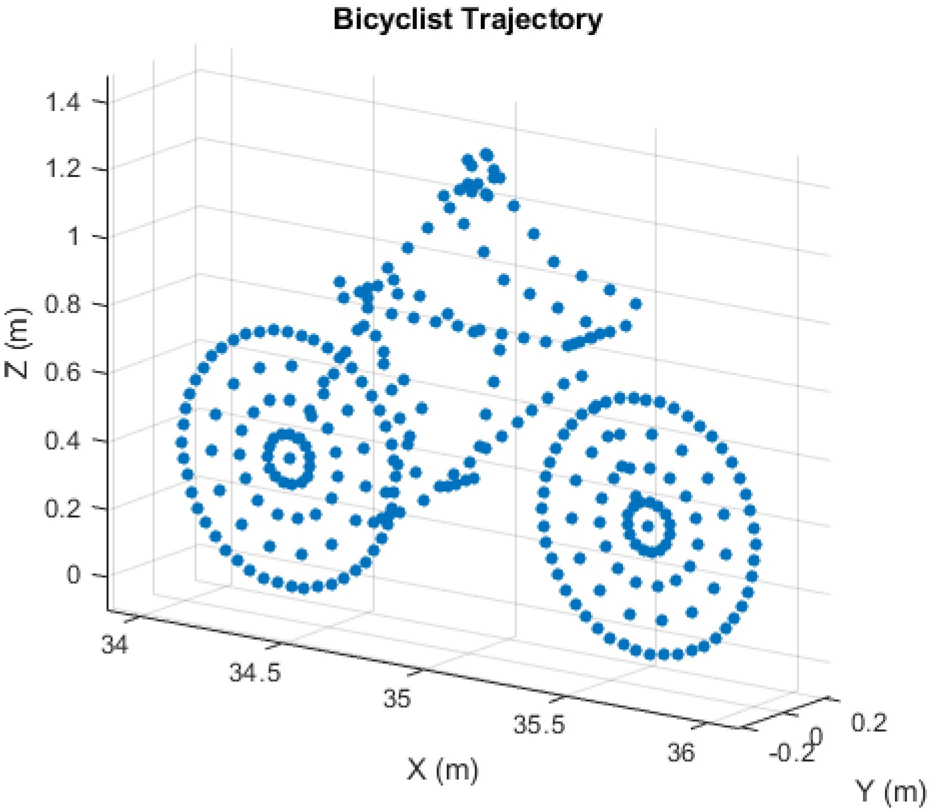
Propagate the signal to all scatterers and obtain the cumulative reflected return signal.

```
N = getNumScatterers(bicyclist);
sigtrns = chan(repmat(sig,1,N),radarpos,bpos,[0;0;0],bvel);
[rngs,ang] = rangeangle(radarpos,bpos,bax);
y0 = reflect(bicyclist,sigtrns,ang);
```

### Plot Bicyclist Position After Position Update

After the bicyclist has moved, obtain the scatterer positions and velocities and then move the bicycle along its trajectory for another second.

```
[bpos,bvel,bax] = move(bicyclist,dt,0);
plot(bicyclist)
```



### Obtain Second Reflected Signal

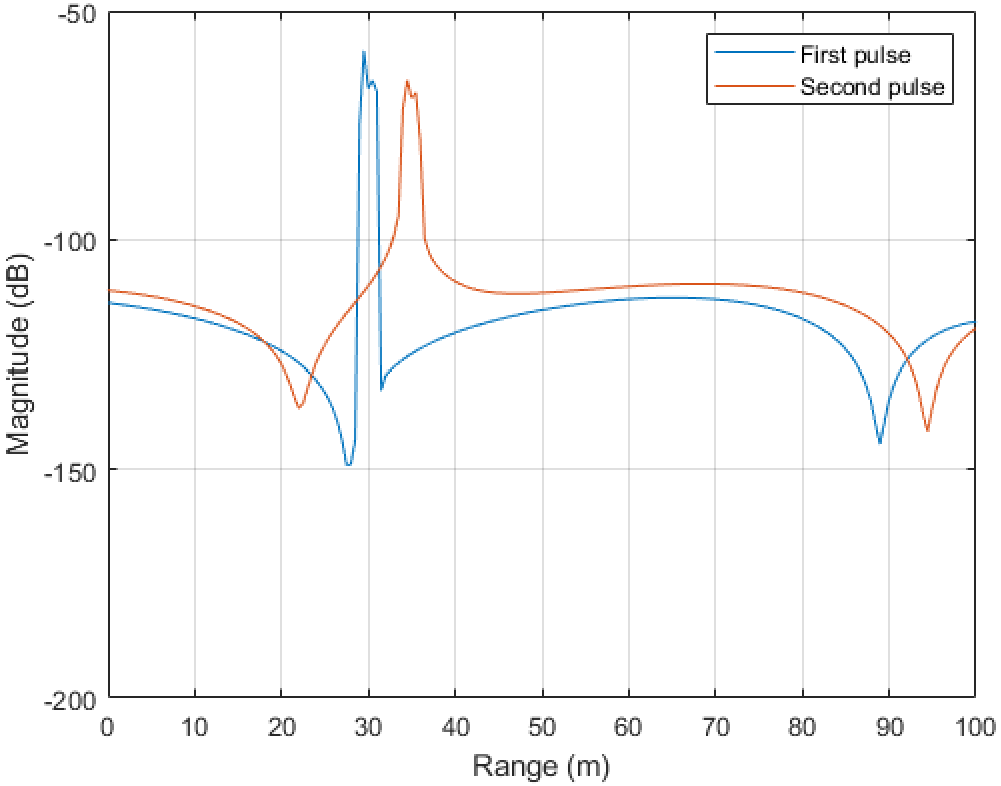
Propagate the signal to all scatterers at their new positions and obtain the cumulative reflected return signal.

```
sigtrns = chan(repmat(sig,1,N),radarpos,bpos,[0;0;0],bvel);
[~,ang] = rangeangle(radarpos,bpos,bax);
y1 = reflect(bicyclist,sigtrns,ang);
```

### Match Filter Reflected Signals

Match filter the reflected signals and plot them together.

```
mfsig = getMatchedFilter(lfmwav);
nsamp = length(mfsig);
mf = phased.MatchedFilter('Coefficients',mfsig);
ymf = mf([y0 y1]);
fdelay = (nsamp-1)/fs;
t = (0:size(ymf,1)-1)/fs - fdelay;
c = physconst('LightSpeed');
plot(c*t/2,mag2db(abs(ymf)))
ylim([-200 -50])
xlabel('Range (m)')
ylabel('Magnitude (dB)')
ax = axis;
axis([0,100,ax(3),ax(4)])
grid
legend('First pulse','Second pulse')
```



Compute the difference in range between the maxima of the two pulses.

```
[maxy,idx] = max(abs(ymf));
dpeaks = t(1,idx(2)) - t(1,idx(1));
drng = c*dpeaks/2
```

```
drng = 4.9965
```

The range difference is 5 m, as expected given the bicyclist speed.

## Input Arguments

### `bicyclist` — Bicyclist target

`backscatterBicyclist` object

Bicyclist, specified as a `backscatterBicyclist` object.

### `X` — Incident radar signals

complex-valued *M*-by-*N* matrix

Incident radar signals on each bicyclist scatterer, specified as a complex-valued *M*-by-*N* matrix. *M* is the number of samples in the signal. *N* is the number of point scatterers on the bicyclist and is determined partly from the number of spokes in each wheel, $N_{ws}$. See "Bicycle Scatterer Indices" on page 1-95 for the column representing the incident signal at each scatterer.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

### `ang` — Directions of incident signals

real-valued 2-by-*P* matrix

Directions of incident signals on the bicyclist scatterers, specified as a real-valued 2-by-*N* matrix. *N* equals the number of columns in `X`. Each column of `Ang` specifies the incident direction of the signal to a scatterer taking the form of an azimuth-elevation pair, *[AzimuthAngle;ElevationAngle]*. Units are in degrees. See "Bicycle Scatterer Indices" on page 1-95 for the column representing the incident direction at each scatterer.

Data Types: `double`

## Output Arguments

### `Y` — Total reflected radar signals

complex-valued *M*-by-1 column vector

Total reflected radar signals, returned as a complex-valued *M*-by-1 column vector. *M* equals the number of samples in the input signal, X.

Data Types: double
Complex Number Support: Yes

# More About

## Bicycle Scatterer Indices

Bicyclist scatterer indices define which columns in the scatterer position or velocity matrices contain the position and velocity data for a specific scatterer. For example, column 92 of bpos specifies the 3-D position of one of the scatterers on a pedal.

The wheel scatterers are equally divided between the wheels. You can determine the total number of wheel scatterers, *N*, by subtracting 113 from the output of the getNumScatterers function. The number of scatterers per wheel is $N_{sw} = N/2$.

**Bicyclist Scatterer Indices**

| Bicyclist Component | Bicyclist Scatterer Index |
|---|---|
| Frame and rider | 1 … 90 |
| Pedals | 91 … 99 |
| Rider legs | 100 … 113 |
| Front wheel | 114 … 114 + $N_{sw}$ - 1 |
| Rear wheel | 114 + $N_{sw}$ … 114 + $N$ - 1 |

# Algorithms

## Radar Cross-Section

The value of the radar cross-section (RCS) of a scatterer generally depends upon the incident angle of the reflected radiation. The backscatterBicyclist object uses a simplified RCS model: the RCS pattern of an individual scatterer equals the total bicyclist pattern divided by the number of scatterers. The value of the RCS is computed from the RCS pattern evaluated at an average over all scatterers of the azimuth and elevation incident angles. Therefore, the RCS value is the same for all scatterers. You can specify the RCS pattern using the `RCSPattern` property of the `backscatterBicyclist` object or use the default value.

# backscatterPedestrian

Backscatter radar signals from pedestrian

## Description

backscatterPedestrian creates an object that simulates signals reflected from a walking pedestrian. The pedestrian walking model coordinates the motion of 16 body segments to simulate natural motion. The model also simulates the radar reflectivity of each body segment. From this model, you can obtain the position and velocity of each segment and the total backscattered radiation as the body moves.

After creating the pedestrian, you can move the pedestrian by calling the `move` object function. To obtain the reflected signal, call the `reflect` object function. You can plot the instantaneous position of the body segments using the `plot` object function.

## Creation

## Syntax

```
pedestrian = backscatterPedestrian
pedestrian = backscatterPedestrian(Name,Value,...)
```

### Description

`pedestrian = backscatterPedestrian` creates a pedestrian target model object, `pedestrian`. The pedestrian model includes 16 body segments – left and right feet, left and right lower legs, left and right upper legs, left and right hip, left and right lower arms, left and right upper arms, left and right shoulders, neck, and head.

`pedestrian = backscatterPedestrian(Name,Value,...)` creates a pedestrian object, `pedestrian`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Any unspecified properties take default values. For example,

```
pedestrian = backscatterPedestrian( ...
              'Height',2,'WalkingSpeed',0.5, ...
              'InitialPosition',[0;0;0],'InitialHeading',90);
```

models a two-meter tall woman or man moving along the positive *y*-axis at one-half meter per second.

## Properties

### `Height` — Height of pedestrian

`1.65` (default) | positive scalar

Height of pedestrian, specified as a positive scalar. Units are in meters.

Data Types: `double`

### `WalkingSpeed` — Walking speed of pedestrian

`1.4` times pedestrian height (default) | non-negative scalar

Walking speed of pedestrian, specified as a non-negative scalar. The motion model limits the walking speed to 1.4 times the pedestrian height set in the `Height` property. Units are in meters per second.

Data Types: `double`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Carrier frequency

`300e6` (default) | positive scalar

Carrier frequency of narrowband incident signals, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `InitialPosition` — Initial position of pedestrian

`[0;0;0]` (default) | 3-by-1 real-valued vector

Initial position of the pedestrian, specified as a 3-by-1 real-valued vector in the form of `[x;y;z]`. Units are in meters.

Data Types: `double`

### `InitialHeading` — Initial heading of pedestrian

`0` (default) | scalar

Initial heading of pedestrian, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards *y*-axis. Units are in degrees.

Data Types: `double`

## Object Functions

### Specific to This Object

| | |
|---|---|
| move | Position and velocity of walking pedestrian |
| plot | Display stick figure showing the positions of all body segments of pedestrian |
| reflect | Reflected signal from walking pedestrian |

### Common to All Objects

| | |
|---|---|
| clone | Create identical object |
| release | Release resources and allow changes to object property values and input characteristics |
| reset | Reset object state and property values |

## Examples

### Reflected Signal from Moving Pedestrian

Compute the reflected radar signal from a pedestrian moving along the *x*-axis away from the origin. The radar operates at 24 GHz and is located at the origin. The pedestrian is initially 100 meters from the radar. Transmit a linear FM waveform having a 300 MHz bandwidth. The reflected signal is captured at the moment the pedestrian starts to move and at two seconds into the motion.

Create a linear FM waveform and a free space channel to propagate the waveform.

```
c = physconst('Lightspeed');
bw = 300.0e6;
fs = bw;
fc = 24.0e9;
wav = phased.LinearFMWaveform('SampleRate',fs,'SweepBandwidth',bw);
x = wav();
channel = phased.FreeSpace('OperatingFrequency',fc,'SampleRate',fs, ...
    'TwoWayPropagation',true);
```

Create the pedestrian object. Set the initial position of the pedestrian to 100 m on the *x*-axis with initial heading along the positive *x*-direction. The pedestrian height is 1.8 m and the pedestrian is walking at 0.5 meters per second.

```
pedest = phased.BackscatterPedestrian( 'Height',1.8, ...
    'OperatingFrequency',fc,'InitialPosition',[100;0;0], ...
    'InitialHeading',0,'WalkingSpeed',0.5);
```

The first call to the `move` function returns the initial position, initial velocity, and initial orientation of all body segments and then advances the pedestrian motion two seconds ahead.

```
[bppos,bpvel,bpax] = move(pedest,2,0);
```

Transmit the first pulse to the pedestrian. Create 16 replicas of the signal and propagate them to the positions of the pedestrian body segments. Use the `rangeangle` function to compute the arrival angle of each replica at the corresponding body segment. Then use the `reflect` function to return the coherent sum of all the reflected signals from the body segments at the pedestrian initial position.

```
radarpos = [0;0;0];
xp = channel(repmat(x,1,16),radarpos,bppos,[0;0;0],bpvel);
[~,ang] = rangeangle(radarpos,bppos,bpax);
y0 = reflect(pedest,xp,ang);
```

Obtain the position, velocity, and orientation of each body segment then advance the pedestrian motion another two seconds.

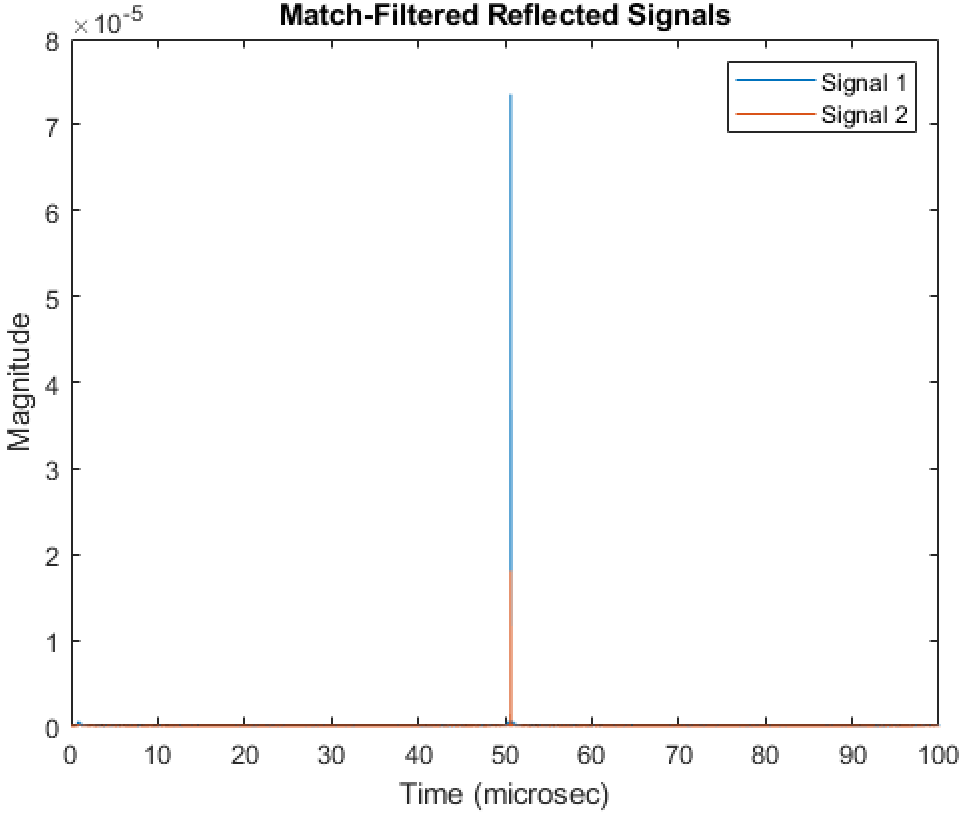
```
[bppos,bpvel,bpax] = move(pedest,2,0);
```

Transmit and propagate the second pulse to the new position of the pedestrian.

```
radarpos = [0;0;0];
xp = channel(repmat(x,1,16),radarpos,bppos,[0;0;0],bpvel);
[~,ang] = rangeangle(radarpos,bppos,bpax);
y1 = reflect(pedest,xp,ang);
```

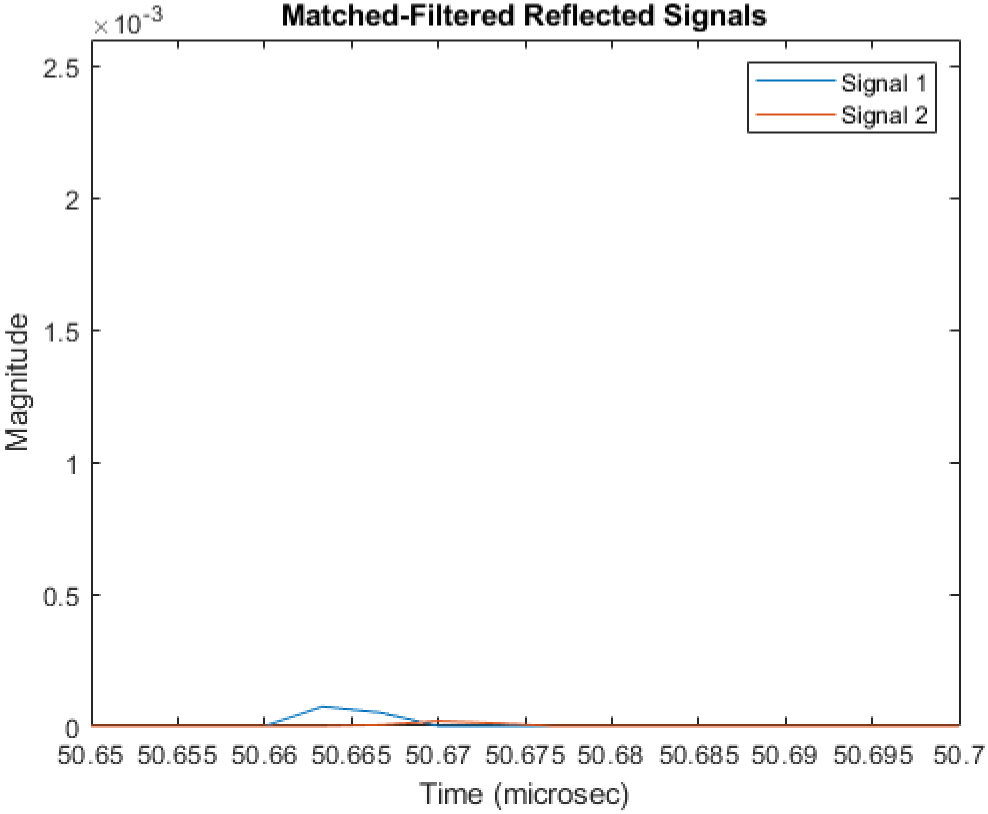
Match-filter and plot both of the reflected pulses. The plot shows the increased delay of the matched filter output as the pedestrian walks away.

```
filter = phased.MatchedFilter('Coefficients',getMatchedFilter(wav));
ymf = filter([y0 y1]);
t = (0:size(ymf,1)-1)/fs;
plot(t*1e6,abs(ymf))
xlabel('Time (microsec)')
ylabel('Magnitude')
title('Match-Filtered Reflected Signals')
legend('Signal 1','Signal 2')
```



Zoom in and show the time delays for each signal.

```
plot(t*1e6,abs(ymf))
xlabel('Time (microsec)')
ylabel('Magnitude')
title('Matched-Filtered Reflected Signals')
axis([50.65 50.7 0 .0026])
legend('Signal 1','Signal 2')
```



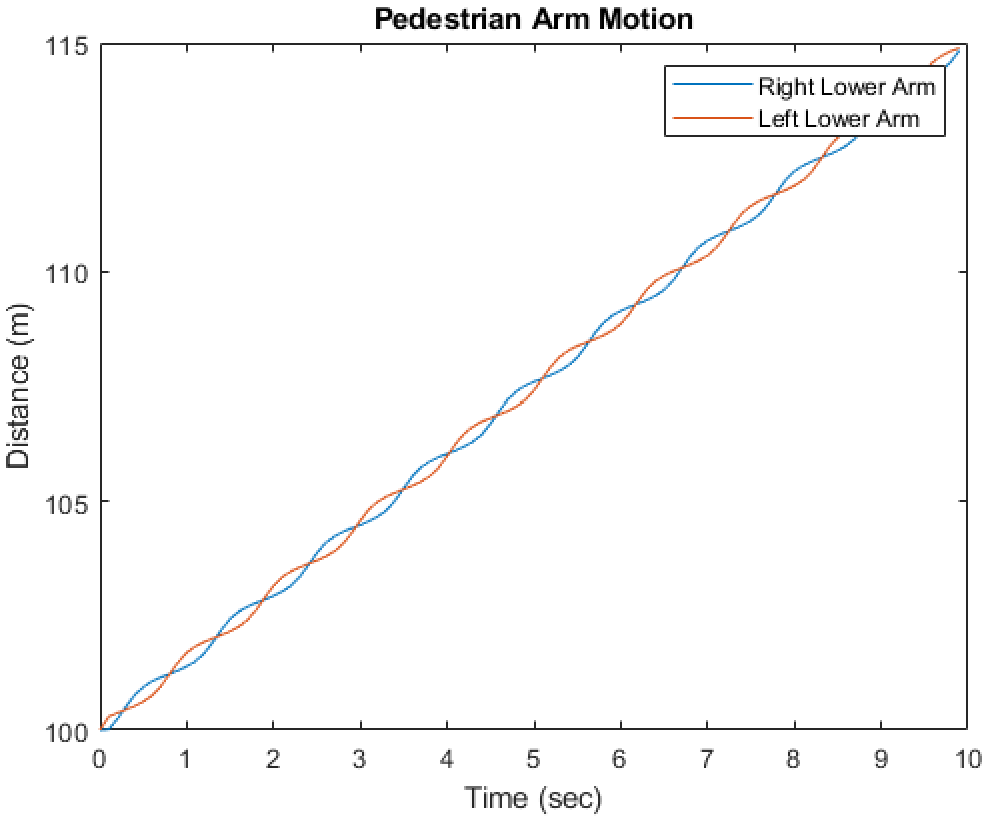
### Plot Arm Motion of Walking Pedestrian

Create a pedestrian object. Set the initial position of the pedestrian to 100 m on the *x*-axis with initial heading along the positive *x*-direction. The pedestrian height is 1.8 m and the pedestrian is walking at 1.5 meters per second.

```
fc = 24.0e9;
pedest = phased.BackscatterPedestrian( 'Height',1.8, ...
    'OperatingFrequency',fc,'InitialPosition',[100;0;0], ...
    'InitialHeading',0,'WalkingSpeed',1.5);
```

Obtain and plot the detailed motion of the right and left lower arms of the pedestrian by capturing their positions every 1/10th of a second.

```
blla = zeros(3,100);
brla = blla;
t = zeros(1,100);
T = .1;
for k = 1:100
    [bppos,bpvel,bpax] = move(pedest,T,0);
    blla(:,k) = bppos(:,9);
    brla(:,k) = bppos(:,10);
    t(k) = T*(k-1);
end
plot(t,brla(1,:),t,blla(1,:))
title('Pedestrian Arm Motion')
xlabel('Time (sec)')
ylabel('Distance (m)')
legend('Right Lower Arm','Left Lower Arm')
```



#### Plot Pedestrian Motion

Display the motion of a pedestrian walking a square path. Create the pedestrian using a `phased.BackscatterPedestrian` object with default values except for height which is 1.7 meters. Advance and display the pedestrian position every 3 milliseconds. First, the pedestrian moves along the positive *x*-axis, then along the positive *y*-axis, along the negative *x*-axis, and finally along the negative *y*-axis to return to the starting point.

```
ped = phased.BackscatterPedestrian('Height',1.7);
dt = 0.003;
N = 3600;
```

```
for m = 1:N
    if (m < N/4)
        angstep = 0.0;
    end
    if (m >= N/4)
        angstep = 90.0;
    end
    if (m >= N/2)
        angstep = 180.0;
    end
    if (m >= 3*N/4)
        angstep = 270.0;
    end
    move(ped,dt,angstep);
    plot(ped)
end
```

# move

Position and velocity of walking pedestrian

## Syntax

```
[BPPOS,BPVEL,BPAX] = move(pedestrian,T,ANGH)
```

## Description

`[BPPOS,BPVEL,BPAX] = move(pedestrian,T,ANGH)` returns the position, `BPPOS`, velocity, `BPVEL`, and orientation axes, `BPAX`, of body segments of a moving pedestrian. The object then simulates the walking motion for the next duration, specified in `T`. `ANGH` specifies the current heading angle.

## Input Arguments

**`pedestrian` — Pedestrian target**
`backscatterPedestrian` object

Pedestrian target model, specified as a `backscatterPedestrian` object.

**`T` — Duration of next walking interval**
scalar

Duration of next walking interval, specified as a positive scalar. Units are in seconds.

Example: `0.75`

Data Types: `double`

**`ANGH` — Pedestrian heading**
scalar

Heading of the pedestrian, specified as a scalar. Heading is measured in the *xy*-plane from the *x*-axis towards the *y*-axis. Units are in degrees.

Example: `-34`

Data Types: `double`

## Output Arguments

### `BPPOS` — Positions of body segments

real-valued 3-by-16 matrix

Positions of body segments, returned as a real-valued 3-by-16 matrix. Each column represents the Cartesian position, `[x;y;z]`, of one of 16 body segments. Units are in meters. See "Body Segment Indices" on page 1-111 for the column representing the position of each body segment.

Data Types: `double`

### `BPVEL` — Velocity of body segments

real-valued 3-by-16 matrix

Velocity of body segments, returned as a real-valued 3-by-16 matrix. Each column represents the Cartesian velocity vector, `[vx;vy;vz]`, of one of 16 body segments. Units are in meters per second. See "Body Segment Indices" on page 1-111 for the column representing the velocity of each body segment.

Data Types: `double`

### `BPAX` — Orientation of body segments

real-valued 3-by-3-by-16 array

Orientation axes of body segments, returned as a real-valued 3-by-3-by-16 array. Each page represents the 3-by-3 orientation axes of one of 16 body segments. Units are dimensionless. See "Body Segment Indices" on page 1-111 for the page representing the orientation of each body segment.

Data Types: `double`

# More About

## Body Segment Indices

Body segment indices define which columns in BPPOS and BPVEL contain the position and velocity data for a specific body segment. The indices also point to the page of BPAX containing the orientation matrix for a specific body segment. For example, column three of BPPOS contains the 3-D position of the left lower leg. Page three of BPAX contains the orientation matrix of the left lower leg.

**Body Segment Indices**

| Body segment | Body segment index |
|---|---|
| left foot | 1 |
| right foot | 2 |
| left lower leg | 3 |
| right lower leg | 4 |
| left upper leg | 5 |
| right upper leg | 6 |
| left hip | 7 |
| right hip | 8 |
| left lower arm | 9 |
| right lower arm | 10 |
| left upper arm | 11 |
| right upper arm | 12 |
| left shoulder | 13 |
| right shoulder | 14 |
| neck | 15 |
| head | 16 |

# reflect

Reflected signal from walking pedestrian

## Syntax

```
Y = reflect(pedestrian,X,ANG)
```

## Description

`Y = reflect(pedestrian,X,ANG)` returns the reflected signal, `Y`, from incident signals, `X`, on a pedestrian. The reflected signal is the sum of signals from all body segments. `ANG` defines the directions of the incident and reflected signals with respect to the body segments.

## Input Arguments

### `pedestrian` — Pedestrian target

`backscatterPedestrian` object

Pedestrian target model, specified as a `backscatterPedestrian` object.

### `X` — Incident radar signals

complex-valued *M*-by-16 matrix

Incident radar signals on each body segment, specified as a complex-valued *M*-by-16 matrix. *M* is the number of samples in the signal. See “Body Segment Indices” on page 1-114 for the column representing the incident signal at each body segment.

Data Types: `double`
Complex Number Support: Yes

### `ANG` — Directions of incident signals

real-valued 2-by-16 matrix

Directions of incident signals on the body segments, specified as a real-valued 2-by-16 matrix. Each column of `ANG` specifies the incident direction of the signal to the corresponding body part. Each column takes the form of an azimuth-elevation pair, `[AzimuthAngle;ElevationAngle]`. Units are in degrees. See "Body Segment Indices" on page 1-114 for the column representing the incident direction at each body segment.

Data Types: `double`

## Output Arguments

**Y — Combined reflected radar signals**
complex-valued *M*-by-1 column vector

Combined reflected radar signals, returned as a complex-valued *M*-by-1 column vector. *M* equals the same number of samples as in the input signal, `X`.

Data Types: `double`
Complex Number Support: Yes

## More About

### Body Segment Indices

Body segment indices define which columns in `X` and `ANG` contain the data for a specific body segment. For example, column 3 of `X` contains sample data for the left lower leg. Column 3 of `ANG` contains the arrival angle of the signal at the left lower leg.

# plot

Display stick figure showing the positions of all body segments of pedestrian

## Syntax

```
plot(pedestrian)
fhndl = plot(pedestrian)
```

## Description

`plot(pedestrian)` displays a stick figure showing the positions of all body segments of a pedestrian. The lines of the figure represent body segments while the dots represent the joints connecting body segments.

`fhndl = plot(pedestrian)` returns the figure handle of the display window.

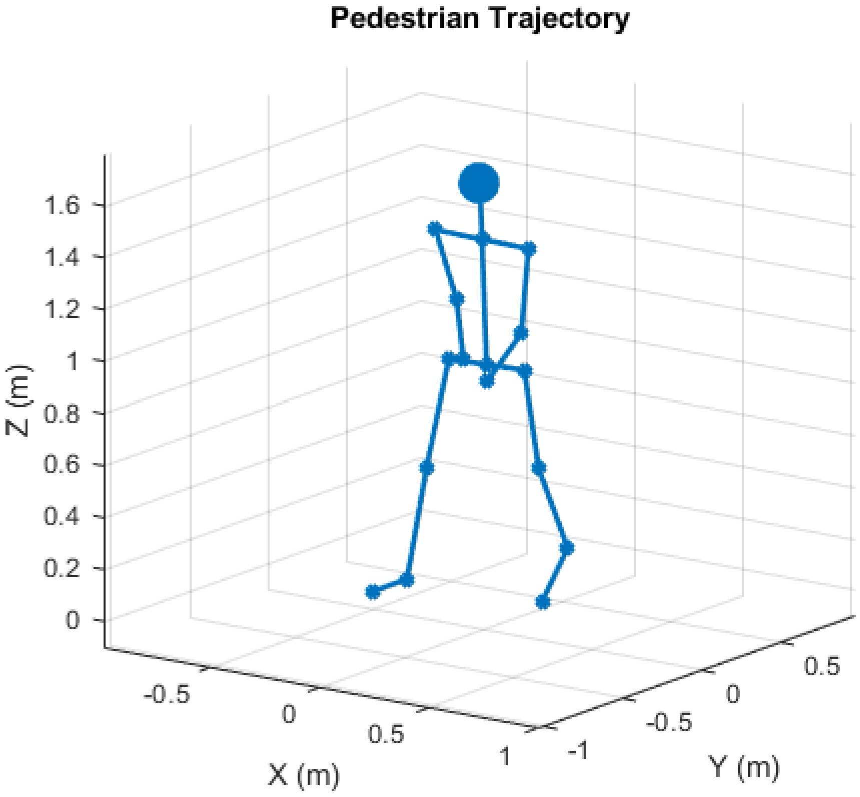
## Examples

### Plot Pedestrian Motion

Display the motion of a pedestrian walking a square path. Create the pedestrian using a `phased.BackscatterPedestrian` object with default values except for height which is 1.7 meters. Advance and display the pedestrian position every 3 milliseconds. First, the pedestrian moves along the positive *x*-axis, then along the positive *y*-axis, along the negative *x*-axis, and finally along the negative *y*-axis to return to the starting point.

```
ped = phased.BackscatterPedestrian('Height',1.7);
dt = 0.003;
N = 3600;
for m = 1:N
    if (m < N/4)
        angstep = 0.0;
    end
    if (m >= N/4)
```

```
            angstep = 90.0;
        end
        if (m >= N/2)
            angstep = 180.0;
        end
        if (m >= 3*N/4)
            angstep = 270.0;
        end
        move(ped,dt,angstep);
        plot(ped)
    end
```



# Input Arguments

**`pedestrian` — Pedestrian target**
`backscatterPedestrian` object

Pedestrian target, specified as a `backscatterPedestrian` object.

# Output Arguments

**`fhndl` — figure handle**
figure handle

Figure handle of plot window

# phased.BackscatterRadarTarget

**Package:** phased

Backscatter radar target

## Description

The phased.BackscatterRadarTarget System object models the backscattering of a signal from a target. Backscattering is a special case of radar target scattering when the incident and reflected angles are the same. This type of scattering applies to monostatic radar configurations. The radar cross-section determines the backscattering response of a target to an incoming signal. This System object lets you specify an angle-dependent radar cross-section model that covers a range of incident angles.

The phased.BackscatterRadarTarget System object creates a backscattered signal for polarized and nonpolarized signals. While electromagnetic radar signals are polarized, you can often ignore polarization in your simulation and process the signals as scalar signals. To ignore polarization, specify the EnablePolarization property as false. To employ polarization, specify the EnablePolarization property as true.

For nonpolarized signals, you specify the radar cross section as an array of radar cross-section (RCS) values at discrete azimuth and elevation points. The System object interpolates values for incident angles between array points. For polarized signals, you specify the *radar scattering matrix* using three arrays defined at discrete azimuth and elevation points. These three arrays correspond to the *HH*, *HV*, and *VV* polarization components. The *VH* component is computed from the conjugate symmetry of the *HV* component.

For both nonpolarized and polarized signal cases, you can employ one of four Swerling models to generate random fluctuations in the RCS or radar scattering matrix. Choose the model using the Model property. Then, use the SeedSource and Seed properties to control the fluctuations.

| EnablePolarization | Use these properties |
|---|---|
| false | RCSPattern |

| **EnablePolarization** | **Use these properties** |
|---|---|
| true | ShhPattern, SvvPattern, and ShvPattern |

To model a backscattered radar signal:

1. Define and set up your radar target. You can set phased.BackscatterRadarTarget System object properties at construction time or leave them to their default values. See “Construction” on page 1-125. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the reflected signal, call the step method of phased.BackscatterRadarTarget. The output of the method depends on the properties of the phased.BackscatterRadarTarget System object. You can change tunable properties at any time.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

target = phased.BackscatterRadarTarget creates a backscatter radar target System object, target.

target = phased.BackscatterRadarTarget(Name,Value) creates a backscatter radar target System object, target, with each specified property Name set to the specified Value. You can specify additional name and value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### EnablePolarization — Enable polarized signals

false (default) | true

Option to enable processing of polarized signals, specified as `false` or `true`. Set this property to `true` to allow the target to simulate the reflection of polarized radiation. Set this property to `false` to ignore polarization.

Example: `true`

Data Types: `logical`

### `AzimuthAngles` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the azimuth angles as a length *P* vector. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

### `ElevationAngles` — Elevation angles

`[-90:90]` (default) | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the elevation angles as a length *Q* vector. *Q* must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

### `RCSPattern` — Radar cross-section pattern

`ones(181,361)` (default) | *Q*-by-*P* real-valued matrix | *Q*-by-*P*-by-*M* real-valued array | 1-by-*P* real-valued vector | *M*-by-*P* real-valued matrix

Radar cross-section (RCS) pattern, specified as a *Q*-by-*P* real-valued matrix or a *Q*-by-*P*-by-*M* real-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the `step` method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Pattern units are square-meters.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `false`.

Example: `[1,.5;.5,1]`

Data Types: `double`

### `ShhPattern` — Radar-scattering matrix *HH* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar scattering matrix *HH* polarization component, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the `step` method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Scattering matrix units are meters.

You can also specify the pattern as a function only of azimuth for a single elevation. Then, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `true`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

### `SvvPattern` — Radar scattering matrix *VV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar scattering matrix *VV* polarization component, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the `step` method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Scattering matrix units are meters.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `true`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

### `ShvPattern` — Radar scattering matrix *HV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar scattering matrix *HV* polarization component, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the `step` method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Scattering matrix units are meters.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `true`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

### `Model` — Target fluctuation model

`'Nonfluctuating'` (default) | `'Swerling1'` | `'Swerling2'` | `'Swerling3'` | `'Swerling4'`

Target fluctuation model, specified as `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, use the `update` input argument when calling `step`.

Example: `'Swerling3'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

physconst('LightSpeed') (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by physconst('LightSpeed'). See physconst for more information.

Example: 3e8

Data Types: double

### OperatingFrequency — Operating frequency

300e6 (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: 1e9

Data Types: double

### SeedSource — Seed source of random number generator for RCS fluctuation model

'Auto' (default) | 'Property'

Seed source of random number generator for RCS fluctuation model, specified as 'Auto' or 'Property'. When you set this property to 'Auto', the System object generates random numbers using the default MATLAB random number generator. When you set this property to 'Property', you specify the random number generator seed using the Seed property. This property applies when you set the Model property to'Swerling1', 'Swerling2', 'Swerling3', or 'Swerling4'. When you use this object with Parallel Computing Toolbox™ software, you set this property to 'Auto'.

Example: 'Property'

Data Types: char

### Seed — Random number generator seed

0 (default) | nonnegative integer less than $2^{32}$

Random number generator seed, specified as a nonnegative integer less than $2^{32}$. This property applies when the SeedSource property is set to 'Property'.

Example: 32301

Data Types: double

# Examples

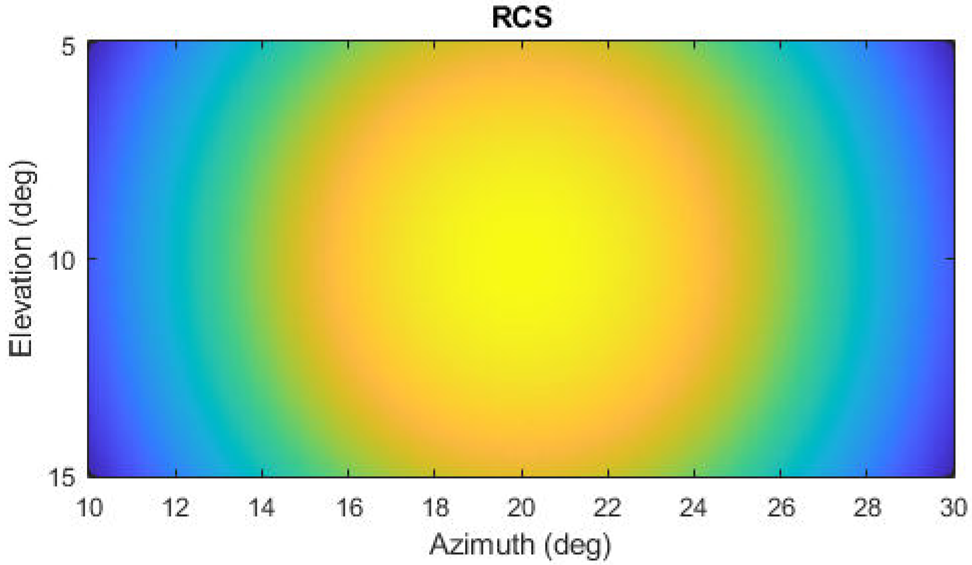
### Backscatter Nonpolarized Signal

Calculate the reflected radar signal from a nonfluctuating point target with a peak RCS of 10.0 $m^2$. Use a simplified expression of an RCS pattern of a target for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid at 1 MHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

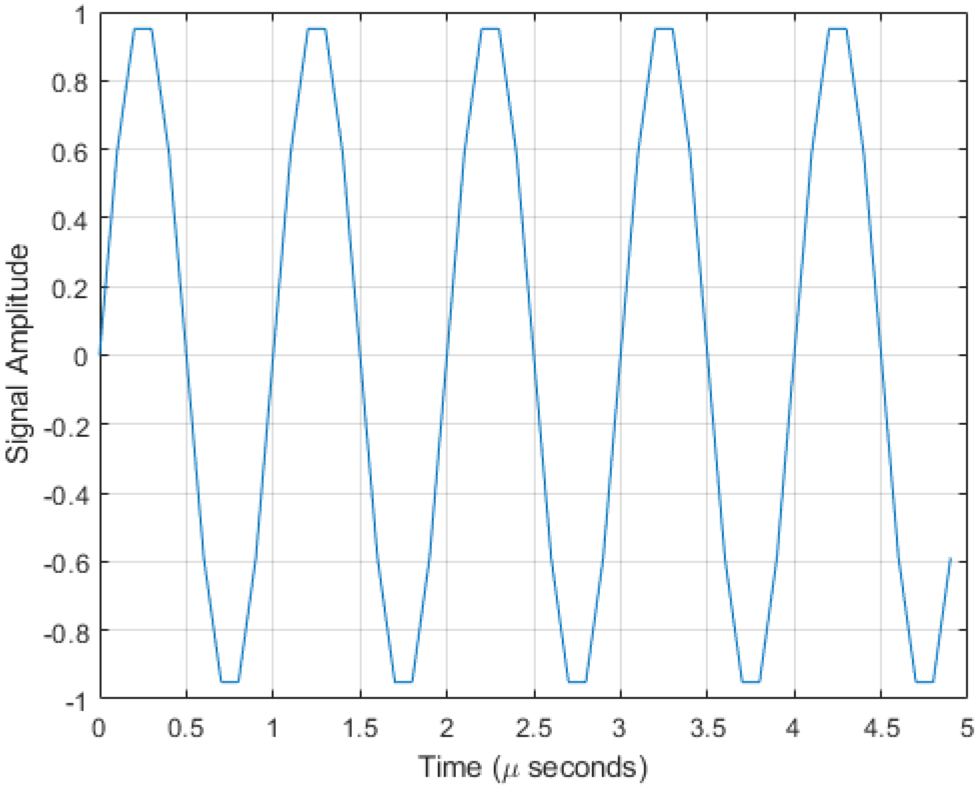
Create and plot the RCS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:30.0];
elpatangs = [5.0:0.1:15.0];
rcspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
imagesc(azpatangs,elpatangs,rcspattern)
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the radar signal.

```
foper = 1.0e9;
freq = 1.0e6;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```



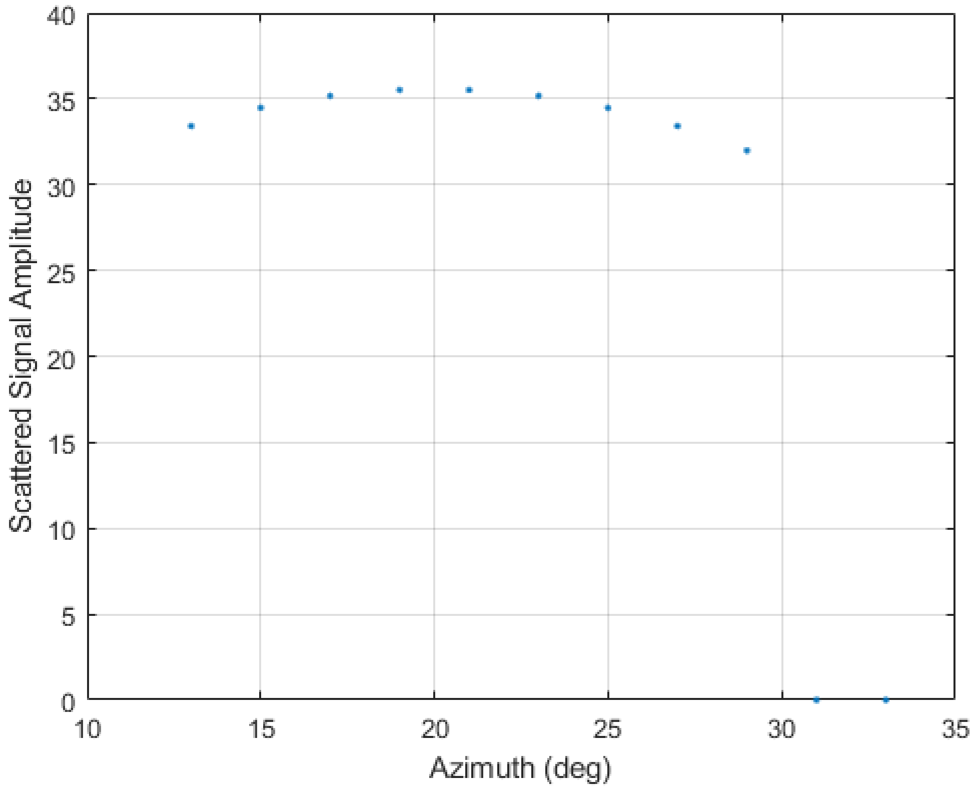
Create the `phased.BackscatterRadarTarget` System object™.

```
target = phased.BackscatterRadarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'RCSPattern',rcspattern,'OperatingFrequency',foper);
```

For a sequence of incident angles at constant elevation angle, find and plot the scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:2:20];
naz = length(az);
```

```
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



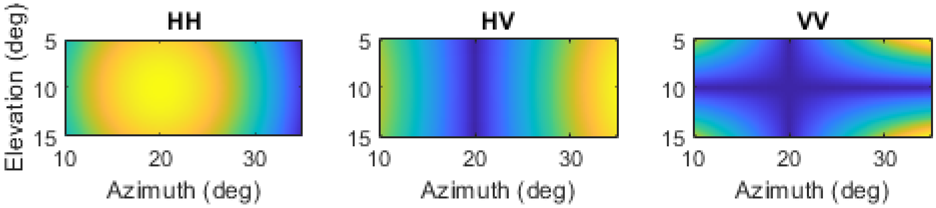
### Backscatter Polarized Signal

Calculate the polarized radar signal scattered from a Swerling1 fluctuating point target. Assume the target axis is rotated from the global coordinate system. Use simple expressions for the scattering patterns for illustration. Real scattering patterns are more complicated. For polarized signals, you need to specify the *HH*, *HV*, and *VV* components of the scattering matrix for a range of incident angles. In this example, the patterns cover the range 10°–30° in azimuth and 5°–15° in elevation. Angles are with respect to the target local coordinate system. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid with a frequency of 1 MHz. The incident angle is 13.0° azimuth and 14.0° elevation with respect to the target orientation.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create and plot the scattering matrix patterns.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
shhpat = cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
shvpat = 1i*cosd(4*(elpatangs - elmax))'*sind(4*(azpatangs - azmax));
svvpat = sind(4*(elpatangs - elmax))'*sind(4*(azpatangs - azmax));
subplot(1,3,1)
imagesc(azpatangs,elpatangs,abs(shhpat))
axis image
axis tight
title('HH')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
subplot(1,3,2)
imagesc(azpatangs,elpatangs,abs(shvpat))
axis image
axis tight
title('HV')
xlabel('Azimuth (deg)')
subplot(1,3,3)
imagesc(azpatangs,elpatangs,abs(svvpat))
axis image
axis tight
title('VV')
xlabel('Azimuth (deg)')
```



Create the `phased.BackscatterRadarTarget` System object™.

```
target = phased.BackscatterRadarTarget('EnablePolarization',true,...
    'Model','Swerling1','AzimuthAngles',azpatangs,...
    'ElevationAngles',elpatangs,'ShhPattern',shhpat,'ShvPattern',shvpat,...
    'SvvPattern',svvpat);
```

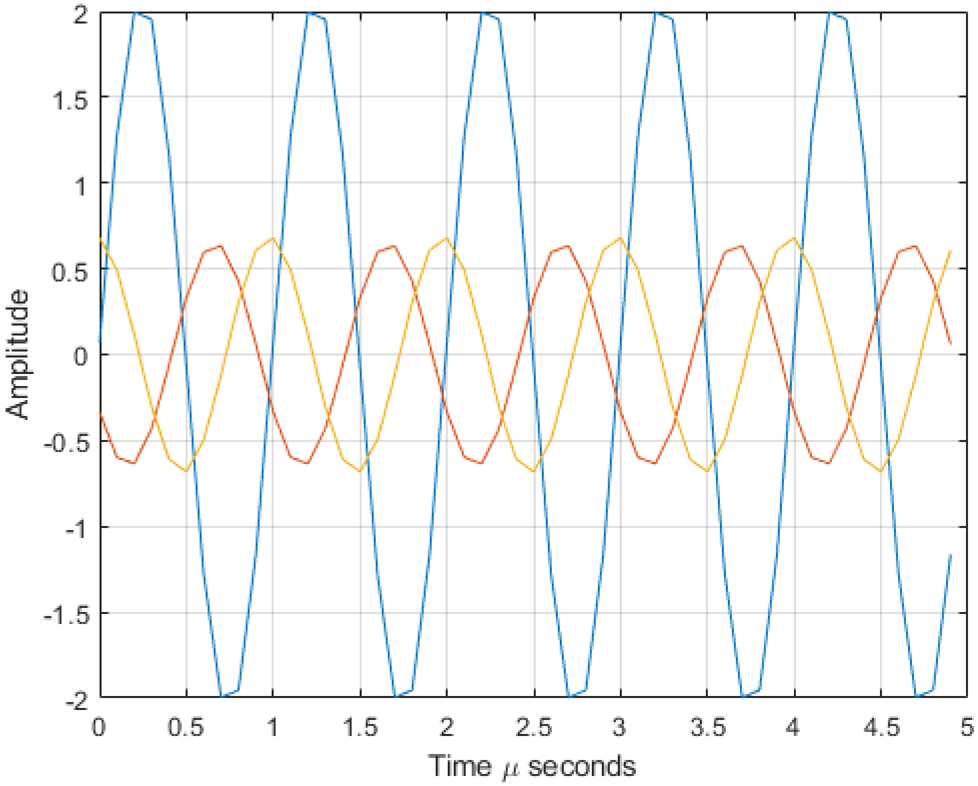
Generate 50 samples of a polarized radar signal.

```
foper = 1.0e9;
freq = 1.0e6;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
```

```
signal.X = exp(1i*2*pi*freq*t);
signal.Y = exp(1i*2*pi*freq*t + pi/3);
signal.Z = zeros(size(signal.X));
tgtaxes = azelaxes(60,10);
ang = [13.0;14.0];
```

Reflect the signal from the target and plot its components.

```
refl_signal = target(signal,ang,tgtaxes,true);
figure
plot(t*1e6,real(refl_signal.X))
hold on
plot(t*1e6,real(refl_signal.Y))
plot(t*1e6,real(refl_signal.Z))
hold off
xlabel('Time \mu seconds')
ylabel('Amplitude')
grid
```



# More About

## Backscattered Radiation

For a narrowband nonpolarized signal, the reflected signal, $Y$, is

$$Y = \sqrt{G} \cdot X,$$

where:

- $X$ is the incoming signal.
- $G$ is the target gain factor, a dimensionless quantity given by

  $$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, $X$, is replaced by a vector signal, $(E_H, E_V)$, with horizontal and vertical components. The scattering matrix, $S$, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see [1] or [2].

“Swerling Target Models”

**Introduced in R2016a**

# reset

**System object:** `phased.BackscatterRadarTarget`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(sBSTgt)
```

## Description

`reset(sBSTgt)` resets the internal state of the `phased.BackscatterRadarTarget` object, `sBSTgt`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

## Input Arguments

**`sBSTgt` — Backscatter radar target**
System object

Backscatter radar target, specified as a System object.

Example: `phased.BackscatterRadarTarget`

**Introduced in R2016a**

# step

**System object:** `phased.BackscatterRadarTarget`
**Package:** `phased`

Backscatter incoming signal

## Syntax

```
refl_sig = step(target,sig,ang)
refl_sig = step(target,sig,ang,update)

refl_sig = step(target,sig,ang,laxes)
refl_sig = step(target,sig,ang,laxes,update)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`refl_sig = step(target,sig,ang)` returns the reflected signal, `refl_sig`, of an incident nonpolarized signal, `sig`, arriving at the target from the angle, `ang`. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to `'Nonfluctuating'`. In this case, the values specified in the `RCSPattern` property are used to compute the RCS values for the incident and reflected directions, `ang`.

`refl_sig = step(target,sig,ang,update)` uses `update` to control whether to update the RCS values. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to one of the fluctuating RCS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new RCS value is generated. If `update` is `false`, the previous RCS value is used.

refl_sig = step(target,sig,ang,laxes) returns the reflected signal, refl_sig, of an incident polarized signal, sig. The matrix, laxes, specifies the local target coordinate system. This syntax applies when you set EnablePolarization to true and the Model property to 'Nonfluctuating'. The values specified in the ShhPattern, SvvPattern, and ShvPattern properties are used to compute the scattering matrices for the incident and reflected directions, ang.

refl_sig = step(target,sig,ang,laxes,update) uses the update argument to control whether to update the scattering matrix values. This syntax applies when you set the EnablePolarization property to true and the Model property to one of the fluctuating RCS models: 'Swerling1', 'Swerling2', 'Swerling3', or 'Swerling4'. If update is true, a new RCS value is generated. If update is false, the previous RCS value is used.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### target — Backscatter target

System object

Backscatter target, specified as a System object.

Example: phased.BackscatterRadarTarget

### sig — Narrowband signal

*N*-by-*M* complex-valued matrix | *1*-by-*M* struct array containing complex-valued fields

- Narrowband nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix.The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to an independent signal incident at a different reflecting angle.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

- Narrowband polarized signal, specified as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target.

  For polarized fields, the `struct` element contains three *N*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

**ang — Incident signal direction**
*2*-by-*1* positive real-valued column vector | *2*-by-*M* positive real-valued column matrix

Incident signal direction, specified as a *2*-by-*1* positive real-valued column vector or a *2*-by-*M* positive real-valued column matrix. Each column of `ang` specifies the incident direction of the corresponding signal in the form of an `[AzimuthAngle;ElevationAngle]` pair. Units are degrees. The number of columns in `ang` must match the number of independent signals in `sig`.

Example: `[30;45]`

Data Types: `double`

**update — Update RCS**
`false` (default) | `true`

Allow the RCS values for fluctuation models to update, specified as `false` or `true`. When `update` is `true`, a new RCS value is generated with each call to the `step` method. If `update` is `false`, the RCS remains unchanged with each call to `step`.

Example: `true`

Data Types: `logical`

### `laxes` — Local coordinate matrix

`eye(3,3)` (default) | 3-by-3 real-valued orthonormal matrix | 3-by-3-by-*M* real-valued array

Local coordinate system matrix, specified as a 3-by-3 real-valued orthonormal matrix or a 3-by-3-by-*M* real-valued array. The matrix columns specify the local coordinate system orthonormal *x*-axis, *y*-axis, and *z*-axis, respectively. Each axis is a vector of the form *(x;y;z)* with respect to the global coordinate system. When `sig` has only one signal, `laxes` is a 3-by-3 matrix. When `sig` has multiple signals, you can use a single 3-by-3 matrix for multiple signals in `sig`. In this case, all targets have the same local coordinate systems. When you specify `laxes` as a 3-by-3-by-*M* MATLAB array, each page (third index) defines a 3-by-3 local coordinate matrix for the corresponding target.

Example: `[1,0,0;0,0.7071,-0.7071;0,0.7071,0.7071]`

Data Types: `double`

## Output Arguments

### `refl_sig` — Narrowband reflected signal

*N*-by-*M* complex-valued matrix | *1*-by-*M* `struct` array containing complex-valued fields

- Narrowband nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. Each column contains an independent signal reflected from the target.

  The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to a reflecting angle.
- Narrowband polarized signal, specified as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target.

  For polarized fields, the `struct` element contains three *N*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The output `refl_sig` contains signal samples arriving at the signal destination within the current input time frame. When the propagation time from source to destination exceeds the current time frame duration, the output does not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

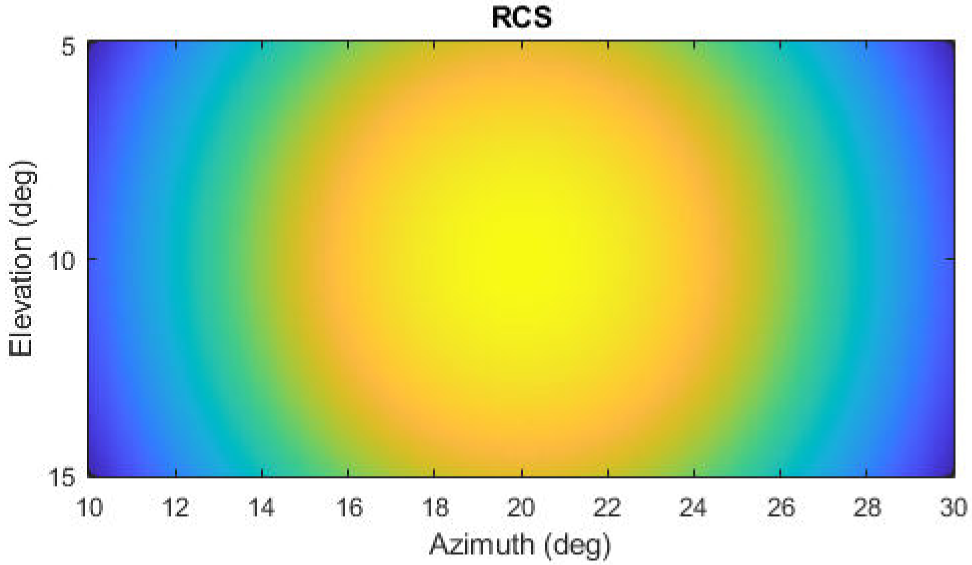
### Backscatter Nonpolarized Signal

Calculate the reflected radar signal from a nonfluctuating point target with a peak RCS of 10.0 $m^2$. Use a simplified expression of an RCS pattern of a target for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid at 1 MHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

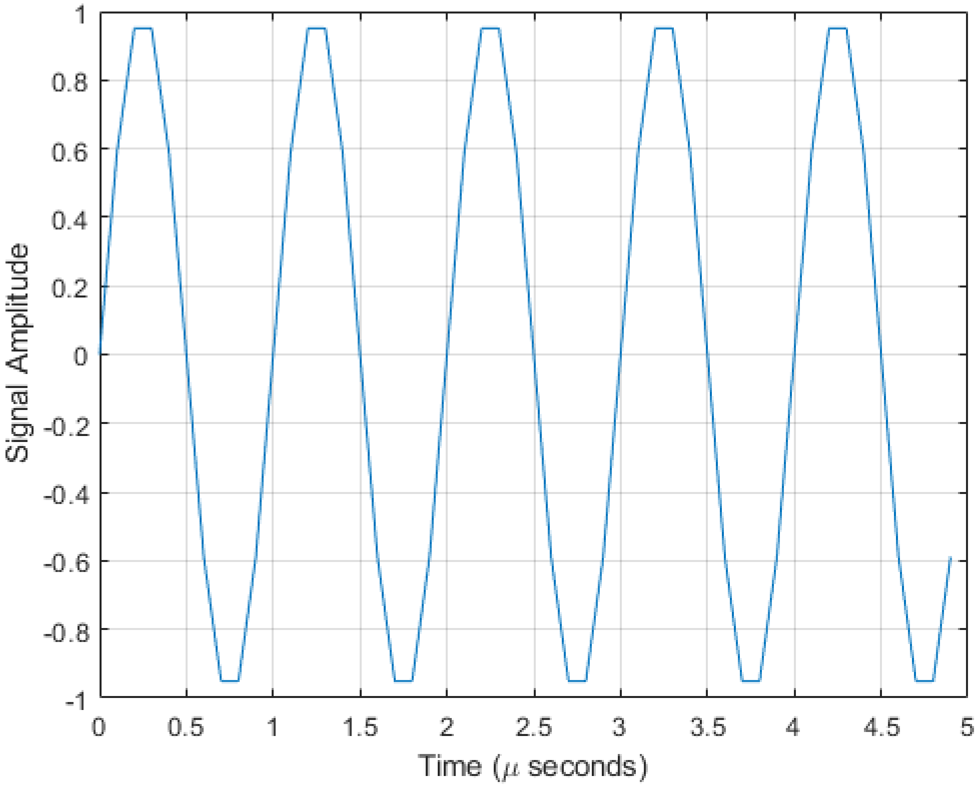
Create and plot the RCS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:30.0];
elpatangs = [5.0:0.1:15.0];
rcspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
imagesc(azpatangs,elpatangs,rcspattern)
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the radar signal.

```
foper = 1.0e9;
freq = 1.0e6;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```



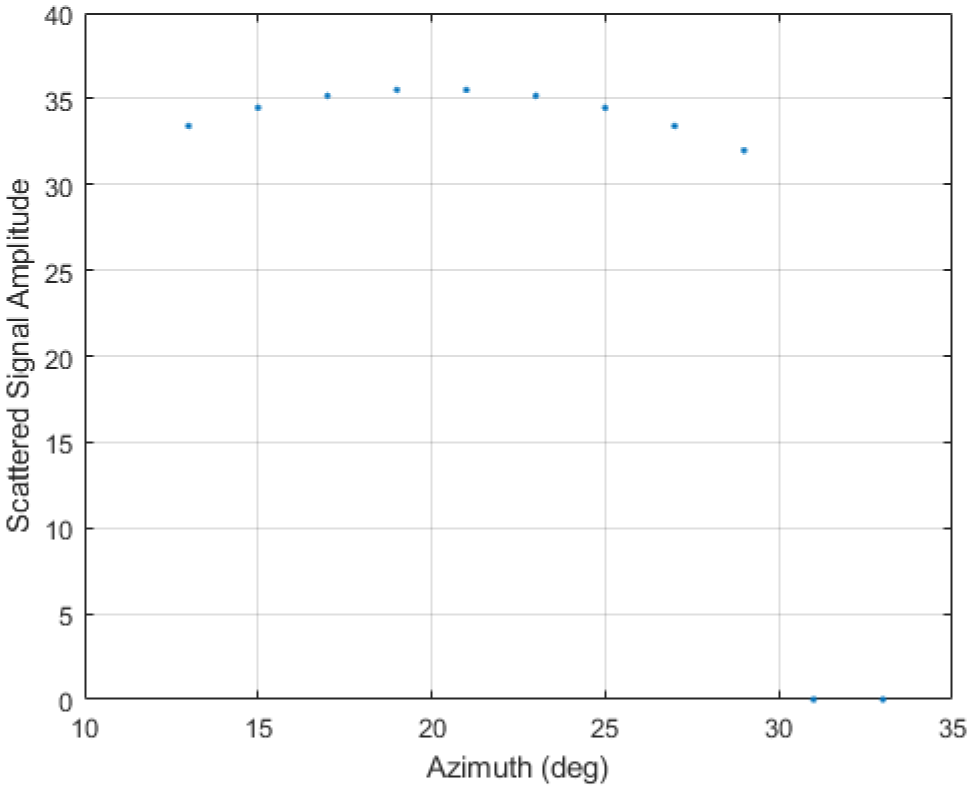
Create the `phased.BackscatterRadarTarget` System object™.

```
target = phased.BackscatterRadarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'RCSPattern',rcspattern,'OperatingFrequency',foper);
```

For a sequence of incident angles at constant elevation angle, find and plot the scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:2:20];
naz = length(az);
```

```
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



### Backscatter Polarized Signal

Calculate the polarized radar signal scattered from a Swerling1 fluctuating point target. Assume the target axis is rotated from the global coordinate system. Use simple expressions for the scattering patterns for illustration. Real scattering patterns are more complicated. For polarized signals, you need to specify the *HH*, *HV*, and *VV* components of the scattering matrix for a range of incident angles. In this example, the patterns cover the range 10°–30° in azimuth and 5°–15° in elevation. Angles are with respect to the target local coordinate system. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid with a frequency of 1 MHz. The incident angle is 13.0° azimuth and 14.0° elevation with respect to the target orientation.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create and plot the scattering matrix patterns.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
shhpat = cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
shvpat = 1i*cosd(4*(elpatangs - elmax))'*sind(4*(azpatangs - azmax));
svvpat = sind(4*(elpatangs - elmax))'*sind(4*(azpatangs - azmax));

**Package:** phased

Sonar target backscatter

## Description

The phased.BackscatterSonarTarget System object models the backscattering of a signal from an underwater or surface target. Backscattering is a special case of sonar target scattering when the incident and reflected angles are the same. This type of scattering applies to monostatic sonar configurations. The sonar target strength (TS) determines the backscattering response of a target to an incoming signal. This object lets you specify an angle-dependent sonar target strength model that covers a range of incident angles.

The object lets you specify the target strength as an array of values at discrete azimuth and elevation points. The object interpolates values for incident angles between array points.

You can employ one of four Swerling models to generate random fluctuations in the target strength. Choose the fluctuation model using the Model property. Then, use the SeedSource and Seed properties to control the fluctuations.

To model a backscattered reflected sonar signal:

1. Define and set up your sonar target. You can set phased.BackscatterSonarTarget System object properties at construction time or leave them to their default values. See “Construction” on page 1-154. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the reflected signal, call the step method of phased.BackscatterSonarTarget. The output of the method depends on the properties of the phased.BackscatterSonarTarget System object. You can change tunable properties at any time.

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`target = phased.BackscatterSonarTarget` creates a backscatter sonar target System object, `target`.

`target = phased.BackscatterSonarTarget(Name,Value)` creates a backscatter sonar target System object, `target`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `AzimuthAngles` — Target strength azimuth angles

`[-180:180]` (default) | real-valued 1-by-*P* row vector | real-valued *P*-by-1 column vector

Target strength azimuth angles, specified as a real-valued 1-by-*P* row vector or *P*-by-1 column vector. These angles define the azimuth coordinates of each column of the matrix specified by the `TSPattern` property. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

### `ElevationAngles` — Elevation angles

`[-90:90]` (default) | real-valued 1-by-*Q* row vector | real-valued *Q*-by-1 column vector

Target strength elevation angles, specified as a real-valued 1-by-*Q* row vector or *Q*-by-1 column vector. These angles define the elevation coordinates of each row of the matrix specified by the `TSPattern` property. *Q* must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

### `TSPattern` — Sonar target strength pattern

`zeros(181,361)` (default) | *Q*-by-*P* real-valued matrix | *Q*-by-*P*-by-*M* real-valued array | 1-by-*P* real-valued vector | *M*-by-*P* real-valued matrix

Sonar target strength (TS) pattern, specified as a real-valued *Q*-by-*P* matrix or *Q*-by-*P*-by-*M* array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the `step` method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Pattern units are dB.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

Example: `[1,2;3,4]`

Data Types: `double`

### `Model` — Target fluctuation model

`'Nonfluctuating'` (default) | `'Swerling1'` | `'Swerling2'` | `'Swerling3'` | `'Swerling4'`

Target fluctuation model, specified as `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, use the `update` input argument when calling the `step` method.

Example: `'Swerling3'`

Data Types: `char`

### `SeedSource` — Seed source of random number generator for TS fluctuation model

`'Auto'` (default) | `'Property'`

Seed source of random number generator for TS fluctuation model, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the System object generates random numbers using the default MATLAB random number generator. When you set this property to `'Property'`, you specify the random number generator seed using the `Seed` property. This property applies when you set the `Model` property to`'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4`'. When you use this object with Parallel Computing Toolbox software, you set this property to `'Auto'`.

Example: `'Property'`

Data Types: `char`

**Seed — Random number generator seed**
`0` (default) | nonnegative integer less than $2^{32}$

Random number generator seed, specified as a nonnegative integer less than $2^{32}$.

Example: `32301`

**Dependencies**

To enable this property, set the `SeedSource` property to `'Property'`.

Data Types: `double`

## Methods

| | |
|---|---|
| reset | Reset states of System object |
| step | Backscatter incoming sonar signal |

| Common to All System Objects | |

| `release` | Allow System object property value changes |

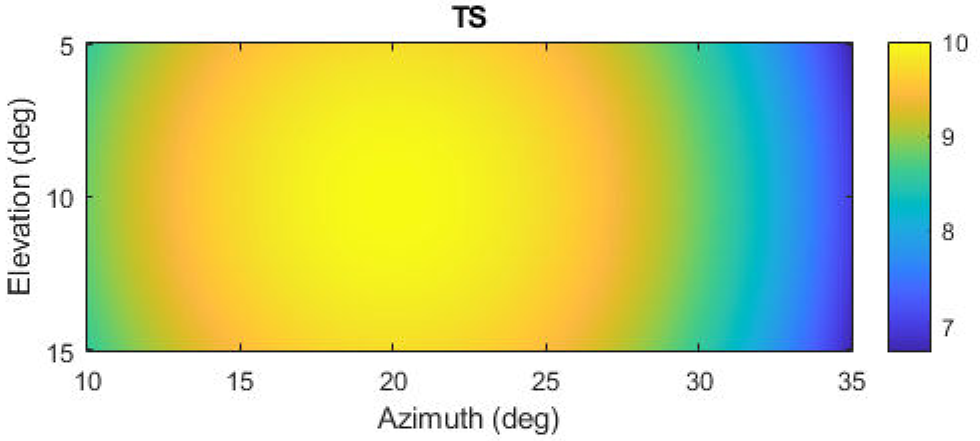
## Examples

### Backscatter Sonar Signal from Nonfluctuating Target

Calculate the reflected sonar signal from a nonfluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10° to 30° in azimuth and from 5° to 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

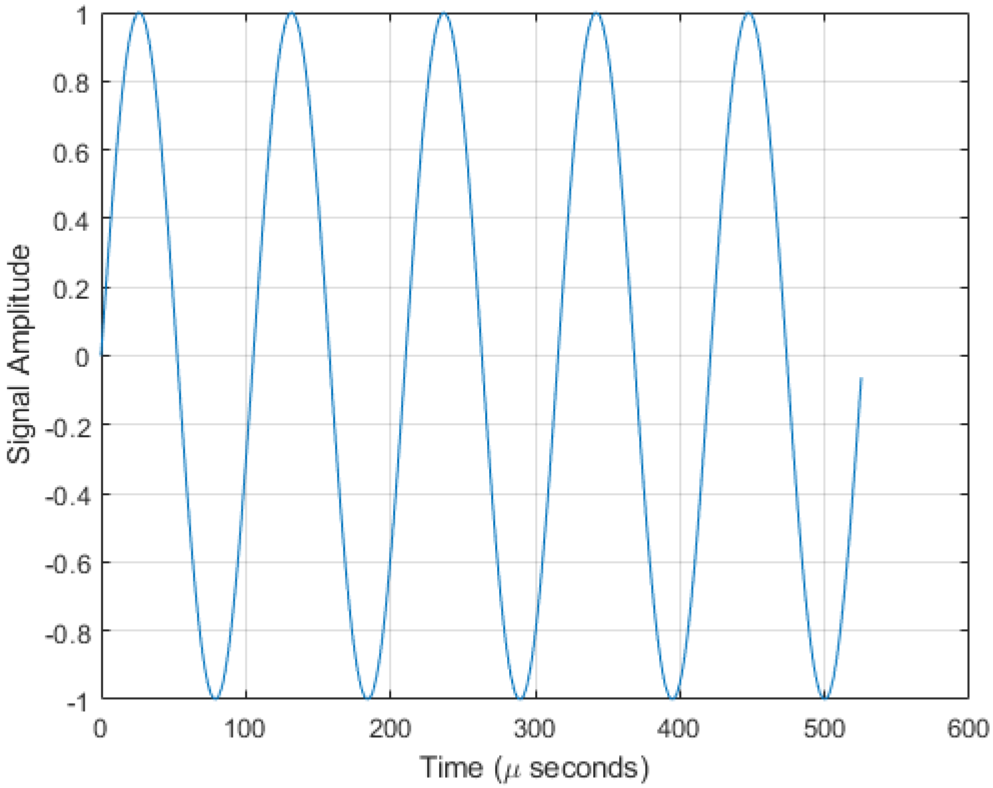
Create and plot the TS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the sonar signal.

```
freq = 9.5e3;
fs = 100*freq;
nsamp = 500;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```

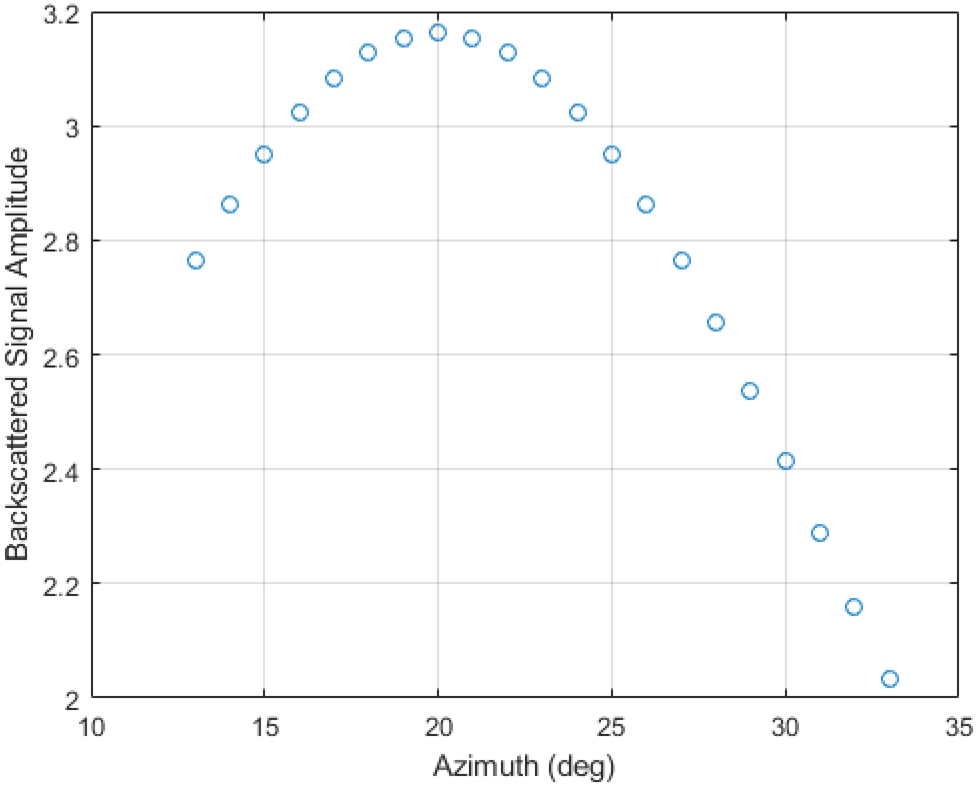


Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs, ...
    'TSPattern',tspattern);
```

For a sequence of different azimuth incident angles (at constant elevation angle), plot the maximum scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:1:20];
naz = length(az);
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'o')
xlabel('Azimuth (deg)')
ylabel('Backscattered Signal Amplitude')
grid
```

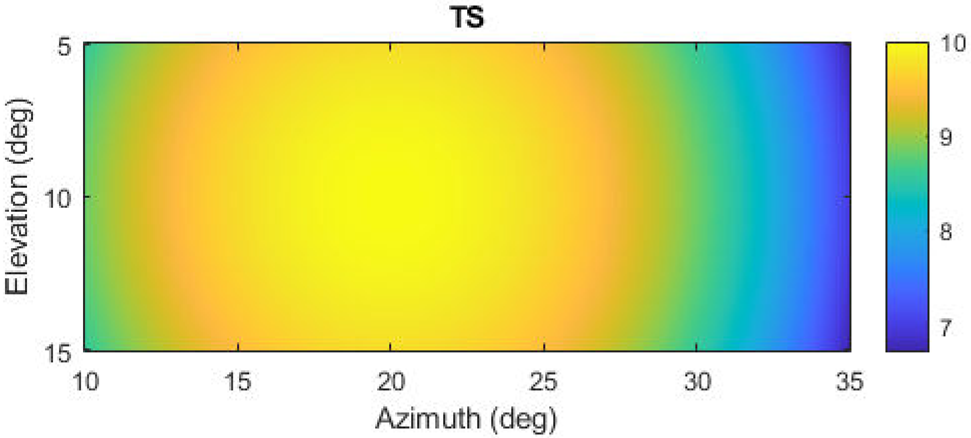


### Backscatter Sonar Signal from Fluctuating Target

Calculate the reflected sonar signal from a Swerling2 fluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10°to 30° in azimuth and from 5° ro 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate the sonar signal.

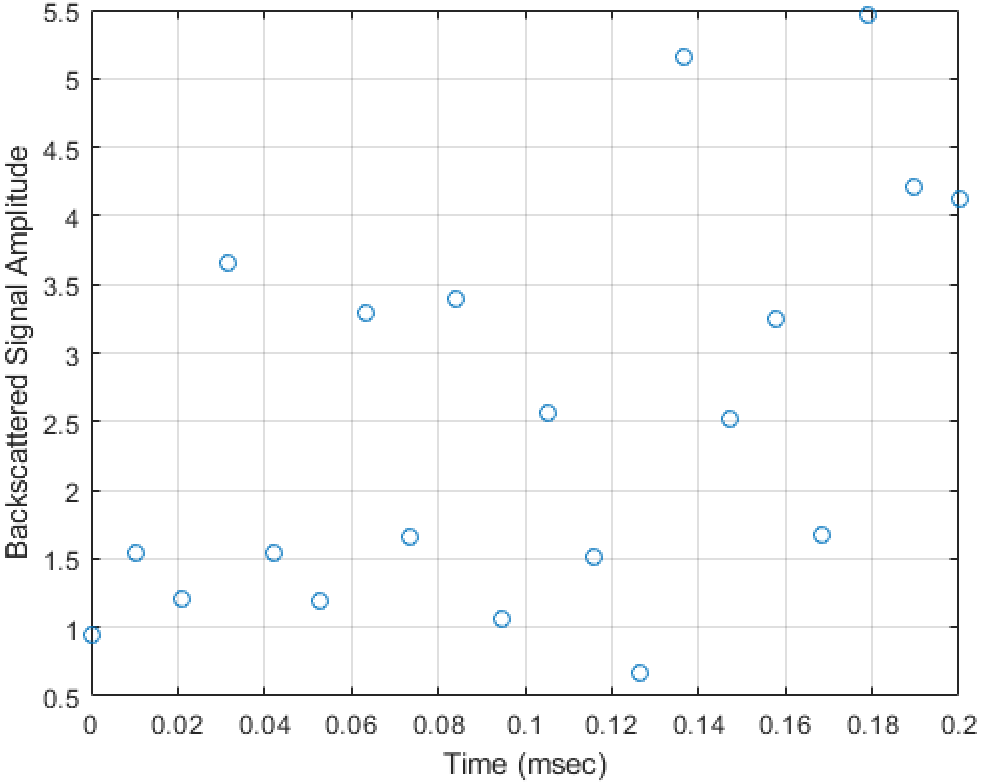
```
freq = 9.5e3;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
```

Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'TSPattern',tspattern,'Model','Swerling2');
```

Compute and plot the fluctuating signal amplitude for 20 time steps.

```
az = 20.0;
el = 10.0;
nsteps = 20;
ss = zeros(1,nsteps);
for k = 1:nsteps
    y = target(sig,[az;el],true);
    ss(k) = max(abs(y));
end
plot([0:(nsteps-1)]*1000/fs,ss,'o')
xlabel('Time (msec)')
ylabel('Backscattered Signal Amplitude')
grid
```



# More About

## Backscattered Sound Radiation

For narrowband acoustic signals, the reflected signal, $Y$, is given by

$$Y = \sqrt{G} \cdot X,$$

where

- *X* is the incoming signal.
- *G* is the target gain factor given by $10^{TS/10}$ where *TS* is the target strength in dB. Specify target strength using the `TSPattern` property.

For a more detailed explanation of target strength, see “[1] [2]” on page 1-164.

**Introduced in R2017a**

# reset

**System object:** `phased.BackscatterSonarTarget`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(target)
```

## Description

`reset(target)` resets the internal state of the `phased.BackscatterSonarTarget` object, `target`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

## Input Arguments

**`target` — Backscatter sonar target**
`phased.BackscatterSonarTarget` System object

Backscatter sonar target, specified as a `phased.BackscatterSonarTarget` System object.

Example: `phased.BackscatterSonarTarget`

**Introduced in R2017a**

# step

**System object:** `phased.BackscatterSonarTarget`
**Package:** `phased`

Backscatter incoming sonar signal

## Syntax

```
refl_sig = step(target,sig,ang)
refl_sig = step(target,sig,ang,update)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`refl_sig = step(target,sig,ang)` returns the reflected signal, `refl_sig`, of an incident sonar signal, `sig`, arriving at the target from the angle, `ang`.

`refl_sig = step(target,sig,ang,update)` uses `update` to control whether to update the target strength (TS) values. This syntax applies when you set the `Model` property to one of the fluctuating TS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new TS value is generated. If `update` is `false`, the previous TS value is used.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`target` — Backscatter sonar target**
`phased.BackscatterSonarTarget` System object

Backscatter sonar target, specified as a `phased.BackscatterSonarTarget` System object.

**`sig` — Sonar signal**
*N*-by-*M* complex-valued matrix

Sonar signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to an independent signal incident at a different reflecting angle.

When you specify the `TSPattern` property as a *Q*-by-*P*-by-*M*, a separate pattern is used for each signal. When you specify `TSPattern` as a *Q*-by-*P*matrix, the same pattern is used for every signal.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

**ang — Incident signal direction**
*2*-by-*1* positive real-valued column vector | *2*-by-*M* positive real-valued column matrix

Incident signal direction, specified as a *2*-by-*1* positive real-valued column vector or a *2*-by-*M* positive real-valued column matrix. Each column of `ang` specifies the incident direction of the corresponding signal in the form of an `[AzimuthAngle;ElevationAngle]` pair. Units are degrees. The number of columns in `ang` must match the number of independent signals in `sig`.

Example: `[30;45]`

Data Types: `double`

**`update` — Update target strength**
`false` (default) | `true`

Allow the TS values for fluctuation models to update, specified as `false` or `true`. When `update` is `true`, a new TS value is generated with each call to the `step` method. If `update` is `false`, TS remains unchanged with each call to `step`.

Example: `true`

Data Types: `logical`

# Output Arguments

**`refl_sig` — Narrowband reflected sonar signal**
*N*-by-*M* complex-valued matrix

Narrowband reflected sonar signal, specified as an *N*-by-*M* complex-valued matrix. Each column contains an independent signal reflected from the target.

The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to a reflecting angle.

The output `refl_sig` contains signal samples arriving at the signal destination within the current input time frame. When the propagation time from source to destination exceeds the current time frame duration, the output will not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

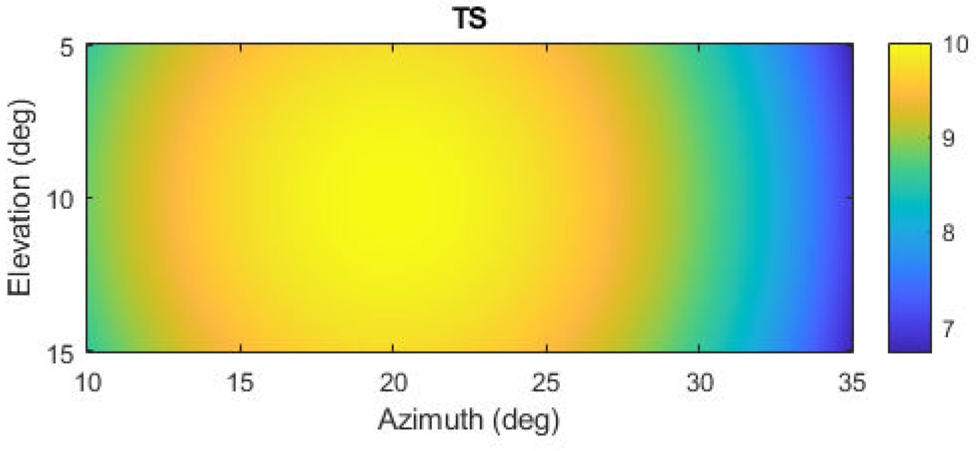
### Backscatter Sonar Signal from Nonfluctuating Target

Calculate the reflected sonar signal from a nonfluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10° to 30° in azimuth and from 5° to 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

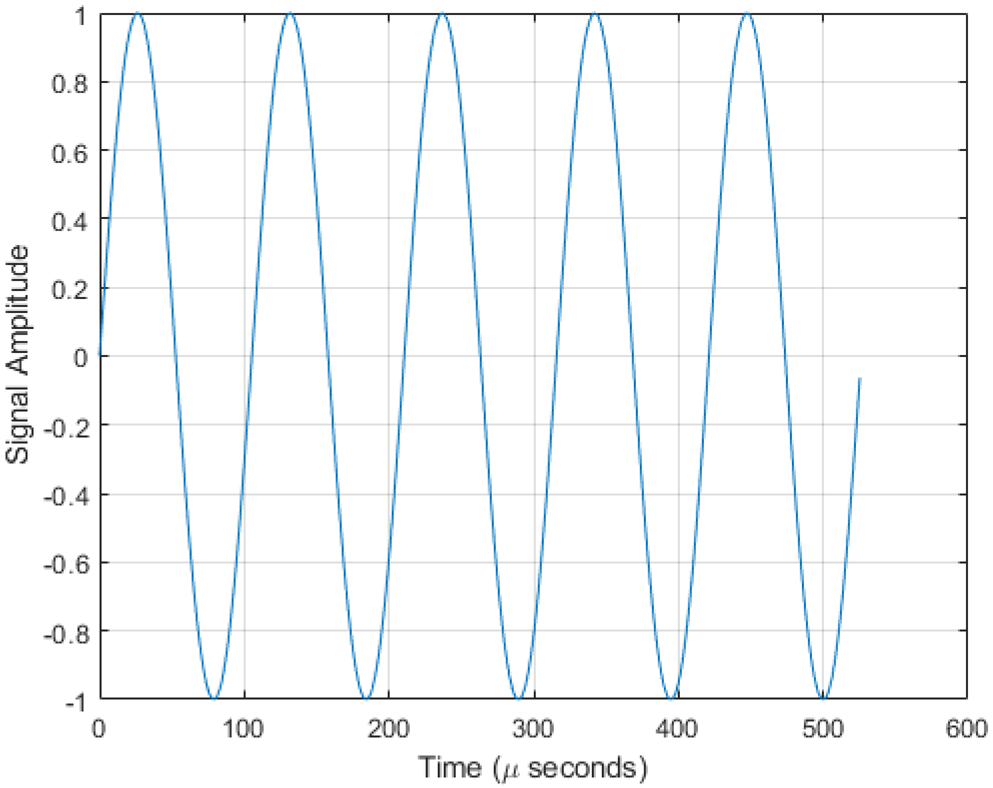
```
azmax = 20.0;
elmax = 10.0;
```

```
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the sonar signal.

```
freq = 9.5e3;
fs = 100*freq;
nsamp = 500;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```

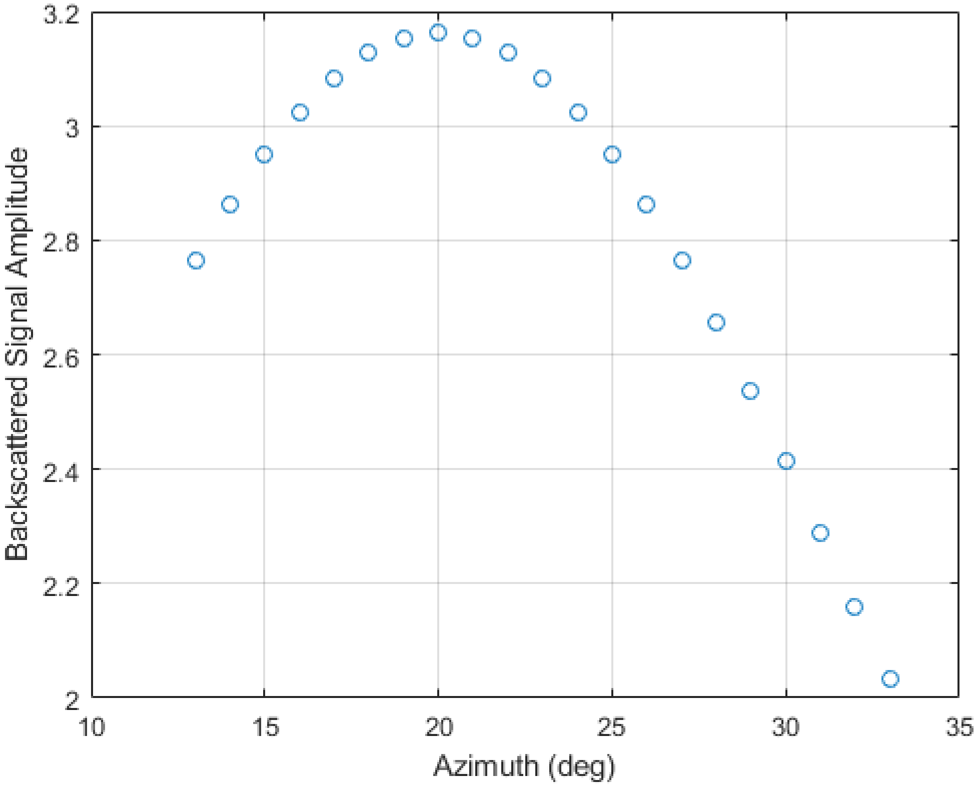


Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs, ...
    'TSPattern',tspattern);
```

For a sequence of different azimuth incident angles (at constant elevation angle), plot the maximum scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:1:20];
naz = length(az);
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'o')
xlabel('Azimuth (deg)')
ylabel('Backscattered Signal Amplitude')
grid
```

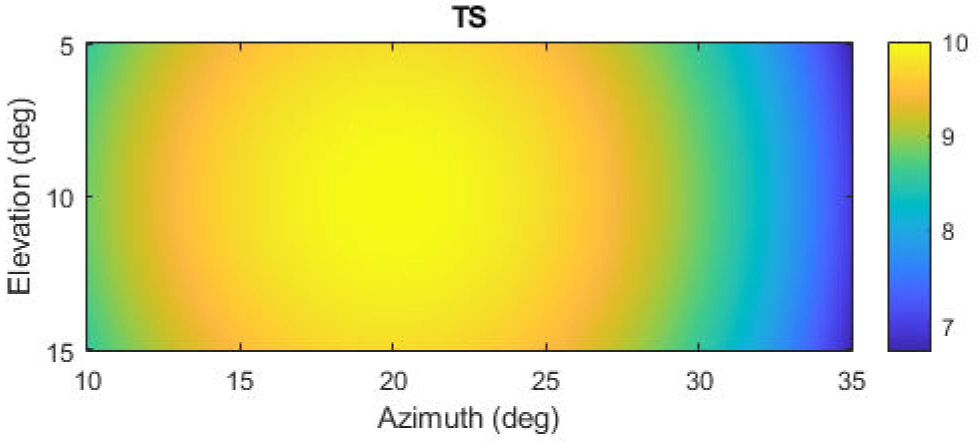


### Backscatter Sonar Signal from Fluctuating Target

Calculate the reflected sonar signal from a Swerling2 fluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10°to 30° in azimuth and from 5° ro 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate the sonar signal.

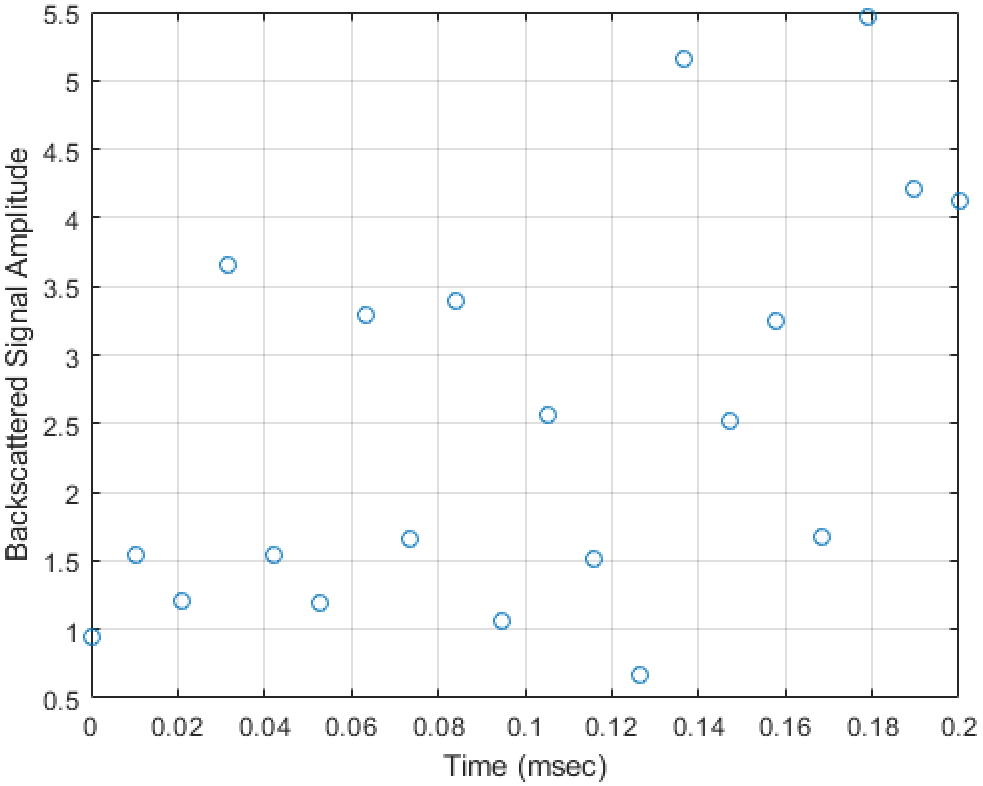
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'TSPattern',tspattern,'Model','Swerling2');
```

Compute and plot the fluctuating signal amplitude for 20 time steps.

```
az = 20.0;
el = 10.0;
nsteps = 20;
ss = zeros(1,nsteps);
for k = 1:nsteps
    y = target(sig,[az;el],true);
    ss(k) = max(abs(y));
end
plot([0:(nsteps-1)]*1000/fs,ss,'o')
xlabel('Time (msec)')
ylabel('Backscattered Signal Amplitude')
grid
```



**Introduced in R2017a**

# phased.BarrageJammer

**Package:** phased

Barrage jammer

## Description

The BarrageJammer object implements a white Gaussian noise jammer.

To obtain the jamming signal:

1. Define and set up your barrage jammer. See "Construction" on page 1-177.
2. Call step to compute the jammer output according to the properties of phased.BarrageJammer. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.BarrageJammer creates a barrage jammer System object, H. This object generates a complex white Gaussian noise jamming signal.

H = phased.BarrageJammer(Name,Value) creates object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = phased.BarrageJammer(E,Name,Value) creates a barrage jammer object, H, with the ERP property set to E and other specified property Names set to the specified Values.

## Properties

### ERP

Effective radiated power

Specify the effective radiated power (ERP) (in watts) of the jamming signal as a positive scalar.

**Default:** `5000`

### SamplesPerFrameSource

Source of number of samples per frame

Specify whether the number of samples of the jamming signal comes from the `SamplesPerFrame` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `SamplesPerFrame` property of this object specifies the number of samples of the jamming signal. |
| `'Input port'` | An input argument in each invocation of `step` specifies the number of samples of the jamming signal. |

**Default:** `'Property'`

### SamplesPerFrame

Number of samples per frame

Specify the number of samples in the output jamming signal as a positive integer. This property applies when you set the `SamplesPerFrameSource` property to `'Property'`.

**Default:** `100`

### SeedSource

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

| | |
|---|---|
| 'Auto' | The default MATLAB random number generator produces the random numbers. Use 'Auto' if you are using this object with Parallel Computing Toolbox software. |
| 'Property' | The object uses its own private random number generator to produce random numbers. The Seed property of this object specifies the seed of the random number generator. Use 'Property' if you want repeatable results and are not using this object with Parallel Computing Toolbox software. |

**Default:** 'Auto'

### Seed

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}$–1. This property applies when you set the SeedSource property to 'Property'.

**Default:** 0

## Methods

| | |
|---|---|
| reset | Reset random number generator for noise generation |
| step | Generate noise jamming signal |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

## Examples

### Plot Barrage Jammer Output

Create a barrage jammer with an effective radiated power of 1000W. Then plot the magnitude of the jammer output. Your plot might vary because of random numbers.

```
Hjammer = phased.BarrageJammer('ERP',1000);
x = step(Hjammer);
plot(abs(x)); xlabel('Samples'); ylabel('Magnitude');
```

reset(H)
```

## Description

reset(H) resets the states of the BarrageJammer object, H. This method resets the random number generator state if the SeedSource property is set to 'Property'.

# step

**System object:** `phased.BarrageJammer`
**Package:** `phased`

Generate noise jamming signal

## Syntax

```
Y = step(H)
Y = step(H,N)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` returns a column vector, `Y`, that is a complex white Gaussian noise jamming signal. The power of the jamming signal is specified by the `ERP` property. The length of the jamming signal is specified by the `SamplesPerFrame` property. This syntax is available when the `SamplesPerFrameSource` property is `'Property'`.

`Y = step(H,N)` returns the jamming signal with length `N`. This syntax is available when the `SamplesPerFrameSource` property is `'Input port'`.

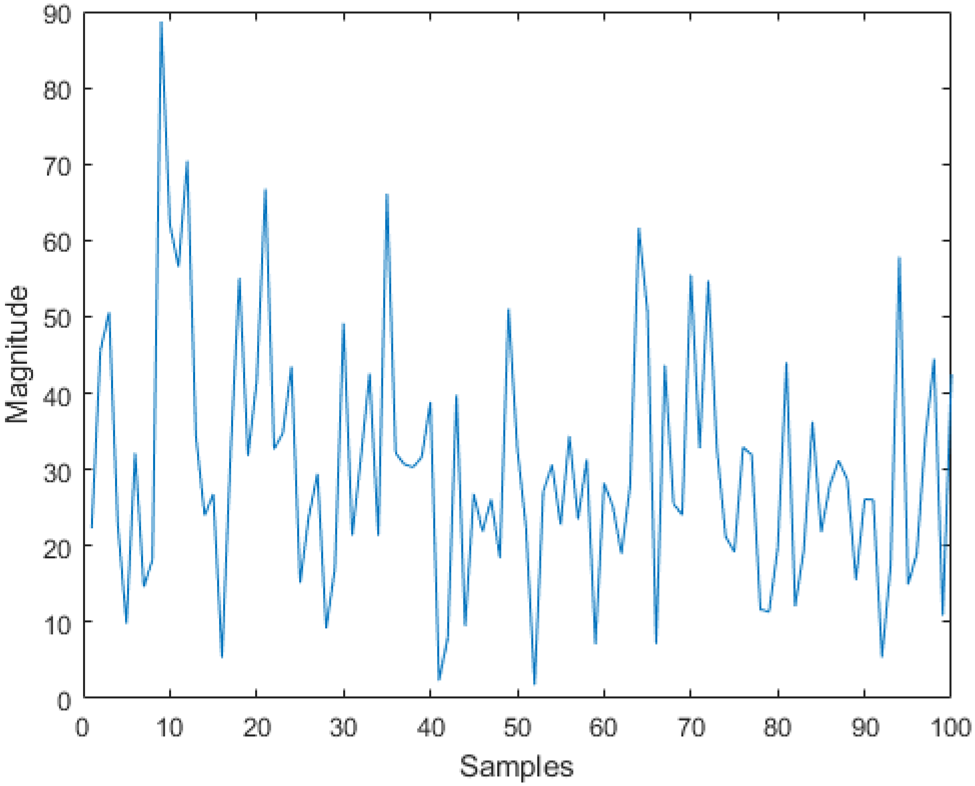
**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

### Plot Barrage Jammer Output

Create a barrage jammer with an effective radiated power of 1000W. Then plot the magnitude of the jammer output. Your plot might vary because of random numbers.

```
Hjammer = phased.BarrageJammer('ERP',1000);
x = step(Hjammer);
plot(abs(x)); xlabel('Samples'); ylabel('Magnitude');
```



# phased.BeamscanEstimator

**Package:** `phased`

Beamscan spatial spectrum estimator for ULA

## Description

The `phased.BeamscanEstimator` System object calculates a beamscan spatial spectrum estimate for a uniform linear array (ULA). The object estimates the incoming signal spatial spectrum using a narrowband conventional beamformer.

To estimate the spatial spectrum:

1. Create the `phased.BeamscanEstimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
estimator = phased.BeamscanEstimator
estimator = phased.BeamscanEstimator(Name,Value)
```

### Description

`estimator = phased.BeamscanEstimator` creates a beamscan spatial spectrum estimator System object.

`estimator = phased.BeamscanEstimator(Name,Value)` creates an object, `estimator`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**`SensorArray` — ULA sensor array**
`phased.ULA` System object (default)

ULA sensor array, specified as a `phased.ULA` System object. If you do not specify any name-value pair properties for the ULA sensor array, the default properties of the array are used.

**`PropagationSpeed` — Signal propagation speed**
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

**`OperatingFrequency` — Operating frequency**
`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `single` | `double`

**`NumPhaseShifterBits` — Number of phase shifter quantization bits**
`0` (default) | non-negative scalar

The number of bits used to quantize the phase shift component of beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: 5

Data Types: single | double

### ForwardBackwardAveraging — Enable forward-backward averaging

false (default) | true

Enable forward-backward averaging, specified as false or true. Set this property to true to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Data Types: logical

### SpatialSmoothing — Enable spatial smoothing

0 (default) | nonnegative integer

Option to enable spatial smoothing, specified as a nonnegative integer. Use spatial smoothing to compute the arrival directions of coherent signals. A value of zero specifies no spatial smoothing. A positive value represents the number of subarrays used to compute the smoothed (averaged) source covariance matrix. Each increment in this value lets you handle one additional coherent source, but reduces the effective number of array elements by one. The length of the smoothing aperture, $L$, depends on the array length, $M$, and the averaging number, $K$, by $L = M – K + 1$. The maximum value of $K$ is $M – 2$.

Example: 5

Data Types: double

### ScanAngles — Broadside scan angles

[-90:90] (default) | real-valued $K$-length vector

Broadside scan angles, specified as a real-valued vector. Units are in degrees. Broadside angles are between the search direction and the ULA array axis. The angles lie between –90° and 90°, inclusive. Specify the angles in increasing value.

Example: [-20:20]

Data Types: single | double

### DOAOutputPort — Enable directions of arrival output

false (default) | true

Option to enable directions-of-arrival (DOA) output, specified as false or true. To obtain the DOA of signals, set this property to true. The DOAs are returned in the second output argument when the object is executed.

Data Types: `logical`

**`NumSignals` — Number of arriving signals**
`1` (default) | positive integer

Number of arriving signals for DOA estimation, specified as a positive integer.

Example: `3`

**Dependencies**

To enable this property, set the `DOAOutputPort` property to `true`.

Data Types: `single` | `double`

# Usage

# Syntax

```
Y = estimator(X)
[Y,ANG] = estimator(X)
```

## Description

`Y = estimator(X)` estimates the spatial spectrum from data `X`.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`[Y,ANG] = estimator(X)` returns the directions of arrival, `ANG`, of the signals. To enable this syntax, set the `DOAOutputPort` property to `true`. `ANG` is a row vector of the estimated broadside angles (in degrees). You can specify `ANG` as single or double precision. If the object cannot identify a signal direction, it will return `NaN`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `X` — Channel data

complex-valued matrix

Channel data, specified as a complex-valued matrix. Columns of the data matrix correspond to channels.

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### `Y` — Magnitude of estimated spatial spectrum

real-valued 1-by-*L* column vector

Magnitude of the estimated spatial spectrum, returned as a real-valued 1-by-*L* column vector. *L* is the number of scan angles specified by the `ScanAngles` property.

Data Types: `single` | `double`

### `ANG` — Estimated broadside angles

real-valued 1-by-*K* row vector | `NaN`

Estimated broadside angles of signal arrivals, returned as a real-valued 1-by-*K* row vector. Units are in degrees. The `NaN` value in any vector element indicates that an estimate could not be found.

Data Types: `single` | `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to spectral estimation

| | |
|---|---|
| plotSpectrum | Plot spatial spectrum |

### Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

## Examples

#### Estimate Directions of Arrival of Two Signals

Estimate the DOA's of two signals received by a 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

Create the signals and array.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
antenna = phased.IsotropicAntennaElement('FrequencyRange',[100e6 300e6]);
array = phased.ULA('Element',antenna,'NumElements',10,'ElementSpacing',1);
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[10 20;60 -5]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Solve for the DOAs.

```
estimator = phased.BeamscanEstimator('SensorArray',array, ...
    'OperatingFrequency',fc,'DOAOutputPort',true,'NumSignals',2);
[~,doas] = estimator(x + noise);
doas = broadside2az(sort(doas),[20 -5]);
disp(doas)
```

```
    9.5829   60.3813
```

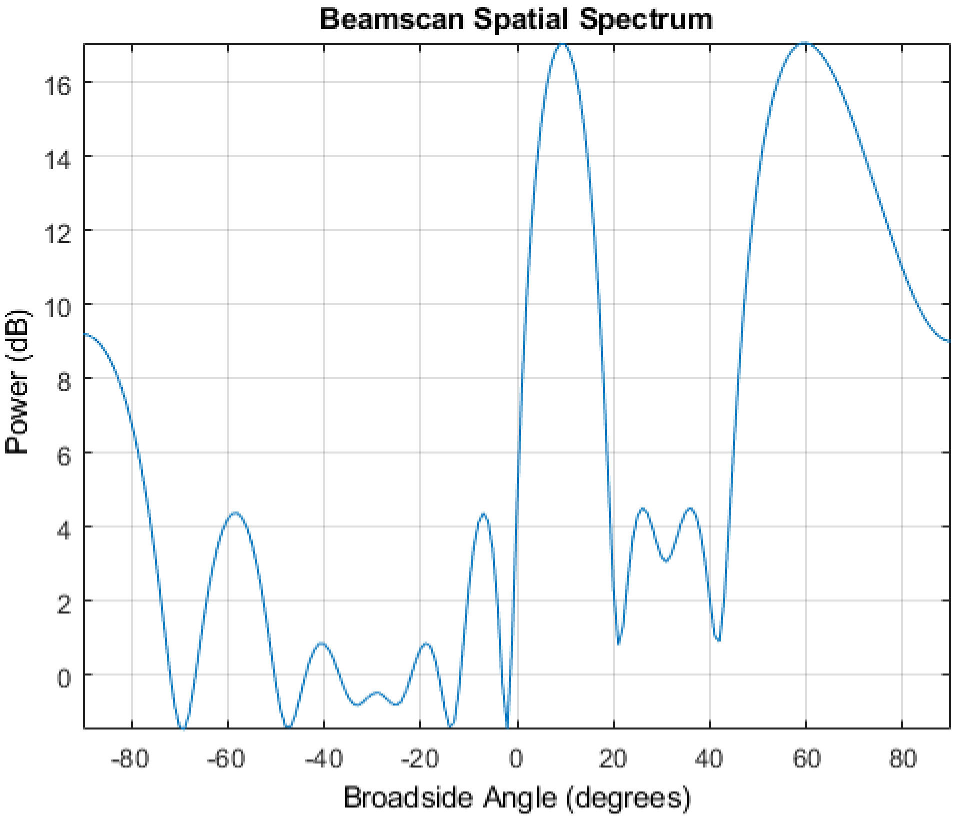
Because the default values for the `ScanAngles` property has a granularity of 1°, the DOA estimates are not accurate. Improve the accuracy by choosing a finer grid.

```
estimator2 = phased.BeamscanEstimator('SensorArray',array, ...
    'OperatingFrequency',fc,'ScanAngles',-60:0.1:60, ...
    'DOAOutputPort',true,'NumSignals',2);
[~,doas] = estimator2(x + noise);
doas = broadside2az(sort(doas),[20 -5]);
disp(doas)
```

```
   10.0093   59.9751
```

### Plot the beamscan spectrum

```
plotSpectrum(estimator)
```



# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Package:** phased

2-D beamscan spatial spectrum estimator

## Description

The phased.BeamscanEstimator2D System object calculates a beamscan 2-D spatial spectrum estimate for an arbitrary array (ULA). The object estimates the incoming signal spatial spectrum using a narrowband conventional beamformer.

To estimate the spatial spectrum:

1. Create the phased.BeamscanEstimator2D object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
estimator = phased.BeamscanEstimator2D
estimator = phased.BeamscanEstimator2D(Name,Value)
```

### Description

estimator = phased.BeamscanEstimator2D creates a beamscan 2-D spatial spectrum estimator System object.

estimator = phased.BeamscanEstimator2D(Name,Value) creates an object, estimator, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**`SensorArray` — Sensor array**
phased.ULA array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object.

Example: `phased.URA`

**`PropagationSpeed` — Signal propagation speed**
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

**`OperatingFrequency` — Operating frequency**
`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `single` | `double`

**`NumPhaseShifterBits` — Number of phase shifter quantization bits**
`0` (default) | non-negative scalar

The number of bits used to quantize the phase shift component of beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: `5`

Data Types: `single` | `double`

### `ForwardBackwardAveraging` — Enable forward-backward averaging

`false` (default) | `true`

Enable forward-backward averaging, specified as `false` or `true`. Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Data Types: `logical`

### `AzimuthScanAngles` — Azimuth scan angles

`[-90:90]` (default) | real-valued row vector

Azimuth scan angles, specified as a or real-valued row vector. Angle units are in degrees. The angle values must lie between –180° and 180°, inclusive, and be in ascending order.

Example: `[-30:20]`

Data Types: `single` | `double`

### `ElevationScanAngles` — Elevation scan angles

`0` (default) | real-valued row vector

Elevation scan angles, specified as a real-valued row vector. Angle units are in degrees. The angle values must lie between –90° and 90°, inclusive, and be in ascending order.

Example: `[-70:75]`

Data Types: `single` | `double`

### `DOAOutputPort` — Enable directions of arrival output

`false` (default) | `true`

Option to enable directions-of-arrival (DOA) output, specified as `false` or `true`. To obtain the DOA of signals, set this property to `true`. The DOAs are returned in the second output argument when the object is executed.

Data Types: `logical`

### NumSignals — Number of arriving signals

1 (default) | positive integer

Number of arriving signals for DOA estimation, specified as a positive integer.

Example: 3

**Dependencies**

To enable this property, set the DOAOutputPort property to true.

Data Types: single | double

# Usage

# Syntax

```
Y = estimator(X)
[Y,ANG] = estimator(X)
```

## Description

Y = estimator(X) estimates the spatial spectrum from data X.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

[Y,ANG] = estimator(X) returns the directions of arrival, ANG, of the signals. To enable this syntax, set the DOAOutputPort property to true. ANG is a 2-by-*N* matrix of the estimated azimuths and elevations of the signal direction. *N* is specified by the NumSignals property. If the object cannot identify a signal direction, it will return NaN.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### X — Array data

complex-valued matrix

Array data, specified as a complex-valued matrix. Columns of the data matrix correspond to channels.

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### Y — Magnitude of estimated spatial spectrum

positive, real-valued, *K*-by-*L* matrix

Magnitude of the estimated spatial spectrum, returned as a positive, real-valued, *K*-by-*L* matrix.

Data Types: `single` | `double`

### ANG — Estimated direction angles of signal arrivals

real-valued 2-by-*K* matrix | `NaN`

Estimated direction angles of signal arrivals, returned as a real-valued 2-by-*K* matrix. Each column has the form `[azimuth;elevation]`. The `NaN` value in any matrix element indicates that an estimate could not be found. Units are in degrees.

Data Types: `single` | `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to spectral estimation

Plot spatial spectrum

## Syntax

```
plotSpectrum(estimator)
plotSpectrum(estimator,Name,Value)
hl = plotSpectrum( ___ )
```

## Description

`plotSpectrum(estimator)` plots the spatial spectrum resulting from the most recent execution of the object.

`plotSpectrum(estimator,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`hl = plotSpectrum( ___ )` returns the line handle in the figure.

## Input Arguments

**`H`**

Spatial spectrum estimator object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**NormalizeResponse**

Set this value to `true` to plot the normalized spectrum. Setting this value to `false` plots the spectrum without normalization.

**Default:** `false`

**Title**

Character vector to use as figure title.

**Default:** `''`

**Unit**

Plot units, specified as `'db'`, `'mag'`, or `'pow'`.

**Default:** `'db'`

# reset

**System object:** `phased.BeamscanEstimator2D`
**Package:** `phased`

Reset states of 2-D beamscan spatial spectrum estimator object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `BeamscanEstimator2D` object, `H`.

# step

**System object:** `phased.BeamscanEstimator2D`
**Package:** `phased`

Perform 2-D spatial spectrum estimation

## Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the spatial spectrum from `X` using the estimator `H`. `X` is a matrix whose columns correspond to channels. `Y` is a matrix representing the magnitude of the estimated 2-D spatial spectrum. `Y` has a row dimension equal to the number of elevation angles specified in `ElevationScanAngles` and a column dimension equal to the number of azimuth angles specified in `AzimuthScanAngles`. You can specify `X` as single or double precision.

`[Y,ANG] = step(H,X)` returns additional output `ANG` as the signal's direction of arrival (DOA) when the `DOAOutputPort` property is `true`. `ANG` is a two row matrix where the first row represents the estimated azimuth and the second row represents the estimated elevation (in degrees).

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

### Estimate DOAs of Two Sinusoidal Signals

Estimate the DOAs of two sinusoidal signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is -37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° in elevation.

Create the signals and solve for the DOA's.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[-37 0; 17 20]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
estimator = phased.BeamscanEstimator2D('SensorArray',array, ...
    'OperatingFrequency',fc, ...
    'DOAOutputPort',true,'NumSignals',2, ...
    'AzimuthScanAngles',-50:50, ...
    'ElevationScanAngles',-30:30);
[~,doas] = estimator(x + noise)
```

```
doas = 2×2

   -37    17
     0    20
```

Plot the spatial spectrum.

```
plotSpectrum(estimator)
```

# phased.BeamspaceESPRITEstimator

**Package:** `phased`

Beamspace ESPRIT direction of arrival (DOA) estimator for ULA

## Description

The `BeamspaceESPRITEstimator` object computes a DOA estimate for a uniform linear array. The computation uses the estimation of signal parameters via rotational invariance techniques (ESPRIT) algorithm in beamspace.

To estimate the direction of arrival (DOA):

1. Define and set up your DOA estimator. See “Construction” on page 1-210.
2. Call `step` to estimate the DOA according to the properties of `phased.BeamspaceESPRITEstimator`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.BeamspaceESPRITEstimator` creates a beamspace ESPRIT DOA estimator System object, `H`. The object estimates the signal's direction of arrival using the beamspace ESPRIT algorithm with a uniform linear array (ULA).

`H = phased.BeamspaceESPRITEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `SpatialSmoothing`

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of element by 1. The maximum value of this property is M–2, where M is the number of sensors. You can specify this property as single or double precision.

**Default:** `0`, indicating no spatial smoothing

**NumSignalsSource**

Source of number of signals

Specify the source of the number of signals as one of 'Auto' or 'Property'. If you set this property to 'Auto', the number of signals is estimated by the method specified by the NumSignalsMethod property. You can specify this property as single or double precision.

**Default:** 'Auto'

**NumSignalsMethod**

Method to estimate number of signals

Specify the method to estimate the number of signals as one of 'AIC' or 'MDL'. 'AIC' uses the Akaike Information Criterion and 'MDL' uses Minimum Description Length Criterion. This property applies when you set the NumSignalsSource property to 'Auto'.

**Default:** 'AIC'

**NumSignals**

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the NumSignalsSource property to 'Property'. You can specify this property as single or double precision.

**Default:** 1

**Method**

Type of least square method

Specify the least squares method used for ESPRIT as one of 'TLS' or 'LS'. 'TLS' refers to total least squares and 'LS' refers to least squares.

**Default:** 'TLS'

**BeamFanCenter**

Beam fan center direction (in degrees)

Specify the direction of the center of the beam fan (in degrees) as a real scalar value between –90 and 90. You can specify this property as single or double precision. This property is tunable.

**Default:** `0`

**`NumBeamsSource`**

Source of number of beams

Specify the source of the number of beams as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of beams equals N–L, where N is the number of array elements and L is the value of the `SpatialSmoothing` property.

**Default:** `'Auto'`

**`NumBeams`**

Number of beams

Specify the number of beams as a positive scalar integer. The lower the number of beams, the greater the reduction in computational cost. This property applies when you set the `NumBeamsSource` to `'Property'`. You can specify this property as single or double precision.

**Default:** `2`

## Methods

| `release` | Allow System object property value changes |

## Examples

### Estimate DOA of Two Signals Using Beamspace ESPRIT

Estimate the directions of arrival (DOA) of two signals received by a standard 10-element ULA with element spacing 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and 60° in elevation.

Create the two signals arriving at the array.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[10 20;45 60]',fc);
noise = 0.1/sqrt(2)*(randn(size(x)) + 1i*randn(size(x)));
```

Set up the beamspace ESPRIT estimator and solve for the DOAs.

```
estimator = phased.BeamspaceESPRITEstimator('SensorArray',array, ...
    'OperatingFrequency',fc,'NumSignalsSource','Property','NumSignals',2);
doas = estimator(x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az = 1×2

    9.9972   45.0061
```

# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# step

**System object:** `phased.BeamspaceESPRITEstimator`
**Package:** `phased`

Perform DOA estimation

## Syntax

```
ANG = step(H,X)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ANG = step(H,X)` estimates the DOAs from `X` using the DOA estimator `H`. `X` is a matrix whose columns correspond to channels. `ANG` is a row vector of the estimated broadside angles (in degrees). You can specify the input data `X` as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# phased.CFARDetector

**Package:** `phased`

Constant false alarm rate (CFAR) detector

## Description

The `CFARDetector` object implements a one-dimensional constant false-alarm rate (CFAR) detector. Detection processing is performed on selected elements (called cells) of the input data. A detection is declared when an image cell value exceeds a threshold. To maintain a constant false alarm-rate, the threshold is set to a multiple of the image noise power. The detector estimates noise power for a cell-under-test (CUT) from surrounding cells using one of three cell averaging methods, or an order statistics method. The cell-averaging methods are cell averaging (CA), greatest-of cell averaging (GOCA), or smallest-of cell averaging (SOCA).

For more information about CFAR detectors, see [1].

For each test cell, the detector:

1. estimates the noise statistic from the cell values in the training band surrounding the CUT cell.
2. computes the threshold by multiplying the noise estimate by the threshold factor.
3. compares the CUT cell value to the threshold to determine whether a target is present or absent. If the value is greater than the threshold, a target is present.

To run the detector

1. Define and set up your CFAR detector. See “Construction” on page 1-219.
2. Call `step` to perform CFAR detection according to the properties of `phased.CFARDetector`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.CFARDetector` creates a CFAR detector System object, `H`. The object performs CFAR detection on input data.

`H = phased.CFARDetector(Name,Value)` creates the object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### Method

CFAR algorithm

Specify the CFAR detector algorithm as one of

| | |
|---|---|
| 'CA' | Cell-averaging CFAR |
| 'GOCA' | Greatest-of cell-averaging CFAR |
| 'OS' | Order statistic CFAR |
| 'SOCA' | Smallest-of cell-averaging CFAR |

**Default:** `'CA'`

### Rank

Rank of order statistic

Specify the rank of the order statistic as a positive integer scalar. The value must be less than or equal to the value of the `NumTrainingCells` property. This property applies only when you set the `Method` property to `'OS'`. This property supports single and double precision,

**Default:** 1

### NumGuardCells

Number of guard cells

Specify the number of guard cells used in training as an even integer. This property specifies the total number of cells on both sides of the cell under test. This property supports single and double precision,

**Default:** `2`, indicating that there is one guard cell at both the front and back of the cell under test

### NumTrainingCells

Number of training cells

Specify the number of training cells used in training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test. This property supports single and double precision, This property supports single and double precision,

**Default:** `2`, indicating that there is one training cell at both the front and back of the cell under test

### ThresholdFactor

Methods of obtaining threshold factor

Specify whether the threshold factor comes from an automatic calculation, the `CustomThresholdFactor` property of this object, or an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Auto'` | The application calculates the threshold factor automatically based on the desired probability of false alarm specified in the `ProbabilityFalseAlarm` property. The calculation assumes each independent signal in the input is a single pulse coming out of a square law detector with no pulse integration. The calculation also assumes the noise is white Gaussian. |
| `'Custom'` | The `CustomThresholdFactor` property of this object specifies the threshold factor. |

| | |
|---|---|
| `'Input port'` | An input argument in each invocation of `step` specifies the threshold factor. |

**Default:** `'Auto'`

**`ProbabilityFalseAlarm`**

Desired probability of false alarm

Specify the desired probability of false alarm as a scalar between 0 and 1 (not inclusive). This property applies only when you set the `ThresholdFactor` property to `'Auto'`.

**Default:** `0.1`

**`CustomThresholdFactor`**

Custom threshold factor

Specify the custom threshold factor as a positive scalar. This property applies only when you set the `ThresholdFactor` property to `'Custom'`. This property is tunable. This property supports single and double precision,

**Default:** `1`

**`OutputFormat`**

Format of detection results

Format of detection results returned by the `step` method, specified as `'CUT result'` or `'Detection index'`.

- When set to `'CUT result'`, the results are logical detection values (`1` or `0`) for each tested cell. `1` indicates that the value of the tested cell exceeds a detection threshold.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells which exceed a detection threshold. You can use this format as input to the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects.

**Default:** `'CUT result'`

**`ThresholdOutputPort`**

Output detection threshold

To obtain the detection threshold, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the detection threshold, set this property to `false`.

**Default:** `false`

### NoisePowerOutputPort

Output estimated noise

To obtain the estimated noise, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the estimated noise, set this property to `false`.

**Default:** `false`

### NumDetectionsSource

Source of the number of detections

Source of the number of detections, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the number of detection indices reported is the total number of cells under test that have detections. If you set this property to `'Property'`, the number of reported detections is determined by the value of the `NumDetections` property.

**Dependencies**

To enable this property, set the `OutputFormat` property to `'Detection index'`.

**Default:** `'Auto'`

### NumDetections

Maximum number of detections to report

Maximum number of detection indices to report, specified as a positive integer.

**Dependencies**

To enable this property, set the `OutputFormat` property to `'Detection index'` and the `NumDetectionsSource` property to `'Property'`.

Data Types: `double`

**Default:** 1

## Methods

|  |  |

|---|---|
| release | Allow System object property value changes |

## Examples

### Compute PFA Using CFAR Detector On Noise

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.1. Assume that the data comes from a square law detector and no pulse integration is performed. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Perform the detection on all cells of the input.

```
detector = phased.CFARDetector('NumTrainingCells',50,...
    'NumGuardCells',2,'ProbabilityFalseAlarm',0.1);
N = 1000;
x = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
dets = detector(abs(x).^2,1:N);
pfa = sum(dets)/N
```

```
pfa = 0.1140
```

### Compute CFAR Detection Indices

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.005. Assume that the data comes from a square law detector and no pulse integration is performed. Perform the detection on all cells of the input. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Display the detection indices.

```
rng default;
detector = phased.CFARDetector('NumTrainingCells',50,'NumGuardCells',2, ...
    'ProbabilityFalseAlarm',0.005,'OutputFormat','Detection index');
N = 1000;
x1 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x2 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x = [x1,x2];
cutidx = 1:N;
dets = detector(abs(x).^2,cutidx)
```

```
dets = 2×11

   339   537   538   734   786   827   979   136   418   539   874
     1     1     1     1     1     1     1     2     2     2     2
```

# Algorithms

## CFAR Detection

`phased.CFARDetector` uses cell averaging in three steps:

1. Identify the training cells from the input, and form the noise estimate. The next table indicates how the detector forms the noise estimate, depending on the `Method` property value.

| Method | Noise Estimate |
|---|---|
| 'CA' | Use the average of the values in all the training cells. |
| 'GOCA' | Select the greater of the averages in the front training cells and rear training cells. |
| 'OS' | Sort the values in the training cells in ascending order. Select the *N*th item, where *N* is the value of the `Rank` property. |
| 'SOCA' | Select the smaller of the averages in the front training cells and rear training cells. |

2. Multiply the noise estimate by the threshold factor to form the threshold.
3. Compare the value in the test cell against the threshold to determine whether the target is present or absent. If the value is greater than the threshold, the target is present.

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

Perform CFAR detection

## Syntax

```
Y = step(H,X,cutidx)
[Y,th] = step(___)
[Y,noise] = step(___)
Y = step(H,X,cutidx,thfac)
[Y,TH,N] = step(H,X,cutidx,thfac)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X,cutidx) performs CFAR detection on specified elements of the input data, X. X can either be a real-valued *M*-by-1 column vector or a real-valued *M*-by-*N* matrix. cutidx is a length-*D* vector of indices specifying the input elements or cells under test (CUT) on which to perform detection processing. When X is a vector, cutidx specifies the element. When X is a matrix, cutidx specifies the row of the element. The same index applies to all columns of the matrix. Detection is performed independently along each column of X for the indices specified in cutidx. You can specify the input arguments as single or double precision.

The output argument Y contains detection results. The format of Y depends on the OutputFormat property.

- When OutputFormat is 'Cut result', Y is a *D*-by-1 vector or a *D*-by-*N* matrix containing logical detection results. *D* is the length of cutidx and *N* is the number of columns of X. The rows of Y correspond to the rows in cutidx. For each row, Y contains 1 in a column if there is a detection in the corresponding column of X. Otherwise, Y contains a 0.
- When OutputFormat is 'Detection report', Y is a *1*-by-*L* vector or a 2-by-*L* matrix containing detections indices. *L* is the number of detections found in the input data. When X is a column vector, Y contains the index for each detection in X. When X is a matrix, Y contains the row and column indices of each detection in X. Each column of Y has the form [detrow;detcol]. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

[Y,th] = step( ___ ) also returns the detection threshold, th, applied to detected cells under test.

- When OutputFormat is 'CUT result', th returns the detection threshold whenever an element of Y is 1 and NaN whenever an element of Y is 0. th has the same size as Y.
- When OutputFormat is 'Detection index', th returns a detection threshold for each corresponding detection in Y. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

To enable this syntax, set the ThresholdOutputPort property to true.

[Y,noise] = step( ___ ) also returns the estimated noise power, noise, for each detected cell under test in X.

- When OutputFormat is 'CUT result', noise returns a noise power estimate when Y is 1 and NaN whenever Y is zero. noise has the same size as Y.
- When OutputFormat is 'Detection index', noise returns a noise power estimate for each corresponding detection in Y. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

To enable this syntax, set the NoisePowerOutputPort property to true.

Y = step(H,X,cutidx,thfac), in addition, specifies thfac as the threshold factor used to calculate the detection threshold. thfac must be a positive scalar. To enable this syntax, set the ThresholdFactor property to 'Input port'.

You can combine optional input and output arguments when their enabling properties are set. Optional inputs and outputs must be listed in the same order as the order of the enabling properties. For example, [Y,TH,N] = step(H,X,cutidx,thfac).

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Examples

### Compute PFA Using CFAR Detector On Noise

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.1. Assume that the data comes from a square law detector and no pulse integration is performed. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Perform the detection on all cells of the input.

```
detector = phased.CFARDetector('NumTrainingCells',50,...
    'NumGuardCells',2,'ProbabilityFalseAlarm',0.1);
N = 1000;
x = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
dets = detector(abs(x).^2,1:N);
pfa = sum(dets)/N
```

```
pfa = 0.1140
```

### Compute CFAR Detection Indices

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.005. Assume that the data comes from a square law detector and no pulse integration is performed. Perform the detection on all cells of the input. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Display the detection indices.

```
rng default;
detector = phased.CFARDetector('NumTrainingCells',50,'NumGuardCells',2, ...
    'ProbabilityFalseAlarm',0.005,'OutputFormat','Detection index');
N = 1000;
x1 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x2 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x = [x1,x2];
cutidx = 1:N;
dets = detector(abs(x).^2,cutidx)
```

```
dets = 2×11

   339   537   538   734   786   827   979   136   418   539   874
     1     1     1     1     1     1     1     2     2     2     2
```

## Algorithms

`phased.CFARDetector` uses cell averaging in three steps:

1. Identify the training cells from the input, and form the noise estimate. The next table indicates how the detector forms the noise estimate, depending on the `Method` property value.

| Method | Noise Estimate |
|---|---|
| 'CA' | Use the average of the values in all the training cells. |
| 'GOCA' | Select the greater of the averages in the front training cells and rear training cells. |
| 'OS' | Sort the values in the training cells in ascending order. Select the *N*th item, where *N* is the value of the `Rank` property. |
| 'SOCA' | Select the smaller of the averages in the front training cells and rear training cells. |

2. Multiply the noise estimate by the threshold factor to form the threshold.

3 Compare the value in the test cell against the threshold to determine whether the target is present or absent. If the value is greater than the threshold, the target is present.

For details, see [1].

# phased.CFARDetector2D

**Package:** `phased`

Two-dimensional CFAR detector

## Description

`phased.CFARDetector2D` System object implements a constant false-alarm rate detector (CFAR) for selected elements (called cells) of two-dimensional image data. A detection is declared when an image cell value exceeds a threshold. To maintain a constant false alarm-rate, the threshold is set to a multiple of the image noise power. The detector estimates noise power for a cell-under-test (CUT) from surrounding cells using one of three cell averaging methods, or an order statistics method. The cell-averaging methods are cell averaging (CA), greatest-of cell averaging (GOCA), or smallest-of cell averaging (SOCA).

For each test cell, the detector:

1. estimates the noise statistic from the cell values in the training band surrounding the CUT cell.
2. computes the threshold by multiplying the noise estimate by the threshold factor.
3. compares the CUT cell value to the threshold to determine whether a target is present or absent. If the value is greater than the threshold, a target is present.

To run the detector

1. Define and set up your 2-D CFAR detector. You can set the `phased.CFARDetector2D` System object properties when you create the object, or leave them set to their default values. See “Construction” on page 1-232. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. Find the detections by calling the `step` method. The output of this method depends on the properties of the `phased.CFARDetector2D` System object.

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`detector = phased.CFARDetector2D` creates a 2-D CFAR detector System object, `detector`.

`detector = phased.CFARDetector2D(Name,Value)` creates a 2-D CFAR System object, `detector`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `Method` — Two-dimensional CFAR averaging method

`'CA'` (default) | `'GOCA'` | `'SOCA'` | `'OS'`

Two-dimensional CFAR averaging method, specified as `'CA'`, `'GOCA'`, `'SOCA'`, or `'OS'`. For `'CA'`, `'GOCA'`, `'SOCA'`, the noise power is the sample mean derived from the training band. For `'OS'`, the noise power is the *k*th cell value obtained from numerically ordering all training cell values. Set *k* using the `Rank` property.

| Averaging Method | Description |
|---|---|
| `CA` — Cell-averaging algorithm | Computes the sample mean of all training cells surrounding the CUT cell. |
| `GOCA` — Greatest-of cell-averaging algorithm | Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the largest mean. |

| Averaging Method | Description |
|---|---|
| SOCA — Smallest-of cell-averaging algorithm | Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the smallest mean. |
| OS — Order statistic algorithm | Sorts training cells in ascending order of numeric values. Then the algorithm selects the *k*th value from the list. *k* is the rank specified by the Rank parameter. |

Example: 'OS'

Data Types: char

**GuardBandSize — Widths of guard band**
[1 1] (default) | nonnegative integer | 2-element vector of nonnegative integers

The number of rows and columns of the guard band cells on each side of the CUT cell, specified as nonnegative integers. The first element specifies the guard band size along the row dimension. The second element specifies the guard band size along the column dimension. Specifying this property as a single integer is equivalent to specifying a guard band with the same value for both dimensions. For example, a value of [1 1], indicates that there is a one guard-cell-wide region surrounding each CUT cell. A value of zero indicates there are no guard cells.

Example: [2 3]

Data Types: single | double

**TrainingBandSize — Widths of training band**
[1 1] (default) | positive integer | 2-element vector of positive integers

The number of rows and columns of the training band cells on each side of the CUT cell, specified as a positive integer or a 1-by-2 matrix of positive integers. The first element specifies the training band size along the row dimension. The second element specifies the training band size along the column dimension. Specifying this property as a scalar is equivalent to specifying a training band with the same value for both dimensions. For example, a value of [1 1] indicates a 1 training-cell-wide region surrounding the CUT cell.

Example: [-30:0.1:30]

Data Types: `single` | `double`

### Rank — Rank of order statistic

1 (default) | positive integer

Rank of the order statistic used in the 2-D CFAR algorithm, specified as a positive integer. The value of this property must lie between 1 and $N_{train}$, where $N_{train}$ is the number of training cells. A value of 1 selects the smallest value in the training region.

Example: 5

#### Dependencies

To enable this property, set the `Method` property to `'OS'`.

Data Types: `single` | `double`

### `ThresholdFactor` — Threshold factor method

`'Auto'` (default) | `'Input port'` | `'Custom'`

Threshold factor method, specified as `'Auto'`, `'Input port'`, or `'Custom'`.

When you set the `ThresholdFactor` property to `'Auto'`, the threshold factor is calculated from the desired probability of false alarm set in the `ProbabilityFalseAlarm` property. The calculation assumes that each independent signal in the input is a single pulse coming out of a square law detector with no pulse integration. In addition, the noise is assumed to be white Gaussian.

When you set the `ThresholdFactor` property to `'Input port'`, the threshold factor is obtained from an input argument of the `step` method.

When you set the `ThresholdFactor` property to `'Custom'`, the threshold factor is obtained from the value of the `CustomThresholdFactor` property.

Example: `'Custom'`

Data Types: `char`

### `ProbabilityFalseAlarm` — Required probability of false alarm

`0.1` (default) | positive scalar between 0 and 1

Required probability of false alarm, specified as a real positive scalar between 0 and 1. The algorithm calculates the threshold factor from the required probability of false alarm.

Example: `0.001`

#### Dependencies

To enable this property, set the ThresholdFactor property to 'Auto'.

Data Types: single | double

### CustomThresholdFactor — Custom threshold factor

1 (default) | positive scalar

Custom threshold factor, specified as a real positive scalar. This property is tunable.

#### Dependencies

To enable this property, set the ThresholdFactor property to 'Custom'.

Data Types: single | double

### OutputFormat — Format of detection results

'CUT result' (default) | 'Detection index'

Format of detection results returned by the step method, specified as 'CUT result' or 'Detection index'.

- When set to 'CUT result', the results are logical detection values (1 or 0) for each tested cell.
- When set to 'Detection index', the results form a vector or matrix containing the indices of tested cells that exceed a detection threshold. You can use this format as input to the phased.RangeEstimator and phased.DopplerEstimator System objects.

Data Types: char

### ThresholdOutputPort — Enable detection threshold output

false (default) | true

Option to enable detection threshold output, specified as false or true. Setting this property to true returns the detection threshold via an output argument, th, of the step method.

Data Types: logical

### NoisePowerOutputPort — Enable noise power output

false (default) | true

Option to enable output of noise power, specified as `false` or `true`. Setting this property to `true` returns the noise power via the output argument, `noise`, of the `step` method.

Data Types: `logical`

### `NumDetectionsSource` — Source of the number of detections

`'Auto'` (default) | `'Property'`

Source of the number of detections, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the number of detection indices reported is the total number of cells under test that have detections. If you set this property to `'Property'`, the number of reported detections is determined by the value of the `NumDetections` property.

#### Dependencies

To enable this property, set the `OutputFormat` property to `'Detection index'`.

Data Types: `char`

### `NumDetections` — Maximum number of detection indices to report

`1` (default) | positive integer

Maximum number of detection indices to report, specified as a positive integer.

Example:

#### Dependencies

To enable this property, set the `OutputFormat` property to `'Detection index'` and the `NumDetectionsSource` property to `'Property'`.

Data Types: `double`

## Methods

# Examples

### Set 2-D CFAR Threshold for Noise-Only Data

This example shows how to set a 2-D CFAR threshold based upon a required probability of false alarm (pfa).

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing Gaussian noise. Estimate the empirical pfa and compare it to the required pfa. To get a good estimate, perform this simulation on 1000 similar matrices. First, set a threshold using the required pfa. In this case, there are no targets and the pfa can be estimated from the number of cells that exceed the threshold. Assume that the data is processed through a square-law detector and that no pulse integration is performed. Use a training-cell band of 3 cells in width and 4 cells in height. Use a guard band of 3 cells in width and 2 cells in height to separate the cells under test (CUT) from the training cells. Specify a required pfa of 5.0e-4.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
detector = phased.CFARDetector2D('TrainingBandSize',[4,3], ...
    'ThresholdFactor','Auto','GuardBandSize',[2,3], ...
    'ProbabilityFalseAlarm',p,'Method','SOCA','ThresholdOutputPort',true);
```

Create a 41-by-41 image containing random complex data. Then, square the data to simulate a square-law detector.

```
x = 2/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
x2 = abs(x).^2;
```

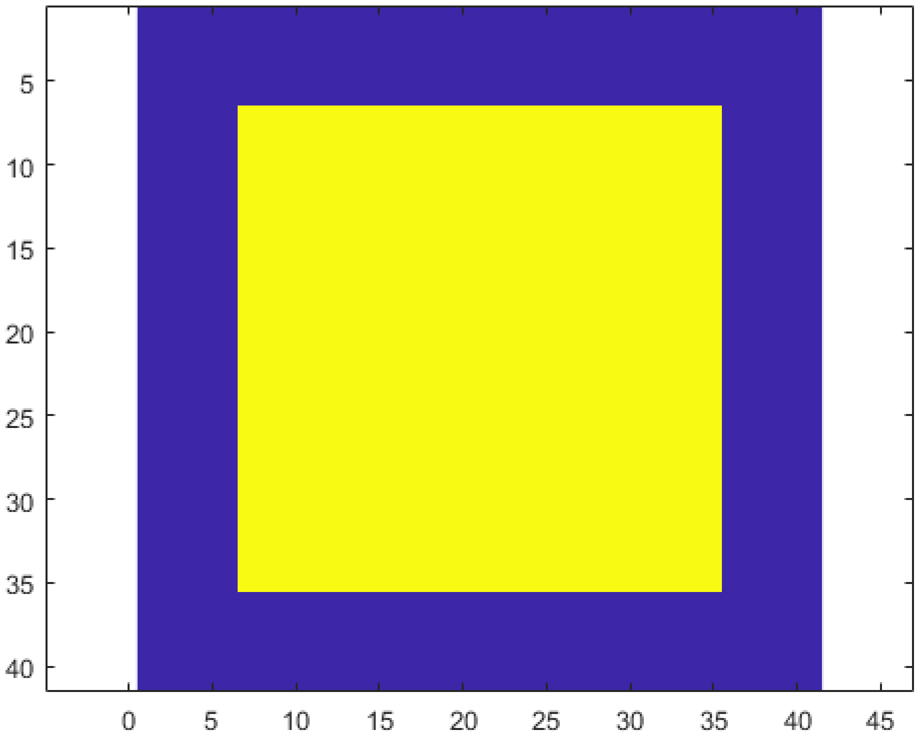
Process all the cells in each image. To do this, find the row and column of each CUT cell whose training region falls entirely within each image.

```
Ngc = detector.GuardBandSize(2);
Ngr = detector.GuardBandSize(1);
Ntc = detector.TrainingBandSize(2);
Ntr = detector.TrainingBandSize(1);
cutidx = [];
```

```
colstart = Ntc + Ngc + 1;
colend = N - ( Ntc + Ngc);
rowstart = Ntr + Ngr + 1;
rowend = N - ( Ntr + Ngr);
for m = colstart:colend
    for n = rowstart:rowend
        cutidx = [cutidx,[n;m]];
    end
end
ncutcells = size(cutidx,2);
```

Display the CUT cells.

```
cutimage = zeros(N,N);
for k = 1:ncutcells
    cutimage(cutidx(1,k),cutidx(2,k)) = 1;
end
imagesc(cutimage)
axis equal
```



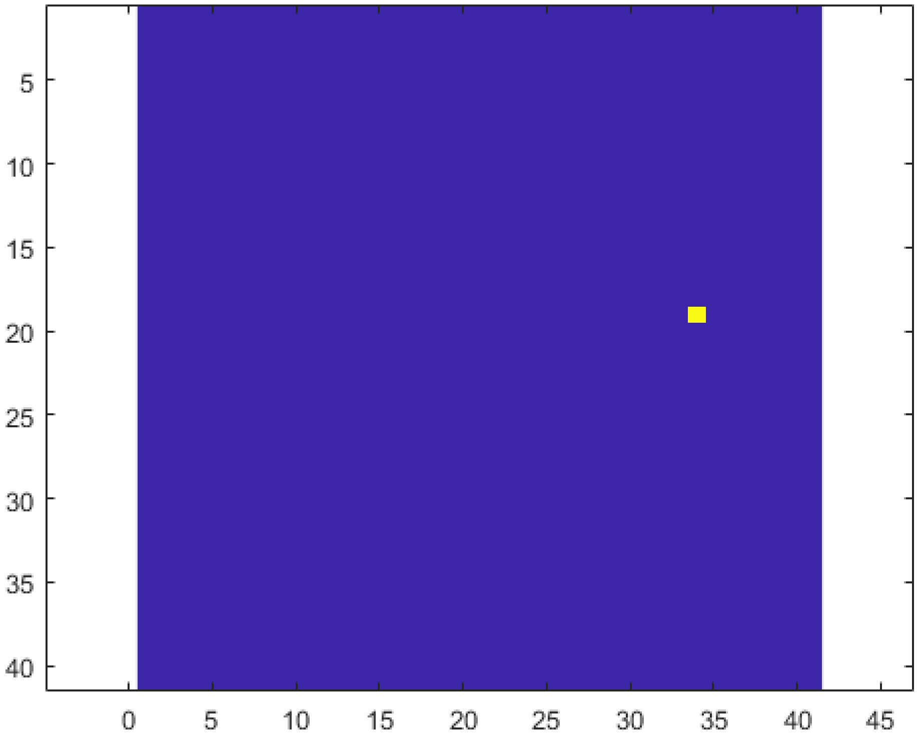
Perform the detection on all CUT cells. Return the detection classification and the threshold used to classify the cell.

```
[dets,th] = detector(x2,cutidx);
```

Find and display an image with a false alarm for illustration.

```
di = [];
for k = 1:ntrials
    d = dets(:,k);
    if (any(d) > 0)
        di = [di,k];
    end
end
```

```
idx = di(1);
detimg = zeros(N,N);
for k = 1:ncutcells
    detimg(cutidx(1,k),cutidx(2,k)) = dets(k,idx);
end
imagesc(detimg)
axis equal
```



Compute the empirical pfa.

```
pfa = sum(dets(:))/ntrials/ncutcells
```

```
pfa = 4.5898e-04
```

The empirical and specified pfa agree.

Display the average empirical threshold value over all images.

```
mean(th(:))
```

```
ans = 31.7139
```

Compute the theoretical threshold factor for the required pfa.

```
threshfactor = npwgnthresh(p,1,'noncoherent');
threshfactor = 10^(threshfactor/10);
disp(threshfactor)
```

```
    7.6009
```

The theoretical threshold factor multiplied by the noise variance should agree with the measured threshold.

```
noisevar = mean(x2(:));
disp(threshfactor*noisevar);
```

```
   30.4118
```

The theoretical threshold and empirical threshold agree to within an acceptable difference.

### Detect Targets in Background Noise

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing five closely-spaced targets in Gaussian noise. Perform this detection on a simulation of 1000 images. Use two detectors with different guard band regions. Set the thresholds manually using the `Custom` threshold factor. Assume that the data is processed through a square law-detector and that no pulse integration is performed. Use a training cell band of 2 cells in width and 2 cells in height. For the first detector, use a guard band of 1 cell all around to separate the CUT cells from the training cells. For the second detector, use a guard band of 8 cells all around.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
```

```
N = 41;
ntrials = 1000;
```

Create 1000 41-by-41 images of complex random noise with standard deviation of 1.

```
s = 1;
x = s/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
```

Set the target cells values to 1.5. Then, square the cell values.

```
A = 1.5;
x(23,20,:) = A;
x(23,18,:) = A;
x(23,23,:) = A;
x(20,22,:) = A;
x(21,18,:) = A;
x2 = abs(x).^2;
```

Display the target cells.

```
xtgt = zeros(N,N);
xtgt(23,20,:) = A;
xtgt(23,18,:) = A;
xtgt(23,23,:) = A;
xtgt(20,22,:) = A;
xtgt(21,18,:) = A;
imagesc(xtgt)
axis equal
axis tight
```

Set the CUT cells to be the target cells.

```
cutidx(1,1) = 23;
cutidx(2,1) = 20;
cutidx(1,2) = 23;
cutidx(2,2) = 18;
cutidx(1,3) = 23;
cutidx(2,3) = 23;
cutidx(1,4) = 20;
cutidx(2,4) = 22;
cutidx(1,5) = 21;
cutidx(2,5) = 18;
```

Perform the detection on all CUT cells using two CFAR 2-D detectors. The first detector has a small guard band region. The training region can include neighboring targets which can affect the computation of the noise power. The second detector has a larger guard band region, which precludes target cells from being used in the noise computation.

Create the two CFAR detectors.

```
detector1 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[1,1],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
detector2 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[8,8],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
```

Return the detection classifications and the thresholds used to classify the cells. Then, compute the probabilities of detection.

```
[dets1,th1] = detector1(x2,cutidx);
ndets = numel(dets1(:));
pd1 = sum(dets1(:))/ndets
```

```
pd1 = 0.6416
```

```
[dets2,th2] = detector2(x2,cutidx);
pd2 = sum(dets2(:))/ndets
```

```
pd2 = 0.9396
```

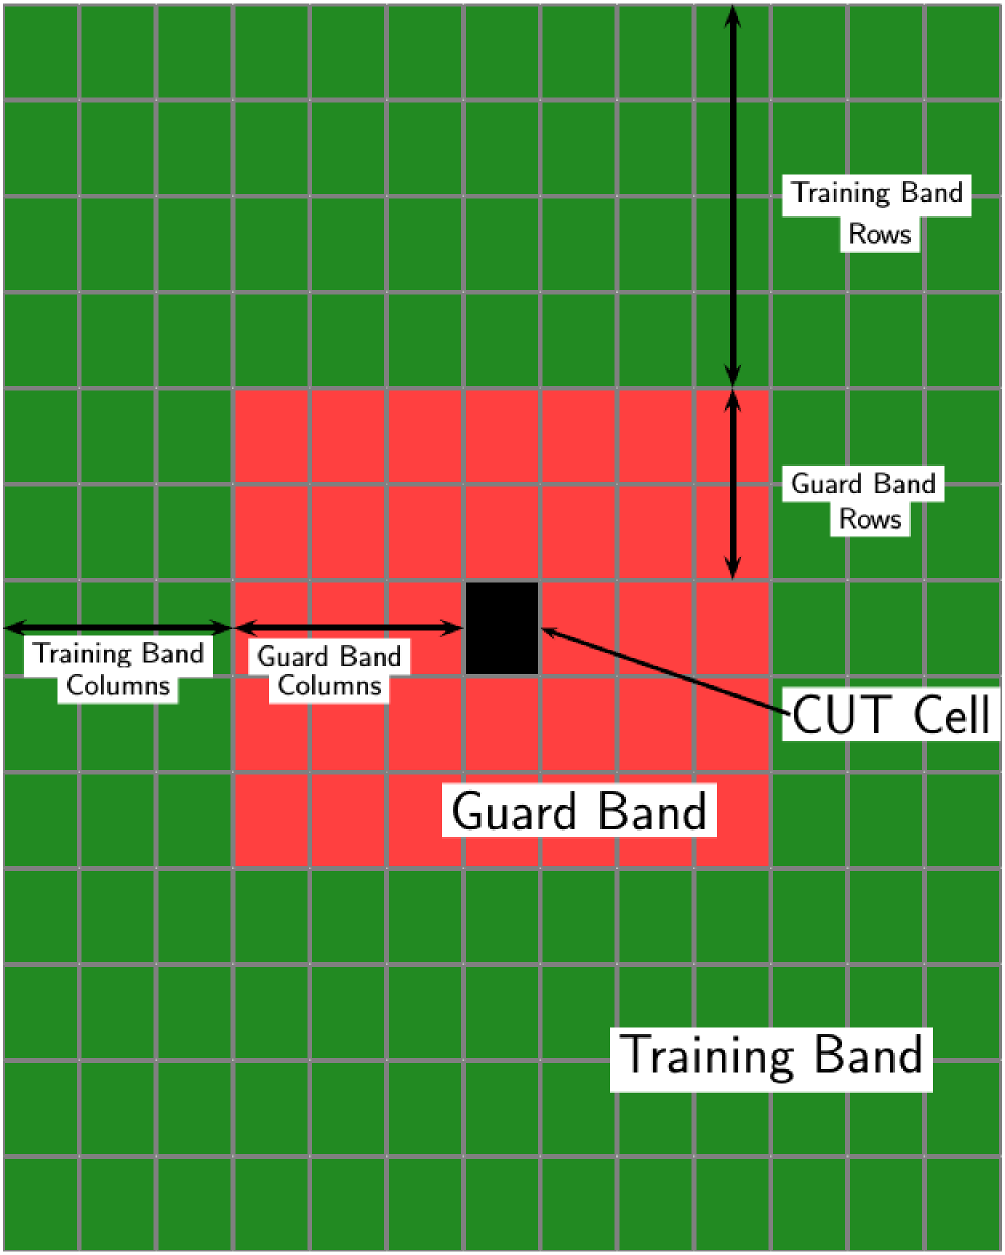
The detector with the larger guard-band region has a higher pfa because the noise is more accurately estimated.

# More About

## Training Cells

CFAR 2-D requires an estimate of the noise power. Noise power is computed from cells that are assumed not to contain any target signal. These cells are the training cells. Training cells form a band around the cell-under-test (CUT) cell but may be separated from the CUT cell by a guard band. The detection threshold is computed by multiplying the noise power by the threshold factor.



Training Band
Rows
Guard Band
Rows
Training Band
Columns
Guard Band
Columns
CUT Cell
Guard Band
Training Band

For GOCA and SOCA averaging, the noise power is derived from the mean value of one of the left or right halves of the training cell region.

Because the number of columns in the training region is odd, the cells in the middle column are assigned equally to either the left or right half.

When using the order-statistic method, the rank cannot be larger than the number of cells in the training cell region, $N_{train}$. You can compute $N_{train}$.

- $N_{TC}$ is the number of training band columns.
- $N_{TR}$ is the number of training band rows.
- $N_{GC}$ is the number of guard band columns.
- $N_{GR}$ is the number of guard band rows.

The total number of cells in the combined training region, guard region, and CUT cell is $N_{total} = (2N_{TC} + 2N_{GC} + 1)(2N_{TR}+ 2N_{GR} + 1)$.

The total number of cells in the combined guard region and CUT cell is $N_{guard} = (2N_{GC} + 1)(2N_{GR} + 1)$.

The number of training cells is $N_{train} = N_{total} - N_{guard}$.

By construction, the number of training cells is always even. Therefore, to implement a median filter, you can choose a rank of $N_{train}/2$ or $N_{train}/2 + 1$.

# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**System object:** `phased.CFARDetector2D`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(detector)
```

## Description

`reset(detector)` resets the internal state of the `phased.CFARDetector2D`object, `detector`.

## Input Arguments

### `detector` — Two-dimensional CFAR detector

`phased.CFARDetector2D` System object

Two-dimensional CFAR detector, specified as a `phased.CFARDetector2D` System object.

**Introduced in R2016b**

# step

**System object:** phased.CFARDetector2D
**Package:** phased

Two-dimensional CFAR detection

## Syntax

```
Y = step(detector,X,cutidx)
Y = step(detector,X,cutidx,K)
[Y,th] = step(___)
[Y,noise] = step(___)
```

## Description

**Note** Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(detector,X,cutidx) performs 2-D CFAR detection on input image data, X, for the image cells under test (CUT) specified by cutidx. Y contains the detection results for the CUT cells.

Y = step(detector,X,cutidx,K) also specifies a threshold factor, K, for setting the detection threshold. This syntax applies when the ThresholdFactor property of the detector is set to 'Input port'.

[Y,th] = step(___) also returns the detection threshold, th, applied to detected cells under test. To enable this syntax, set the ThresholdOutputPort property to true.

[Y,noise] = step(___) also returns the estimated noise power, noise, applied to detected cells under test. To enable this syntax, set the NoisePowerOutputPort property to true.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`detector` — Two-dimensional CFAR detector**
`phased.CFARDetector2D` System object

Two-dimensional CFAR detector, specified as a `phased.CFARDetector2D` System object.

**`X` — Input image**
real *M*-by-*N* matrix | real *M*-by-*N*-by-*P* array

Input image, specified as a real *M*-by-*N* matrix or a real *M*-by-*N*-by-*P* array. *M* and *N* represent the rows and columns of a matrix. Each page is an independent 2-D signal.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;2.5,1;0.5,0.1]`

Data Types: `single` | `double`

**`cutidx` — Test cells**
*2*-by-*D* matrix of positive integers

Test cells, specified as a *2*-by-*D* matrix of positive integers, where *D* is the number of test cells. Each column of `cutidx` specifies the row and column indices of a CUT cell. The same indices apply to all pages in the input array. You must restrict the locations of CUT cells so that their training regions lie completely within the input images.

Example: `[10,15;11,15;12,15]`

Data Types: `single` | `double`

**`K` — Detection threshold factor**
positive scalar

Threshold factor used to calculate the detection threshold, specified as a positive scalar.

#### Dependencies

To enable this input argument, set the `ThresholdFactor` property of the detector object to `'Input port'`

Data Types: `single` | `double`

## Output Arguments

### Y — Detection results

*L*-by-*P* logical matrix

Detection results, whose format depends on the `OutputFormat` property

- When `OutputFormat` is `'Cut result'`, `Y` is a *D*-by-*P* matrix containing logical detection results for cells under test. *D* is the length of `cutidx` and *P* is the number of pages of `X`. The rows of `Y` correspond to the rows of `cutidx`. For each row, `Y` contains `1` in a column if there is a detection in the corresponding cell in `X`. Otherwise, `Y` contains a `0`.
- When `OutputFormat` is `'Detection report'`, `Y` is a *K*-by-*L* matrix containing detections indices. *K* is the number of dimensions of `X`. *L* is the number of detections found in the input data. When `X` is a matrix, `Y` contains the row and column indices of each detection in `X` in the form `[detrow;detcol]`. When `X` is an array, `Y` contains the row, column, and page indices of each detection in `X` in the form `[detrow;detcol;detpage]`. When the `NumDetectionsSource` property is set to `'Property'`, *L* equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Data Types: `single` | `double`

### `th` — Computed detection threshold

real-valued matrix

Computed detection threshold for each detected cell, returned as a real-valued matrix. `Th` has the same dimensions as `Y`.

- When `OutputFormat` is `'CUT result'`, `Th` returns the detection threshold whenever an element of `Y` is `1` and `NaN` whenever an element of `Y` is `0`.

- When `OutputFormat` is `'Detection index'`, `th` returns a detection threshold for each corresponding detection in `Y`. When the `NumDetectionsSource` property is set to `'Property'`, *L* equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

**Dependencies**

To enable this output argument, set the `ThresholdOutputPort` to `true`.

Data Types: `single` | `double`

**noise — Estimated noise power**
real-valued matrix

Estimated noise power for each detected cell, returned as a real-valued matrix. `noise` has the same dimensions as `Y`.

- When `OutputFormat` is `'CUT result'`, `noise` returns the noise power whenever an element of `Y` is `1` and `NaN` whenever an element of `Y` is `0`.
- When `OutputFormat` is `'Detection index'`, `noise` returns a noise power for each corresponding detection in `Y`. When the `NumDetectionsSource` property is set to `'Property'`, *L* equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

**Dependencies**

To enable this output argument, set the `NoisePowerOutputPort` to `true`.

Data Types: `single` | `double`

# Examples

### Set 2-D CFAR Threshold for Noise-Only Data

This example shows how to set a 2-D CFAR threshold based upon a required probability of false alarm (pfa).

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing Gaussian noise. Estimate the empirical pfa and compare it to the required pfa. To get a good estimate, perform this simulation on 1000 similar matrices. First, set a threshold using the required pfa. In this case, there are no targets and the pfa can be estimated from the number of cells that exceed the threshold. Assume that the data is processed through a square-law detector and that no pulse integration is performed. Use a training-cell band of 3 cells in width and 4 cells in height. Use a guard band of 3 cells in width and 2 cells in height to separate the cells under test (CUT) from the training cells. Specify a required pfa of 5.0e-4.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
detector = phased.CFARDetector2D('TrainingBandSize',[4,3], ...
    'ThresholdFactor','Auto','GuardBandSize',[2,3], ...
    'ProbabilityFalseAlarm',p,'Method','SOCA','ThresholdOutputPort',true);
```

Create a 41-by-41 image containing random complex data. Then, square the data to simulate a square-law detector.

```
x = 2/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
x2 = abs(x).^2;
```

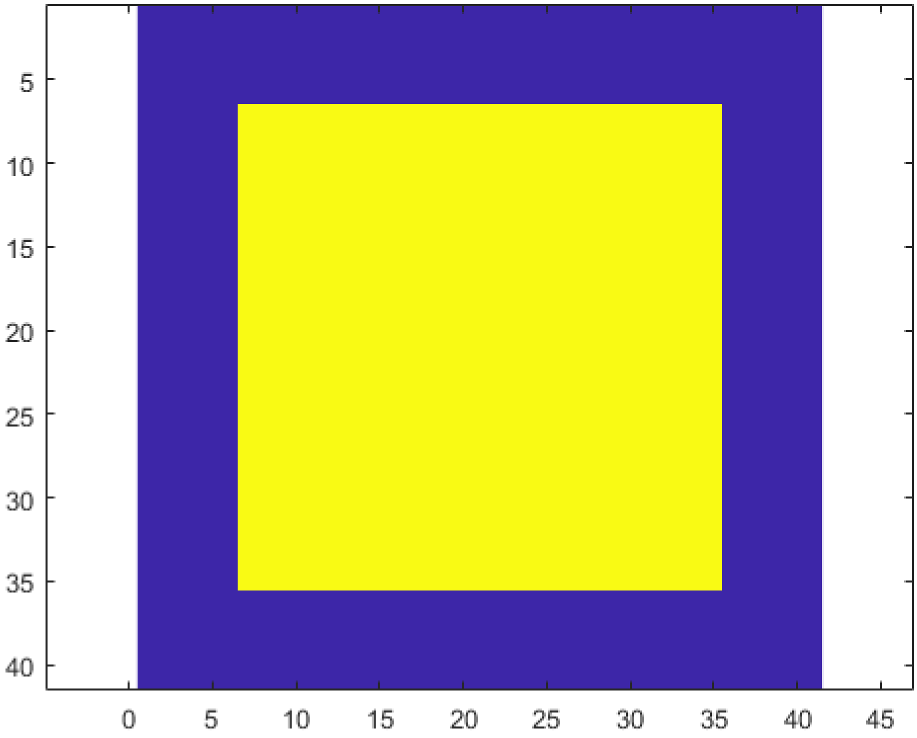
Process all the cells in each image. To do this, find the row and column of each CUT cell whose training region falls entirely within each image.

```
Ngc = detector.GuardBandSize(2);
Ngr = detector.GuardBandSize(1);
Ntc = detector.TrainingBandSize(2);
Ntr = detector.TrainingBandSize(1);
cutidx = [];
colstart = Ntc + Ngc + 1;
colend = N - ( Ntc + Ngc);
rowstart = Ntr + Ngr + 1;
rowend = N - ( Ntr + Ngr);
for m = colstart:colend
    for n = rowstart:rowend
        cutidx = [cutidx,[n;m]];
    end
end
ncutcells = size(cutidx,2);
```

Display the CUT cells.

```
cutimage = zeros(N,N);
for k = 1:ncutcells
```

```
    cutimage(cutidx(1,k),cutidx(2,k)) = 1;
end
imagesc(cutimage)
axis equal
```



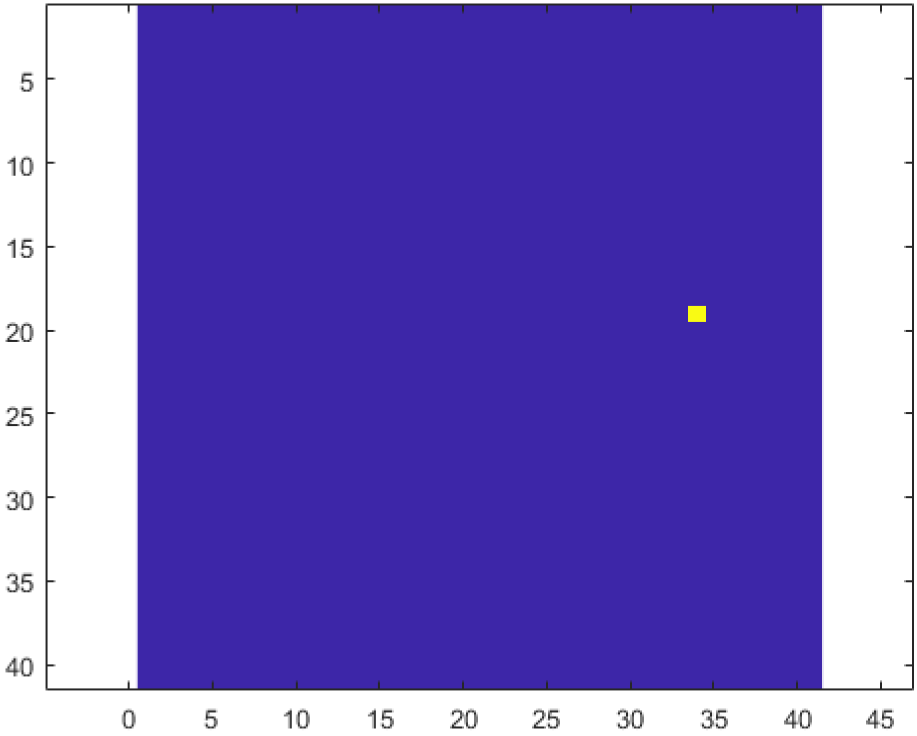
Perform the detection on all CUT cells. Return the detection classification and the threshold used to classify the cell.

```
[dets,th] = detector(x2,cutidx);
```

Find and display an image with a false alarm for illustration.

```
di = [];
for k = 1:ntrials
```

```
    d = dets(:,k);
    if (any(d) > 0)
        di = [di,k];
    end
end
idx = di(1);
detimg = zeros(N,N);
for k = 1:ncutcells
    detimg(cutidx(1,k),cutidx(2,k)) = dets(k,idx);
end
imagesc(detimg)
axis equal
```



Compute the empirical pfa.

```
pfa = sum(dets(:))/ntrials/ncutcells
```

```
pfa = 4.5898e-04
```

The empirical and specified pfa agree.

Display the average empirical threshold value over all images.

```
mean(th(:))
```

```
ans = 31.7139
```

Compute the theoretical threshold factor for the required pfa.

```
threshfactor = npwgnthresh(p,1,'noncoherent');
threshfactor = 10^(threshfactor/10);
disp(threshfactor)
```

```
    7.6009
```

The theoretical threshold factor multiplied by the noise variance should agree with the measured threshold.

```
noisevar = mean(x2(:));
disp(threshfactor*noisevar);
```

```
   30.4118
```

The theoretical threshold and empirical threshold agree to within an acceptable difference.

### Detect Targets in Background Noise

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing five closely-spaced targets in Gaussian noise. Perform this detection on a simulation of 1000 images. Use two detectors with different guard band regions. Set the thresholds manually using the `Custom` threshold factor. Assume that the data is processed through a square law-detector and that no pulse integration is performed. Use a training cell band of 2 cells in width and 2 cells in height. For the first detector, use a guard band of 1 cell all around to separate the CUT cells from the training cells. For the second detector, use a guard band of 8 cells all around.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
```

Create 1000 41-by-41 images of complex random noise with standard deviation of 1.

```
s = 1;
x = s/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
```

Set the target cells values to 1.5. Then, square the cell values.

```
A = 1.5;
x(23,20,:) = A;
x(23,18,:) = A;
x(23,23,:) = A;
x(20,22,:) = A;
x(21,18,:) = A;
x2 = abs(x).^2;
```

Display the target cells.

```
xtgt = zeros(N,N);
xtgt(23,20,:) = A;
xtgt(23,18,:) = A;
xtgt(23,23,:) = A;
xtgt(20,22,:) = A;
xtgt(21,18,:) = A;
imagesc(xtgt)
axis equal
axis tight
```

Set the CUT cells to be the target cells.

```
cutidx(1,1) = 23;
cutidx(2,1) = 20;
cutidx(1,2) = 23;
cutidx(2,2) = 18;
cutidx(1,3) = 23;
cutidx(2,3) = 23;
cutidx(1,4) = 20;
cutidx(2,4) = 22;
cutidx(1,5) = 21;
cutidx(2,5) = 18;
```

Perform the detection on all CUT cells using two CFAR 2-D detectors. The first detector has a small guard band region. The training region can include neighboring targets which can affect the computation of the noise power. The second detector has a larger guard band region, which precludes target cells from being used in the noise computation.

Create the two CFAR detectors.

```
detector1 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[1,1],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
detector2 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[8,8],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
```

Return the detection classifications and the thresholds used to classify the cells. Then, compute the probabilities of detection.

```
[dets1,th1] = detector1(x2,cutidx);
ndets = numel(dets1(:));
pd1 = sum(dets1(:))/ndets
```

```
pd1 = 0.6416
```

```
[dets2,th2] = detector2(x2,cutidx);
pd2 = sum(dets2(:))/ndets
```

```
pd2 = 0.9396
```

The detector with the larger guard-band region has a higher pfa because the noise is more accurately estimated.

# phased.Collector

**Package:** phased

Narrowband signal collector

## Description

The phased.Collector System object implements a narrowband signal collector. A collector converts incident narrowband wave fields arriving from specified directions into signals to be further processed. Wave fields are incident on antenna and microphone elements, sensor arrays, or subarrays. The object collects signals in one of two ways controlled by the Wavefront property.

- If the Wavefront property is set to 'Plane', the collected signals at each element or subarray are formed from the coherent sum of all incident plane wave fields sampled at each array element or subarray.
- If the Wavefront property is set to 'Unspecified', the collected signals are formed from an independent field incident on each individual sensor element.

You can use this object to

- model arriving signals as polarized or nonpolarized fields depending upon whether the element or array supports polarization and the value of the Polarization property. Using polarization, you can receive a signal as a polarized electromagnetic field, or receive two independent signals using dual (i.e. orthogonal) polarization directions.
- model incoming acoustic fields by using nonpolarized microphone and sonar transducer array elements and by setting the “Polarization” on page 1-0 to 'None'. You must also set the PropagationSpeed to a value appropriate for the medium.
- collect fields at subarrays created by the phased.ReplicatedSubarray and phased.PartitionedArray objects. You can steer all subarrays in the same direction using the steering angle argument, STEERANG, or steer each subarray in a different direction using the subarray element weights argument, WS. You cannot set the Wavefront property to 'Unspecified' for subarrays.

To collect arriving signals at the elements or arrays:

1 Create the phased.Collector object and set its properties.
2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

## Syntax

```
collector = phased.Collector
collector = phased.Collector(Name,Value)
```

### Description

collector = phased.Collector creates a narrowband signal collector object, collector, with default property values.

collector = phased.Collector(Name,Value) creates a narrowband signal collector with each property Name set to a specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN). Enclose each property name in single quotes.

Example: collector = phased.collector('Sensor',phased.URA,'OperatingFrequency',300e6) sets the sensor array to a uniform rectangular array (URA) with default URA property values. The beamformer has an operating frequency of 300 MHz.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**`Sensor` — Sensor element or sensor array**
`phased.ULA` array with default property values (default) | Phased Array System Toolbox sensor or array

Sensor element or sensor array, specified as a System object belonging to Phased Array System Toolbox. A sensor array can contain subarrays.

Example: `phased.URA`

**`PropagationSpeed` — Signal propagation speed**
`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

**`OperatingFrequency` — Operating frequency**
`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

**`Wavefront` — Type of incoming wavefront**
`'Plane'` (default) | `'Unspecified'`

The type of incoming wavefront, specified as `'Plane'` or `'Unspecified'`:

- `'Plane'` — input signals are multiple plane waves impinging on the entire array. Each plane wave is received by all collecting elements.
- `'Unspecified'` — collected signals are independent fields incident on individual sensor elements. If the `Sensor` property is an array that contains subarrays, you cannot set the `Wavefront` property to `'Unspecified'`.

Data Types: `char`

**`SensorGainMeasure` — Specify sensor gain**
`'dB'` (default) | `'dBi'`

Sensor gain measure, specified as `'dB'` or `'dBi'`.

- When you set this property to `'dB'`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.
- When you set this property to `'dBi'`, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values predicted by the radar equation that uses dBi to specify the antenna gain. The computation using the `'dBi'` option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor.

#### Dependencies

To enable this property, set the `Wavefront` property to `'Plane'`.

Data Types: `char`

### `Polarization` — Polarization configuration

`'None'` (default) | `'Combined'` | `'Dual'`

Polarization configuration, specified as `'None'`, `'Combined'`, or `'Dual'`. When you set this property to `'None'`, the incident fields are considered scalar fields. When you set this property to `'Combined'`, the incident fields are polarized and represent a single arriving signal whose polarization reflects the sensor's inherent polarization. When you set this property to `'Dual'`, the *H* and *V* polarization components of the fields are independent signals.

Example: `'Dual'`

Data Types: `char`

### `WeightsInputPort` — Enable weights input

`false` (default) | `true`

Enable weights input, specified as `false` or `true`. When `true`, use the object input argument `W` to specify weights. Weights are applied to individual array elements (or at the subarray level when subarrays are supported).

Data Types: `logical`

# Usage

# Syntax

```
Y = collector(X,ANG)
Y = collector(X,ANG,LAXES)
[YH,YV] = collector(X,ANG,LAXES)
[ ___ ] = collector( ___ ,W)
[ ___ ] = collector( ___ ,STEERANG)
[ ___ ] = collector( ___ ,WS)
```

## Description

`Y = collector(X,ANG)` collects the signals, `X`, arriving from the directions specified by `ANG`. `Y` contains the collected signals.

`Y = collector(X,ANG,LAXES)` also specifies `LAXES` as the local coordinate system axes directions. To use this syntax, set the Polarization property to `'Combined'`.

`[YH,YV] = collector(X,ANG,LAXES)` returns an H-polarization component of the field, `YH`, and a V-polarization component, `YV`. To use this syntax, set the Polarization property to `'Dual'`.

`[ ___ ] = collector( ___ ,W)` also specifies `W` as array element or subarray weights. To use this syntax, set the WeightsInputPort property to `true`.

`[ ___ ] = collector( ___ ,STEERANG)` also specifies `STEERANG` as the subarray steering angle. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`.

`[ ___ ] = collector( ___ ,WS)` also specifies `WS` as the weights applied to each element within each subarray. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` of that array to `'Custom'`.

## Input Arguments

### X — Arriving signals

complex-valued *M*-by-*L* matrix | complex-valued 1-by-*L* cell array of structures

Arriving signals, specified as a complex-valued *M*-by-*L* matrix or complex-valued 1-by-*L* cell array of structures. *M* is the number of signal samples and *L* is the number of arrival angles. This argument represents the arriving fields.

- If the `Polarization` property value is set to `'None'`, `X` is an *M*-by-*L* matrix.
- If the `Polarization` property value is set to `'Combined'` or `'Dual'`, `X` is a 1-by-*L* cell array of structures. Each cell corresponds to a separate arriving signal. Each `struct` contains three column vectors containing the *X*, *Y*, and *Z* components of the polarized fields defined with respect to the global coordinate system.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Dependencies**

To enable this argument, set the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### ANG — Arrival directions of signals

real-valued 2-by-*L* matrix

Arrival directions of signals, specified as a real-valued 2-by-*L* matrix. Each column specifies an arrival direction in the form `[AzimuthAngle;ElevationAngle]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive. When the Wavefront property is `false`, the number of angles must equal the number of array elements, *N*. Units are in degrees.

Example: `[30,20;45,0]`

Data Types: `double`

### LAXES — Local coordinate system

real-valued 3-by-3 orthogonal matrix

Local coordinate system, specified as a real-valued 3-by-3 orthogonal matrix. The matrix columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes with respect to the global coordinate system.

Example: `rotx(30)`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Combined'` or `'Dual'`.

Data Types: `double`

### `W` — Element or subarray weights

*N*-by-1 column vector

Element or subarray weights, specified as a complex-valued *N*-by-1 column vector where *N* is the number of array elements (or subarrays when the array supports subarrays).

#### Dependencies

To enable this argument, set the WeightsInputPort property to `true`.

Data Types: `double`
Complex Number Support: Yes

### `WS` — Subarray element weights

complex-valued $N_{SE}$-by-*N* matrix | 1-by-*N* cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-*N* matrix or 1-by-*N* cell array where *N* is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

**Dependencies**

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

**`STEERANG` — Subarray steering angle**
real-valued 2-by-1 vector

Subarray steering angle, specified as a length-2 column vector. The vector has the form `[azimuthAngle;elevationAngle]`. The azimuth angle must be between –180° and

180°, inclusive. The elevation angle must be between –90° and 90°, inclusive. Units are in degrees.

Example: `[20;15]`

#### Dependencies

To enable this argument, set the `Sensor` property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`

Data Types: `double`

## Output Arguments

### Y — Collected signal

complex-valued *M*-by-*N* matrix

Collected signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the length of the input signal. *N* is the number of array elements (or subarrays when subarrays are supported). Each column corresponds to the signal collected by the corresponding array element (or corresponding subarrays when subarrays are supported).

#### Dependencies

To enable this argument, set the `Polarization` property to `'None'` or `'Combined'`.

Data Types: `double`

### YH — Collected horizontal polarization signal

complex-valued *M*-by-*N* matrix

Collected horizontal polarization signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the length of the input signal. *N* is the number of array elements (or subarrays when subarrays are supported). Each column corresponds to the signal collected by the corresponding array element (or corresponding subarrays when subarrays are supported).

#### Dependencies

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`

### YV — Collected vertical polarization signal

complex-valued *M*-by-*N* matrix

Collected horizontal polarization signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the length of the input signal. *N* is the number of array elements (or subarrays when subarrays are supported). Each column corresponds to the signal collected by the corresponding array element (or corresponding subarrays when subarrays are supported).

**Dependencies**

To enable this argument, set the `Polarization` property to `'Dual'`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Collect Wideband Signal at Single Antenna

Use the `phased.Collector` System object™ to construct a signal arriving at a single isotropic antenna from 10° azimuth and 30° elevation.

```
antenna = phased.IsotropicAntennaElement;
collector = phased.Collector('Sensor',antenna);
x = [1;0;-1];
incidentAngle = [10;30];
y = collector(x,incidentAngle)
```

```
y = 3×1
```

```
     1
     0
    -1
```

### Collect Signal at Uniform Linear Array

Collect a far-field signal arriving at a 3-element uniform linear array (ULA) of isotropic antenna elements.

```
antenna = phased.ULA('NumElements',3);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',1e9);
x = [1;0;-1];
incidentAngle = [10 30]';
y = collector(x,incidentAngle)
```

```
y = 3×3 complex

  -0.0051 - 1.0000i   1.0000 + 0.0000i  -0.0051 + 1.0000i
   0.0000 + 0.0000i   0.0000 + 0.0000i   0.0000 + 0.0000i
   0.0051 + 1.0000i  -1.0000 + 0.0000i   0.0051 - 1.0000i
```

### Collect Different Signals at Array Elements

Collect different signals at a three-element array. Each input signal comes from a different direction.

```
array = phased.ULA('NumElements',3);
collector = phased.Collector('Sensor',array,'OperatingFrequency',1e9,...
    'Wavefront','Unspecified');
```

Each column is a signal for one element

```
x = rand(10,3)
```

```
x = 10×3

    0.8147    0.1576    0.6557
    0.9058    0.9706    0.0357
    0.1270    0.9572    0.8491
    0.9134    0.4854    0.9340
    0.6324    0.8003    0.6787
    0.0975    0.1419    0.7577
    0.2785    0.4218    0.7431
    0.5469    0.9157    0.3922
    0.9575    0.7922    0.6555
    0.9649    0.9595    0.1712
```

Specify three incident angles.

```
incidentAngles = [10 0; 20 5; 45 2]';
y = collector(x,incidentAngles)
```

```
y = 10×3

    0.8147    0.1576    0.6557
    0.9058    0.9706    0.0357
    0.1270    0.9572    0.8491
    0.9134    0.4854    0.9340
    0.6324    0.8003    0.6787
    0.0975    0.1419    0.7577
    0.2785    0.4218    0.7431
    0.5469    0.9157    0.3922
    0.9575    0.7922    0.6555
    0.9649    0.9595    0.1712
```

### Collect Plane Wave at ULA

Construct a 4-element uniform linear array (ULA). The array operating frequency is 1 GHz. The array element spacing is one half the corresponding wavelength. Model the collection of a 200 Hz sinusoid from the far field incident on the array at 45° azimuth and 10° elevation.

Create the array.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
array = phased.ULA('NumElements',4,'ElementSpacing',lambda/2);
```

Create the sinusoid signal.

```
t = linspace(0,1,1e3);
x = cos(2*pi*200*t)';
```

Construct the collector object and obtain the received signal.

```
collector = phased.Collector('Sensor',array, ...
    'PropagationSpeed',physconst('LightSpeed'),'Wavefront','Plane', ...
    'OperatingFrequency',fc);
incidentangle = [45;10];
receivedsig = collector(x,incidentangle);
```

### Measure Target Scattering Matrix Using Dual Polarization

Use a dual-polarization system to obtain target scattering information. Simulate a transmitter and receiver where the vertical and horizontal components are transmitted successively using the input ports of the transmitter. The signals from the two polarization output ports of the receiver is then used to determine the target scattering matrix.

```
scmat = [0 1i; 1i 2];
radiator = phased.Radiator('Sensor', ...
    phased.CustomAntennaElement('SpecifyPolarizationPattern',true), ...
    'Polarization','Dual');
target = phased.RadarTarget('EnablePolarization',true,'ScatteringMatrix', ...
    scmat);
collector = phased.Collector('Sensor', ...
    phased.CustomAntennaElement('SpecifyPolarizationPattern',true), ...
    'Polarization','Dual');
xh = 1;
xv = 1;
```

Transmit a horizontal component and display the reflected Shh and Svh polarization components.

```
x = radiator(xh,0,[0;0],eye(3));
xrefl = target(x,[0;0],eye(3));
[Shh,Svh] = collector(xrefl,[0;0],eye(3))
```

```
Shh = 0

Svh = 0.0000 + 3.5474i
```

Transmit a vertical component and display the reflected Shv and Svv polarization components.

```
x = radiator(0,xv,[0;0],eye(3));
xrefl = target(x,[0;0],eye(3));
[Shv,Svv] = collector(xrefl,[0;0],eye(3))
```

```
Shv = 0.0000 + 3.5474i

Svv = 7.0947
```

## Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.Collector` collects each plane wave signal using the phase approximation of the time delays across collecting elements in the far field.

If the `Wavefront` property value is `'Unspecified'`, `phased.Collector` collects each channel independently.

For further details, see [1].

**Package:** phased

Collect signals

## Syntax

```
Y = step(H,X,ANG)
Y = step(H,X,ANG,LAXES)
Y = step(H,X,ANG,WEIGHTS)
Y = step(H,X,ANG,STEERANGLE)
Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X,ANG) collects signals X arriving from directions ANG. The collection process depends on the Wavefront property of H, as follows:

- If Wavefront has the value 'Plane', each collecting element collects all the far field signals in X. Each column of Y contains the output of the corresponding element in response to all the signals in X.
- If Wavefront has the value 'Unspecified', each collecting element collects only one impinging signal from X. Each column of Y contains the output of the corresponding element in response to the corresponding column of X. The 'Unspecified' option is available when the Sensor property of H does not contain subarrays.

`Y = step(H,X,ANG,LAXES)` uses `LAXES` as the local coordinate system axes directions. This syntax is available when you set the `EnablePolarization` property to `true`.

`Y = step(H,X,ANG,WEIGHTS)` uses `WEIGHTS` as the weight vector. This syntax is available when you set the `WeightsInputPort` property to `true`.

`Y = step(H,X,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Collector object.

### X

Arriving signals. Each column of `X` represents a separate signal. The specific interpretation of `X` depends on the `Wavefront` property of `H`.

| Wavefront Property Value | Description |
|---|---|
| `'Plane'` | Each column of `X` is a far field signal. |

| Wavefront Property Value | Description |
|---|---|
| 'Unspecified' | Each column of X is the signal impinging on the corresponding element. In this case, the number of columns in X must equal the number of collecting elements in the Sensor property. |

- If the EnablePolarization property value is set to false, X is a matrix. The number of columns of the matrix equals the number of separate signals.

  The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.
- If the EnablePolarization property value is set to true, X is a row vector of MATLAB struct type. The dimension of the struct array equals the number of separate signals. Each struct member contains three column-vector fields, X, Y, and Z, representing the *x*, *y*, and *z* components of the polarized wave vector signals in the global coordinate system.

  The size of the first dimension of the matrix fields within the struct can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

### ANG

Incident directions of signals, specified as a two-row matrix. Each column specifies the incident direction of the corresponding column of X. Each column of ANG has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

### LAXES

Local coordinate system. LAXES is a 3-by-3 matrix whose columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively. Each axis is specified in terms of [x;y;z] with respect to the global coordinate system. This argument is only used when the EnablePolarization property is set to true.

### WEIGHTS

Vector of weights. WEIGHTS is a column vector of length M, where M is the number of collecting elements.

**Default:** ones(M,1)

### STEERANGLE

Subarray steering angle, specified as a length-2 column vector. The vector has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

## Output Arguments

### Y

Collected signals. Each column of Y contains the output of the corresponding element. The output is the response to all the signals in X, or one signal in X, depending on the Wavefront property of H.

## Examples

### Collect Plane Wave at ULA

Construct a 4-element uniform linear array (ULA). The array operating frequency is 1 GHz. The array element spacing is one half the corresponding wavelength. Model the collection of a 200 Hz sinusoid from the far field incident on the array at 45° azimuth and 10° elevation.

Create the array.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
array = phased.ULA('NumElements',4,'ElementSpacing',lambda/2);
```

Create the sinusoid signal.

```
t = linspace(0,1,1e3);
x = cos(2*pi*200*t)';
```

Construct the collector object and obtain the received signal.

```
collector = phased.Collector('Sensor',array, ...
    'PropagationSpeed',physconst('LightSpeed'),'Wavefront','Plane', ...
    'OperatingFrequency',fc);
incidentangle = [45;10];
receivedsig = collector(x,incidentangle);
```

## Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.Collector` collects each plane wave signal using the phase approximation of the time delays across collecting elements in the far field.

If the `Wavefront` property value is `'Unspecified'`, `phased.Collector` collects each channel independently.

For further details, see [1].

# clusterDBSCAN

Data clustering

## Description

`clusterDBSCAN` clusters data points belonging to a *P*-dimensional feature space using the density-based spatial clustering of applications with noise (DBSCAN) algorithm. The clustering algorithm assigns points that are close to each other in feature space to a single cluster. For example, a radar system can return multiple detections of an extended target that are closely spaced in range, angle, and Doppler. `clusterDBSCAN` assigns these detections to a single detection.

- The DBSCAN algorithm assumes that clusters are dense regions in data space separated by regions of lower density and that all dense regions have similar densities.
- To measure density at a point, the algorithm counts the number of data points in a neighborhood of the point. A neighborhood is a *P*-dimensional ellipse (hyperellipse) in the feature space. The radii of the ellipse are defined by the *P*-vector ε. ε can be a scalar, in which case, the hyperellipse becomes a hypersphere. Distances between points in feature space are calculated using the Euclidean distance metric. The neighborhood is called an ε-neighborhood. The value of ε is defined by the `Epsilon` property. `Epsilon` can either be a scalar or *P*-vector:
  - A vector is used when different dimensions in feature space have different units.
  - A scalar applies the same value to all dimensions.
- Clustering starts by finding all *core* points. If a point has a sufficient number of points in its ε-neighborhood, the point is called a core point. The minimum number of points required for a point to become a core point is set by the `MinNumPoints` property.
- The remaining points in the ε-neighborhood of a core point can be core points themselves. If not, they are *border* points. All points in the ε-neighborhood are called *directly density reachable* from the core point.
- If the ε-neighborhood of a core point contains other core points, the points in the ε-neighborhoods of all the core points merge together to form a union of ε-neighborhoods. This process continues until no more core points can be added.

  - All points in the union of ε-neighborhoods are *density reachable* from the first core point. In fact, all points in the union are density reachable from all core points in the union.
  - All points in the union of ε-neighborhoods are also termed *density connected* even though border points are not necessarily *reachable* from each other. A *cluster* is a maximal set of density-connected points and can have an arbitrary shape.
- Points that are not core or border points are *noise* points. They do not belong to any cluster.
- The `clusterDBSCAN` object can estimate ε using a *k*-nearest neighbor search, or you can specify values. To let the object estimate ε, set the `EpsilonSource` property to `'Auto'`.
- The `clusterDBSCAN` object can disambiguate data containing ambiguities. Range and Doppler are examples of possibly ambiguous data. Set `EnableDisambiguation` property to `true` to disambiguate data.

To cluster detections:

1. Create the `clusterDBSCAN` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

# Syntax

```
clusterer = clusterDBSCAN
clusterer = clusterDBSCAN(Name,Value)
```

## Description

`clusterer = clusterDBSCAN` creates a `clusterDBSCAN` object, `clusterer`, object with default property values.

`clusterer = clusterDBSCAN(Name,Value)` creates a `clusterDBSCAN` object, `clusterer`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Any unspecified properties take default values. For example,

```
clusterer = clusterDBSCAN('MinNumPoints',3,'Epsilon',2, ...
'EnableDisambiguation',true,'AmbiguousDimension',[1 2]);
```

creates a clusterer with the `EnableDisambiguation` property set to true and the `AmbiguousDimension` set to `[1,2]`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### EpsilonSource — Source of epsilon

`'Property'` (default) | `'Auto'`

Source of epsilon values defining an ε-neighborhood, specified as `'Property'` or `'Auto'`.

- When you set the `EpsilonSource` property to `'Property'`, ε is obtained from the `Epsilon` property.
- When you set the `EpsilonSource` property to `'Auto'`, ε is estimated automatically using a $k$-nearest neighbor ($k$-NN) search over a range of $k$ values from $k_{\min}$ to $k_{\max}$.

  $$k_{\min} = \text{MinNumPoints} - 1$$

  $$k_{\max} = \text{MaxNumPoints} - 1$$

  The subtraction of one is needed because the number of neighbors of a point does not include the point itself, whereas `MinNumPoints` and `MaxNumPoints` refer to the total number of points in a neighborhood.

Data Types: `char` | `string`

### `Epsilon` — Radius for neighborhood search

`10.0` (default) | positive scalar | positive, real-valued 1-by-*P* row vector

Radius for a neighborhood search, specified as a positive scalar or positive, real-valued 1-by-*P* row vector. *P* is the number of features in the input data, `X`.

`Epsilon` defines the radii of an ellipse around any point to create an ε-neighborhood. When `Epsilon` is a scalar, the same radius applies to all feature dimensions. You can apply different epsilon values for different features by specifying a positive, real-valued 1-by-*P* row vector. A row vector creates a multidimensional ellipse (hyperellipse) search area, useful when the data features have different physical meanings, such as range and Doppler. See “Estimate Epsilon” on page 1-304 for more information about this property.

You can use the `clusterDBSCAN.estimateEpsilon` or `clusterDBSCAN.discoverClusters` object functions to help estimate a scalar value for epsilon.

Example: `[11 21.0]`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `EpsilonSource` property to `'Property'`.

Data Types: `double`

### `MinNumPoints` — Minimum number of points required for cluster

`3` (default) | positive integer

Minimum number of points in an ε-neighborhood of a point for that point to become a core point, specified as a positive integer. See “Choosing the Minimum Number of Points” on page 1-307 for more information. When the object automatically estimates epsilon using a *k*-NN search, the starting value of *k* ($k_{\text{min}}$) is `MinNumPoints` - 1.

Example: `5`

Data Types: `double`

### `MaxNumPoints` — Set end of *k*-NN search range

`10` (default) | positive integer

Set end of *k*-NN search range, specified as a positive integer. When the object automatically estimates epsilon using a *k*-NN search, the ending value of *k* ($k_{\text{max}}$) is `MaxNumPoints` - 1.

Example: 13

**Dependencies**

To enable this property, set the EpsilonSource property to 'Auto'.

Data Types: double

### EpsilonHistoryLength — Length of cluster threshold epsilon history

10 (default) | positive integer

Length of the stored epsilon history, specified as a positive integer. When set to one, the history is memory-less, meaning that each epsilon estimate is immediately used and no moving-average smoothing occurs. When greater than one, epsilon is averaged over the history length specified.

Example: 5

**Dependencies**

To enable this property, set the EpsilonSource property to 'Auto'.

Data Types: double

### EnableDisambiguation — Enable disambiguation of dimensions

false (default) | true

Switch to enable disambiguation of dimensions, specified as false or true. When true, clustering can occur across boundaries defined by the input amblims at execution. Use the AmbiguousDimensions property to specify the column indices of X in which ambiguities can occur. You can disambiguate up to two dimensions. Turning on disambiguation is not recommended for large data sets.

Data Types: logical

### AmbiguousDimension — Indices of ambiguous dimensions

1 (default) | positive integer | 1-by-2 vector of positive integers

Indices of ambiguous dimensions, specified as a positive integer or 1-by-2 vector of positive integers. This property specifies the column of X in which to apply disambiguation. A positive integer indicates a single ambiguous dimension in the input data matrix X. A 1-by-2 row vector specifies two ambiguous dimensions. The size and order of AmbiguousDimension must be consistent with the object input amblims.

Example: [3 4]

**Dependencies**

To enable this property, set the `EnableDisambiguation` property to `true`.

Data Types: `double`

# Usage

# Syntax

```
idx = clusterer(X)
[idx,clusterids] = clusterer(X)
[ ___ ] = clusterer(X,amblims)
[ ___ ] = clusterer(X,update)
[ ___ ] = clusterer(X,amblims,update)
```

## Description

`idx = clusterer(X)` clusters the points in the input data, `X`. `idx` contains a list of IDs identifying the cluster to which each row of `X` belongs. Noise points are assigned as '–1'.

`[idx,clusterids] = clusterer(X)` also returns an alternate set of cluster IDs, `clusterids`, for use in the `phased.RangeEstimator` and `phased.DopplerEstimator` objects. `clusterids` assigns a unique ID to each noise point.

`[ ___ ] = clusterer(X,amblims)` also specifies the minimum and maximum ambiguity limits, `amblims`, to apply to the data.

To enable this syntax, set the `EnableDisambiguation` property to `true`.

`[ ___ ] = clusterer(X,update)` automatically estimates epsilon from the input data matrix, `X`, when `update` is set to `true`. The estimation uses a *k*-NN search to create a set of search curves. For more information, see “Estimate Epsilon” on page 1-320. The estimate is an average of the *L* most recent Epsilon values where *L* is specified in `EpsilonHistoryLength`

To enable this syntax, set the `EpsilonSource` property to `'Auto'`, optionally set the `MaxNumPoints` property, and also optionally set the `EpsilonHistoryLength` property.

[ ___ ] = clusterer(X,amblims,update) sets ambiguity limits and estimates epsilon when update is set to true. To enable this syntax, set EnableDisambiguation to true and set EpsilonSource to 'Auto'.

## Input Arguments

### X — Input feature data

real-valued *N*-by-*P* matrix

Input feature data, specified as a real-valued *N*-by-*P* matrix. The *N* rows correspond to feature points in a *P*-dimensional feature space. The *P* columns contain the values of the features over which clustering takes place. The DBSCAN algorithm can cluster any type of data with appropriate MinNumPoints and Epsilon settings. For example, a two-column input can contain the *xy* Cartesian coordinates, or range and Doppler.

Data Types: double

### amblims — Ambiguity limits

1-by-2 real-valued vector (default) | 2-by-2 real-valued matrix

Ambiguity limits, specified as a real-valued 1-by-2 vector or real-valued 2-by-2 matrix. For a single ambiguity dimension, specify the limits as a 1-by-2 vector *[MinAmbiguityLimitDimension1,MaxAmbiguityLimitDimension1]*. For two ambiguity dimensions, specify the limits as a 2-by-2 matrix *[MinAmbiguityLimitDimension1, MaxAmbiguityLimitDimension1; MinAmbiguityLimitDimension2,MaxAmbiguityLimitDimension2]*. Ambiguity limits allow clustering across boundaries to ensure that ambiguous detections are appropriately clustered.

The ambiguous columns of X are defined in the AmbiguousDimension property. amblims defines the minimum and maximum ambiguity limits in the same units as the data in the AmbiguousDimension columns of X.

Example: [0 20; -40 40]

#### Dependencies

To enable this argument, set EnableDisambiguation to true and set the AmbiguousDimension property.

Data Types: double

### `update` — Enable automatic update of epsilon

`false` (default) | `true`

Enable automatic update of the epsilon estimate, specified as `false` or `true`.

- When `true`, the epsilon threshold is first estimated as the average of the knees of *k*-NN search curves. The estimate is then added to a buffer whose length *L* is set in the `EpsilonHistoryLength` property. The final epsilon that is used is calculated as the average of the *L*-length epsilon history buffer. If `EpsilonHistoryLength` is set to `1`, the estimate is memory-less. Memory-less means that each epsilon estimate is immediately used and no moving-average smoothing occurs.
- When `false`, a previous epsilon estimate is used. Estimating epsilon is computationally intensive and not recommended for large data sets.

#### Dependencies

To enable this argument, set the `EpsilonSource` property to `'Auto'` and specify the `MaxNumPoints` property.

Data Types: `double`

## Output Arguments

### `idx` — Cluster indices

*N*-by-1 integer-valued column vector

Cluster indices, returned as an integer-valued *N*-by-1 column vector. `idx` represents the clustering results of the DBSCAN algorithm. Positive `idx` values correspond to clusters that satisfy the DBSCAN clustering criteria. A value of '`-1`' indicates a DBSCAN noise point.

Data Types: `double`

### `clusterids` — Alternative cluster IDs

1-by-*N* integer-valued row vector

Alternative cluster IDs, returned as a 1-by-*N* row vector of positive integers. Each value is a unique identifier indicating a hypothetical target cluster. This argument contains unique positive cluster IDs for all points including noise. In contrast, the `idx` output argument labels noise points with '–1'. Use `clusterids` as the input to Phased Array System Toolbox objects such as `phased.RangeEstimator` and `phased.DopplerEstimator`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `clusterDBSCAN`

| | |
|---|---|
| clusterDBSCAN.discoverClusters | Find cluster hierarchy in data |
| clusterDBSCAN.estimateEpsilon | Estimate neighborhood clustering threshold |
| plot | Plot clusters |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Cluster Detections in Range and Doppler

Create detections of extended objects with measurements in range and Doppler. Assume the maximum unambiguous range is 20 m and the unambiguous Doppler span extends from −30 Hz to 30 Hz. The data matrix is contained in the `dataClusterDBSCAN.mat` file. The first column represents range, and the second column represents Doppler.

The input data contains the following extended targets and false alarms specified:

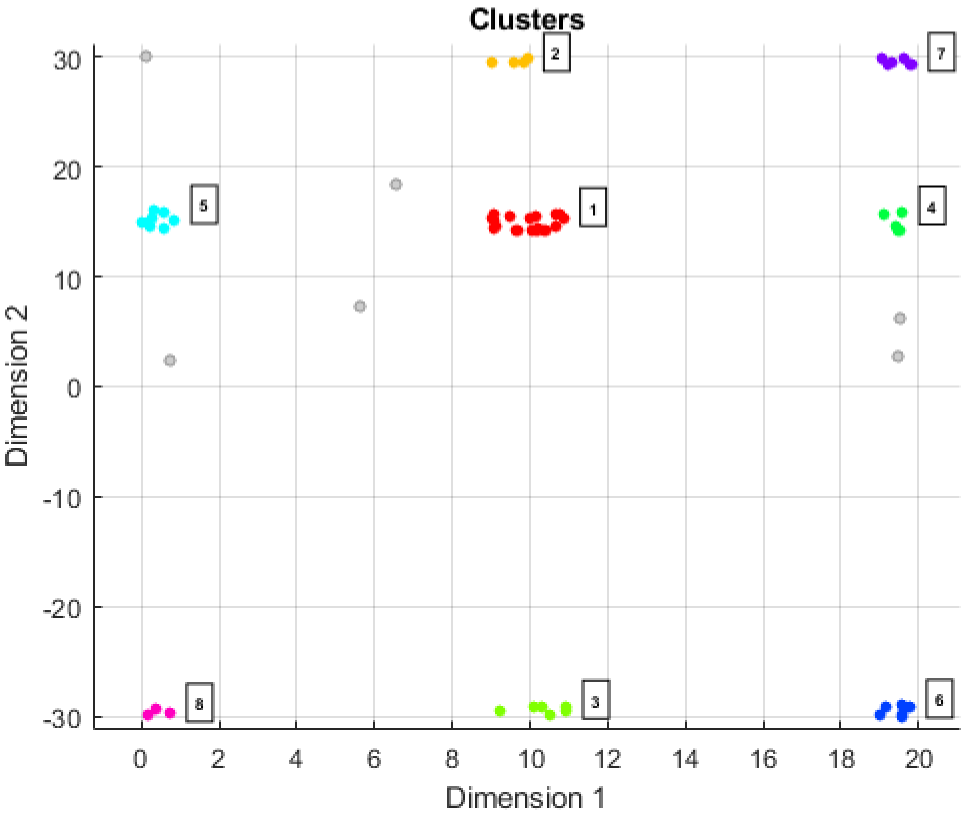
- an unambiguous target located at $(10, 15)$
- an ambiguous target in Doppler located at $(10, -30)$
- an ambiguous target in range located at $(20, 15)$
- an ambiguous target in range and Doppler located at $(20, 30)$
- 5 false alarms

Create a `clusterDBSCAN` object and specify that disambiguation is not performed by setting `EnableDisambiguation` to `false`. Solve for the cluster indices.

```
load('dataClusterDBSCAN.mat');
cluster1 = clusterDBSCAN('MinNumPoints',3,'Epsilon',2, ...
    'EnableDisambiguation',false);
idx = cluster1(x);
```

Use the `clusterDBSCAN` `plot` object function to display the clusters.

```
plot(cluster1,x,idx)
```



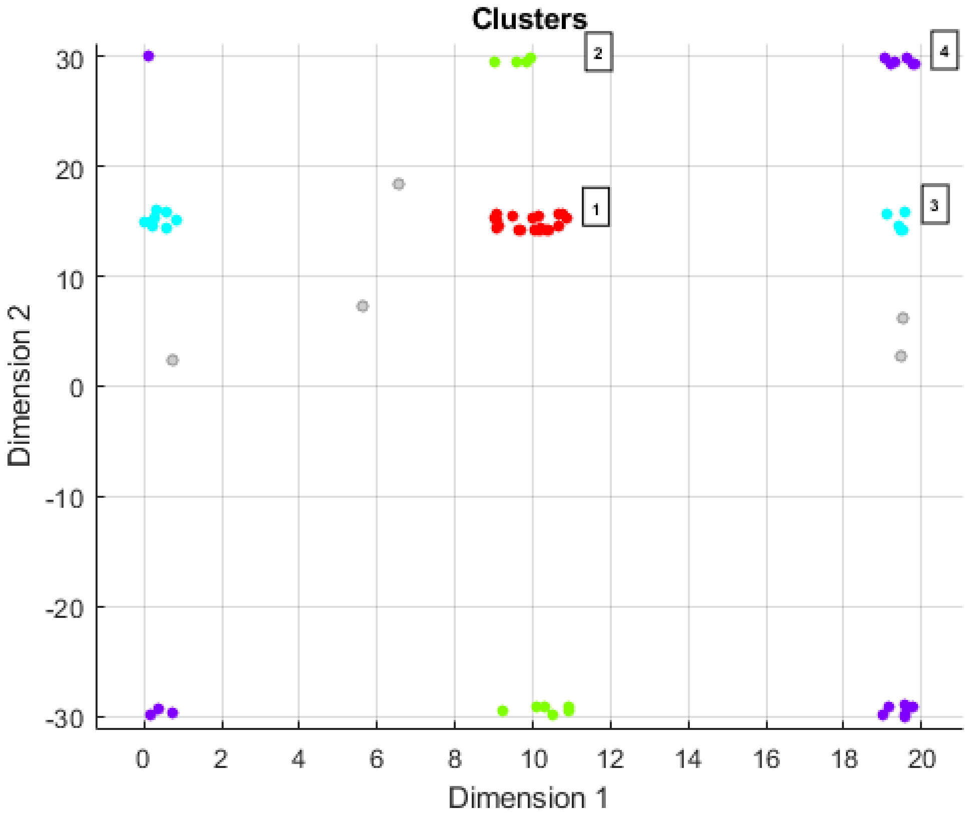
The plot indicates that there are eight apparent clusters and six noise points. The '`Dimension 1`' label corresponds to range and the '`Dimension 2`' label corresponds to Doppler.

Next, create another clusterDBSCAN object and set EnableDisambiguation to true to specify that clustering is performed across the range and Doppler ambiguity boundaries.

```
cluster2 = clusterDBSCAN('MinNumPoints',3,'Epsilon',2, ...
    'EnableDisambiguation',true,'AmbiguousDimension',[1 2]);
```

Perform the clustering using ambiguity limits and then plot the clustering results. The DBSCAN clustering results correctly show four clusters and five noise points. For example, the points at ranges close to zero are clustered with points near 20 m because the maximum unambiguous range is 20 m.

```
amblims = [0 maxRange; minDoppler maxDoppler];
idx = cluster2(x,amblims);
plot(cluster2,x,idx)
```

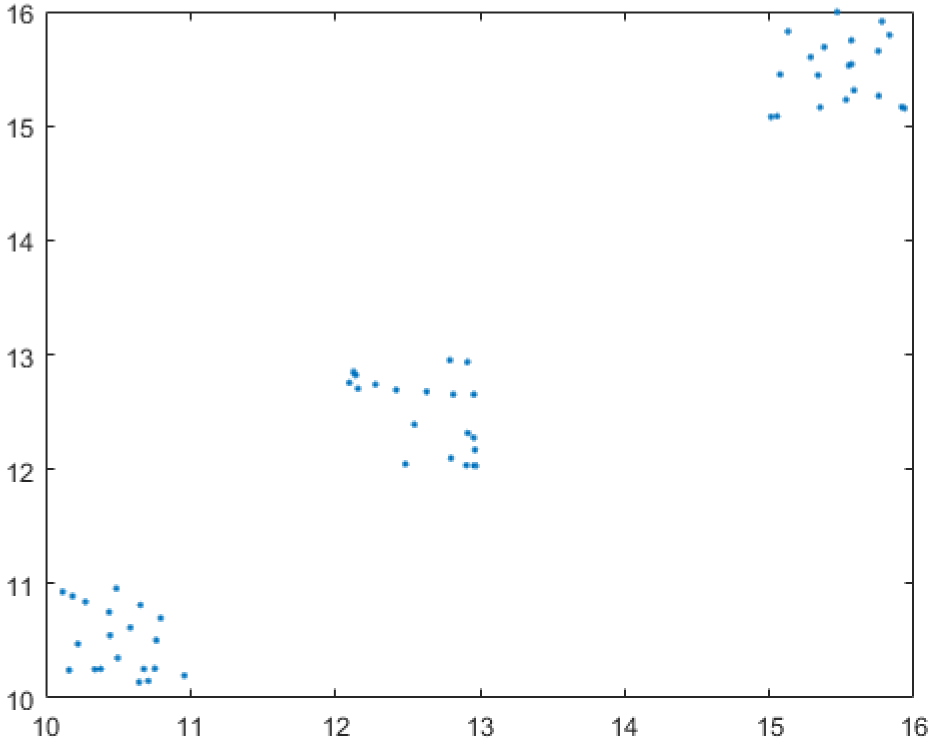


### Effect of Epsilon on Clustering

Cluster two-dimensional Cartesian position data using `clusterDBSCAN`. To illustrate how the choice of epsilon affects clustering, compare the results of clustering with `Epsilon` set to 1 and `Epsilon` set to 3.

Create random target data position data in *xy* coordinates.

```
x = [rand(20,2)+12; rand(20,2)+10; rand(20,2)+15];
plot(x(:,1),x(:,2),'.')
```



Create a `clusterDBSCAN` object with the `Epsilon` property set to 1 and the `MinNumPoints` property set to 3.

```
clusterer = clusterDBSCAN('Epsilon',1,'MinNumPoints',3);
```

Cluster the data when `Epsilon` equals one.

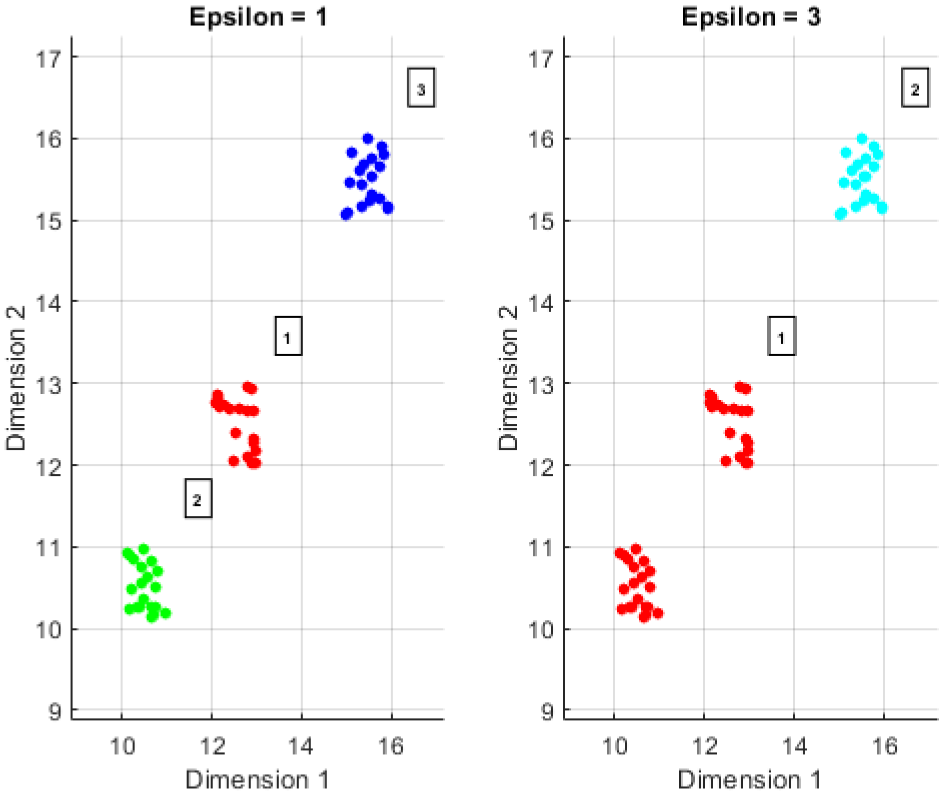
```
idxEpsilon1 = clusterer(x);
```

Cluster the data again but with `Epsilon` set to 3. You can change the value of `Epsilon` because it is tunable.

```
clusterer.Epsilon = 3;
idxEpsilon2 = clusterer(x);
```

Plot the clustering results side-by-side. Do this by passing in the axes handles and titles into the `plot` method.

```
hAx1 = subplot(1,2,1);
plot(clusterer,x,idxEpsilon1, ...
    'Parent',hAx1,'Title','Epsilon = 1')
hAx2 = subplot(1,2,2);
plot(clusterer,x,idxEpsilon2, ...
    'Parent',hAx2,'Title','Epsilon = 3')
```



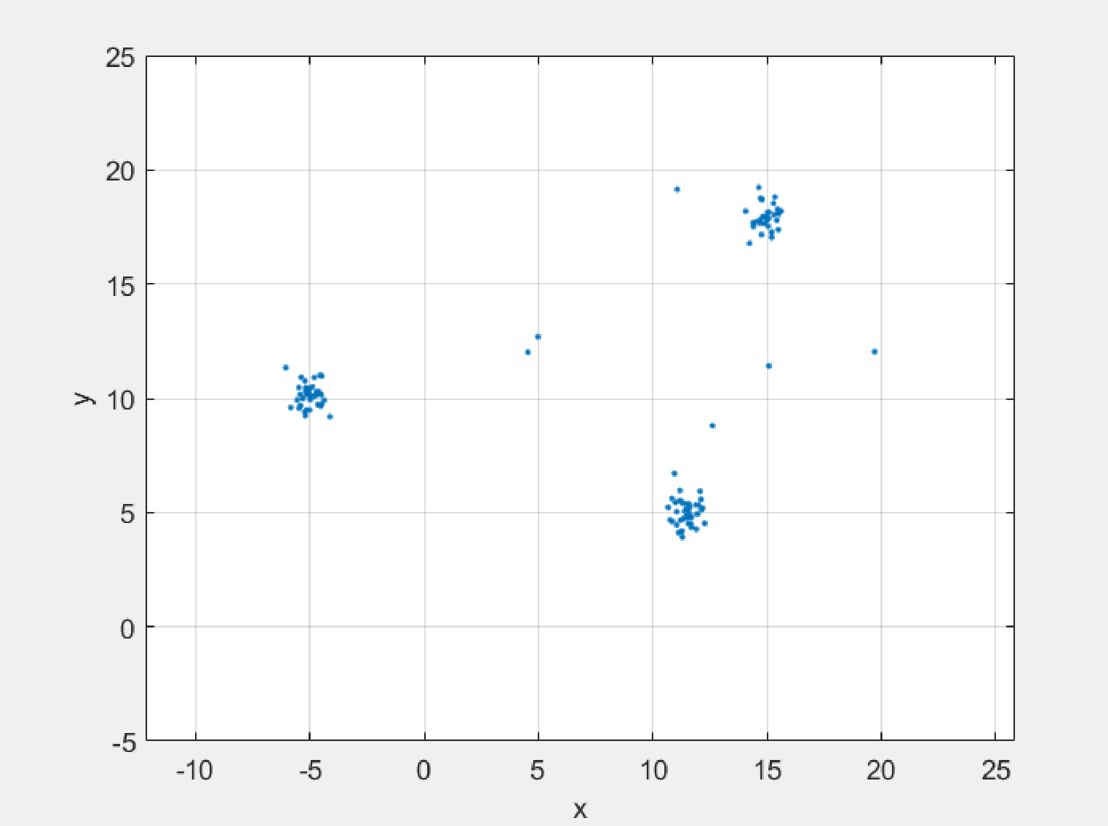
For `Epsilon` set to 1, three clusters appear. When `Epsilon` is 3, the two lower clusters are merged into one.

# Algorithms

## Clustering Algorithm

### Clustering Overview

This section illustrates the basic principles of cluster formation. The figure shows points in a two-dimensional feature space. The clusters are compact and well-separated. A few noise points appear.



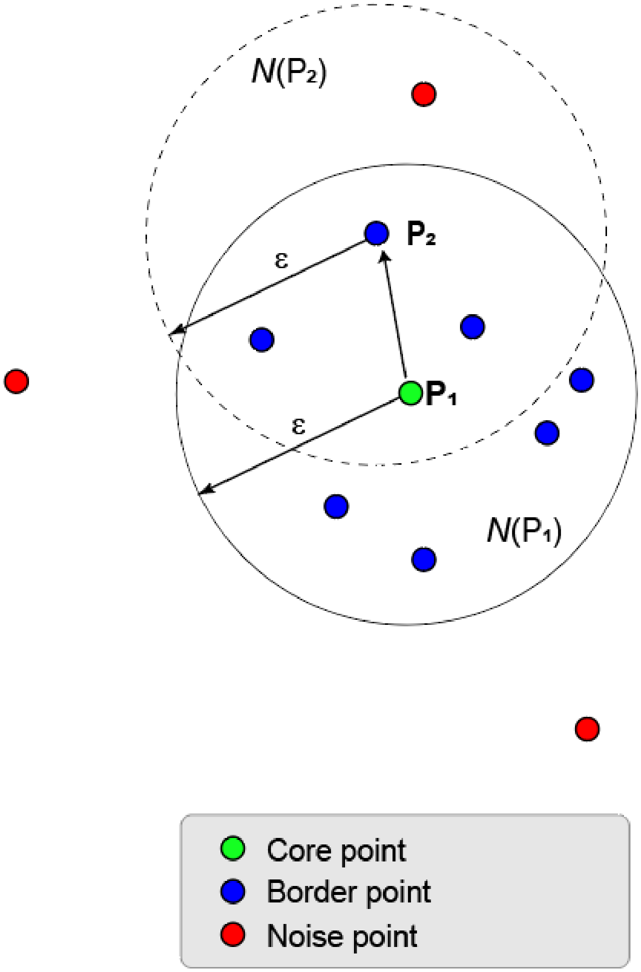
### Clusters Formed from a Single ε-Neighborhood

- Clusters start from core points. The first step in the algorithm is identifying all core points.

  The figure here shows the point $P_1$ and its ε-neighborhood $N_ε(P_1)$. The ε-neighborhood has eight points (including itself) within a radius ε. Using the `MinNumPoints` property to set the threshold to 8 means that $P_1$ is a core point. The blue points that lie within $N_ε$ are called *border points*. These border points are *directly density reachable* from the core point $P_1$.
- No other points in the figure have enough neighboring points in their ε-neighborhood to become a core point. $P_2$ is not a core point because it has only five points within its neighborhood. $P_2$ is directly density reachable from $P_1$. The reverse is not true because $P_2$ is not a core point. The one-way arrow connecting the two points shows this asymmetry.
- Points that fall outside $N_ε(P_1)$ are *noise* points (red) and do not belong to the cluster.
- Because no other points are core points, the core point and border points are a maximal set of density-connected points and therefore form a cluster.

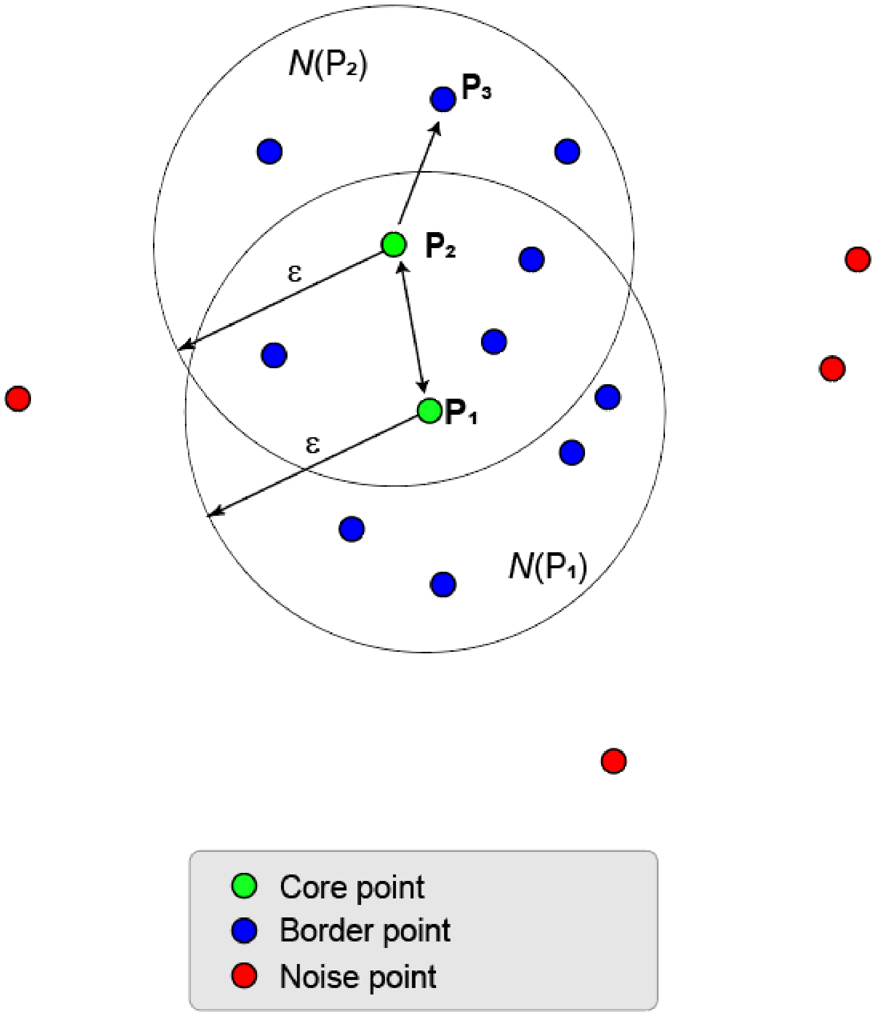
### Cluster of Points from Two ε-Neighborhoods

- The next figure shows a larger set of points containing two core points, $P_1$ and $P_2$. $P_2$ is a border point of $P_1$ but $P_2$ also has enough points in its own neighborhood to become a core point. Because they are both core points, $P_1$ is directly density reachable from $P_2$, and $P_1$ is directly density reachable from $P_2$. The two-way arrow connecting them shows this symmetry.



$N(\mathrm{P}_2)$
$\mathrm{P}_2$
ε
$\mathrm{P}_1$
ε
$N(\mathrm{P}_1)$
Core point
Border point
Noise point

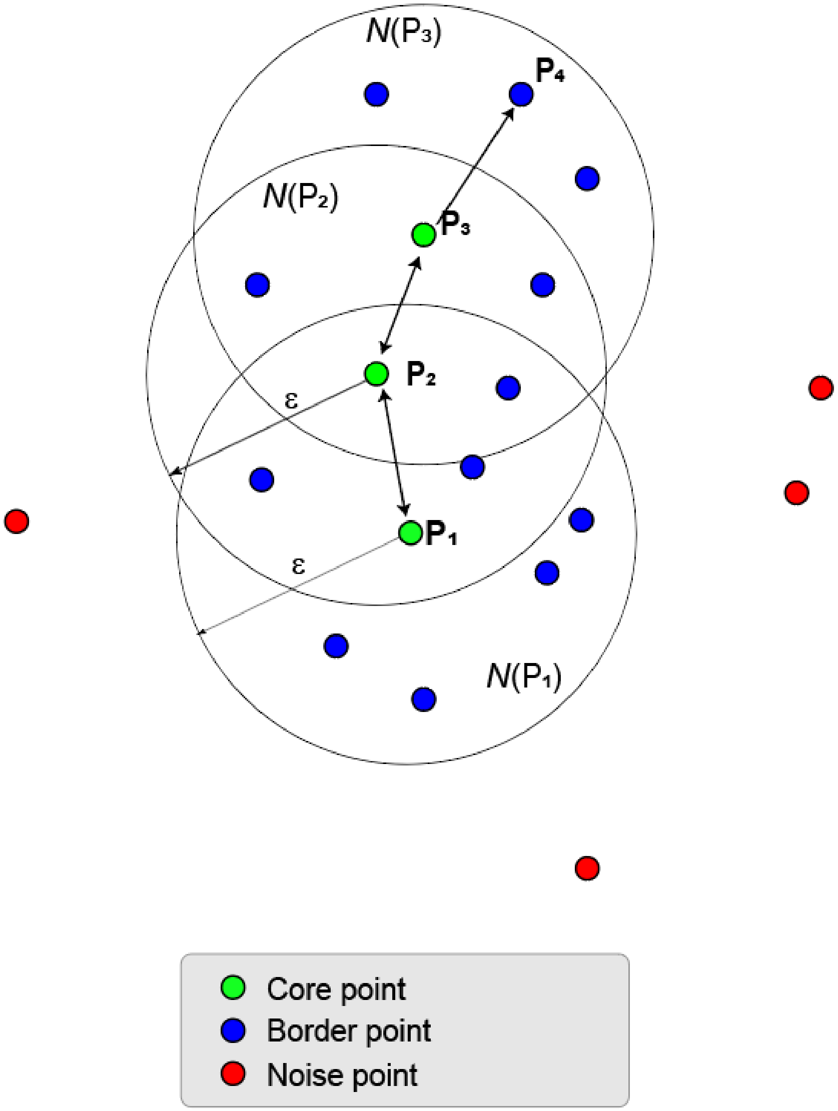
- $P_3$ is directly density reachable from $P_2$ but not from $P_1$ (as indicated by the one-way arrow). However, $P_3$ is called simply *density reachable* from $P_1$.
- Because no other points are core points, the two core points and their border points form a maximal set of density-connected points and form one cluster.



$N(P_2)$
$P_3$
$P_2$
ε
$P_1$
ε
$N(P_1)$
Core point
Border point
Noise point

### Cluster Points in Adjacent ε-Neighborhoods

- This process of growing a cluster can be extended from core point to core point until there are no more core points to add. The core points and the border points belong to the same cluster. In general, a point $P_n$ is density reachable from point $P_1$ when there is a chain of core points, $P_1$,$P_2$, $P_3$, …, $P_{n-1}$ such that each core point $P_{i+1}$ is directly density reachable from $P_i$, and $P_n$ is directly density reachable from $P_{n-1}$.

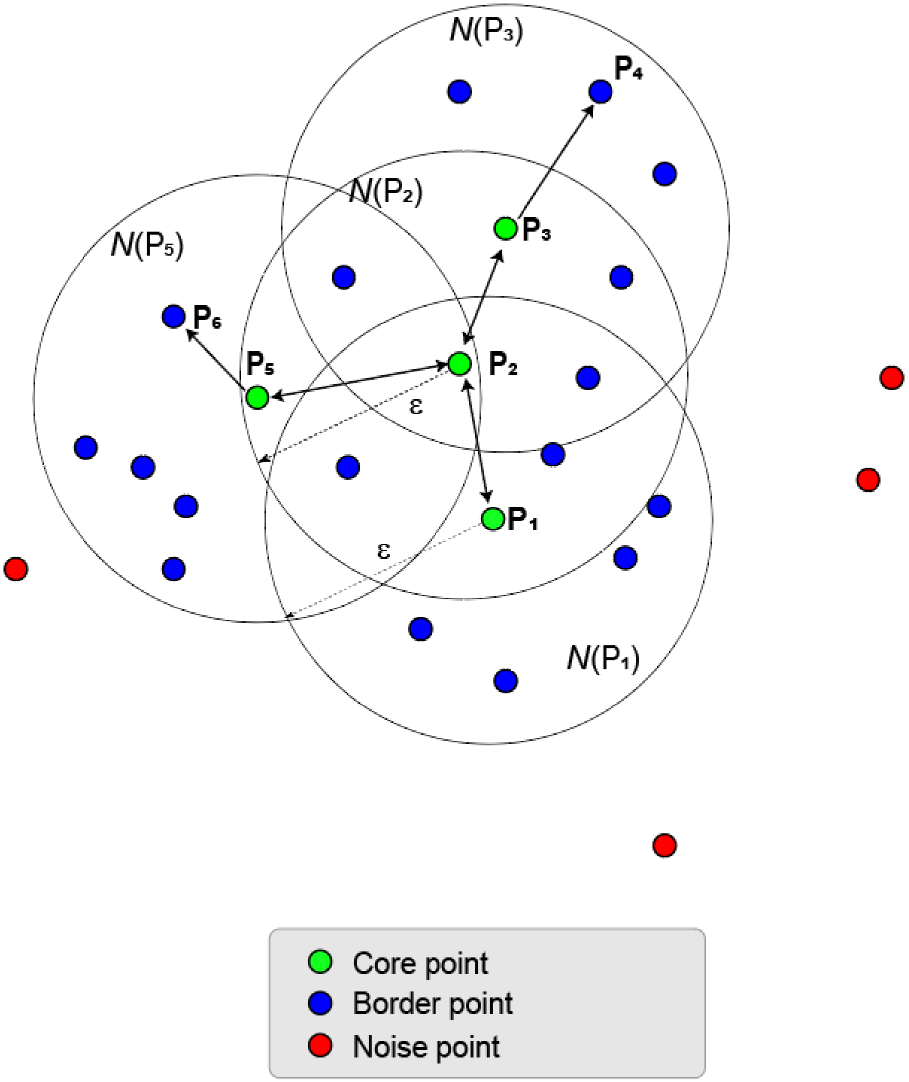


$N(P_3)$
$P_4$
$N(P_2)$
$P_3$
$P_2$
ε
$P_1$
ε
$N(P_1)$
Core point
Border point
Noise point

### Density Connectivity

The next figure illustrates some properties of density connectivity.

- A cluster can have multiple branching chains, for example ($P_1$, $P_2$, $P_3$, $P_4$) and ($P_1$, $P_2$, $P_5$, $P_6$).
- Two points, $P_6$ and $P_4$, are *density connected* when there is a third point $P_2$ such that $P_6$ and $P_4$ are density reachable from $P_2$.
- Two density connected points are not necessarily density reachable from one another.
- A maximal set of density connected points define a cluster. It does not matter which core point is the starting core point.
- All points in a cluster are density reachable from all core points.



$N(P_3)$
$P_4$
$N(P_2)$
$P_3$
$N(P_5)$

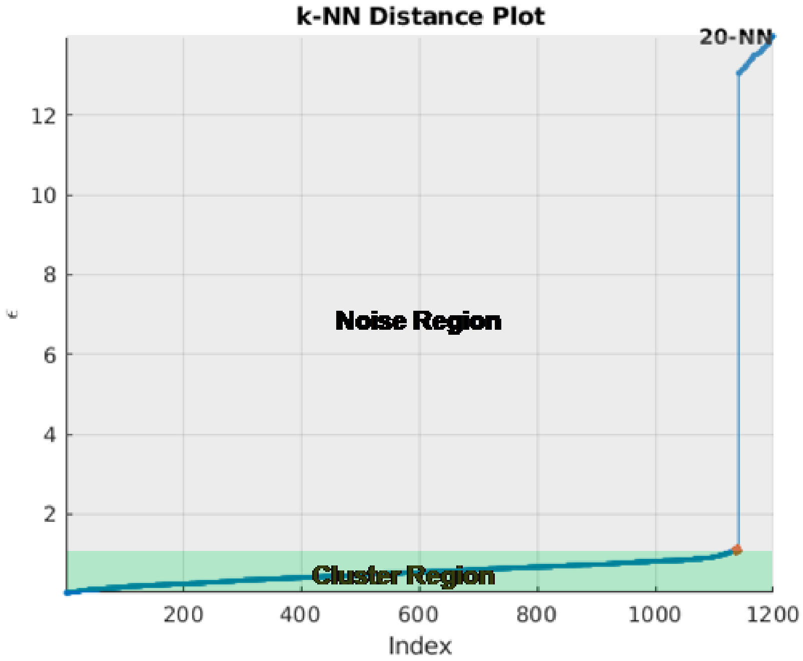
$N(P_1)$
Core point
Border point
Noise point

## Estimate Epsilon

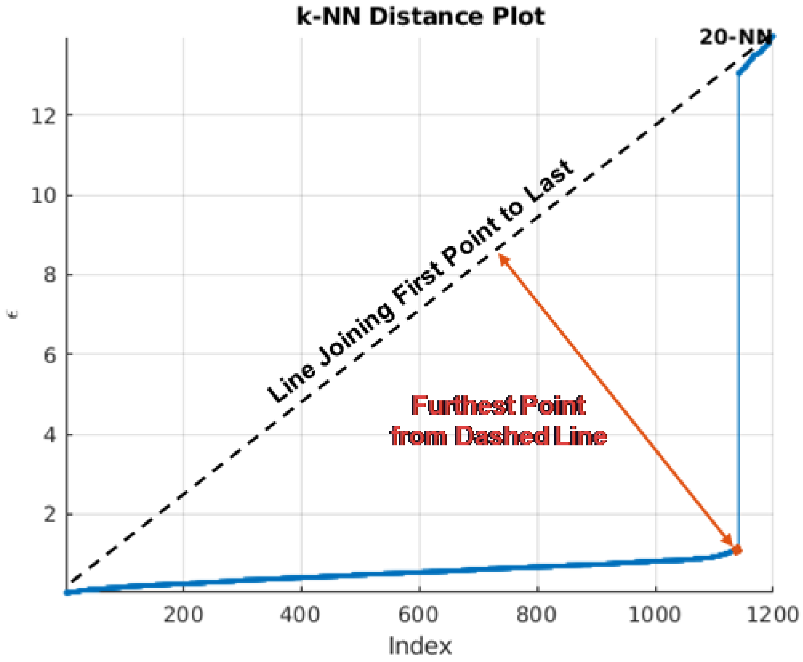
DBSCAN clustering requires a value for the neighborhood size parameter ε. The `clusterDBSCAN` object and the `clusterDBSCAN.estimateEpsilon` function use a $k$-nearest-neighbor search to estimate a scalar epsilon. Let $D$ be the distance of any point $P$ to its $k^{\text{th}}$ nearest neighbor. Define a $D_k(P)$-neighborhood as a neighborhood surrounding $P$ that contains its $k$-nearest neighbors. There are $k + 1$ points in the $D_k(P)$-neighborhood including the point $P$ itself. An outline of the estimation algorithm is:

- For each point, find all the points in its $D_k(P)$-neighborhood
- Accumulate the distances in all $D_k(P)$-neighborhoods for all points into a single vector.
- Sort the vector by increasing distance.
- Plot the sorted $k$-dist graph, which is the sorted distance against point number.
- Find the knee of the curve. The value of the distance at that point is an estimate of epsilon.

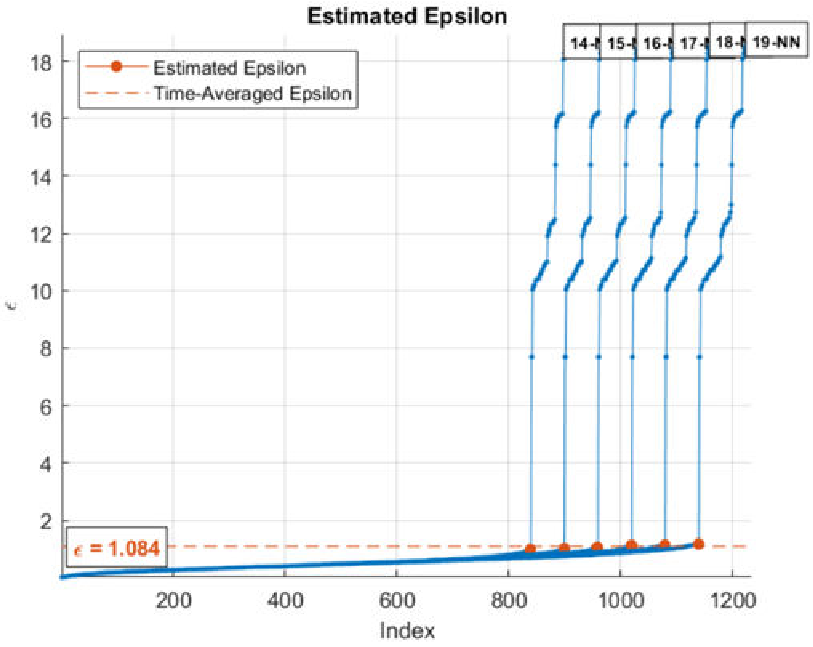
The figure here shows distance plotted against point index for $k = 20$. The knee occurs at approximately 1.5. Any points below this threshold belong to a cluster. Any points above this value are noise.



There are several methods to find the knee of the curve. `clusterDBSCAN` and `clusterDBSCAN.estimateEpsilon` first define the line connecting the first and last points of the curve. The ordinate of the point on the sorted *k*-dist graph furthest from the line and perpendicular to the line defines epsilon.



When you specify a range of *k* values, the algorithm averages the estimate epsilon values for all curves. This figure shows that epsilon is fairly insensitive to *k* for *k* ranging from 14 through 19.



To create a single *k*-NN distance graph, set the `MinNumPoints` property equal to the `MaxNumPoints` property.

## Choosing the Minimum Number of Points

The purpose of `MinNumPoints` is to smooth the density estimates. Because a cluster is a maximal set of density-connected points, choose smaller values when the expected number of detections in a cluster is unknown. However, smaller values make the DBSCAN algorithm more susceptible to noise. A general guideline for choosing `MinNumPoints` is:

- Generally, set `MinNumPoints` = 2*P* where *P* is the number of feature dimensions in `X`.
- For data sets that have one or more of the following properties:
  - many noise points
  - large number of points, `N`

- large dimensionality, `P`
- many duplicates

increasing `MinNumPoints` can often improve clustering results.

## Ambiguous Data

The clustering algorithm is general enough to process ambiguities in any feature, but applying clustering to range and Doppler ambiguities in radar are important applications.

### Range Ambiguity

The time delay between pulse transmission and reception determines the range, *R*, of a target. *R* is proportional to time delay, *t*, by

$$R = \frac{ct}{2}$$

where *c* is the speed of light. Time is measured from the transmission time of the pulse. If only one pulse is transmitted, the equation accurately determines the range.

Often, the radar transmits multiple pulses spaced at intervals *T*, the pulse repetition interval (PRI). Range ambiguities occur when the echoes from one pulse are not received before the next pulse is transmitted. Range is computed from the time difference of the arrival of the received pulse from the transmission time of the most recent transmitted pulse. Therefore the range can be incorrect by some integer multiple of the unambiguous range. The unambiguous range of a radar system is the maximum range at which a target can be located to guarantee that the reflected pulse from that target corresponds to the most recent transmitted pulse. The PRI determines the unambiguous range.

$$R_{\mathrm{max}} = \frac{cT}{2}$$

The range of a detection less than $R_{\mathrm{max}}$ is an unambiguous range. Range disambiguation clusters detections that cross ambiguous range boundaries.

Turn on disambiguation by setting the `EnableDisambiguation` to `true`. Then, use the `AmbiguousDimension` property to select the column in the input data corresponding to range. Set the actual ambiguity limits for range using the `amblims` argument at execution time.

### Doppler Ambiguity

Doppler aliasing occurs when echoes arrive from targets that move fast enough for the Doppler frequency to exceed the pulse repetition frequency (PRF). If the Doppler shift is greater than ½ PRF or less than –½ PRF, the Doppler shift is aliased into the range (–½ PRF, ½ PRF). This range is called the unambiguous Doppler. Turn on disambiguation by setting the `EnableDisambiguation` to `true`. Then, use the `AmbiguousDimension` property to select the column in the input data corresponding to Doppler. Set the actual ambiguity limits for Doppler using the `amblims` argument at execution time. Doppler ambiguity implies radial speed ambiguity as well. Make sure that `amblims` matches the interpretation of the feature.

# clusterDBSCAN.discoverClusters

Find cluster hierarchy in data

## Syntax

```
[order,reachdist] = clusterDBSCAN.discoverClusters(X,maxepsilon,
minnumpoints)
clusterDBSCAN.discoverClusters(X,maxepsilon,minnumpoints)
```

## Description

`[order,reachdist] = clusterDBSCAN.discoverClusters(X,maxepsilon,minnumpoints)` returns a cluster-ordered list of points, `order`, and the reachability distances, `reachdist`, for each point in the data `X`. Specify the maximum epsilon, `maxepsilon`, and the minimum number of points, `minnumpoints`. The method implements the *Ordering Points To Identify the Clustering Structure* (OPTICS) algorithm. The OPTICS algorithm is useful when clusters have varying densities.

`clusterDBSCAN.discoverClusters(X,maxepsilon,minnumpoints)` displays a bar graph representing the cluster hierarchy.

## Examples

### Display Cluster Hierarchy

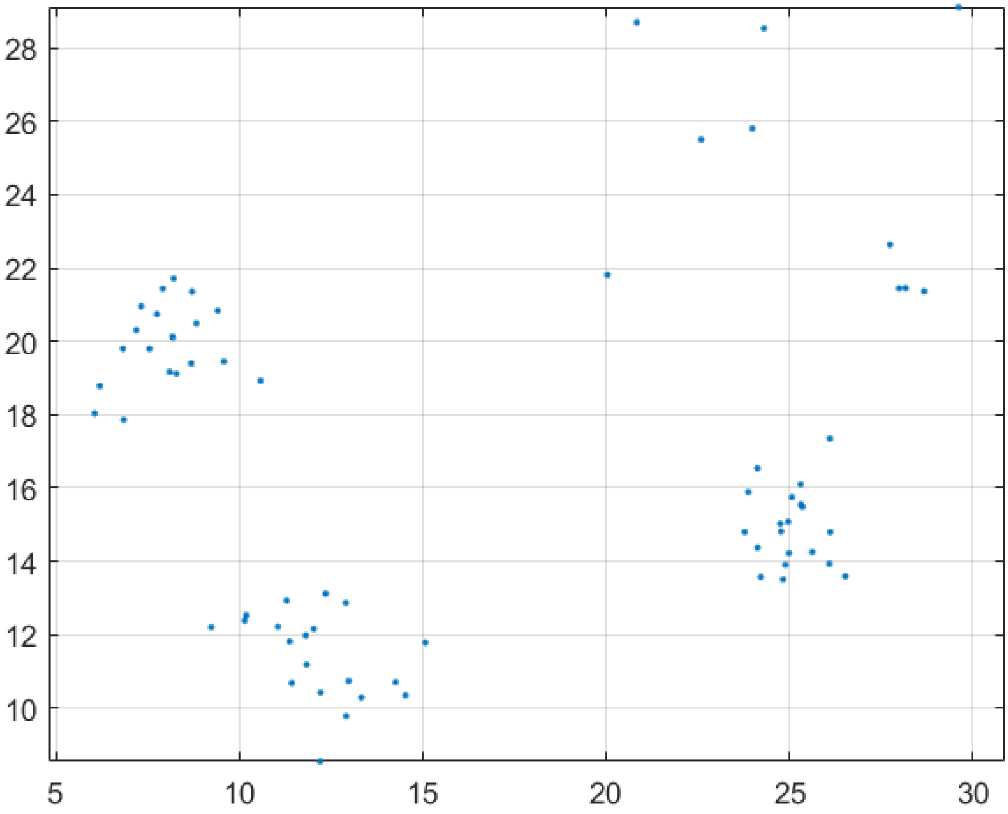
Create target data with random detections in *xy* Cartesian coordinates. Use the clusterDBSCAN.`discoverClusters` object function to reveal the underlying cluster hierarchy.

First, set the `clusterDBSCAN.discoverClusters` parameters.

```
maxEpsilon = 10;
minNumPoints = 6;
```

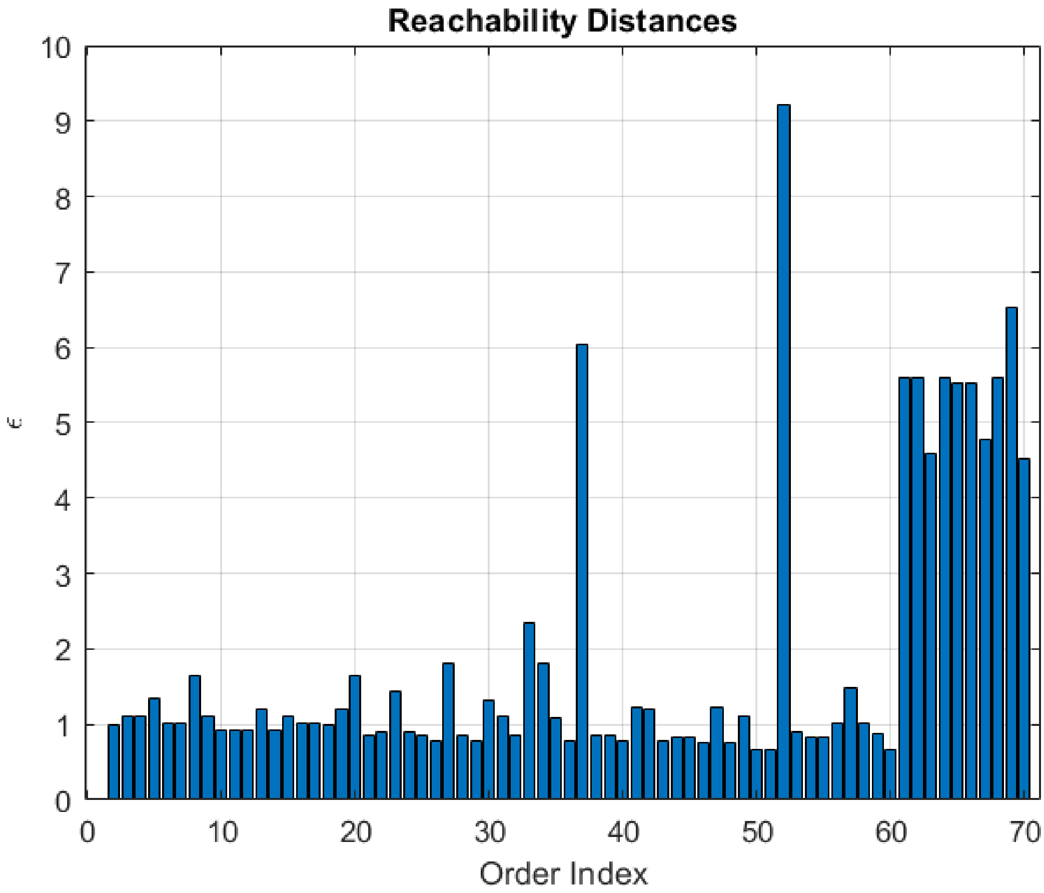
Create random target data.

```
X = [randn(20,2) + [11.5,11.5]; randn(20,2) + [25,15]; randn(20,2) + [8,20]; 10*rand(10
plot(X(:,1),X(:,2),'.')
axis equal
grid
```



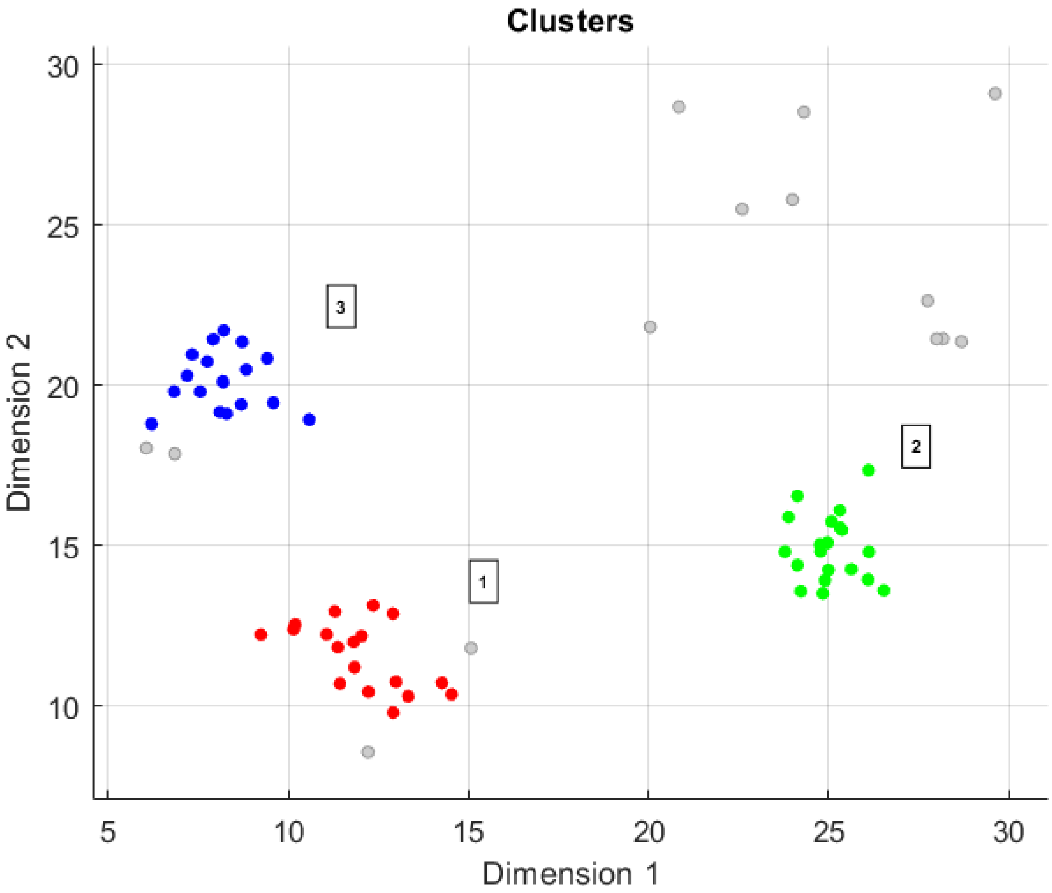
Plot the cluster hierarchy.

```
clusterDBSCAN.discoverClusters(X,maxEpsilon,minNumPoints)
```



From a visual inspection of the plot, choose `Epsilon` as 1.5 and then perform the clustering using `clusterDBSCAN` and plot the resultant clusters.

```
clusterer = clusterDBSCAN('MinNumPoints',6,'Epsilon',1.5,'EnableDisambiguation',false)
[idx,cidx] = clusterer(X);
plot(clusterer,X,idx)
```



## Input Arguments

**X — Input feature data**
real-valued *N*-by-*P* matrix

Input feature data, specified as a real-valued *N*-by-*P* matrix. The *N* rows correspond to feature points in a *P*-dimensional feature space. The *P* columns contain the values of the features over which clustering takes place. The DBSCAN algorithm can cluster any type of data with appropriate `MinNumPoints` and `Epsilon` settings. For example, a two-column input can contain the *xy* Cartesian coordinates, or range and Doppler.

Data Types: `double`

**`maxepsilon` — Maximum epsilon size**
positive scalar

Maximum epsilon size to use in the cluster hierarchy search, specified as a positive scalar. The epsilon parameter defines the clustering neighborhood around a point. Reducing `maxepsilon` results in shorter run times. Setting `maxepsilon` to `inf` identifies all possible clusters.

The OPTICS algorithm is relatively insensitive to parameter settings, but choosing larger parameters can improve results.

Example: `5.0`

Data Types: `double`

**`minnumpoints` — Minimum number of points**
positive integer

Minimum number of points used as a threshold, specified as a positive integer. The threshold sets the minimum number of points for a cluster.

The OPTICS algorithm is relatively insensitive to parameter settings, but choosing larger parameters can improve results.

Example: `10`

Data Types: `double`

## Output Arguments

**`order` — Cluster hierarchy**
integer-valued 1-by-*N* row vector

Cluster ordered list of sample indices, returned as an integer-valued 1-by-*N* row vector.*N* is the number of rows in the input data matrix `X`.

**`reachdist` — Reachability distance**
positive, real-valued 1-by-*N* row vector

Reachability distance, returned as a positive, real-valued 1-by-*N* row vector. *N* is the number of rows in the input data matrix `X`.

Data Types: `double`

## Algorithms

The outputs of `clusterDBSCAN.discoverClusters` let you create a reachability-plot from which the hierarchical structure of the clusters can be visualized. A reachability-plot contains ordered points on the *x*-axis and the reachability distances on the *y*-axis. Use the outputs to examine the cluster structure over a broad range of parameter settings. You can use the output to help estimate appropriate epsilon clustering thresholds for the DBSCAN algorithm. Points belonging to a cluster have small reachability distances to their nearest neighbor, and clusters appear as valleys in the reachability plot. Deeper valleys correspond to denser clusters. Determine epsilon from the ordinate of the bottom of the valleys.

OPTICS assumes that dense clusters are entirely contained by less dense clusters. OPTICS processes data in the correct order by tracking the point density neighborhoods. This process is performed by ordering data points by the shortest reachability distances, guaranteeing that clusters with higher density are identified first.

# clusterDBSCAN.estimateEpsilon

Estimate neighborhood clustering threshold

## Syntax

```
epsilon = clusterDBSCAN.estimateEpsilon(X,MinNumPoints,MaxNumPoints)
clusterDBSCAN.estimateEpsilon(X,MinNumPoints,MaxNumPoints)
```

## Description

`epsilon = clusterDBSCAN.estimateEpsilon(X,MinNumPoints,MaxNumPoints)` returns an estimate of the neighborhood clustering threshold, `epsilon`, used in the density-based spatial clustering of applications with noise (DBSCAN)algorithm. `epsilon` is computed from input data `X` using a *k*-nearest neighbor (*k*-NN) search. `MinNumPoints` and `MaxNumPoints` set a range of *k*-values for which epsilon is calculated. The range extends from `MinNumPoints` – 1 through `MaxNumPoints` – 1. *k* is the number of neighbors of a point, which is one less than the number of points in a neighborhood.

`clusterDBSCAN.estimateEpsilon(X,MinNumPoints,MaxNumPoints)` displays a figure showing the *k*-NN search curves and the estimated epsilon.

## Examples

### Estimate Epsilon from Data

Create target data and use the `estimateEpsilon` object function to calculate an appropriate epsilon threshold.

Create the target data as *xy* Cartesian coordinates.

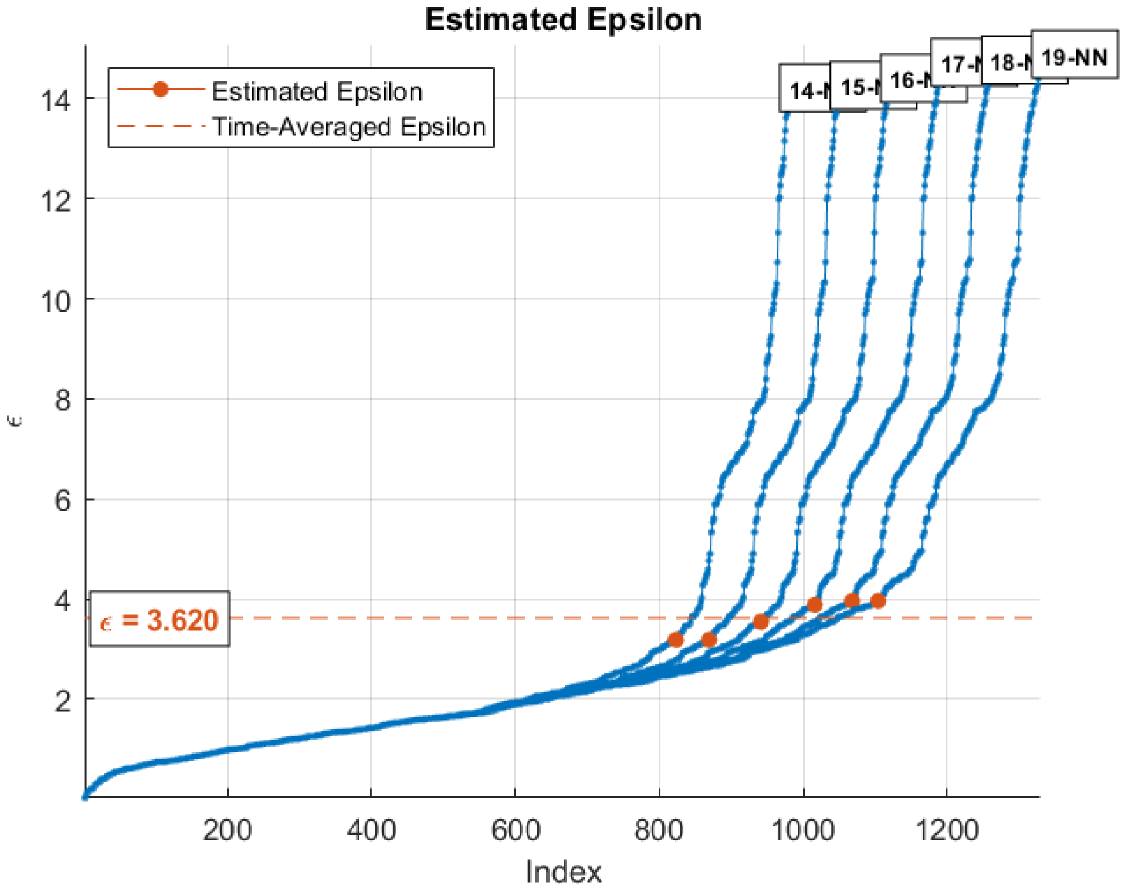
```
X = [randn(20,2) + [11.5,11.5]; randn(20,2) + [25,15]; randn(20,2) ...
    + [8,20]; 10*rand(10,2) + [20,20]];
```

Set the range of values for the *k*-NN search.

```
minNumPoints = 15;
maxNumPoints = 20;
```

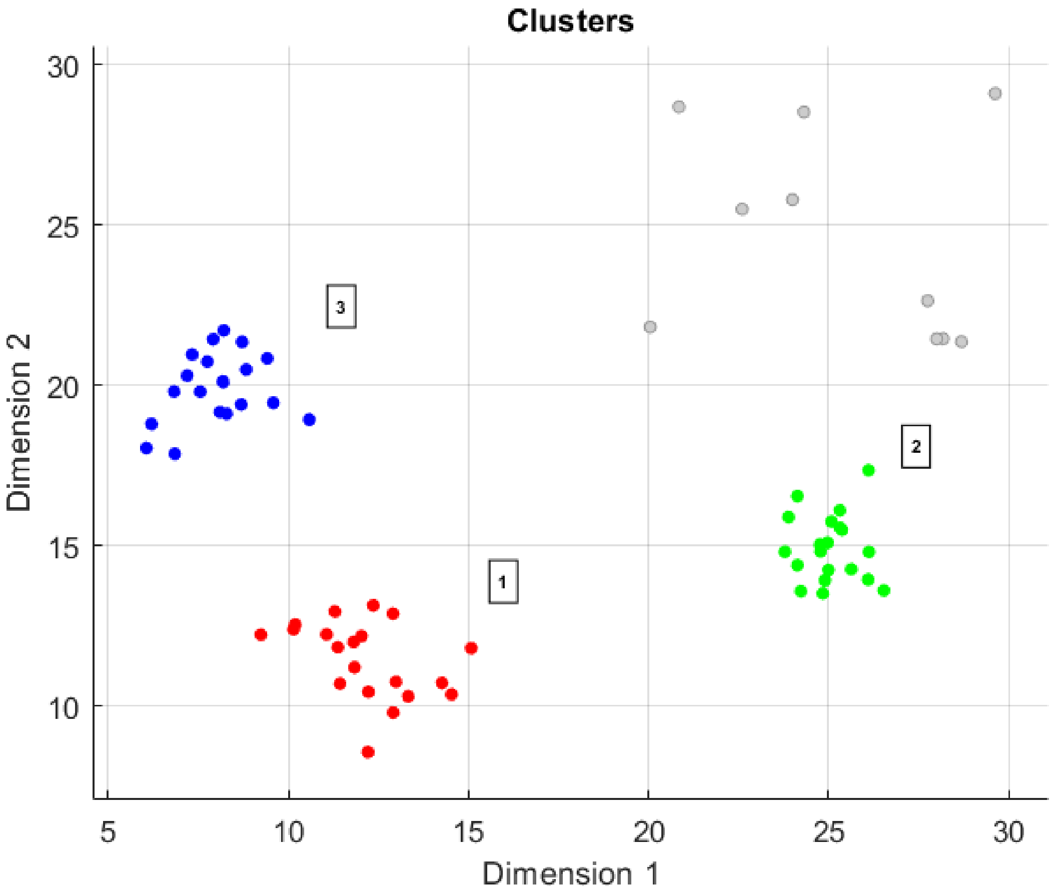
Estimate clustering threshold and display the value on the plot.

```
clusterDBSCAN.estimateEpsilon(X,minNumPoints,maxNumPoints)
```



Use the estimated Epsilon value, 3.62, in the clusterer. Then plot the clusters.

```
clusterer = clusterDBSCAN('MinNumPoints',6,'Epsilon',3.62,'EnableDisambiguation',false
[idx,cidx] = clusterer(X);
plot(clusterer,X,idx)
```



## Input Arguments

### X — Input feature data

real-valued *N*-by-*P* matrix

Input feature data, specified as a real-valued *N*-by-*P* matrix. The *N* rows correspond to feature points in a *P*-dimensional feature space. The *P* columns contain the values of the features over which clustering takes place. The DBSCAN algorithm can cluster any type of data with appropriate `MinNumPoints` and `Epsilon` settings. For example, a two-column input can contain the *xy* Cartesian coordinates, or range and Doppler.

Data Types: `double`

**`MinNumPoints` — Starting value of *k*-NN search range**
positive integer

The starting value of the *k*-NN search range, specified as a positive integer. `MinNumPoints` is used to specify the starting value of $k$ in the *k*-NN search range. The starting value of $k$ is one less than `MinNumPoints`.

Example: `10`

Data Types: `double`

**`MaxNumPoints` — Set end value of *k*-NN search range**
positive integer

The end value of *k*-NN search range, specified as a positive integer. `MaxNumPoints` is used to specify the ending value of $k$ in the *k*-NN search range. The ending value of $k$ is one less than `MaxNumPoints`.

# Output Arguments

**`epsilon` — Estimated epsilon**
positive scalar

Estimated epsilon, returned as a positive scalar.

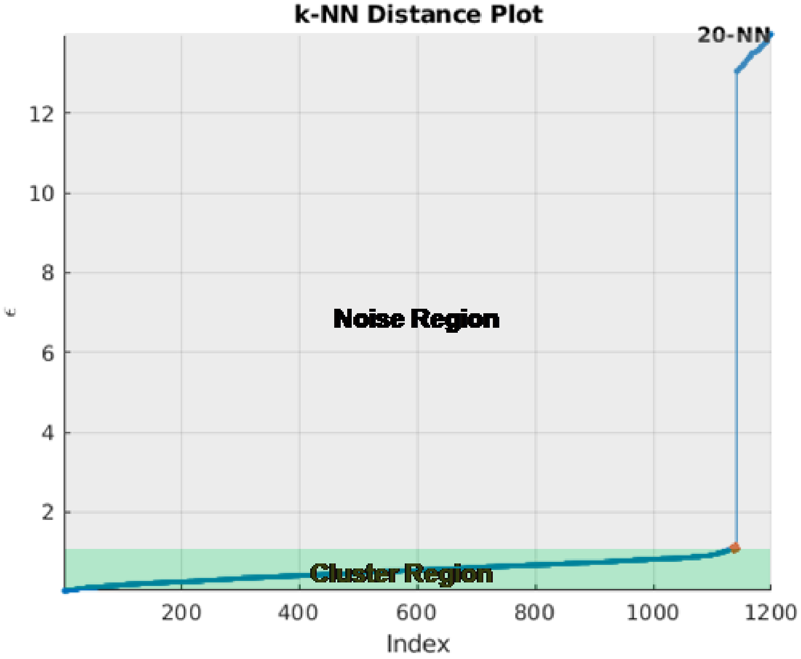
# Algorithms

## Estimate Epsilon

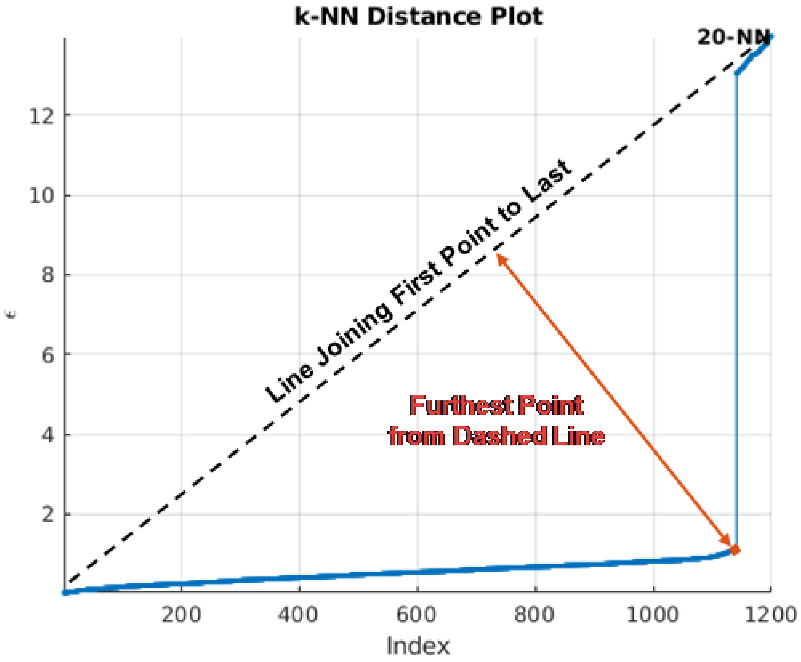
DBSCAN clustering requires a value for the neighborhood size parameter ε. The `clusterDBSCAN` object and the `clusterDBSCAN.estimateEpsilon` function use a *k*-nearest-neighbor search to estimate a scalar epsilon. Let $D$ be the distance of any point $P$ to its $k^{\text{th}}$ nearest neighbor. Define a $D_k(P)$-neighborhood as a neighborhood surrounding $P$ that contains its *k*-nearest neighbors. There are $k + 1$ points in the $D_k(P)$-neighborhood including the point $P$ itself. An outline of the estimation algorithm is:

- For each point, find all the points in its $D_k(P)$-neighborhood
- Accumulate the distances in all $D_k(P)$-neighborhoods for all points into a single vector.
- Sort the vector by increasing distance.
- Plot the sorted $k$-dist graph, which is the sorted distance against point number.
- Find the knee of the curve. The value of the distance at that point is an estimate of epsilon.

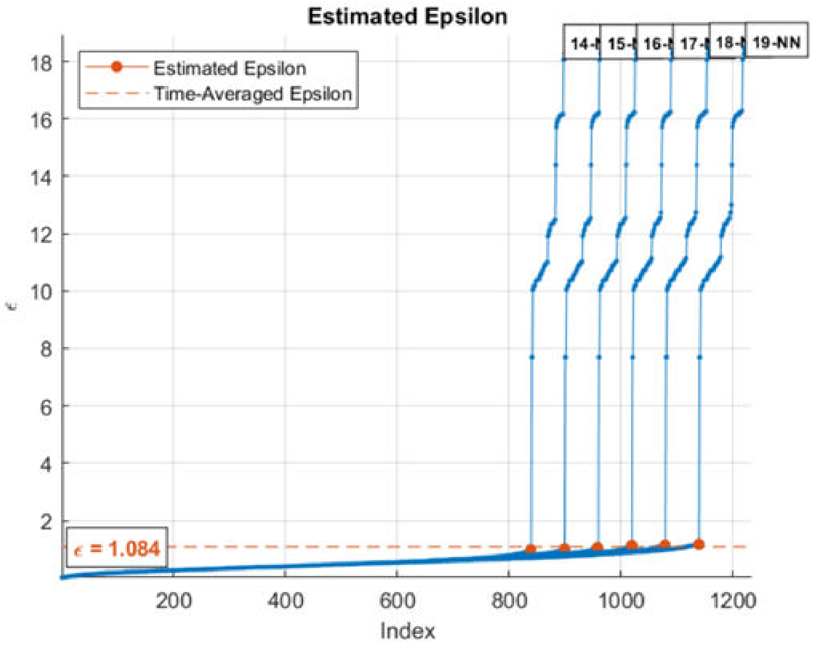
The figure here shows distance plotted against point index for $k = 20$. The knee occurs at approximately 1.5. Any points below this threshold belong to a cluster. Any points above this value are noise.



There are several methods to find the knee of the curve. `clusterDBSCAN` and `clusterDBSCAN.estimateEpsilon` first define the line connecting the first and last points of the curve. The ordinate of the point on the sorted $k$-dist graph furthest from the line and perpendicular to the line defines epsilon.



When you specify a range of *k* values, the algorithm averages the estimate epsilon values for all curves. This figure shows that epsilon is fairly insensitive to *k* for *k* ranging from 14 through 19.



To create a single *k*-NN distance graph, set the `MinNumPoints` property equal to the `MaxNumPoints` property.

## Choosing the Minimum and Maximum Number of Points

The purpose of `MinNumPoints` is to smooth the density estimates. Because a cluster is a maximal set of density-connected points, choose smaller values when the expected number of detections in a cluster is unknown. However, smaller values make the DBSCAN algorithm more susceptible to noise. A general guideline for choosing `MinNumPoints` is:

- Generally, set `MinNumPoints` = 2*P* where *P* is the number of feature dimensions in `X`.
- For data sets that have one or more of the following properties:
  - many noise points
  - large number of points, `N`

- large dimensionality, P
- many duplicates

increasing MinNumPoints can often improve clustering results.

# Extended Capabilities

clusterDBSCAN | clusterDBSCAN.discoverClusters | plot

**Introduced in R2019b**

# plot

Plot clusters

## Syntax

```
fh = plot(clusterer,X,idx)
fh = plot(___,'Parent',ax)
fh = plot(___,'Title',titlestr)
```

## Description

`fh = plot(clusterer,X,idx)` displays a plot of DBSCAN clustering results and returns a figure handle, `fh`. Inputs are the cluster object, `clusterer`, the input data matrix, `X`, and cluster indices, `idx`.

`fh = plot(___,'Parent',ax)` also specifies the axes, `ax`, of the cluster results plot.

`fh = plot(___,'Title',titlestr)` also specifies the title, `titlestr`, of the cluster results plot.

## Examples

### Cluster Detections in Range and Doppler

Create detections of extended objects with measurements in range and Doppler. Assume the maximum unambiguous range is 20 m and the unambiguous Doppler span extends from −30 Hz to 30 Hz. The data matrix is contained in the `dataClusterDBSCAN.mat` file. The first column represents range, and the second column represents Doppler.

The input data contains the following extended targets and false alarms specified:

- an unambiguous target located at $(10, 15)$
- an ambiguous target in Doppler located at $(10, -30)$

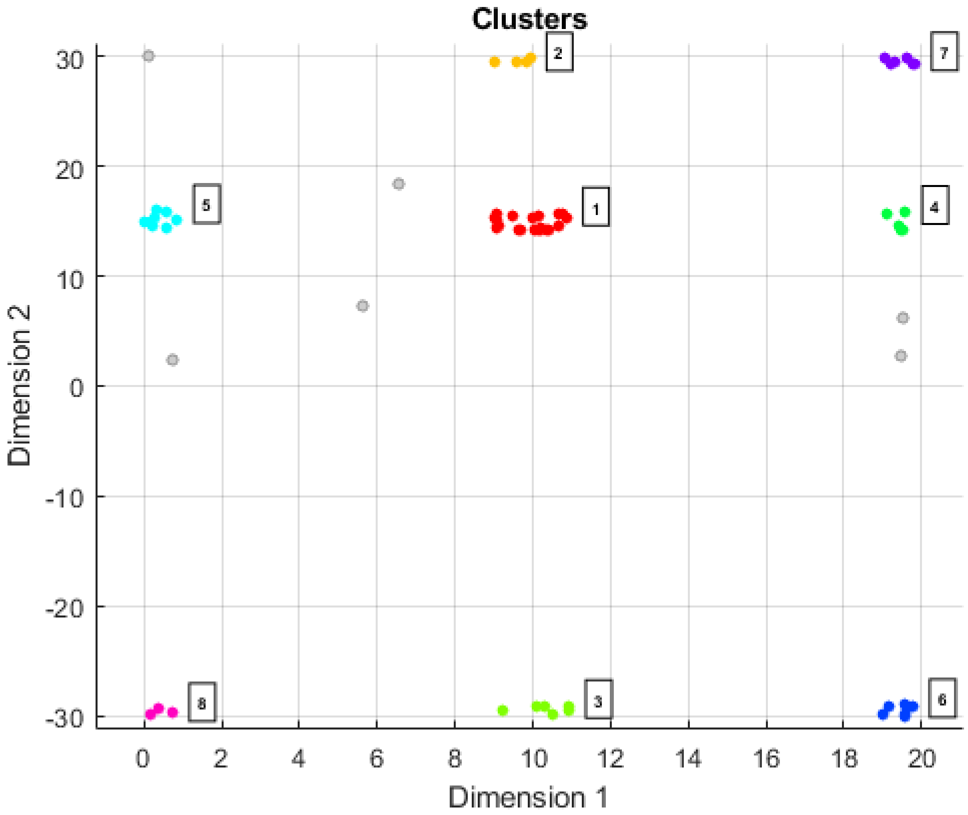
- an ambiguous target in range located at $(20, 15)$
- an ambiguous target in range and Doppler located at $(20, 30)$
- 5 false alarms

Create a `clusterDBSCAN` object and specify that disambiguation is not performed by setting `EnableDisambiguation` to `false`. Solve for the cluster indices.

```
load('dataClusterDBSCAN.mat');
cluster1 = clusterDBSCAN('MinNumPoints',3,'Epsilon',2, ...
    'EnableDisambiguation',false);
idx = cluster1(x);
```

Use the `clusterDBSCAN` `plot` object function to display the clusters.

```
plot(cluster1,x,idx)
```



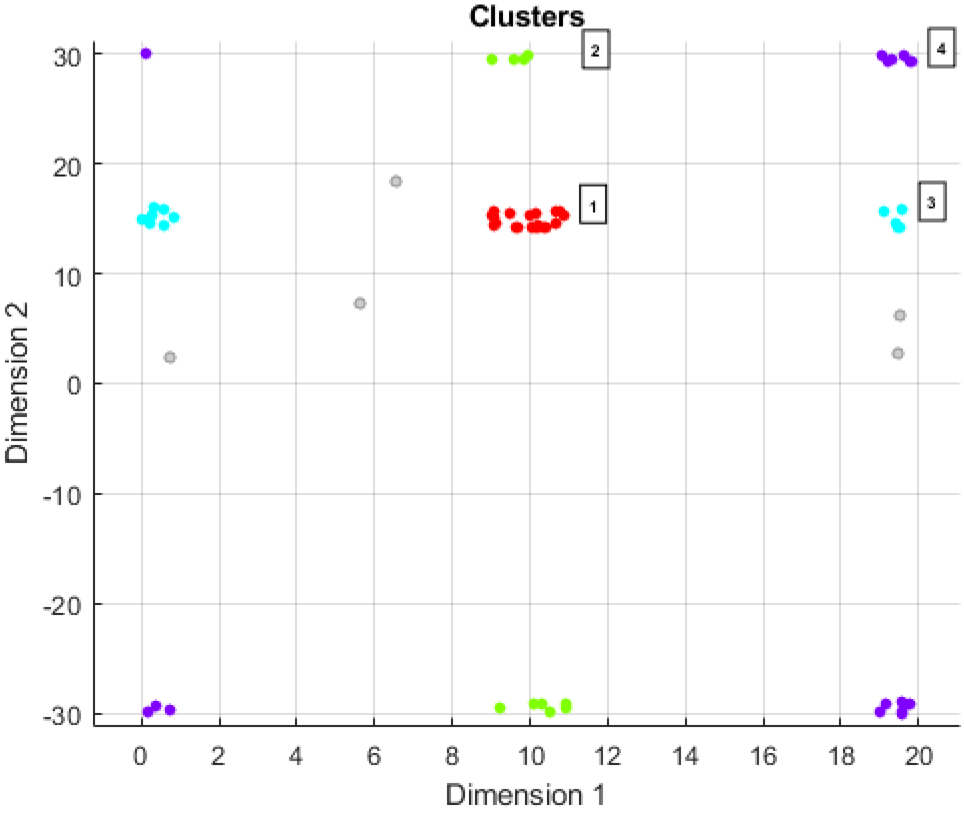
The plot indicates that there are eight apparent clusters and six noise points. The 'Dimension 1' label corresponds to range and the 'Dimension 2' label corresponds to Doppler.

Next, create another clusterDBSCAN object and set EnableDisambiguation to true to specify that clustering is performed across the range and Doppler ambiguity boundaries.

```
cluster2 = clusterDBSCAN('MinNumPoints',3,'Epsilon',2, ...
    'EnableDisambiguation',true,'AmbiguousDimension',[1 2]);
```

Perform the clustering using ambiguity limits and then plot the clustering results. The DBSCAN clustering results correctly show four clusters and five noise points. For example, the points at ranges close to zero are clustered with points near 20 m because the maximum unambiguous range is 20 m.

```
amblims = [0 maxRange; minDoppler maxDoppler];
idx = cluster2(x,amblims);
plot(cluster2,x,idx)
```



## Input Arguments

**clusterer — Clusterer object**
clusterDBSCAN object

Clusterer object, specified as a `clusterDBSCAN` object.

### `X` — Input data to cluster

real-valued *N*-by-*P* matrix

Input data, specified as a real-valued *N*-by-*P* matrix. The *N* rows correspond to points in a *P*-dimensional feature space. The *P* columns contain the values of the features over which clustering takes place. For example, a two-column input can contain Cartesian coordinates *x* and *y*, or range and Doppler.

Data Types: `double`

### `idx` — Cluster indices

*N*-by-1 integer-valued column vector

Cluster indices, specified as an *N*-by-1 integer-valued column vector. Cluster indices represent the clustering results of the DBSCAN algorithm contained in the first output argument of `clusterDBSCAN`. `idx` values start at one and are consecutively numbered. The plot object function labels each cluster with the cluster index. A value of –1 in `idx` indicates a DBSCAN noise point. Noise points are not labeled.

Data Types: `double`

### `ax` — Axes of plot

`Axes` handle

Axes of plot, specified as an `Axes` object handle.

Data Types: `double`

### `titlestr` — Plot title

character vector | string

Plot title, specified as a character vector or string.

Example: `'Range-Doppler Clusters'`

Data Types: `char` | `string`

## Output Arguments

### `fh` — Figure handle of plot

positive scalar

Figure handle of plot, returned as a positive scalar.

**Introduced in R2019b**

# phased.ConformalArray

**Package:** phased

Conformal array

## Description

The ConformalArray object constructs a conformal array. A conformal array can have elements in any position pointing in any direction.

To compute the response for each element in the array for specified directions:

1. Define and set up your conformal array. See "Construction" on page 1-331.
2. Call step to compute the response according to the properties of phased.ConformalArray. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.ConformalArray creates a conformal array System object, H. The object models a conformal array formed with identical sensor elements.

H = phased.ConformalArray(Name,Value) creates object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = phased.ConformalArray(POS,NV,Name,Value) creates a conformal array object, H, with the ElementPosition property set to POS, the ElementNormal property set to NV, and other specified property Names set to the specified Values. POS and NV are value-only arguments. When specifying a value-only argument, specify all preceding value-only arguments. You can specify name-value arguments in any order.

## Properties

### `Element`

Element of array

Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

**Default:** Isotropic antenna element with default properties

### `ElementPosition`

Element positions

`ElementPosition` specifies the positions of the elements in the conformal array. `ElementPosition` must be a 3-by-N matrix, where N indicates the number of elements in the conformal array. Each column of `ElementPosition` represents the position, in the form `[x; y; z]` (in meters), of a single element in the local coordinate system of the array. The local coordinate system has its origin at an arbitrary point. The default value of this property represents a single element at the origin of the local coordinate system.

**Default:** `[0; 0; 0]`

### `ElementNormal`

Element normal directions

`ElementNormal` specifies the normal directions of the elements in the conformal array. Angle units are degrees. The value assigned to `ElementNormal` must be either a 2-by-*N* matrix or a 2-by-1 column vector. The variable *N* indicates the number of elements in the array. If the value of `ElementNormal` is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the value of `ElementNormal` is a 2-by-1 column vector, it specifies the same pointing direction for all elements in the array.

You can use the `ElementPosition` and `ElementNormal` properties to represent any arrangement in which pairs of elements differ by certain transformations. The

transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Default:** `[0; 0]`

### `Taper`

Element taper or weighting

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. Weights are applied to each element in the sensor array. *N* is the number of elements along in the array as determined by the size of the `ElementPosition` property. If the `Taper` parameter is a scalar, the same taper value is applied to all elements. If the value of `Taper` is a vector, each taper values is applied to the corresponding element.

**Default:** 1

## Methods

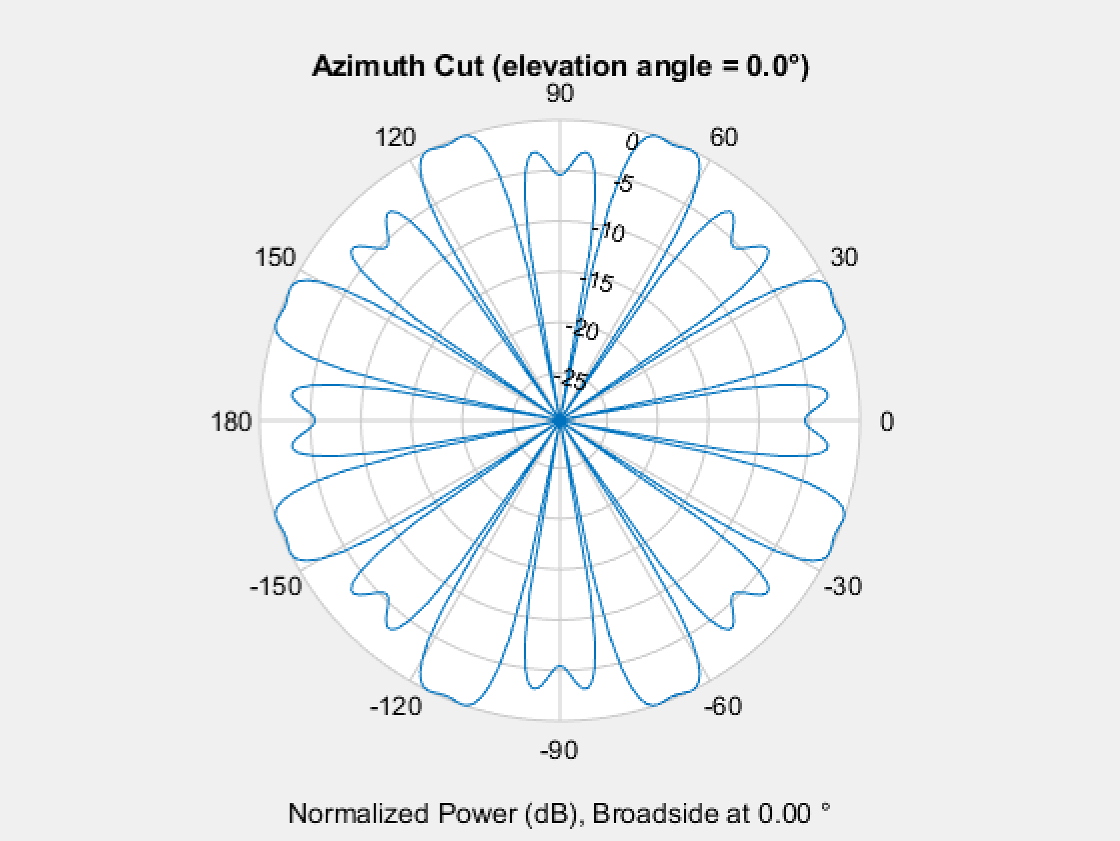
## Examples

### Plot Power Pattern of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. Plot a normalized azimuth power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
fc = 1e9;
c = physconst('LightSpeed');
pattern(sCA,fc,[-180:180],0,...
    'PropagationSpeed',c,'Type','powerdb',...
    'CoordinateSystem','polar')
```



### Plot Pattern of 31-Element Uniform Circular Sonar Array

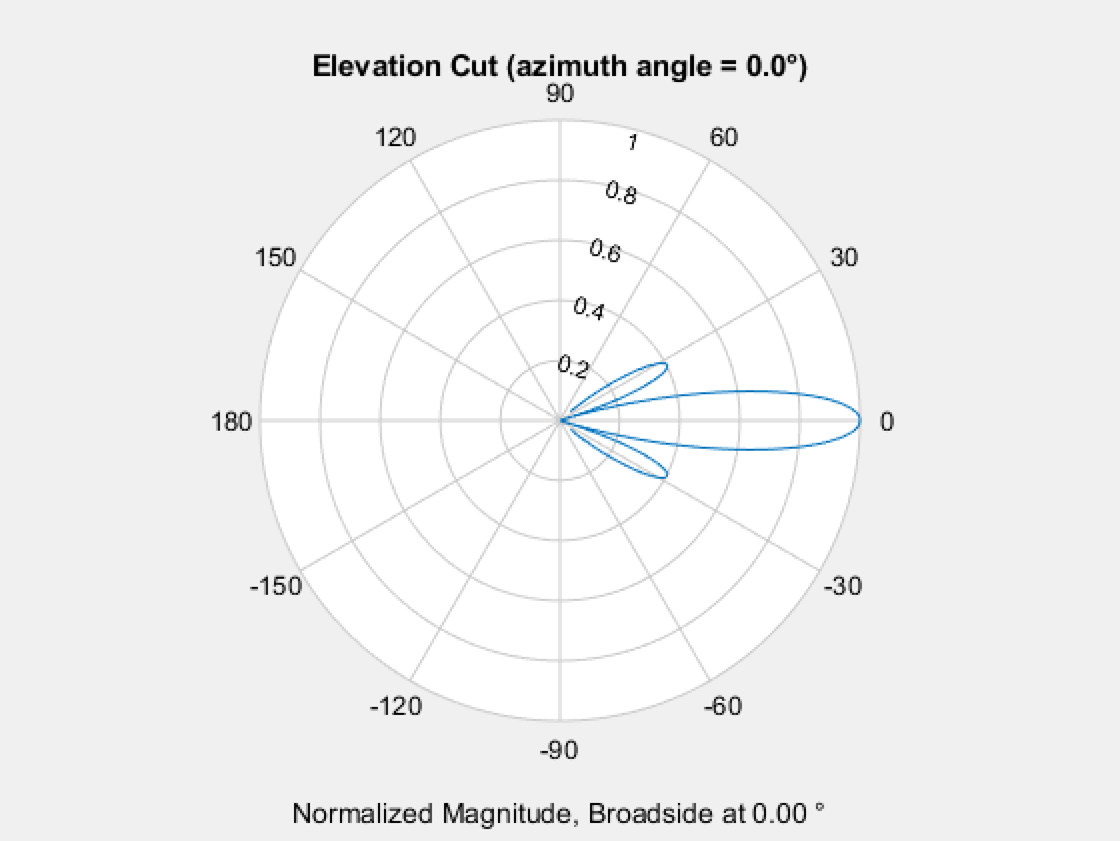
Construct a 31-element acoustic uniform circular sonar array (UCA) using the ConformalArray System object. Assume the array is one meter in diameter. Using the `ElevationAngles` parameter, restrict the display to +/-40 degrees in 0.1 degree increments. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

### Construct the array

```
N = 31;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',Radius*[zeros(1,N);cosd(theta);sind(theta)],...
    'ElementNormal',[ones(1,N);zeros(1,N)]);
```

### Plot the magnitude pattern

```
fc = 4000;
c = 1500.0;
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','efield')
```



### Plot the directivity pattern

```
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','directivity')
```

Directivity of conformal array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` computes the “Directivity” on page 1-344 of a conformal array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### H — Conformal array

System object

Conformal array specified as a `phased.ConformalArray` System object.

Example: `H = phased.ConformalArray;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

**ANGLE — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**D — Directivity**

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Conformal Array

Compute the directivity of a circular array constructed using a conformal array System object™.

Construct a 21-element uniform circular sonar array (UCA) of backbaffled omnidirectional microphones. The array is one meter in diameter. Set the operating frequency to 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

```
N = 21;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
myMic = phased.OmnidirectionalMicrophoneElement;
myMicFrequencyRange = [0,5000];
myMic.BackBaffled = true;
myArray = phased.ConformalArray;
myArray.Element = myMic;
myArray.ElementPosition = Radius*[zeros(1,N);cosd(theta);sind(theta)];
myArray.ElementNormal = [ones(1,N);zeros(1,N)];
c = 1500.0;
fc = 4000;
```

Steer the array to 30 degrees in azimuth and compute the directivity in the steering direction.

```
lambda = c/fc;
ang = [30;0];
w = steervec(getElementPosition(myArray)/lambda,ang);
```

```
d = directivity(myArray,fc,ang,...
    'PropagationSpeed',c,...
    'Weights',w)
```

```
d = 15.1633
```

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox™ antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## See Also

`pattern` | `patternAzimuth` | `patternElevation`

# collectPlaneWave

**System object:** `phased.ConformalArray`
**Package:** `phased`

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

## Output Arguments

**Y**

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

## Examples

### Simulate Received Signals at Conformal Array

Simulate two received signals at an 8-element uniform circular array. The signals arrive from 10° and 30° azimuth, respectively. Both signals have an elevation angle of 0°.

Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.ConformalArray('ElementPosition', ...
    [cosd(azang);sind(azang);zeros(1,N)],'ElementNormal',[azang;zeros(1,N)]);
y = collectPlaneWave(array,randn(4,2),[10 30],100e6);
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

# getElementNormal

**System object:** phased.ConformalArray
**Package:** phased

Normal vector to array elements

## Syntax

```
normvec = getElementNormal(sConfArray)
normvec = getElementNormal(sConfArray,elemidx)
```

## Description

`normvec = getElementNormal(sConfArray)` returns the normal vectors of the array elements of the `phased.sConfArray` System object, `sConfArray`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sConfArray`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form`[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sConfArray,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Input Arguments

### `sConfArray` — Conformal array

`phased.ConformalArray` System object

Conformal array, specified as a `phased.ConformalArray` System object.

Example: `phased.ConformalArray`

**elemidx — Element indices**

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

## Output Arguments

**normvec — Element normal vectors**

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

## Examples

### Conformal Array Element Normals

Construct a 5-element acoustic cross array (UCA) using the ConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Display the array normal vectors.

```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sConformArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[45*ones(1,N);zeros(1,N)]);
pos = getElementPosition(sConformArray)
pos = 3×5

         0         0         0         0         0
   -0.1875         0    0.1875         0         0
         0         0         0   -0.1875    0.1875
```

```
normvec = getElementNormal(sConformArray)
```

```
normvec = 2×5

    45    45    45    45    45
     0     0     0     0     0
```

**Introduced in R2016a**

# getElementPosition

**System object:** `phased.ConformalArray`
**Package:** `phased`

Positions of array elements

## Syntax

```
POS = getElementPosition(H)
POS = getElementPosition(H,ELEIDX)
```

## Description

`POS = getElementPosition(H)` returns the element positions of the conformal array `H`. `POS` is an 3xN matrix where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

For details regarding the local coordinate system of the conformal array, enter `phased.ConformalArray.coordinateSystemInfo`.

`POS = getElementPosition(H,ELEIDX)` returns the positions of the elements that are specified in the element index vector `ELEIDX`.

## Examples

### Element Positions of Conformal Array

Construct a three-element conformal array and obtain the element positions.

```
array = phased.ConformalArray('ElementPosition',[-1,0,1;0,0,0;0,0,0]);
pos = getElementPosition(array)
```

```
pos = 3×3
```

```
    -1     0     1
     0     0     0
     0     0     0
```

# getNumElements

**System object:** `phased.ConformalArray`
**Package:** `phased`

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

`N = getNumElements(H)` returns the number of elements, N, in the conformal array object `H`.

## Examples

### Number of Elements of Conformal Array

Construct a three-element conformal array and obtain the number of elements.

```
array = phased.ConformalArray('ElementPosition',[-1,0,1;0,0,0;0,0,0]);
N = getNumElements(array)
```

```
N = 3
```

# getTaper

**System object:** phased.ConformalArray
**Package:** phased

Array element tapers

## Syntax

```
wts = getTaper(h)
```

## Description

`wts = getTaper(h)` returns the tapers applied to each element of a conformal array, `h`. Tapers are often referred to as weights.

## Input Arguments

### h — Conformal array

`phased.ConformalArray` System object

Conformal array specified as a `phased.ConformalArray` System object.

## Output Arguments

### wts — Array element tapers

*N*-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector, where *N* is the number of elements in the array.

## Examples

### Create and View a Tapered Array

#### Create a two-ring tapered disk array

Create a two-ring disk array and set the taper values on the outer ring to be smaller than those on the inner ring.

```
elemAngles = ([0:5]*360/6);
elemPosInner = 0.5*[zeros(size(elemAngles));...
    cosd(elemAngles);...
    sind(elemAngles)];
elemPosOuter = [zeros(size(elemAngles));...
    cosd(elemAngles);...
    sind(elemAngles)];
elemNorms = repmat([0;0],1,12);
taper =  [ones(size(elemAngles)),0.3*ones(size(elemAngles))];
ha = phased.ConformalArray(...
    [elemPosInner,elemPosOuter],elemNorms,'Taper',taper);
```

#### Display the taper values

```
w = getTaper(ha)
```

```
w = 12×1

    1.0000

# isPolarizationCapable

**System object:** `phased.ConformalArray`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

### h — Conformal array

Conformal array specified as a `phased.ConformalArray` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

## Examples

### Conformal Array of Short-Dipole Antennas Supports Polarization

Show that a circular conformal array of `phased.ShortDipoleAntennaElement` antenna elements supports polarization.

```
N = 8;
azang = (0:N-1)*360/N-180;
antenna = phased.ShortDipoleAntennaElement;
array = phased.ConformalArray(...
    'Element',antenna,'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

The returned value `1` shows that this array supports polarization.

# pattern

**System object:** `phased.ConformalArray`
**Package:** `phased`

Plot conformal array pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern(___,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern(___)
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern(___,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern(___)` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-371 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sArray` — Conformal array

System object

Conformal array, specified as a `phased.ConformalArray` System object.

Example: `sArray= phased.ConformalArray;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

**`PropagationSpeed` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**`Weights` — Array weights**
1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: 'Weights',ones(N,M)

Data Types: double
Complex Number Support: Yes

## Output Arguments

### PAT — Array pattern

*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

### AZ_ANG — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

### EL_ANG — Elevation angles

scalar | 1-by-*M* real-valued row vector

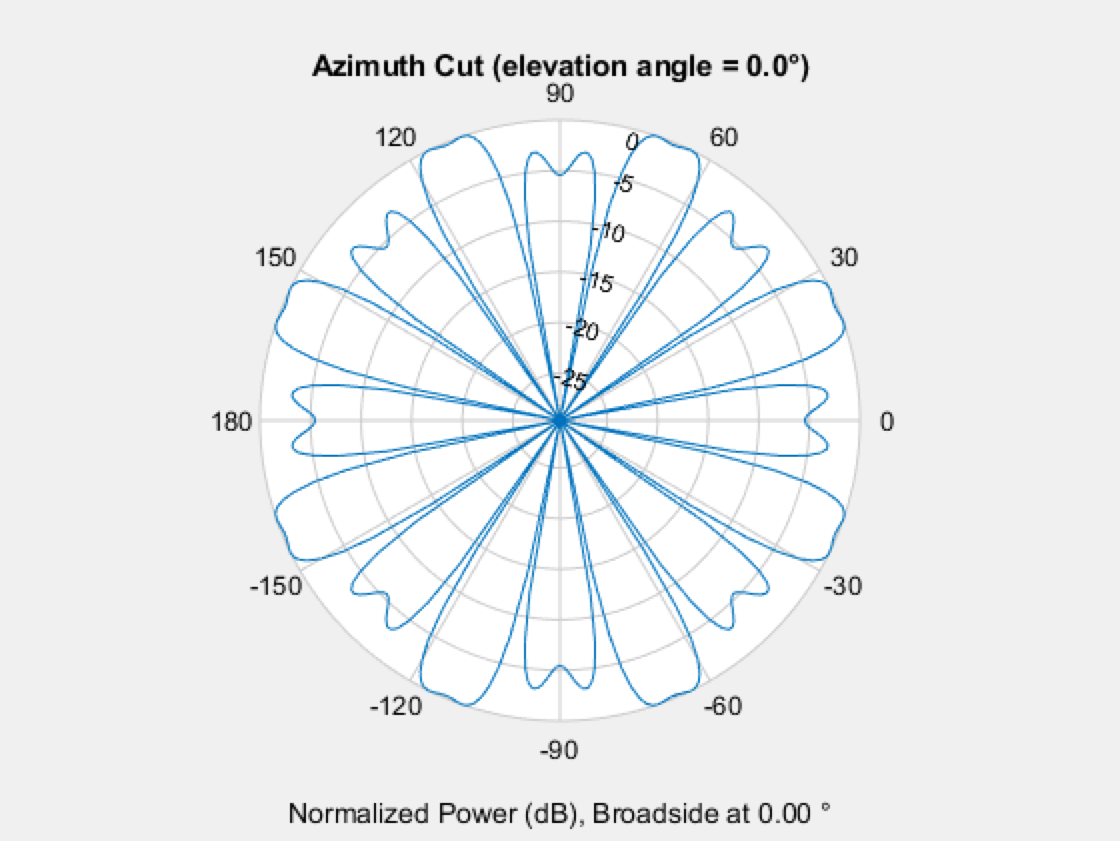
Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

### Plot Power Pattern of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. Plot a normalized azimuth power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
fc = 1e9;
c = physconst('LightSpeed');
pattern(sCA,fc,[-180:180],0,...
    'PropagationSpeed',c,'Type','powerdb',...
    'CoordinateSystem','polar')
```



### Plot Pattern of 31-Element Uniform Circular Sonar Array

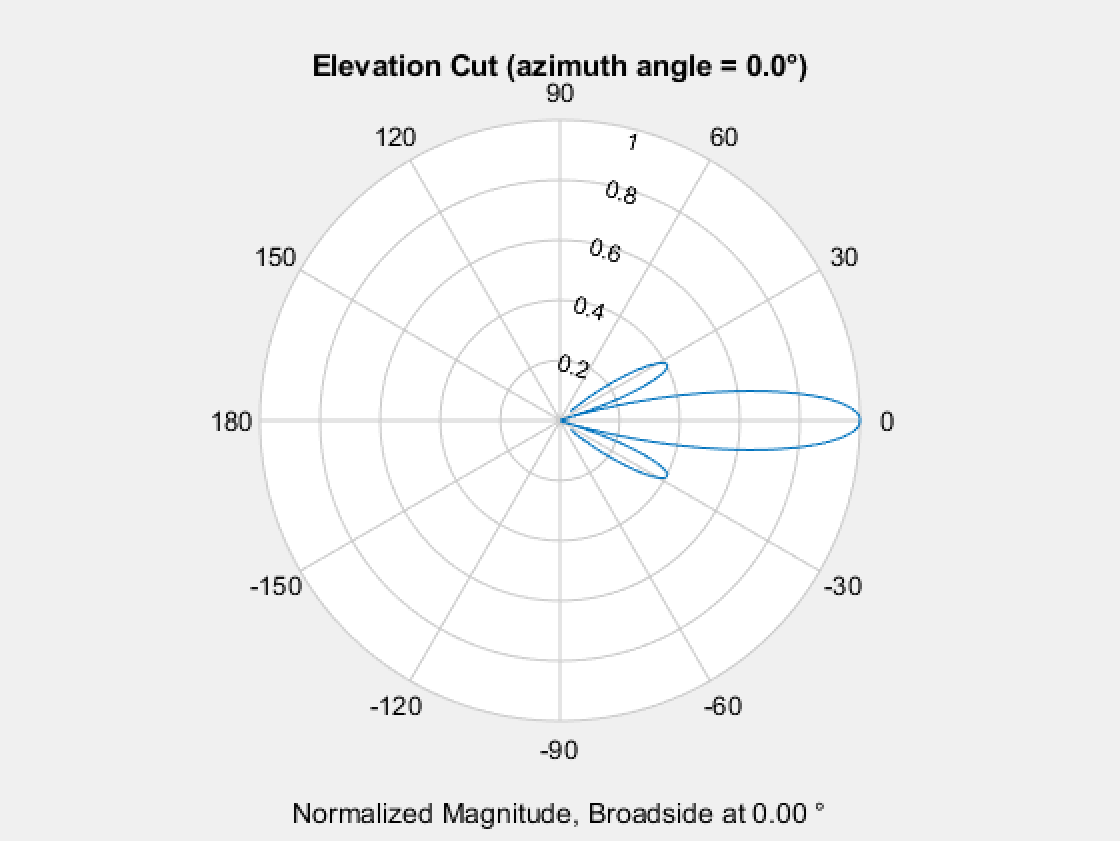
Construct a 31-element acoustic uniform circular sonar array (UCA) using the ConformalArray System object. Assume the array is one meter in diameter. Using the `ElevationAngles` parameter, restrict the display to +/-40 degrees in 0.1 degree increments. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

### Construct the array

```
N = 31;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',Radius*[zeros(1,N);cosd(theta);sind(theta)],...
    'ElementNormal',[ones(1,N);zeros(1,N)]);
```

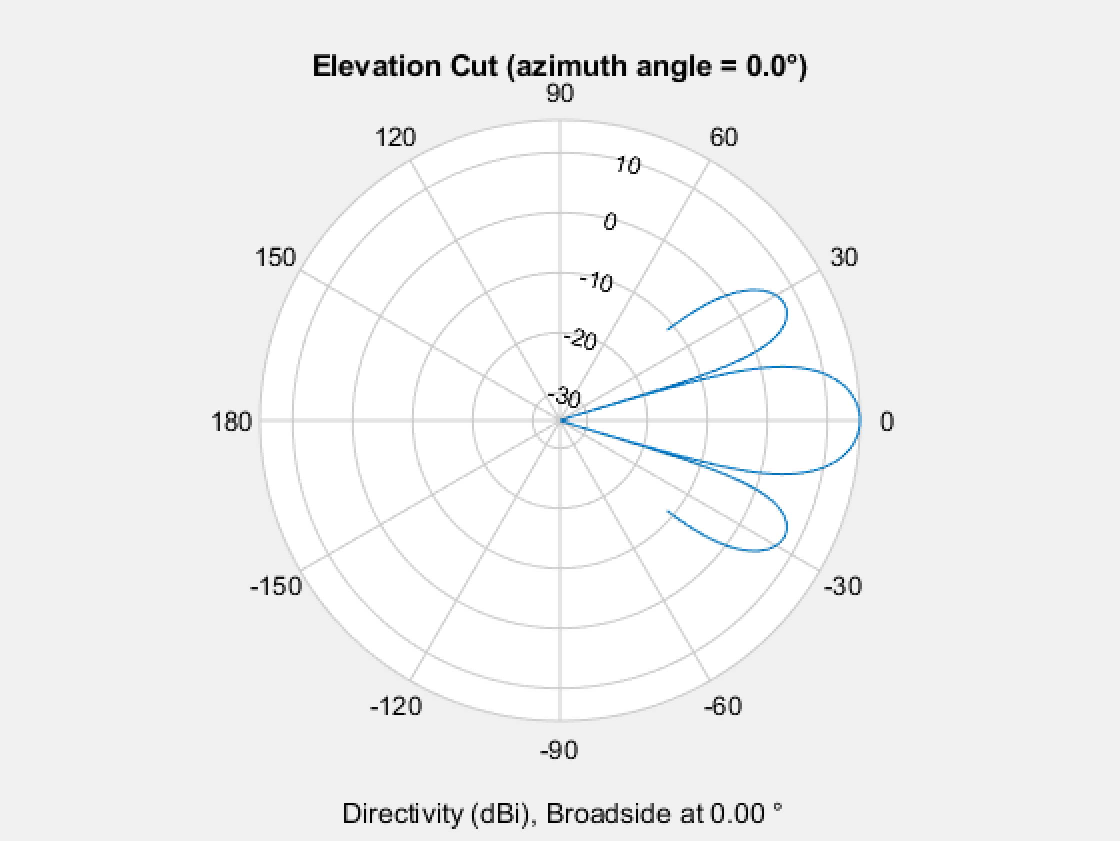
### Plot the magnitude pattern

```
fc = 4000;
c = 1500.0;
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','efield')
```



### Plot the directivity pattern

```
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','directivity')
```



## More About

### Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>

Plot conformal array directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**`sArray` — Conformal array**
System object

Conformal array, specified as a `phased.ConformalArray` System object.

Example: `sArray= phased.ConformalArray;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Type` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Azimuth` — Azimuth angles**
`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

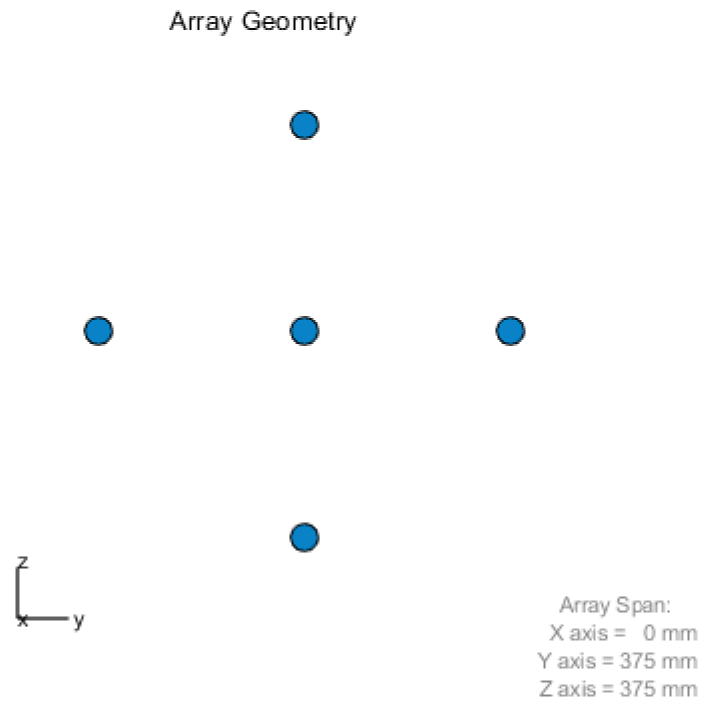
## Examples

### Plot Azimuth Pattern of 5-Element Cross Sonar Array

Construct a 5-element acoustic cross array (UCA) using the ConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Plot the array patterns at two different elevation angles.

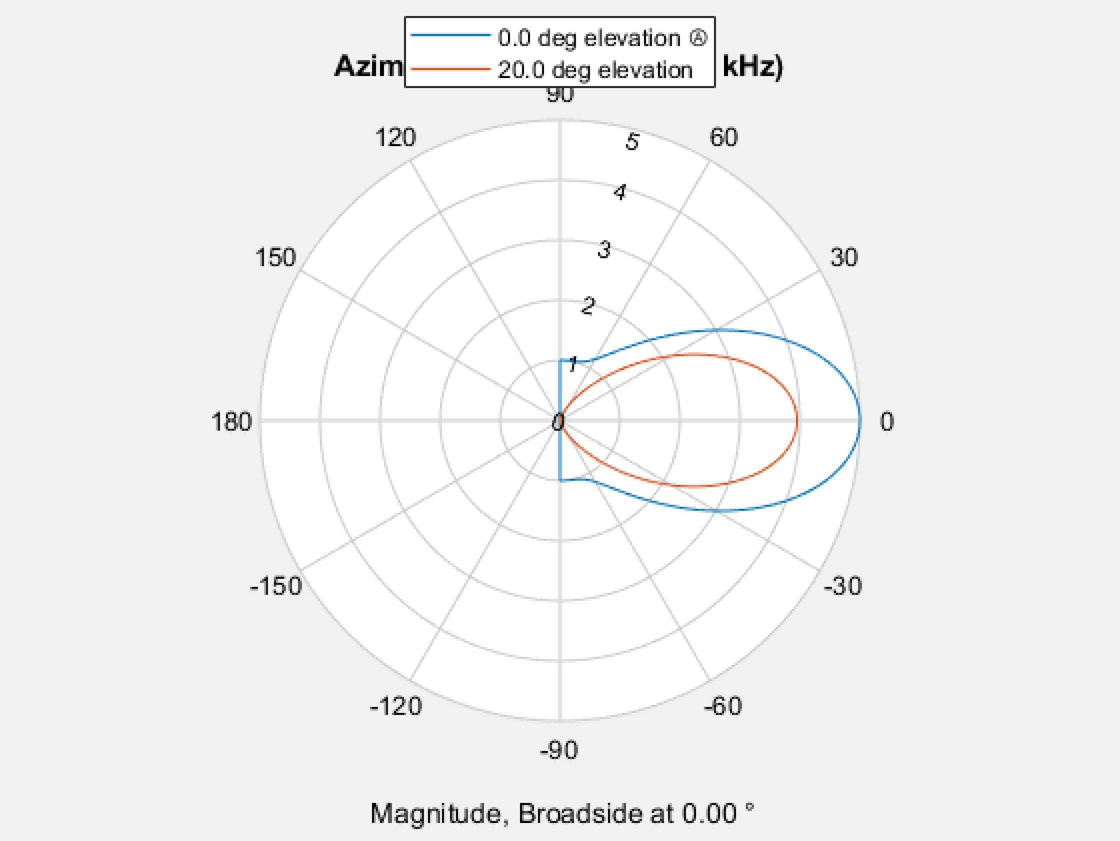
### Construct and view array

```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[zeros(1,N);zeros(1,N)]);
viewArray(sArray)
```



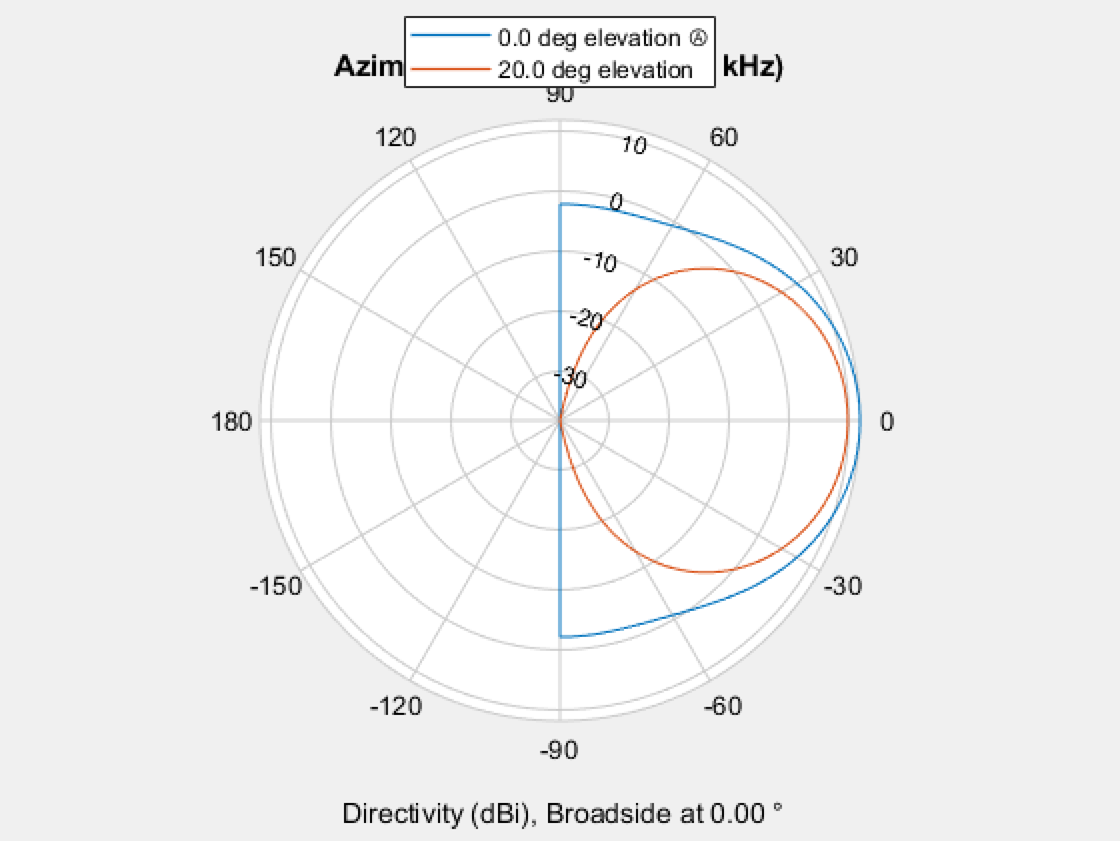
### Plot azimuth pattern for magnitude

```
fc = 4000;
c = 1500.0;
patternAzimuth(sArray,fc,[0,20],...
    'PropagationSpeed',c,...
    'Type','efield')
```



### Plot azimuth pattern for directivity

```
patternAzimuth(sArray,fc,[0,20],...
    'PropagationSpeed',c,...
    'Type','directivity')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternElevation`

**Introduced in R2015a**

# patternElevation

**System object:** phased.ConformalArray
**Package:** phased

Plot conformal array array directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(sArray,FREQ) plots the 2-D array directivity pattern versus elevation (in dBi) for the array sArray at zero degrees azimuth angle. When AZ is a vector, multiple overlaid plots are created. The argument FREQ specifies the operating frequency.

patternElevation(sArray,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(sArray,FREQ,AZ,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the array pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**sArray — Conformal array**
System object

Conformal array, specified as a `phased.ConformalArray` System object.

Example: `sArray= phased.ConformalArray;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

**AZ — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Type — Displayed pattern type**
`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

**`PropagationSpeed` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**`Weights` — Array weights**
*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Elevation` — Elevation angles**
`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Plot Elevation Pattern of 5-Element Cross Sonar Array

Construct a 5-element acoustic cross array (UCA) using the ConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Plot the array patterns at two different azimuth angles.

### Construct and view array

```
N = 5;

patternElevation(sArray,fc,[0,90],...
    'PropagationSpeed',c,...
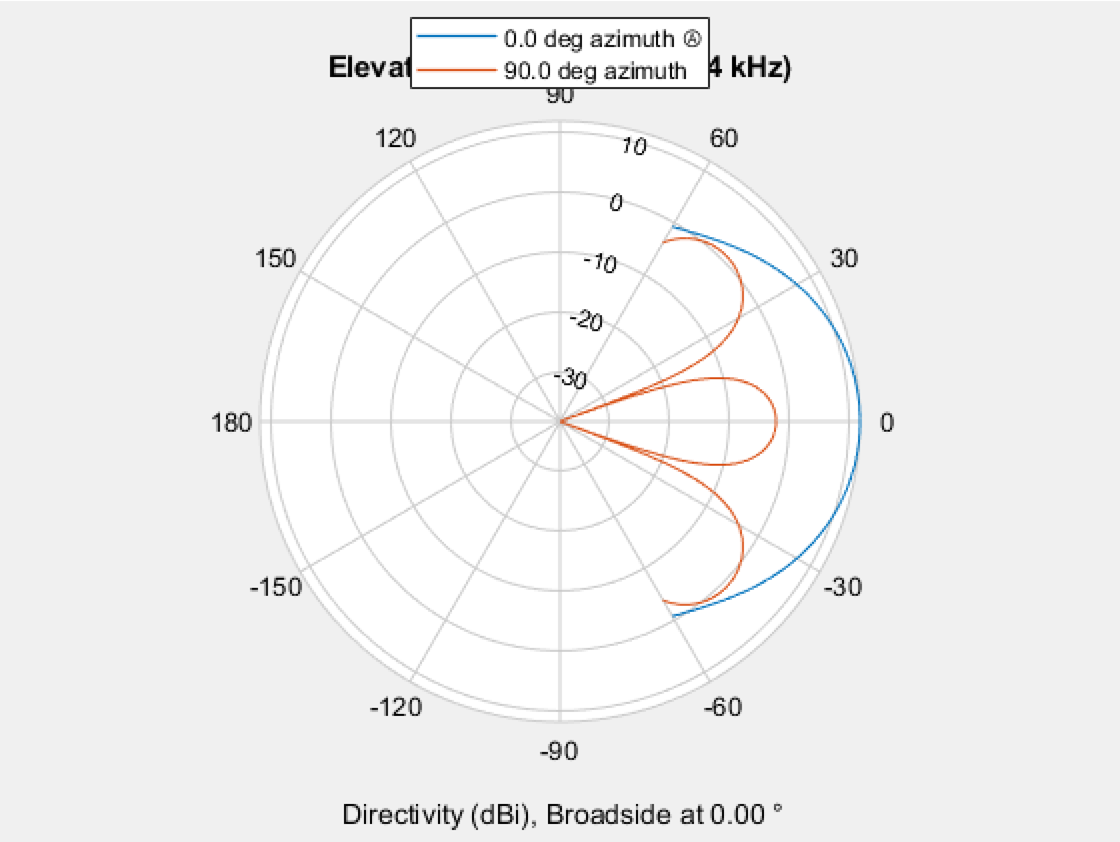
    'Type','directivity',...
    'Elevation',[-60:0.1:60])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# plotResponse

**System object:** `phased.ConformalArray`
**Package:** `phased`

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

### H

Array object

### FREQ

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no

response at frequencies outside that range. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

**V**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**CutAngle**

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

**Format**

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

**NormalizeResponse**

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

**OverlayFreq**

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

**Polarization**

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `'None'`

**RespCut**

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

**Unit**

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimensions | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

**ElevationAngles**

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

**Default:** `[-90:90]`

**UGrid**

*U* coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

**VGrid**

*V* coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

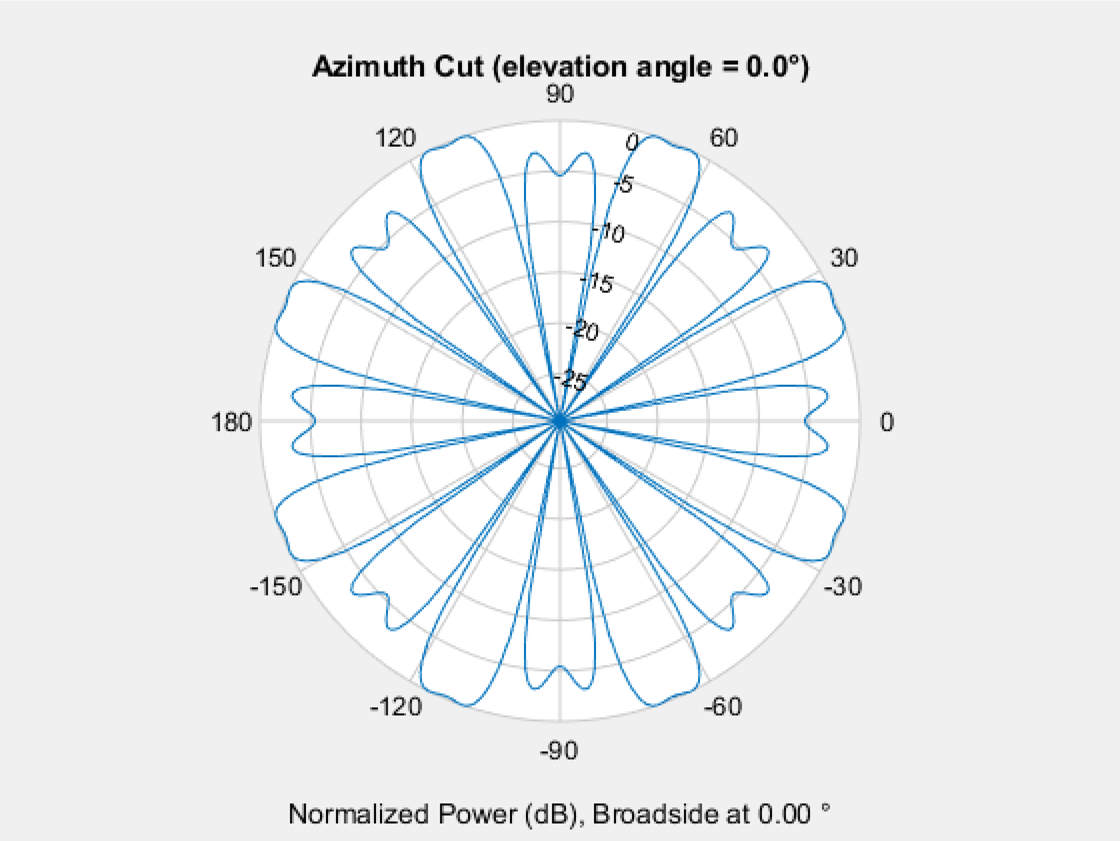
**Default:** `[-1:0.01:1]`

# Examples

### Plot Power Pattern of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. Plot a normalized azimuth power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
fc = 1e9;
c = physconst('LightSpeed');
pattern(sCA,fc,[-180:180],0,...
    'PropagationSpeed',c,'Type','powerdb',...
    'CoordinateSystem','polar')
```



### Plot Pattern of 31-Element Uniform Circular Sonar Array

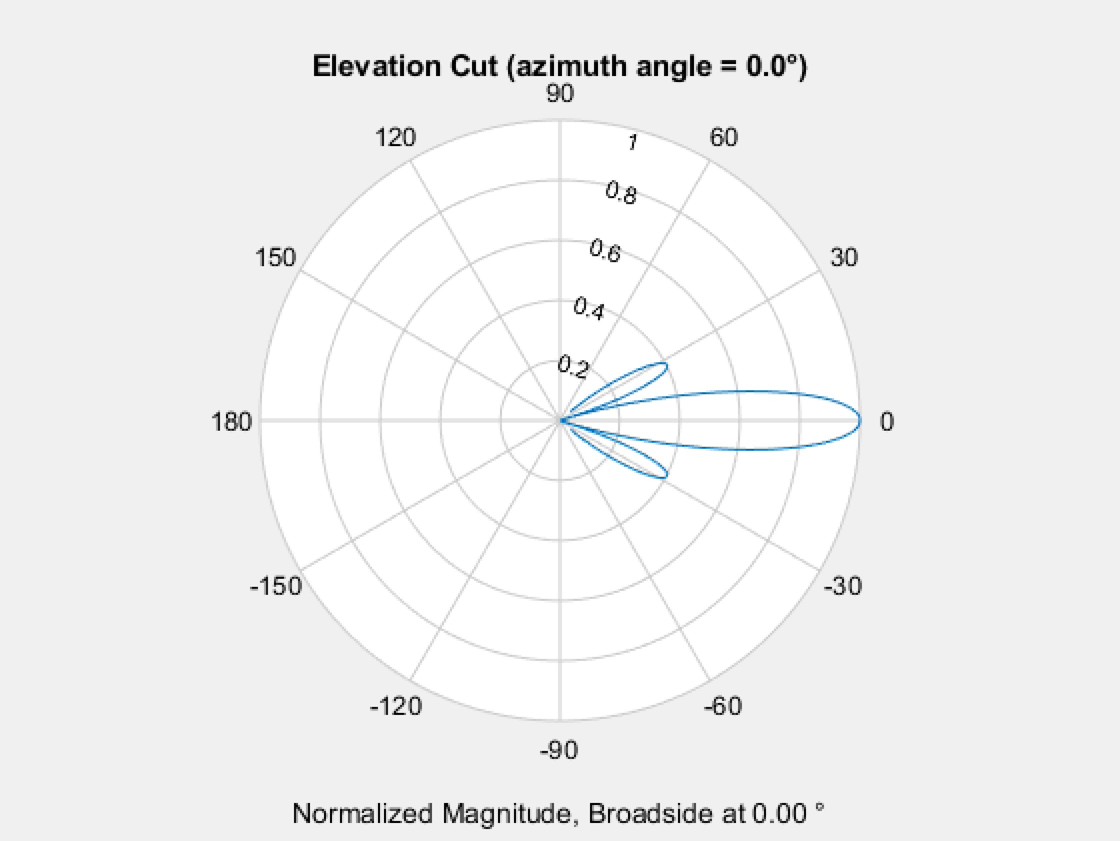
Construct a 31-element acoustic uniform circular sonar array (UCA) using the ConformalArray System object. Assume the array is one meter in diameter. Using the `ElevationAngles` parameter, restrict the display to +/-40 degrees in 0.1 degree increments. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

#### Construct the array

```
N = 31;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',Radius*[zeros(1,N);cosd(theta);sind(theta)],...
    'ElementNormal',[ones(1,N);zeros(1,N)]);
```

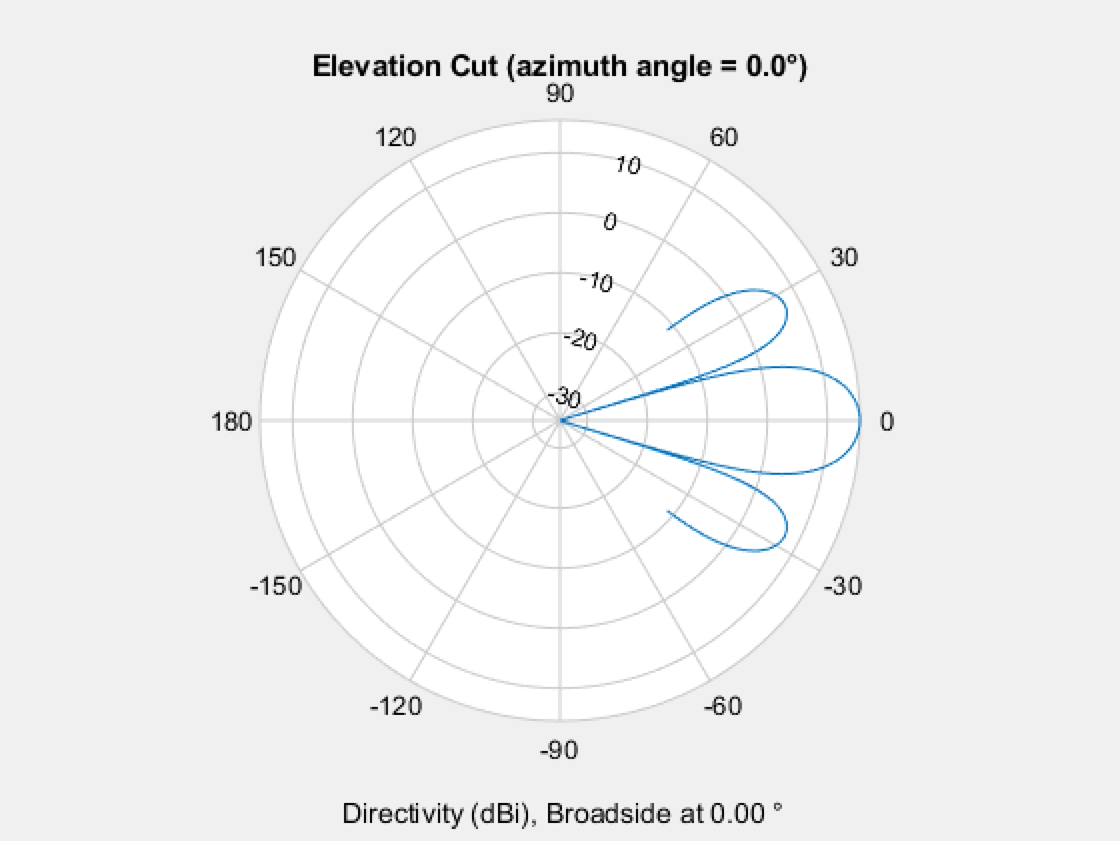
#### Plot the magnitude pattern

```
fc = 4000;
c = 1500.0;
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','efield')
```



### Plot the directivity pattern

```
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','directivity')
```



## See Also

`azel2uv` | `uv2azel`

# step

**System object:** `phased.ConformalArray`
**Package:** `phased`

Output responses of array elements

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the response of the array elements, `RESP`, at operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Array object

**FREQ**

Operating frequencies of array in hertz. FREQ is a row vector of length *L*. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

**ANG**

Directions in degrees. ANG is either a 2-by-*M* matrix or a row vector of length *M*.

If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

## Output Arguments

**RESP**

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each

of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

# Examples

### Response of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. The radius of the array is one meter. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
```

Get the element response at 35 degrees azimuth and 5 degrees elevation.

```
fc = 1e9;
ang = [30;5];
resp = step(sCA,fc,ang)
```

```
resp = 8×1

     1
     1
     1
     1
     1
     1
     1

# viewArray

**System object:** `phased.ConformalArray`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### ShowIndex

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

### ShowNormals

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

### ShowTaper

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

### Title

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

### hPlot

Handle of array elements in figure window.

## Examples

### View Uniform Circular Array

Display the element positions and normal directions of all elements of an 8-element uniform circular array.

#### Create the uniform circular array

```
N = 8;
azang = (0:N-1)*360/N - 180;
ha = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
```

#### Display the positions and normal directions of the elements

```
viewArray(ha,'ShowNormals',true);
```

# phased.ConstantGammaClutter

**Package:** `phased`

Constant gamma clutter simulation

## Description

The `ConstantGammaClutter` object simulates clutter.

To compute the clutter return:

1. Define and set up your clutter simulator. See “Construction” on page 1-412.
2. Call `step` to simulate the clutter return for your system according to the properties of `phased.ConstantGammaClutter`. The behavior of `step` is specific to each object in the toolbox.

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. Coherence time indicates how frequently the software changes the set of random numbers in the clutter simulation.
- Because the signal is narrowband, the spatial response and Doppler shift can be approximated by phase shifts.
- The radar system maintains a constant height during simulation.
- The radar system maintains a constant speed during simulation.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ConstantGammaClutter` creates a constant gamma clutter simulation System object, `H`. This object simulates the clutter return of a monostatic radar system using the constant gamma model.

`H = phased.ConstantGammaClutter(Name,Value)` creates a constant gamma clutter simulation object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name on page 1-412, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

## Properties

**`Sensor`**

Handle of sensor

Specify the sensor as an antenna element object or as an array object whose `Element` property value is an antenna element object. If the sensor is an array, it can contain subarrays.

**Default:** `phased.ULA` with default property values

**`PropagationSpeed`**

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Default:** Speed of light

**`OperatingFrequency`**

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

**Default:** `3e8`

**`SampleRate`**

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The default value corresponds to 1 MHz.

**Default:** `1e6`

**`PRF`**

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The*PRF* must satisfy these restrictions:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of PRF must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* using property settings alone or using property settings in conjunction with the `prfidx` input argument of the `step` method.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties only. You can

  - implement a constant *PRF* by specifying PRF as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying PRF as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying PRF as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an argument specifying an index into the *PRF* vector.

In all cases, the number of output samples is fixed when you set the `OutputFormat` property to `'Samples'`. When you use a varying *PRF* and set the `OutputFormat` property to `'Pulses'`, the number of samples can vary.

**Default:** `10e3`

**`PRFSelectionInputPort`**

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property. When you set this property to `true`, you pass an index argument into the `step` method to select a value from the PRF vector.

**Default:** `false`

**`Gamma`**

Terrain gamma value

Specify the $\gamma$ value used in the constant $\gamma$ clutter model, as a scalar in decibels. The $\gamma$ value depends on both terrain type and the operating frequency.

**Default:** `0`

**`EarthModel`**

Earth model

Specify the earth model used in clutter simulation as one of | `'Flat'` | `'Curved'` |. When you set this property to `'Flat'`, the earth is assumed to be a flat plane. When you set this property to `'Curved'`, the earth is assumed to be a sphere.

**Default:** `'Flat'`

**`PlatformHeight`**

Radar platform height from surface

Specify the radar platform height (in meters) measured upward from the surface as a nonnegative scalar.

**Default:** `300`

### `PlatformSpeed`

Radar platform speed

Specify the radar platform’s speed as a nonnegative scalar in meters per second.

**Default:** `300`

### `PlatformDirection`

Direction of radar platform motion

Specify the direction of radar platform motion as a 2-by-1 vector in the form [AzimuthAngle; ElevationAngle] in degrees. The default value of this property indicates that the platform moves perpendicular to the radar antenna array’s broadside.

Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180 and 180 degrees. Elevation angle must be between –90 and 90 degrees.

**Default:** `[90;0]`

### `BroadsideDepressionAngle`

Depression angle of array broadside

Specify the depression angle in degrees of the broadside of the radar antenna array. This value is a scalar. The broadside is defined as zero degrees azimuth and zero degrees elevation. The depression angle is measured downward from horizontal.

**Default:** `0`

### `MaximumRange`

Maximum range for clutter simulation

Specify the maximum range in meters for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the `PlatformHeight` property.

**Default:** `5000`

**`AzimuthCoverage`**

Azimuth coverage for clutter simulation

Specify the azimuth coverage in degrees as a positive scalar. The clutter simulation covers a region having the specified azimuth span, symmetric to 0 degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but the `PatchAzimuthWidth` value can cause some patches to extend beyond the region.

**Default:** `60`

**`PatchAzimuthWidth`**

Azimuth span of each clutter patch

Specify the azimuth span of each clutter patch in degrees as a positive scalar.

**Default:** `1`

**`TransmitSignalInputPort`**

Add input to specify transmit signal

Set this property to `true` to add input to specify the transmit signal in the `step` syntax. Set this property to `false` omit the transmit signal in the `step` syntax. The `false` option is less computationally expensive; to use this option, you must also specify the `TransmitERP` property.

**Default:** `false`

**`TransmitERP`**

Effective transmitted power

Specify the transmitted effective radiated power (ERP) of the radar system in watts as a positive scalar. This property applies only when you set the `TransmitSignalInputPort` property to `false`.

**Default:** `5000`

**`CoherenceTime`**

Clutter coherence time

Specify the coherence time in seconds for the clutter simulation as a positive scalar. After the coherence time elapses, the `step` method updates the random numbers it uses for the clutter simulation at the next pulse. A value of `inf` means the random numbers are never updated.

**Default:** `inf`

**`OutputFormat`**

Output signal format

Specify the format of the output signal as one of | `'Pulses'` | `'Samples'` |. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method is in the form of multiple pulses. In this case, the number of pulses is the value of the `NumPulses` property.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of samples is the value of the `NumSamples` property. In staggered PRF applications, you might find the `'Samples'` option more convenient because the `step` output always has the same matrix size.

**Default:** `'Pulses'`

**`NumPulses`**

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

**Default:** `1`

**`NumSamples`**

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. Typically, you use the number of samples in one pulse. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

### SeedSource

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

| | |
|---|---|
| 'Auto' | The default MATLAB random number generator produces the random numbers. Use 'Auto' if you are using this object with Parallel Computing Toolbox software. |
| 'Property' | The object uses its own private random number generator to produce random numbers. The Seed property of this object specifies the seed of the random number generator. Use 'Property' if you want repeatable results and are not using this object with Parallel Computing Toolbox software. |

**Default:** 'Auto'

### Seed

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}$–1. This property applies when you set the SeedSource property to 'Property'.

**Default:** 0

## Methods

| | |
|---|---|

| step | Simulate clutter using constant gamma model |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

## Examples

### Simulate Clutter for System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kW.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system uses a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
array = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1000.0;
direction = [90;0];
speed = 2.0e3;
depang = 30.0;
```

Create the clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

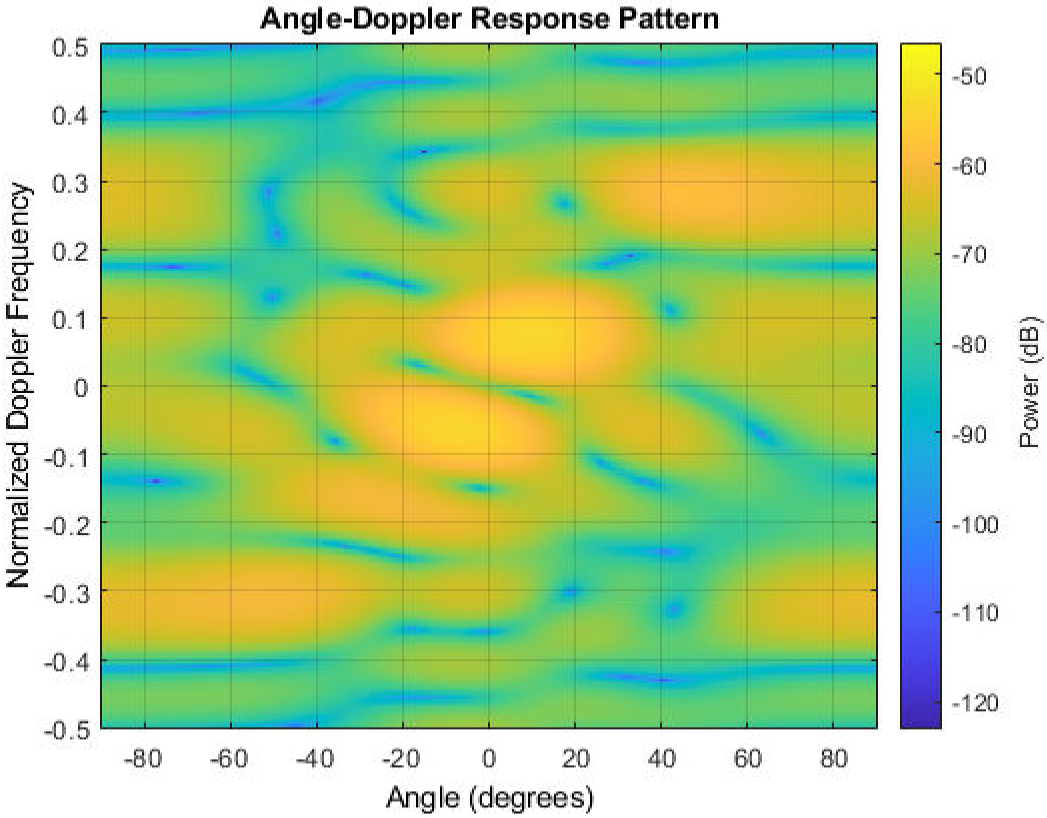
```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
tpower = 5000.0;
clutter = phased.ConstantGammaClutter('Sensor',array,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    sig(:,:,m) = clutter();
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```



### Simulate Clutter Using Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. You input the transmit signal of the radar system when creating clutter. In this case, you do not use the `TransmitERP` property.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
ula = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1.0e3;
direction = [90;0];
speed = 2.0e3;
depang = 30;
```

Create the clutter simulation object and configure it to accept an transmit signal as an input argument. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
clutter = phased.ConstantGammaClutter('Sensor',ula,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses. At each step, pass the transmit signal as an input argument. The software computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 μs.

```
tpower = 5.0e3;
pw = 2.0e-6;
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    sig(:,:,m) = step(clutter,X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',ula,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```

# reset

**System object:** `phased.ConstantGammaClutter`
**Package:** `phased`

Reset random numbers and time count for clutter simulation

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `ConstantGammaClutter` object, `H`. This method resets the random number generator state if the `SeedSource` property is set to `'Property'`. This method resets the elapsed coherence time. Also, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

# step

**System object:** `phased.ConstantGammaClutter`
**Package:** `phased`

Simulate clutter using constant gamma model

## Syntax

```
Y = step(H)
Y = step(H,X)
Y = step(H,STEERANGLE)
Y = step(H,X,WS)
Y = step(H,PRFIDX)
Y = step(H,X,STEERANGLE)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` computes the collected clutter return at each sensor. This syntax is available when you set the `TransmitSignalInputPort` property to `false`.

`Y = step(H,X)` specifies the transmit signal in `X`. Transmit signal refers to the output of the transmitter while it is on during a given pulse. This syntax is available when you set the `TransmitSignalInputPort` property to `true`.

`Y = step(H,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Y = step(H,X,WS) uses WS as weights applied to each element within each subarray. To use this syntax, set the Sensor property to an array that supports subarrays and set the SubarraySteering property of the array to 'Custom'.

Y = step(H,PRFIDX) uses the index, PRFIDX, to select the PRF from a predetermined list of PRFs specified by the PRF property. To enable this syntax, set the PRFSelectionInputPort to true.

Y = step(H,X,STEERANGLE) combines all input arguments. This syntax is available when you configure H so that H.TransmitSignalInputPort is true, H.Sensor is an array that contains subarrays, and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

## Input Arguments

### H

Constant gamma clutter object.

### X

Transmit signal, specified as a column vector.

### STEERANGLE

Subarray steering angle in degrees. STEERANGLE can be a length-2 column vector or a scalar.

If STEERANGLE is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 degrees and 180 degrees, and the elevation angle must be between –90 degrees and 90 degrees.

If STEERANGLE is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

### WS

Subarray element weights

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

### Subarray Element Weights

| Sensor Array | Subarray Weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | When subarrays do not have the same dimensions and sizes, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

#### Dependencies

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

### `PRFIDX`

Index of pulse repetition frequency, specified as a positive integer. The index selects one of the entries specified in the `PRF` property as the PRF for the next transmission.

Example: 3

**Dependencies**

To enable this argument, set the `PRFSelectionInputPort` to `true`.

# Output Arguments

**Y**

Collected clutter return at each sensor. `Y` has dimensions $N$-by-$M$ matrix. If `H.Sensor` contains subarrays, $M$ is the number of subarrays in the radar system. Otherwise it is the number of sensors. When you set the `OutputFormat` property to `'Samples'`, $N$ is defined by the `NumSamples` property. When you set the `OutputFormat` property to `'Pulses'`, $N$ is the total number of samples in the next $L$ pulses. In this case, $L$ is defined by the `NumPulses` property.

# Examples

### Simulate Clutter for System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kW.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system uses a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
array = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
```

```
fs = 1.0e6;
prf = 10.0e3;
height = 1000.0;
direction = [90;0];
speed = 2.0e3;
depang = 30.0;
```

Create the clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

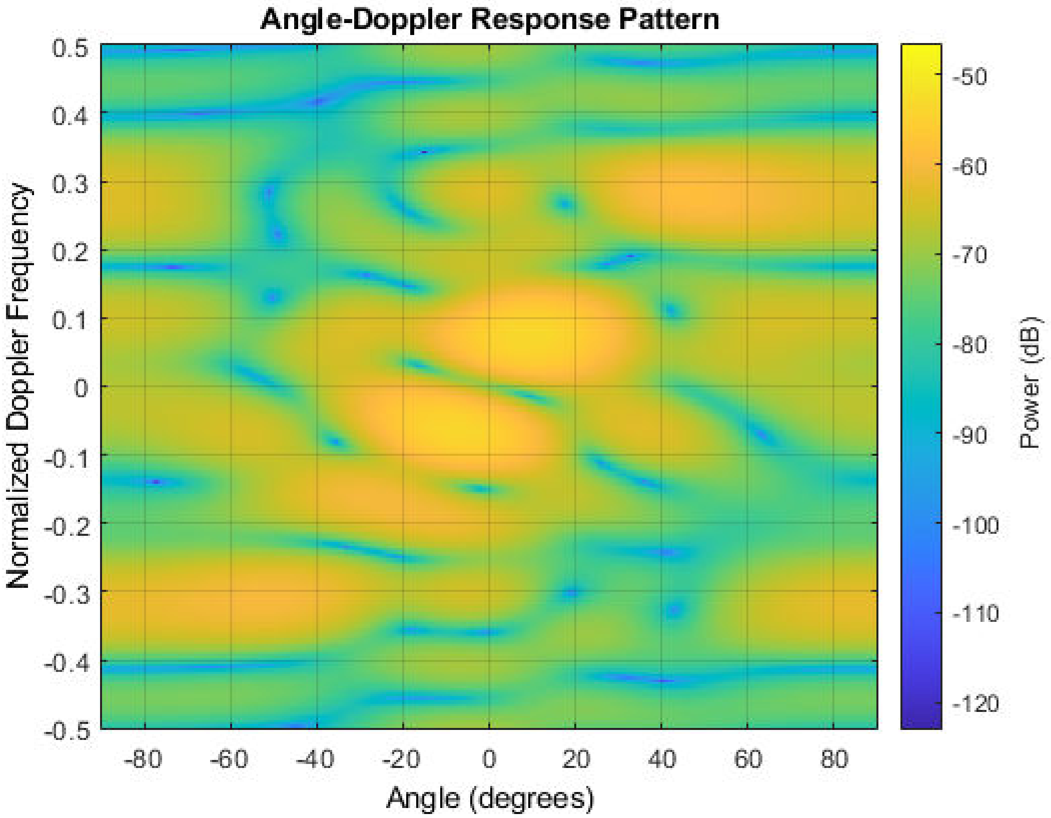
```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
tpower = 5000.0;
clutter = phased.ConstantGammaClutter('Sensor',array,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    sig(:,:,m) = clutter();
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```



### Simulate Clutter Using Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. You input the transmit signal of the radar system when creating clutter. In this case, you do not use the `TransmitERP` property.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
ula = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1.0e3;
direction = [90;0];
speed = 2.0e3;
depang = 30;
```

Create the clutter simulation object and configure it to accept an transmit signal as an input argument. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
clutter = phased.ConstantGammaClutter('Sensor',ula,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

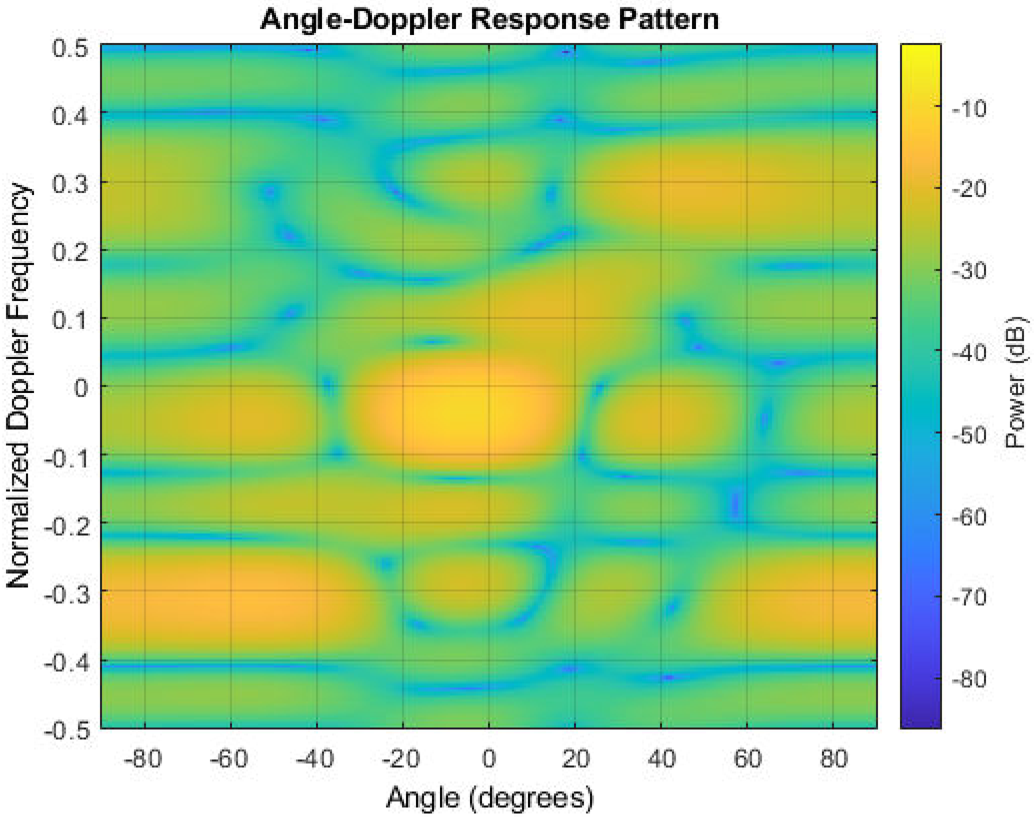
Simulate the clutter return for 10 pulses. At each step, pass the transmit signal as an input argument. The software computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 μs.

```
tpower = 5.0e3;
pw = 2.0e-6;
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
```

```
for m = 1:Npulse
    sig(:,:,m) = step(clutter,X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',ula,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```



## Tips

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. Coherence time indicates how frequently the software changes the set of random numbers in the clutter simulation.
- Because the signal is narrowband, the spatial response and Doppler shift can be approximated by phase shifts.
- The radar system maintains a constant height during simulation.
- The radar system maintains a constant speed during simulation.

# phased.CosineAntennaElement

**Package:** `phased`

Cosine antenna element

## Description

The `CosineAntennaElement` object models an antenna with a cosine response on page 1-450 in both azimuth and elevation. The main response axis (MRA) points to 0° azimuth and 0° elevation in the antenna coordinate system. When placed in a linear array, the MRA is normal to the array axis (see, for example, `phased.ULA`). When placed in a planar array, the MRA points along the array normal (see, for example, `phased.URA`).

To compute the response of the antenna element for specified directions:

1. Create the `phased.CosineAntennaElement` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

This antenna element does not support polarization.

## Creation

## Syntax

```
antenna = phased.CosineAntennaElement
antenna = phased.CosineAntennaElement(Name,Value)
```

### Description

`antenna = phased.CosineAntennaElement` creates a cosine antenna System object, `antenna`. This object models an antenna element whose response is a cosine function raised to nonnegative powers in the azimuth and elevation directions.

`antenna = phased.CosineAntennaElement(Name,Value)` creates a cosine antenna object, `antenna`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `FrequencyRange` — Operating frequency range

`[0 1e20]` (default) | non-negative, real-valued, 1-by-2 row vector

Operating frequency range of the antenna, specified as a non-negative, real-valued, 1-by-2 row vector in the form `[LowerBound HigherBound]`. The antenna element has no response outside the specified frequency range. Units are in Hz.

Data Types: `double`

### `CosinePower` — Exponent of cosine pattern

`[1.5 1.5]` (default) | non-negative scalar | non-negative, real-valued, 1-by-2 vector

Exponents of the cosine pattern, specified as a non-negative scalar or a non-negative, real-valued, 1-by-2 vector. Exponent values must be real numbers greater than or equal to zero. When you set `CosinePower` to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power. When you set `CosinePower` to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern. The second element is the exponent for the elevation direction cosine pattern.

Example: `[1.5 1.3]`

Data Types: `double`

# Usage

# Syntax

```
RESP = antenna(FREQ,ANG)
```

## Description

`RESP = antenna(FREQ,ANG)` returns the antenna voltage response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**FREQ — Operating frequency of antenna, microphone, transducer**

non-negative scalar | non-negative, real-valued, 1-by-*L* row vector

Operating frequency of antenna, microphone, or transducer, specified as a non-negative scalar or non-negative, real-valued, 1-by-*L* row vector. Frequency units are in Hz.

For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the response is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

Example: `[1e8 2e6]`

Data Types: `double`

### ANG — Azimuth and elevation angles of response directions

real-valued, 1-by-*M* row vector | real-valued, 2-by-*M* matrix

Azimuth and elevation angles of response directions, specified as a real-valued, 1-by-*M* row vector or a real-valued, 2-by-*M* matrix, where *M* is the number of angular directions. Angle units are in degrees. The azimuth angle must lie in the range from –180° to 180°, inclusive. The elevation angle must lie in the range from –90° to 90°, inclusive.

- If `ANG` is a 1-by-*M* vector, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be zero.
- If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation].

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[110 125; 15 10]`

Data Types: `double`

## Output Arguments

### RESP — Voltage response of antenna

complex-valued *M*-by-*L* matrix

Voltage response of antenna element, returned as a complex-valued *M*-by-*L* matrix. In this matrix, *M* represents the number of angles specified in `ANG` and *L* represents the number of frequencies specified in `FREQ`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Antenna and Transducer Element System Objects

| | |
|---|---|
| directivity | Directivity of antenna or transducer element |
| isPolarizationCapable | Antenna element polarization capability |
| pattern | Plot antenna or transducer element directivity and patterns |
| patternAzimuth | Plot antenna or transducer element directivity and pattern versus azimuth |
| patternElevation | Plot antenna or transducer element directivity and pattern versus elevation |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Cosine Antenna Response

Construct a cosine antenna element and find its response in one direction. The cosine response is raised to a power of 1.5 in both azimuth and elevation. The antenna frequency range lies in the X band (from 8 to 12 GHz) at 10 GHz. Obtain the antenna's response for an incident angle of 30° azimuth and 5° elevation.

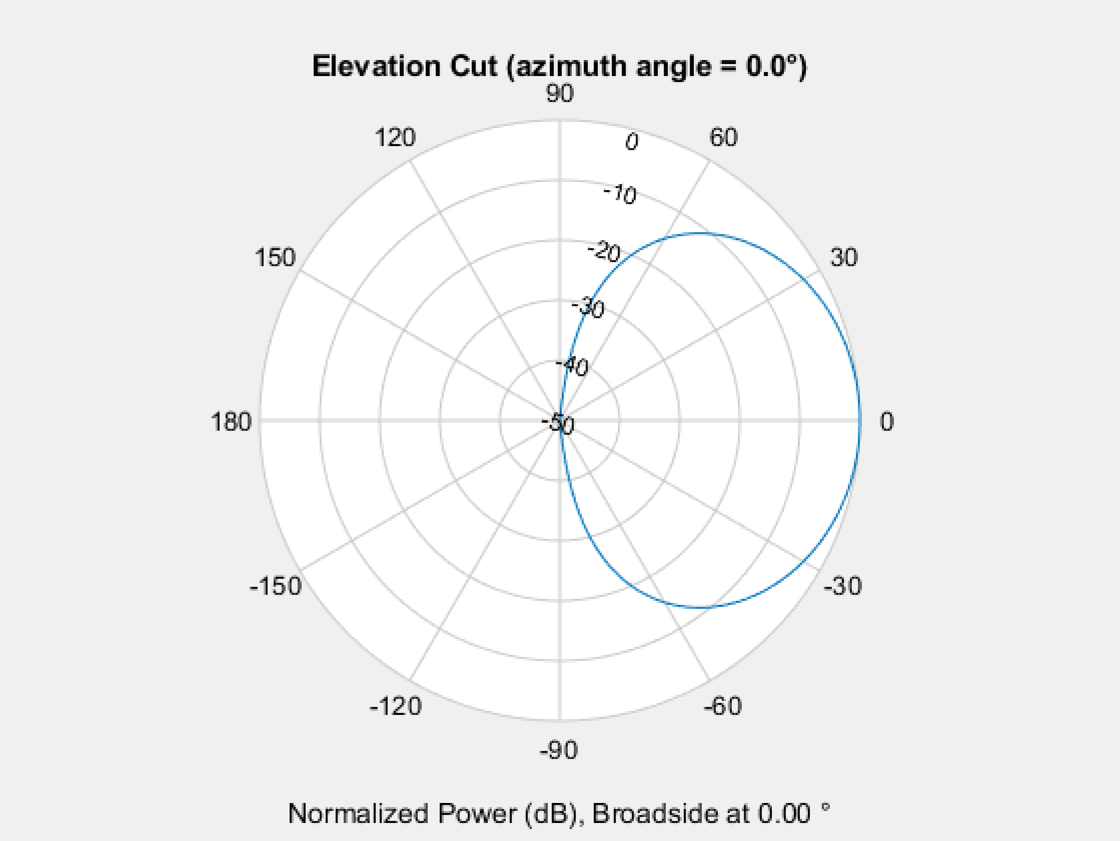
```
antenna = phased.CosineAntennaElement('FrequencyRange',[8e9 12e9], ...
    'CosinePower',1.5);
fc = 10.0e9;
ang = [30;5];
resp = antenna(fc,ang)
```

```
resp = 0.8013
```

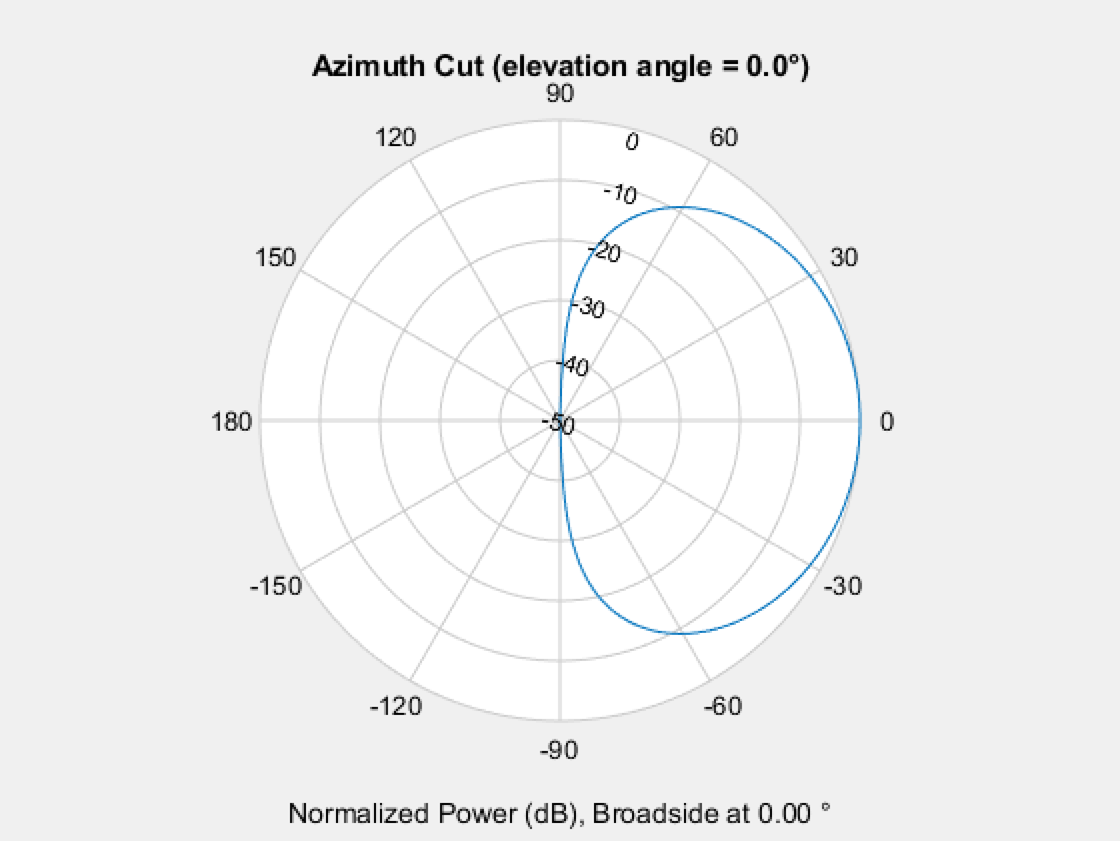
### Plot Power Response of Cosine Antenna

Construct a cosine pattern antenna and calculate its response at boresight (0 degrees azimuth and 0 degrees elevation). Then, plot the antenna pattern. Assume the antenna works between 800 MHz and 1.2 GHz and its operating frequency is 1 GHz. Set the azimuth exponent to 1.5 and elevation exponent to 2.5.

```
antenna = phased.CosineAntennaElement('FrequencyRange',[800e6 1.2e9],...
    'CosinePower',[1.5 2.5]);
fc = 1e9;
resp = antenna(fc,[0;0]);
pattern(antenna,fc,0,-90:90,'Type','powerdb','CoordinateSystem','polar')
```



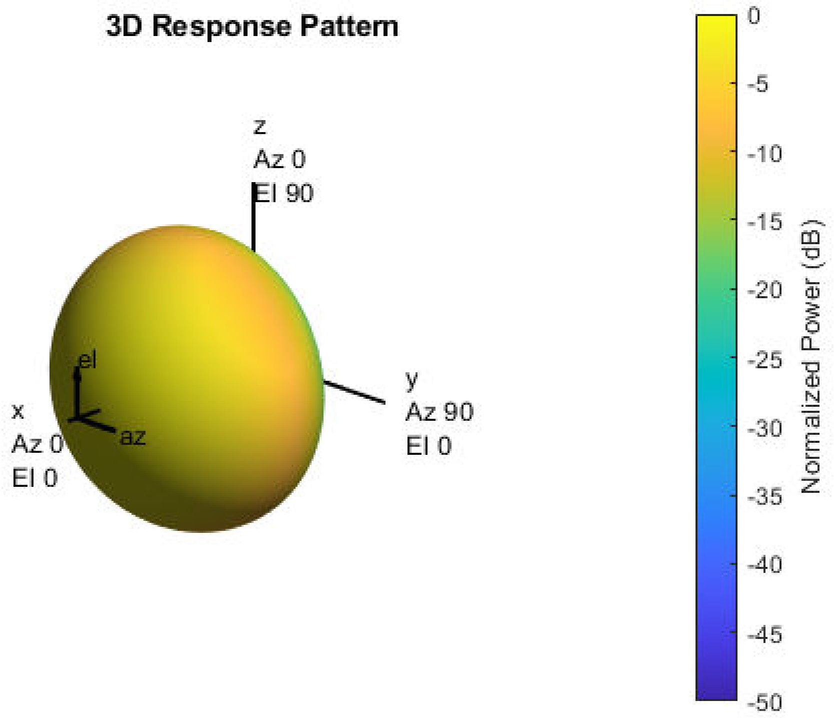
```
pattern(antenna,fc,-180:180,0,'Type','powerdb','CoordinateSystem','polar')
```



### Plot 3-D Polar Pattern of Cosine Antenna

Construct a cosine antenna element using default parameters. Assume the antenna operating frequency is 1 GHz. Then, plot the antenna response in 3-D polar format.

```
antenna = phased.CosineAntennaElement;
fc = 1e9;
pattern(antenna,fc,[-180:180],[-90:90],'Type','powerdb', ...
    'CoordinateSystem','polar')
```



### Directivity of Cosine Antenna

Compute the directivity of a cosine antenna element at seven azimuth directions centered around boresight (zero degrees azimuth and zero degrees elevation). All elevation angles are set to zero degrees.

Create a cosine antenna element system object with the `CosinePower` exponents set to 1.8.

```
antenna = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
```

Set the directivity angles so that the elevation angles are zero. Set the frequency to 1 GHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1e9;
```

Compute the directivity

```
d = directivity(antenna,freq,ang)
```

```
d = 7×1

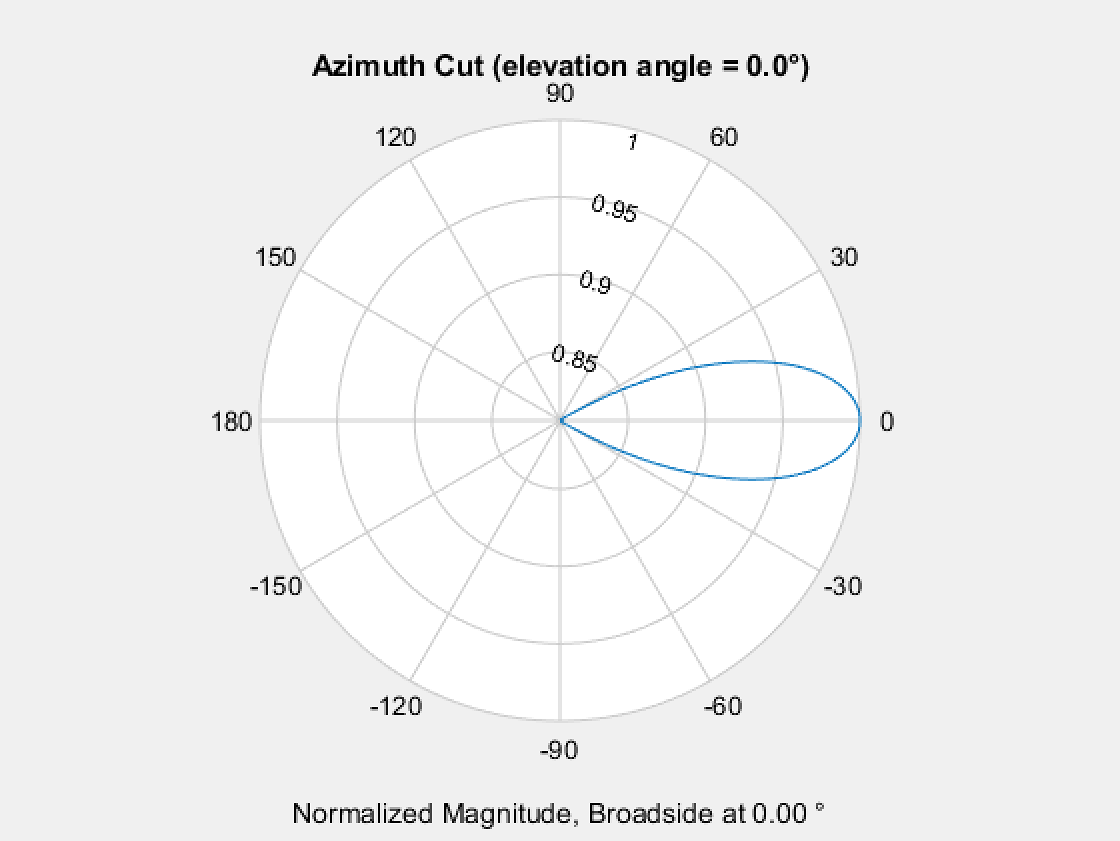
    7.3890
    8.6654
    9.3985
    9.6379
    9.3985
    8.6654
    7.3890
```

The maximum directivity is at boresight.

### Plot Azimuth-Cut of Cosine Antenna Response Pattern

Construct a cosine antenna element using default parameters. Then, plot the pattern of the field magnitude. Assume the antenna operating frequency is 1 GHz. Restrict the response to the range of azimuth angles from -30 to 30 degrees in 0.1 degree increments. The default elevation angle is 0 degrees.

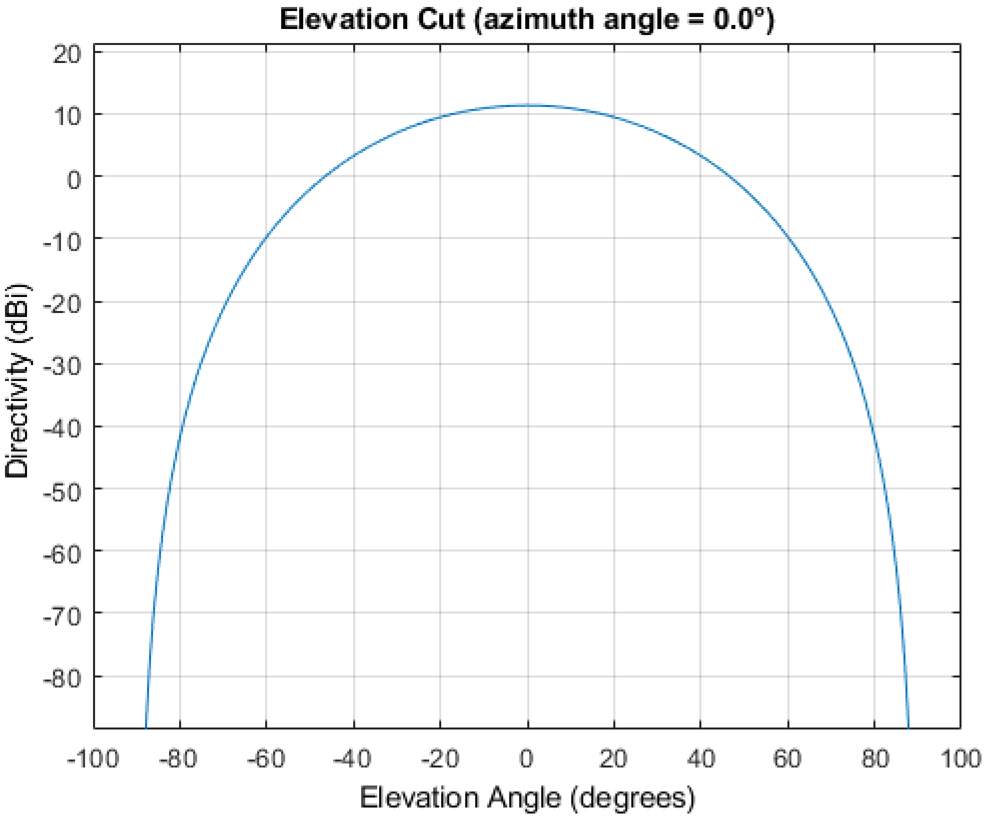
```
antenna = phased.CosineAntennaElement;
fc = 1e9;
pattern(antenna,fc,[-30:0.1:30],0,'Type','efield', ...
    'CoordinateSystem','polar')
```



### Plot Directivity of Cosine Antenna

Construct a cosine-pattern antenna. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Set the azimuth angle cosine power to 2.5 and the elevation angle cosine power to 3.5. Then, plot an elevation cut of its directivity.

```
antenna = phased.CosineAntennaElement('FrequencyRange', ...
    [1e9 2e9],'CosinePower',[2.5,3.5]);
fc = 1.5e9;
pattern(antenna,fc,0,-90:90,'Type','directivity', ...
    'CoordinateSystem','rectangular')
```

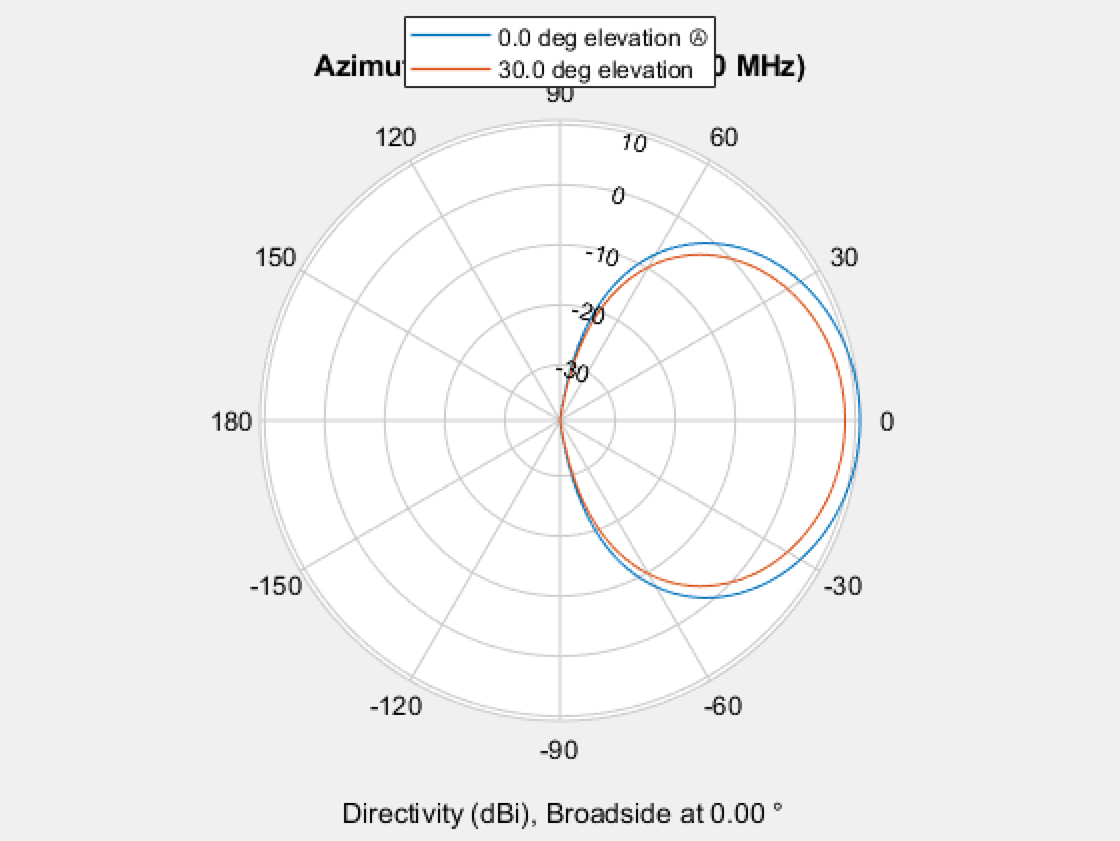


The directivity is maximum at 0 degrees elevation and attains a value of approximately 12 dB.

### Limited-Angle Azimuth Pattern of Cosine Antenna

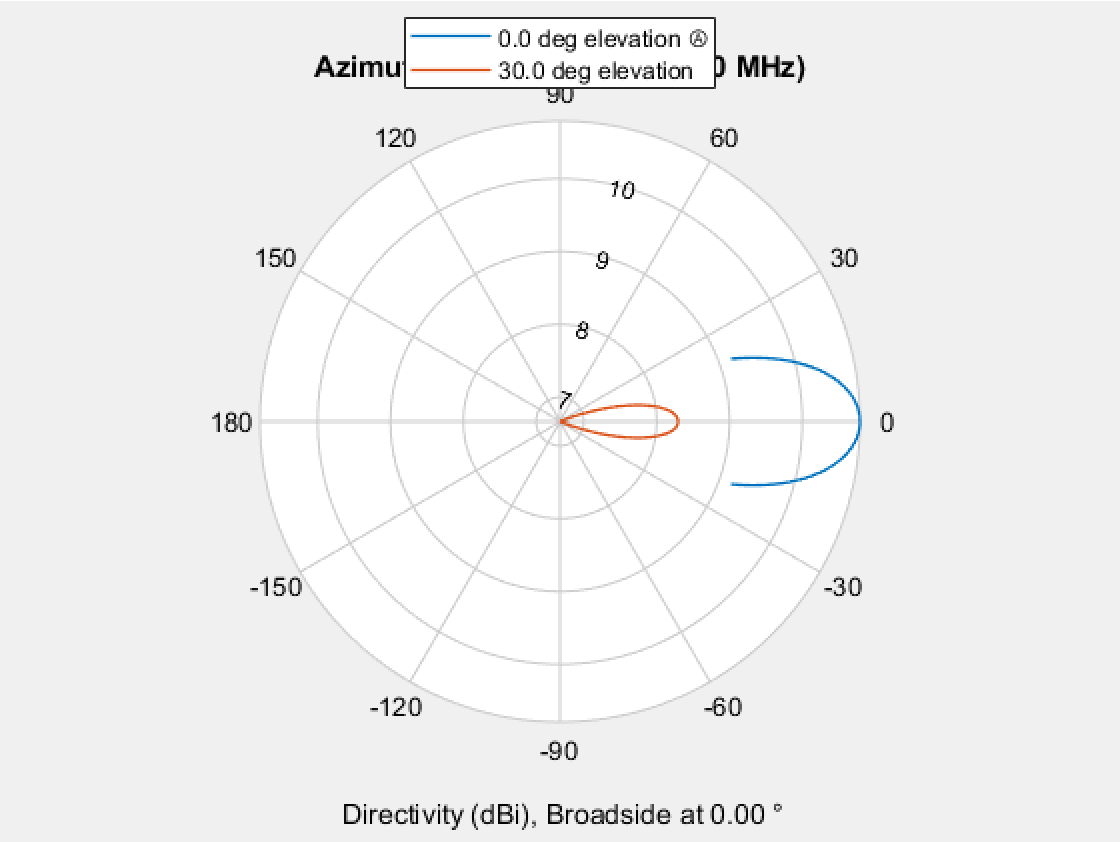
Plot constant-elevation azimuth directivity patterns of a cosine antenna element at 0 degrees and 10 degrees elevation. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
antenna = phased.CosineAntennaElement('FrequencyRange',[100,900]*1e6, ...
    'CosinePower',[3,2]);
patternAzimuth(antenna,fc,[0 30])
```



Plot a limited range of azimuth angles by specifying the `Azimuth` parameter. Note the change in scale.

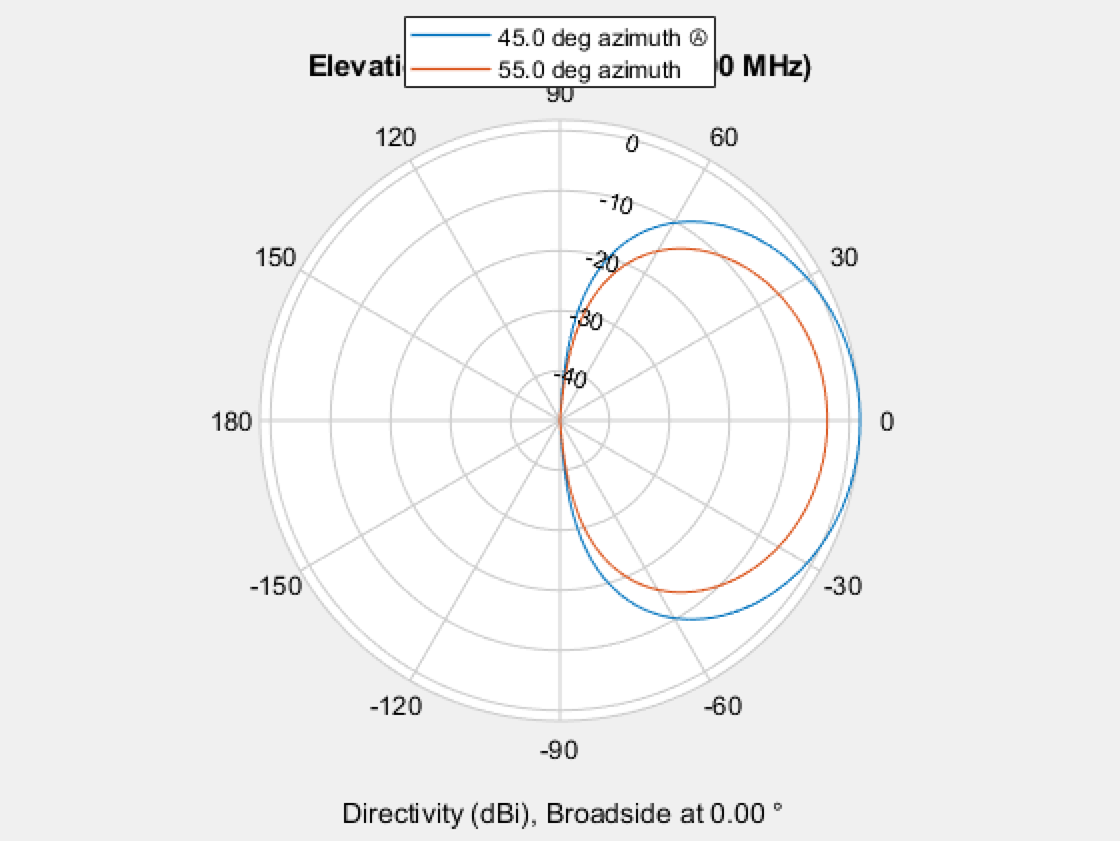
```
patternAzimuth(antenna,fc,[0 30],'Azimuth',-20:20)
```



### Limited-Angle Elevation Pattern of Cosine Antenna

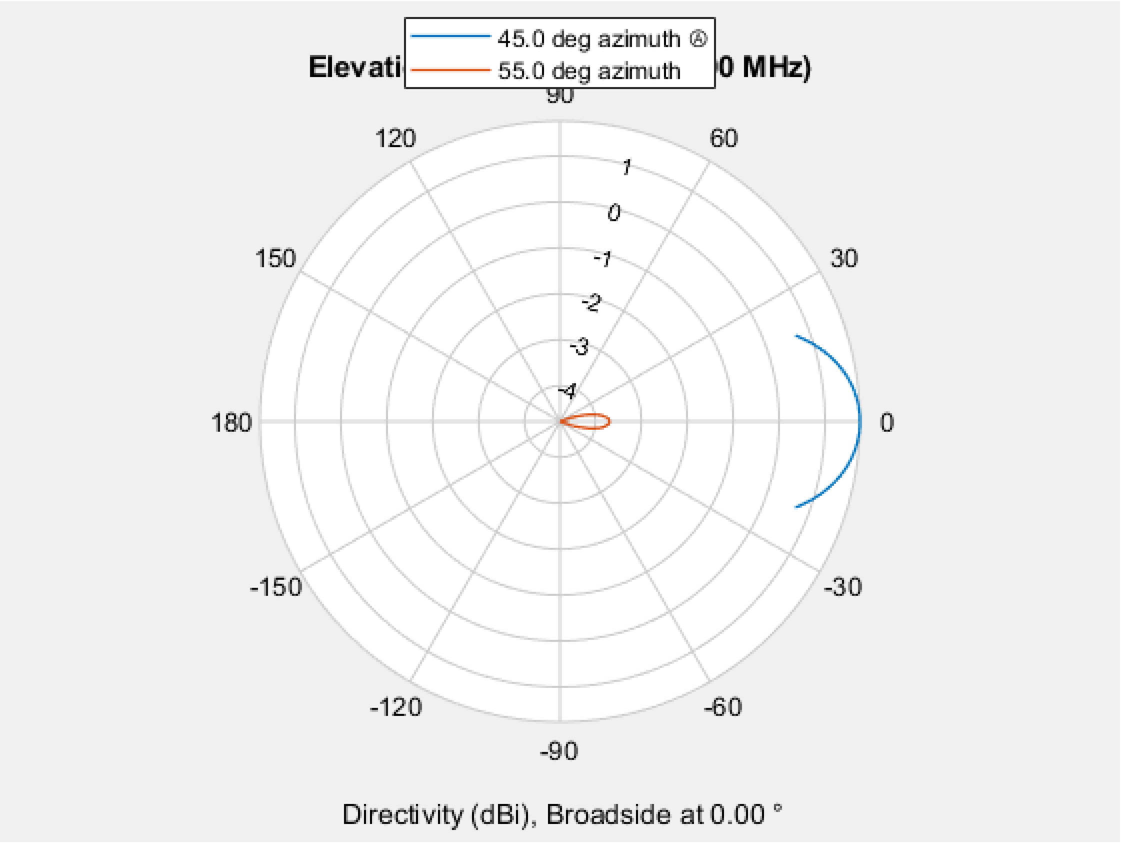
Plot constant-azimuth elevation directivity patterns of a cosine antenna element at 45 and 55 degrees azimuth. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
antenna = phased.CosineAntennaElement('FrequencyRange',[100,900]*1e6, ...
    'CosinePower',[3,2]);
patternElevation(antenna,fc,[45 55])
```



Plot a limited range of elevation angles using the Elevation parameter. Note the change in scale.

```
patternElevation(antenna,fc,[45 55],'Elevation',-20:20)
```



### Cosine Antenna Does Not Support Polarization

Create a cosine antenna element using the `phased.CosineAntennaElement` System object™ and show that it does not support polarization.

```
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0,10]*1e9);
isPolarizationCapable(antenna)
```

```
ans = logical
   0
```

The returned value `0` shows that the antenna element does not support polarization.

# More About

## Cosine Response

The object returns the field response (also called field pattern)

$$f(az,el) = \cos^m(az)\cos^n(el)$$

of the cosine antenna element.

In this expression

- *az* is the azimuth angle.
- *el* is the elevation angle.
- The exponents *m* and *n* are real numbers greater than or equal to zero.

The response is defined for azimuth and elevation angles between –90° and 90°, inclusive, and is always positive. There is no response at the backside of a cosine antenna. The cosine response pattern achieves a maximum value of 1 at 0° azimuth and 0° elevation. Larger exponent values narrow the response pattern of the element and increase the directivity.

The power response (or power pattern) is the squared value of the field response.

$$P(az,el) = \cos^{2m}(az)\cos^{2n}(el)$$

# Extended Capabilities

# C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `pattern`, `patternAzimuth`, and `patternElevation` object functions are not supported.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# phased.CrossedDipoleAntennaElement

**Package:** `phased`

Crossed-dipole antenna element

## Description

The `phased.CrossedDipoleAntennaElement` System object models a crossed-dipole antenna element which is used to generate circularly polarized fields. A crossed-dipole antenna is formed from two orthogonal short-dipole antennas. By default, one dipole lies along *y*-axis and the other along the *z*-axis in the antenna local coordinate system. You can rotate the antenna in the *yz*-plane using the `RotationAngle` property. This antenna object generates right hand or left hand circularly polarized fields, or linearly polarized fields controlled using the `Polarization` property. These fields are pure along the *x*-axis (defined by 0° azimuth and 0° elevation angles).

To compute the response of the antenna element:

1. Create the `phased.CrossedDipoleAntennaElement` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
antenna = phased.CrossedDipoleAntennaElement
antenna = phased.CrossedDipoleAntennaElement(Name,Value)
```

### Description

`antenna = phased.CrossedDipoleAntennaElement` creates a crossed-dipole `antenna` with default property values.

`antenna = phased.CrossedDipoleAntennaElement(Name,Value)` creates a crossed-dipole `antenna` with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `FrequencyRange` — Operating frequency range

`[0 1e20]` (default) | non-negative, real-valued, 1-by-2 row vector

Operating frequency range of the antenna, specified as a non-negative, real-valued, 1-by-2 row vector in the form `[LowerBound HigherBound]`. The antenna element has no response outside the specified frequency range. Units are in Hz.

Data Types: `double`

### `RotationAngle` — Crossed-dipole rotation angle

`0` (default) | scalar between -45° and +45°

Crossed-dipole rotation angle, specified as a scalar between -45° and +45°. The rotation angle specifies the angle of rotation of the two dipoles around the *x*-axis. The rotation angle is measured counter-clockwise around the *x*-axis looking towards to origin. A default value of 0° corresponds to the case where one dipole is along the *z*-axis and the other dipole is along the *y*-axis. Units are in degrees.

Data Types: `double`

### `Polarization` — Crossed-dipole field polarization

`'RHCP'` (default) | `'LHCP'` | `'Linear'`

Polarization of the field generated by the antenna, specified as `'RHCP'`, `'LHCP'`, or `'Linear'`.

- `'RHCP'` – right hand circularly polarize field. The horizontal field has a 90° phase advance compared to the vertical field.
- `'LHCP'` – left hand circularly polarize field. The horizontal field has a 90° delay compared to the vertical field.
- `'Linear'` – linearly polarized field. The horizontal and vertical fields are in phase.

Example: `'Linear'`

Data Types: `char` | `string`

# Usage

# Syntax

```
RESP = antenna(FREQ,ANG)
```

### Description

`RESP = antenna(FREQ,ANG)` returns the antenna voltage response, `RESP`, at the operating frequencies specified in `FREQ` and in the directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

### Input Arguments

**FREQ — Operating frequency of antenna, microphone, transducer**
non-negative scalar | non-negative, real-valued, 1-by-*L* row vector

Operating frequency of antenna, microphone, or transducer, specified as a non-negative scalar or non-negative, real-valued, 1-by-*L* row vector. Frequency units are in Hz.

For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or the FrequencyVector property of the element. Otherwise, the element produces no response and the response is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.

Example: [1e8 2e6]

Data Types: double

### ANG — Azimuth and elevation angles of response directions

real-valued, 1-by-*M* row vector | real-valued, 2-by-*M* matrix

Azimuth and elevation angles of response directions, specified as a real-valued, 1-by-*M* row vector or a real-valued, 2-by-*M* matrix, where *M* is the number of angular directions. Angle units are in degrees. The azimuth angle must lie in the range from –180° to 180°, inclusive. The elevation angle must lie in the range from –90° to 90°, inclusive.

- If ANG is a 1-by-*M* vector, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be zero.
- If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation].

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [110 125; 15 10]

Data Types: double

## Output Arguments

### RESP — Antenna voltage response

structure

Voltage response of the antenna, returned as a MATLAB structure with fields H and V. H and V contain responses for the horizontal and vertical polarization components of the radiation fields, respectively. Both H and V are complex-valued, *M*-by-*L* matrices. *M* represents the number of angles specified in ANG, and *L* represents the number of frequencies specified in FREQ.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Antenna and Transducer Element System Objects

| | |
|---|---|
| directivity | Directivity of antenna or transducer element |
| isPolarizationCapable | Antenna element polarization capability |
| pattern | Plot antenna or transducer element directivity and patterns |
| patternAzimuth | Plot antenna or transducer element directivity and pattern versus azimuth |
| patternElevation | Plot antenna or transducer element directivity and pattern versus elevation |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Compute Crossed-Dipole Antenna Response

Find the response of a crossed-dipole antenna at boresight, 0° azimuth and 0° elevation, and off-boresight at 30° azimuth and 0° elevation. The antenna operates at 250 MHz.

```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[100 900]*1e6);
ang = [0 30;0 0];
fc = 250e6;
resp = antenna(fc,ang);
disp(resp.H)
```

```
   0.0000 - 1.2247i
   0.0000 - 1.0607i
```

```
disp(resp.V)
```

```
   -1.2247
   -1.2247
```

### Plot Response of a Crossed-Dipole Antenna

Plot the response patterns of a crossed-dipole antenna used in an L-band radar with a frequency range between 1-2 GHz. First, set up the radar parameters, and obtain the vertical and horizontal polarization responses in five different directions specified by elevation angles of -30, -15, 0, 15 and 30 degrees, all at 0 degrees azimuth angle. The responses are computed at an operating frequency of 1.5 GHz.

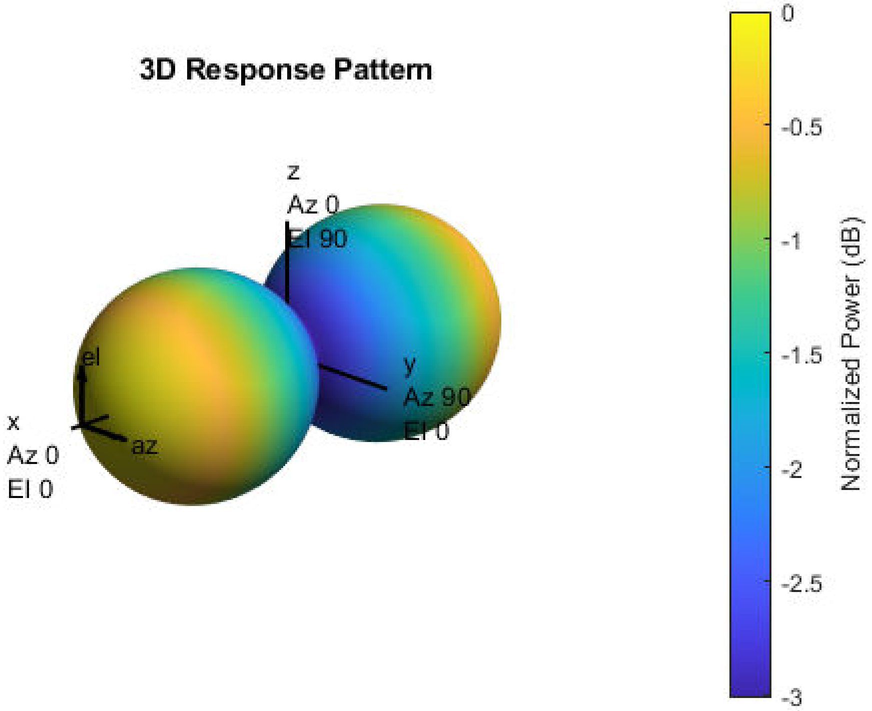
```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[1,2]*1e9);
fc = 1.5e9;
resp = antenna(fc,[0,0,0,0,0;-30,-15,0,15,30]);
[resp.V, resp.H]
```

```
ans = 5×2 complex

  -1.0607 + 0.0000i   0.0000 - 1.2247i
  -1.1830 + 0.0000i   0.0000 - 1.2247i
  -1.2247 + 0.0000i   0.0000 - 1.2247i
  -1.1830 + 0.0000i   0.0000 - 1.2247i
  -1.0607 + 0.0000i   0.0000 - 1.2247i
```

Next, draw a 3-D plot of the combined polarization response.

```
pattern(antenna,fc,-180:180,-90:90,'CoordinateSystem','polar', ...
    'Type','powerdb','Polarization','combined')
```



### Directivity of Crossed-Dipole Antenna Element

Compute the directivity of a crossed-dipole antenna element in several different directions.

Create a crossed-dipole antenna element system object.

```
antenna = phased.CrossedDipoleAntennaElement;
```

Set the angles of interest to be at zero-degrees constant elevation angle. The seven azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation). Set the desired frequency to 1 GHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1e9;
```

Compute the directivity along the constant elevation cut.

```
d = directivity(antenna,freq,ang)
```

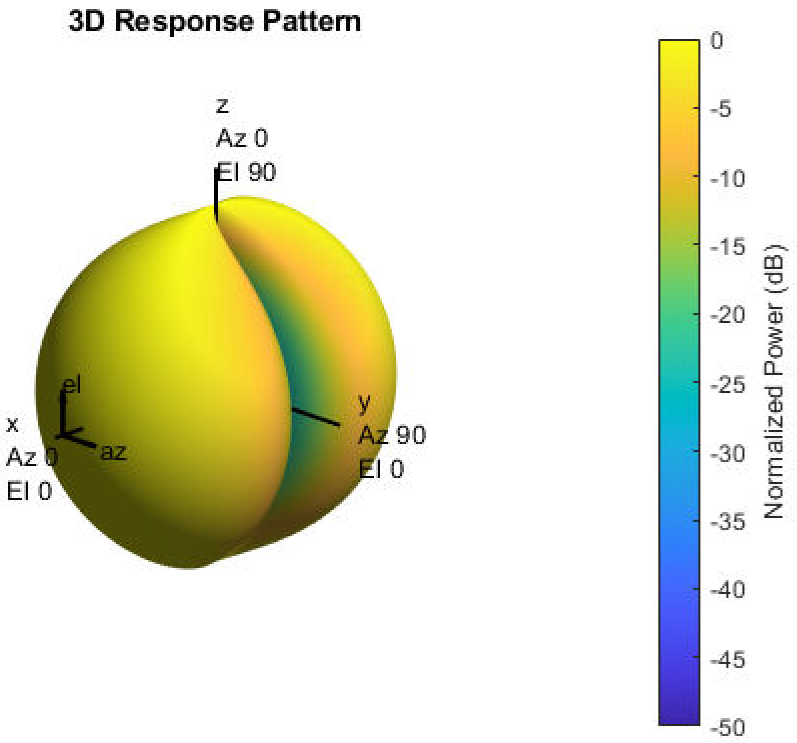
```
d = 7×1

    1.1811
    1.4992
    1.6950
    1.7610
    1.6950
    1.4992
    1.1811
```

### Plot 3-D Polar Patterns of Crossed-Dipole Antenna

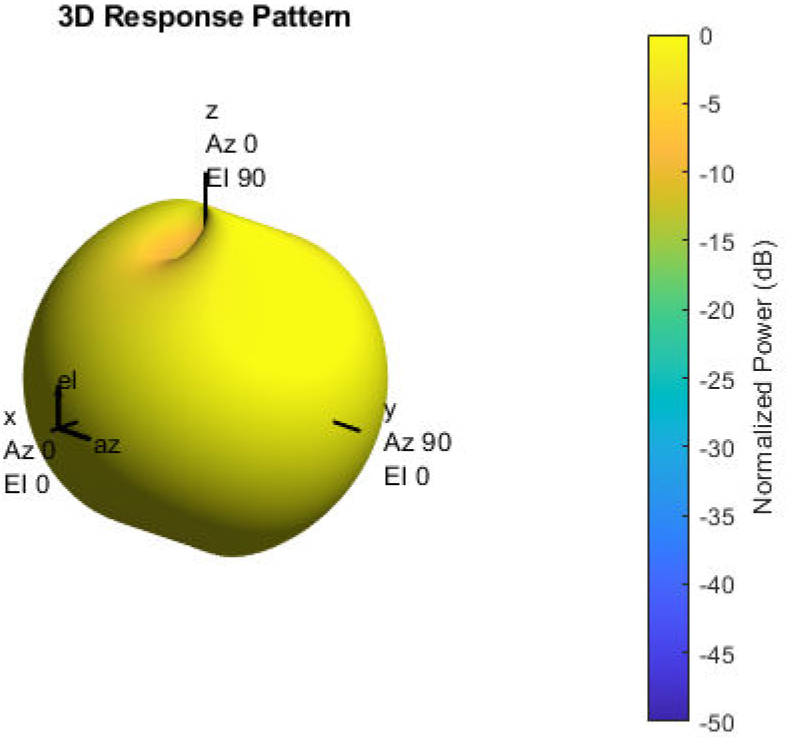
Construct a crossed-dipole antenna element that operates in the frequency range from 100 MHz to 1.5 GHz. Then, plot the 3-D polar power pattern for the horizontal polarization component. Assume the antenna operates at 1 GHz.

```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[100 1500]*1e6);
fc = 1e9;
pattern(antenna,fc,-180:180,-90:90,'Type','powerdb', ...
    'CoordinateSystem','polar','Polarization','H')
```



Next, plot the vertical polarization component.

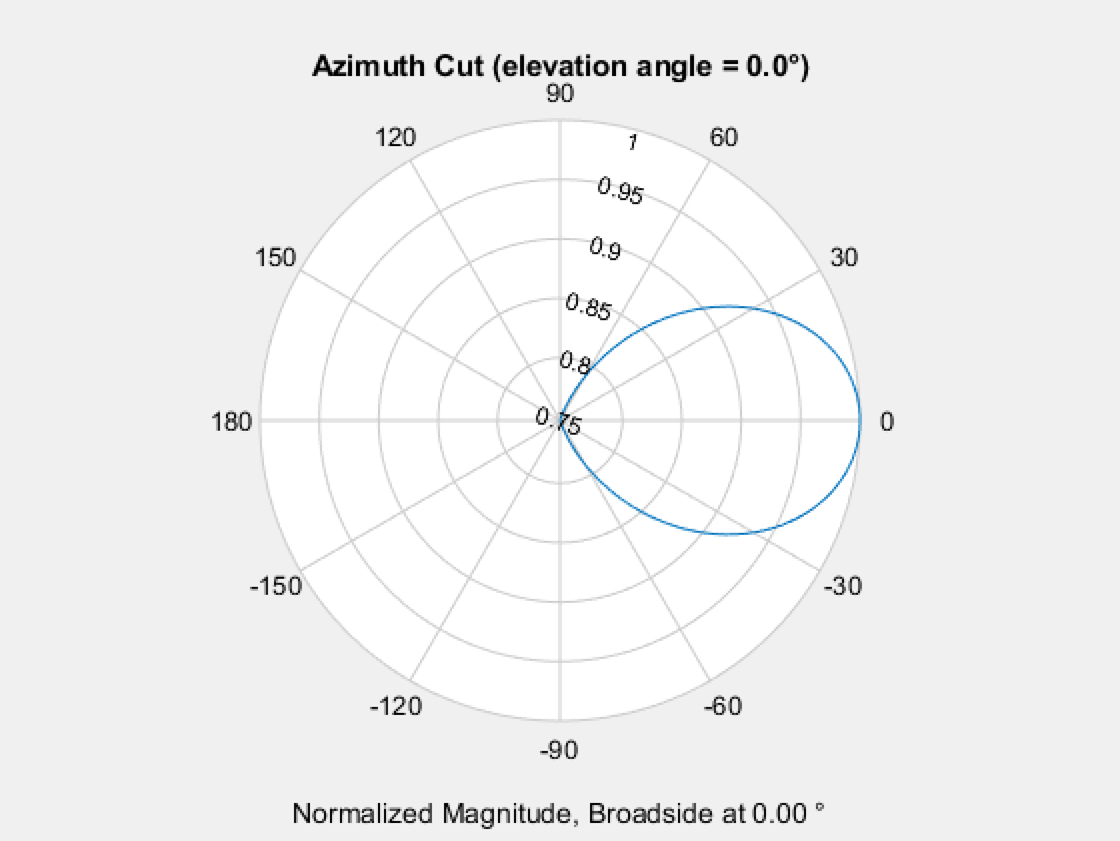
```
pattern(antenna,fc,-180:180,-90:90,'Type','powerdb', ...
    'CoordinateSystem','polar','Polarization','V')
```



### Plot Crossed-Dipole Antenna Pattern at Constant Elevation

Construct a crossed-dipole antenna element. Then, plot the pattern of the horizontal component of the field magnitude at an elevation angle of 0 degrees. Assume the antenna operating frequency is 1 GHz. Restrict the response to the range of azimuth angles from -70 to 70 degrees in 0.1 degree increments.

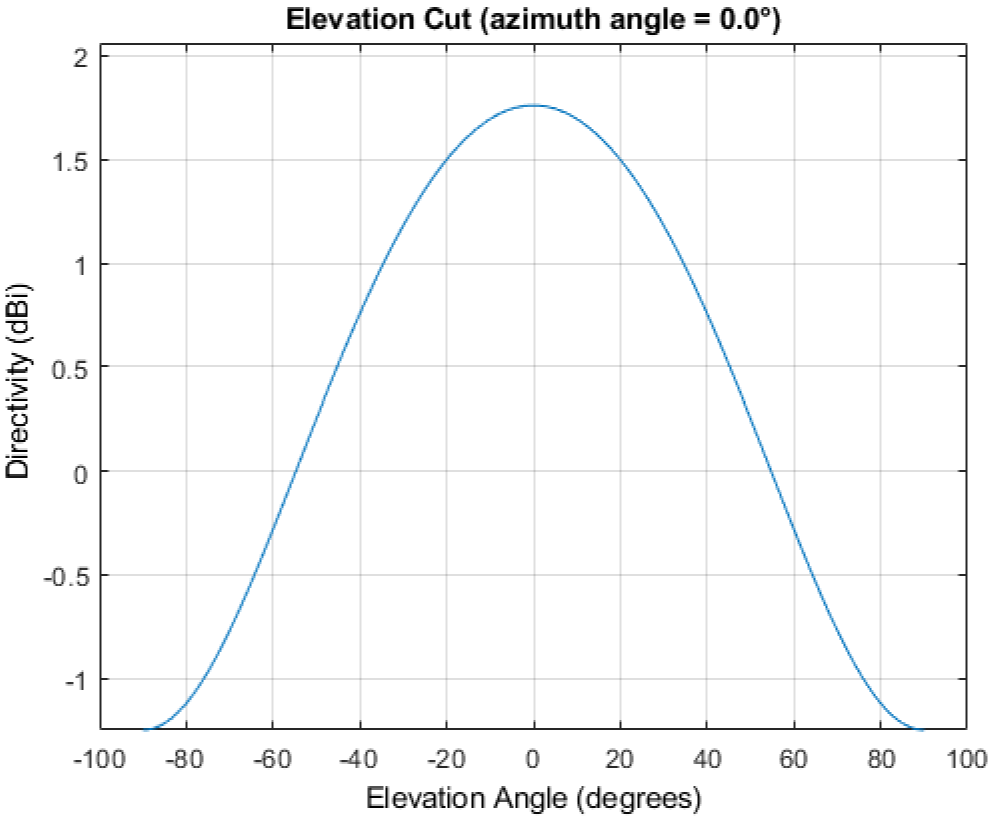
```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[0.5 1.5]*1e9);
fc = 1e9;
pattern(antenna,fc,-70:0.1:70,0,'Type','efield', ...
    'CoordinateSystem','polar','Polarization','combined')
```



### Plot Directivity of Crossed-Dipole Antenna

Create a crossed-dipole antenna. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Then, plot the directivity at a constant azimuth of 0˚.

```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[1e9 2e9]);
fc = 1.5e9;
pattern(antenna,fc,0,-90:90,'Type','directivity', ...
    'CoordinateSystem','rectangular')
```

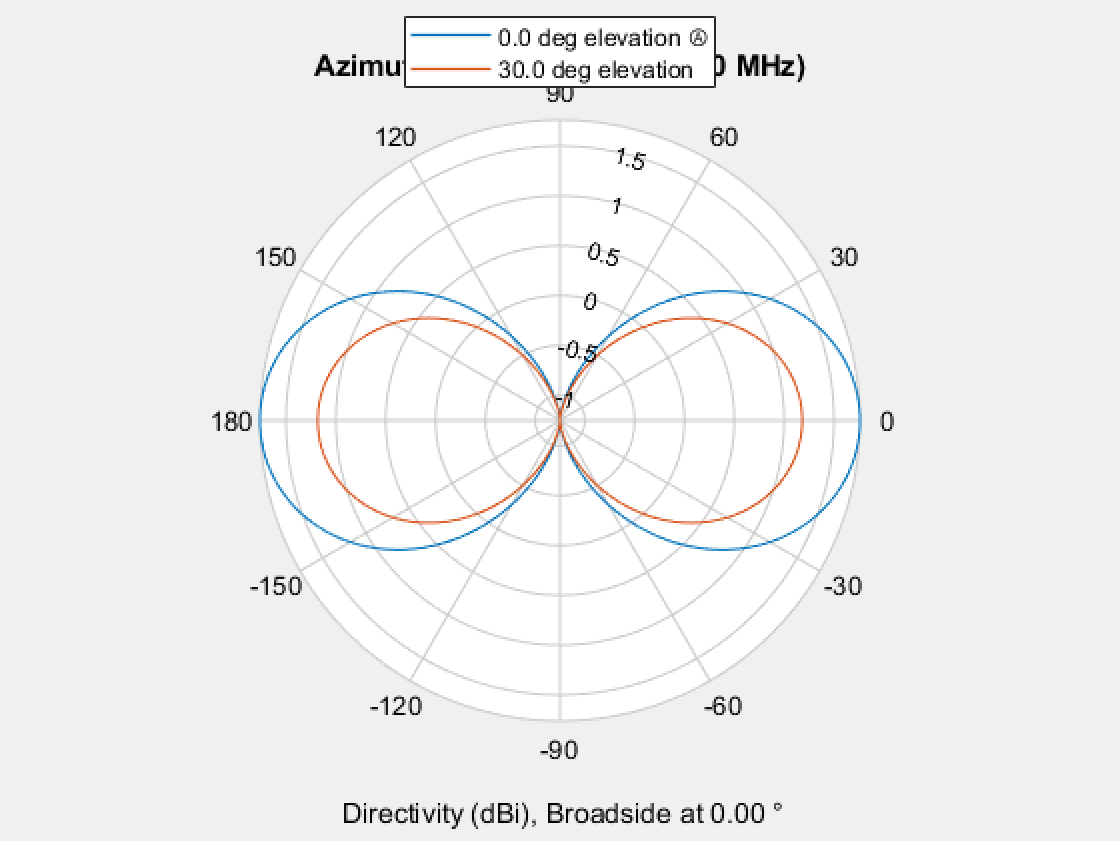


The directivity is maximum at 0˚ elevation and attains a value of approximately 1.75 dB.

### Plot Azimuth Pattern of Crossed-Dipole Antenna Element

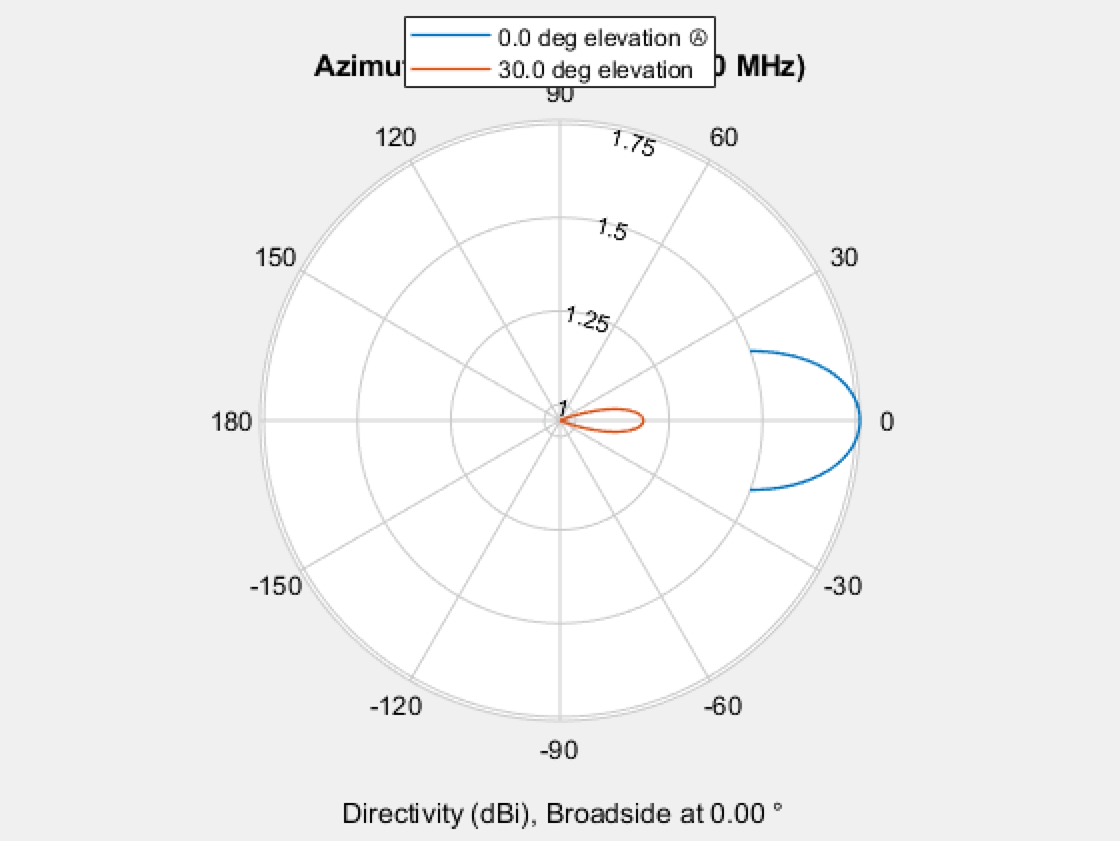
Plot the azimuth directivity pattern of a crossed-dipole antenna at two different elevations: 0˚ and30˚. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
patternAzimuth(antenna,fc,[0 30])
```



Plot a limited range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

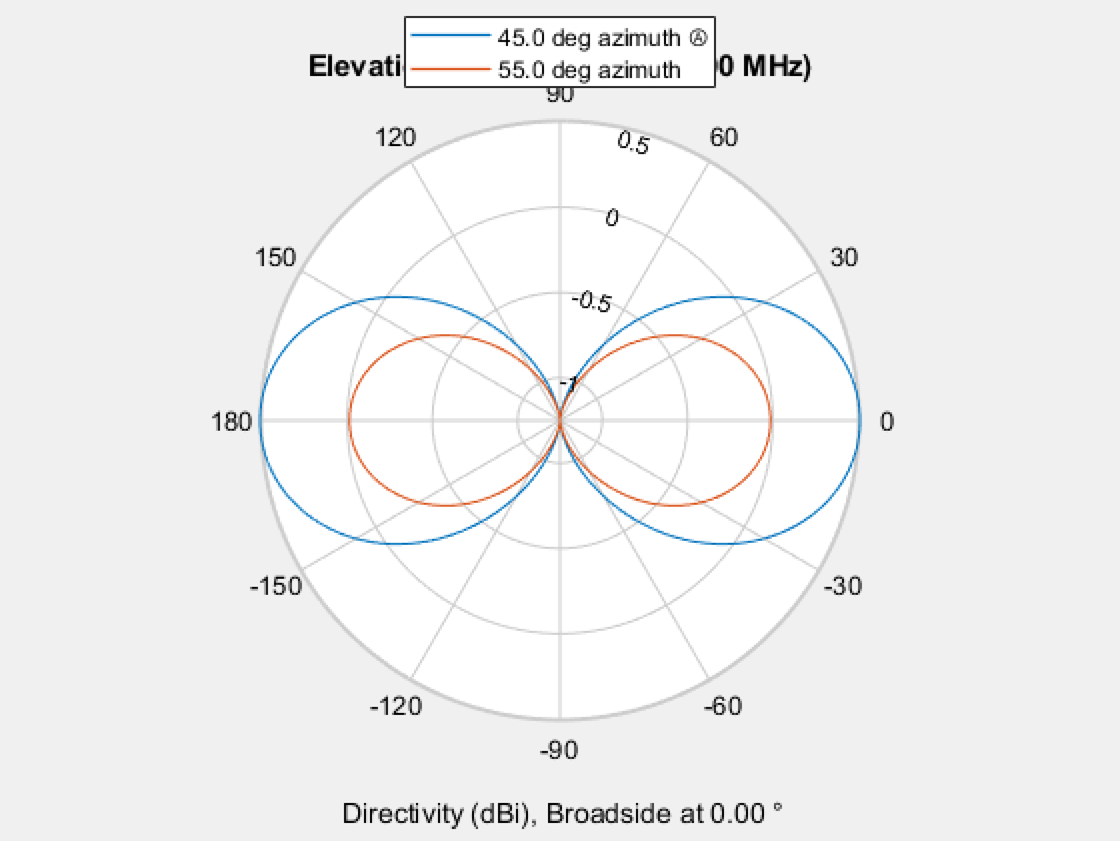
```
patternAzimuth(antenna,fc,[0 30],'Azimuth',[-20:20])
```



### Plot Elevation Pattern of Crossed-Dipole Antenna Element

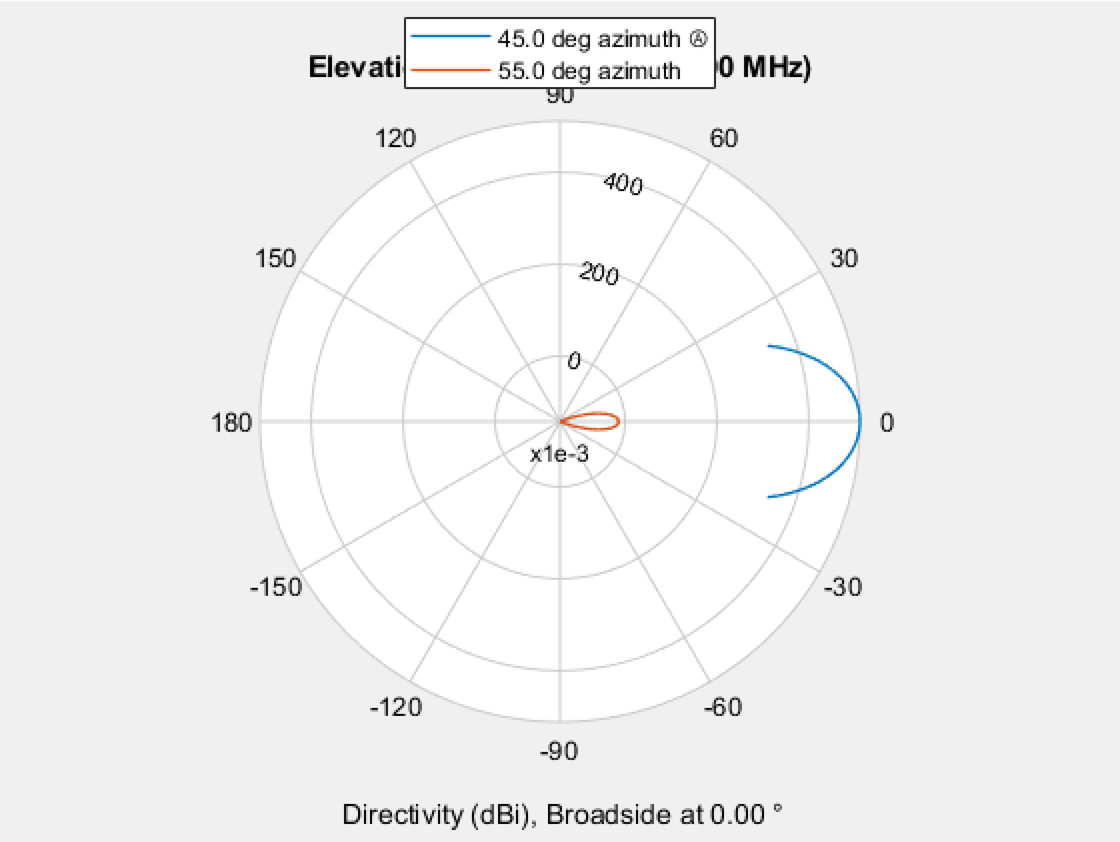
Plot the elevation directivity pattern of a crossed-dipole antenna at two different azimuths: 45° and 55°. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
patternElevation(sCD,fc,[45 55])
```



Plot a reduced range of elevation angles using the `Elevation` parameter. Notice the change in scale.

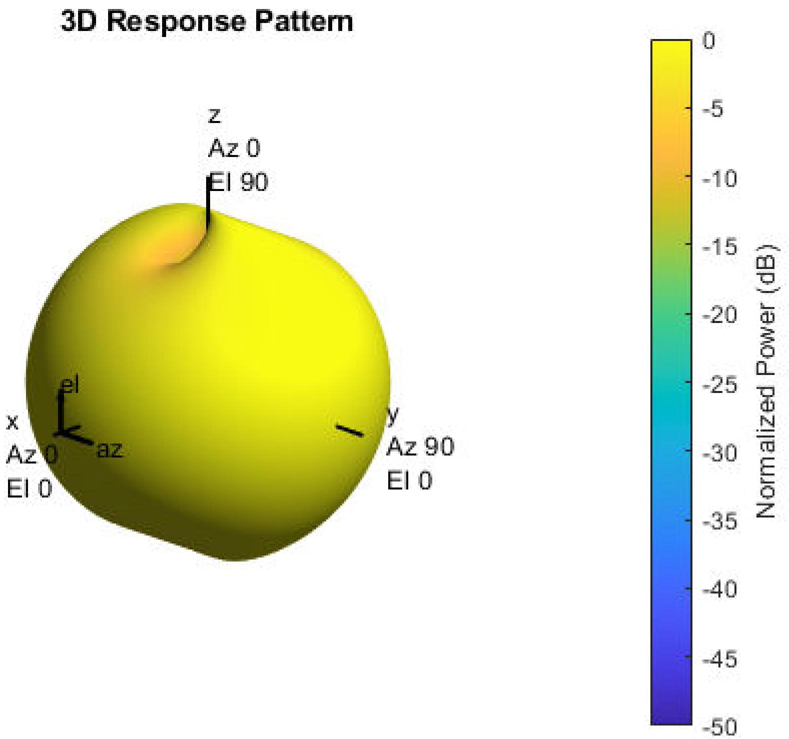
```
patternElevation(sCD,fc,[45 55],'Elevation',-20:20)
```



### Vertical and Horizontal Responses of Crossed-Dipole Antenna

This example shows how to create a crossed-dipole antenna operating between 100 and 900 MHz and then how to plot its vertical and horizontal polarization response at 250 MHz in the form of a 3-D polar plot.

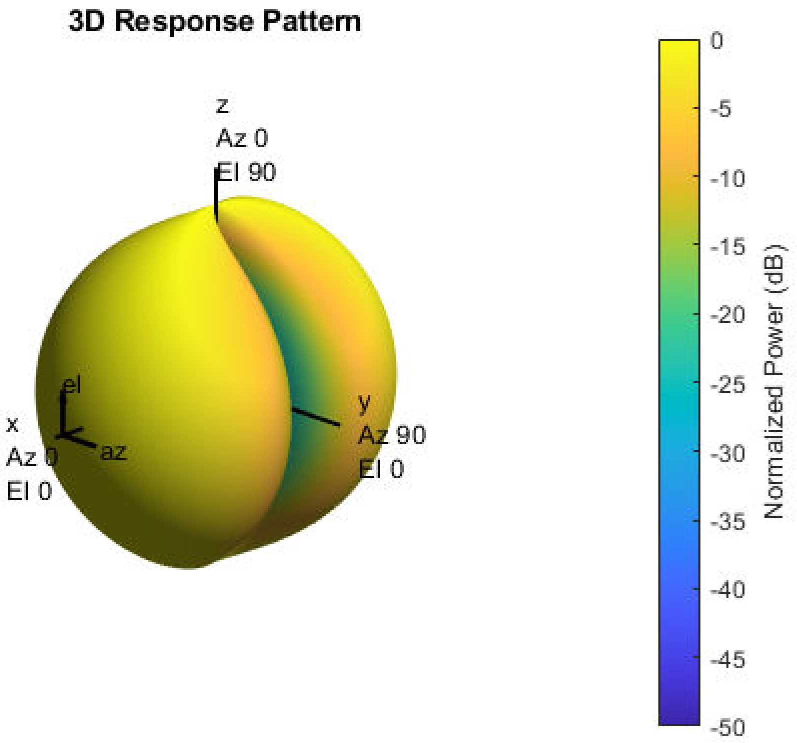
```
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6);
pattern(antenna,250e6,-180:180,-90:90,'CoordinateSystem','polar','Polarization','V', .
    'Type','powerdb')
```



The antenna pattern of the vertical-polarization component is almost isotropic and has a maximum at 0° elevation and 0° azimuth, as shown in the figure above.

Plot the antenna's horizontal polarization response. The pattern of the horizontal polarization response also has a maximum at 0° elevation and 0° azimuth but no response at ±90° azimuth.

```
pattern(antenna,250e6,-180:180,-90:90,'CoordinateSystem','polar','Polarization','H', .
    'Type','powerdb')
```



### Crossed-Dipole Antenna Supports Polarization

Show that the `phased.CrossedDipoleAntennaElement` antenna element supports polarization.

```
antenna = phased.CrossedDipoleAntennaElement;
isPolarizationCapable(antenna)
```

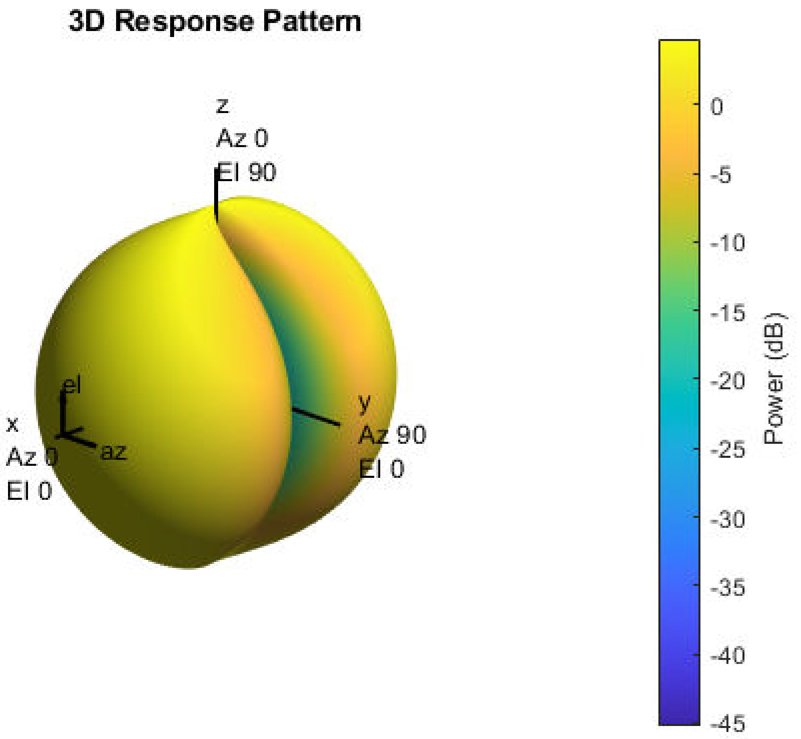
```
ans = logical
   1
```

The returned value of 1 shows that the crossed-dipole antenna element supports polarization.

### Plot 3-D Polar Patterns of Rotated Crossed-Dipole Antenna

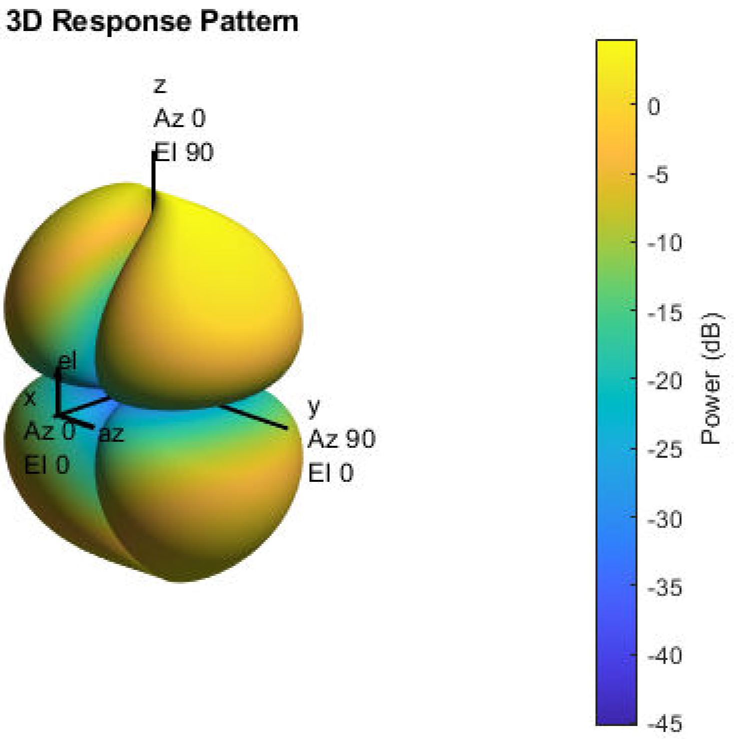
Construct a crossed-dipole antenna element designed to operate in the frequency range from 100 MHz to 1.5 GHz. Assume the polarization is linear. Rotate the antenna by -45 degrees. Plot the 3-D polar power pattern for the horizontal and vertical polarization components at 1 GHz.

```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[100 1500]*1e6, ...
   'RotationAngle',-45.0,'Polarization','Linear');
fc = 1e9;
pattern(antenna,fc,-180:180,-90:90,'Type','powerdb','Normalize',false, ...
    'CoordinateSystem','polar','Polarization','H')
```



Next, plot the vertical polarization component.

```
pattern(antenna,fc,-180:180,-90:90,'Type','powerdb','Normalize',false, ...
    'CoordinateSystem','polar','Polarization','V')
```



## Algorithms

The total response of a crossed-dipole antenna element is a combination of its frequency response and spatial response. `phased.CrossedDipoleAntennaElement` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

# phased.CustomAntennaElement

**Package:** `phased`

Custom antenna element

## Description

The `phased.CustomAntennaElement` object models an antenna element with a custom response pattern. The response pattern can be defined for polarized or non-polarized fields.

To compute the response of the antenna element for specified directions:

1. Define and set up your custom antenna element. See “Construction” on page 1-474.
2. Call `step` to compute the antenna response according to the properties of `phased.CustomAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.CustomAntennaElement` creates a system object, `H`, to model an antenna element with a custom response pattern. How the response pattern is specified depends upon whether polarization is desired or not. The default pattern has an isotropic spatial response.

- To create a nonpolarized response pattern, set the `SpecifyPolarizationPattern` property to `false` (default). Then, use the `MagnitudePattern` property to set the response pattern.
- To create a polarized response pattern, set the `SpecifyPolarizationPattern` property to `true`. Then, use any or all of the `HorizontalMagnitudePattern`,

HorizontalPhasePattern, VerticalMagnitudePattern, and VerticalPhasePattern properties to set the response pattern.

The output response of the step method depends on whether polarization is set or not.

H = phased.CustomAntennaElement(Name,Value) creates a custom antenna object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### FrequencyVector

Response and pattern frequency vector

Specify the frequencies (in Hz) at which the frequency response and antenna patterns are to be returned, as a 1-by-*L* row vector. The elements of the vector must be in increasing order. The antenna element has no response outside the frequency range specified by the minimum and maximum elements of the frequency vector.

**Default:** [0 1e20]

### AzimuthAngles

Azimuth angles

Specify the azimuth angles (in degrees) as a length-*P* vector. These values are the azimuth angles where the custom radiation pattern is to be specified. *P* must be greater than 2. The azimuth angles must lie between –180° and 180° and be in strictly increasing order.

**Default:** [-180:180]

### ElevationAngles

Elevation angles

Specify the elevation angles (in degrees) as a length-*Q* vector. These values are the elevation angles where the custom radiation pattern is to be specified. *Q* must be greater than 2. The elevation angles must lie between –90° and 90° and be in strictly increasing order.

**Default:** [-90:90]

**FrequencyResponse**

Frequency responses of antenna element

Specify the frequency responses in decibels measured at the frequencies defined in FrequencyVector property as a 1-by-*L* row vector. *L* equals the length of the vector specified in the FrequencyVector property.

**Default:** [0 0]

**SpecifyPolarizationPattern**

Polarized array response

- When the SpecifyPolarizationPattern property is set to false, the antenna element transmits or receives non-polarized radiation. In this case, use the MagnitudePattern property to set the antenna response pattern.
- When the SpecifyPolarizationPattern property is set to true, the antenna element transmits or receives polarized radiation. In this case, use the HorizontalMagnitudePattern and HorizontalPhasePattern properties to set the horizontal polarization response pattern and the VerticalMagnitudePattern and VerticalPhasePattern properties to set the vertical polarization response pattern.

**Default:** false

**MagnitudePattern**

Magnitude of combined antenna radiation pattern

The magnitude of the combined polarization antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the SpecifyPolarizationPattern property is set to false. Magnitude units are in dB.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the FrequencyVector property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the FrequencyVector property.

If the pattern contains a NaN at any azimuth and elevation direction, it is converted to -Inf, indicating zero response in that direction. The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern must contain azimuth angles in the range `[–180,180]` degrees. Set the range of elevation angles to `[–90,90]` degrees.

**Default:** A 181-by-361 matrix with all elements equal to 0 dB

### `PhasePattern`

Phase of combined antenna radiation pattern

The phase of the combined polarization antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `false`. Phase units are in degrees.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern must contain azimuth angles in the range *[–180°,180°]*. Set the range of elevation angles to *[–90°,90°]*.

**Default:** A 181-by-361 matrix with all elements equal to 0

### `HorizontalMagnitudePattern`

Magnitude of horizontal polarization component of antenna radiation pattern

The magnitude of the horizontal polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Magnitude units are in dB.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

If the magnitude pattern contains a `NaN` at any azimuth and elevation direction, it is converted to `-Inf`, indicating zero response in that direction. The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern must contain azimuth angles in the range `[–180,180]°` and elevation angles in the range `[–90,90]°`.

**Default:** A 181-by-361 matrix with all elements equal to 0 dB

### `HorizontalPhasePattern`

Phase of horizontal polarization component of antenna radiation pattern

The phase of the horizontal polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Phase units are in degrees.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern must contain azimuth angles in the range `[–180,180]°` and elevation angles in the range `[–90,90]°`.

**Default:** A 181-by-361 matrix with all elements equal to 0°

### `VerticalMagnitudePattern`

Magnitude of vertical polarization component of antenna radiation pattern

The magnitude of the vertical polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Magnitude units are in dB.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

If the pattern contains a `NaN` at any azimuth and elevation direction, it is converted to `-Inf`, indicating zero response in that direction. The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern must contain azimuth angles in the range`[–180,180]°` and elevation angles in the range `[–90,90]°`.

**Default:** A 181-by-361 matrix with all elements equal to 0 dB

### VerticalPhasePattern

Phase of vertical polarization component of antenna radiation pattern

The phase of the vertical polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Phase units are in degrees.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern must contain azimuth angles in the range `[–180,180]°` and elevation angles in the range `[–90,90]°`.

**Default:** A 181-by-361 matrix with all elements equal to 0°

### MatchArrayNormal

Match element normal to array normal

Set this property to `true` to align the antenna element to an array normal. The antenna pattern is rotated so that the *x*-axis of the element coordinate system points along the array normal. This property is used only when the antenna element belongs to an array. Use the property in conjunction with the `ArrayNormal` property of the `phased.URA` and `phased.UCA` System objects. Set this property to `false` to use the element pattern without rotation. The default value is `true`.

## Methods

| | |
|---|---|
| directivity | Directivity of custom antenna element |
| isPolarizationCapable | Polarization capability |
| pattern | Plot custom antenna element directivity and patterns |
| patternAzimuth | Plot custom antenna element directivity or pattern versus azimuth |
| patternElevation | Plot custom antenna element directivity or pattern versus elevation |
| plotResponse | Plot response pattern of antenna |
| step | Output response of antenna element |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Response and Directivity of Custom Antenna

Create a user-defined antenna with a cosine pattern. Then, plot an elevation cut of the antenna's power response.

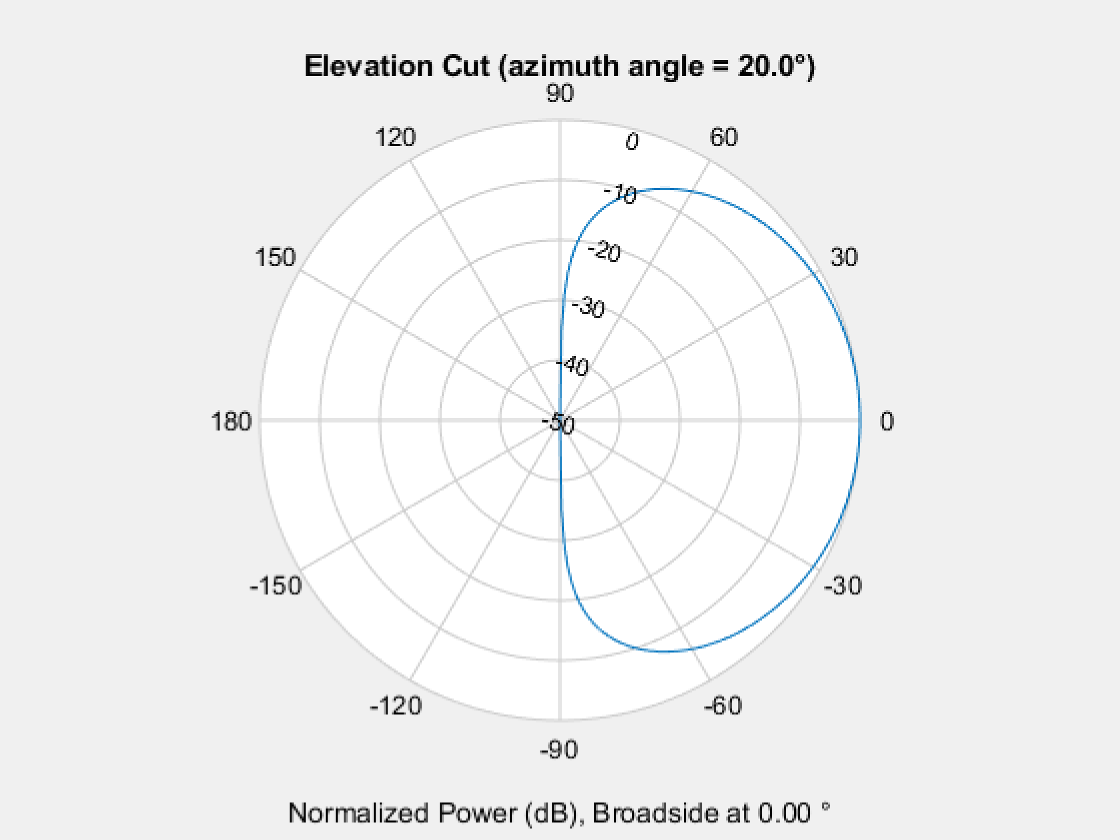
The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at 1 GHz. Obtain the response at 20° azimuth and 30° elevation.

```
fc = 1e9;
azang = -180:180;
elang = -90:90;
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
resp = antenna(fc,[20;30])
```

```
resp = 0.8660
```

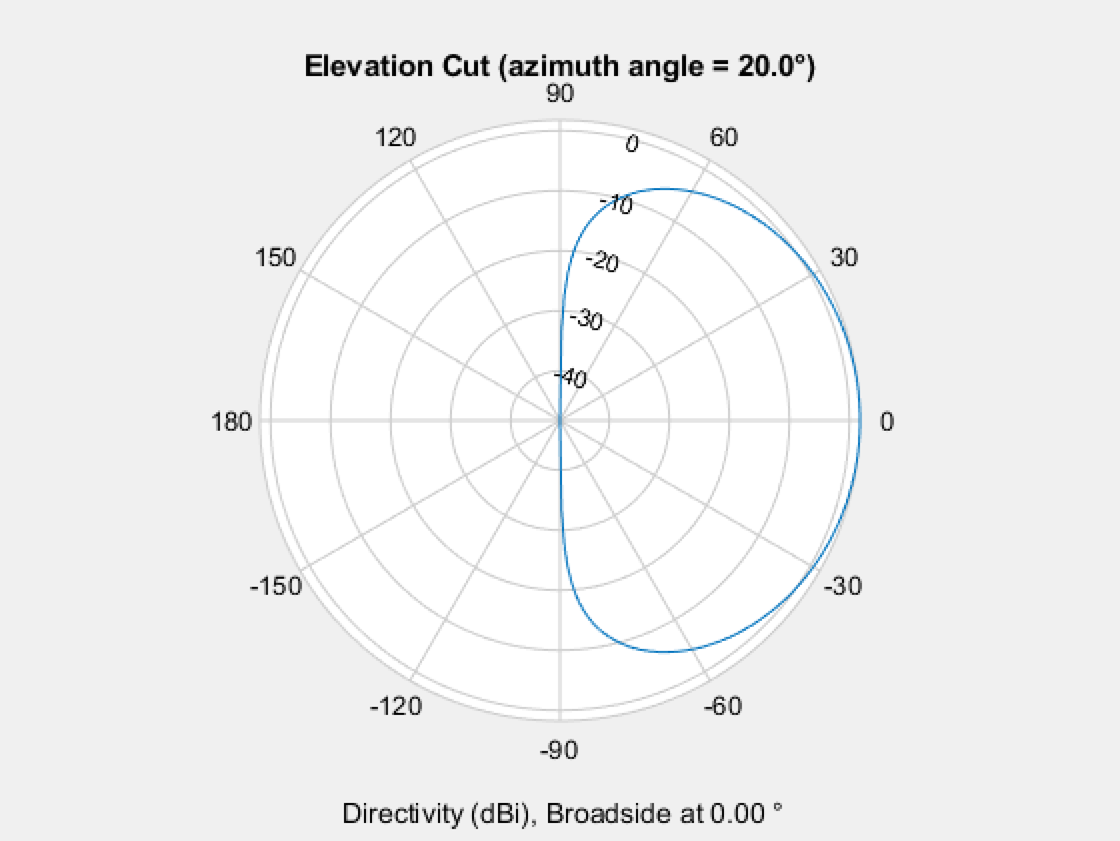
Plot an elevation cut of the power response.

```
pattern(antenna,fc,20,-90:90,'CoordinateSystem','polar','Type','powerdb')
```



Plot an elevation cut of the directivity.

```
pattern(antenna,fc,20,-90:90,'CoordinateSystem','polar','Type','directivity')
```



### Antenna Radiation Pattern in U-V Coordinates

Define a custom antenna in *u*-*v* space. Then, calculate and plot the response.

Define the radiation pattern (in dB) of an antenna in terms of *u* and *v* coordinates within the unit circle.

```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Create an antenna with this radiation pattern. Convert *u*-*v* coordinates to azimuth and elevation coordinates.

```
[pat_azel,az,el] = uv2azelpat(pat_uv,u,v);
array = phased.CustomAntennaElement('AzimuthAngles',az,'ElevationAngles',el, ...
    'MagnitudePattern',mag2db(pat_azel),'PhasePattern',45*ones(size(pat_azel)));
```

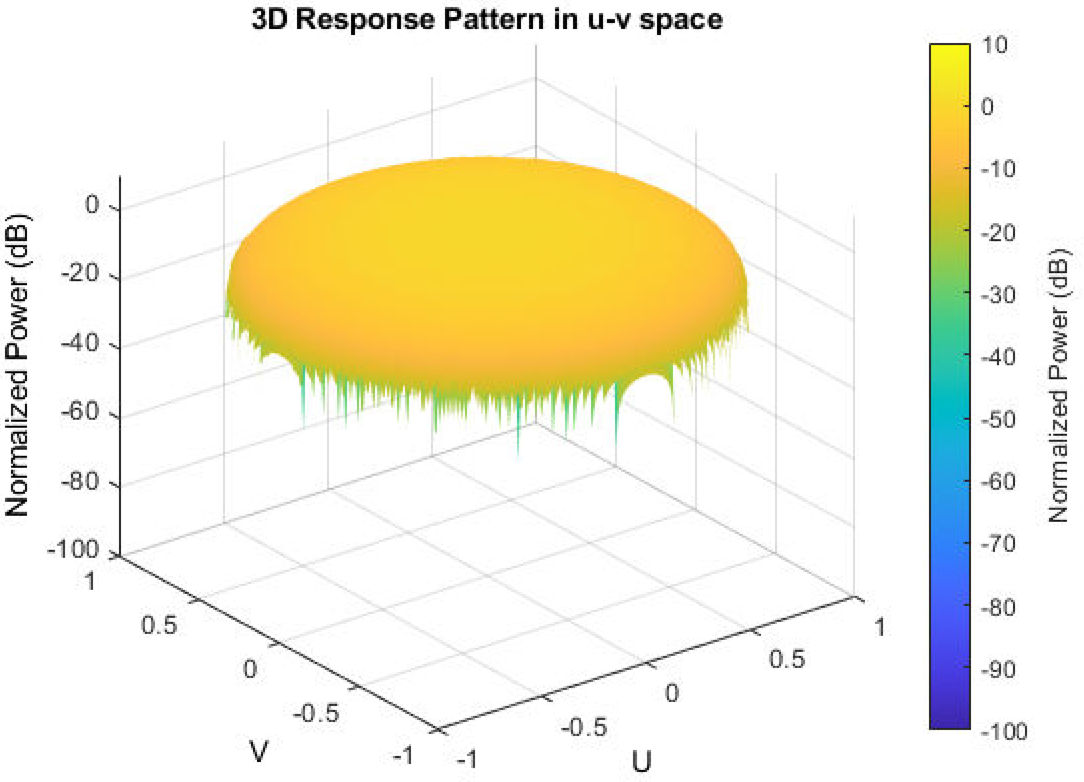
Calculate the response in the direction $u = 0.5, v = 0$. Assume the antenna operates at 1 GHz. The output of the step method is in linear units.

```
dir_uv = [0.5;0];
dir_azel = uv2azel(dir_uv);
fc = 1e9;
resp = array(fc,dir_azel)
```

```
resp = 0.6124 + 0.6124i
```

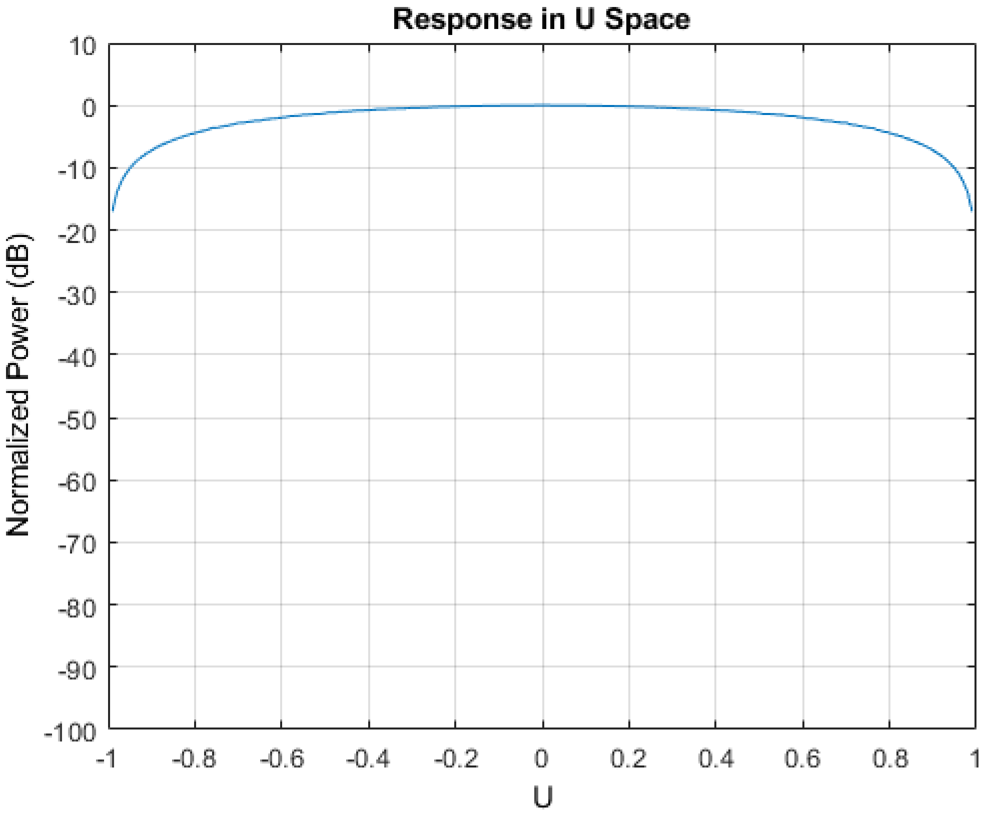
Plot the 3D response in *u*-*v* coordinates.

```
pattern(array,fc,[-1:.01:1],[-1:.01:1],'CoordinateSystem','uv','Type','powerdb')
```



Display the antenna response as a line plot in *u*-*v* coordinates.

```
pattern(array,fc,[-1:.01:1],0,'CoordinateSystem','uv','Type','powerdb')
```



### Polarized Antenna Radiation Patterns

Model a short dipole antenna oriented along the *x*-axis of the local antenna coordinate system. For this type of antenna, the horizontal and vertical components of the electric field are given by $E_H = \frac{j\omega\mu IL}{4\pi r}\sin(\text{az})$ and $E_V = -\frac{j\omega\mu IL}{4\pi r}\sin(\text{el})\cos(\text{az})$.

Specify a normalized radiation pattern of a short dipole antenna terms of azimuth, *az*, and elevation, *el*, coordinates. The vertical and horizontal radiation patterns are normalized to a maximum of unity.

```
az = [-180:180];
el = [-90:90];
[az_grid,el_grid] = meshgrid(az,el);
horz_pat_azel = ...
    mag2db(abs(sind(az_grid)));
vert_pat_azel = ...
    mag2db(abs(sind(el_grid).*cosd(az_grid)));
```

Set up the antenna. Specify the SpecifyPolarizationPattern property to produce polarized radiation. In addition, use the HorizontalMagnitudePattern and VerticalMagnitudePattern properties to specify the pattern magnitude values. The HorizontalPhasePattern and VerticalPhasePattern properties take default values of zero.

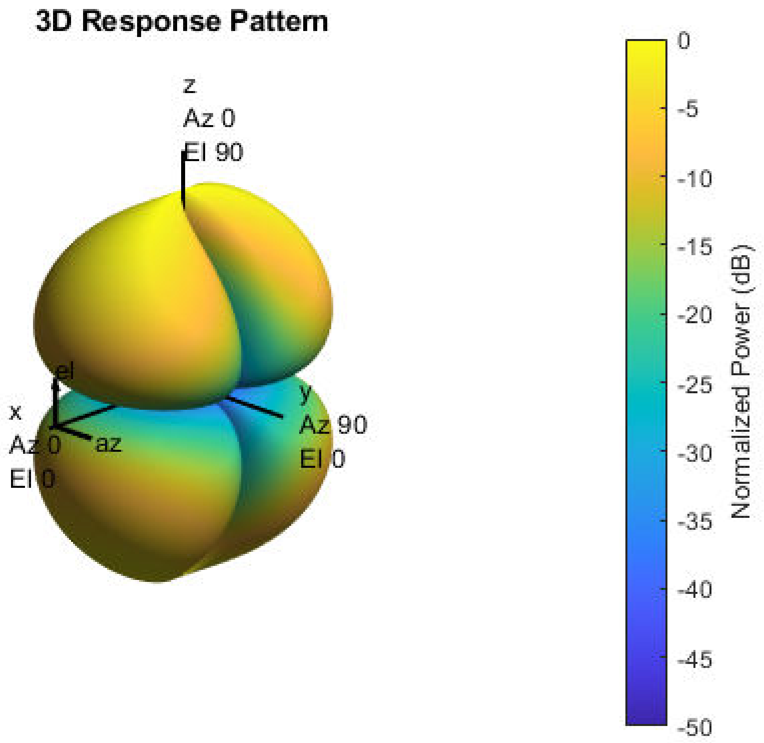
```
sCust = phased.CustomAntennaElement(...
    'AzimuthAngles',az,'ElevationAngles',el,...
    'SpecifyPolarizationPattern',true,...
    'HorizontalMagnitudePattern',horz_pat_azel,...
    'VerticalMagnitudePattern',vert_pat_azel);
```

Assume the antenna operates at 1 GHz.

```
fc = 1e9;
```

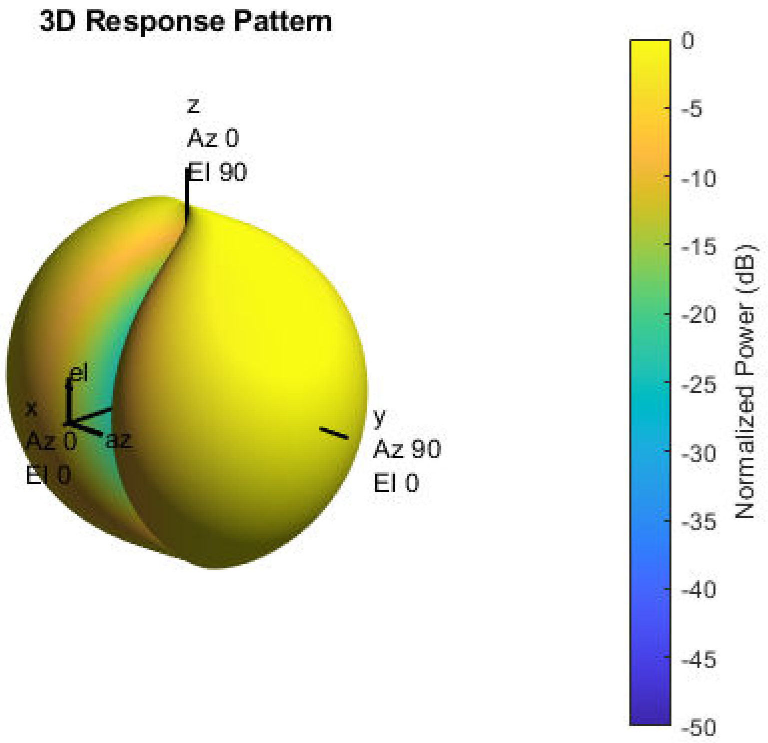
Display the vertical response pattern.

```
pattern(sCust,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','V')
```



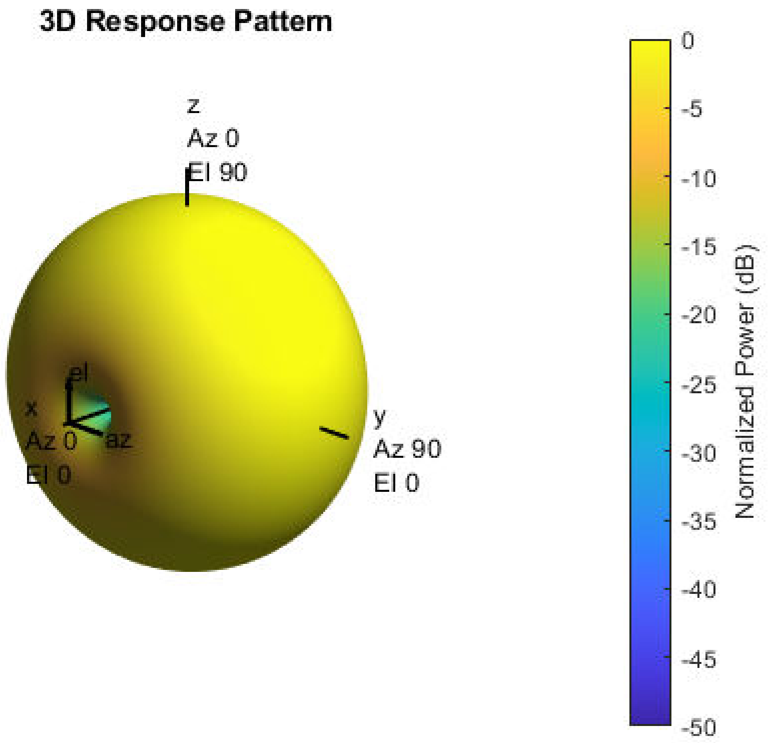
Display the horizontal response pattern.

```
pattern(sCust,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','H')
```



The combined polarization response, shown below, illustrates the *x*-axis null of the dipole.

```
pattern(sCust,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



### Match Custom Antenna Normal to Array Normal

Define a custom antenna in *u*-*v* space. Show how the array response pattern is affected by the choice of the `MatchArrayNormal` property of the `phased.CustomAntennaElement`.

Define the response pattern (in dB) of an antenna as a function of *u* and *v* coordinates within the unit circle. The antenna operates at 1 GHz.

```
fc = 1e9;
c = physconst('LightSpeed');
```

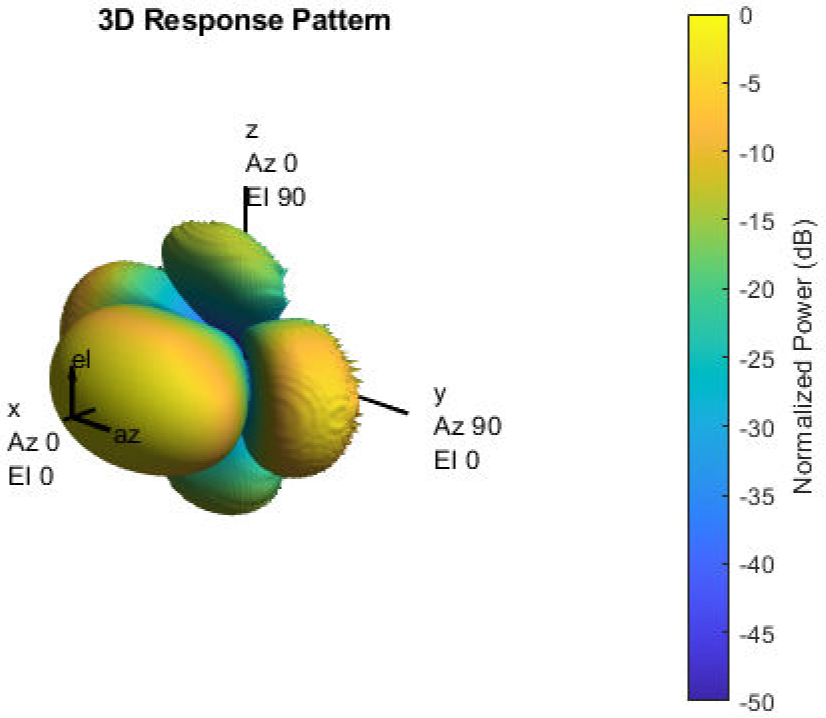
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Create a custom antenna with this pattern. Convert *u*-*v* coordinates to azimuth and elevation coordinates. Set `MatchArrayNormal` to `false`.

```
[pat_azel,az,el] = uv2azelpat(pat_uv,u,v);
element = phased.CustomAntennaElement('AzimuthAngles',az,'ElevationAngles',el, ...
    'MagnitudePattern',mag2db(pat_azel),'PhasePattern',45*ones(size(pat_azel)), ...
    "MatchArrayNormal",false);
```

Construct a 3-by-3 URA with this element and display the antenna pattern in 3-D polar coordinates. The element spacing is one-half wavelength. The array normal points along the *y*-axis.

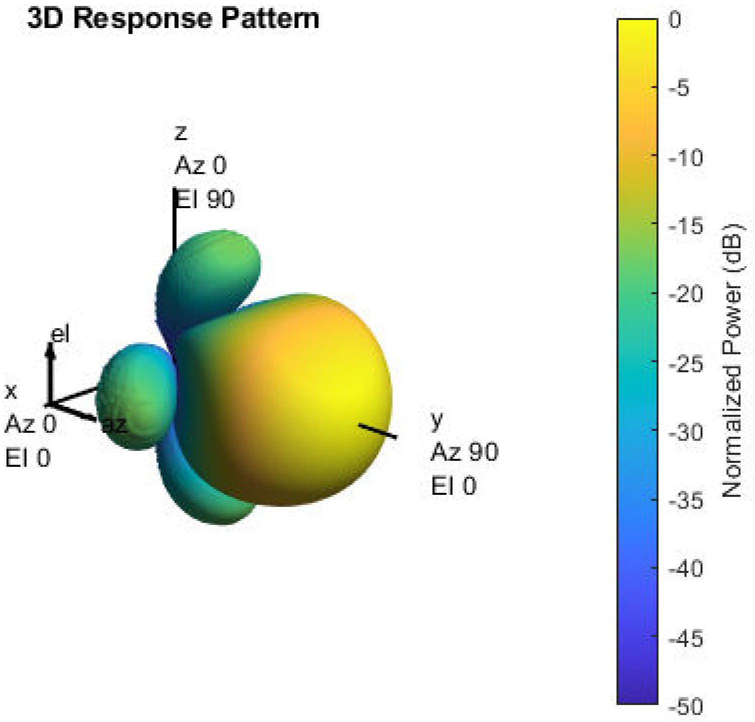
```
lam = c/fc;
array = phased.URA('Element',element,'Size',[3 3],'ElementSpacing', ...
    [lam/2 lam/2],'ArrayNormal','y');
pattern(array,fc,-180:180,-90:90,'PropagationSpeed',c, ...
    'CoordinateSystem','polar','Type','powerdb','Normalize',true)
```



The pattern shows the interplay between the element pattern pointing along the *x*-axis and the array pattern pointing along the *y*-axis.

Create another custom antenna with the same radiation pattern. Set `MatchArrayNormal` to true. Then create another array with this element.

```
element2 = phased.CustomAntennaElement('AzimuthAngles',az,'ElevationAngles',el, ...
    'MagnitudePattern',mag2db(pat_azel),'PhasePattern',45*ones(size(pat_azel)), ...
    "MatchArrayNormal",true);
array2 = phased.URA('Element',element2,'Size',[3 3],'ElementSpacing', ...
    [lam/2 lam/2],'ArrayNormal','y');
pattern(array2,fc,-180:180,-90:90,'PropagationSpeed',c, ...
    'CoordinateSystem','polar','Type','powerdb','Normalize',true)
```



This pattern shows the aligned element and array patterns pointing along the *y*-axis.

## Algorithms

The total response of a custom antenna element is a combination of its frequency response and spatial response. `phased.CustomAntennaElement` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

# Extended Capabilities

**Introduced in R2011a**

# directivity

**System object:** `phased.CustomAntennaElement`
**Package:** `phased`

Directivity of custom antenna element

## Syntax

```
D = directivity(H,FREQ,ANGLE)
```

## Description

`D = directivity(H,FREQ,ANGLE)` returns the “Directivity” on page 1-497 of a custom antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

## Input Arguments

### H — Custom antenna element

System object

Custom antenna element specified as a `phased.CustomAntennaElement` System object.

Example: `H = phased.CustomAntennaElement;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

### `D` — Directivity

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Custom Antenna

Compute the directivity of a custom antenna element.

Define an antenna pattern for a custom antenna element in azimuth-elevation space. The pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at 1 GHz. Get the response at zero degrees azimuth and from -30 to 30 degrees elevation.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

Calculate the directivities as a function of elevation for 0° azimuth angle.

```
angs = [0,0,0,0,0,0,0;-30,-20,-10,0,10,20,30];
freq = 1e9;
d = directivity(antenna,freq,angs)
```

```
d = 7×1

    0.5115
    1.2206
    1.6279
    1.7609
    1.6279
    1.2206
    0.5115
```

The directivity is maximum at 0˚ elevation.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** phased.CustomAntennaElement
**Package:** phased

Polarization capability

## Syntax

```
flag = isPolarizationCapable(antenna)
```

## Description

flag = isPolarizationCapable(antenna) returns a Boolean value, flag, indicating whether the phased.CustomAntennaElement System object supports polarization. An antenna element supports polarization if it can create or respond to polarized fields. This antenna object supports both polarized and nonpolarized fields.

## Input Arguments

### antenna — Custom antenna element

phased.CustomAntennaElement System object

Custom antenna element, specified as a phased.CustomAntennaElement System object.

## Output Arguments

### flag — Polarization-capability flag

Polarization-capability returned as a Boolean value true if the antenna element supports polarization or false if it does not. The returned value depends upon the value of the SpecifyPolarizationPattern property. If SpecifyPolarizationPattern is true, then flag is true. Otherwise it is false.

# Examples

### Custom Antenna Element Supports Polarization

Show that the `CustomAntennaElement` antenna element supports polarization when the `SpecifyPolarizationPattern` property is set to `true`.

```
antenna = phased.CustomAntennaElement('SpecifyPolarizationPattern',true);
isPolarizationCapable(antenna)
```

```
ans = logical
   1
```

The returned value `1` shows that this antenna element supports polarization.

# pattern

**System object:** `phased.CustomAntennaElement`
**Package:** `phased`

Plot custom antenna element directivity and patterns

## Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-509 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sElem` — Custom antenna element

System object

Custom antenna element, specified as a `phased.CustomAntennaElement` System object.

Example: `sElem = phased.CustomAntennaElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

**Type — Displayed pattern type**
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

**`Normalize` — Display normalize pattern**
`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize`' and a Boolean. Set this parameter to `true` to display a normalized pattern. This parameter does not apply when you set `'Type'` to `'directivity'`. Directivity patterns are already normalized.

Data Types: `logical`

**`PlotStyle` — Plotting style**
`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Data Types: `char`

**`Polarization` — Polarized field component**
`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

## Output Arguments

### `PAT` — Element pattern

*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of `PAT` correspond to the azimuth angles in the vector specified by `EL_ANG`. The columns correspond to the elevation angles in the vector specified by `AZ_ANG`.

### `AZ_ANG` — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

### `EL_ANG` — Elevation angles

scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Power and Directivity Patterns of Custom Antenna

Create a custom antenna with a cosine pattern. Show the response at boresight. Then, plot the antenna's field and directivity patterns.

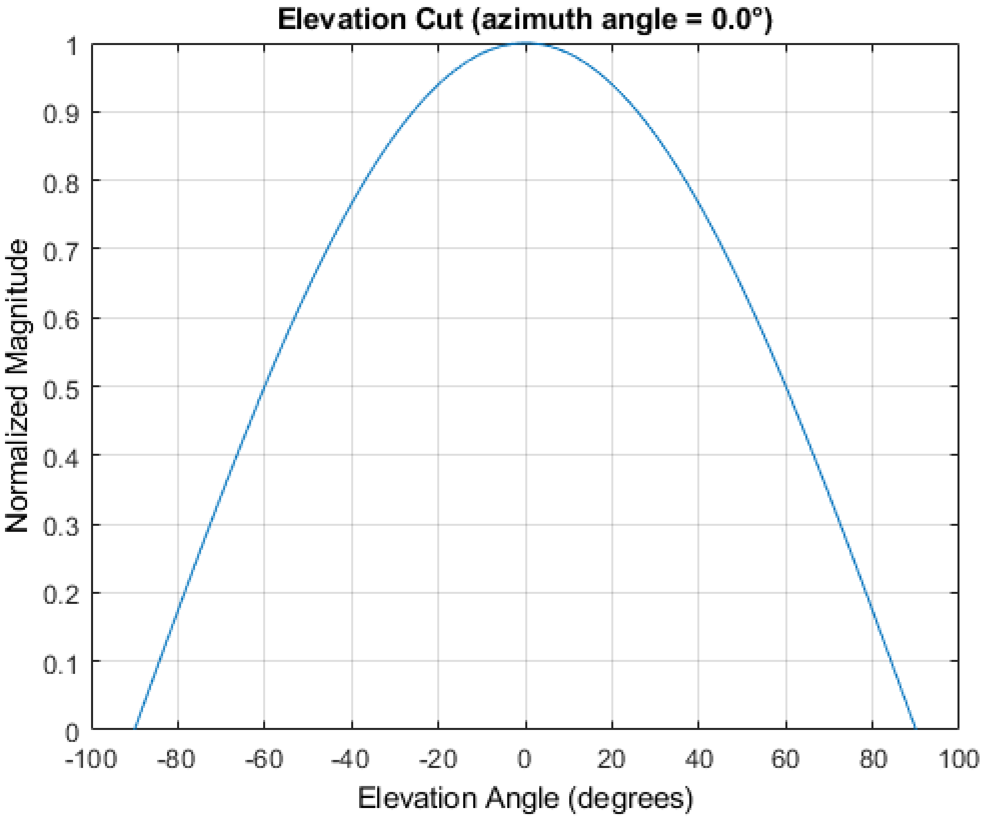
Create the antenna and calculate the response. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna works at 1 GHz.

```
fc = 1e9;
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(repmat(cosd(antenna.ElevationAngles)', ...
    1,numel(antenna.AzimuthAngles)));
resp = antenna(fc,[0;0])
```

```
resp = 1
```

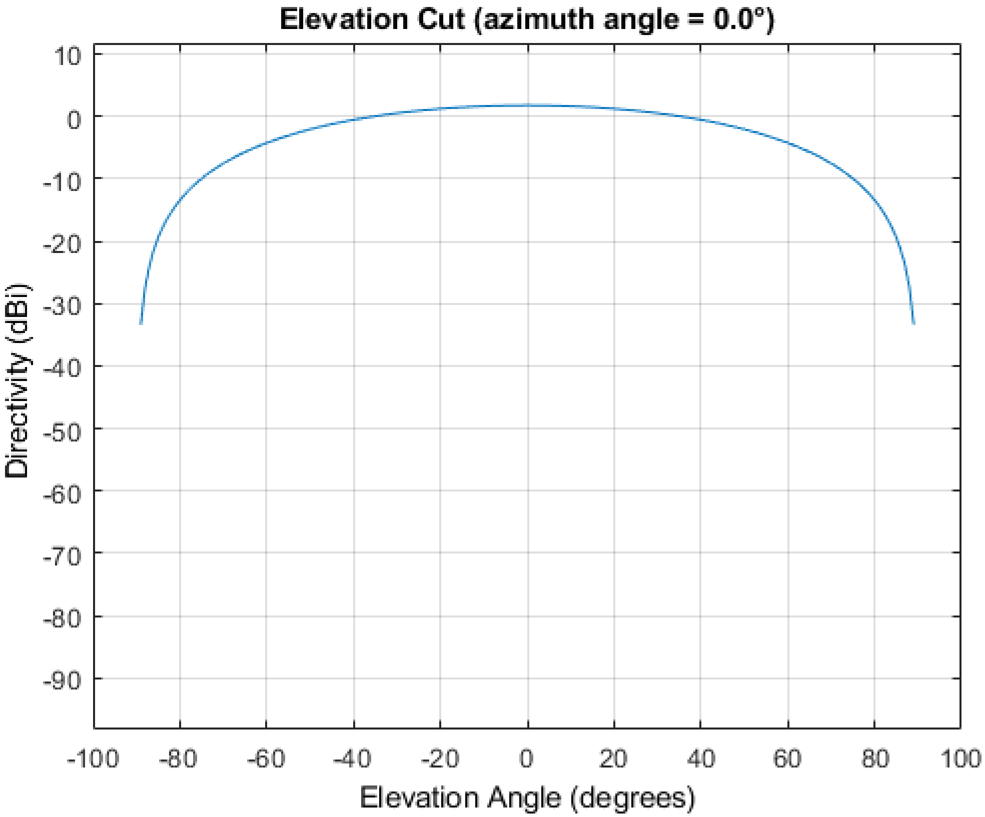
Plot an elevation cut of the magnitude response as a line plot.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','rectangular', ...
    'Type','efield')
```



Plot an elevation cut of the directivity as a line plot, showing that the maximum directivity is approximately 2 dB.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','rectangular', ...
    'Type','directivity')
```



### Pattern of Custom Antenna Over Selected Range of Angles

Create an custom antenna System object. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 1 GHz. First show the response at boresight. Display the 3-D pattern for a 60 degree range of azimuth and elevation angles centered at 0 degrees azimuth and 0 degrees elevation in 0.1 degree increments.

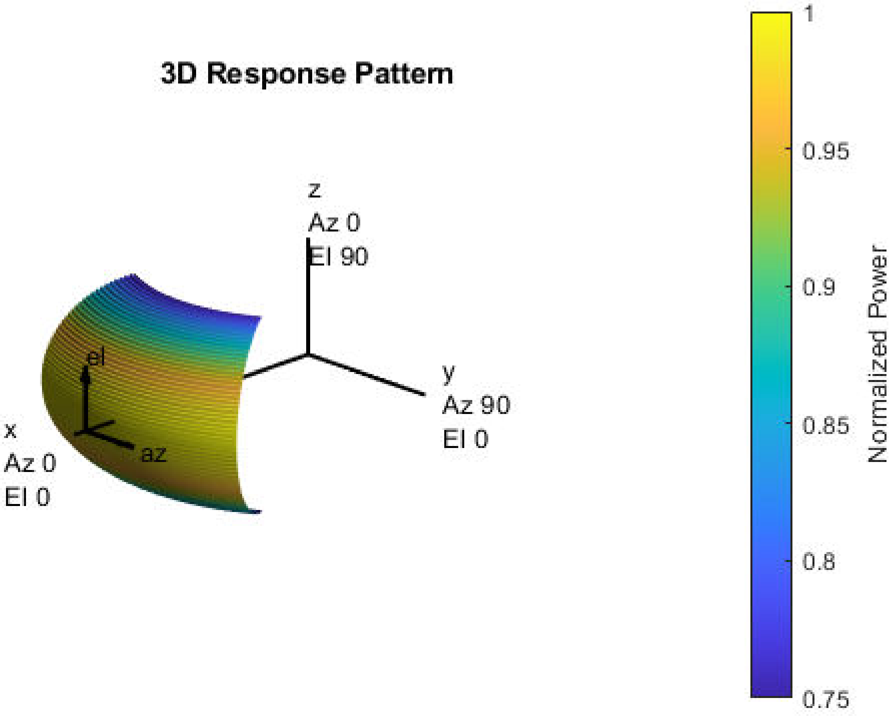
```
fc = 1e9;
azang = -180:180;
elang = -90:90;
```

```
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern);
resp = antenna(fc,[0;0])
```

```
resp = 1
```

Plot the power pattern for a range of angles.

```
pattern(antenna,fc,[-30:0.1:30],[-30:0.1:30],'CoordinateSystem','polar', ...
    'Type','power')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.CustomAntennaElement
**Package:** phased

Plot custom antenna element directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

patternAzimuth(sElem,FREQ) plots the 2-D element directivity pattern versus azimuth (in dBi) for the element sElem at zero degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(sElem,FREQ,EL), in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(sElem,FREQ,EL,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

### sElem — Custom antenna element

System object

Custom antenna element, specified as a `phased.CustomAntennaElement` System object.

Example: `sElem = phased.CustomAntennaElement;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Azimuth — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

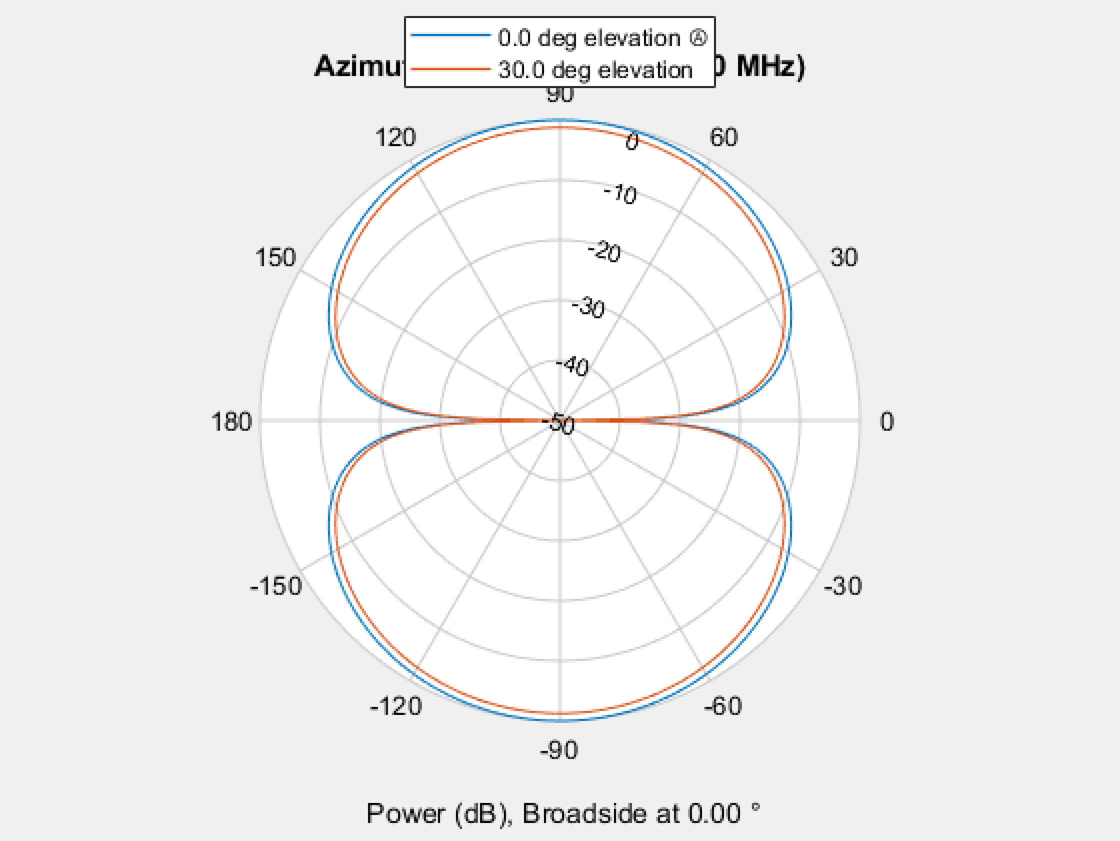
## Examples

### Reduced Azimuth Pattern of Custom Antenna Element

Create an antenna with a custom response. The user-defined pattern has a sine pattern in the azimuth direction and a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 500 MHz. Plot an azimuth cut of the power pattern of the custom antenna element at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

Create the antenna element.

```
fc = 500e6;
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(abs(cosd(antenna.ElevationAngles)'*sind(antenna.Azimu
patternAzimuth(antenna,fc,[0 30],'Type','powerdb')
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(antenna,fc,[0 30],'Azimuth',[-45:45],'Type','powerdb')
```

# patternElevation

**System object:** `phased.CustomAntennaElement`
**Package:** `phased`

Plot custom antenna element directivity or pattern versus elevation

## Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

**`sElem` — Custom antenna element**
System object

Custom antenna element, specified as a `phased.CustomAntennaElement` System object.

Example: `sElem = phased.CustomAntennaElement;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

**AZ — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

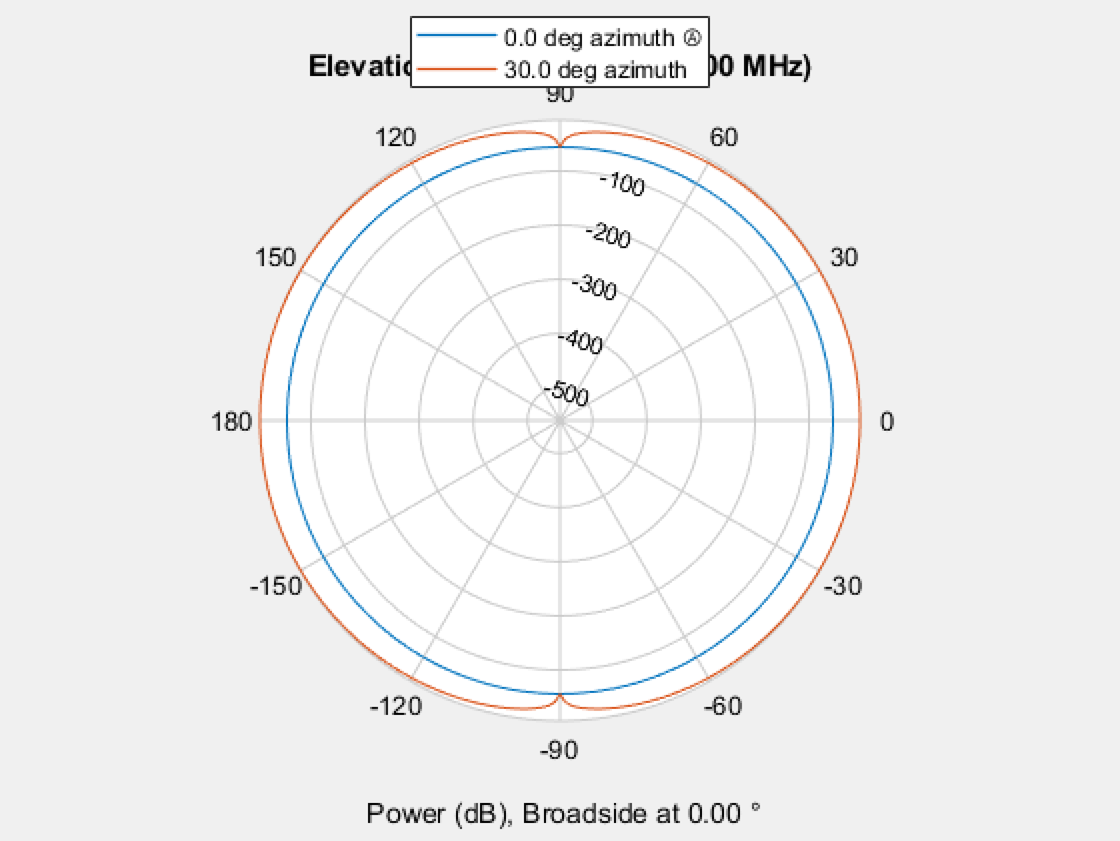
# Examples

### Reduced Elevation Pattern of Custom Antenna Element

Create an antenna with a custom response. The user-defined pattern has a sine pattern in the azimuth direction and a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 500 MHz. Plot an elevation cut of the power of the custom antenna element at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

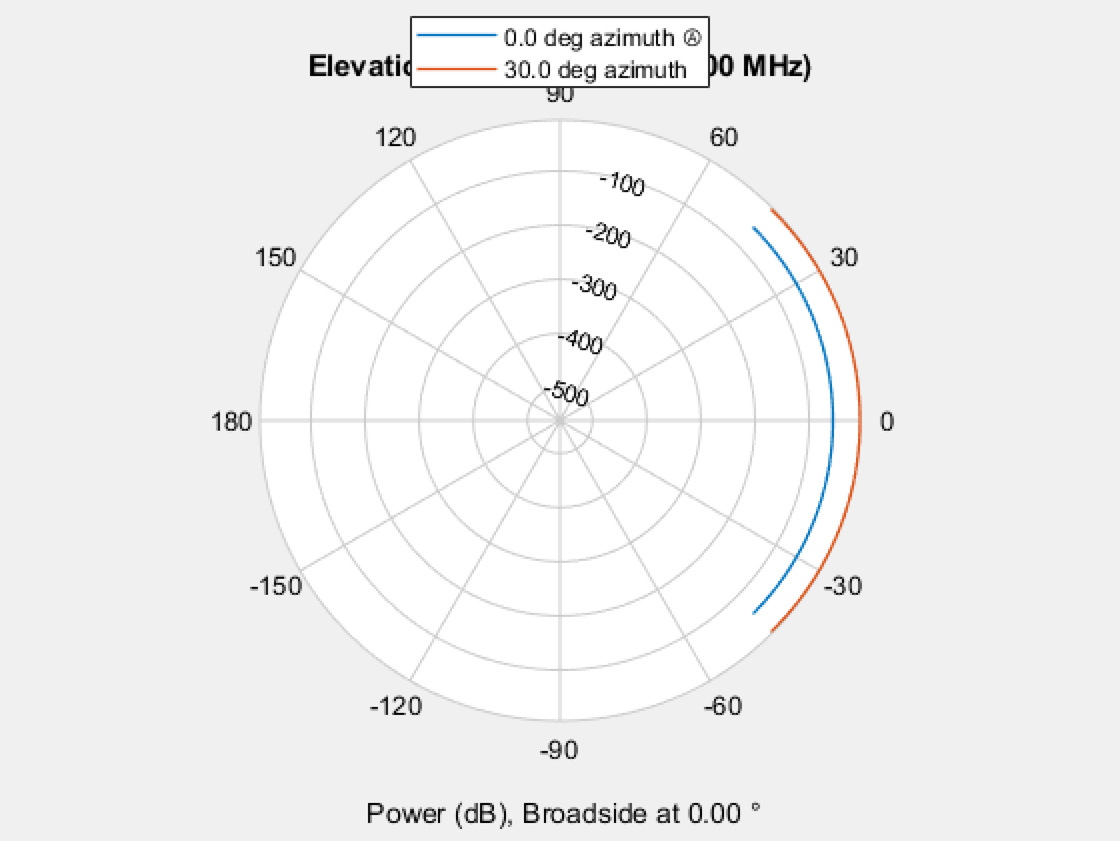
Create the antenna element.

```
fc = 500e6;
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(abs(cosd(antenna.ElevationAngles)'*sind(antenna.Azimu
patternElevation(antenna,fc,[0 30],'Type','powerdb')
```



Plot a reduced range of elevation angles using the `Azimuth` parameter.

```
patternElevation(antenna,fc,[0 30],'Elevation',[-45:45],'Type','powerdb')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2015a**

# plotResponse

**System object:** `phased.CustomAntennaElement`
**Package:** `phased`

Plot response pattern of antenna

## Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

### H

Element System object

### FREQ

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CutAngle`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

### `Format`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

### `NormalizeResponse`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### `OverlayFreq`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the antenna response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| db | power pattern in dB scale |
| mag | field pattern |
| pow | power pattern |
| dbi | directivity |

**Default:** 'db'

**AzimuthAngles**

Azimuth angles for plotting element response, specified as a row vector. The AzimuthAngles parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'Az' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the AzimuthAngles and ElevationAngles parameters simultaneously.

**Default:** [-180:180]

**ElevationAngles**

Elevation angles for plotting element response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

**UGrid**

*U* coordinate values for plotting element response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

**VGrid**

*V* coordinate values for plotting element response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid

should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

## Examples

### Plot Response and Directivity of Custom Antenna

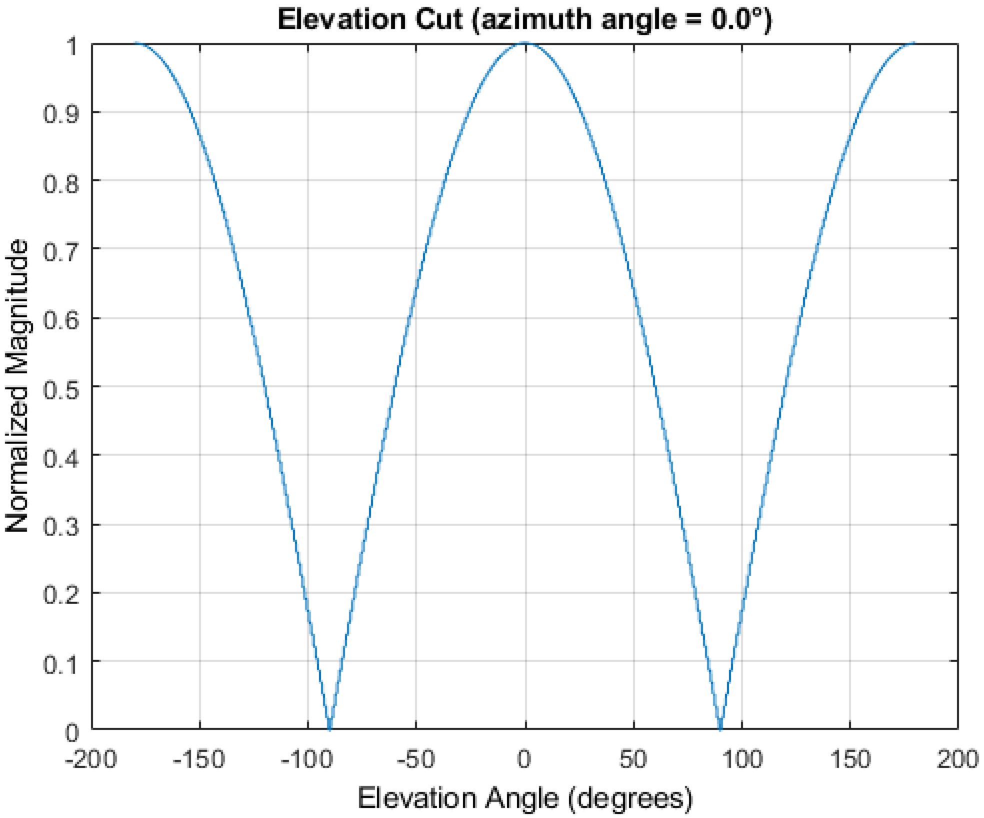
Create a custom antenna with a cosine pattern. Then, plot the antenna's response.

Create the antenna and calculate the response. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna works at 1 GHz.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

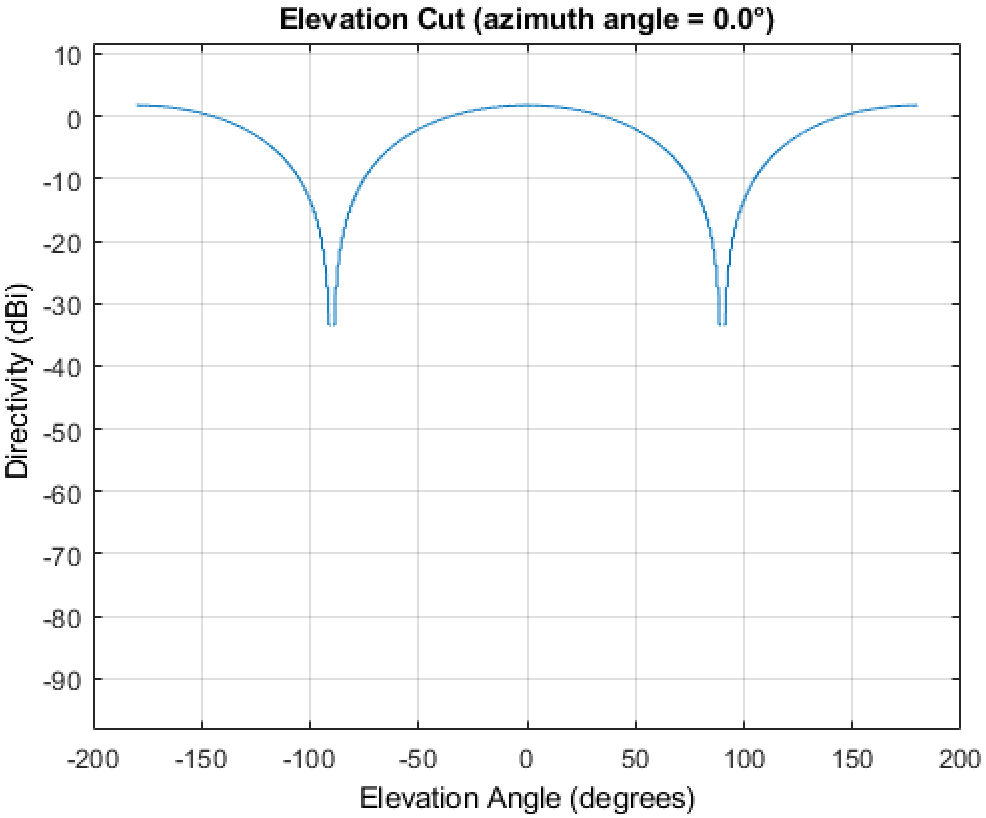
Plot an elevation cut of the magnitude response as a line plot.

```
plotResponse(antenna,fc,'RespCut','El','ElevationAngles',[-90:0.1:90],...
    'Format','Line','Unit','mag')
```



Plot an elevation cut of the directivity as a line plot, showing that the maximum directivity is approximately 2 dB.

```
plotResponse(antenna,fc,'RespCut','El','ElevationAngles',[-90:0.1:90],...
    'Format','Line','Unit','dbi')
```

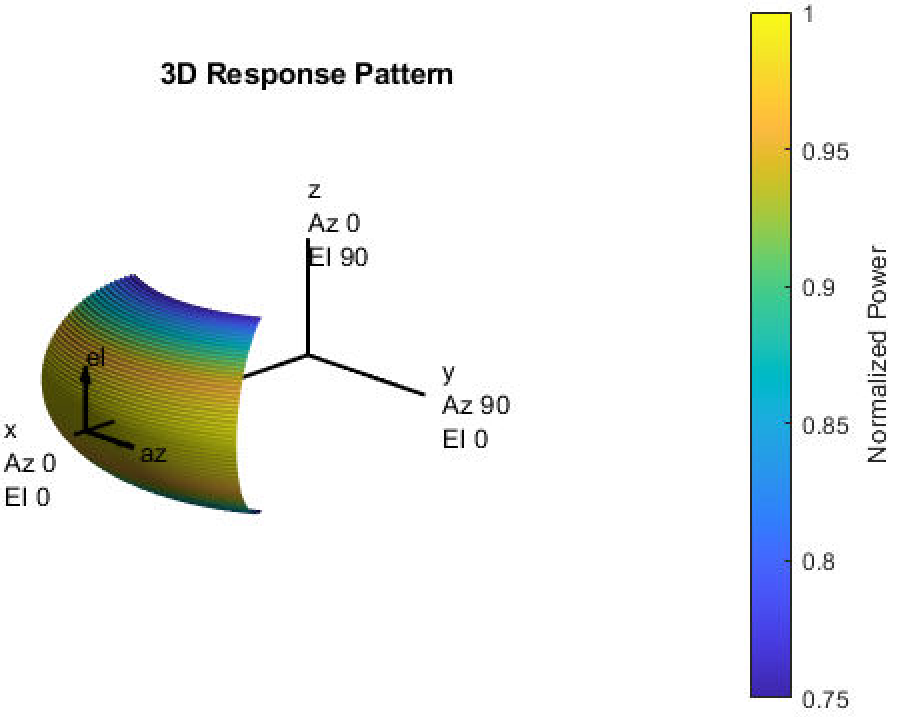


### Plot Response of Custom Antenna Over Selected Range of Angles

Create an antenna with a custom response. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 1 GHz. Display the 3-D response for a 60 degree range of azimuth and elevation angles centered at 0 degrees azimuth and 0 degrees elevation in 0.1 degree increments.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
```

```
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
resp = antenna(fc,[0;0]);
plotResponse(antenna,fc,'RespCut','3D','AzimuthAngles',[-30:0.1:30],...
    'ElevationAngles',[-30:0.1:30],'Format','Polar','Unit','pow')
```



## See Also

# step

**System object:** `phased.CustomAntennaElement`
**Package:** `phased`

Output response of antenna element

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna’s voltage response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`. The form of `RESP` depends upon whether the antenna element supports polarization as determined by the `SpecifyPolarizationPattern` property. If `SpecifyPolarizationPattern` is set to `false`, `RESP` is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`. If `SpecifyPolarizationPattern` is set to `true`, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`, representing the antenna's response in horizontal and vertical polarization, respectively. Each field is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# Input Arguments

**H**

Antenna element object.

**FREQ**

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

**ANG**

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

# Output Arguments

**RESP**

Voltage response of antenna element. The output depends on whether the antenna element supports polarization or not.

- If the antenna element does not support polarization, RESP is an *M*-by-*L* matrix. In this matrix, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.
- If the antenna element supports polarization, RESP is a MATLAB `struct` with fields RESP.H and RESP.V containing responses for the horizontal and vertical polarization components of the antenna radiation pattern. RESP.H and RESP.V are *M*-by-*L* matrices. In these matrices, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.

## Examples

### Custom Antenna Element Response at 30° Elevation

Construct a user-defined antenna with an omnidirectional response in azimuth and a cosine pattern in elevation. The antenna operates at 1 GHz. Plot the response pattern. Then, find the antenna response at 30°.

```
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(repmat(cosd(antenna.ElevationAngles)',...
    1,numel(antenna.AzimuthAngles)));
```

Find the response at 30° elevation for an operating frequency of 1 GHz.

```
fc = 1.0e9;
resp = antenna(fc,[0;30])
```

```
resp = 0.8660
```

### Antenna with Custom Radiation Pattern

Create a custom antenna element object. The radiation pattern has a cosine dependence on elevation angle but is independent of azimuth angle.

```
az = -180:90:180;
el = -90:45:90;
elresp = cosd(el);
magpattern = mag2db(repmat(elresp',1,numel(az)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',az,...
    'ElevationAngles',el,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

Display the radiation pattern.

```
disp(antenna.MagnitudePattern)
```

```
      -Inf      -Inf      -Inf      -Inf      -Inf
   -3.0103   -3.0103   -3.0103   -3.0103   -3.0103
```

```
         0         0         0         0         0
   -3.0103   -3.0103   -3.0103   -3.0103   -3.0103
      -Inf      -Inf      -Inf      -Inf      -Inf
```

Calculate the antenna response at the azimuth-elevation pairs *(-30,0)* and *(-45,0)* at 500 MHz.

```
ang = [-30 0; -45 0];
resp = antenna(500.0e6,ang);
disp(resp)
```

```
    0.7071
    1.0000
```

The following code illustrates how nearest-neighbor interpolation is used to find the antenna voltage response in the two directions. The total response is the product of the angular response and the frequency response.

```
g = interp2(deg2rad(antenna.AzimuthAngles),...
    deg2rad(antenna.ElevationAngles),...
    db2mag(antenna.MagnitudePattern),...
    deg2rad(ang(1,:))', deg2rad(ang(2,:))','nearest',0);
h = interp1(antenna.FrequencyVector,...
    db2mag(antenna.FrequencyResponse),500e6,'nearest',0);
antresp = h.*g;
```

Compare the value of `antresp` to the response of the antenna.

```
disp(mag2db(antresp))
```

```
   -3.0103
         0
```

## Algorithms

The total response of a custom antenna element is a combination of its frequency response and spatial response. `phased.CustomAntennaElement` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

# phased.CustomMicrophoneElement

**Package:** `phased`

Custom microphone

## Description

The `CustomMicrophoneElement` object creates a custom microphone element.

To compute the response of the microphone element for specified directions:

1. Define and set up your custom microphone element. See “Construction” on page 1-542.
2. Call `step` to compute the response according to the properties of `phased.CustomMicrophoneElement`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.CustomMicrophoneElement` creates a custom microphone system object, `H`, that models a custom microphone element.

`H = phased.CustomMicrophoneElement(Name,Value)` creates a custom microphone object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `FrequencyVector`

Operating frequency vector

Specify the frequencies in hertz where the frequency responses of element are measured as a vector. The elements of the vector must be increasing. The microphone element has no response outside the specified frequency range.

**Default:** `[0 1e20]`

### `FrequencyResponse`

Frequency responses

Specify the frequency responses in decibels measured at the frequencies defined in the `FrequencyVector` property as a row vector. The length of the vector must equal the length of the frequency vector specified in the `FrequencyVector` property.

**Default:** `[0 0]`

### `PolarPatternFrequencies`

Polar pattern measuring frequencies

Specify the measuring frequencies in hertz of the polar patterns as a row vector of length M. The measuring frequencies must be within the frequency range specified in the `FrequencyVector` property.

**Default:** `1e3`

### `PolarPatternAngles`

Polar pattern measuring angles

Specify the measuring angles in degrees of the polar patterns as a row vector of length N. The angles are measured from the central pickup axis of the microphone, and must be between –180 and 180, inclusive.

**Default:** `[-180:180]`

### PolarPattern

Polar pattern

Specify the polar patterns of the microphone element as an M-by-N matrix. M is the number of measuring frequencies specified in the `PolarPatternFrequencies` property. N is the number of measuring angles specified in the `PolarPatternAngles` property. Each row of the matrix represents the magnitude of the polar pattern (in decibels) measured at the corresponding frequency specified in the `PolarPatternFrequencies` property and corresponding angles specified in the `PolarPatternAngles` property. The pattern is assumed to be measured in the azimuth plane where the elevation angle is 0 and where the central pickup axis is assumed to be 0 degrees azimuth and 0 degrees elevation. The polar pattern is assumed to be symmetric around the central axis and therefore the microphone's response pattern in 3-D space can be constructed from the polar pattern.

**Default:** An omnidirectional pattern with 0 dB response everywhere

## Methods

| | |
|---|---|
| directivity | Directivity of custom microphone element |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Custom Cardioid Microphone Response

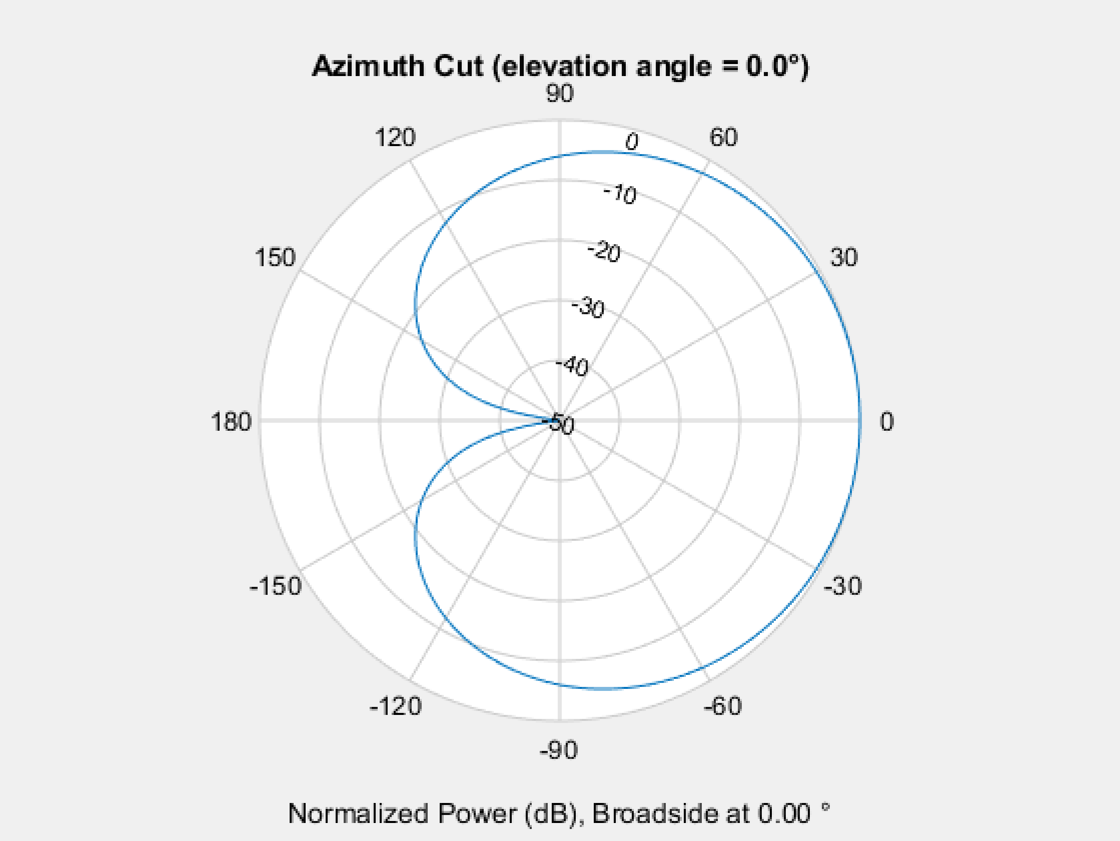
Create a custom cardioid microphone, and calculate the microphone response at 500, 1500, and 2000 Hz in two directions: *(0,0)* azimuth and elevation, and *(40,50)* azimuth and elevation.

```
sCustMic = phased.CustomMicrophoneElement;
sCustMic.PolarPatternFrequencies = [500 1000];
sCustMic.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMic.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMic.PolarPatternAngles)]);
resp = step(sCustMic,[500 1500 2000],[0 0; 40 50]')
```

```
resp = 2×3

    1.0000    1.0000    1.0000
    0.7424    0.7939    0.7939
```

```
pattern(sCustMic,500,[-180:180],0,'Type','powerdb')
```



# Algorithms

The total response of a custom microphone element is a combination of its frequency response and spatial response. `phased.CustomMicrophoneElement` calculates both responses using nearest neighbor interpolation and then multiplies them to form the total response. When the `PolarPatternFrequencies` property value is nonscalar, the object specifies multiple polar patterns. In this case, the interpolation uses the polar pattern that is measured closest to the specified frequency.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2011a**

# directivity

**System object:** `phased.CustomMicrophoneElement`
**Package:** `phased`

Directivity of custom microphone element

## Syntax

```
D = directivity(H,FREQ,ANGLE)
```

## Description

`D = directivity(H,FREQ,ANGLE)` returns the “Directivity (dBi)” on page 1-551 of a custom microphone element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

## Input Arguments

### H — Custom microphone element

System object

Custom microphone element specified as a `phased.CustomMicrophoneElement` System object.

Example: `H = phased.CustomMicrophoneElement;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

**`ANGLE` — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

# Output Arguments

**`D` — Directivity**
*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

# Examples

### Directivity of Custom Microphone Element

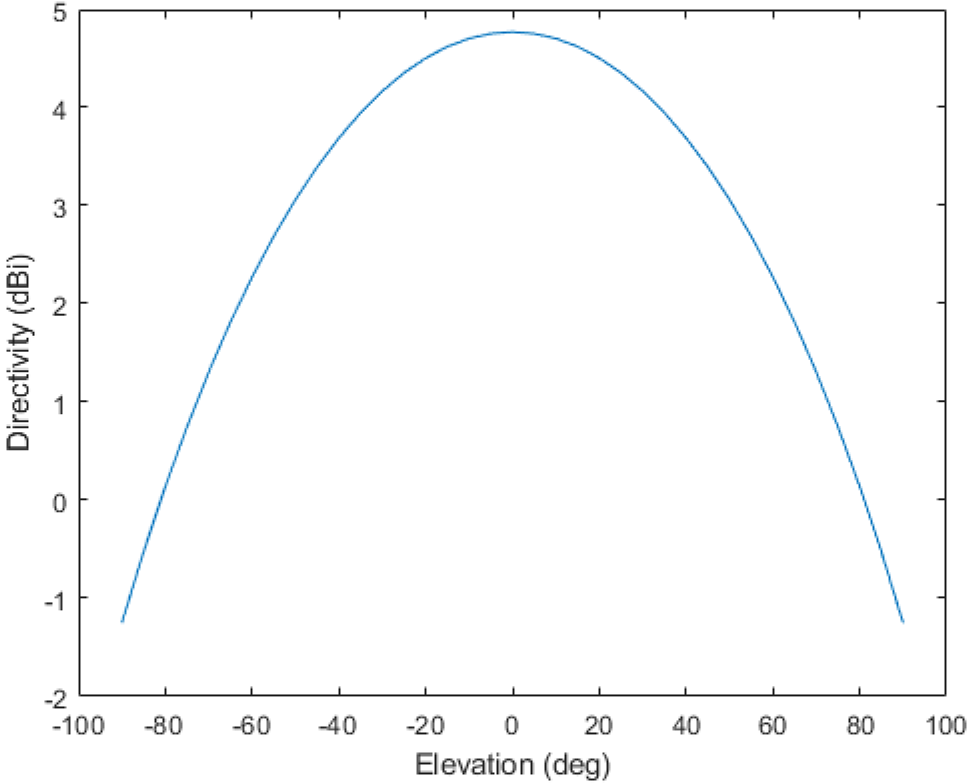
Compute the directivity of a custom microphone element. Create a custom cardioid microphone, and plot the microphone's response at 700 Hz for elevations between -90 and +90 degrees.

Define the pattern for the custom microphone element. The System object's `PolarPatternAngles` property has default value of `[-180:180]` degrees.

```
myAnt = phased.CustomMicrophoneElement;
myAnt.PolarPatternFrequencies = [500 1000];
myAnt.PolarPattern = mag2db([...
    0.5+0.5*cosd(myAnt.PolarPatternAngles);...
    0.6+0.4*cosd(myAnt.PolarPatternAngles)]);
```

Calculate the directivity as a function of elevation at zero degrees azimuth.

```
elev = [-90:5:90];
azm = zeros(size(elev));
ang = [azm;elev];
freq = 700;
d = directivity(myAnt,freq,ang);
plot(elev,d)
xlabel('Elevation (deg)')
ylabel('Directivity (dBi)')
```



The directivity is maximum at 0˚ elevation.

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified

direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** `phased.CustomMicrophoneElement`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the `phased.CustomMicrophoneElement` supports polarization. An element supports polarization if it can create or respond to polarized fields. This microphone element, as with all microphone elements, does not support polarization.

## Input Arguments

### h — Custom microphone element

Custom microphone element specified as a `phased.CustomMicrophoneElement` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the microphone element supports polarization or `false` if it does not. Because the `phased.CustomMicrophoneElement` object does not support polarization, `flag` is always returned as `false`.

## Examples

### Custom Microphone Does Not Support Polarization

Show that the `phased.CustomMicrophoneElement` microphone element does not support polarization.

```
microphone = phased.CustomMicrophoneElement;
isPolarizationCapable(microphone)
```

```
ans = logical
   0
```

The returned value `0` shows that the custom microphone element does not support polarization.

# pattern

**System object:** phased.CustomMicrophoneElement
**Package:** phased

Plot custom microphone element directivity and patterns

## Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

pattern(sElem,FREQ) plots the 3-D array directivity pattern (in dBi) for the element specified in sElem. The operating frequency is specified in FREQ.

pattern(sElem,FREQ,AZ) plots the element directivity pattern at the specified azimuth angle.

pattern(sElem,FREQ,AZ,EL) plots the element directivity pattern at specified azimuth and elevation angles.

pattern( ___ ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

[PAT,AZ_ANG,EL_ANG] = pattern( ___ ) returns the element pattern in PAT. The AZ_ANG output contains the coordinate values corresponding to the rows of PAT. The EL_ANG output contains the coordinate values corresponding to the columns of PAT. If the 'CoordinateSystem' parameter is set to 'uv', then AZ_ANG contains the *U* coordinates of the pattern and EL_ANG contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-564 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sElem` — Custom microphone element

System object

Custom microphone element, specified as a `phased.CustomMicrophoneElement` System object.

Example: `sElem = phased.CustomMicrophoneElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### CoordinateSystem — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

**Type — Displayed pattern type**
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

**Normalize — Display normalize pattern**
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

**PlotStyle — Plotting style**
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

## Output Arguments

**PAT — Element pattern**
*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

### AZ_ANG — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

### EL_ANG — Elevation angles

scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

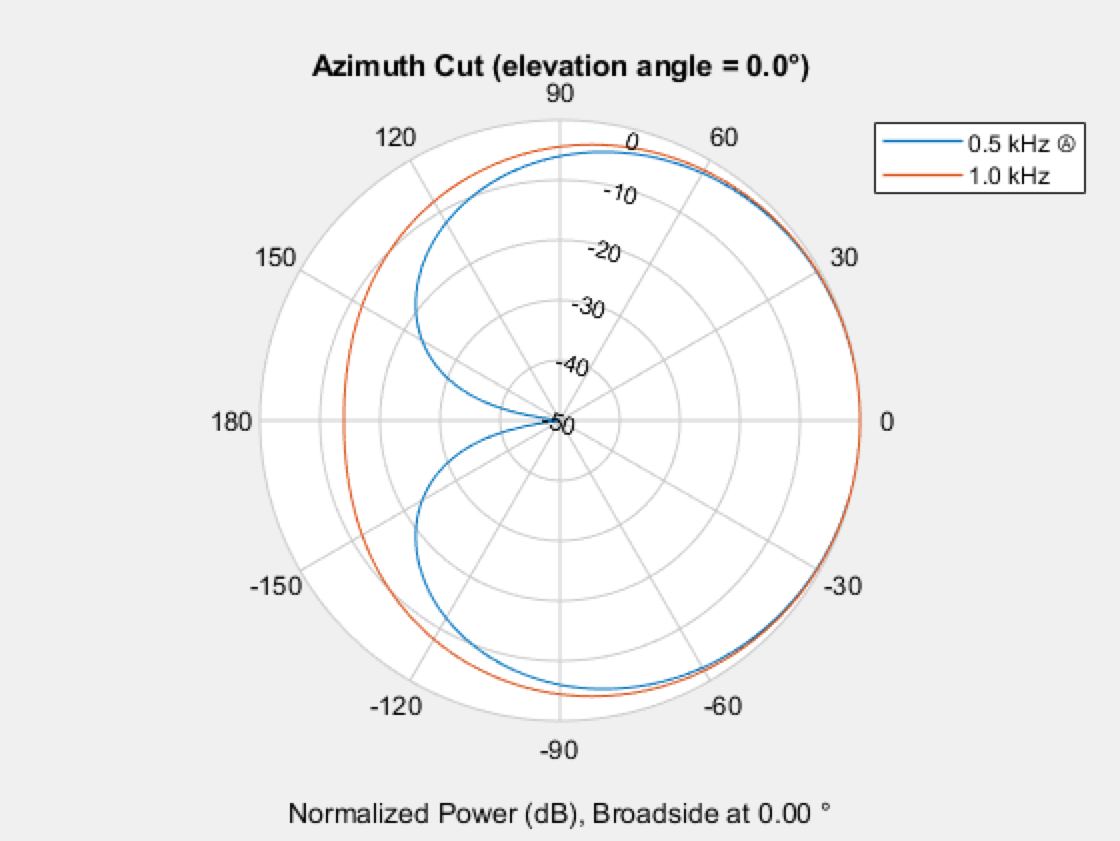
### Azimuth Power Pattern and Directivity of Cardioid Microphone

Design a cardioid microphone to operate in the frequency range between 500 and 1000 Hz.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

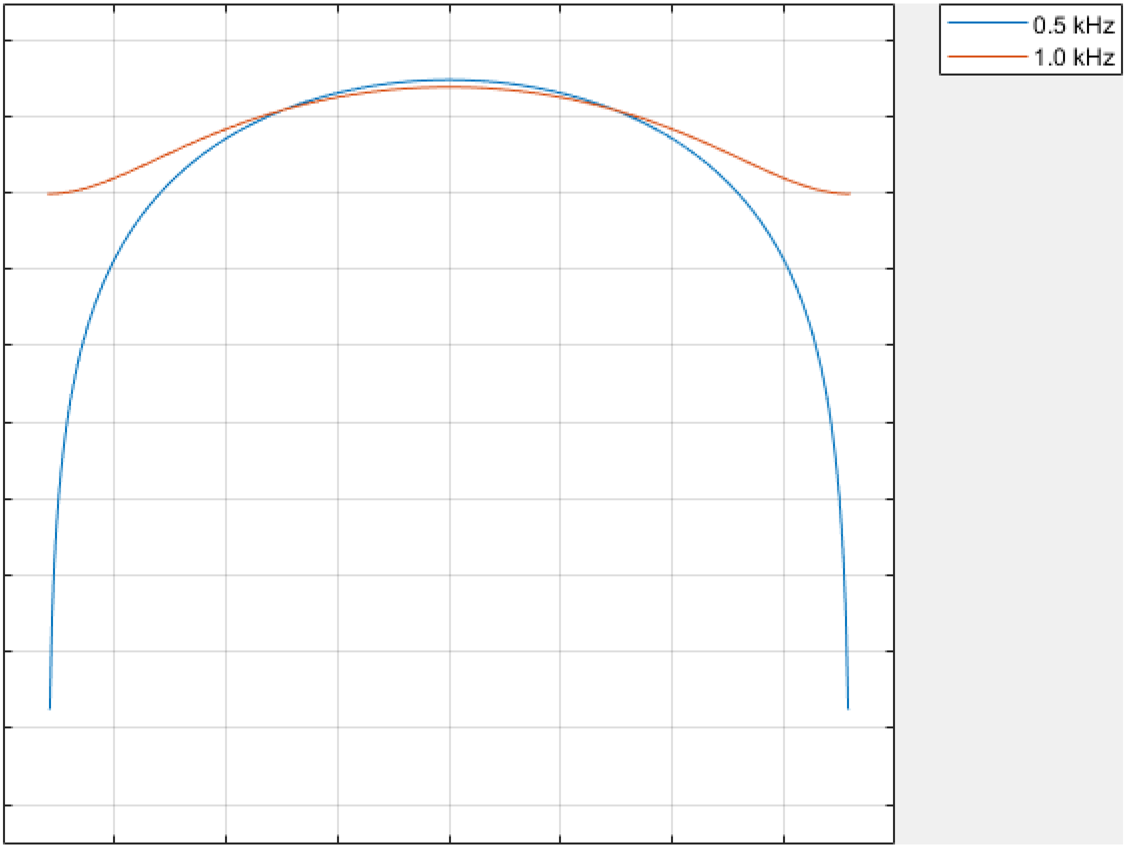
Display a polar plot of an azimuth cut of the response at 500 Hz and 1000 Hz.

```
fc = 500;
pattern(sCustMike,[fc 2*fc],[-180:180],0,...
    'CoordinateSystem','polar',...
    'Type','powerdb');
```



Plot the directivity as a line plot for the same two frequencies.

```
pattern(sCustMike,[fc 2*fc],[-180:180],0,...
    'CoordinateSystem','rectangular',...
    'Type','directivity');
```



### Power Pattern of Cardioid Microphone in U/V Space

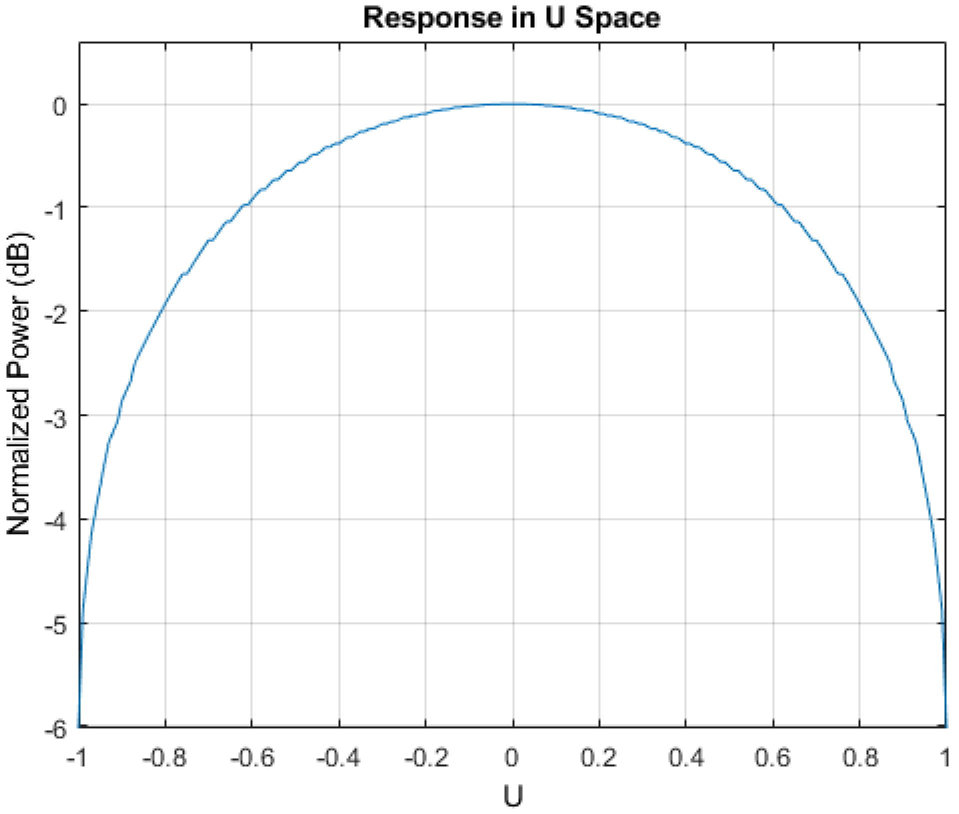
Plot a *u*-cut of the power pattern of a custom cardioid microphone designed to operate in the frequency range 500-1000 Hz.

Create a cardioid microphone.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the power pattern.

```
fc = 500;
pattern(sCustMike,fc,[-1:.01:1],0,...
    'CoordinateSystem','uv',...
    'Type','powerdb');
```



### 3-D Pattern of Cardioid Microphone Over Restricted Range of Angles

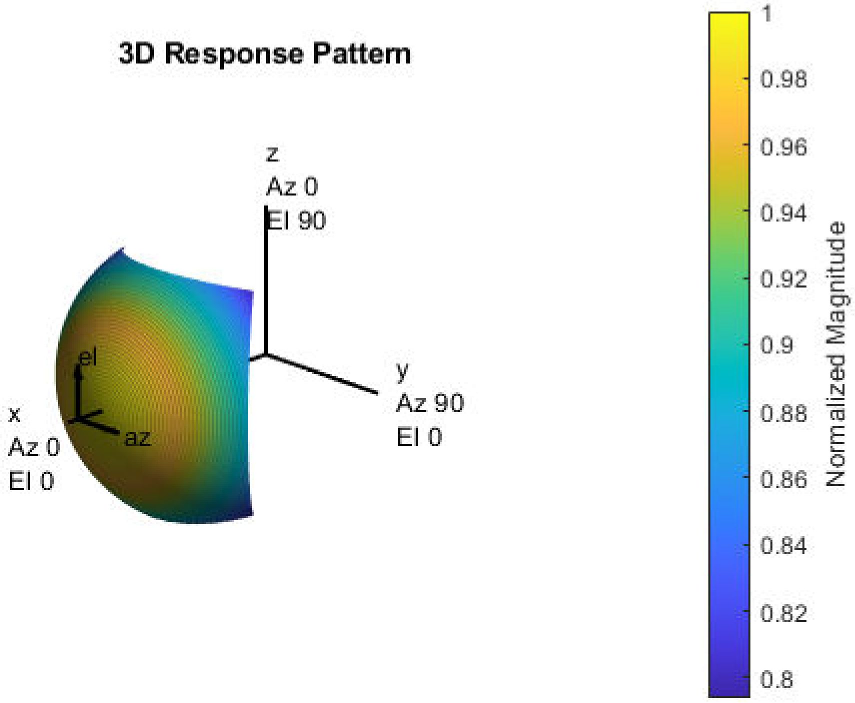
Plot the 3-D magnitude pattern of a custom cardioid microphone with both the azimuth and elevation angles restricted to the range -40 to 40 degrees in 0.1 degree increments.

Create a custom microphone element with a cardioid pattern.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the 3-D magnitude pattern.

```
fc = 500;
pattern(sCustMike,fc,[-40:0.1:40],[-40:0.1:40],...
    'CoordinateSystem','polar',...
    'Type','efield');
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>`'Format'` and `'RespCut'` name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or *UV* space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using `plotResponse`.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set `'RespCut'` `to 'Az' or` `'El'`. Set `'Format'` to `'line'` or `'polar'`.<br>Set the display axis using either the `'AzimuthAngles'` or `'ElevationAngles'` name-value pairs.</td></tr>

## See Also

patternAzimuth | patternElevation

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.CustomMicrophoneElement
**Package:** phased

Plot custom microphone element directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

patternAzimuth(sElem,FREQ) plots the 2-D element directivity pattern versus azimuth (in dBi) for the element sElem at zero degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(sElem,FREQ,EL), in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(sElem,FREQ,EL,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

**sElem — Custom microphone element**
System object

Custom microphone element, specified as a `phased.CustomMicrophoneElement` System object.

Example: `sElem = phased.CustomMicrophoneElement;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Azimuth — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Azimuth Pattern of Cardioid Microphone Over Reduced Angular Range

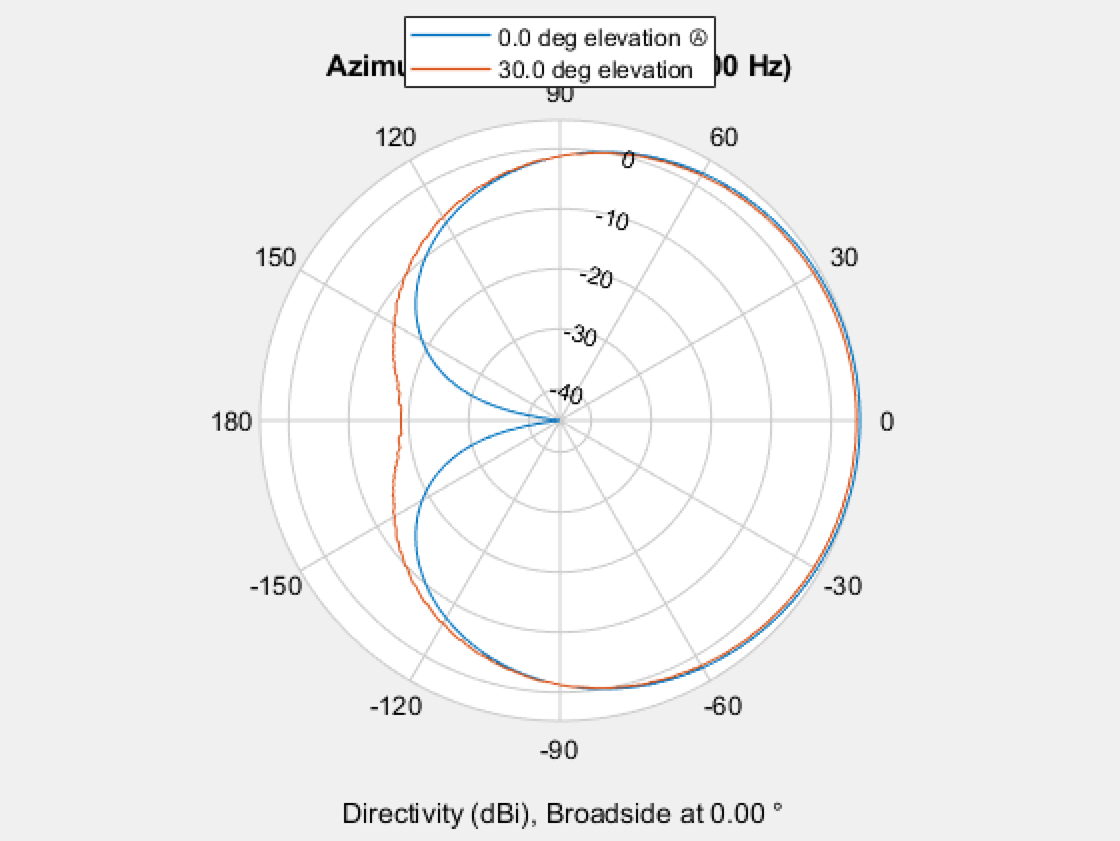
Plot the azimuth directivity pattern of a custom cardioid microphone at both 0 and 30 degrees elevation.

Create a custom microphone element with a cardioid pattern.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the directivity at 500 Hz.

```
fc = 500;
patternAzimuth(sCustMike,fc,[0 30])
```



Plot the directivity for a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
fc = 500;
patternAzimuth(sCustMike,fc,[0 30],...
    'Azimuth',[-40:.1:40])
```

# patternElevation

**System object:** `phased.CustomMicrophoneElement`
**Package:** `phased`

Plot custom microphone element directivity or pattern versus elevation

## Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

**`sElem` — Custom microphone element**
System object

Custom microphone element, specified as a `phased.CustomMicrophoneElement` System object.

Example: `sElem = phased.CustomMicrophoneElement;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**AZ — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Elevation Pattern of Cardioid Microphone Over Reduced Angular Range

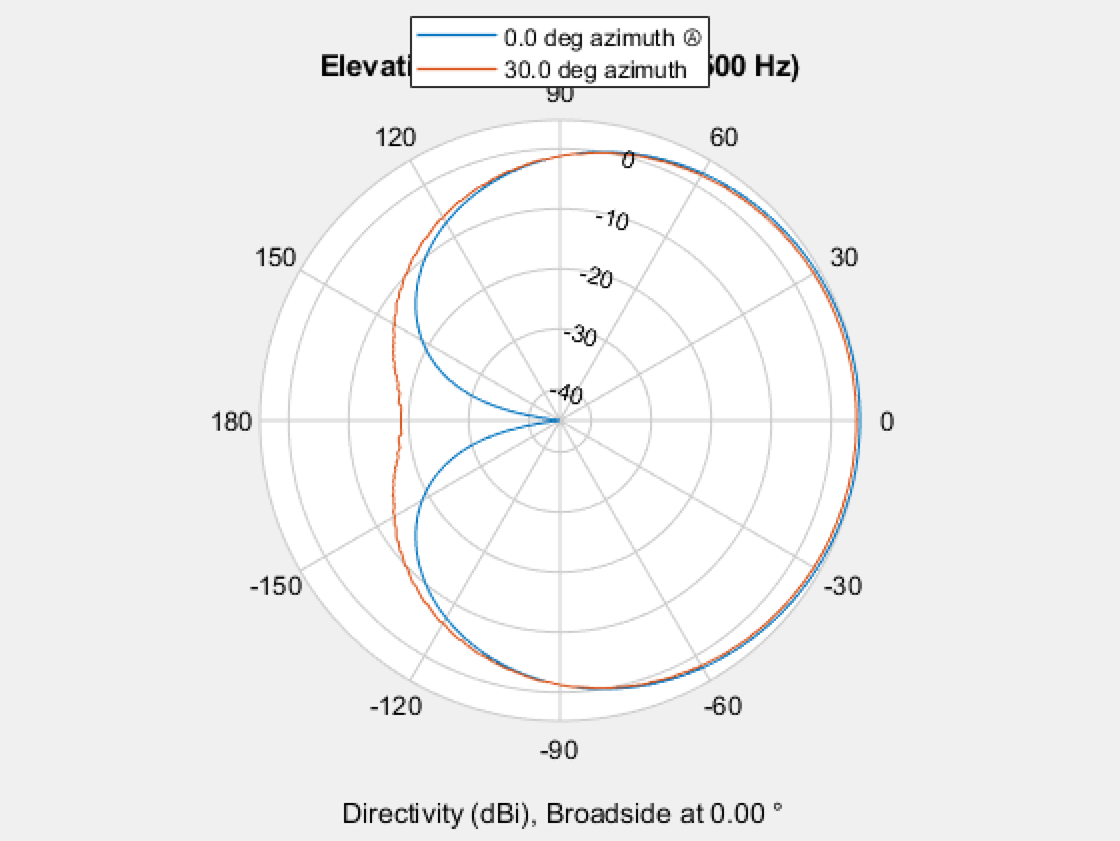
Plot the elevation directivity pattern of a custom cardioid microphone at both 0 and 45 degrees azimuth.

Create a custom microphone element with a cardioid pattern.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

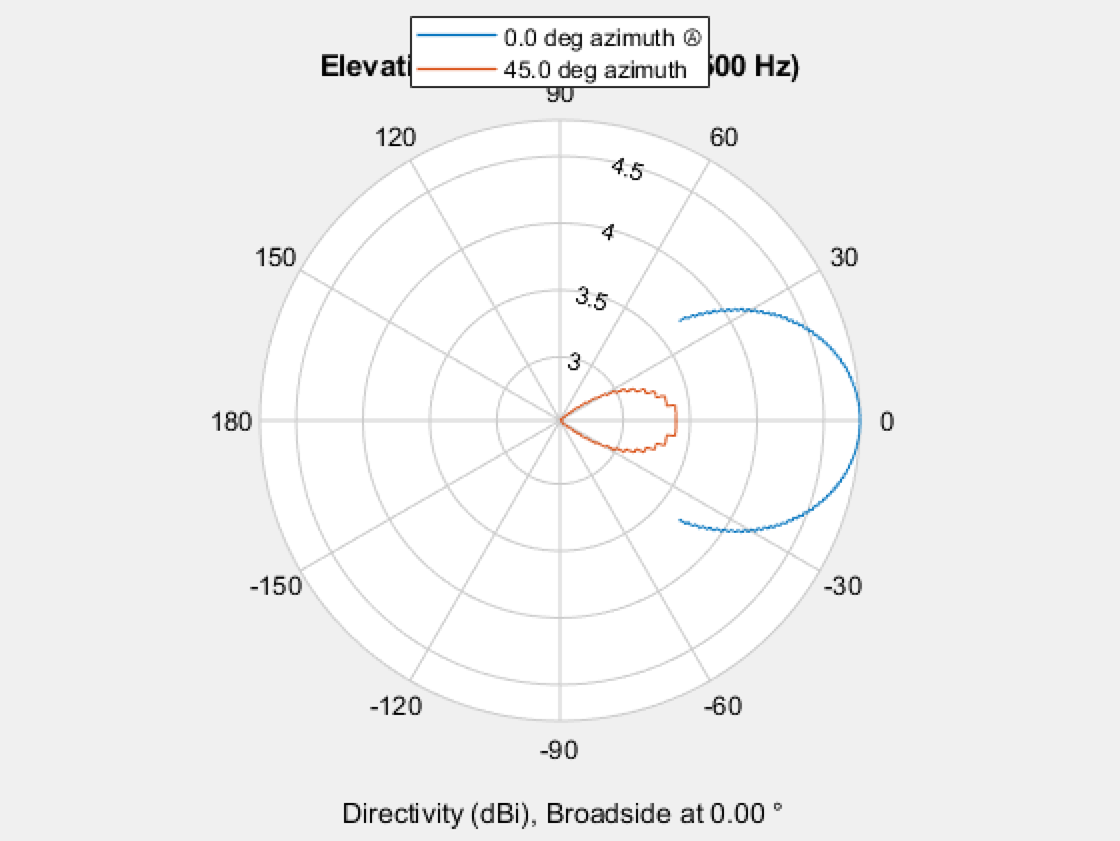
Plot the directivity at 500 Hz.

```
fc = 500;
patternElevation(sCustMike,fc,[0 30])
```



Plot the directivity for a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
fc = 500;
patternElevation(sCustMike,fc,[0 45],...
    'Elevation',[-40:.1:40])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# plotResponse

**System object:** phased.CustomMicrophoneElement
**Package:** phased

Plot response pattern of microphone

## Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

plotResponse(H,FREQ) plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in FREQ.

plotResponse(H,FREQ,Name,Value) plots the element response with additional options specified by one or more Name,Value pair arguments.

hPlot = plotResponse( ___ ) returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

### H

Element System object

### FREQ

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. FREQ must lie within the range specified by the FrequencyVector property of H. If you set the 'RespCut' property of H to '3D', FREQ must be a scalar. When FREQ is a row vector, plotResponse draws multiple frequency responses on the same axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CutAngle`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

### `Format`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

### `NormalizeResponse`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### `OverlayFreq`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the antenna response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| db | power pattern in dB scale |
| mag | field pattern |
| pow | power pattern |
| dbi | directivity |

**Default:** 'db'

### AzimuthAngles

Azimuth angles for plotting element response, specified as a row vector. The AzimuthAngles parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'Az' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the AzimuthAngles and ElevationAngles parameters simultaneously.

**Default:** [-180:180]

### ElevationAngles

Elevation angles for plotting element response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

### UGrid

*U* coordinate values for plotting element response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

### VGrid

*V* coordinate values for plotting element response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid

should be between –1 and 1 and should be specified in nondecreasing order. You can set the VGrid and UGrid parameters simultaneously.

**Default:** [-1:0.01:1]

# Examples

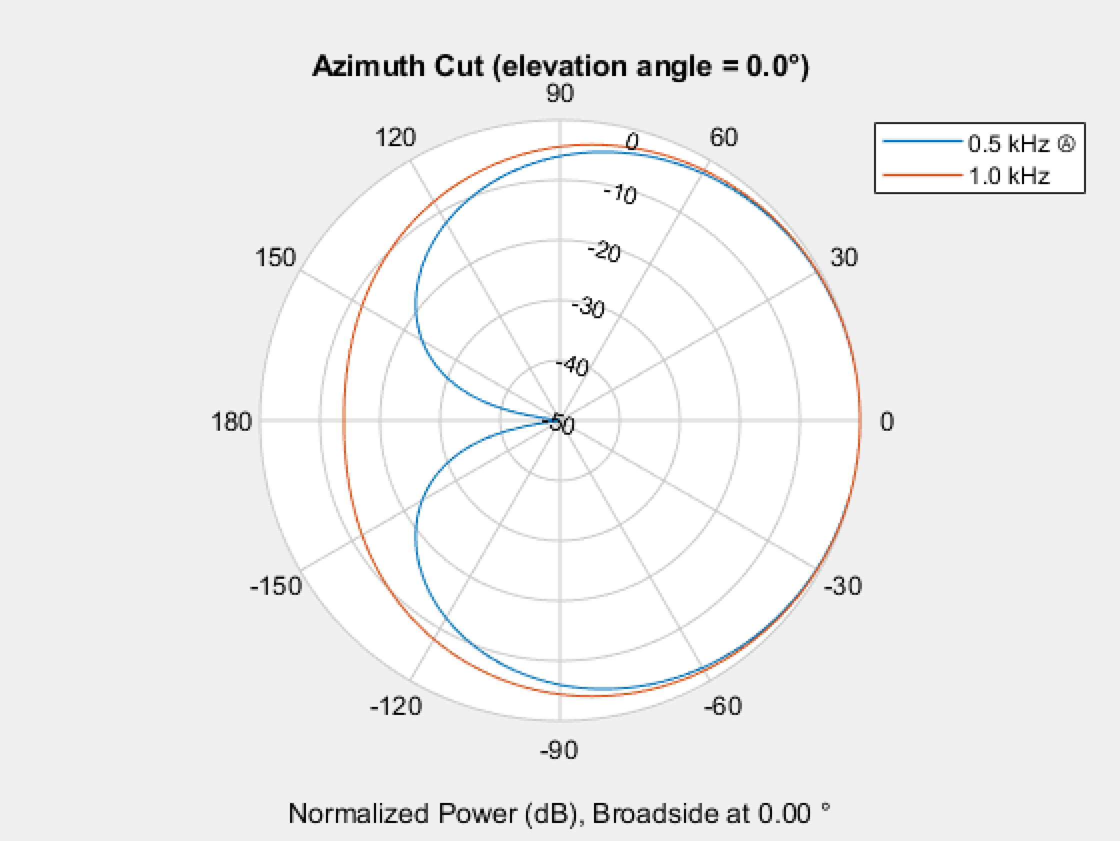
### Azimuth Response and Directivity of Cardioid Microphone

Design a cardioid microphone to operate in the frequency range between 500 and 1000 Hz.

```
h = phased.CustomMicrophoneElement;
h.PolarPatternFrequencies = [500 1000];
h.PolarPattern = mag2db([...
    0.5+0.5*cosd(h.PolarPatternAngles);...
    0.6+0.4*cosd(h.PolarPatternAngles)]);
```

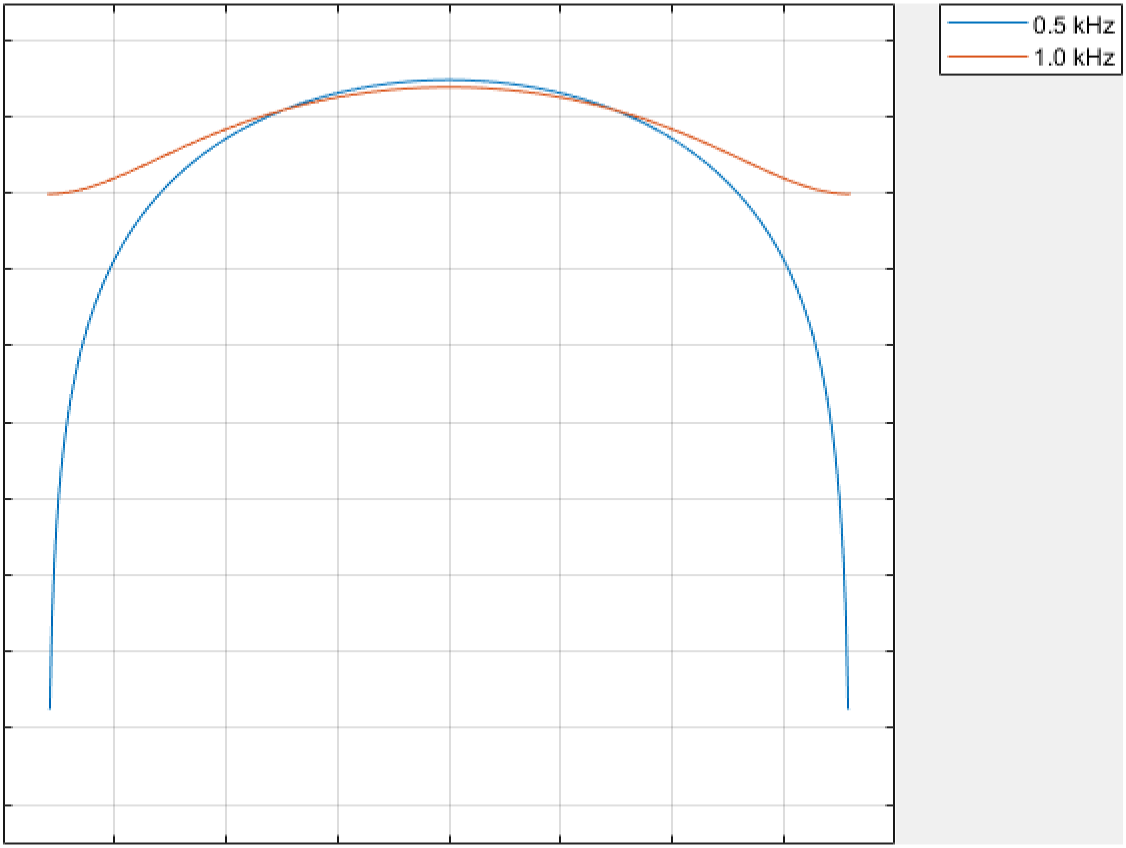
Display a polar plot of an azimuth cut of the response at 500 Hz and 1000 Hz.

```
fc = 500;
plotResponse(h,[fc 2*fc],'RespCut','Az','Format','Polar');
```



Plot the directivity as a line plot for the same two frequencies.

```
plotResponse(h,[fc 2*fc],'RespCut','Az','Format','Line','Unit','dbi');
```



### Response of Cardioid Microphone in U/V Space

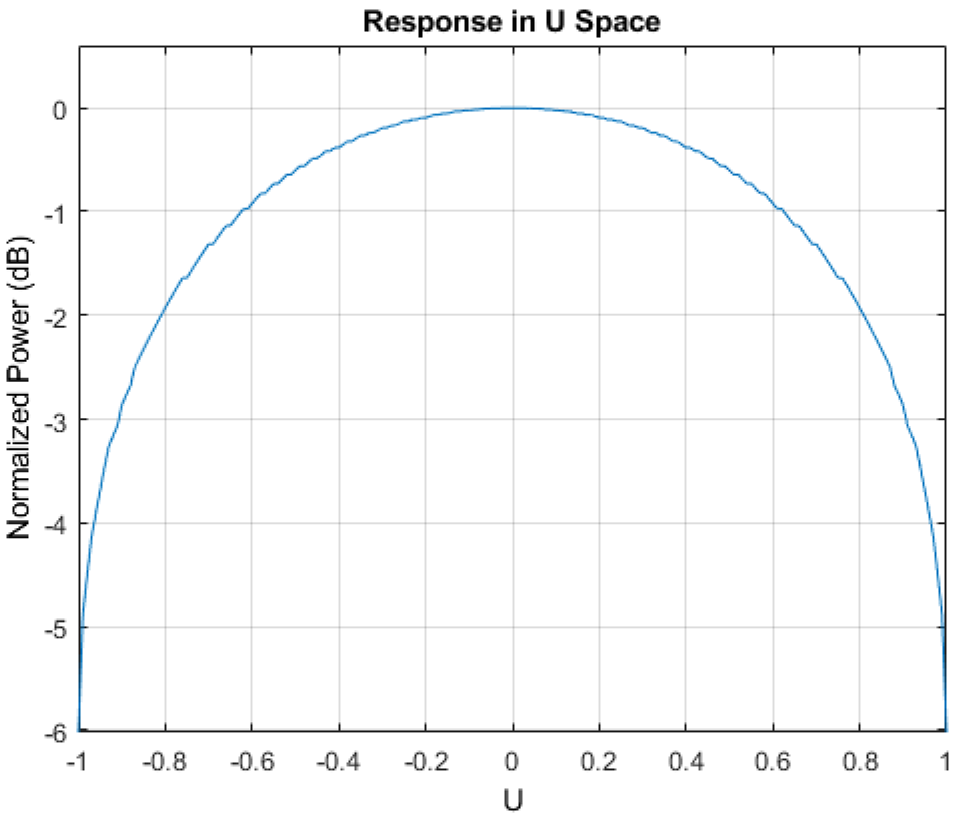
Plot a *u*-cut of the response of a custom cardioid microphone that is designed to operate in the frequency range 500-1000 Hz.

Create a cardioid microphone.

```
h = phased.CustomMicrophoneElement;
h.PolarPatternFrequencies = [500 1000];
h.PolarPattern = mag2db([...
    0.5+0.5*cosd(h.PolarPatternAngles);...
    0.6+0.4*cosd(h.PolarPatternAngles)]);
```

Plot the response.

```
fc = 500;
plotResponse(h,fc,'Format','UV');
```



### 3-D Response of Cardioid Microphone Over Restricted Range of Angles

Plot the 3-D response of a custom cardioid microphone in space but with both the azimuth and elevation angles restricted to the range -40 to 40 degrees in 0.1 degree increments.

Create a custom microphone element with a cardioid pattern.

```
h = phased.CustomMicrophoneElement;
h.PolarPatternFrequencies = [500 1000];
h.PolarPattern = mag2db([...
    0.5+0.5*cosd(h.PolarPatternAngles);...
    0.6+0.4*cosd(h.PolarPatternAngles)]);
```

Plot the 3-D response.

```
fc = 500;
plotResponse(h,fc,'Format','polar','RespCut','3D',...
    'Unit','mag','AzimuthAngles',[-40:0.1:40],...
    'ElevationAngles',[-40:0.1:40]);
```

# step

**System object:** `phased.CustomMicrophoneElement`
**Package:** `phased`

Output response of microphone

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the microphone's magnitude response, `RESP`, at frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Microphone object.

**FREQ**

Frequencies in hertz. FREQ is a row vector of length L.

**ANG**

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction’s azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

## Output Arguments

**RESP**

Response of microphone. RESP is an M-by-L matrix that contains the responses of the microphone element at the M angles specified in ANG and the L frequencies specified in FREQ.

## Examples

### Custom Microphone Response

Construct a custom cardioid microphone with an operating frequency of 500 Hz. Find the microphone response in the directions: *(0,0)* degrees azimuth and elevation and *(40,50)* degrees azimuth and elevation.

```
sCustMic = phased.CustomMicrophoneElement;
sCustMic.PolarPatternFrequencies = [500 1000];
sCustMic.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMic.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMic.PolarPatternAngles)]);
fc = 700;
ang = [0 0; 40 50]';
resp = step(sCustMic,fc,ang)
resp = 2×1

    1.0000
    0.7424
```

## Algorithms

The total response of a custom microphone element is a combination of its frequency response and spatial response. `phased.CustomMicrophoneElement` calculates both responses using nearest neighbor interpolation and then multiplies them to form the total response. When the `PolarPatternFrequencies` property value is nonscalar, the object specifies multiple polar patterns. In this case, the interpolation uses the polar pattern that is measured closest to the specified frequency.

# phased.DopplerEstimator

**Package:** phased

Doppler estimation

## Description

The phased.DopplerEstimator System object estimates Doppler frequencies of targets. Input to the estimator consists of detection locations output from a detector, and a range-Doppler response data cube. When detections are clustered, the Doppler frequencies are computed using cluster information. Clustering associates multiple detections into one extended detection.

To compute Doppler values for detections:

1. Define and set up your Doppler estimator using the “Construction” on page 1-597 procedure that follows.
2. Call the step method to compute the Doppler of detections, using the properties you specify for the phased.DopplerEstimator System object.

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

estimator = phased.DopplerEstimator creates a Doppler estimator System object, estimator.

estimator = phased.DopplerEstimator(Name,Value) creates a System object, estimator, with each specified property Name set to the specified Value. You can specify additional name and value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### NumEstimatesSource — Source of requested number of Doppler estimates

'Auto' (default) | 'Property'

Source of the number of requested Doppler estimates, specified as 'Auto' or 'Property'.

If you set this property to 'Auto', the number of estimates equals the number of columns in the detidx input argument of the step method. If cluster IDs are provided, the number of estimates equals the number of unique cluster IDs.

If you set this property to 'Property', the number of reported estimates is obtained from the value of the NumEstimates property.

Data Types: char

### NumEstimates — Maximum number of estimates

1 (default) | positive integer

The maximum number of estimates to report, specified as a positive integer. When the number of requested estimates is greater than the number of columns in the detidx argument of the step method, the remainder is filled with NaN.

**Dependencies**

To enable this property, set the NumEstimatesSource property to 'Property'.

Data Types: c | double

### ClusterInputPort — Accept clusterids as input

false (default) | true

Option to accept clusterids as an input argument to the step method, specified as false or true. Setting this property to true enables the clusterid input argument of the step method.

Data Types: logical

### VarianceOutputPort — Enable output of Doppler variance estimates

false (default) | true

Option to enable output of Doppler variance estimate, specified as `false` or `true`. Doppler variances estimates are returned in the `dopvar` output argument of the `step` method.

Data Types: `logical`

**`NumPulses` — Number of pulses in Doppler-processed waveform**
`2` (default) | positive integer

The number of pulses in the Doppler processed data cube, specified as a positive integer.

**Dependencies**

To enable this property, set the `VarianceOutputPort` property to `true`.

Data Types: `single` | `double`

**`NoisePowerSource` — Source of noise power values**
`'Property'` (default) | `'Input port'`

Source of noise power values, specified as `'Property'` or `'Input port'`. Noise power is used to compute Doppler estimation variance and SNR. If you set this property to `'Property'`, the value of the `NoisePower` property represents the noise power at the detection locations. If you set this property to `'Input port'`, you can specify noise power using the `noisepower` input argument of the `step` method.

Data Types: `char`

**`NoisePower` — Noise power**
`1.0` (default) | positive scalar

Constant noise power value over the range-Doppler data cube, specified as a positive scalar. Noise power units are linear. The same noise power value is applied to all detections.

**Dependencies**

To enable this property, set the `VarianceOutputPort` property to `true` and set `NoisePowerSource` to `'Property'`.

Data Types: `single` | `double`

## Examples

### Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the phased.RangeDopplerResponse System object™. Then use the phased.RangeEstimator and phased.DopplerEstimator System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis. The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
```

```
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

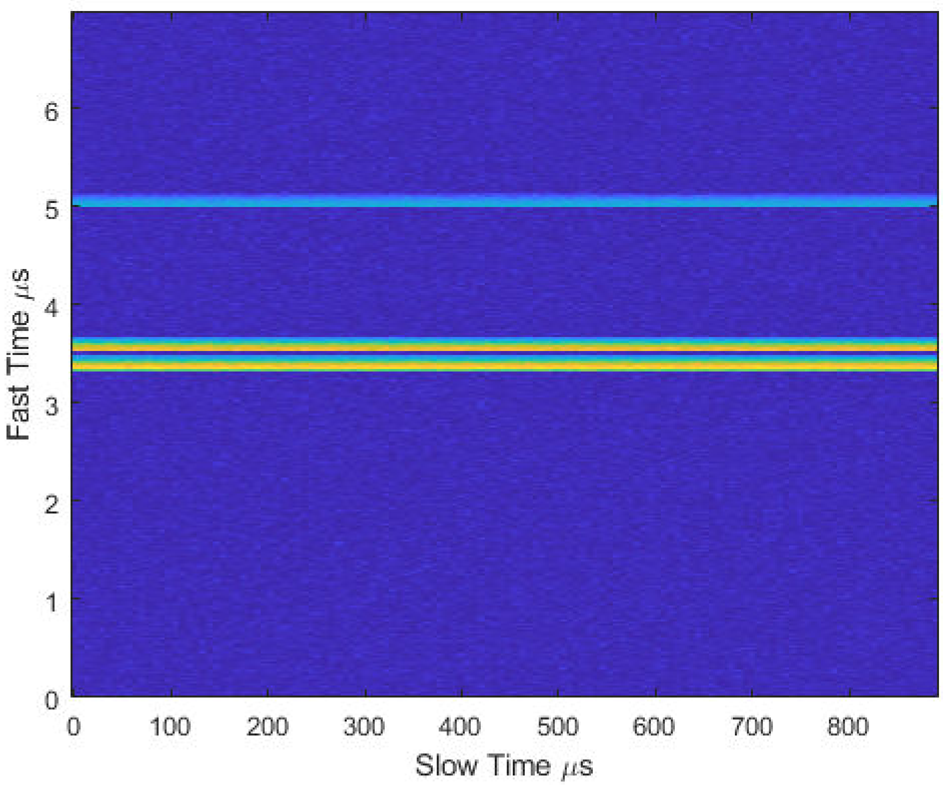
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

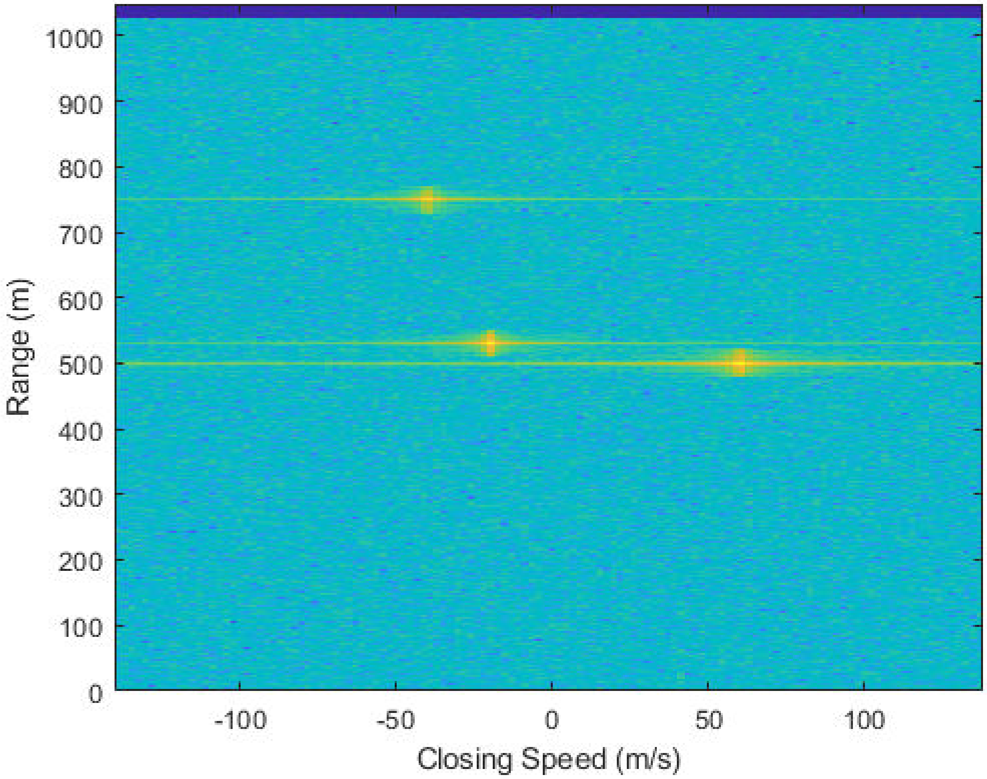
Display the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest = 3×1

  499.7911
  529.8380
  750.0983

rngvar = 3×1
10^-4 ×

    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest = 3×1

   60.5241
  -19.6167
  -39.5838

spdvar = 3×1

    0.0806
    0.0816
    0.6188
```

# Algorithms

## Estimation Algorithm

The `phased.DopplerEstimator` System object estimates the Doppler frequency of a detection by following these steps of the Doppler estimator are

1. Input a Doppler-processed response data cube obtained from the `phased.RangeDopplerResponse` System object. The first dimension of the cube represents the fast-time or equivalent range of the returned signal samples. The second dimension represents the spatial information, such as sensors or beams. The last dimension represents the response as a function of Doppler frequency. Only this dimension is used to estimate detection Doppler frequency. All others are ignored. See “Radar Data Cube”.
2. Input the matrix of detection indices that specify the location of detections in the data cube. Each column denotes a separate detection. The row entries designate indices into the data cube. To return these detection indices as an output of the `phased.CFARDetector` or `phased.CFARDetector2D` detectors. To return these indices, set the detector `OutputFormat` property of either CFAR detector to `'Detection index'`.

3. Optionally input a row vector of cluster IDs. This vector is equal in length to the number of detections. Each element of this vector assigns an ID to a corresponding detection. To form clusters of detections, the same ID can be assigned to more than one detection. To enable this option, set the `ClusterInputPort` property to `true`.
4. When `ClusterInputPort` is `false`, the object computes Doppler frequencies for each detection. The algorithm finds the response values at the detection index and at two adjacent indices in the cube along the Doppler dimension. Then, the algorithm fits a quadratic curve to the magnitudes of the Doppler response at these three indices. The peak of the curve indicates the detection location. When detections occur at the first or last sample in the Doppler dimension, the object estimates the detection location from a two-point centroid. The centroid is formed using the location of the detection index and the sample next to the detection index.

   When the object computes Doppler frequencies for each cluster. The algorithm finds the indices of the largest response value in the cluster. Then, the algorithm fits a quadratic curve to that detection in the same way as for individual detections.
5. The object converts the fractional index values to Doppler frequency or speed by using appropriate units from the `dopgrid` input argument of the `step` method. You can obtain values for `dopgrid` using the `phased.RangeDopplerResponse` System object.

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

### System Objects

phased.CFARDetector | phased.CFARDetector2D | phased.RangeDopplerResponse | phased.RangeEstimator

## Topics

“Radar Data Cube”

**Introduced in R2017a**

# step

**System object:** phased.DopplerEstimator
**Package:** phased

Estimate target Doppler

## Syntax

```
dopest = step(estimator,resp,dopgrid,detidx)
[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower)
[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,clusterids)
[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower,
clusterids)
```

## Description

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

dopest = step(estimator,resp,dopgrid,detidx) estimates Doppler frequencies of detections derived from the range-Doppler response data, resp. Doppler estimates are computed for each detection position reported in detidx. The dopgrid argument sets the units for the Doppler dimension of the response data cube.

[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower) also specifies the noise power. This syntax applies when you set the VarianceOutputPort property to true and the NoisePowerSource property to 'Input port'.

[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,clusterids) also specifies the clusterids for the detections. This syntax applies when you set the ClusterInputPort property to true.

You can combine optional input and output arguments when their enabling properties are set. Optional inputs and outputs must be listed in the same order as the order of the enabling properties. For example, `[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower,clusterids)`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `estimator` — Doppler estimator

`phased.DopplerEstimator` System object

Doppler estimator, specified as a `phased.DopplerEstimator` System object.

Example: `phased.DopplerEstimator`

### `resp` — Doppler-processed response data cube

complex-valued *P*-by-1 column vector | complex-valued *M*-by-*P* matrix | complex-valued *M*-by-*N*-by-*P* array

Doppler-processed response data cube, specified as a complex-valued *P*-by-1 column vector, a complex-valued *M*-by-*P* matrix, or a complex-valued *M*-by-*N*-by-*P* array. *M* represents the number of fast-time or range samples. *N* is the number of spatial elements, such as sensor elements or beams. *P* is the number of Doppler bins.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`

### `dopgrid` — Doppler grid values along Doppler dimension

real-valued *P*-by-1 column vector

Doppler grid values along the Doppler dimension of the `resp` argument, specified as a real-valued *P*-by-1 column vector. `dopgrid` defines the Doppler values corresponding to the Doppler dimension of the `resp` argument. Doppler values must be monotonically increasing and equally spaced. You can specify the grid values to be velocity or frequency. Units are in hertz or meters/sec.

Example: `[-0.3,-0.2,-0.1,0,0.1,0.2,0.3]`

Data Types: `single` | `double`

### `detidx` — Detection indices

real-valued $N_d$-by-$Q$ matrix

Detection indices, specified as a real-valued $N_d$-by-$Q$ matrix. $Q$ is the number of detections and $N_d$ is the number of dimensions of the response data cube, `resp`. Each column of `detidx` contains the $N_d$ indices of the detection in the response data cube.

To generate detection indices, you can use the `phased.CFARDetector` or `phased.CFARDetector2D` objects.

Data Types: `single` | `double`

### `noisepower` — Noise power at detection locations

positive scalar | real-valued 1-by-$Q$ row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-$Q$ row vector of positive values. $Q$ is the number of detections specified in `detidx`.

#### Dependencies

To enable this input argument, set the `NoisePowerSource` property to `Input port`.

Data Types: `single` | `double`

### `clusterids` — Cluster IDs

real-valued 1-by-$Q$ row vector of positive values

Cluster IDs, specified as a real-valued 1-by-$Q$ row vector where $Q$ is the number of detections specified in `detidx`. Each element of `clusterids` corresponds to a column in `detidx`. Detections with the same cluster ID belong to the same cluster.

#### Dependencies

To enable this input argument, set the `ClusterInputPort` property to `true`.

Data Types: `single` | `double`

## Output Arguments

**dopest — Doppler estimates**
real-valued *K*-by-1 column vector

Doppler estimates, returned as a real-valued *K*-by-1 column vector.

- When ClusterInputPort is false, Doppler estimates are computed for each detection location in the detidx argument. Then *K* equals the column dimension, *Q*, of detidx.
- When ClusterInputPort is true, Doppler estimates are computed for each cluster ID in the clusterids argument. Then *K* equals the number of unique cluster IDs, *Q*.

Data Types: single | double

**dopvar — Doppler estimation variance**
positive, real-valued *K*-by-1 column vector

Doppler estimation variance, returned as a positive, real-valued *K*-by-1 column vector, where *K* is the dimension of dopest. Each element of dopvar corresponds to an element of dopest. The estimator variance is computed using the Ziv-Zakai bound.

Data Types: single | double

## Examples

### Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the phased.RangeDopplerResponse System object™. Then use the phased.RangeEstimator and phased.DopplerEstimator System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
```

```
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis. The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.

3 Propagate the waveform signal to the target.

4 Reflect the signal from the target.

5 Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.

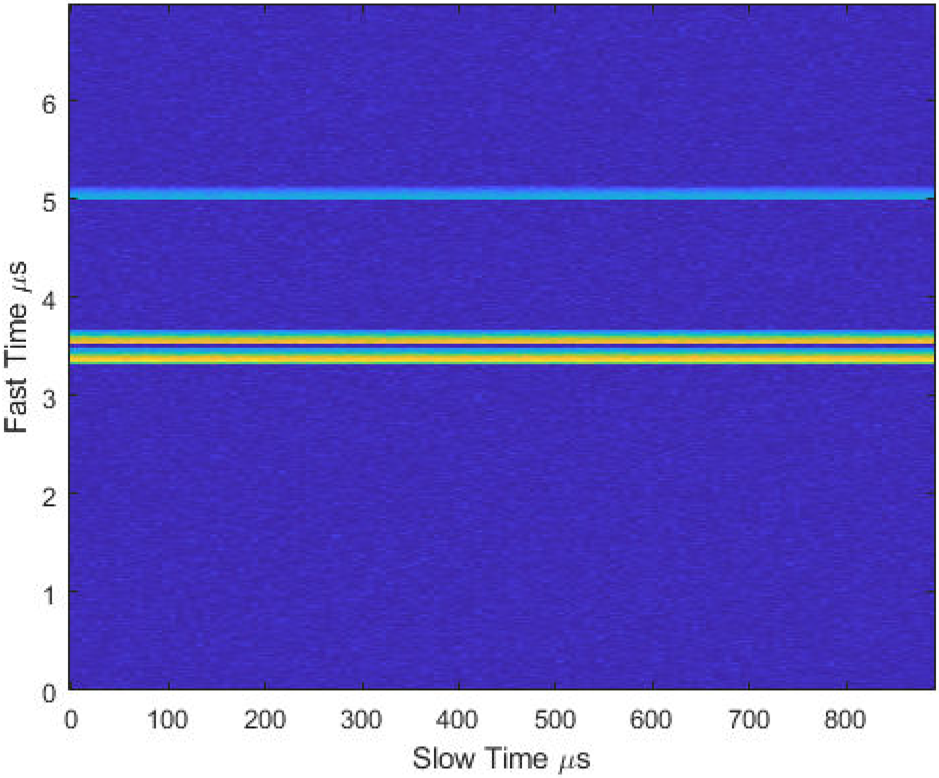
6 Receive the signal at the radar.

7 Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Display the data cube containing signals per pulse.

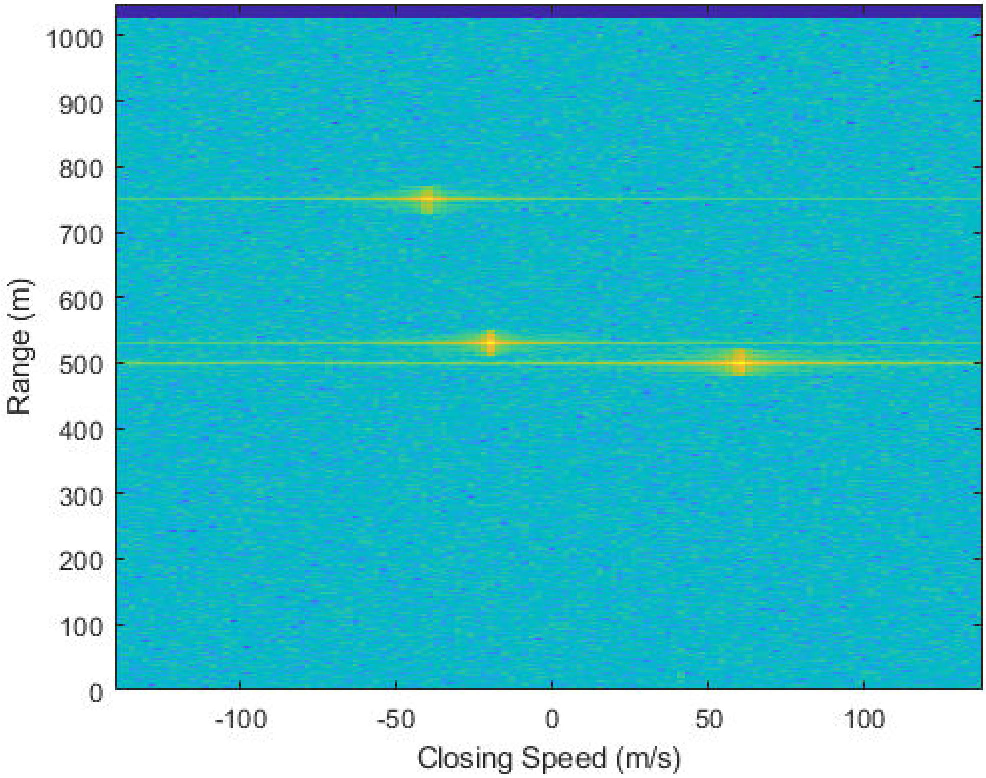
```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
```

```
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
```

```
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest = 3×1

  499.7911
  529.8380
  750.0983

rngvar = 3×1
10^-4 ×
```

```
    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest = 3×1

   60.5241
  -19.6167
  -39.5838

spdvar = 3×1
10^-5 ×

    0.0806
    0.0816
    0.6188
```

**Introduced in R2017a**

# phased.DPCACanceller

**Package:** `phased`

Displaced phase center array (DPCA) pulse canceller

## Description

The `DPCACanceller` object implements a displaced phase center array pulse canceller for a uniform linear array (ULA).

To compute the output signal of the space time pulse canceller:

1. Define and set up your DPCA pulse canceller. See “Construction” on page 1-621.
2. Call `step` to execute the DPCA algorithm according to the properties of `phased.DPCACanceller`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.DPCACanceller` creates a displaced phase center array (DPCA) canceller System object, `H`. The object performs two-pulse DPCA processing on the input data.

`H = phased.DPCACanceller(Name,Value)` creates a DPCA object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

# Properties

### `SensorArray`

Uniform linear array

Uniform linear array, specified as a `phased.ULA` System object.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `PRFSource`

Source of pulse repetition frequency

Source of the PRF values for the STAP processor, specified as `'Property'` or `'Input port'`. When you set this property to `'Property'`, the PRF is determined by the value of the `PRF` property. When you set this property to `'Input port'`, the PRF is determined by an input argument to the `step` method at execution time.

**Default:** `'Property'`

### `PRF`

Pulse repetition frequency

Pulse repetition frequency (PRF) of the received signal, specified as a positive scalar. Units are in Hertz. This property can be specified as single or double precision.

**Dependencies**

To enable this property, set the `PRFSource` property to `'Property'`.

**Default:** `1`

### `DirectionSource`

Source of receiving mainlobe direction

Specify whether the targeting direction for the STAP processor comes from the `Direction` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Direction` property of this object specifies the targeting direction. |
| `'Input port'` | An input argument in each invocation of `step` specifies the targeting direction. |

**Default:** `'Property'`

### `Direction`

Receiving mainlobe direction

Specify the receiving mainlobe direction of the receiving sensor array as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle;ElevationAngle]` (in degrees). The azimuth angle should be between –180° and 180°. The elevation angle should be between –90° and 90°. This property applies when you set the `DirectionSource` property to `'Property'`. You can specify this argument as single or double precision.

**Default:** `[0; 0]`

### `NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed. You can specify this property as single or double precision.

**Default:** `0`

### `DopplerSource`

Source of targeting Doppler

Specify whether the targeting Doppler for the STAP processor comes from the `Doppler` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Doppler` property of this object specifies the Doppler. |
| `'Input port'` | An input argument in each invocation of `step` specifies the Doppler. |

**Default:** `'Property'`

### `Doppler`

Targeting Doppler frequency (hertz)

Specify the targeting Doppler of the STAP processor as a scalar. This property applies when you set the `DopplerSource` property to `'Property'`. You can specify this property as single or double precision.

**Default:** `0`

### `WeightsOutputPort`

Output processing weights

To obtain the weights used in the STAP processor, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the weights, set this property to `false`.

**Default:** `false`

### `PreDopplerOutput`

Output pre-Doppler result

Set this property to `true` to output the processing result before applying the Doppler filtering. Set this property to `false` to output the processing result after the Doppler filtering.

**Default:** `false`

# Methods

| | |
|---|---|
| step | Perform DPCA processing on input data |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

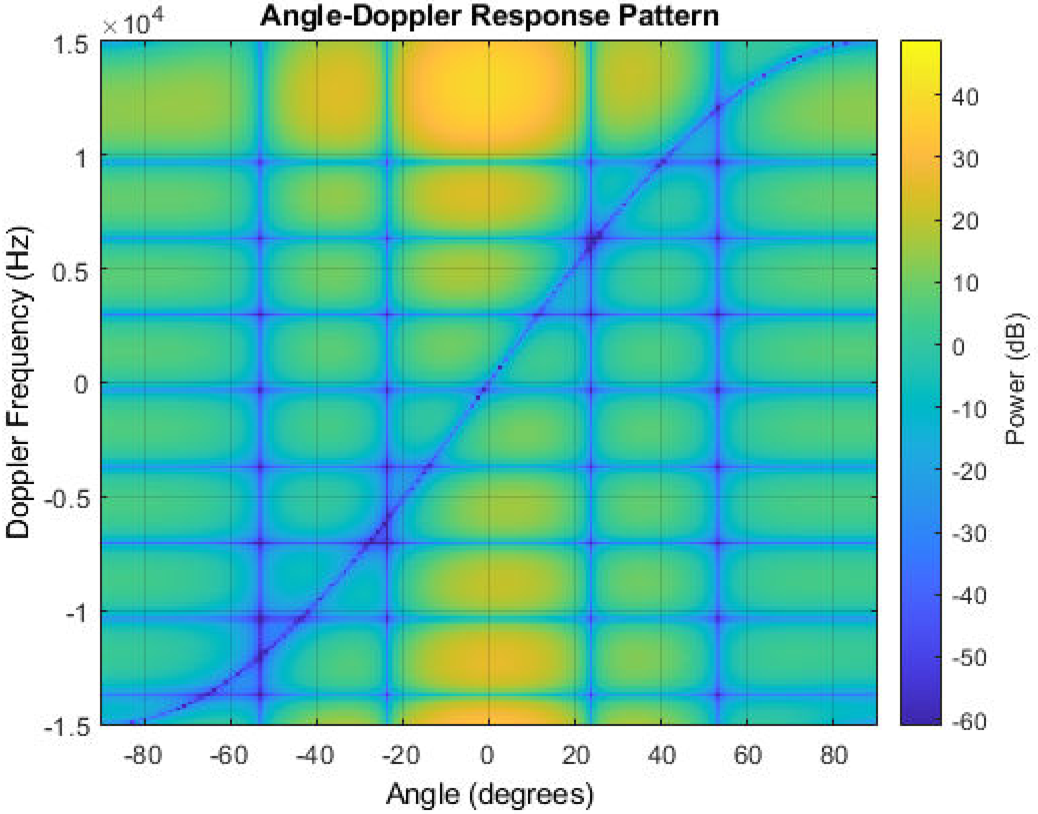
# Examples

### Process Data Cube Using DPCA

Process a data cube using a DPCA processor. The weights are calculated for the 71st cell of the collected data cube. The look direction is *(0,0)* degrees and the Doppler shift is 12.980 kHz.

```
load STAPExampleData;
Hs = phased.DPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port');
[y,w] = step(Hs,STAPEx_ReceivePulse,71,[0;0],12.980e3);

sAngDop = phased.AngleDopplerResponse(...
    'SensorArray',Hs.SensorArray,...
    'OperatingFrequency',Hs.OperatingFrequency,...
    'PRF',Hs.PRF,...
    'PropagationSpeed',Hs.PropagationSpeed);
plotResponse(sAngDop,w)
```



# Algorithms

## Single Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2012a**

# step

**System object:** phased.DPCACanceller
**Package:** phased

Perform DPCA processing on input data

## Syntax

```
Y = step(H,X,CUTIDX)
Y = step(H,X,CUTIDX,ANG)
Y = step(H,X,CUTIDX,DOP)
Y = step(H,X,CUTIDX,PRF)
[Y,W] = step(___)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X,CUTIDX) applies the DPCA pulse cancellation algorithm to the input data X. The algorithm calculates the processing weights according to the range cell specified by CUTIDX. This syntax is available when the DirectionSource property is 'Property' and the DopplerSource property is 'Property'. The receiving mainlobe direction is the Direction property value. The output Y contains the result of pulse cancellation either before or after Doppler filtering, depending on the PreDopplerOutput property value.

Y = step(H,X,CUTIDX,ANG) uses ANG as the receiving main lobe direction. This syntax is available when the DirectionSource property is 'Input port' and the DopplerSource property is 'Property'.

`Y = step(H,X,CUTIDX,DOP)` uses `DOP` as the targeting Doppler frequency. This syntax is available when the `DopplerSource` property is `'Input port'`.

`Y = step(H,X,CUTIDX,PRF)` uses `PRF` as the pulse repetition frequency. This syntax is available when the `PRFSource` property is `'Input port'`.

`[Y,W] = step(___)` also returns the processing weights, `W`. This syntax is available when the `WeightsOutputPort` property is `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Pulse canceller object.

### X

Input data. `X` must be a 3-dimensional M-by-N-by-P numeric array whose dimensions are (range, channels, pulses). You can specify this argument as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

### CUTIDX

Range cell. You can specify this argument as single or double precision.

### PRF

Pulse repetition frequency specified as a positive scalar. To enable this argument, set the `PRFSource` property to `'Input port'`. You can specify this argument as single or double precision. Units are in Hertz.

**ANG**

Receiving main lobe direction. ANG must be a 2-by-1 vector in the form [AzimuthAngle; ElevationAngle], in degrees. The azimuth angle must be between –180 and 180. The elevation angle must be between –90 and 90. You can specify this argument as single or double precision.

**Default:** Direction property of H

**DOP**

Targeting Doppler frequency in hertz. DOP must be a scalar. You can specify this argument as single or double precision.

**Default:** Doppler property of H

## Output Arguments

**Y**

Result of applying pulse cancelling to the input data. The meaning and dimensions of Y depend on the PreDopplerOutput property of H:

- If PreDopplerOutput is true, Y contains the pre-Doppler data. Y is an M-by-(P–1) matrix. Each column in Y represents the result obtained by cancelling the two successive pulses.
- If PreDopplerOutput is false, Y contains the result of applying an FFT-based Doppler filter to the pre-Doppler data. The targeting Doppler is the Doppler property value. Y is a column vector of length M.

**W**

Processing weights the pulse canceller used to obtain the pre-Doppler data. The dimensions of W depend on the PreDopplerOutput property of H:

- If PreDopplerOutput is true, W is a 2N-by-(P-1) matrix. The columns in W correspond to successive pulses in X.
- If PreDopplerOutput is false, W is a column vector of length (N*P).

# Examples

### Process Data Cube Using DPCA

Process a data cube using a DPCA processor. The weights are calculated for the 71st cell of the collected data cube. The look direction is *(0,0)* degrees and the Doppler shift is 12.980 kHz.

```
load STAPExampleData;
Hs = phased.DPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port');
[y,w] = step(Hs,STAPEx_ReceivePulse,71,[0;0],12.980e3);

sAngDop = phased.AngleDopplerResponse(...
    'SensorArray',Hs.SensorArray,...
    'OperatingFrequency',Hs.OperatingFrequency,...
    'PRF',Hs.PRF,...
    'PropagationSpeed',Hs.PropagationSpeed);
plotResponse(sAngDop,w)
```

# phased.ElementDelay

**Package:** `phased`

Sensor array element delay estimator

## Description

The `ElementDelay` object calculates the signal delay for elements in an array.

To compute the signal delay across the array elements:

1. Define and set up your element delay estimator. See "Construction" on page 1-633.
2. Call `step` to estimate the delay according to the properties of `phased.ElementDelay`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.ElementDelay` creates an element delay estimator System object, `H`. The object calculates the signal delay for elements in an array when the signal arrives the array from specified directions. By default, a 2-element uniform linear array (ULA) is used.

`H = phased.ElementDelay(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

# Properties

### `SensorArray`

Handle to sensor array used to calculate the delay

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

# Methods

# Examples

### Element Delay for Uniform Linear Array

Calculate the element delay for a uniform linear array when the input is impinging on the array from 30° azimuth and 20° elevation.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
array = phased.ULA('NumElements',4);
delay = phased.ElementDelay('SensorArray',array);
tau = delay([30;20])
```

```
tau = 4×1
10^-8 ×

    0.1175
    0.0392
   -0.0392
   -0.1175
```

**Introduced in R2012a**

# step

**System object:** `phased.ElementDelay`
**Package:** `phased`

Calculate delay for elements

## Syntax

```
TAU = step(H,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`TAU = step(H,ANG)` returns the delay `TAU` of each element relative to the array's phase center for the signal incident directions specified by `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Element delay object.

### ANG

Signal incident directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M. This argument can be single or double precision.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction’s azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

## Output Arguments

### TAU

Delay in seconds.TAU is an N-by-M matrix, where N is the number of elements in the array. Each column of TAU contains the delays of the array elements for the corresponding direction specified in ANG. This argument can be single or double precision.

## Examples

### Element Delay for Uniform Linear Array

Calculate the element delay for a uniform linear array when the input is impinging on the array from 30° azimuth and 20° elevation.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
array = phased.ULA('NumElements',4);
delay = phased.ElementDelay('SensorArray',array);
tau = delay([30;20])
```

```
tau = 4×1
10^-8 ×
```

```
    0.1175
    0.0392

# phased.ESPRITEstimator

**Package:** phased

ESPRIT direction of arrival (DOA) estimator for ULA

## Description

The phased.ESPRITEstimator System object estimate the direction of arrival of signals parameters via rotational invariance (ESPRIT) direction of arrival estimate.

To estimate the direction of arrival (DOA):

1. Define and set up your DOA estimator. See "Construction" on page 1-640.
2. Call step to estimate the DOA according to the properties of phased.ESPRITEstimator. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.ESPRITEstimator creates an ESPRIT DOA estimator System object, H. The object estimates the signal's direction-of-arrival (DOA) using the ESPRIT algorithm with a uniform linear array (ULA).

H = phased.ESPRITEstimator(Name,Value) creates object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

# Properties

**SensorArray**

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

**Default:** `phased.ULA` with default property values

**PropagationSpeed**

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

**OperatingFrequency**

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

**ForwardBackwardAveraging**

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

**Default:** `false`

**SpatialSmoothing**

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of element by 1. The maximum value of this property is M–2, where M is the number of sensors. You can specify this property as single or double precision.

**Default:** `0`, indicating no spatial smoothing

**`NumSignalsSource`**

Source of number of signals

Specify the source of the number of signals as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of signals is estimated by the method specified by the `NumSignalsMethod` property.

**Default:** `'Auto'`

**`NumSignalsMethod`**

Method to estimate number of signals

Specify the method to estimate the number of signals as one of `'AIC'` or `'MDL'`. The `'AIC'` uses the Akaike Information Criterion and the `'MDL'` uses Minimum Description Length criterion. This property applies when you set the `NumSignalsSource` property to `'Auto'`.

**Default:** `'AIC'`

**`NumSignals`**

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the `NumSignalsSource` property to `'Property'`. The number of signals, $N_{sig}$, must be smaller than the number of elements, $N_{sub}$, in the subarray derived from the array specified in the `SensorArray` property. See “ESPRIT Subarrays” on page 1-644. You can specify this property as single or double precision.

**Default:** `1`

**`Method`**

Type of least squares method

Specify the least squares method used for ESPRIT as one of `'TLS'` or `'LS'`. `'TLS'` refers to total least squares and `'LS'`refers to least squares.

**Default:** `'TLS'`

**`RowWeighting`**

Row weighting factor

Specify the row weighting factor for signal subspace eigenvectors as a positive integer scalar. This property controls the weights applied to the selection matrices. In most cases the higher value the better. However, it can never be greater than *(Nsub – 1)/2* where *Nsub* is the number of elements in the subarray derived from the array specified in the `SensorArray` property. See “ESPRIT Subarrays” on page 1-644. You can specify this property as single or double precision.

**Default:** `1`

## Methods

| | |

## Examples

### Estimate DOAs of Two Signals

Estimate the directions-of-arrival (DOA) of two signals received by a standard 10-element ULA with element spacing 1 m. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and 60° in elevation.

Create the signals.

```
fs = 8.0e3;
t = (0:1/fs:1).';
```

```
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
```

Create the plane waves and add noise.

```
x = collectPlaneWave(array,[x1 x2],[10 20;45 60]',fc);
noise = 0.1/sqrt(2)*(randn(size(x)) + 1i*randn(size(x)));
```

Estimate the arrival angles.

```
estimator = phased.ESPRITEstimator('SensorArray',array,...
    'OperatingFrequency',fc);
doas = estimator(x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az = 1×2

   10.0000   45.0126
```

# Algorithms

## ESPRIT Subarrays

The ESPRIT algorithm, as implemented in the `phased.ESPRITEstimator` System object, reorganizes the ULA elements into two overlapping subarrays. For an original N-element array, the first subarray consist of elements $1,...,N - 1$ of the original array. The second subarray consist of elements $2, ... ,N$ of the original array. There are $N_{sub} = N - 1$ elements in each subarray.

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# step

**System object:** `phased.ESPRITEstimator`
**Package:** `phased`

Perform DOA estimation

## Syntax

```
ANG = step(H,X)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ANG = step(H,X)` estimates the DOAs from `X` using the DOA estimator, `H`. `X` is a matrix whose columns correspond to channels. `ANG` is a row vector of the estimated broadside angles (in degrees). You can specify this argument as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# phased.FMCWWaveform

**Package:** `phased`

FMCW waveform

## Description

The `FMCWWaveform` object creates an FMCW (frequency modulated continuous wave) waveform.

To obtain waveform samples:

1. Define and set up your FMCW waveform. See “Construction” on page 1-648.
2. Call `step` to generate the FMCW waveform samples according to the properties of `phased.FMCWWaveform`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

## Construction

`H = phased.FMCWWaveform` creates an FMCW waveform System object, `H`. The object generates samples of an FMCW waveform.

`H = phased.FMCWWaveform(Name,Value)` creates an FMCW waveform object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name on page 1-649, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

## Properties

### SampleRate

Sample rate

Specify the same rate, in hertz, as a positive scalar. The default value of this property corresponds to 1 MHz.

The quantity (SampleRate .* SweepTime) is a scalar or vector that must contain only integers.

**Default:** 1e6

### SweepTime

Duration of each linear FM sweep

Specify the duration of the upsweep or downsweep, in seconds, as a row vector of positive, real numbers. The default value corresponds to 100 $\mu$s.

If SweepDirection is 'Triangle', the sweep time is half the sweep period because each period consists of an upsweep and a downsweep. If SweepDirection is 'Up' or 'Down', the sweep time equals the sweep period.

The quantity (SampleRate .* SweepTime) is a scalar or vector that must contain only integers.

To implement a varying sweep time, specify SweepTime as a nonscalar row vector. The waveform uses successive entries of the vector as the sweep time for successive periods of the waveform. If the last element of the vector is reached, the process continues cyclically with the first entry of the vector.

If SweepTime and SweepBandwidth are both nonscalar, they must have the same length.

**Default:** 1e-4

### SweepBandwidth

FM sweep bandwidth

Specify the bandwidth of the linear FM sweeping, in hertz, as a row vector of positive, real numbers. The default value corresponds to 100 kHz.

To implement a varying bandwidth, specify SweepBandwidth as a nonscalar row vector. The waveform uses successive entries of the vector as the sweep bandwidth for successive periods of the waveform. If the last element of the SweepBandwidth vector is reached, the process continues cyclically with the first entry of the vector.

If SweepTime and SweepBandwidth are both nonscalar, they must have the same length.

**Default:** 1e5

**SweepDirection**

FM sweep direction

Specify the direction of the linear FM sweep as one of 'Up' | 'Down' | 'Triangle'.

**Default:** 'Up'

**SweepInterval**

Location of FM sweep interval

If you set this property value to 'Positive', the waveform sweeps in the interval between 0 and *B*, where *B* is the SweepBandwidth property value. If you set this property value to 'Symmetric', the waveform sweeps in the interval between –*B*/2 and *B*/2.

**Default:** 'Positive'

**OutputFormat**

Output signal format

Specify the format of the output signal as one of 'Sweeps' or 'Samples'. When you set the OutputFormat property to 'Sweeps', the output of the step method is in the form of multiple sweeps. In this case, the number of sweeps is the value of the NumSweeps property. If the SweepDirection property is 'Triangle', each sweep is half a period.

When you set the OutputFormat property to 'Samples', the output of the step method is in the form of multiple samples. In this case, the number of samples is the value of the NumSamples property.

**Default:** 'Sweeps'

### NumSamples

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

### NumSweeps

Number of sweeps in output

Specify the number of sweeps in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Sweeps'`.

**Default:** `1`

## Methods

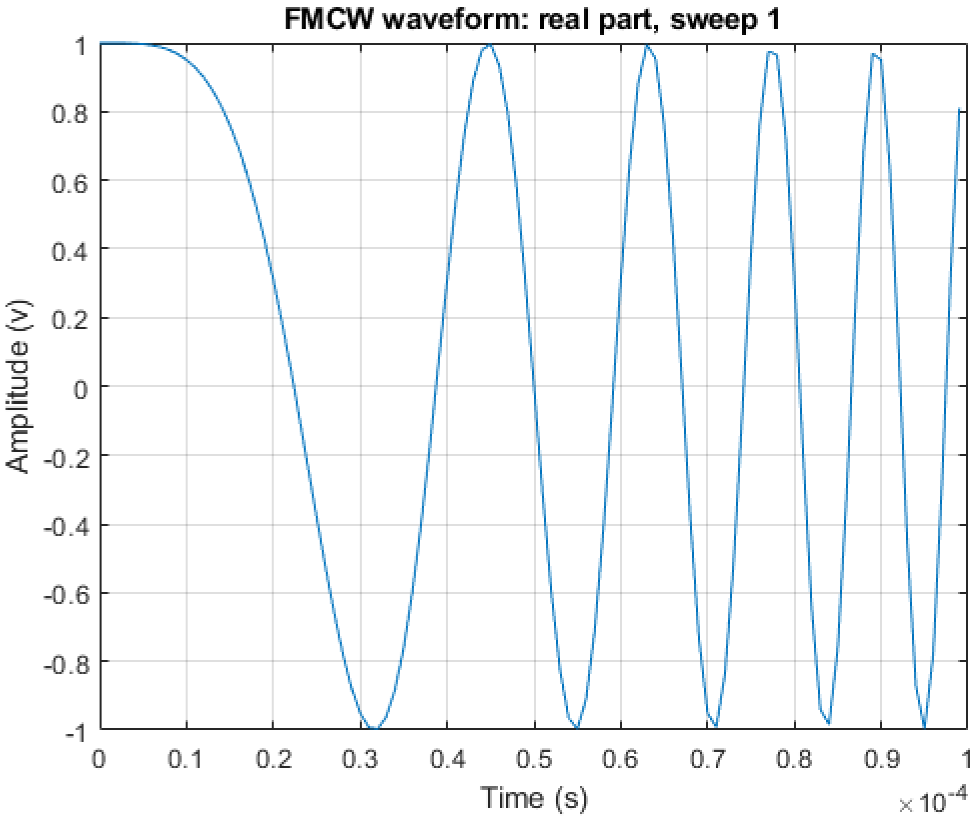
## Examples

### Plot FMCW Waveform

Create and plot an upsweep FMCW waveform.

```
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,...
    'OutputFormat','Sweeps','NumSweeps',2);
plot(waveform)
```

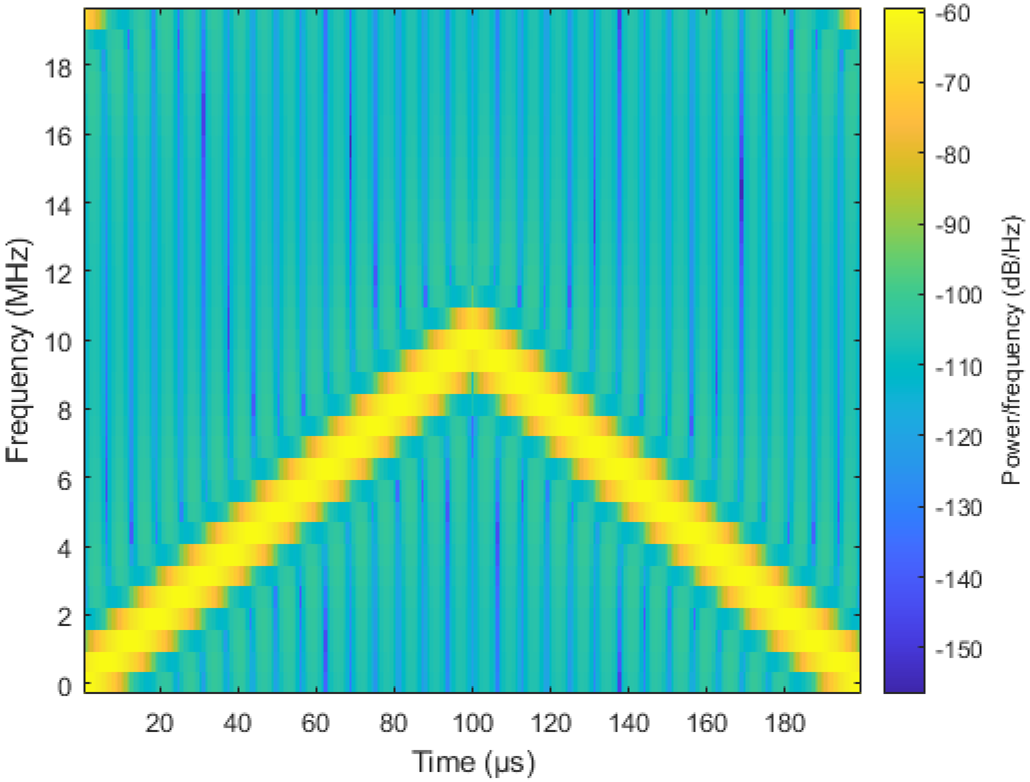


### Spectrogram of Triangle Sweep FMCW Waveform

Generate samples of a triangle sweep FMCW Waveform. Then, plot the spectrogram of the sweep. The sweep has a 10 MHz bandwidth.

```
sFMCW = phased.FMCWWaveform('SweepBandwidth',10.0e6,...
   'SampleRate',20.0e6,'SweepDirection','Triangle',...
   'NumSweeps',2);
sig = step(sFMCW);
windowlength = 32;
noverlap = 16;
```

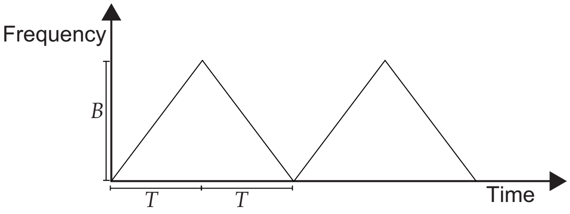
```
nfft = 32;
spectrogram(sig,windowlength,noverlap,nfft,sFMCW.SampleRate,'yaxis')
```



# More About

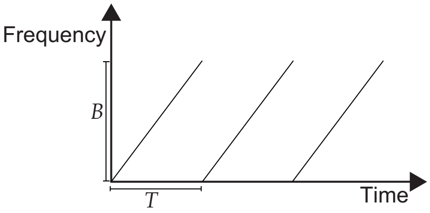
## Triangle Sweep

In each period of a triangle sweep, the waveform sweeps up with a slope of *B*/*T* and then down with a slope of –*B*/*T*. *B* is the sweep bandwidth, and *T* is the sweep time. The sweep period is 2*T*.



### Upsweep

In each period of an upsweep, the waveform sweeps with a slope of *B*/*T*. *B* is the sweep bandwidth, and *T* is the sweep time.



### Downsweep

In each period of a downsweep, the waveform sweeps with a slope of –*B*/*T*. *B* is the sweep bandwidth, and *T* is the sweep time.

Automotive Adaptive Cruise Control Using FMCW Technology

**Introduced in R2012b**

# plot

**System object:** `phased.FMCWWaveform`
**Package:** `phased`

Plot FMCW waveform

## Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

## Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

## Input Arguments

### Hwav

Waveform object. This variable must be a scalar that represents a single waveform object.

**LineSpec**

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

**Default:** `'b'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**PlotType**

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

**Default:** `'real'`

**SweepIdx**

Index of the sweep to plot. This value must be a positive integer scalar.

**Default:** `1`

# Output Arguments

**h**

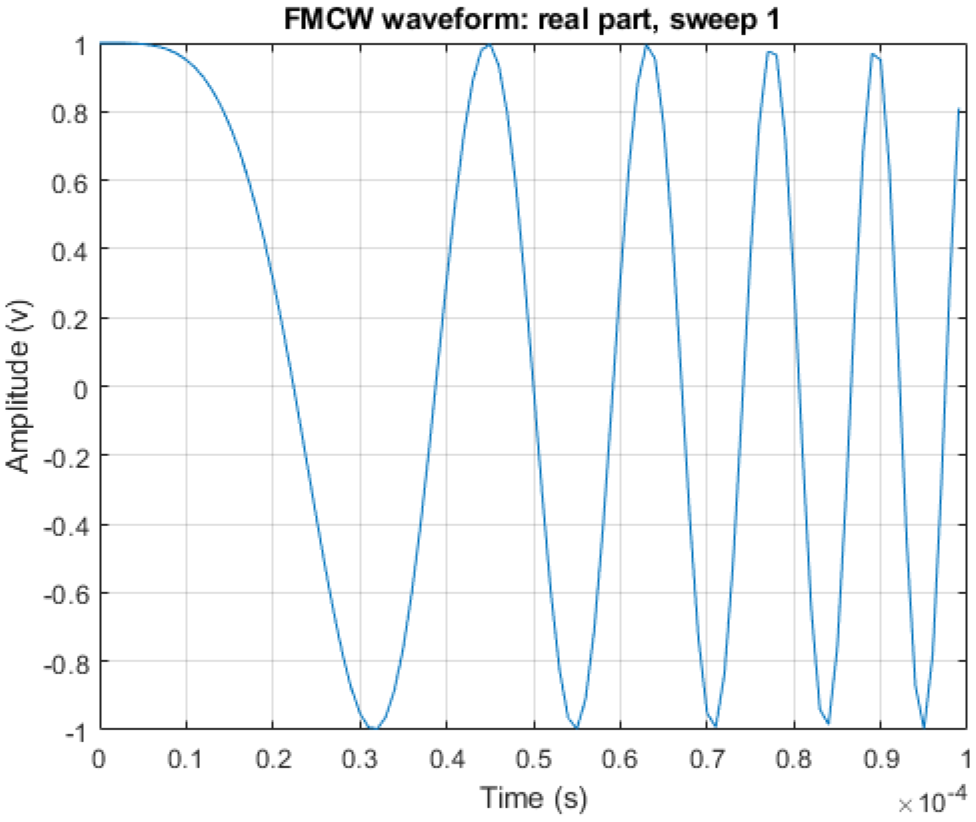
Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

# Examples

### Plot FMCW Waveform

Create and plot an upsweep FMCW waveform.

```
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,...
    'OutputFormat','Sweeps','NumSweeps',2);
plot(waveform)
```



# reset

**System object:** phased.FMCWWaveform
**Package:** phased

Reset states of FMCW waveform object

## Syntax

```
reset(H)
```

## Description

reset(H) resets the states of the FMCWWaveform object, H. Afterward, the next call to step restarts the sweep of the waveform.

# step

**System object:** `phased.FMCWWaveform`
**Package:** `phased`

Samples of FMCW waveform

## Syntax

```
Y = step(H)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(H)` returns samples of the FMCW waveform in a column vector, `Y`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

FMCW waveform object.

## Output Arguments

**Y**

Column vector containing the waveform samples.

If `H.OutputFormat` is `'Samples'`, Y consists of `H.NumSamples` samples.

If `H.OutputFormat` is `'Sweeps'`, Y consists of `H.NumSweeps` sweeps. Also, if `H.SweepDirection` is `'Triangle'`, each sweep is half a period.

## Examples

### Spectrogram of Triangle Sweep FMCW Waveform

Generate samples of a triangle sweep FMCW Waveform. Then, plot the spectrogram of the sweep. The sweep has a 10 MHz bandwidth.

```
sFMCW = phased.FMCWWaveform('SweepBandwidth',10.0e6,...
   'SampleRate',20.0e6,'SweepDirection','Triangle',...
   'NumSweeps',2);
sig = step(sFMCW);
windowlength = 32;
noverlap = 16;
nfft = 32;
spectrogram(sig,windowlength,noverlap,nfft,sFMCW.SampleRate,'yaxis')

# phased.FreeSpace

**Package:** phased

Free space environment

## Description

The phased.FreeSpace System object models narrowband signal propagation from one point to another in a free-space environment. The object applies range-dependent time delay, gain and phase shift to the input signal. The object accounts for doppler shift when either the source or destination is moving. A free-space environment is a boundaryless medium with a speed of signal propagation independent of position and direction. The signal propagates along a straight line from source to destination. For example, you can use this object to model the propagation of a signal from a radar to a target and back to the radar.

For non-polarized signals, the FreeSpace System object lets you propagate signals from a single point to multiple points or from multiple points to a single point. Multiple-point to multiple-point propagation is not supported.

To compute the propagated signal in free space:

1. Define and set up your free space environment. See “Construction” on page 1-664.
2. Call step to propagate the signal through a free space environment according to the properties of phased.FreeSpace. The behavior of step is specific to each object in the toolbox.

When propagating a round trip signal in free-space, you can either use one FreeSpace System object to compute the two-way propagation delay or two separate FreeSpace System objects to compute one-way propagation delays in each direction. Due to filter distortion, the total round trip delay when you employ two-way propagation can differ from the delay when you use two one-way phased.FreeSpace System objects. It is more accurate to use a single two-way phased.FreeSpace System object. This option is set by the TwoWayPropagation property.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.FreeSpace` creates a free space environment System object, `H`.

`H = phased.FreeSpace(Name,Value)` creates a free space environment object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `PropagationSpeed`

Signal propagation speed

Specify signal wave propagation speed in free space as a real positive scalar. Units are meters per second.

**Default:** Speed of light

### `OperatingFrequency`

Signal carrier frequency

A scalar containing the carrier frequency of the narrowband signal. Units are hertz.

**Default:** `3e8`

### `TwoWayPropagation`

Perform two-way propagation

Set this property to `true` to perform round-trip propagation between the origin and destination that you specify in the `step` command. Set this property to `false` to perform one-way propagation from the origin to the destination.

**Default:** `false`

**`SampleRate`**

Sample rate

A scalar containing the sample rate. Units of sample rate are hertz. The algorithm uses this value to determine the propagation delay in number of samples.

**Default:** `1e6`

**`MaximumDistanceSource`**

Source of maximum distance value

Source of maximum distance value, specified as `'Auto'` or `'Property'`. This choice selects how the maximum one-way propagation distance is determined. The maximum one-way propagation distance is used to allocate sufficient memory for delay computation. When you set this property to `'Auto`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

**Default:** `'Auto'`

**`MaximumDistance`**

Maximum one-way propagation distance

Maximum one-way propagation distance, specified as a real-valued positive scalar. Units are meters. This property applies when you set the `MaximumDistanceSource` property to `'Property'`. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance should be greater than or equal to the largest position-to-position distance.

**Default:** `10000`

**`MaximumNumInputSamplesSource`**

Source of maximum number of samples.

The source of the maximum number of samples in the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, specify the maximum number of samples in the input signal using the MaximumNumInputSamples property. Any input signal longer than that value is truncated.

This property applies when you set the MaximumDistanceSource property to 'Property'.

To use this object with variable-size input signals in a MATLAB Function Block in Simulink®, set the MaximumNumInputSamplesSource property to 'Property' and set a value for the MaximumNumInputSamples property.

**Default:** 'Auto'

**MaximumNumInputSamples**

Maximum number of input signal samples.

Maximum number of samples in the input signal, specified as a positive integer. This property limits the size of the input signal. Any input signal longer than this value is truncated. The input signal is the first argument to the step method. The number of samples is the number of rows in the input.

This property applies when you set the MaximumNumInputSamplesSource property to 'Property'.

**Default:** 100

## Methods

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

## Examples

### Signal Propagation from Stationary Radar to Stationary Target

Calculate the amplitude of a signal propagating in free-space from a radar at (1000,0,0) to a target at (300,200,50). Assume both the radar and the target are stationary. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. Transmit five samples of a unit amplitude signal. The signal propagation speed takes the default value of the speed of light. Examine the amplitude of the signal at the target.

```
fs = 8e3;
fop = 3e8;
henv = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Compute the received signal at the target.

```
x = ones(5,1);
y = step(henv,x,...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
```

The first sample is zero because the signal has not yet reached the target.

Manually compute the loss using the formula

$$L = (4\pi R/\lambda)^2$$

```
R = sqrt( (pos1-pos2)'*(pos1-pos2));
lambda = physconst('Lightspeed')/fop;
L = (4*pi*R/lambda)^2
```

```
L = 8.4205e+07
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4205e+07
```

### Signal Propagation from Moving Radar to Moving Target

Calculate the result of propagating a signal in free space from a radar at (1000,0,0) to a target at (300,200,50). Assume the radar moves at 10 m/s along the *x*-axis, while the target moves at 15 m/s along the *y*-axis. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. The signal propagation speed takes the default value of the speed of light. Transmit five samples of a unit amplitude signal and examine the amplitude of the signal at the target.

```
fs = 8000;
fop = 3e8;
sProp = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [10;0;0];
vel2 = [0;15;0];
y = step(sProp,ones(5,1),...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0117 - 0.1083i
   0.0105 - 0.1085i
   0.0094 - 0.1086i
   0.0082 - 0.1087i
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4206e+07
```

# More About

## Freespace Time Delay and Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [2].

# reset

**System object:** phased.FreeSpace
**Package:** phased

Reset internal states of propagation channel

## Syntax

```
reset(H)
```

## Description

reset(H) resets the states of the FreeSpace object, H.

# step

**System object:** `phased.FreeSpace`
**Package:** `phased`

Propagate signal from one location to another

## Syntax

```
Y = step(SFS,F,origin_pos,dest_pos,origin_vel,dest_vel)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(SFS,F,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal `Y` when the narrowband signal `F` propagates in free space from the position or positions specified in `origin_pos` to the position or positions specified in `dest_pos`. For non-polarized signals, either the `origin_pos` or `dest_pos` arguments can specify more than one point. Using both arguments to specify multiple points is not allowed. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# Input Arguments

### SFS — Free-space propagator

System object

Free-space propagator, specified as a System object.

### F — Narrowband signal

*M*-element complex-valued column vector, *M*-by-*N* complex-valued matrix or structure containing complex-valued fields.

Narrowband signal, specified as an *M*-element complex-valued column vector, *M*-by-*N* complex-valued matrix or structure containing complex-valued fields.

| Polarization | Signal structure |
|---|---|
| Not enabled | The signal `X` can be a complex-valued 1-by-*M* column vector or complex-valued *M*-by-*N* matrix. The quantity *M* is the number of sample values of the signal and *N* is the number of signals to propagate. When you specify *N* signals, you need to specify *N* signal origins or *N* signal destinations.<br>The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency. |
| Enabled | The signal `X` is a MATLAB `struct` containing three matrix fields:`X.X`, `X.Y`, and `X.Z` representing the *x*, *y*, and *z* components of the polarized signals.<br>The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency. |

### `origin_pos` —

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. Position units are meters. The quantity *N* is the number of signals arriving from *N* signal origins and matches the dimension specified in the signal `X`. If `origin_pos` is a column vector, it takes the form `[x; y; z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x; y; z]`. `origin_pos` and `dest_pos` cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

### `dest_pos` —

Destination of the signal or signals, specified as a 3-by-1 column vector or 3-by-*N* matrix. Position units are meters. The quantity *N* is the number of signals arriving at *N* signal destinations and matches the dimension specified in the signal `X`. If `dest_pos` is a column vector, it takes the form `[x; y; z]`. If `dest_pos` is a matrix, each column specifies a different destination and has the form `[x; y; z]`. `dest_pos` and `origin_pos` cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

### `origin_vel` —

Velocity of signal origin, specified as a 3-by-1 column vector or 3-by-*N* matrix. Velocity units are meters/second. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx; Vy; Vz]`. If `origin_vel` is a 3–by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx; Vy; Vz]`.

### `dest_vel` —

Velocity of signal destinations, specified as a 3-by-1 column vector or 3–by-*N* matrix. Velocity units are meters/second. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx; Vy; Vz]`. If `dest_vel` is a 3–by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx; Vy; Vz]`.

## Output Arguments

### Y

Propagated signal, returned as a *M*-element complex-valued column vector, *M*-by-*N* complex-valued matrix or MATLAB structure containing complex-valued fields.

If X is a column vector or matrix, Y is also a column vector or matrix with the same dimensions.

If X is a `struct`, Y is also a `struct` with the same fields. Each field in Y contains the resulting signal of the corresponding field in X.

The output Y contains signal samples arriving at the signal destination within the current time frame. The current time frame is defined as the time spanned by the current input. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output contains no contribution from the input of the current time frame.

## Examples

### Signal Propagation from Stationary Radar to Stationary Target

Calculate the amplitude of a signal propagating in free-space from a radar at (1000,0,0) to a target at (300,200,50). Assume both the radar and the target are stationary. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. Transmit five samples of a unit amplitude signal. The signal propagation speed takes the default value of the speed of light. Examine the amplitude of the signal at the target.

```
fs = 8e3;
fop = 3e8;
henv = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Compute the received signal at the target.

```
x = ones(5,1);
y = step(henv,x,...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
```

The first sample is zero because the signal has not yet reached the target.

Manually compute the loss using the formula

$$L = (4\pi R/\lambda)^2$$

```
R = sqrt( (pos1-pos2)'*(pos1-pos2));
lambda = physconst('Lightspeed')/fop;
L = (4*pi*R/lambda)^2
```

```
L = 8.4205e+07
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4205e+07
```

### Signal Propagation from Moving Radar to Moving Target

Calculate the result of propagating a signal in free space from a radar at (1000,0,0) to a target at (300,200,50). Assume the radar moves at 10 m/s along the *x*-axis, while the target moves at 15 m/s along the *y*-axis. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. The signal propagation speed takes the default value of the speed of light. Transmit five samples of a unit amplitude signal and examine the amplitude of the signal at the target.

```
fs = 8000;
fop = 3e8;
sProp = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [10;0;0];
vel2 = [0;15;0];
y = step(sProp,ones(5,1),...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0117 - 0.1083i
   0.0105 - 0.1085i
   0.0094 - 0.1086i
   0.0082 - 0.1087i
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4206e+07
```

### Propagation of Polarized Field from Source to Target

Create a uniform linear array (ULA) consisting of four short-dipole antenna elements that support polarization. Set the orientation of each dipole to the z-direction. Set the operating frequency to 300 MHz and the element spacing of the array to 0.4 meters. While the antenna element supports polarization, you must explicitly enable polarization in the Radiator System object.

Create the short-dipole antenna element, ULA array, and radiator System objects. Set the `CombineRadiatedSignals` property to `true` to coherently combine the radiated signals from all antennas and the Polarization property to 'Combined' to process polarized waves.

```
freq = 300e6;
nsensors = 4;
c = physconst('LightSpeed');
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 900e6],...
    'AxisDirection','Z');
array = phased.ULA('Element',antenna,...
    'NumElements',nsensors,...
    'ElementSpacing',0.4);
radiator = phased.Radiator('Sensor',array,...
    'PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'CombineRadiatedSignals',true,...
    'Polarization','Combined',...
    'WeightsInputPort',true);
```

Create a signal to be radiated. In this case, the signal consists of one cycle of a 4 kHz sinusoid. Set the signal amplitude to unity. Set the sampling frequency to 8 kHz. Choose a radiating angles of 0 degrees azimuth and 20 degrees elevation. polarization, you must set a local axes - in this case chosen to coincide with the global axes. Set uniform weights on the elements of the array.

```
fsig = 4000;
fs = 8000;
A = 1;
t = [0:0.01:2]/fs;
signal = A*sin(2*pi*fsig*t');
radiatingAngles = [0;20];
laxes = ones(3,3);
y = radiator(signal,radiatingAngles,laxes,[1,1,1,1].');
disp(y)
```

```
    X: [201x1 double]
    Y: [201x1 double]
    Z: [201x1 double]
```

The radiated signal is a struct containing the polarized field.

Use a FreeSpace System object to propagate the field from the origin to the destination.

```
propagator = phased.FreeSpace('PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'TwoWayPropagation',false,...
    'SampleRate',fs);
```

Set the signal origin, signal origin velocity, signal destination, and signal destination velocity.

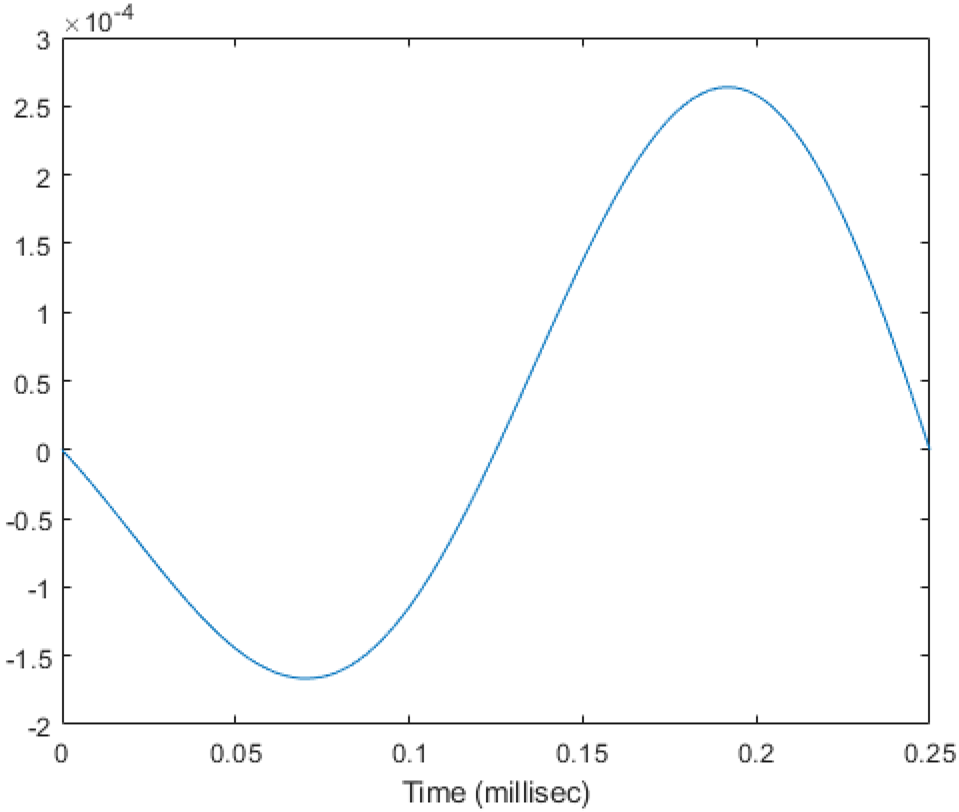
```
origin_pos = [0; 0; 0];
dest_pos = [500; 200; 50];
origin_vel = [10; 0; 0];
dest_vel = [0; 15; 0];
```

Call the FreeSpace object to propagate the signals.

```
yprop = propagator(y,origin_pos,dest_pos,...
    origin_vel,dest_vel);
```

Plot the x-component of the propagated signals.

```
figure
plot(1000*t,real(yprop.X))
xlabel('Time (millisec)')
```



### Propagate Signal to Multiple Destinations

Create a FreeSpace System object to propagate a signal from one point to multiple points in space. Start by defining a signal origin and three destination points, all at different ranges.

Compute the propagation direction angles from the source to the destination locations. The source and destination are stationary.

```
pos1 = [0,0,0]';
vel1 = [0,0,0]';
```

```
pos2 = [[700;700;100],[1400;1400;200],2*[2100;2100;400]];
vel2 = zeros(size(pos2));
[rngs,radiatingAngles] = rangeangle(pos2,pos1);
```

Create the cosine antenna element, ULA array, and Radiator System objects.

```
fs = 8000;
freq = 300e6;
nsensors = 4;
sAnt = phased.CosineAntennaElement;
sArray = phased.ULA('Element',sAnt,'NumElements',nsensors);
sRad = phased.Radiator('Sensor',sArray,...
    'OperatingFrequency',freq,...
    'CombineRadiatedSignals',true,'WeightsInputPort',true);
```

Create a signal to be one cycle of a sinusoid of amplitude one and having a frequency of 4 kHz.

```
fsig = 4000;
t = [0:0.01:2]'/fs;
signal = sin(2*pi*fsig*t);
```

Radiate the signals in the destination directions. Apply a uniform weighting to the array.

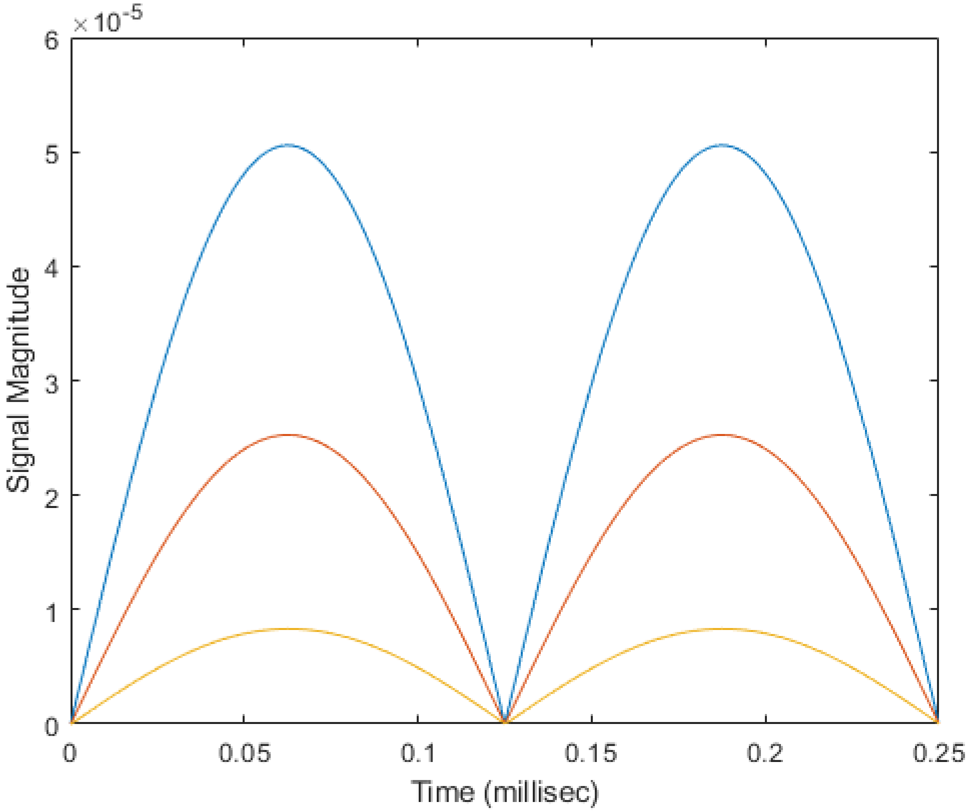
```
y = step(sRad,signal,radiatingAngles,[1,1,1,1].');
```

Propagate the signals to the destination points.

```
sFSp = phased.FreeSpace('OperatingFrequency',freq,'SampleRate',fs);
yprop = step(sFSp,y,pos1,pos2,vel1,vel2);
```

Plot the propagated signal magnitudes for each range.

```
figure
plot(1000*t,abs(yprop(:,1)),1000*t,abs(yprop(:,2)),1000*t,abs(yprop(:,3)))
ylabel('Signal Magnitude')
xlabel('Time (millisec)')
```



## Algorithms

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t\text{-}\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

For further details, see [2].

# phased.FrostBeamformer

**Package:** phased

Frost beamformer

## Description

The phased.FrostBeamformer object implements a Frost beamformer. A Frost beamformer consists of a time-domain MVDR beamformer combined with a bank of FIR filters. The beamformer steers the beam towards a given direction while the FIR filters preserve the input signal power.

To compute the beamformed signal:

1. Create the phased.FrostBeamformer object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
beamformer = phased.FrostBeamformer
beamformer = phased.FrostBeamformer(Name,Value)
```

### Description

beamformer = phased.FrostBeamformer creates a Frost beamformer System object, beamformer, with default property values.

beamformer = phased.FrostBeamformer(Name,Value) creates a Frost beamformer object, beamformer, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `beamformer = phased.FrostBeamformer('SensorArray',phased.ULA('NumElements',20),'SampleRate',300e3)` sets the sensor array to a uniform linear array (ULA) with default ULA property values except for the number of elements. The beamformer has a sample rate of 300 kHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**`SensorArray` — Sensor array**
phased.ULA array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object. The array cannot contain subarrays.

Example: `phased.URA`

**`PropagationSpeed` — Signal propagation speed**
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

**`SampleRate` — Sample rate of signal**
`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: 1e6

Data Types: single | double

### FilterLength — FIR filter length

2 (default) | positive integer

Length of FIR filter for each sensor element, specified as a positive integer.

Example: 7

Data Types: single | double

### DiagonalLoadingFactor — Diagonal loading factor

0 (default) | nonnegative scalar

Diagonal loading factor, specified as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample size is small. A small sample size can lead to an inaccurate estimate of the covariance matrix. Diagonal loading also provides robustness due to steering vector errors. The diagonal loading technique adds a positive scalar multiple of the identity matrix to the sample covariance matrix.

**Tunable:** Yes

Data Types: single | double

### TrainingInputPort — Enable training data input

false (default) | true

Enable training data input, specified as false or true. When you set this property to true, use the training data input argument, XT, when running the object. Set this property to false to use the input data, X, as the training data.

Data Types: logical

### DirectionSource — Source of beamforming direction

'Property' (default) | 'Input port'

Source of beamforming direction, specified as 'Property' or 'Input port'. Specify whether the beamforming direction comes from the Direction property of this object or from the input argument, ANG. Values of this property are:

| | |
|---|---|
| 'Property' | Specify the beamforming direction using the Direction property. |
| 'Input port' | Specify the beamforming direction using the input argument, ANG. |

Data Types: char

### Direction — Beamforming directions

[0;0] (default) | real-valued 2-by-1 vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 vector or a real-valued 2-by-*L* matrix. For a matrix, each column specifies a different beamforming direction. Each column has the form [AzimuthAngle;ElevationAngle]. Azimuth angles must lie between –180° and 180° and elevation angles must lie between –90° and 90°. All angles are defined with respect to the local coordinate system of the array. Units are in degrees.

Example: [40;30]

**Dependencies**

To enable this property, set the DirectionSource property to 'Property'.

Data Types: single | double

### WeightsOutputPort — Enable beamforming weights output

false (default) | true

Enable the output of beamforming weights, specified as false or true. To obtain the beamforming weights, set this property to true and use the corresponding output argument, W. If you do not want to obtain the weights, set this property to false.

Data Types: logical

# Usage

# Syntax

```
Y = beamformer(X)
Y = beamformer(X,XT)
Y = beamformer(X,ANG)
```

```
Y = beamformer(X,XT,ANG)
[Y,W] = beamformer( ___ )
```

## Description

`Y = beamformer(X)` performs Frost beamforming on the input, `X`, and returns the beamformed output, `Y`. This syntax uses the input data, `X`, as training samples to calculate the beamforming weights.

`Y = beamformer(X,XT)` uses `XT` as training data to calculate the beamforming weights. To use this syntax, set the TrainingInputPort property to `true`.

`Y = beamformer(X,ANG)` uses `ANG` as the beamforming direction. To use this syntax, set the DirectionSource property to `'Input port'`.

`Y = beamformer(X,XT,ANG)` combines all input arguments. To use this syntax, set the TrainingInputPort property to `true` and set the DirectionSource property to `'Input port'`.

`[Y,W] = beamformer( ___ )` returns the beamforming weights, `W`. To use this syntax, set the WeightsOutputPort property to `true`.

## Input Arguments

### X — Input signal

complex-valued *M*-by-*N* matrix

Input signal, specified as a complex-valued *M*-by-*N* matrix. *M* is the signal length and *N* is the number of array elements specified in the SensorArray property. *M* must be larger than the length of the filter specified by the FilterLength property.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`
Complex Number Support: Yes

### XT — Training data

complex-valued *M*-by-*N* matrix

Training data, specified as a complex-valued *M*-by-*N* matrix. *M* and *N* are equal to the values for X.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1 0.5 2.6; 2 -0.2 0; 3 -2 -1]`

#### Dependencies

To enable this argument, set the TrainingInputPort property to `true`.

Data Types: `single` | `double`
Complex Number Support: Yes

### `ANG` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 column vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 column vector The vector has the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees. The azimuth angle must lie between –180° and 180°, and the elevation angle must lie between –90° and 90°.

Example: `[40;10]`

#### Dependencies

To enable this argument, set the DirectionSource property to `'Input port'`.

Data Types: `double`

## Output Arguments

### Y — Beamformed output

complex-valued 1-by-*M* vector

Beamformed output, returned as a complex-valued 1-by-*M*vector, where *M* is the number of rows of the input X.

Data Types: `single` | `double`
Complex Number Support: Yes

### `W` — Beamforming weights

complex-valued *L*-by-1 vector.

Beamforming weights, returned as a complex-valued *L*-by-1 vector where *L* is the number of degrees of freedom of the beamformer. The number of degrees of freedom is given by the product of the number of elements specified by the SensorArray property and the FIR filter length specified by FilterLength property.

**Dependencies**

To enable this output, set the WeightsOutputPort property to `true`.

Data Types: `single` | `double`
Complex Number Support: Yes

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Apply Frost Beamforming to ULA

Apply Frost beamforming to an 11-element acoustic ULA array. The incident angle of the incoming signal is -50 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is assumed to be 340 m/sec. The signal has added gaussian white noise.

Simulate the signal.

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.04);
array.Element.FrequencyRange = [20 20000];
fs = 8e3;
```

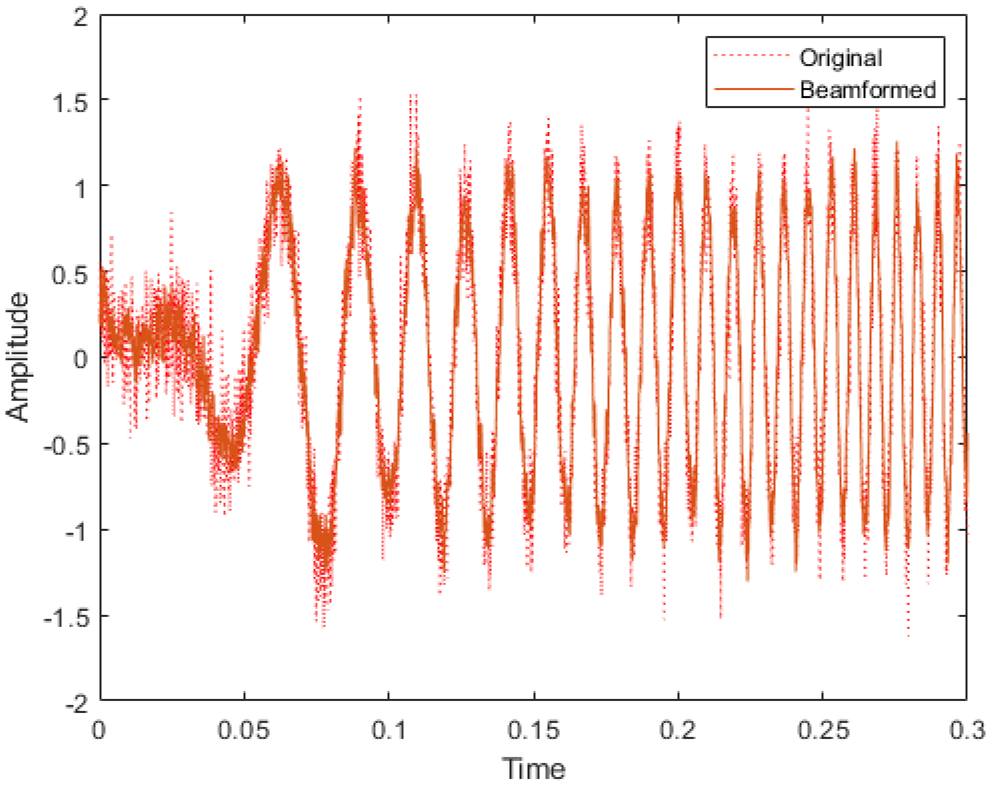
```
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false,'NumSubbands',8192);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Beamform the signal.

```
beamformer = phased.FrostBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'Direction',incidentAngle,'FilterLength',5);
y = beamformer(rx);
```

Plot the beamformed output.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



### Find Frost Beamforming Weights

Find the beamformer weights of a Frost beamforming applied to signals received at a 7-element acoustic ULA array. The incident angle of the incoming signal is $-20^\circ$ in azimuth and $30^\circ$ in elevation. The signal has added gaussian white noise. The speed of sound in air is assumed to be 340 m/s. Use a filter length of 15.

First, create the signal.

```
numelements = 7;
element = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[50,10000]);
```

```
array = phased.ULA('Element',element,'NumElements',numelements,'ElementSpacing',0.04);
fs = 8e3;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340.0;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false,'NumSubbands',8192);
incidentAngle = [-20;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Create a beamformer with a filter length of 15. Then, beamform the arriving signal and obtain the beamformer weights.

```
filterlength = 15;
beamformer = phased.FrostBeamformer('SensorArray',array, ...
    'PropagationSpeed',c,'SampleRate',fs,'WeightsOutputPort',true, ...
    'Direction',incidentAngle,'FilterLength',filterlength);
[y,wt] = beamformer(rx);
size(wt)
```

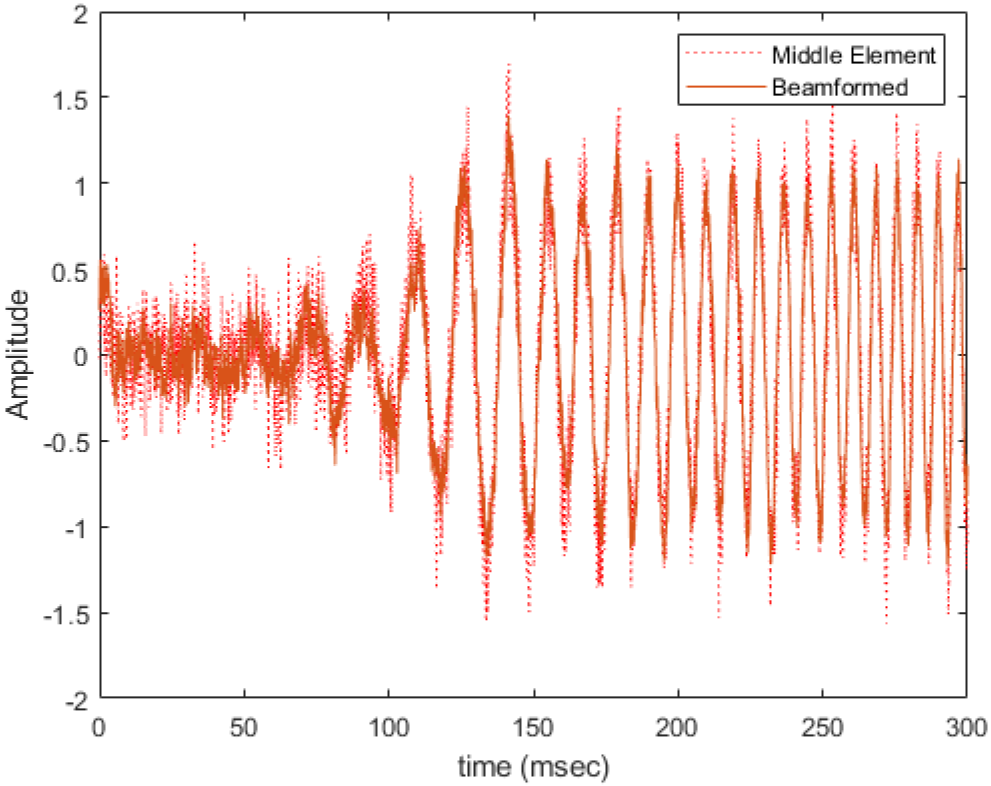
```
ans = 1×2

   105     1
```

There are 7*15 = 105 weights computed as expected.

Compare the beamformed output with the signal arriving at the middle element of the array.

```
plot(1000*t,rx(:,4),'r:',1000*t,y)
xlabel('time (msec)')
ylabel('Amplitude')
legend('Middle Element','Beamformed')
```



## Algorithms

`phased.FrostBeamformer` uses a beamforming algorithm proposed by Frost. It can be considered the time-domain counterpart of the minimum variance distortionless response (MVDR) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the distortionless response constraint. The filter is specific to each sensor.

3 This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

For more information about Frost beamforming, see [1].

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Requires dynamic memory allocation. See “Limitations for System Objects that Require Dynamic Memory Allocation”.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2012a**

# step

**System object:** phased.FrostBeamformer
**Package:** phased

Perform Frost beamforming

## Syntax

```
Y = step(H,X)
Y = step(H,X,XT)
Y = step(H,X,ANG)
Y = step(H,X,XT,ANG)
[Y,W] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) performs Frost beamforming on the input, X, and returns the beamformed output in Y.

Y = step(H,X,XT) uses XT as the training samples to calculate the beamforming weights. This syntax is available when you set the TrainingInputPort property to true.

Y = step(H,X,ANG) uses ANG as the beamforming direction. This syntax is available when you set the DirectionSource property to 'Input port'.

Y = step(H,X,XT,ANG) combines all input arguments. This syntax is available when you set the TrainingInputPort property to true and set the DirectionSource property to 'Input port'.

`[Y,W] = step(___)` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**H**

Beamformer object.

**X**

Input signal, specified as an *M*-by-*N* matrix. *M* must be larger than the FIR filter length specified in the `FilterLength` property. *N* is the number of elements in the sensor array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**XT**

Training samples, specified as an *M*-by-*N* matrix. *M* and *N* have the same dimensions as `X`.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**ANG**

Beamforming directions, specified as a length-2 column vector. The vector has the form `[AzimuthAngle; ElevationAngle]`, in degrees. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

# Output Arguments

**Y**

Beamformed output. Y is a column vector of length *M*, where *M* is the number of rows in X.

**W**

Beamforming weights. W is a column vector of length *L*, where *L* is the degrees of freedom of the beamformer. For a Frost beamformer, H, *L* is given by the product of the number of elements in the array and the FIR filter length.

# Examples

### Apply Frost Beamforming to ULA

Apply Frost beamforming to an 11-element acoustic ULA array. The incident angle of the incoming signal is -50 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is assumed to be 340 m/sec. The signal has added gaussian white noise.

Simulate the signal.

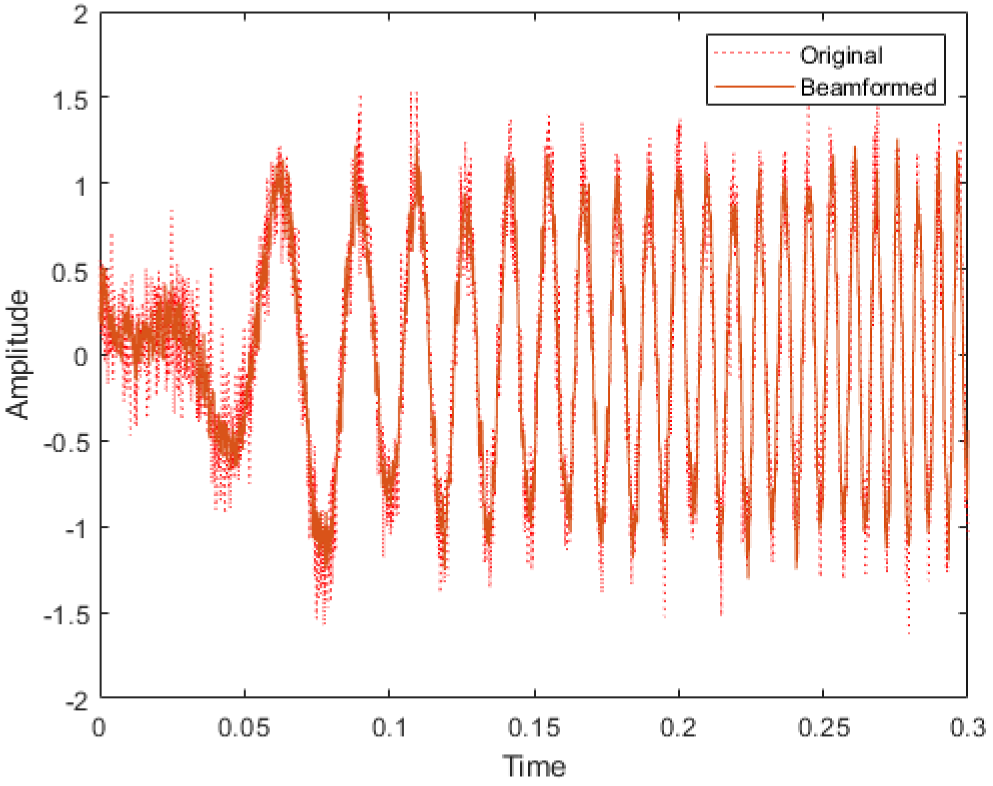
```
array = phased.ULA('NumElements',11,'ElementSpacing',0.04);
array.Element.FrequencyRange = [20 20000];
fs = 8e3;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false,'NumSubbands',8192);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Beamform the signal.

```
beamformer = phased.FrostBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'Direction',incidentAngle,'FilterLength',5);
y = beamformer(rx);
```

Plot the beamformed output.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



## Algorithms

`phased.FrostBeamformer` uses a beamforming algorithm proposed by Frost. It can be considered the time-domain counterpart of the minimum variance distortionless response (MVDR) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the distortionless response constraint. The filter is specific to each sensor.

For further details, see [1].

# phased.gpu.ConstantGammaClutter

**Package:** `phased.gpu`

Simulate constant-gamma clutter using GPU

## Description

The `phased.gpu.ConstantGammaClutter` object simulates clutter, performing the computations on a GPU.

**Note** To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

To compute the clutter return:

1. Define and set up your clutter simulator. See “Construction” on page 1-703.
2. Call `step` to simulate the clutter return for your system according to the properties of `phased.gpu.ConstantGammaClutter`. The behavior of `step` is specific to each object in the toolbox.

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. Coherence time indicates how frequently the software changes the set of random numbers in the clutter simulation.
- Because the signal is narrowband, the spatial response and Doppler shift can be approximated by phase shifts.
- The radar system maintains a constant height during simulation.

- The radar system maintains a constant speed during simulation.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.gpu.ConstantGammaClutter` creates a constant-gamma clutter simulation System object, `H`. This object simulates the clutter return of a monostatic radar system using the constant gamma model.

`H = phased.gpu.ConstantGammaClutter(Name,Value)` creates a constant gamma clutter simulation object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name on page 1-703, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

## Properties

### `Sensor`

Handle of sensor

Specify the sensor as an antenna element object or as an array object whose `Element` property value is an antenna element object. If the sensor is an array, it can contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

**Default:** `3e8`

### `SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The default value corresponds to 1 MHz.

**Default:** `1e6`

### `PRF`

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The*PRF* must satisfy these restrictions:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of `PRF` must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* using property settings alone or using property settings in conjunction with the `prfidx` input argument of the `step` method.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties only. You can
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this

vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.

- When PRFSelectionInputPort is true, you can implement a selectable *PRF* by specifying PRF as a row vector with positive real-valued entries. But this time, when you execute the step method, select a *PRF* by passing an argument specifying an index into the *PRF* vector.

In all cases, the number of output samples is fixed when you set the OutputFormat property to 'Samples'. When you use a varying *PRF* and set the OutputFormat property to 'Pulses', the number of samples can vary.

**Default:** 10e3

**PRFSelectionInputPort**

Enable PRF selection input

Enable the PRF selection input, specified as true or false. When you set this property to false, the step method uses the values set in the PRF property. When you set this property to true, you pass an index argument into the step method to select a value from the PRF vector.

**Default:** false

**Gamma**

Terrain gamma value

Specify the $\gamma$ value used in the constant $\gamma$ clutter model, as a scalar in decibels. The $\gamma$ value depends on both terrain type and the operating frequency.

**Default:** 0

**EarthModel**

Earth model

Specify the earth model used in clutter simulation as one of | 'Flat' | 'Curved' |. When you set this property to 'Flat', the earth is assumed to be a flat plane. When you set this property to 'Curved', the earth is assumed to be a sphere.

**Default:** 'Flat'

### `PlatformHeight`

Radar platform height from surface

Specify the radar platform height (in meters) measured upward from the surface as a nonnegative scalar.

**Default:** `300`

### `PlatformSpeed`

Radar platform speed

Specify the radar platform’s speed as a nonnegative scalar in meters per second.

**Default:** `300`

### `PlatformDirection`

Direction of radar platform motion

Specify the direction of radar platform motion as a 2-by-1 vector in the form [AzimuthAngle; ElevationAngle] in degrees. The default value of this property indicates that the platform moves perpendicular to the radar antenna array’s broadside.

Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180 and 180 degrees. Elevation angle must be between –90 and 90 degrees.

**Default:** `[90;0]`

### `BroadsideDepressionAngle`

Depression angle of array broadside

Specify the depression angle in degrees of the broadside of the radar antenna array. This value is a scalar. The broadside is defined as zero degrees azimuth and zero degrees elevation. The depression angle is measured downward from horizontal.

**Default:** `0`

### `MaximumRange`

Maximum range for clutter simulation

Specify the maximum range in meters for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the `PlatformHeight` property.

**Default:** `5000`

### `AzimuthCoverage`

Azimuth coverage for clutter simulation

Specify the azimuth coverage in degrees as a positive scalar. The clutter simulation covers a region having the specified azimuth span, symmetric to 0 degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but the `PatchAzimuthWidth` value can cause some patches to extend beyond the region.

**Default:** `60`

### `PatchAzimuthWidth`

Azimuth span of each clutter patch

Specify the azimuth span of each clutter patch in degrees as a positive scalar.

**Default:** `1`

### `TransmitSignalInputPort`

Add input to specify transmit signal

Set this property to `true` to add input to specify the transmit signal in the `step` syntax. Set this property to `false` omit the transmit signal in the `step` syntax. The `false` option is less computationally expensive; to use this option, you must also specify the `TransmitERP` property.

**Default:** `false`

### `TransmitERP`

Effective transmitted power

Specify the transmitted effective radiated power (ERP) of the radar system in watts as a positive scalar. This property applies only when you set the `TransmitSignalInputPort` property to `false`.

**Default:** `5000`

**`CoherenceTime`**

Clutter coherence time

Specify the coherence time in seconds for the clutter simulation as a positive scalar. After the coherence time elapses, the `step` method updates the random numbers it uses for the clutter simulation at the next pulse. A value of `inf` means the random numbers are never updated.

**Default:** `inf`

**`OutputFormat`**

Output signal format

Specify the format of the output signal as one of | `'Pulses'` | `'Samples'` |. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method is in the form of multiple pulses. In this case, the number of pulses is the value of the `NumPulses` property.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of samples is the value of the `NumSamples` property. In staggered PRF applications, you might find the `'Samples'` option more convenient because the `step` output always has the same matrix size.

**Default:** `'Pulses'`

**`NumPulses`**

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

**Default:** `1`

**`NumSamples`**

Number of output samples

Specify the number of output samples of the `step` method as a positive integer. Typically, you use the number of samples in one pulse. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

**`SeedSource`**

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

| | |
|---|---|
| `'Auto'` | Random numbers come from the global GPU random number stream.<br>`'Auto'` is appropriate in a variety of situations. In particular, if you want to use a generator algorithm other than `mrg32k3a`, set `SeedSource` to `'Auto'`. Then, configure the global GPU random number stream to use the generator of your choice. You can configure the global GPU random number stream using `parallel.gpu.RandStream` and `parallel.gpu.RandStream.setGlobalStream`. |
| `'Property'` | Random numbers come from a private stream of random numbers. The stream uses the `mrg32k3a` generator algorithm, with a seed specified in the `Seed` property of this object.<br>If you do not want clutter computations to affect the global GPU random number stream, set `SeedSource` to `'Property'`. |

**Default:** `'Auto'`

**`Seed`**

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}$–1. This property applies when you set the `SeedSource` property to `'Property'`.

**Default:** `0`

## Methods

| | |
|---|---|
| reset | Reset random numbers and time count for clutter simulation |
| step | Simulate clutter using constant gamma model |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### GPU Clutter Simulation of Radar System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kW.

Set up the characteristics of the radar system. This system uses a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300e6;
lambda = c/fc;
array = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1e6;
prf = 10e3;
height = 1000.0;
direction = [90;0];
speed = 2.0e3;
depang = 30.0;
```

Create the GPU clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

```
Rmax = 5000;
Azcov = 120;
```

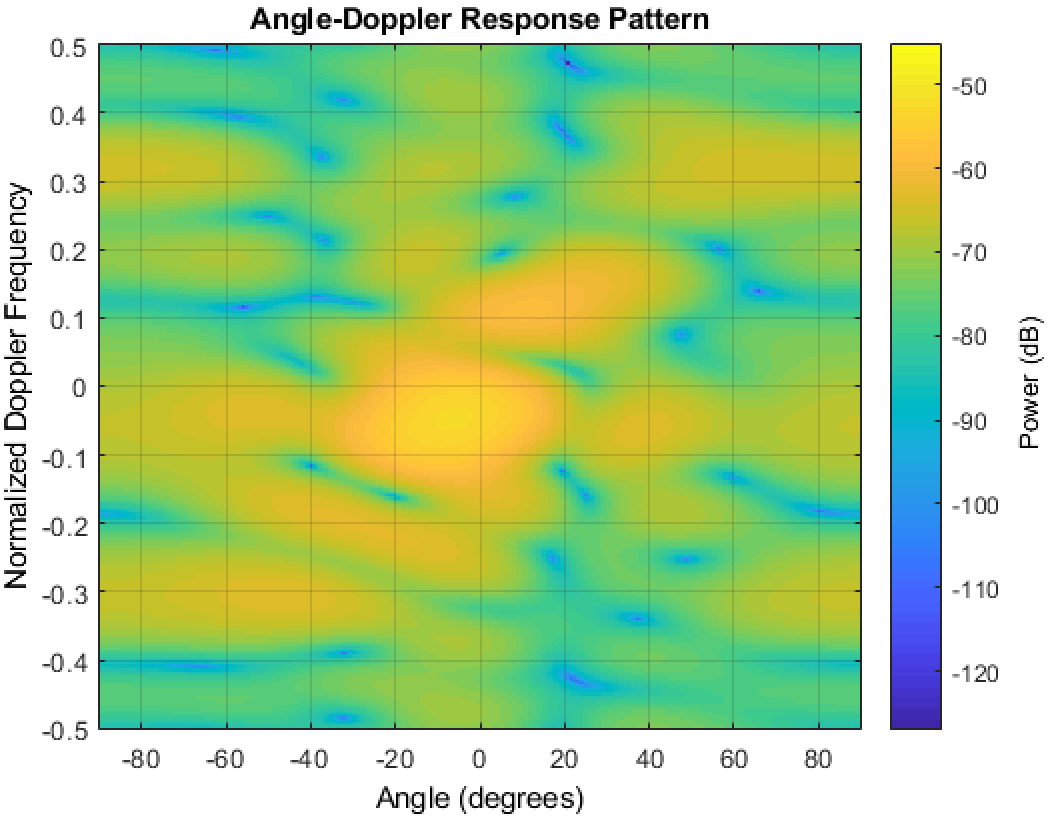
```
tergamma = 0;
tpower = 5000;
clutter = phased.gpu.ConstantGammaClutter('Sensor',array, ...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf, ...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat' ,...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction, ...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax, ...
    'AzimuthCoverage',Azcov,'SeedSource','Property', ...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf;
Npulse = 10;
clsig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    clsig(:,:,m) = clutter();
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',array, ...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(clsig(20,:,:)),'NormalizeDoppler',true);
```



The results are not identical to the results obtained by using `phased.ConstantGammaClutter` because of differences between CPU and GPU computations.

### GPU Clutter Simulation With Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. You input the transmit signal of the radar system when creating clutter. In this case, you do not specify the effective transmitted power of the signal in a property.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
ha = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1e6;
prf = 10e3;
height = 1000;
direction = [90;0];
speed = 2000;
depang = 30;
```

Create the GPU clutter simulation object and configure it to take a transmitted signal as an input argument. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

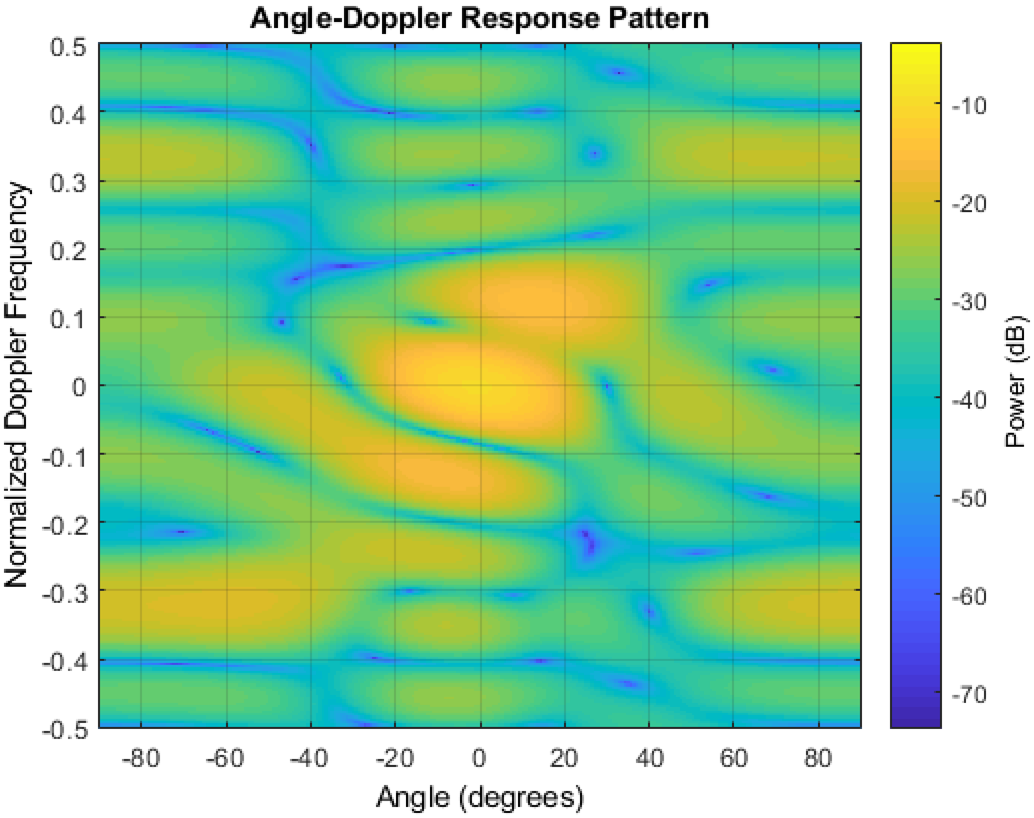
```
Rmax = 5000;
Azcov = 120;
tergamma = 0;
clutter = phased.gpu.ConstantGammaClutter('Sensor',ha,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property','Seed',40547);
```

Simulate the clutter return for 10 pulses. At each object call, pass the transmit signal as an input argument. The software automatically computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 μs.

```
tpower = 5000;
pw = 2e-6;
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf;
Npulse = 10;
clsig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    clsig(:,:,m) = clutter(X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',ha,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(clsig(20,:,:)),...
    'NormalizeDoppler',true);
```



The results are not identical to the results obtained by using phased.ConstantGammaClutter because of differences between CPU and GPU computations.

### Random Number Comparison Between GPU and CPU

In most cases, it does not matter that the GPU and CPU use different random numbers. Sometimes, you may need to reproduce the same stream on both GPU and CPU. In such cases, you can set up the two global streams so they produce identical random numbers. Both GPU and CPU support the combined multiple recursive generator (`mrg32k3a`) with the `NormalTransform` parameter set to `'Inversion'`.

Define a seed value to use for both the GPU stream and the CPU stream.

```
seed = 7151;
```

Create a CPU random number stream that uses the combined multiple recursive generator and the chosen seed value. Then, use this stream as the global stream for random number generation on the CPU.

```
stream_cpu = RandStream('CombRecursive','Seed',seed, ...
    'NormalTransform','Inversion');
RandStream.setGlobalStream(stream_cpu);
```

Create a GPU random number stream that uses the combined multiple recursive generator and the same seed value. Then, use this stream as the global stream for random number generation on the GPU.

```
stream_gpu = parallel.gpu.RandStream('CombRecursive','Seed',seed, ...
    'NormalTransform','Inversion');
parallel.gpu.RandStream.setGlobalStream(stream_gpu);
```

Generate clutter on both the CPU and the GPU, using the global stream on each platform.

```
clutter_cpu = phased.ConstantGammaClutter('SeedSource','Auto');
clutter_gpu = phased.gpu.ConstantGammaClutter('SeedSource','Auto');
cl_cpu = clutter_cpu();
cl_gpu = clutter_gpu();
```

Check that the element-wise differences between the CPU and GPU results are negligible.

```
maxdiff = max(max(abs(cl_cpu - cl_gpu)))
eps
```

```
maxdiff =

   4.6709e-18
```

```
ans =

   2.2204e-16
```

# reset

**System object:** `phased.gpu.ConstantGammaClutter`
**Package:** `phased.gpu`

Reset random numbers and time count for clutter simulation

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `ConstantGammaClutter` object, `H`. This method resets the random number generator state if the `SeedSource` property is set to `'Property'`. This method resets the elapsed coherence time. Also, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

# step

**System object:** `phased.gpu.ConstantGammaClutter`
**Package:** `phased.gpu`

Simulate clutter using constant gamma model

## Syntax

```
Y = step(H)
Y = step(H,X)
Y = step(H,STEERANGLE)
Y = step(H,WS)
Y = step(H,PRFIDX)
Y = step(H,X,STEERANGLE)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` computes the collected clutter return at each sensor. This syntax is available when you set the `TransmitSignalInputPort` property to `false`.

`Y = step(H,X)` specifies the transmit signal in `X`. Transmit signal refers to the output of the transmitter while it is on during a given pulse. This syntax is available when you set the `TransmitSignalInputPort` property to `true`.

`Y = step(H,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Y = step(H,WS) uses WS as weights applied to each element within each subarray. To use this syntax, set the Sensor property to an array that supports subarrays and set the SubarraySteering property of the array to 'Custom'.

Y = step(H,PRFIDX) uses the index, PRFIDX, to select the PRF from a predetermined list of PRFs specified by the PRF property. To enable this syntax, set the PRFSelectionInputPort to true.

Y = step(H,X,STEERANGLE) combines all input arguments. This syntax is available when you configure H so that H.TransmitSignalInputPort is true, H.Sensor is an array that contains subarrays, and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

## Input Arguments

**H**

Constant gamma clutter object.

**X**

Transmit signal, specified as a column vector of data type double. The System object handles data transfer between the CPU and GPU.

**STEERANGLE**

Subarray steering angle in degrees. STEERANGLE can be a length-2 column vector or a scalar.

If STEERANGLE is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 degrees and 180 degrees, and the elevation angle must be between –90 degrees and 90 degrees.

If STEERANGLE is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

**WS**

Subarray element weights

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray Element Weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | When subarrays do not have the same dimensions and sizes, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

**Dependencies**

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

### `PRFIDX`

Index of pulse repetition frequency, specified as a positive integer. The index selects one of the entries specified in the `PRF` property as the PRF for the next transmission.

Example: 4

**Dependencies**

To enable this argument, set the PRFSelectionInputPort to true.

## Output Arguments

**Y**

Collected clutter return at each sensor. Y has dimensions $N$-by-$M$ matrix. If H.Sensor contains subarrays, $M$ is the number of subarrays in the radar system. Otherwise it is the number of sensors. When you set the OutputFormat property to 'Samples', $N$ is defined by the NumSamples property. When you set the OutputFormat property to 'Pulses', $N$ is the total number of samples in the next $L$ pulses. In this case, $L$ is defined by the NumPulses property.

## Examples

### GPU Clutter Simulation of Radar System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kW.

Set up the characteristics of the radar system. This system uses a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300e6;
lambda = c/fc;
array = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1e6;
prf = 10e3;
height = 1000.0;
direction = [90;0];
```

```
speed = 2.0e3;
depang = 30.0;
```

Create the GPU clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

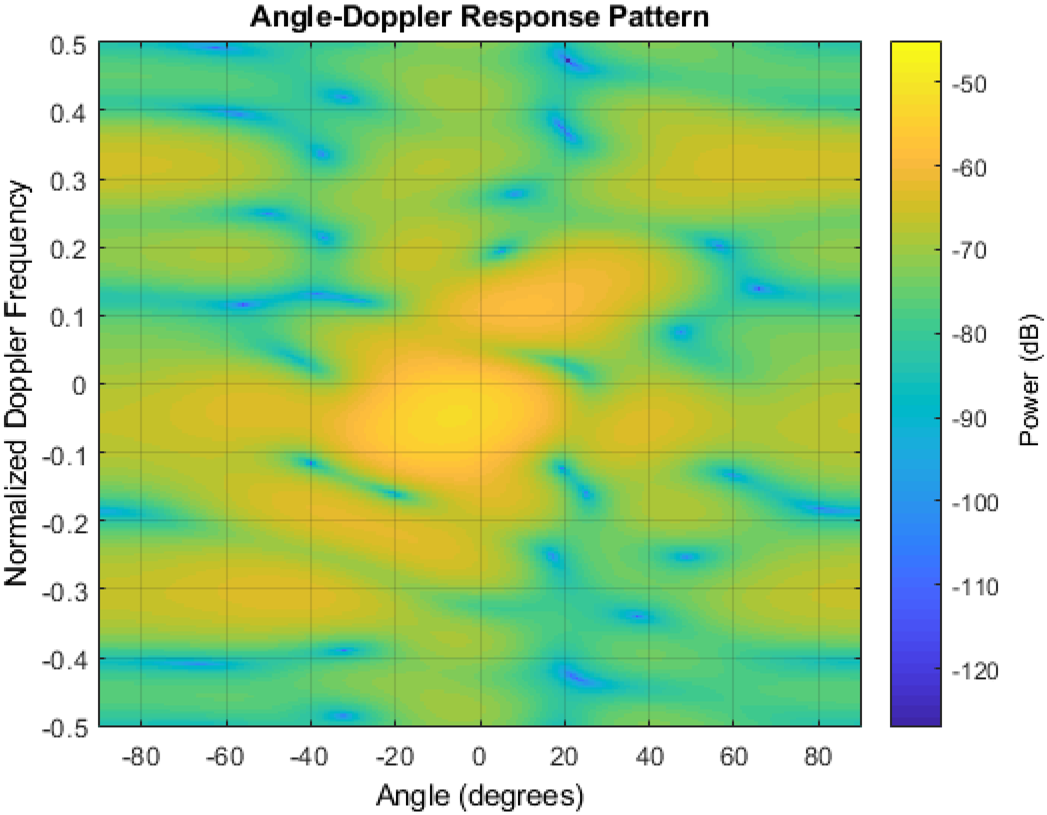
```
Rmax = 5000;
Azcov = 120;
tergamma = 0;
tpower = 5000;
clutter = phased.gpu.ConstantGammaClutter('Sensor',array, ...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf, ...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat' ,...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction, ...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax, ...
    'AzimuthCoverage',Azcov,'SeedSource','Property', ...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf;
Npulse = 10;
clsig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    clsig(:,:,m) = clutter();
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',array, ...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(clsig(20,:,:)),'NormalizeDoppler',true);
```



The results are not identical to the results obtained by using `phased.ConstantGammaClutter` because of differences between CPU and GPU computations.

### GPU Clutter Simulation With Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. You input the transmit signal of the radar system when creating clutter. In this case, you do not specify the effective transmitted power of the signal in a property.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
ha = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1e6;
prf = 10e3;
height = 1000;
direction = [90;0];
speed = 2000;
depang = 30;
```

Create the GPU clutter simulation object and configure it to take a transmitted signal as an input argument. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

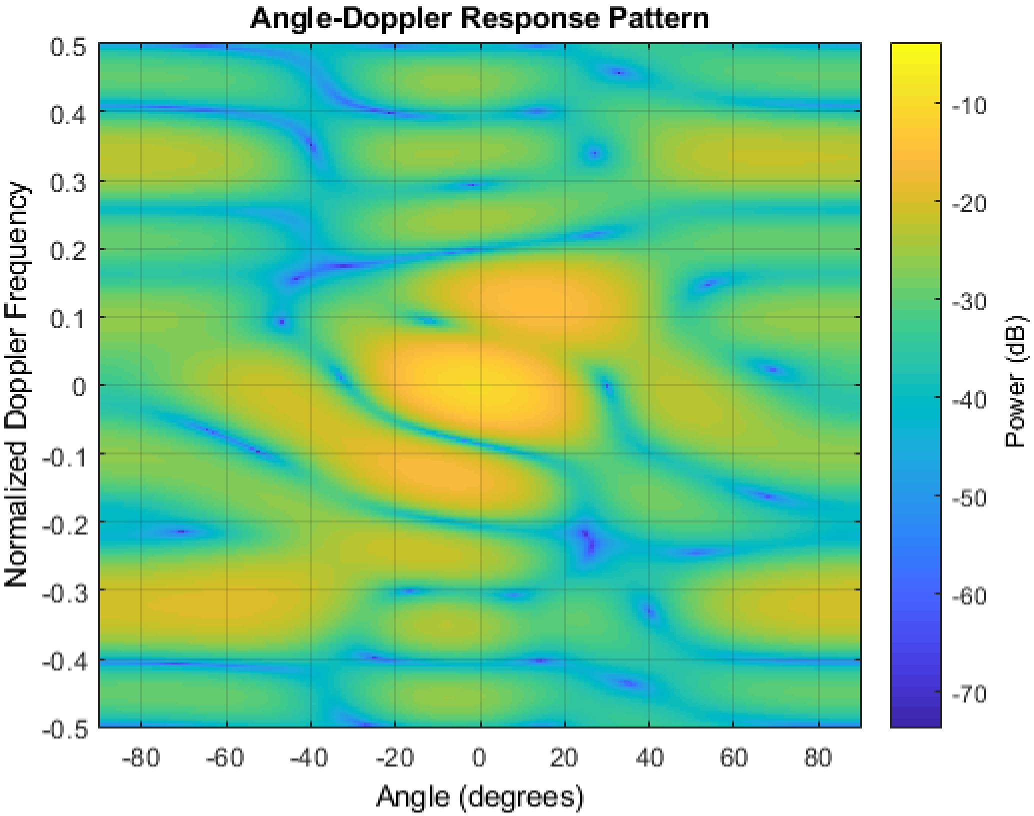
```
Rmax = 5000;
Azcov = 120;
tergamma = 0;
clutter = phased.gpu.ConstantGammaClutter('Sensor',ha,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property','Seed',40547);
```

Simulate the clutter return for 10 pulses. At each object call, pass the transmit signal as an input argument. The software automatically computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 μs.

```
tpower = 5000;
pw = 2e-6;
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf;
Npulse = 10;
clsig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    clsig(:,:,m) = clutter(X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',ha,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(clsig(20,:,:)),...
    'NormalizeDoppler',true);
```



The results are not identical to the results obtained by using phased.ConstantGammaClutter because of differences between CPU and GPU computations.

## Tips

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. Coherence time indicates how frequently the software changes the set of random numbers in the clutter simulation.
- Because the signal is narrowband, the spatial response and Doppler shift can be approximated by phase shifts.
- The radar system maintains a constant height during simulation.
- The radar system maintains a constant speed during simulation.

# phased.GCCEstimator

**Package:** `phased`

Wideband direction of arrival estimation

## Description

The `phased.GCCEstimator` System object creates a direction of arrival estimator for wideband signals. This System object estimates the direction of arrival or time of arrival among sensor array elements using the generalized cross-correlation with phase transform algorithm (GCC-PHAT). The algorithm assumes that all signals propagate from a single source lying in the array far field so the direction of arrival is the same for all sensors. The System object first estimates the correlations between all specified sensor pairs using GCC-PHAT and then finds the largest peak in each correlation. The peak identifies the delay between the signals arriving at each sensor pair. Finally, a least-squares estimate is used to derive the direction of arrival from all estimated delays.

To compute the direction of arrival for pairs of element in the array:

1. Define and set up a GCC-PHAT estimator System object, `phased.GCCEstimator`, using the "Construction" on page 1-727 procedure.
2. Call `step` to compute the direction of arrival of a signal using the properties of the `phased.GCCEstimator` System object.

   The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`sGCC = phased.GCCEstimator` creates a GCC direction of arrival estimator System object, `sGCC`. This object estimates the direction of arrival or time of arrival between sensor array elements using the GCC-PHAT algorithm.

`sGCC = phased.GCCEstimator(Name,Value)` returns a GCC direction of arrival estimator object, `sGCC`, with the specified property `Name` set to the specified `Value`. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Properties

**`SensorArray` — Sensor array**
`phased.ULA` System object (default) | Phased Array System Toolbox sensor array

Sensor array, specified as a Phased Array System Toolbox System object. The array can also consist of subarrays. If you do not specify this property, the default sensor array is a `phased.ULA` System object with default array property values.

Example: `phased.URA`

**`PropagationSpeed` — Signal propagation speed**
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

**`SampleRate` — Signal sample rate**
`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `single` | `double`

**`SensorPairSource` — Source of sensor pairs**
`'Auto'` (default) | `'Property'`

Source of sensor pairs, specified as either `'Auto'` or `'Property'`.

- `'Auto'` — choose this property value to compute correlations between the first sensor and all other sensors. The first sensor of the array is the reference channel.
- `'Property'` — choose this property value when you want to explicitly specify the sensor pairs to be used for computing correlations. Set the sensor pair indices using the `SensorPair` property. You can view the array indices using the `viewArray` method of any array System object.

Example: `'Auto'`

Data Types: `char`

### `SensorPair` — Sensor pairs

`[2;1]` (default) | 2-by-*N* positive integer valued matrix

Sensor pairs used to compute correlations, specified as a 2-by-*N* positive integer-valued matrix. Each column of the matrix specifies a pair of sensors between which the correlation is computed. The second row specifies the reference sensors. Each entry in the matrix must be less than the number of array sensors or subarrays. To use the `SensorPair` property, you must also set the `SensorPairSource` value to `'Property'`.

Example: `[1,3,5;2,4,6]`

Data Types: `double`

### `DelayOutputPort` — Option to enable delay output

`false` (default) | `true`

Option to enable output of time delay values, specified as a Boolean. Set this property to `true` to output the delay values as an output argument of the `step` method. The delays correspond to the arrival angles of a signal between sensor pairs. Set this property to `false` to disable the output of delays.

Example: `false`

Data Types: `logical`

### `CorrelationOutputPort` — Option to enable correlation output

`false` (default) | `true`

Option to enable output of correlation values, specified as a Boolean. Set this property to `true` to output the correlations and lags between sensor pairs as output arguments of the `step` method. Set this property to `false` to disable output of correlations.

Example: false

Data Types: `logical`

## Methods

| | |
|---|---|
| reset | Reset states of phased.GCCEstimator System object |
| step | Estimate direction of arrival using generalized cross-correlation |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### GCC Estimate of Direction of Arrival at Microphone Array

Estimate the direction of arrival of a signal using the GCC-PHAT algorithm. The receiving array is a 5-by-5-element URA microphone array with elements spaced 0.25 meters apart. The arriving signal is a sequence of wideband chirps. The signal arrives from 17� azimuth and 0� elevation. Assume the speed of sound in air is 340 m/s.

Load the chirp signal.

```
load chirp;
c = 340.0;
```

Create the 5-by-5 microphone URA.

```
d = 0.25;
N = 5;
mic = phased.OmnidirectionalMicrophoneElement;
array = phased.URA([N,N],[d,d],'Element',mic);
```

Simulate the incoming signal using the `WidebandCollector` System object�.

```
arrivalAng = [17;0];
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',Fs,'ModulatedInput',false);
signal = collector(y,arrivalAng);
```

Estimate the direction of arrival.

```
estimator = phased.GCCEstimator('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',Fs);
ang = estimator(signal)
```

```
ang = 2×1

   16.4538
   -0.7145
```

# Algorithms

## GCC-PHAT Cross-Correlation Algorithm

You can use generalized cross-correlation to estimate the time difference of arrival of a signal at two different sensors.

A model of a signal emitted by a source and received at two sensors is given by:

$$r_1(t) = s(t) + n_1(t)$$
$$r_2(t) = s(t - D) + n_2(t)$$

where $D$ is the time difference of arrival (*TDOA*), or time lag, of the signal at one sensor with respect to the arrival time at a second sensor. You can estimate the time delay by finding the time lag that maximizes the cross-correlation between the two signals.

From the TDOA, you can estimate the broadside arrival angle of the plane wave with respect to the line connecting the two sensors. For two sensors separated by distance $L$, the broadside arrival angle, “Broadside Angles”, is related to the time lag by

$$\sin\beta = \frac{c\tau}{L}$$

where $c$ is the propagation speed in the medium.

A common method of estimating time delay is to compute the cross-correlation between signals received at two sensors. To identify the time delay, locate the peak in the cross-correlation. When the signal-to-noise ratio (SNR) is large, the correlation peak, $\tau$, corresponds to the actual time delay $D$.

$$R(\tau) = E\{r_1(t)r_2(t+\tau)\}$$

$$\widehat{D} = \underset{\tau}{\operatorname{argmax}} R(\tau)$$

When the correlation function is more sharply peaked, performance improves. You can sharpen a cross correlation peak using a weighting function that whitens the input signals. This technique is called generalized cross-correlation (GCC). One particular weighting function normalizes the signal spectral density by the spectrum magnitude, leading to the generalized cross-correlation phase transform method (*GCC-PHAT*).

$$S(f) = \int_{-\infty}^{\infty} R(\tau) e^{-i2\pi f\tau} d\tau$$

$$\tilde{R}(\tau) = \int_{-\infty}^{\infty} \frac{S(f)}{|S(f)|} e^{+i2\pi f\tau} df$$

$$\tilde{D} = \underset{\tau}{\operatorname{argmax}}\ \tilde{R}(\tau)$$

If you use just two sensor pairs, you can only estimate the broadside angle of arrival. However, if you use multiple pairs of non-collinear sensors, for example, in a URA, you can estimate the arrival azimuth and elevation angles of the plane wave using least-square estimation. For $N$ sensors, you can write the delay time $\tau_{kj}$ of a signal arriving at the $k^{th}$ sensor with respect to the $j^{th}$ sensor by

$$c\tau_{kj} = -\left(\vec{x}_k - \vec{x}_j\right) \cdot \vec{u}$$

$$\vec{u} = \cos\alpha\sin\theta\,\widehat{i} + \sin\alpha\sin\theta\,\widehat{j} + \cos\theta\,\widehat{k}$$

where $u$ is the unit propagation vector of the plane wave. The angles α and θ are the azimuth and elevation angles of the propagation vector. All angles and vectors are defined with respect to the local axes. You can solve the first equation using least-squares to yield the three components of the unit propagation vector. Then, you can solve the second equation for the azimuth and elevation angles.

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If

the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2015b**

# reset

**System object:** phased.GCCEstimator
**Package:** phased

Reset states of phased.GCCEstimator System object

## Syntax

```
reset(S)
```

## Description

reset(S) resets the internal state of the phased.GCCEstimator object, S. This method resets the random number generator state if the SeedSource property is applicable and has the value 'Property'.

## Input Arguments

**S — GCC-PHAT estimator**
phased.GCCEstimator System object

GCC-PHAT estimator, specified as a phased.GCCEstimator System object.

Example: phased.GCCEstimator()

**Introduced in R2015b**

# step

**System object:** `phased.GCCEstimator`
**Package:** `phased`

Estimate direction of arrival using generalized cross-correlation

## Syntax

```
ang = step(sGCC,X)
[ang,tau] = step(sGCC,X)
[ang,R,lag] = step(sGCC,X)
[ang,tau,R,lag] = step(sGCC,X)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ang = step(sGCC,X)` returns the direction of arrival, `ang`, of an input signal `X`. The argument `X` is a matrix specifying the received signals at the elements of the array specified in the `SensorArray` property. Signals propagate from a single source. Each column in `X` corresponds to the elements in the array (if an array is used) or the number of subarrays (if a subarray is used). Each row of `X` represents a single time snapshot.

`[ang,tau] = step(sGCC,X)` returns the time delays, `tau`, estimated from the correlations between pairs of sensors. To use this syntax, set the `DelayOutputPort` property to `true`. The argument `tau` is a *P*-element row vector, where *P* is the number of sensor pairs, and where *P = N(N-1)*.

`[ang,R,lag] = step(sGCC,X)` returns the estimated correlations, `R`, between pairs of sensors, when you set the `CorrelationOutputPort` property to true. `R` is a matrix with *P* columns where *P* is the number of sensor pairs. Each column in `R` contains the correlation for the corresponding pair of sensors. `lag` is a column vector containing the time lags corresponding to the rows of the correlation matrix. The time lags are the same for all sensor pairs.

You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as their enabling properties. For example,`[ang,tau,R,lag] = step(sGCC,X)` is valid when you set both `DelayOutputPort` and `CorrelationOutputPort` to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `sGCC` — GCC-PHAT estimator

`phased.GCCEstimator` System object

GCC-PHAT estimator, specified as a `phased.GCCEstimator` System object.

Example: `phased.GCCEstimator`

### X — Received signal

*M*-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) of the signal and *N* is the number of sensor elements in the array. For subarrays, *N* is the number of subarrays.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### ang — Direction of arrival

2-by-1 real-valued column vector | scalar

Direction of arrival of a signal, returned as a 2-by-1 real-valued column vector in the form `[azimuth;elevation]`. If the array is a uniform linear array, `ang` is a scalar representing the broadside angle. Angle units are in degrees, defined with respect to the local coordinate system of the array.

### `tau` — Time delays of arrival

1-by-*P* real-valued row vector

Time delays of arrival, returned as 1-by-*P* real-valued row vector. *P* is the number of sensor pairs selected from the array.

- When `SensorPairSource` is set to `'Auto'`, $P = N - 1$. *N* is the number of elements in the array.
- When `SensorPairSource` is set to `'Property'`, *P* is the number of sensor pairs specified by the `SensorPair` property.

Time units are seconds. This output is enabled when you set the `DelayOutputPort` property to `true`.

### R — Estimated cross-correlation

(2*M*+1)-by-*P* complex-valued matrix

Estimated cross-correlation between pairs of sensors, returned as a (2*M*+1)-by-*P* complex-valued matrix, where *P* is the number of sensor pairs selected from the array.

- When `SensorPairSource` is set to `'Auto'`, $P = N - 1$. *N* is the number of elements in the array. The columns in `R` contain the correlations between the first sensor and all other sensors.
- When `SensorPairSource` is set to `'Property'`, *P* is the number of sensor pairs specified by the `SensorPair` property. Each column in `R` contains the correlation for the corresponding pair of sensors.

*M* is the number of time samples in the input signal. This output is enabled when you set the `CorrelationOutputPort` property to `true`.

### `lag` — Time lags

*M*-by-1 real-valued column vector

Time lags, returned as an (2$M$+1)-by-1 real-valued column vector. $M$ is the number of time samples in the input signal. Each time lag applies to the corresponding row in the cross-correlation matrix.

## Examples

### Plot Correlations from GCC Estimator

Estimate the direction of arrival of a signal using GCC-PHAT. The receiving array is a 5-by-5-element URA microphone array with elements spaced 25 centimeters apart. Choose 10 element pairs to compute the arrival angle. Assume the speed of sound in air is 340 meters/second. The arriving signal is a sequence of wideband sounds. Assume the signal arrives from 54 degrees azimuth and five degrees elevation. Estimate the arrival angle, and then plot the correlation function versus lag for a pair of elements.

Load the signal and extract a small portion for computation.

```
load gong;
y1 = y(1:100);
```

Set up the receiving array.

```
N = 5;
d = 0.25;
sMic = phased.OmnidirectionalMicrophoneElement;
sURA = phased.URA([N,N],[d,d],'Element',sMic);
```

Simulate the arriving plane wave using the `WidebandCollector` System object™.

```
c = 340.0;
arrivalAng = [54;5];
sWBC = phased.WidebandCollector('Sensor',sURA,...
    'PropagationSpeed',c,...
    'SampleRate',Fs,...
    'ModulatedInput',false);
signal = step(sWBC,y1,arrivalAng);
```

Estimate direction of arrival. Choose 10 sensors to correlate with the first element of the URA.

```
sensorpairs = [[2,4,6,8,10,12,14,16,18,20];ones(1,10)];
sGCC = phased.GCCEstimator('SensorArray',sURA,...
    'PropagationSpeed',c,'SampleRate',Fs,...
    'SensorPairSource','Property',...
    'SensorPair',sensorpairs,...
    'DelayOutputPort',true','CorrelationOutputPort',true);
[estimatedAng,taus,R,lags] = step(sGCC,signal);
```

The estimated angle is:

```
disp(estimatedAng)
```

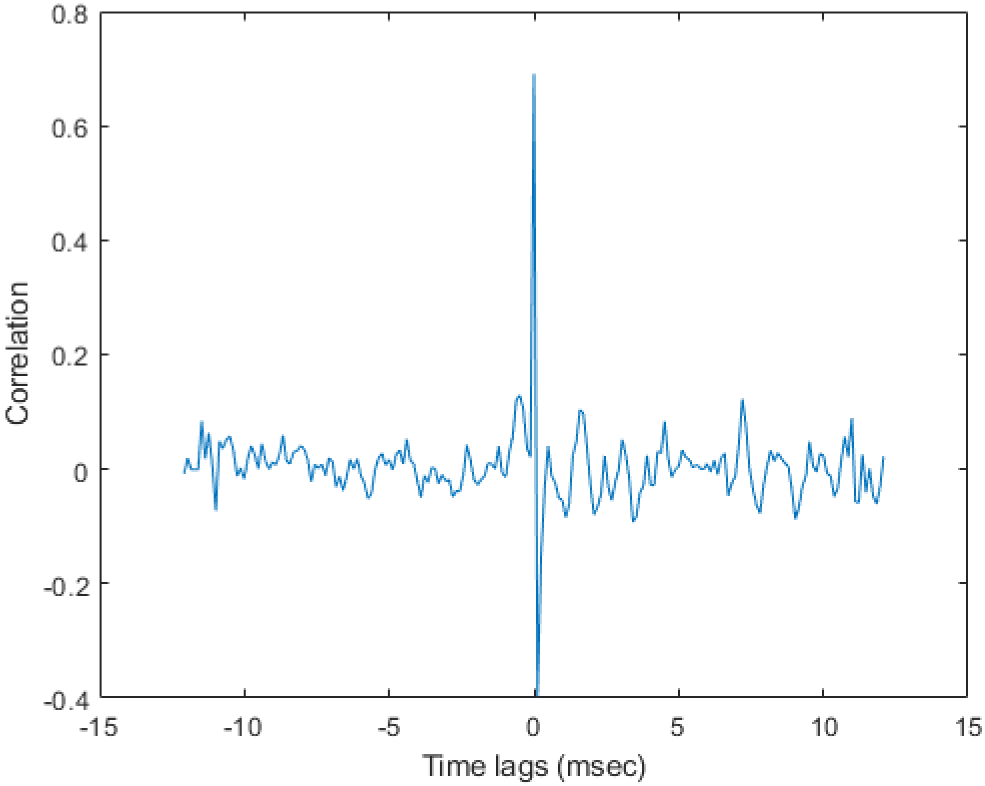
```
   11.6720
    4.2189
```

Plot the correlation between sensor 8 and sensor 1. This pair corresponds to the fourth column of the correlation matrix. The estimated value of tau (in milliseconds) for this pair is:

```
disp(1000*taus(4))
```

```
    0.0238
```

```
plot(1000*lags,real(R(:,4)))
xlabel('Time lags (msec)')
ylabel('Correlation')
```



# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# phased.GSCBeamformer

**Package:** `phased`

Generalized sidelobe canceler beamformer

## Description

The `phased.GSCBeamformer` System object implements a generalized sidelobe cancellation (GSC) beamformer. A GSC beamformer splits the incoming signals into two channels. One channel goes through a conventional beamformer path and the second goes into a sidelobe canceling path. The algorithm first pre-steers the array to the beamforming direction and then adaptively chooses filter weights to minimize power at the output of the sidelobe canceling path. The algorithm uses least mean squares (LMS) to compute the adaptive weights. The final beamformed signal is the difference between the outputs of the two paths.

To compute the beamformed signal:

1. Create the `phased.GSCBeamformer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
beamformer = phased.GSCBeamformer
beamformer = phased.GSCBeamformer(Name,Value)
```

### Description

`beamformer = phased.GSCBeamformer` creates a GSC beamformer System object, `beamformer`, with default property values.

`beamformer = phased.GSCBeamformer(Name,Value)` creates a GSC beamformer object, `beamformer`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `beamformer = phased.GSCBeamformer('SensorArray',phased.ULA('NumElements',20),'SampleRate',300e3)` sets the sensor array to a uniform linear array (ULA) with default ULA property values except for the number of elements. The beamformer has a sample rate of 300 kHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### SensorArray — Sensor array

phased.ULA array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object. The array cannot contain subarrays.

Example: `phased.URA`

### PropagationSpeed — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

### SampleRate — Sample rate of signal

1e6 (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: 1e6

Data Types: single | double

### FilterLength — FIR filter length

1 (default) | positive integer

Length of the signal path FIR filters, specified as a positive integer. This property determines the adaptive filter size for the sidelobe canceling path. The FIR filter for the conventional beamforming path is a delta function of the same length.

Example: 4

Data Types: double | single

### LMSStepSize — Adaptive filter step size factor

0.1 (default) | positive real-valued scalar

The adaptive filter step size factor, specified as a positive real-valued scalar. This quantity, when divided by the total power in the sidelobe canceling path, sets the actual adaptive filter step size that is used in the LMS algorithm.

Data Types: double | single

### DirectionSource — Source of beamforming direction

'Property' (default) | 'Input port'

Source of beamforming direction, specified as 'Property' or 'Input port'. Specify whether the beamforming direction comes from the Direction property of this object or from the input argument, ANG. Values of this property are:

| | |
|---|---|
| 'Property' | Specify the beamforming direction using the Direction property. |
| 'Input port' | Specify the beamforming direction using the input argument, ANG. |

Data Types: char

### `Direction` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 vector or a real-valued 2-by-*L* matrix. For a matrix, each column specifies a different beamforming direction. Each column has the form `[AzimuthAngle;ElevationAngle]`. Azimuth angles must lie between –180° and 180° and elevation angles must lie between –90° and 90°. All angles are defined with respect to the local coordinate system of the array. Units are in degrees.

Example: `[40;30]`

#### Dependencies

To enable this property, set the `DirectionSource` property to `'Property'`.

Data Types: `single` | `double`

# Usage

# Syntax

```
Y = beamformer(X)
Y = beamformer(X,ANG)
```

## Description

`Y = beamformer(X)` performs GSC beamforming on the input, `X`, and returns the beamformed output, `Y`.

`Y = beamformer(X,ANG)` uses `ANG` as the beamforming direction. To use this syntax, set the DirectionSource property to `'Input port'`.

## Input Arguments

### `X` — Input signal

complex-valued *M*-by-*N* matrix

Input signal, specified as a complex-valued *M*-by-*N* matrix. *M* is the signal length and *N* is the number of array elements specified in the SensorArray property. *M* must be larger than the length of the filter specified by the FilterLength property.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double` | `single`
Complex Number Support: Yes

### `ANG` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 column vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 column vector The vector has the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees. The azimuth angle must lie between –180° and 180°, and the elevation angle must lie between –90° and 90°.

Example: `[40;10]`

#### Dependencies

To enable this argument, set the DirectionSource property to `'Input port'`.

Data Types: `double`

## Output Arguments

### Y — Beamformed output

complex-valued 1-by-*M* vector

Beamformed output, returned as a complex-valued 1-by-*M*vector, where *M* is the number of rows of the input X.

Data Types: `double` | `single`
Complex Number Support: Yes

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

# Examples

### Generalized Sidelobe Cancellation on Uniform Linear Array

Create a GSC beamformer for a 11-element acoustic array in air. A chirp signal is incident on the array at −50° in azimuth and 0° in elevation. Compare the GSC beamformed signal to a Frost beamformed signal. The signal propagation speed is 340 m/s and the sample rate is 8 kHz.

Create the microphone and array System objects. The array element spacing is one-half wavelength. Set the signal frequency to the one-half the Nyquist frequency.

```
c = 340.0;
fs = 8.0e3;
fc = fs/2;
lam = c/fc;
transducer = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[20 20000]);
array = phased.ULA('Element',transducer,'NumElements',11,'ElementSpacing',lam/2);
```

Simulate a chirp signal with a 500 Hz bandwidth.

```
t = 0:1/fs:.5;
signal = chirp(t,0,0.5,500);
```

Create an incident wave arriving at the array. Add gaussian noise to the wave.

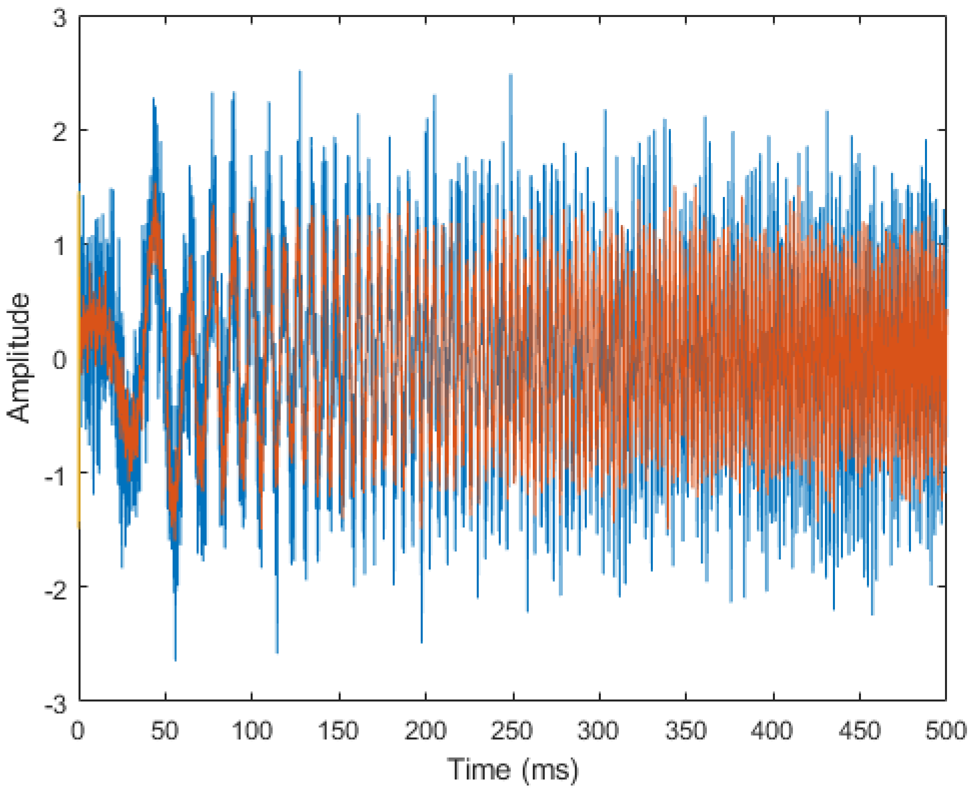
```
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c, ...
    'SampleRate',fs,'ModulatedInput',false,'NumSubbands',512);
incidentAngle = [-50;0];
signal = collector(signal.',incidentAngle);
noise = 0.5*randn(size(signal));
recsignal = signal + noise;
```

Perform Frost beamforming at the actual incident angle.

```
frostbeamformer = phased.FrostBeamformer('SensorArray',array,'PropagationSpeed', ...
    c,'SampleRate',fs,'Direction',incidentAngle,'FilterLength',15);
yfrost = frostbeamformer(recsignal);
```

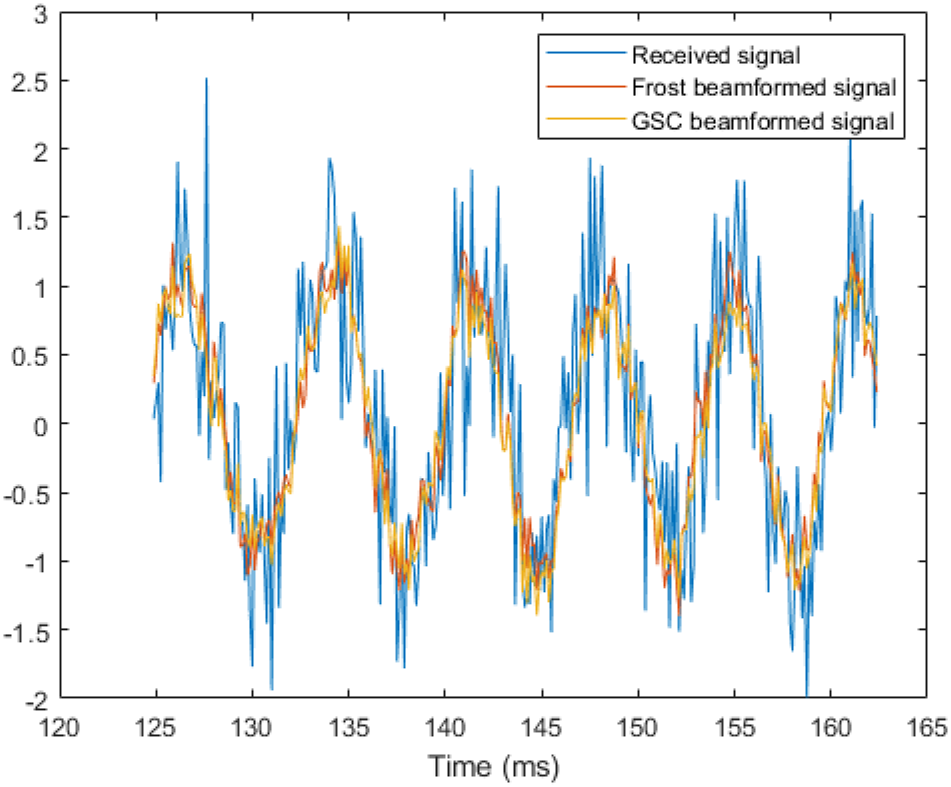
Perform GSC beamforming and plot the beamformer output against the Frost beamformer output. Also plot the nonbeamformed signal arriving at the middle element of the array.

```
gscbeamformer = phased.GSCBeamformer('SensorArray',array, ...
    'PropagationSpeed',c,'SampleRate',fs,'Direction',incidentAngle, ...
    'FilterLength',15);
ygsc = gscbeamformer(recsignal);
plot(t*1000,recsignal(:,6),t*1000,yfrost,t,ygsc)
xlabel('Time (ms)')
ylabel('Amplitude')
```



Zoom in on a small portion of the output.

```
idx = 1000:1300;
plot(t(idx)*1000,recsignal(idx,6),t(idx)*1000,yfrost(idx),t(idx)*1000,ygsc(idx))
xlabel('Time (ms)')
legend('Received signal','Frost beamformed signal','GSC beamformed signal')
```



### Generalized Sidelobe Cancellation in Two Directions

Create a GSC beamformer for a 11-element acoustic array in air. A chirp signal is incident on the array at $-50^\circ$ in azimuth and $0^\circ$ in elevation. Compute the beamformed signal in the direction of the incident wave and in another direction. Compare the two beamformed outputs. The signal propagation speed is 340 m/s and the sample rate is 8 kHz. Create the microphone and array System objects. The array element spacing is one-half wavelength. Set the signal frequency to the one-half the Nyquist frequency.

```
c = 340.0;
fs = 8.0e3;
fc = fs/2;
lam = c/fc;
transducer = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[20 20000]);
array = phased.ULA('Element',transducer,'NumElements',11,'ElementSpacing',lam/2);
```

Simulate a chirp signal with a 500 Hz bandwidth.

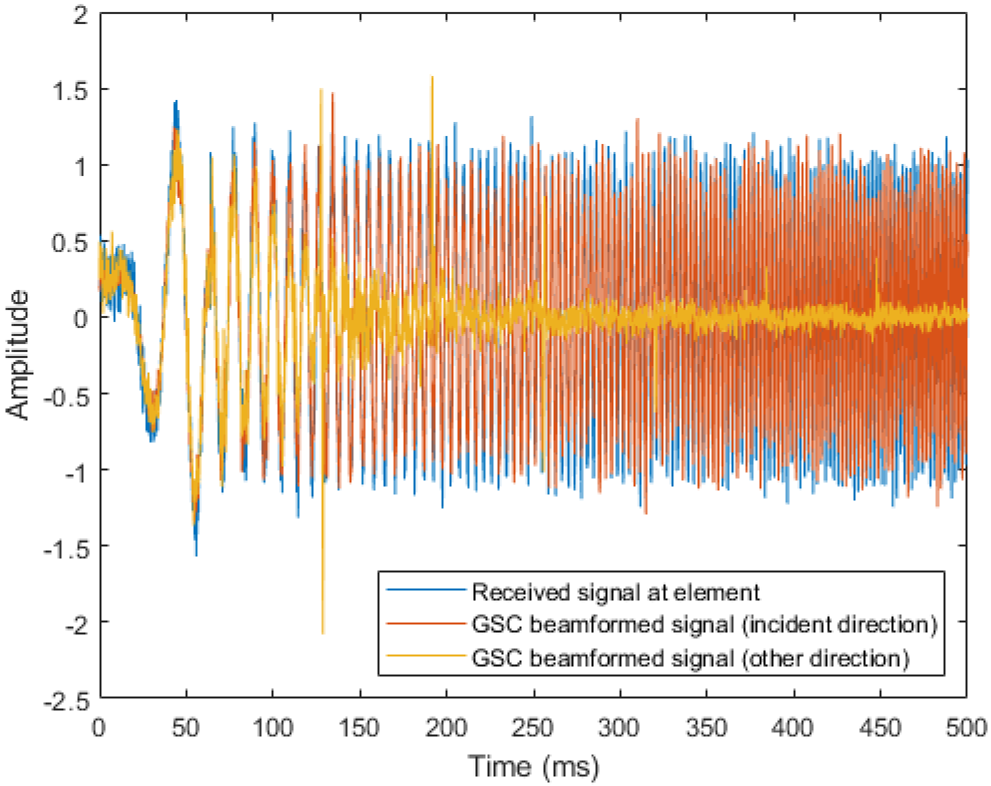
```
t = 0:1/fs:0.5;
signal = chirp(t,0,0.5,500);
```

Create an incident wavefield hitting the array.

```
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c, ...
    'SampleRate',fs,'ModulatedInput',false,'NumSubbands',512);
incidentAngle = [-50;0];
signal = collector(signal.',incidentAngle);
noise = 0.1*randn(size(signal));
recsignal = signal + noise;
```

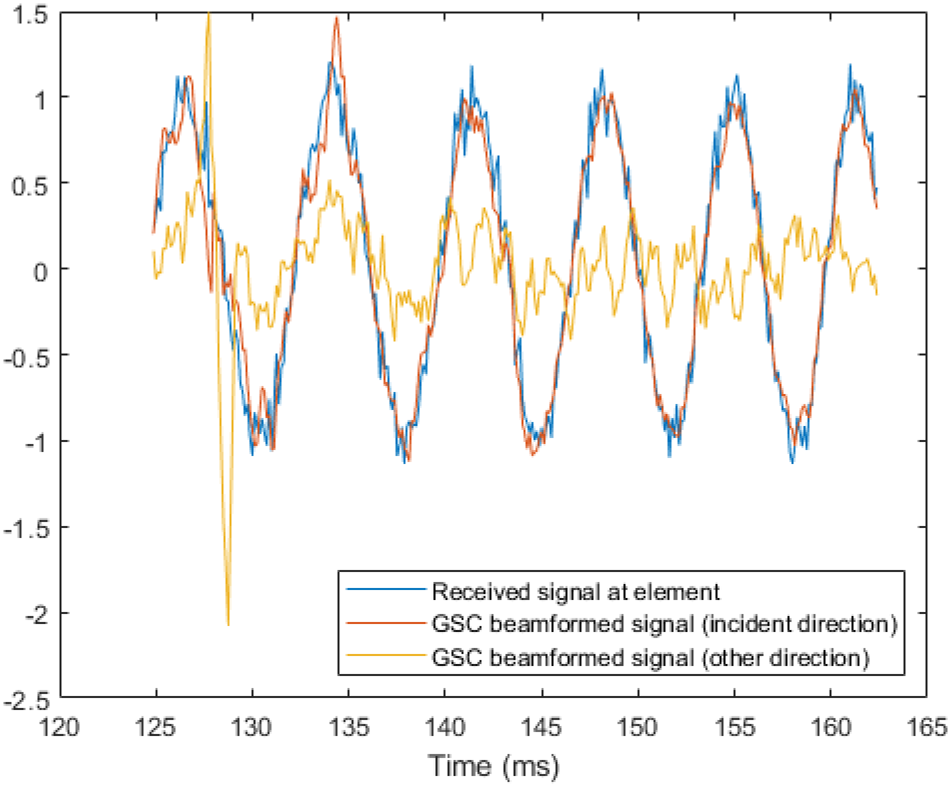
Perform GSC beamforming and plot the beamformer outputs. Also plot the nonbeamformed signal arriving at the middle element of the array.

```
gscbeamformer = phased.GSCBeamformer('SensorArray',array, ...
    'PropagationSpeed',c,'SampleRate',fs,'DirectionSource','Input port', ...
    'FilterLength',5);
ygsci = gscbeamformer(recsignal,incidentAngle);
ygsco = gscbeamformer(recsignal,[20;30]);
plot(t*1000,recsignal(:,6),t*1000,ygsci,t*1000,ygsco)
xlabel('Time (ms)')
ylabel('Amplitude')
legend('Received signal at element','GSC beamformed signal (incident direction)', ...
    'GSC beamformed signal (other direction)','Location','southeast')
```



Zoom in on a small portion of the output.

```
idx = 1000:1300;
plot(t(idx)*1000,recsignal(idx,6),t(idx)*1000,ygsci(idx),t(idx)*1000,ygsco(idx))
xlabel('Time (ms)')
legend('Received signal at element','GSC beamformed signal (incident direction)', ...
    'GSC beamformed signal (other direction)','Location','southeast')
```



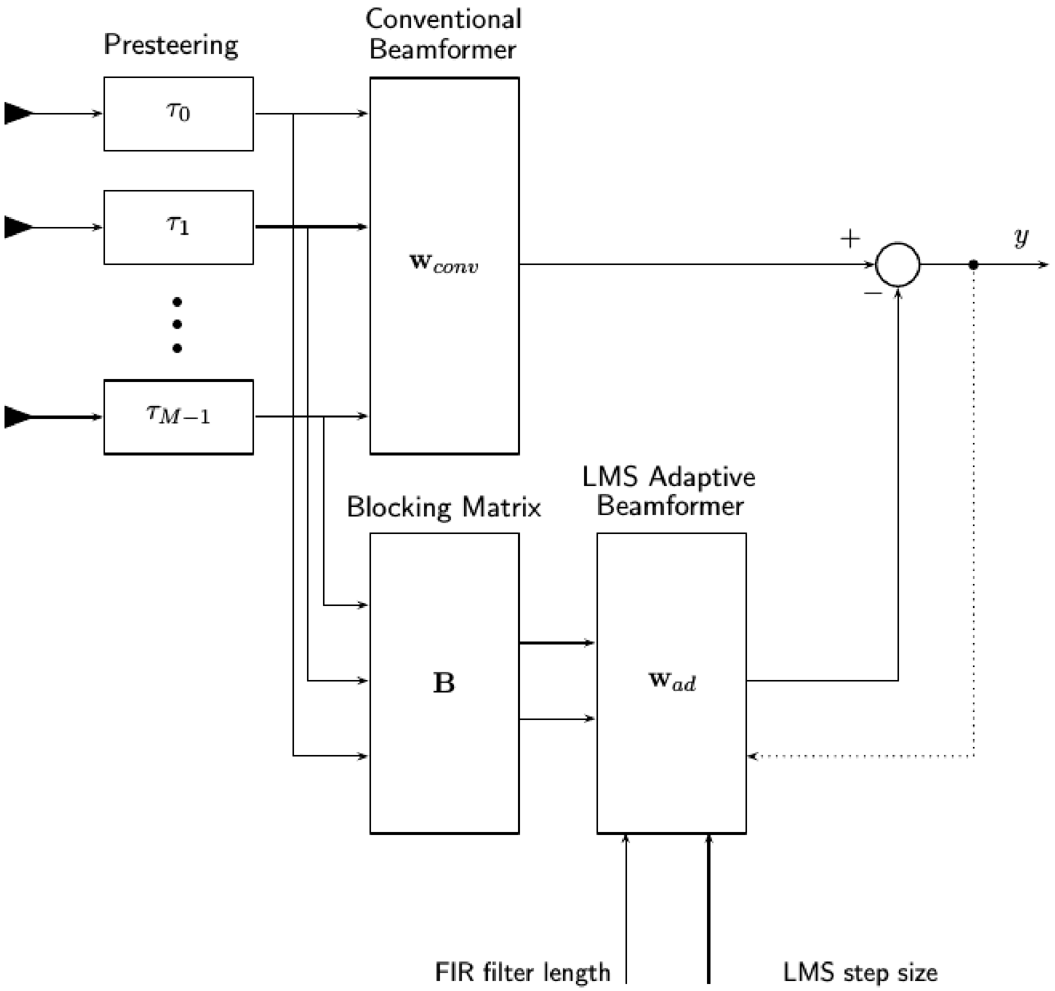
# Algorithms

## Generalized Sidelobe Cancellation

The generalized sidelobe canceler (GSC) is an efficient implementation of a linear constraint minimum variance (LCMV) beamformer. LCMV beamforming minimizes the output power of an array while preserving the power in one or more specified directions. This type of beamformer is called a *constrained beamformer*. You can compute exact weights for the constrained beamformer but the computation is costly when the number of elements is large. The computation requires the inversion of a large spatial covariance matrix. The GSC formulation converts the adaptive constrained optimization LCMV problem into an adaptive unconstrained problem, which simplifies the implementation.

In the GSC algorithm, incoming sensor data is split into two signal paths as shown in the block diagram. The upper path is a conventional beamformer. The lower path is an adaptive unconstrained beamformer whose purpose is to minimize the GSC output power. The GSC algorithm consists of these steps:

1. Presteer the element sensor data by time-shifting the incoming signals. Presteering time-aligns all sensor element signals. The time shifts depend on the arrival angle of the signal.
2. Pass the presteered signals through the upper path into a conventional beamformer with fixed weights, $\mathbf{w}_{conv}$.
3. Also pass the presteered signals through the lower path into the blocking matrix, $\mathbf{B}$. The blocking matrix is orthogonal to the signal and removes the signal from the lower path.
4. Filter the lower path signals through a bank of FIR filters. The FilterLength property sets the length of the filters. The filter coefficients are the adaptive filter weights, $\mathbf{w}_{ad}$.
5. Compute the difference between the upper and lower signal paths. This difference is the beamformed GSC output.
6. Feed the beamformed output back into the filter. The filter adapts its weights using a least mean-square (LMS) algorithm. The actual adaptive LMS step size is equal to the value of the LMSStepSize property divided by the total signal power.



For more information, see [1].

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If

the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2016b**

# phased.HeterogeneousConformalArray

**Package:** `phased`

Heterogeneous conformal array

## Description

The `HeterogeneousConformalArray` object constructs a conformal array from a heterogeneous set of antenna elements. A heterogeneous array is an array which consists of different kinds of antenna elements or an array of different kinds of microphone elements. A conformal array can have elements in any position pointing in any direction.

To compute the response for each element in the array for specified directions:

1. Define and set up your conformal array. See "Construction" on page 1-757.
2. Call `step` to compute the response according to the properties of `phased.HeterogeneousConformalArray`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.HeterogeneousConformalArray` creates a heterogeneous conformal array System object, `H`. This object models a heterogeneous conformal array formed with different kinds of sensor elements.

`H = phased.HeterogeneousConformalArray(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `ElementSet`

Set of elements used in the array

Specify the set of different elements used in the sensor array as a row MATLAB cell array. Each member of the cell array contains an element object in the phased package. Elements specified in the `ElementSet` property must be either all antennas or all microphones. In addition, all specified antenna elements must have the same polarization capability. Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

**Default:** One cell containing one isotropic antenna element

### `ElementIndices`

Elements location assignment

This property specifies the mapping of elements in the array. The property assigns elements to their locations in the array using the indices into the `ElementSet` property. The value of `ElementIndices` must be an length-*N* row vector. In this vector, *N* represents the number of elements in the array. The values in the vector specified by `ElementIndices` must be less than or equal to the number of entries in the `ElementSet` property.

**Default:** `[1 2 2 1]`

### `ElementPosition`

Element positions

`ElementPosition` specifies the positions of the elements in the conformal array. The value of the `ElementPosition` property must be a 3-by-*N* matrix, where *N* indicates the number of elements in the conformal array. Each column of `ElementPosition` represents the position, in the form `[x; y; z]` (in meters), of a single element in the local coordinate system of the array. The local coordinate system has its origin at an arbitrary point.

**Default:** `[0; 0; 0]`

### `ElementNormal`

Element normal directions

`ElementNormal` specifies the normal directions of the elements in the conformal array. Angle units are degrees. The value assigned to `ElementNormal` must be either a 2-by-*N* matrix or a 2-by-1 column vector. The variable *N* indicates the number of elements in the array. If the value of `ElementNormal` is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the value of `ElementNormal` is a 2-by-1 column vector, it specifies the pointing direction of all elements in the array.

You can use the `ElementPosition` and `ElementNormal` properties to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

**Default:** `[0; 0]`

### `Taper`

Element taper or weighting

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. The quantity *N* is the number of elements in the array as determined by the size of the `ElementIndices` property. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all elements. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

**Default:** 1

## Methods

| `release` | Allow System object property value changes |

## Examples

### Heterogeneous Uniform Circular Array

Construct an 8-element heterogeneous uniform circular array (UCA) using the ConformalArray System object. Four of the elements have a cosine pattern with a power of 1.6 while the remaining elements have a cosine pattern with a power of 2.0. Plot the 3-D power response. Assume a 1 GHz operating frequency. The wave propagation speed is the speed of light.

### Construct the array

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.6);
sElement2 = phased.CosineAntennaElement('CosinePower',2.0);
```

```
N = 8;
azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2],...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
c = physconst('LightSpeed');
fc = 1e9;
```

**Create the 3-D power pattern**

```
pattern(sArray,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','power')
```

## Topics

Phased Array Gallery

**Introduced in R2013a**

# directivity

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Directivity of heterogeneous conformal array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` computes the “Directivity” on page 1-768 of a heterogeneous conformal array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `H` — Heterogeneous conformal array

System object

Heterogeneous conformal array specified as a `phased.HeterogeneousConformalArray` System object.

Example: `H = phased.HeterogeneousConformalArray;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

**ANGLE — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**D — Directivity**

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Heterogeneous Conformal Array

Compute the directivity of a steered heterogeneous conformal array. Construct a 24-element heterogeneous disk array using elements having different antenna patterns and then show how to compute the array's directivity.

Set the signal speed to the speed of light and the signal frequency to 2GHz.

```
c = physconst('LightSpeed');
freq = 2e9;
```

Choose two different types of elements - both are cosine antenna elements with different powers.

```
myElement1 = phased.CosineAntennaElement('CosinePower',1.5);
myElement2 = phased.CosineAntennaElement('CosinePower',1.8);
```

Set up a three-ring disk array with 8 elements per ring. The inner ring has different elements from the outer rings.

```
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
myArray = phased.HeterogeneousConformalArray;
myArray.ElementPosition = posn;
myArray.ElementNormal = zeros(2,3*N);
myArray.ElementSet = {myElement1,myElement2};
myArray.ElementIndices = [1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2];
```

Set up the steering vector to point at 30 degrees azimuth and compute the directivity in that direction.

```
lambda = c/freq;
ang = [30;0];
w = steervec(getElementPosition(myArray)/lambda,ang);
d = directivity(myArray,freq,ang,'PropagationSpeed',c,...
            'Weights',w)
```

```
d = 20.9519
```

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# collectPlaneWave

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

# Output Arguments

**Y**

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

# Examples

### Simulate Received Signal at Heterogeneous Conformal Array

Simulate the received signal at an 8-element heterogeneous uniform circular array created using the phased.HeterogeneousConformalArray System object™. The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray('ElementPosition', ...
    [cosd(azang);sind(azang);zeros(1,N)],'ElementNormal',[azang;zeros(1,N)], ...
    'ElementSet',{antenna1,antenna2},'ElementIndices',[1 1 1 1 2 2 2 2]);
c = physconst('LightSpeed');
y = collectPlaneWave(array,randn(4,2),[10 30],c);
disp(y(:,1:2))
```

```
   0.7476 + 0.2890i   0.5378 + 0.5554i
   0.9544 - 0.8005i  -0.5059 + 1.3857i
  -2.5374 - 0.5387i  -1.3746 - 2.1411i
   1.0865 + 0.3377i   0.6977 + 0.8549i
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see Van Trees [1].

# getElementNormal

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Normal vector to array elements

## Syntax

```
normvec = getElementNormal(sConfArray)
normvec = getElementNormal(sConfArray,elemidx)
```

## Description

`normvec = getElementNormal(sConfArray)` returns the normal vectors of the array elements of the `phased.sConfArray` System object, `sConfArray`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sConfArray`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form`[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sConfArray,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Input Arguments

**`sConfArray` — Heterogeneous conformal array**
`phased.HeterogeneousConformalArray` System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousConformalArray` System object.

Example: `phased.HeterogeneousConformalArray`

### elemidx — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices, specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

## Output Arguments

### normvec — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

## Examples

### Display Heterogeneous Conformal Array Element Normals

Construct a 5-element acoustic cross array (UCA) composed of two different types of cosine antenna elements. Use the Phased.HeterogeneousConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Display the array normal vectors.

```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
sCos1 = phased.CosineAntennaElement('CosinePower',1.5);
sCos2 = phased.CosineAntennaElement('CosinePower',1.8);
sHCA = phased.HeterogeneousConformalArray('ElementSet',{sCos1,sCos2},...
    'ElementIndices',[1,2,2,2,1],...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[[-20,-10,0,10,20];zeros(1,N)]);
pos = getElementPosition(sHCA)
```

```
pos = 3×5

         0         0         0         0         0
   -0.1875         0    0.1875         0         0
         0         0         0   -0.1875    0.1875
```

```
normvec = getElementNormal(sHCA)
```

```
normvec = 2×5

   -20   -10     0    10    20
     0     0     0     0     0
```

**Introduced in R2016a**

# getElementPosition

**System object:** phased.HeterogeneousConformalArray
**Package:** phased

Positions of array elements

## Syntax

```
pos = getElementPosition(sHCA)
pos = getElementPosition(sHCA,elemidx)
```

## Description

pos = getElementPosition(sHCA) returns the element positions of the HeterogeneousConformalArray System object, sHCA. POS is an 3-by-*N* matrix where *N* is the number of elements in H. Each column of pos defines the position of an element in the local coordinate system, in meters, in the form [x;y;z].

For details regarding the local coordinate system of the conformal or heterogeneous conformal array, enter phased.ConformalArray.coordinateSystemInfo.

pos = getElementPosition(sHCA,elemidx) returns the positions of the elements that are specified in the element index vector elemidx.

## Examples

### Element Positions of Heterogeneous Conformal Array

Construct an 8-element heterogeneous conformal array with oriented short-dipole antenna elements. Then, obtain the positions of the first four elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
```

```
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
N = 8; azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    [cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)],...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
pos = getElementPosition(sArray);
disp(pos(:,1:4));
```

```
   -1.0000   -0.7071         0    0.7071
         0   -0.7071   -1.0000   -0.7071
         0         0         0         0
```

# getNumElements

**System object:** phased.HeterogeneousConformalArray
**Package:** phased

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

N = getNumElements(H) returns the number of elements, N, in the conformal array object H.

## Examples

### Number of Elements in Heterogeneous Conformal Array

Construct a heterogeneous 8-element circular array and use the getNumElements method to return the number of elements.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray('ElementPosition', ...
    [cosd(azang);sind(azang);zeros(1,N)], ...
    'ElementNormal',[azang;zeros(1,N)], ...
    'ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
N = getNumElements(array)
```

```
N = 8
```

# getTaper

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Array element tapers

## Syntax

```
wts = getTaper(h)
```

## Description

`wts = getTaper(h)` returns the tapers applied to each element of a conformal array, `h`. Tapers are often referred to as weights.

## Input Arguments

**h — Conformal array**
`phased.HeterogeneousConformalArray` System object

Conformal array specified as a `phased.HeterogeneousConformalArray` System object.

## Output Arguments

**`wts` — Array element tapers**
*N*-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector, where *N* is the number of elements in the array.

# Examples

### Create Tapered Heterogeneous Conformal Disk Array

Create a 12-element, 2-ring tapered disk array where the outer ring is more heavily tapered than the inner ring.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
elemAngles = ([0:5]*360/6);
elemPosInner = 0.5*[zeros(size(elemAngles));cosd(elemAngles); ...
    sind(elemAngles)];
elemPosOuter = [zeros(size(elemAngles));cosd(elemAngles); ...
    sind(elemAngles)];
elemNorms = repmat([0;0],1,12);
taper =  [ones(size(elemAngles)),0.3*ones(size(elemAngles))];
array = phased.HeterogeneousConformalArray('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 1 1 1 1 1 2 2 2 2 2 2], ...
    'ElementPosition',[elemPosInner,elemPosOuter],'ElementNormal',elemNorms, ...
    'Taper',taper);
w = getTaper(array)
```

```
w = 12×1

# isPolarizationCapable

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

### h — Conformal array

Conformal array specified as a `phased.HeterogeneousConformalArray` System object.

## Output Arguments

### `flag` — Polarization-capability flag

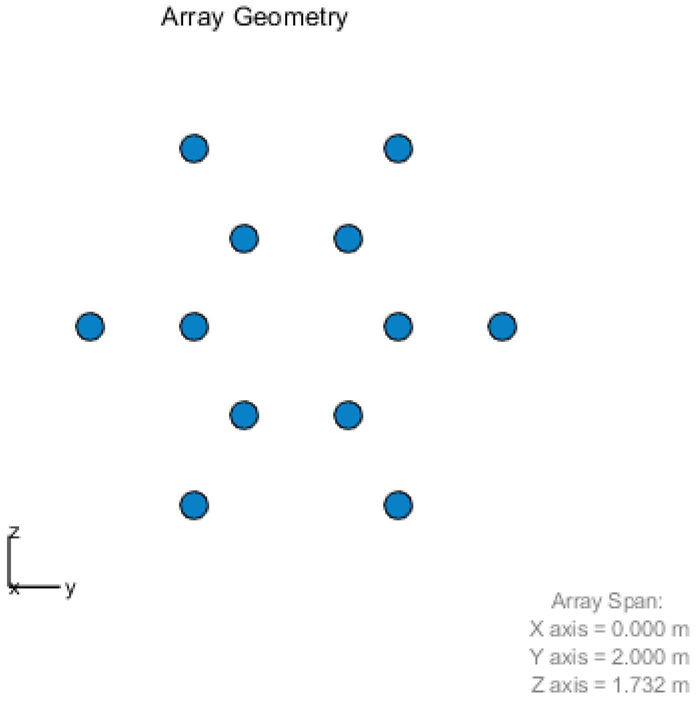
Polarization-capability returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

## Examples

### Conformal Heterogeneous Array Supports Polarization

Show that a disk heterogeneous conformal array of short-dipole antennas supports polarization.

```
antenna1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
elemAngles = ([0:5]*360/6);
elemPosInner = 0.5*[zeros(size(elemAngles));...
    cosd(elemAngles); sind(elemAngles)];
elemPosOuter = [zeros(size(elemAngles));...
    cosd(elemAngles); sind(elemAngles)];
elemNorms = repmat([0;0],1,12);
array = phased.HeterogeneousConformalArray(...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 1 1 1 1 1 2 2 2 2 2 2],...
    'ElementPosition',[elemPosInner,elemPosOuter],...
    'ElementNormal',elemNorms);
viewArray(array)
```



```
isPolarizationCapable(array)
```

```
ans = logical
   1
```

The returned value of 1 shows that this array supports polarization when used with a polarized antenna.

# pattern

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Plot heterogeneous conformal array pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-798 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sArray` — Heterogeneous conformal array

System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousConformalArray` System object.

Example: `sArray= phased.HeterogeneousConformalArray;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

**EL — Elevation angles**
`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`CoordinateSystem` — Plotting coordinate system**
`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Normalize` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize`' and a Boolean. Set this parameter to `true` to display a normalized pattern. This parameter does not apply when you set `'Type'` to `'directivity'`. Directivity patterns are already normalized.

Data Types: `logical`

### `PlotStyle` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Data Types: `char`

### `Polarization` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### PAT — Array pattern

*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

### AZ_ANG — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

### EL_ANG — Elevation angles

scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Plot Power Patterns of 8-Element Heterogeneous Uniform Circular Array

Create an 8-element uniform circular array using the `HeterogeneousConformalArray` System object with two different types of short-dipole elements. Then, plot the 3-D and 2-D power patterns.

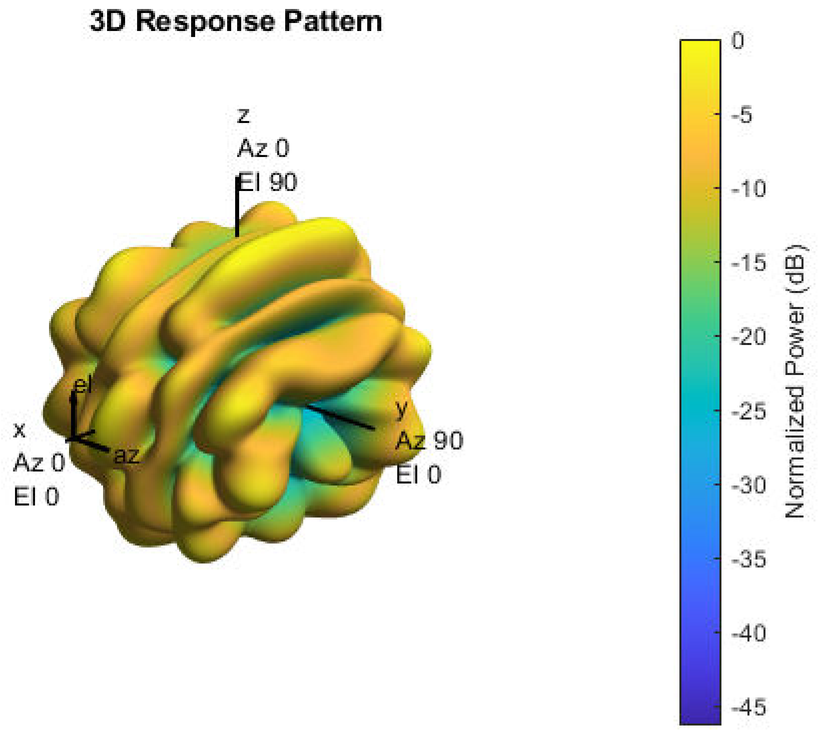
#### Create the array

```
sElement1 = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 5e9],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 5e9],...
    'AxisDirection','Y');
N = 8;
azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    0.4*[zeros(1,N);cosd(azang);sind(azang)],...
    'ElementNormal', zeros(2,N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
```

#### Plot 3-D power pattern

Assume the operating frequency is 1.5 GHz and the wave propagation speed is the speed of light.

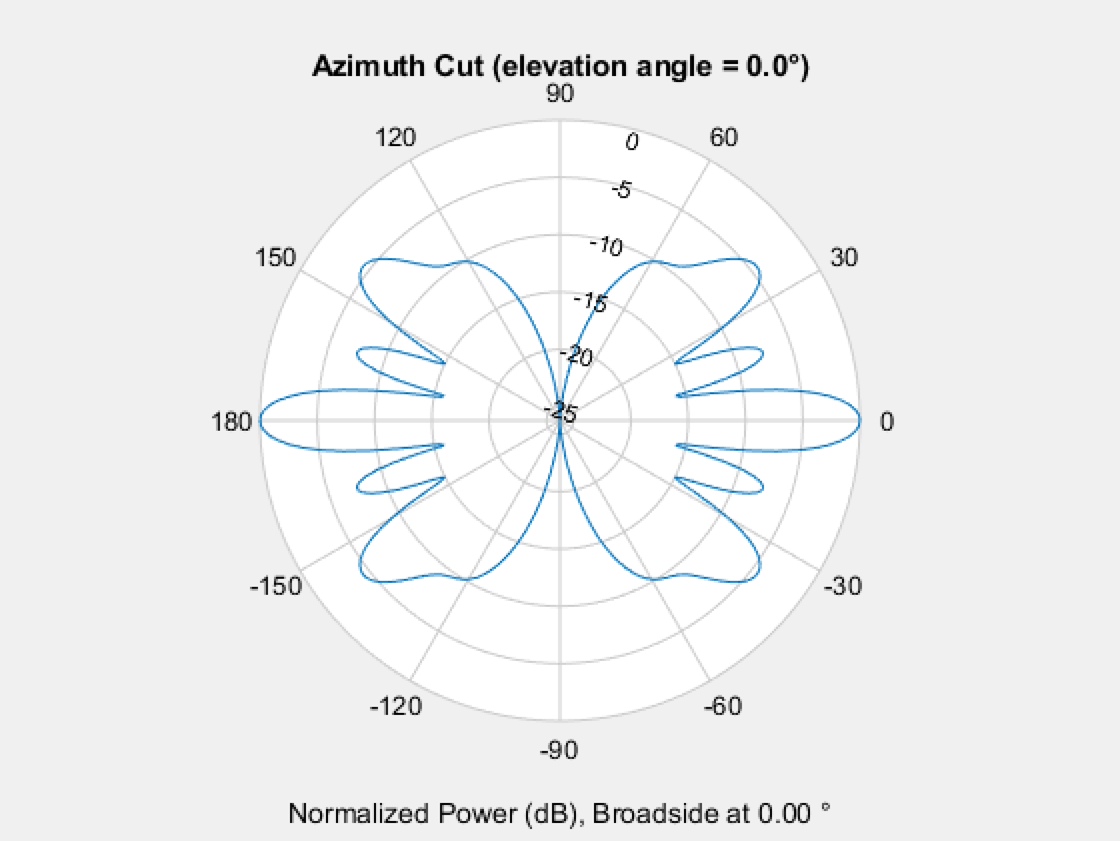
```
c = physconst('LightSpeed');
fc = 1.5e9;
pattern(sArray,fc,[-180:180],[-90:90],...
    'PropagationSpeed',c',...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



### Plot 2-D power pattern

Take a cut of the 3-D power pattern at zero degrees elevation

```
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c',...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



### Plot pattern of disk array

Construct a 24-element disk array using elements with two different types of cosine antennas. Then, plot the array pattern.

### Create the array

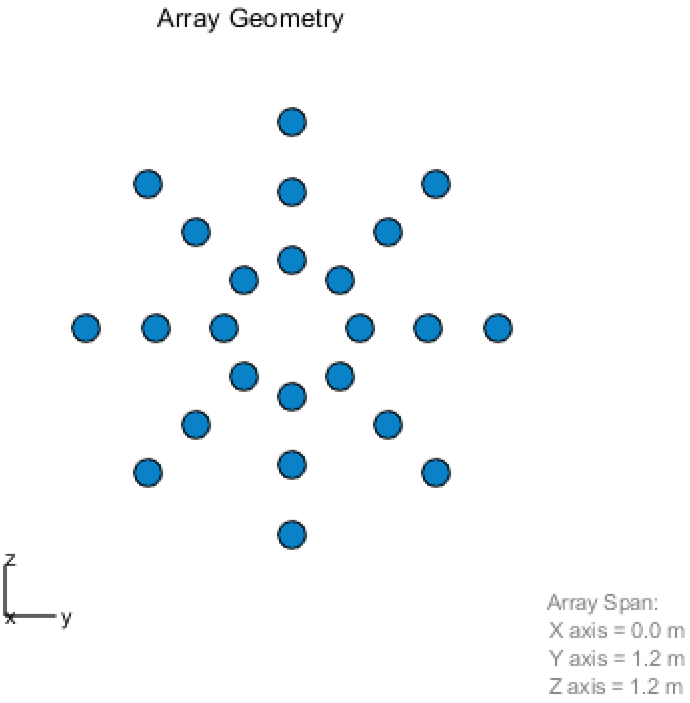
The array consists of cosine antenna elements with different power exponents.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
```

```
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray1 = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

### View the disk array

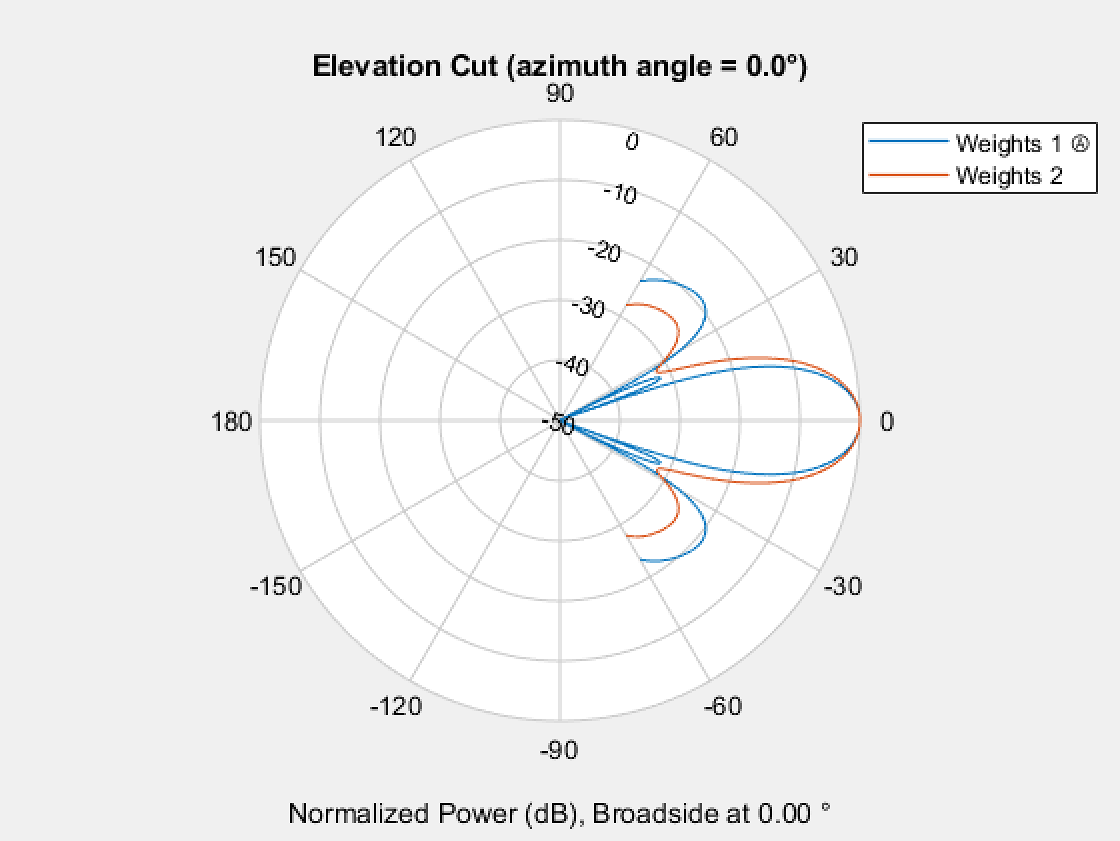
```
viewArray(sArray1)
```



### Plot the power pattern

Plot the elevation power pattern of this array two different sets of element weights. The first set is uniform weights on the elements. The second set is a tapered set of weights set by the `Weights` parameter. Restrict the plot of the response from -60 to 60 degrees in 0.1 degree increments. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts1 = ones(3*N,1);
wts1 = wts1/sum(abs(wts1));
wts2 = [0.5*ones(N,1); 0.7*ones(N,1); 1*ones(N,1)];
wts2 = wts2/sum(abs(wts2));
pattern(sArray1,fc,0,[-60:0.1:60],'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb','Weights',[wts1,wts2])
```



As expected, the tapered weights broaden the mainlobe and reduce the sidelobes.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified

direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

## See Also

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Plot heterogeneous conformal array directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**`sArray` — Heterogeneous conformal array**
System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousConformalArray` System object.

Example: `sArray= phased.HeterogeneousConformalArray;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Type — Displayed pattern type**
`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

**PropagationSpeed — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**Weights — Array weights**
*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Azimuth` — Azimuth angles**
`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

**`PAT` — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Plot azimuthal directivity pattern of disk array

Construct a 24-element disk array using elements with two different types of cosine antennas. Then, plot the array azimuthal directivity pattern.

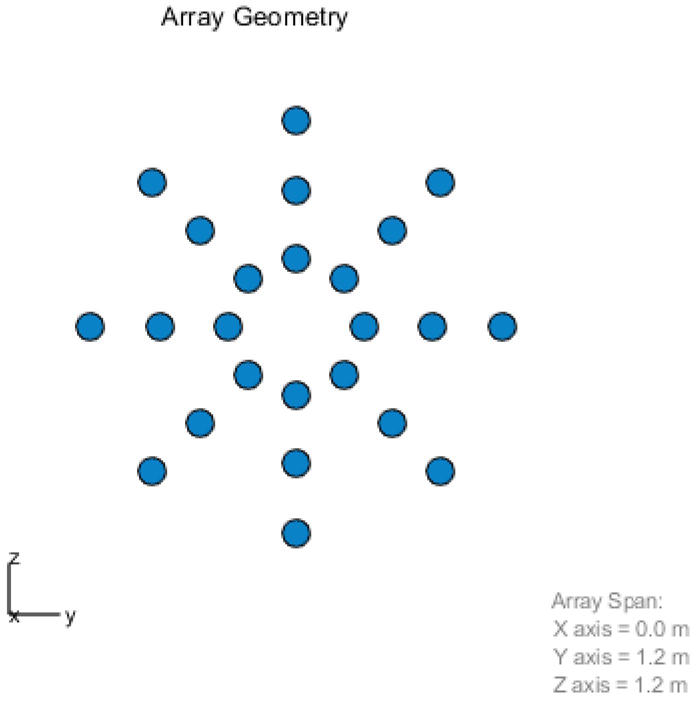
### Create the array

The array consists of cosine antenna elements with different power exponents.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

### View the disk array

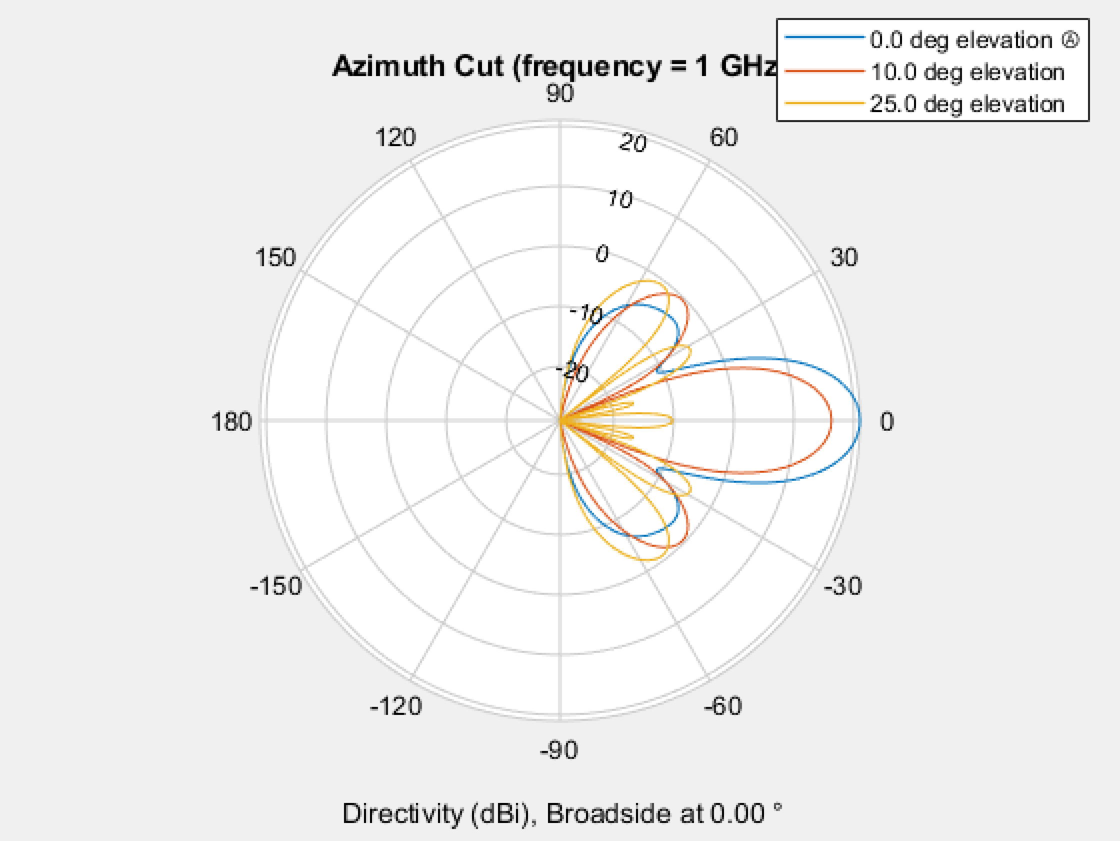
```
viewArray(sArray)
```



### Plot the power pattern

Plot the azimuthal power pattern of this array for three different elevation angles: 0, 10 and 25 degrees. Apply radial tapering to the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts = [0.5*ones(N,1); 0.7*ones(N,1); 1.0*ones(N,1)];
wts = wts/sum(abs(wts));
patternAzimuth(sArray,fc,[0,10,25],'PropagationSpeed',c,...
    'Type','directivity','Weights',wts)
```



## More About

### Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}$*(θ,φ)* is the radiant intensity of a transmitter in the direction *(θ,φ)* and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# patternElevation

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Plot heterogeneous conformal array directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation(___)
```

## Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation(___)` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

**`sArray` — Heterogeneous conformal array**
System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousConformalArray` System object.

Example: `sArray= phased.HeterogeneousConformalArray;`

**`FREQ` — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**`AZ` — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Type` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Plot elevation directivity pattern of disk array

Construct a 24-element disk array using elements with two different types of cosine antennas. Then, plot the array elevation directivity pattern.

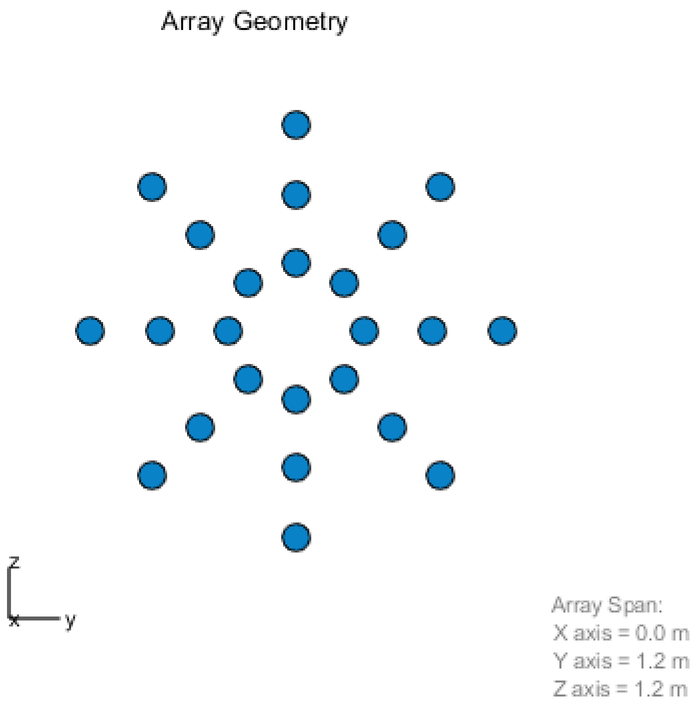
### Create the array

The array consists of cosine antenna elements with different power exponents.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

### View the disk array

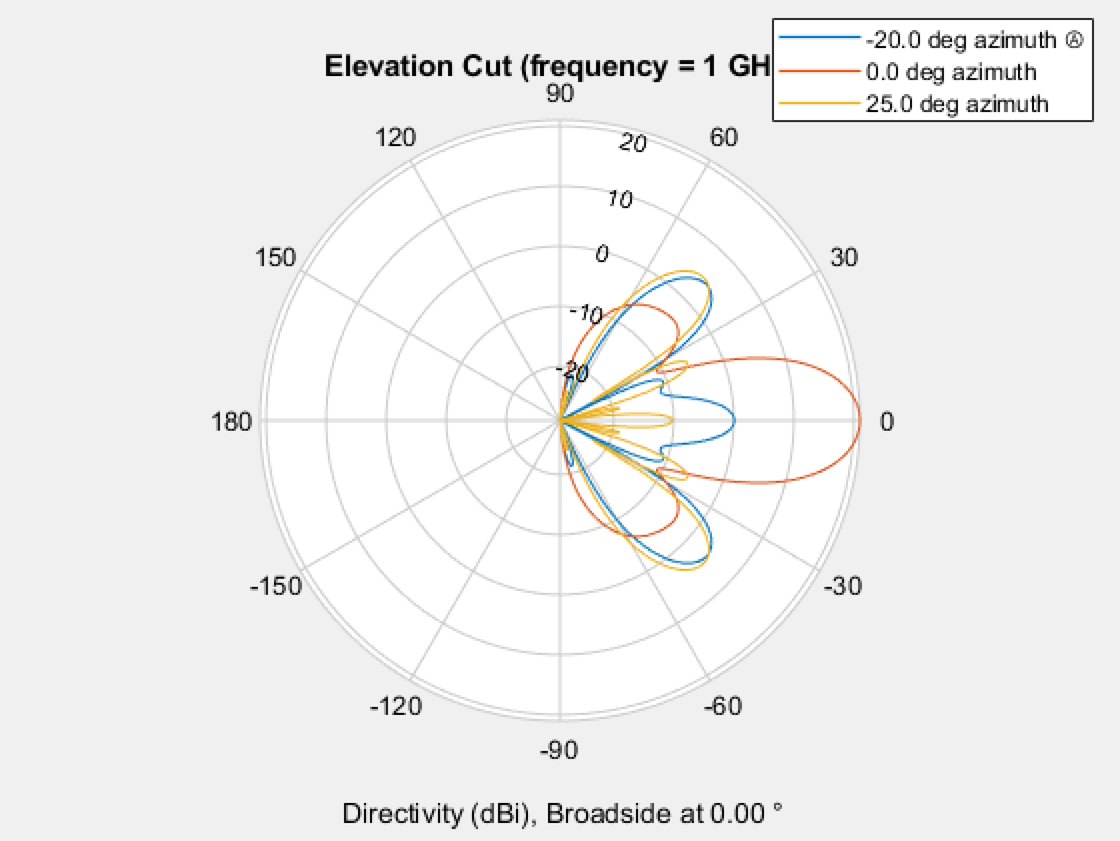
```
viewArray(sArray)
```



### Plot the power pattern

Plot the elevation power pattern of this array for three different azimuth angles: 0, -20 and 25 degrees. Apply radial tapering to the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts = [0.5*ones(N,1); 0.7*ones(N,1); 1*ones(N,1)];
wts = wts/sum(abs(wts));
patternElevation(sArray,fc,[-20,0,25],'PropagationSpeed',c,...
    'Type','directivity','Weights',wts)
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2015a**

# plotResponse

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Array object

**`FREQ`**

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no

response at frequencies outside that range. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

**`V`**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`CutAngle`**

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

**`Format`**

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

**`NormalizeResponse`**

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### OverlayFreq

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, FREQ must be a vector with at least two entries.

This parameter applies only when Format is not 'Polar' and RespCut is not '3D'.

**Default:** true

### Polarization

Specify the polarization options for plotting the array response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimensions | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

**ElevationAngles**

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

**Default:** `[-90:90]`

**UGrid**

*U* coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

**VGrid**

*V* coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

## Examples

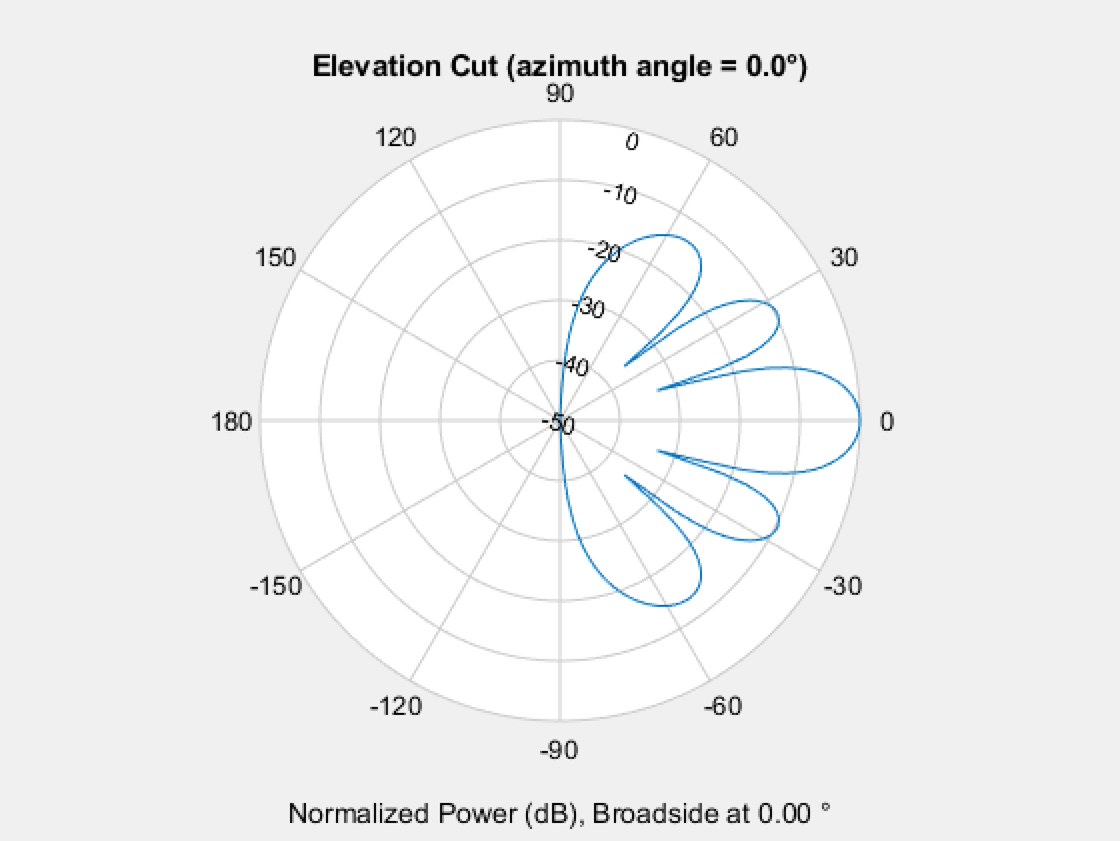
### Plot Response and Directivity of 8-Element Uniform Circular Array

This example shows how to construct an 8-element uniform circular array (UCA) with two different antenna patterns.

```
element1 = phased.CosineAntennaElement('CosinePower',1.5);
element2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray( ...
    'ElementPosition',0.4*[zeros(1,N); cosd(azang); sind(azang)], ...
    'ElementNormal',zeros(2,N),'ElementSet',{element1,element2}, ...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
```

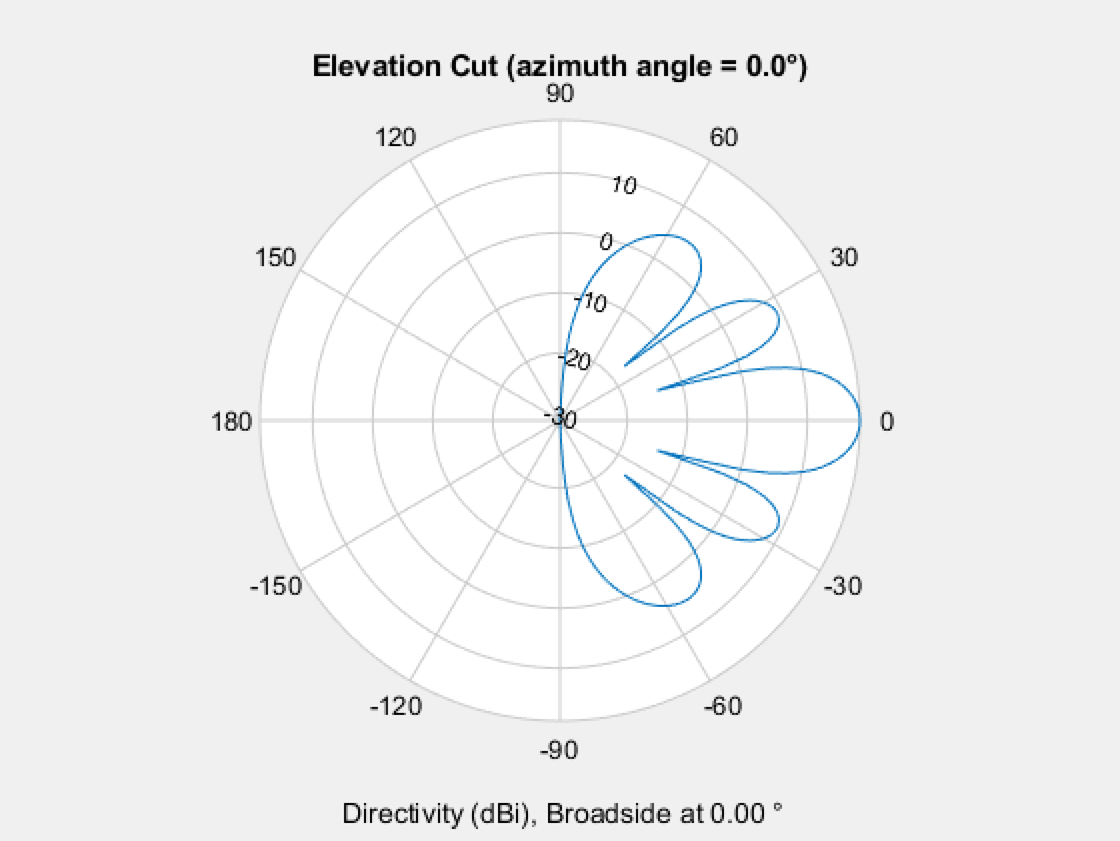
Plot the array elevation response when the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
pattern(array,fc,0.0,-90:90,'PropagationSpeed',c,'CoordinateSystem','polar', ...
    'Type','powerdb')
```



Plot the directivity.

```
pattern(array,fc,0.0,-90:90,'PropagationSpeed',c,'CoordinateSystem','polar', ...
    'Type','directivity')
```



### Plot Response of Disk Array

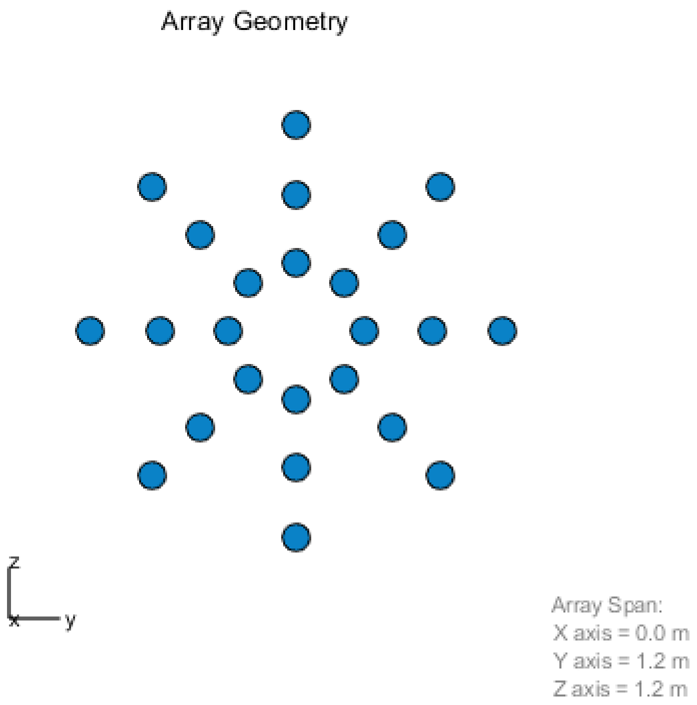
This example shows how to construct a 24-element disk array using elements with two different antenna patterns and plot its response.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8; azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
```

```
sArray1 = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

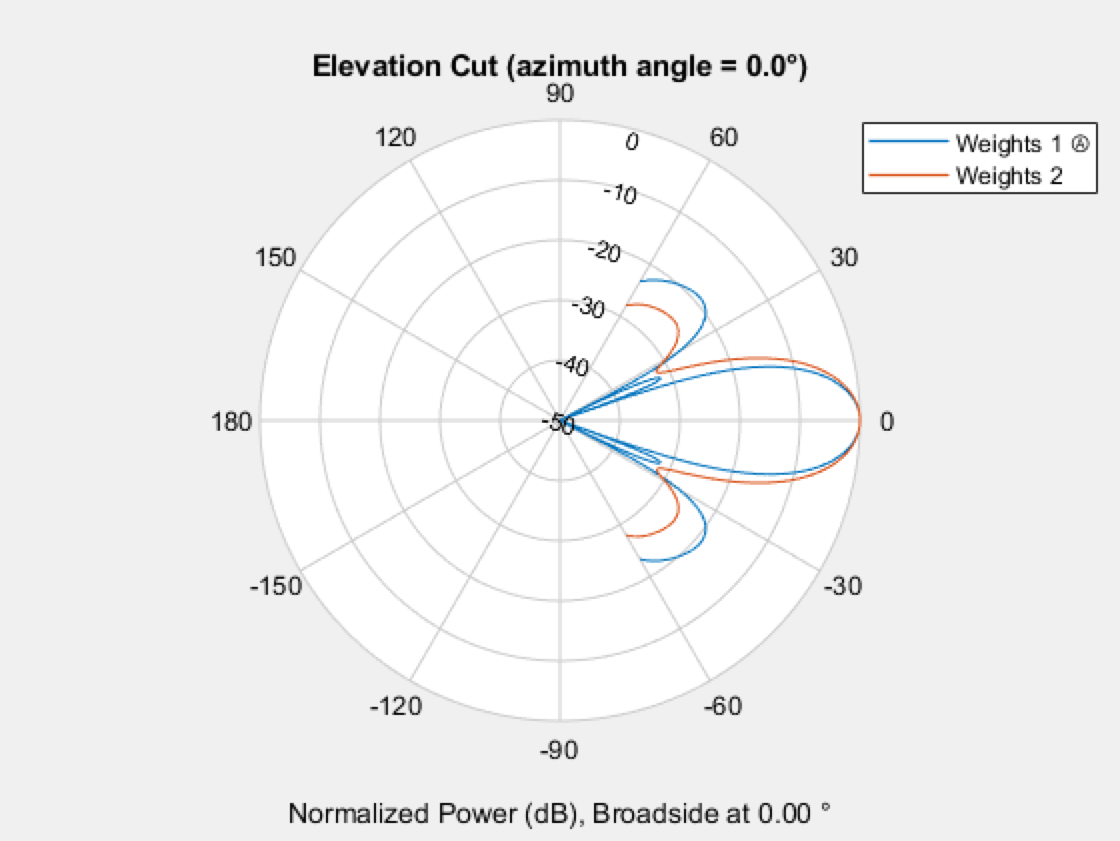
Show the array.

```
viewArray(sArray1);
```



Plot the elevation response of this array using uniform weights on the elements and also a tapered set of weights set by the `Weights` parameter. Using the `ElevationAngles` parameter, restrict the plot of the response from -60 to 60 degrees in 0.1 degree increments. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts1 = ones(3*N,1);
wts1 = wts1/sum(abs(wts1));
wts2 = [0.5*ones(N,1); 0.7*ones(N,1); 1*ones(N,1)];
wts2 = wts2/sum(abs(wts2));
plotResponse(sArray1,fc,c,'RespCut','El',...
    'Format','Polar',...
    'ElevationAngles',[-60:0.1:60],...
    'Weights',...
    [wts1,wts2],...
    'Unit','db');
```



As expected, the tapered weights broaden the mainlobe and reduce the sidelobes.

# step

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

Output responses of array elements

## Syntax

`RESP = step(H,FREQ,ANG)`

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array elements' responses `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `H`

Array object

### FREQ

Operating frequencies of array in hertz. FREQ is a row vector of length *L*. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

### ANG

Directions in degrees. ANG is either a 2-by-*M* matrix or a row vector of length *M*.

If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

## Output Arguments

### RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array’s horizontal polarization response, while RESP.V represents the array’s vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each

of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.

## Examples

### Compute Response of Circular Conformal Array

Construct an 8-element uniform circular array using the `phased.HeterogeneousConformalArray` System object™. Assume the operating frequency is 1 GHz. Find the response of each element in this array in the direction of 30° azimuth and 5°.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    [cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal', zeros(2,N),...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
fc = 1e9;
ang = [30;5];
resp = array(fc,ang)
```

```
resp = 8×1

    0.8013
    0.8013
    0.8013
    0.8013
    0.7666
    0.7666
    0.7666
    0.7666
```

# viewArray

**System object:** `phased.HeterogeneousConformalArray`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### ShowIndex

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

### ShowNormals

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

### ShowTaper

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

### Title

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

### hPlot

Handle of array elements in figure window.

## Examples

### Element Positions and Normal Directions for Uniform Circular Array

Display the element positions and normal directions for all elements of an 8-element heterogeneous uniform circular array.

Create the elements and the array.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    [cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal', zeros(2,N),...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
viewArray(array,'ShowIndex','all','ShowNormal',true);
```

# phased.HeterogeneousULA

**Package:** phased

Heterogeneous uniform linear array

## Description

The phased.HeterogeneousULA object creates a uniform linear array from a heterogeneous set of antenna elements. A heterogeneous array is an array in which the antenna or microphone elements may be of different kinds or have different properties. An example would be an array of elements each having different antenna patterns.

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform linear array. See “Construction” on page 1-839.
2. Call step to compute the response according to the properties of phased.HeterogeneousULA. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.HeterogeneousULA creates a heterogeneous uniform linear array (ULA) System object, H. The object models a heterogeneous ULA formed with generally different sensor elements. The origin of the local coordinate system is the phase center of the array. The positive *x*-axis is the direction normal to the array, and the elements of the array are located along the *y*-axis.

H = phased.HeterogeneousULA(Name,Value) creates object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

**ElementSet**

Set of elements used in the array

Specify the set of different elements used in the sensor array as a row MATLAB cell array. Each member of the cell array contains an element object in the phased package. Elements specified in the `ElementSet` property must be either all antennas or all microphones. In addition, all specified antenna elements should have same polarization capability. Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

**Default:** One cell containing one isotropic antenna element

**ElementIndices**

Elements location assignment

This property specifies the mapping of elements in the array. The property assigns elements to their locations in the array using indices into the `ElementSet` property. `ElementIndices` must be a 1-by-*N* row vector where *N* is greater than 1. *N* is the number of elements in the sensor array. The values in `ElementIndices` should be less than or equal to the number of entries in the `ElementSet` property.

**Default:** `[1 1]`

**ElementSpacing**

Element spacing

A scalar containing the spacing (in meters) between two adjacent elements in the array.

**Default:** `0.5`

**ArrayAxis**

Array axis

Array axis, specified as one of `'x'`, `'y'`, or `'z'`. ULA array elements are located along the selected coordinate system axis.

Element normal vectors are determined by the selected array axis

| ArrayAxis Property Value | Element Normal Direction |
|---|---|
| 'x' | azimuth = 90°, elevation = 0° (*y*-axis) |
| 'y' | azimuth = 0°, elevation = 0° (*x*-axis) |
| 'z' | azimuth = 0°, elevation = 0° (*x*-axis) |

**Default:** 'y'

### Taper

Element tapering

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. The quantity *N* is the number of elements in the array as determined by the size of the ElementIndices property. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If 'Taper' is a scalar, the same taper value is applied to all elements. If 'Taper' is a vector, each taper value is applied to the corresponding sensor element.

**Default:** 1

## Examples

### Power pattern of 10-Element Heterogeneous ULA Array

Create a 10-element heterogeneous ULA consisting of cosine antenna elements with different power exponents. Two elements at each end have power values of 1.5 while the inside elements have power exponents of 1.8. Find the power pattern in dB of each element at boresight.

Construct the heterogeneous array and show the element responses at 1 GHz.

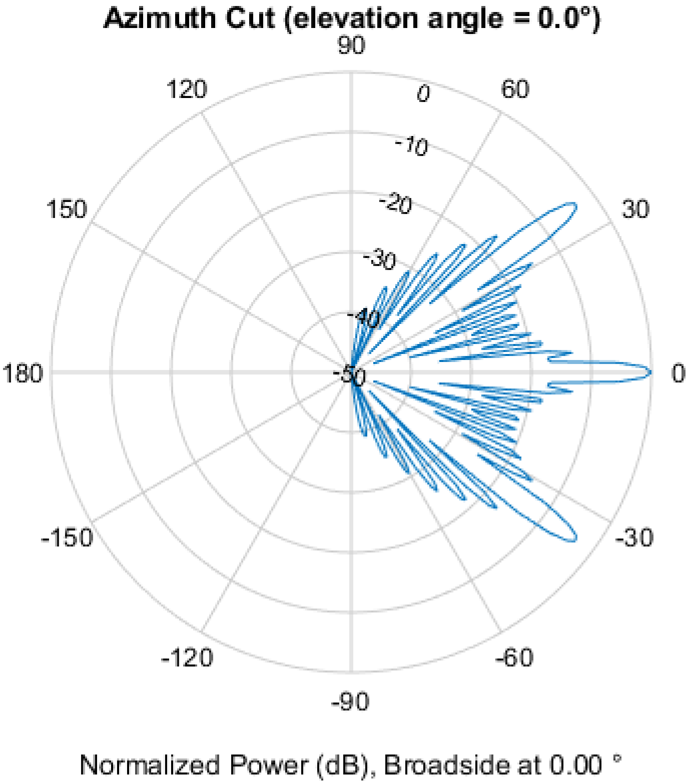
```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 2 2 2 2 2 2 1 1 ]);
fc = 1e9;
ang = [0;0];
resp = step(sArray,fc,ang)
```

```
resp =

     1
     1
     1
     1
     1
     1
     1
     1
     1
     1
```

Plot an azimuth cut of the array response at 1 GHz.

```
c = physconst('LightSpeed');
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar');
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb');
```



### Pattern of Array of Polarized Short-Dipole Antennas

Construct a heterogeneous uniform line array of 10 short-dipole sensor elements. Because short dipoles support polarization, the array should also. Verify that the array supports polarization by looking at the output of `isPolarizationCapable`. Then, draw the array, showing the tapering.

### Construct the array

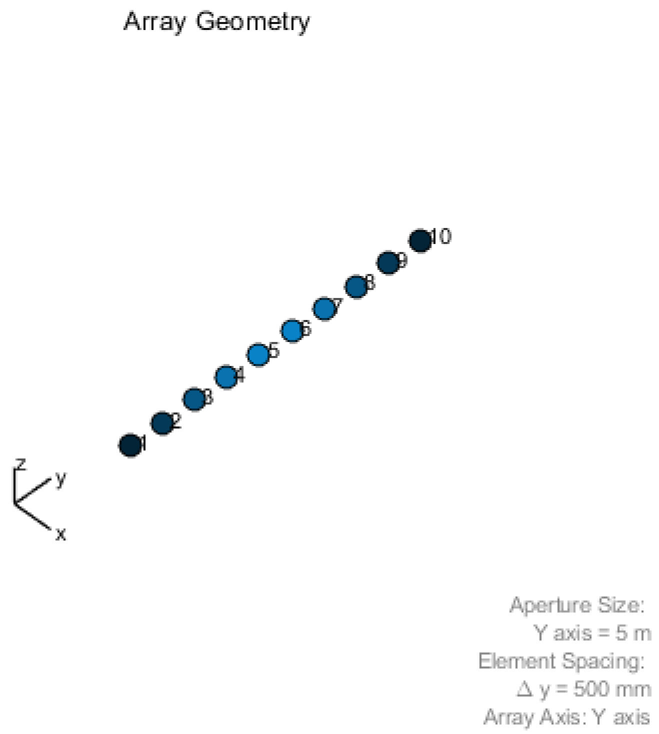
Construct the array. Then, verify that it supports polarization by looking at the returned value of the `isPolarizationCapable` method.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 2 2 2 2 2 2 1 1 ],...
    'Taper',taylorwin(10)');
isPolarizationCapable(sArray)
```

```
ans = logical
   1
```

### View the array

```
viewArray(sArray,'ShowTaper',true,'ShowIndex',...
    'All','ShowTaper',true)
```



### Show the response

Show the element horizontal polarization responses at 10 degrees azimuth angle.

```
fc = 150e6;
ang = [10];
resp = step(sArray,fc,ang)

resp = struct with fields:
    H: [10x1 double]
    V: [10x1 double]

resp.H
```

```
ans = 10×1

         0
         0
   -1.2442
   -1.6279
   -1.8498
   -1.8498
   -1.6279
   -1.2442
         0
         0
```

### Plot the combined polarization response

```
c = physconst('LightSpeed');
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined');
```

# directivity

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Directivity of heterogeneous uniform linear array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` computes the “Directivity (dBi)” on page 1-854 of a heterogeneous uniform linear array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### H — Heterogeneous uniform linear array

System object

Heterogeneous uniform linear array, specified as a `phased.HeterogeneousULA` System object.

Example: `H = phased.HeterogeneousULA;`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

### ANGLE — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

# Output Arguments

### D — Directivity

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

# Examples

### Directivity of Heterogeneous Uniform Linear Array

Compute the directivity of a 10-element heterogeneous ULA consisting of cosine antenna elements with different power factors. The two elements at each end have power values of 1.5 while the inner elements have power values of 1.8.

Construct the heterogeneous array. Set the signal frequency to 1 GHz.

```
c = physconst('LightSpeed');
freq = 1e9;
ang = [30;0];
lambda = c/freq;
```

Create the cosine antenna elements.

```
myElement1 = phased.CosineAntennaElement;
myElement1.CosinePower = 1.5;
myElement2 = phased.CosineAntennaElement;
myElement2.CosinePower = 1.8;
```

Create the Heterogeneous ULA.

```
myArray = phased.HeterogeneousULA;
myArray.ElementSet = {myElement1,myElement2};
myArray.ElementIndices = [1 1 2 2 2 2 2 2 1 1 ];
myArray.ElementSpacing = 0.5*lambda;
```

Create the steering vector and compute the directivity in the same direction as the steering vector.

```
w = steervec(getElementPosition(myArray)/lambda,ang);
d = directivity(myArray,freq,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d = 17.0102
```

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# collectPlaneWave

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

# Output Arguments

**Y**

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

# Examples

### Simulate Received Signals at Heterogeneous ULA

Simulate two received signal at a heterogeneous 4-element ULA. The signals arrive from 10° and 30° degrees azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 1]);
```

Create a random plane wave signals.

```
y = collectPlaneWave(array,randn(4,2),[10 30],1e8,physconst('LightSpeed'));
```

Display the signal at the first element.

```
y(:,1)
```

```
ans = 4×1 complex

   0.7430 - 0.3705i
   0.8418 + 0.4308i
  -2.4817 + 0.9157i
   1.0724 - 0.4748i
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

# getElementNormal

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Normal vector to array elements

## Syntax

```
normvec = getElementNormal(sULA)
normvec = getElementNormal(sULA,elemidx)
```

## Description

`normvec = getElementNormal(sULA)` returns the normal vectors of the array elements of the `phased.HeterogeneousULA` System object, `sULA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sULA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form`[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sULA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Input Arguments

**`sULA` — Uniform line array**
`phased.HeterogeneousULA` System object

Uniform line array, specified as a `phased.HeterogeneousULA` System object.

Example: `sULA = phased.HeterogeneousULA`

**elemidx — Element indices**
all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

## Output Arguments

**normvec — Element normal vectors**
2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

## Examples

### Heterogeneous ULA Element Normals

Construct three 5-element heterogeneous ULA's with elements along the *x*-, *y*-, and *z*-axes. Obtain the element normals.

Create two types of cosine antennas.

```
sCosAnt1 = phased.CosineAntennaElement('CosinePower',[1.5,1.5]);
sCosAnt2 = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
```

First, choose the array axis to lie along the *x*-axis.

```
sULA1 = phased.HeterogeneousULA('ElementSet',{sCosAnt1,sCosAnt2},...
    'ElementIndices',[1 2 2 2 1],'ArrayAxis','x');
norm = getElementNormal(sULA1)
```

```
norm = 2×5
```

```
    90    90    90    90    90
     0     0     0     0     0
```

The element normal vectors point along the *y*-axis.

Next, choose the array axis along the *y*-axis.

```
sULA2 = phased.HeterogeneousULA('ElementSet',{sCosAnt1,sCosAnt2},...
    'ElementIndices',[1 2 2 2 1],'ArrayAxis','y');
norm = getElementNormal(sULA2)
```

```
norm = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

The element normal vectors point along the *x*-axis.

Finally, set the array axis along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sULA3 = phased.HeterogeneousULA('ElementSet',{sCosAnt1,sCosAnt2},...
    'ElementIndices',[1 2 2 2 1],'ArrayAxis','z');
norm = getElementNormal(sULA3,[1,3,5])
```

```
norm = 2×3

     0     0     0
     0     0     0
```

The element normal vectors also point along the *x*-axis.

**Introduced in R2016a**

# getElementPosition

**System object:** phased.HeterogeneousULA
**Package:** phased

Positions of array elements

## Syntax

```
pos = getElementPosition(sHULA)
pos = getElementPosition(sHULA,elemidx)
```

## Description

`pos = getElementPosition(sHULA)` returns the element positions of the `phased.HeterogeneousULA` System object, `sHULA`. `pos` is a 3-by-*N* matrix, where *N* is the number of elements in `sHULA`. Each column of `pos` defines the position of an element in the local coordinate system, in meters, using the form `[x;y;z]`. The origin of the local coordinate system is the phase center of the array. The positions of the array elements depend upon the value of the `ArrayAxis` property.

`pos = getElementPosition(sHULA,elemidx)` returns only the positions of the elements that are specified in the element index vector `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Position of Heterogeneous ULA Elements

Construct a 4-element heterogeneous ULA of different types of short-dipole antenna elements. Then, obtain the element positions.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
```

```
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 1]);
pos = getElementPosition(sArray)
```

```
pos = 3×4

         0         0         0         0
   -0.7500   -0.2500    0.2500    0.7500
         0         0         0         0
```

# getNumElements

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Number of elements in array

## Syntax

```
N = getNumElements(array)
```

## Description

`N = getNumElements(array)` returns the number of elements, *N*, in the heterogeneous ULA object `array`.

## Examples

### Number of Elements of Heterogeneous ULA

Construct a 4-element heterogeneous ULA. Then verify the number of elements in the array.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 1]);
N = getNumElements(array)
```

```
N = 4
```

# getTaper

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Array element tapers

## Syntax

```
wts = getTaper(array)
```

## Description

`wts = getTaper(array)` returns the tapers, `wts`, applied to each element of the phased heterogeneous uniform line array (ULA), `h`. Tapers are often referred to as weights.

## Input Arguments

### `array` — Heterogeneous uniform line array

`phased.HeterogeneousULA` System object

Heterogeneous uniform line array, specified as a `phased.HeterogeneousULA` System object.

## Output Arguments

### `wts` — Array element tapers

*N*-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1 complex-valued vector, where *N* is the number of elements in the array.

## Examples

### Heterogeneous ULA with Taylor Window Taper

Construct a 5-element heterogeneous ULA with a Taylor window taper. The array consists of short-dipole antenna elements with different orientations.Then, obtain the element taper values.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 2 1],'Taper',taylorwin(5)');
w = getTaper(array)
```

```
w = 5×1

    0.5181
    1.2029
    1.5581
    1.2029
    0.5181
```

# isPolarizationCapable

**System object:** phased.HeterogeneousULA
**Package:** phased

Polarization capability

## Syntax

```
flag = isPolarizationCapable(array)
```

## Description

flag = isPolarizationCapable(array) returns a Boolean value, flag, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

**array — Heterogeneous uniform line array**
phased.HeterogeneousULA System object

Heterogeneous uniform line array, specified as a phased.HeterogeneousULA System object.

## Output Arguments

**flag — Polarization-capability flag**

Polarization-capability flag, returned as a Boolean value 1 if the array supports polarization or 0 if it does not.

# Examples

### Heterogeneous ULA of Short-Dipole Antenna Elements Supports Polarization

Show that a heterogeneous array of short-dipole antenna elements supports polarization.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 2 1]);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

# pattern

**System object:** phased.HeterogeneousULA
**Package:** phased

Plot heterogeneous ULA pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

pattern(sArray,FREQ) plots the 3-D array directivity pattern (in dBi) for the array specified in sArray. The operating frequency is specified in FREQ.

pattern(sArray,FREQ,AZ) plots the array directivity pattern at the specified azimuth angle.

pattern(sArray,FREQ,AZ,EL) plots the array directivity pattern at specified azimuth and elevation angles.

pattern( ___ ,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

[PAT,AZ_ANG,EL_ANG] = pattern( ___ ) returns the array pattern in PAT. The AZ_ANG output contains the coordinate values corresponding to the rows of PAT. The EL_ANG output contains the coordinate values corresponding to the columns of PAT. If the 'CoordinateSystem' parameter is set to 'uv', then AZ_ANG contains the *U* coordinates of the pattern and EL_ANG contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-880 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sArray` — Heterogeneous ULA

System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousULA` System object.

Example: `sArray= phased.HeterogeneousULA;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

**EL — Elevation angles**
`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`CoordinateSystem` — Plotting coordinate system**
`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

**PropagationSpeed — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**Weights — Array weights**
1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**`PAT` — Array pattern**
*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

**`AZ_ANG` — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

**`EL_ANG` — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Azimuth Power Pattern For Two Frequencies

Create a 5-element heterogeneous ULA from short-dipole antenna elements with different axis directions. Draw the azimuth power pattern for the horizontal polarization component at 0 degrees elevation for two frequencies, 300 MHz and 400 MHz.

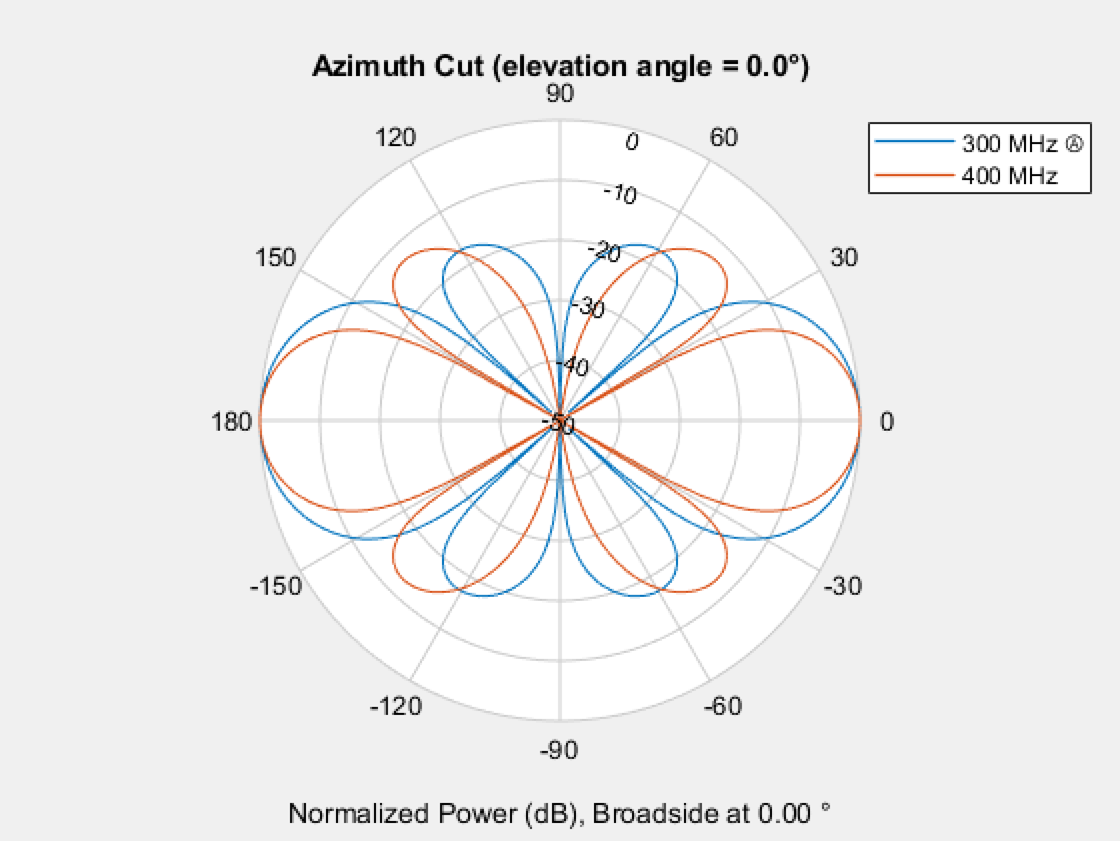
#### Construct Heterogeneous ULA

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
```

#### Plot the patterns

```
fc = [300e6 400e6];
c = physconst('LightSpeed');
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'PlotStyle','overlay',...
    'Polarization','H')
```



### Directivity Pattern in UV Space

Create an 11-element heterogeneous ULA from short-dipole antenna elements with different axis directions. Draw the 3-D power pattern for the horizontal polarization component at 300 MHz.

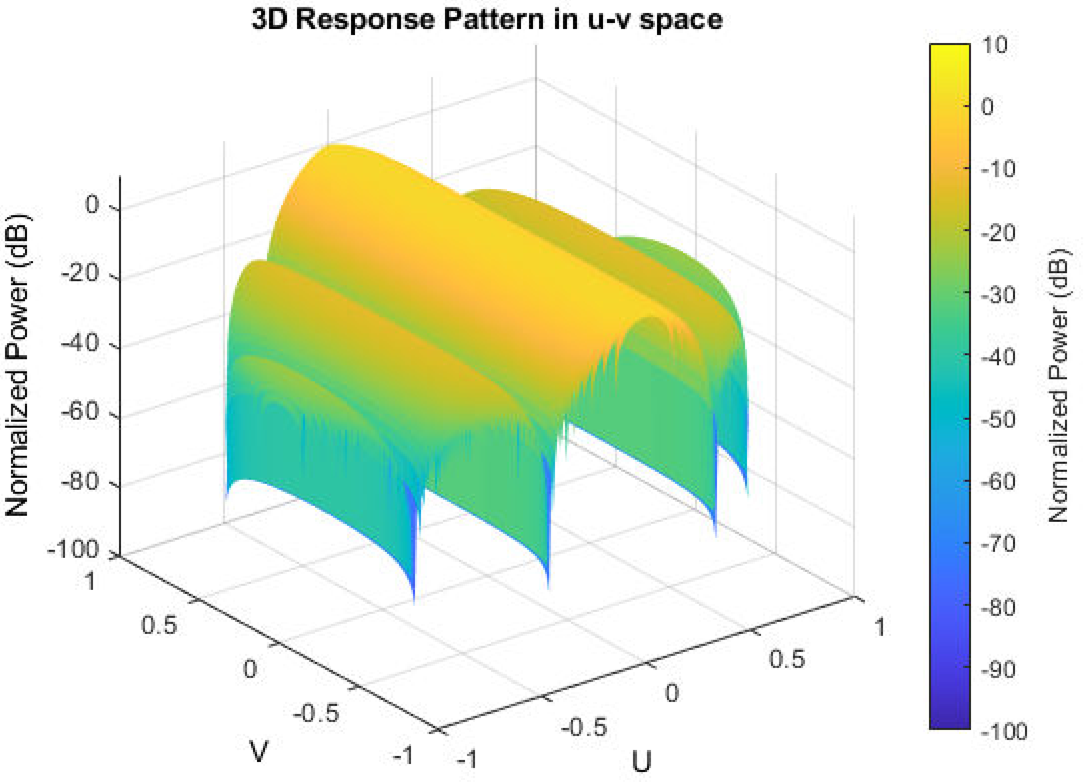
### Construct Heterogeneous ULA

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 2 2 2 2 2 1 1 1]);
```

**Plot the patterns**

```
fc = 300e6;
c = physconst('LightSpeed');
pattern(sArray,fc,-1:.01:1,-1:.01:1,...
    'PropagationSpeed',c,...
    'CoordinateSystem','uv',...
    'Type','powerdb',...
    'Polarization','H')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or <i>UV</i> space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>

## See Also

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Plot heterogeneous ULA directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**`sArray` — Heterogeneous ULA**
System object

Heterogeneous ULA, specified as a `phased.HeterogeneousULA` System object.

Example: `sArray= phased.HeterogeneousULA;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Type — Displayed pattern type**
`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

**`PropagationSpeed` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**`Weights` — Array weights**
*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `Azimuth` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Azimuth Directivity Pattern For Steered Array

Create an 11-element heterogeneous ULA from short-dipole antenna elements with different axis directions. The element spacing is 0.4 meters. Draw the azimuthal directivity pattern for 0 degrees elevation at an operating frequency of 300 MHz. Then, steer the array and draw the azimuthal directivity pattern.

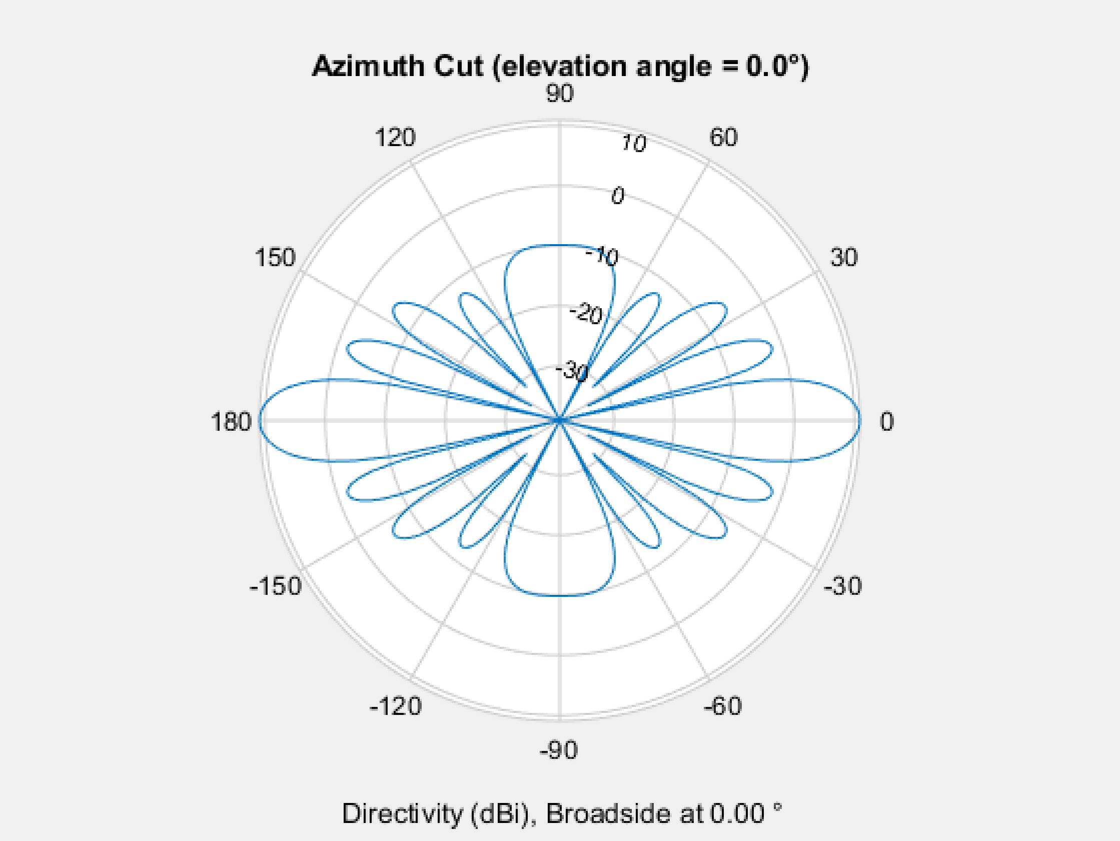
### Construct Heterogeneous ULA

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSpacing',0.4,...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 2 2 2 2 2 1 1 1]);
```

### Plot Directivity Pattern

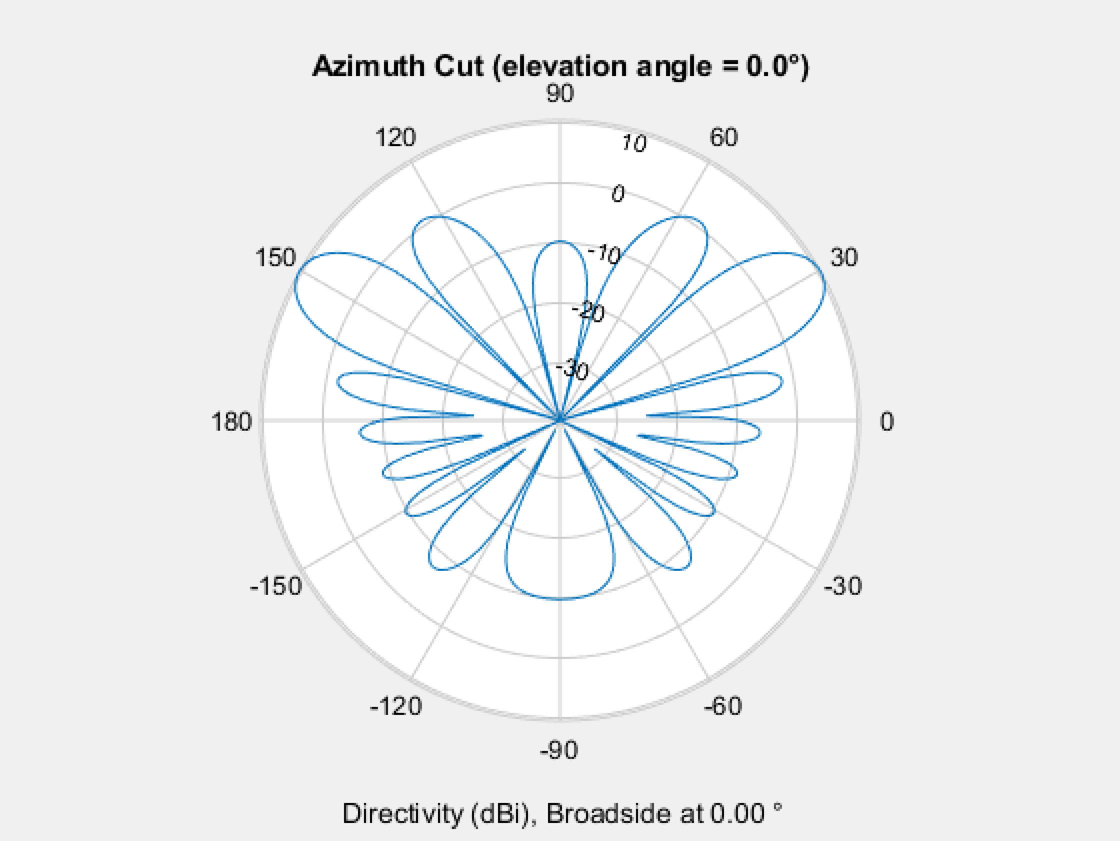
```
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
patternAzimuth(sArray,fc,0,...
    'PropagationSpeed',c,...
    'Type','directivity')
```



### Steer Array and Plot Directivity Pattern

Steer the array to 30 degrees in azimuth by applying weights to achieve a linear phase shift.

```
theta = 30;
d = [0:10]*0.4;
ph = 2*pi*d'/lam*sind(theta);
wts = exp(1i*ph);
patternAzimuth(sArray,fc,0,...
    'PropagationSpeed',c,...
    'Type','directivity',....
    'Weights',wts)
```



## More About

### Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Package:** phased

Plot heterogeneous ULA directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(sArray,FREQ) plots the 2-D array directivity pattern versus elevation (in dBi) for the array sArray at zero degrees azimuth angle. When AZ is a vector, multiple overlaid plots are created. The argument FREQ specifies the operating frequency.

patternElevation(sArray,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(sArray,FREQ,AZ,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the array pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**sArray — Heterogeneous ULA**
System object

Heterogeneous ULA array, specified as a `phased.HeterogeneousULA` System object.

Example: `sArray= phased.HeterogeneousULA;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

**AZ — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Type` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Elevation` — Elevation angles**
`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

# Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

# Examples

### Elevation Power Pattern For Two Azimuth Directions

Create an 11-element heterogeneous ULA from short-dipole antenna elements with different axis directions. The element spacing is 0.4 meters. Draw the elevation power pattern for 0 and 30 degrees azimuth for 300 MHz.

### Construct Heterogeneous ULA

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSpacing',0.4,...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 2 2 2 2 2 1 1 1]);
```

### Plot Directivity Pattern

```
fc = 300e6;
c = physconst('LightSpeed');
patternElevation(sArray,fc,[0,30],...
    'PropagationSpeed',c,...
    'Type','directivity')
```

```

## Description

plotResponse(H,FREQ,V) plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in FREQ. The propagation speed is specified in V.

plotResponse(H,FREQ,V,Name,Value) plots the array response with additional options specified by one or more Name,Value pair arguments.

hPlot = plotResponse( ___ ) returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

### H

Array object

### FREQ

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of H. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has no

response at frequencies outside that range. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

**`V`**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`CutAngle`**

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

**`Format`**

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

**`NormalizeResponse`**

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### OverlayFreq

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, FREQ must be a vector with at least two entries.

This parameter applies only when Format is not 'Polar' and RespCut is not '3D'.

**Default:** true

### Polarization

Specify the polarization options for plotting the array response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimensions | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

### ElevationAngles

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

**Default:** `[-90:90]`

### UGrid

*U* coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

### VGrid

*V* coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

## Examples

### Line Plot Showing Multiple Frequencies

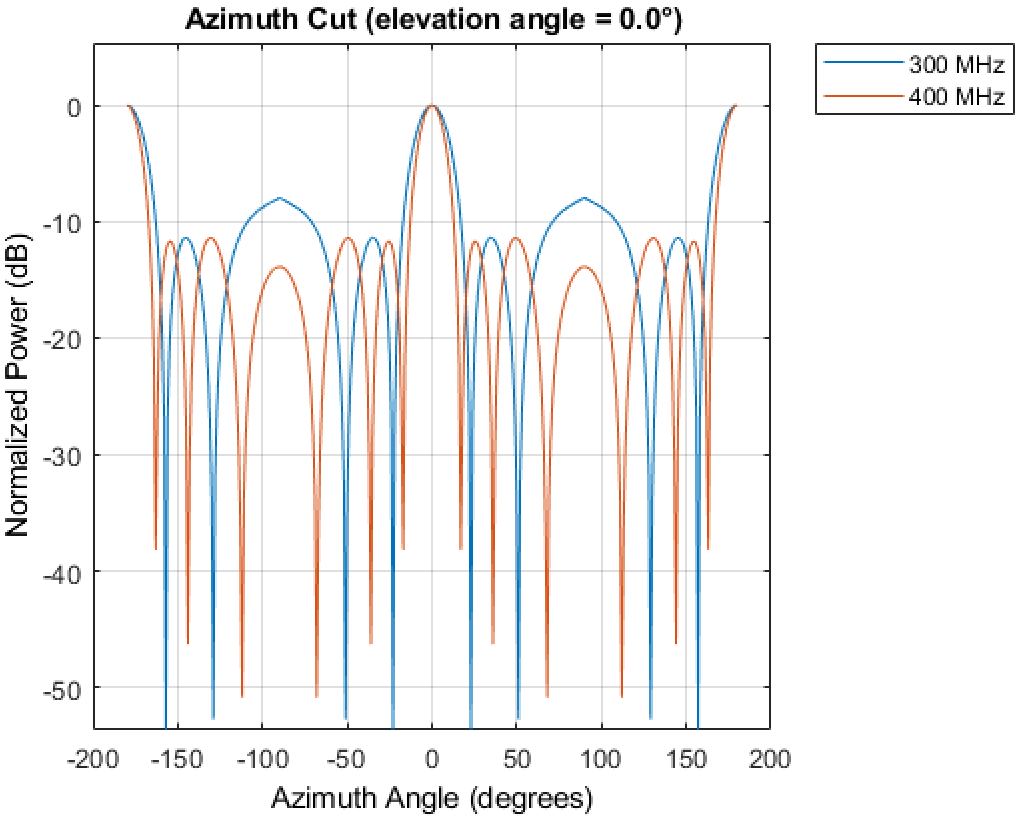
Using a line plot, show the azimuth cut response of a 5-element heterogeneous uniform linear array along 0 degrees elevation. The plot shows the responses at operating frequencies of 200 MHz and 400 MHz.

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
```

Plot the response.

```
fc = [3e8 4e8];
c = physconst('LightSpeed');
plotResponse(sArray,fc,c);
```



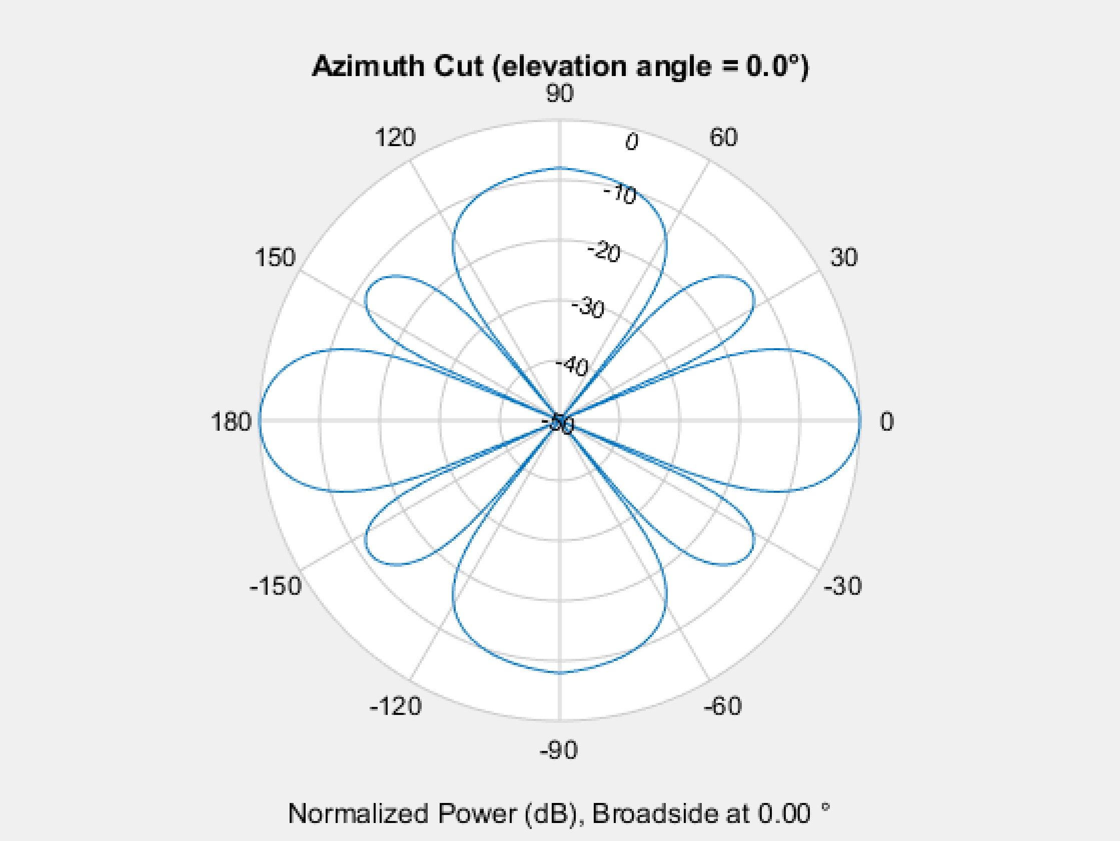
### Plot Response and Directivity for 5-Element Array

Construct a 5-element heterogeneous ULA of short-dipole antenna elements. Using the `plotResponse` method, plot the array's azimuth response in polar format. Assume each element's operating frequency spans 200-500 MHz and the wave propagation speed is the speed of light.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
```

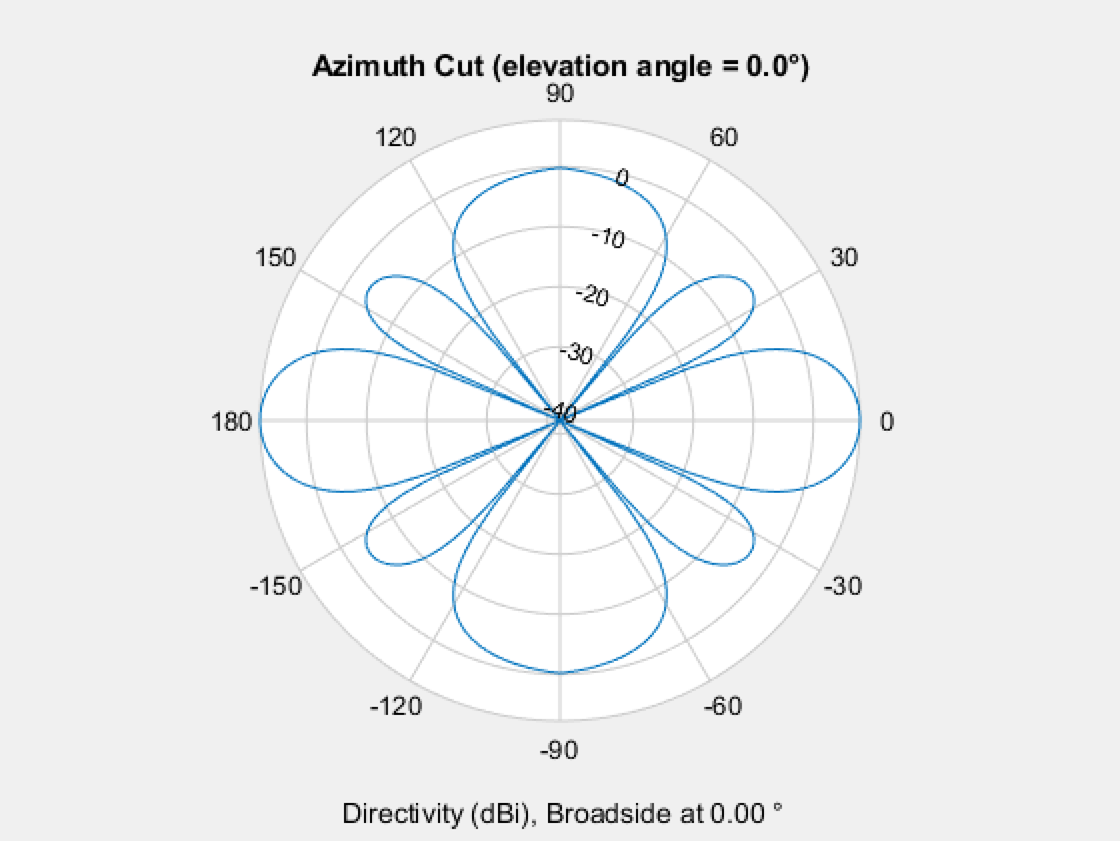
Plot the response at 300 MHz.

```
fc = 3e8;
c = physconst('LightSpeed');
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar');
```



Plot the directivity of the array at 300 MHz.

```
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar',...
    'Unit','dbi');
```



### Plot Response for 9-Element Array with Two Weight Sets

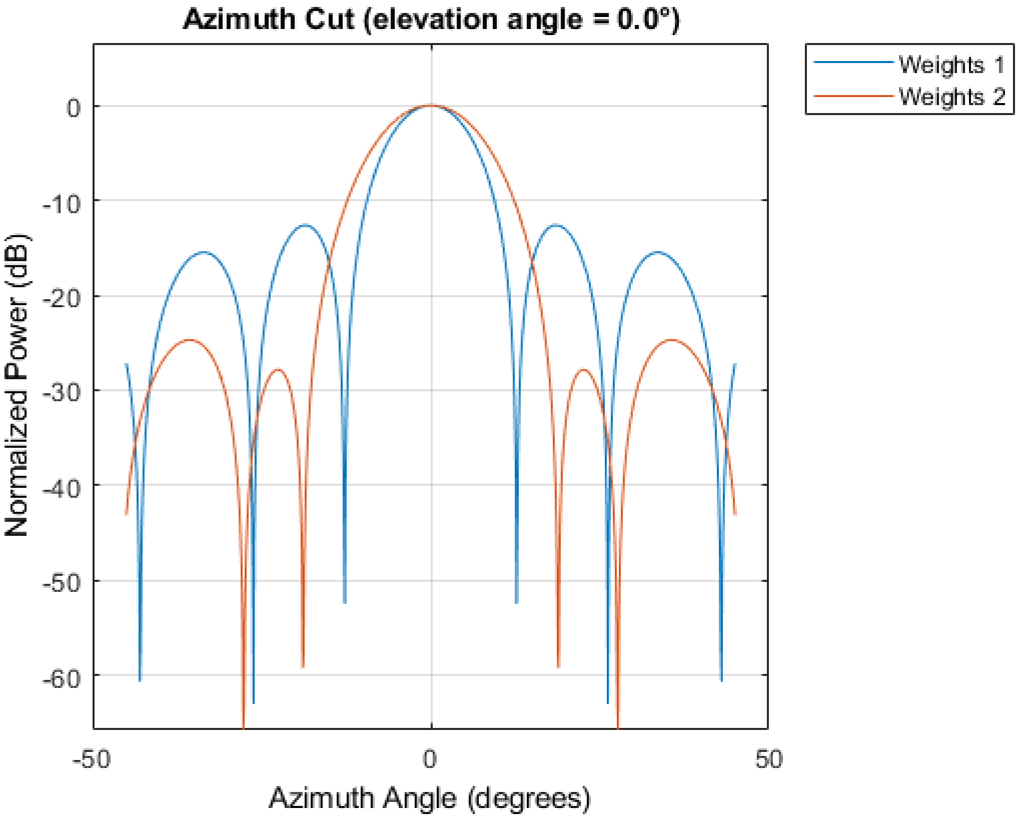
Construct a 9-element heterogeneous ULA of short-dipole antenna elements having different orientations. Assume each element response is in the frequency range 200-500 MHz. Using the `plotResponse` method, plot the array's azimuth response in polar format. Use the `Weights` parameter to set two different sets of tapering weights: a uniform tapering and a Taylor tapering. Use the `AzimuthAngles` parameter to restrict the display range from -45 to 45 degrees in 0.1 degree increments.

Construct the array.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 2 2 2 2 2 1 1]);
```

Plot the response at 300 MHz.

```
fc = 3e8;
wts1 = ones(9,1);
wts2 = taylorwin(9);
c = physconst('LightSpeed');
plotResponse(sArray,fc,c,'RespCut','Az',...
    'AzimuthAngles',[-45:0.1:45],...
    'Weights',[wts1,wts2]);
```



As expected, the tapered weighting broadens the mainlobe and reduces the sidelobes.

# step

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

Output responses of array elements

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array elements' responses `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Array object

### FREQ

Operating frequencies of array in hertz. FREQ is a row vector of length *L*. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

### ANG

Directions in degrees. ANG is either a 2-by-*M* matrix or a row vector of length *M*.

If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

## Output Arguments

### RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array’s horizontal polarization response, while RESP.V represents the array’s vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each

of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

## Examples

### Heterogeneous ULA of Cosine Antenna Elements

Create a 5-element heterogeneous ULA of cosine antenna elements with difference responses, and find the response of each element at 30° azimuth.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
array = phased.HeterogeneousULA(...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 2 2 2 1]);
fc = 1e9;
c = physconst('LightSpeed');
ang = [30;0];
resp = array(fc,ang)
```

```
resp = 5×1

    0.8059
    0.7719
    0.7719
    0.7719
    0.8059
```

### Response of Heterogeneous Microphone ULA Array

Find the response of a heterogeneous ULA array of 7 custom microphone elements with different responses.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

Create two microphones with different response patterns.

```
mic1 = phased.CustomMicrophoneElement(...
    'FrequencyResponse',[20 20e3]);
mic1.PolarPatternFrequencies = [500 1000];
mic1.PolarPattern = mag2db([...
    0.5+0.5*cosd(mic1.PolarPatternAngles);...
    0.6+0.4*cosd(mic1.PolarPatternAngles)]);
mic2 = phased.CustomMicrophoneElement(...
    'FrequencyResponse',[20 20e3]);
mic2.PolarPatternFrequencies = [500 1000];
mic2.PolarPattern = mag2db([...
    ones(size(mic2.PolarPatternAngles));...
    ones(size(mic2.PolarPatternAngles))]);
```

Create the heterogeneous ULA.

```
array = phased.HeterogeneousULA(...
    'ElementSet',{mic1,mic2},...
    'ElementIndices',[1 1 2 2 2 1 1]);
```

Find the array response at 40° and 50° azimuth.

```
fc = [1500, 2000];
ang = [40 50; 0 0];
resp = array(fc,ang)
```

```
resp = 
resp(:,:,1) =

    9.0642    8.5712
    9.0642    8.5712
   10.0000   10.0000
   10.0000   10.0000
   10.0000   10.0000
    9.0642    8.5712
    9.0642    8.5712

resp(:,:,2) =

    9.0642    8.5712
    9.0642    8.5712
   10.0000   10.0000
   10.0000   10.0000
   10.0000   10.0000
    9.0642    8.5712
    9.0642    8.5712
```

# viewArray

**System object:** `phased.HeterogeneousULA`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**ShowIndex**

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

**ShowNormals**

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

**ShowTaper**

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

**Title**

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

**hPlot**

Handle of array elements in figure window.

## Examples

### Geometry and Indices of Heterogeneous ULA Elements

Display the geometry of a 5-element heterogeneous ULA of cosine antenna elements, showing the indices for the first three elements.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
viewArray(sArray,'ShowIndex',[1:3])
```

# phased.HeterogeneousURA

**Package:** `phased`

Heterogeneous uniform rectangular array

## Description

The `HeterogeneousURA` object constructs a heterogeneous uniform rectangular array (URA).

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform rectangular array. See "Construction" on page 1-921.
2. Call `step` to compute the response according to the properties of `phased.HeterogeneousURA`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.HeterogeneousURA` creates a heterogeneous uniform rectangular array (URA) System object, `H`. This object models a heterogeneous URA formed with sensor elements whose pattern may vary from element to element. Array elements are distributed in the *yz*-plane in a rectangular lattice. An *M*-by-*N* heterogeneous URA has *M* rows and *N* columns. The array boresight direction is along the positive *x*-axis. The default array is a 2-by-2 URA of isotropic antenna elements.

`H = phased.HeterogeneousURA(Name,Value)` creates the object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `ElementSet`

Set of elements used in the array

Specify the set of different elements used in the sensor array as a row MATLAB cell array. Each member of the cell array contains an element object in the phased package. Elements specified in the `ElementSet` property must be either all antennas or all microphones. In addition, all specified antenna elements should have same polarization capability. Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

**Default:** One cell containing one isotropic antenna element

### `ElementIndices`

Elements location assignment

This property specifies the mapping of elements in the array. The property assigns elements to their locations in the array using the indices into the `ElementSet` property. The value of `ElementIndices` must be an *M*-by-*N* matrix. In this matrix, *M* represents the number of rows and *N* represents the number of columns. Rows are along *y*-axis and columns are along *z*-axis of the local coordinate system. The values in the matrix specified by `ElementIndices` should be less than or equal to the number of entries in the `ElementSet` property.

**Default:** `[1 1;1 1]`

### `ElementSpacing`

Element spacing

A 1-by-2 vector or a scalar containing the element spacing (in meters) of the array. If `ElementSpacing` is a 1-by-2 vector, it is in the form of `[SpacingBetweenRows,SpacingBetweenColumns]`. See “Spacing Between Columns” on page 1-927 and “Spacing Between Rows” on page 1-927. If `ElementSpacing` is a scalar, both spacings are the same.

**Default:** `[0.5 0.5]`

### `Lattice`

Element lattice

Specify the element lattice as one of `'Rectangular' | 'Triangular'`. When you set the Lattice property to `'Rectangular'`, all elements in the heterogeneous URA are aligned in both row and column directions. When you set the `Lattice` property to `'Triangular'`, the elements in even rows are shifted toward the positive row axis direction by a distance of half the element spacing along the row.

**Default:** `'Rectangular'`

### `ArrayNormal`

Array normal direction

Array normal direction, specified as one of `'x'`, `'y'`, or `'z'`.

URA elements lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction

| ArrayNormal Property Value | Element Positions and Boresight Directions |
|---|---|
| `'x'` | Array elements lie on the *yz*-plane. All element boresight vectors point along the *x*-axis. |
| `'y'` | Array elements lie on the *zx*-plane. All element boresight vectors point along the *y*-axis. |
| `'z'` | Array elements lie on the *xy*-plane. All element boresight vectors point along the *z*-axis. |

**Default:** `'x'`

### `Taper`

Element tapers

Element tapers, specified as a complex-valued scalar, or a complex-valued 1-by-*MN* row vector, *MN*-by-1 column vector, or *M*-by-*N* matrix. Tapers are applied to each element in the sensor array. Tapers are often referred to as element weights. *M* is the number of elements along the *z*-axis, and *N* is the number of elements along *y*-axis. *M* and *N* correspond to the values of `[NumberofRows, NumberOfColumns]` in the `Size` property. If `Taper` is a scalar, the same taper value is applied to all elements. If the value of `Taper` is a vector or matrix, taper values are applied to the corresponding elements. Tapers are used to modify both the amplitude and phase of the received data.

**Default:** 1

## Methods

| | |
|---|---|
| directivity | Directivity of heterogeneous uniform rectangular array |
| collectPlaneWave | Simulate received plane waves |
| getElementNormal | Normal vector to array elements |
| getElementPosition | Positions of array elements |
| getNumElements | Number of elements in array |
| getTaper | Array element tapers |
| isPolarizationCapable | Polarization capability |
| pattern | Plot heterogeneous URA directivity and power pattern |
| patternAzimuth | Plot heterogeneous URA directivity or pattern versus azimuth |
| patternElevation | Plot heterogeneous ULA directivity or pattern versus elevation |
| plotResponse | Plot response pattern of array |
| step | Output responses of array elements |
| viewArray | View array geometry |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Azimuth Pattern of 3-by-2 Heterogeneous URA

Construct a 3-by-2 heterogeneous URA with a rectangular lattice, and find the response of each element at 30 degrees azimuth and 0 degrees elevation. Assume the operating frequency is 1 GHz.

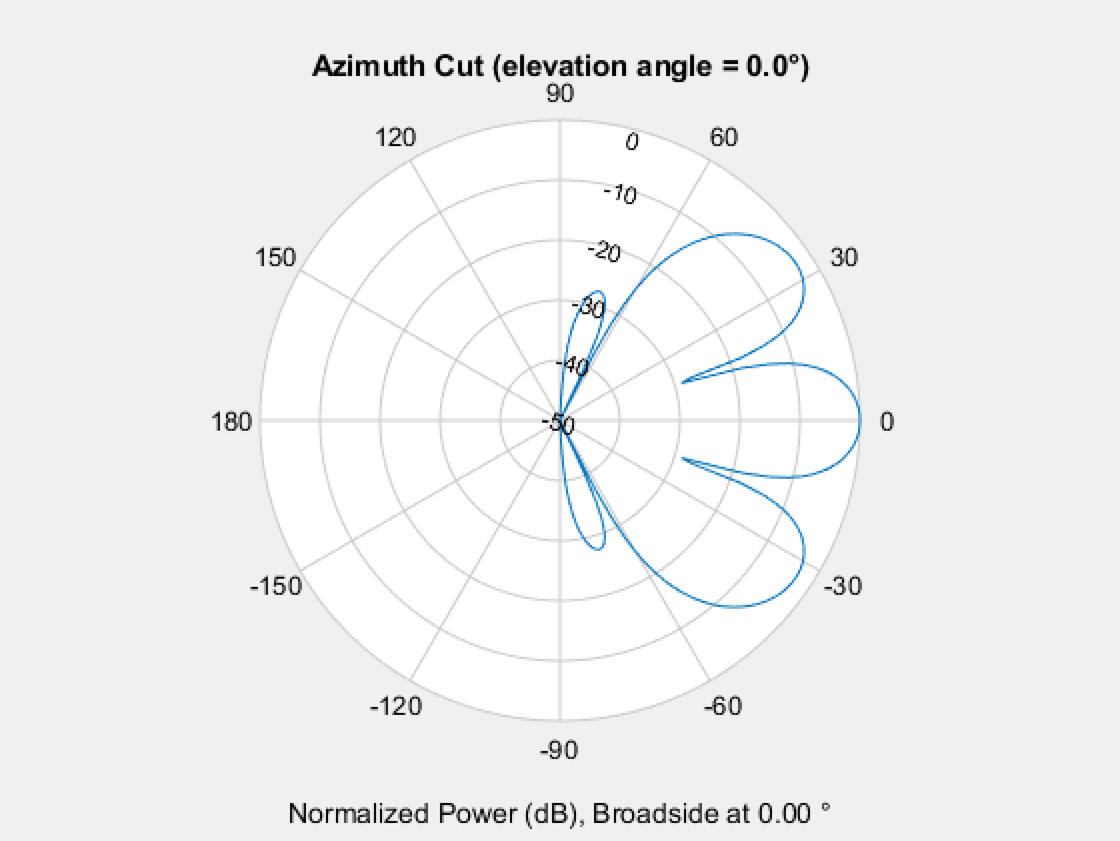
```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 1; 2 2; 1 1]);
fc = 1e9;
ang = [30;0];
resp = array(fc,ang)
```

```
resp = 6×1

    0.8059
    0.7719
    0.8059
    0.8059
    0.7719
    0.8059
```

Plot the azimuth pattern of the array.

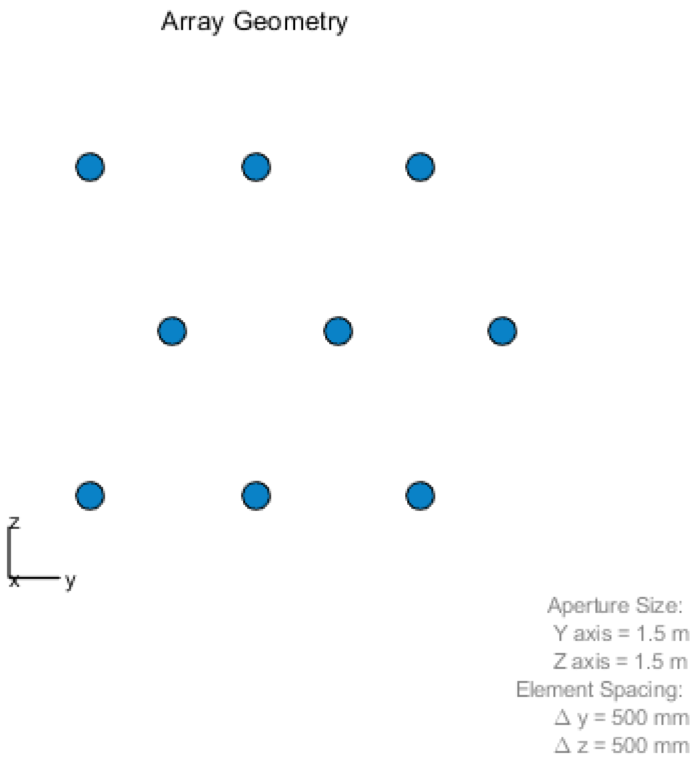
```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','polar','Type','powerdb','Normalize',true)
```



### Draw Heterogeneous Triangular Lattice Array

Construct a 3-by-3 heterogeneous URA with a triangular lattice. The element spacing is 0.5 meter. Display the array shape.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1],...
    'Lattice','Triangular');
viewArray(sArray);
```



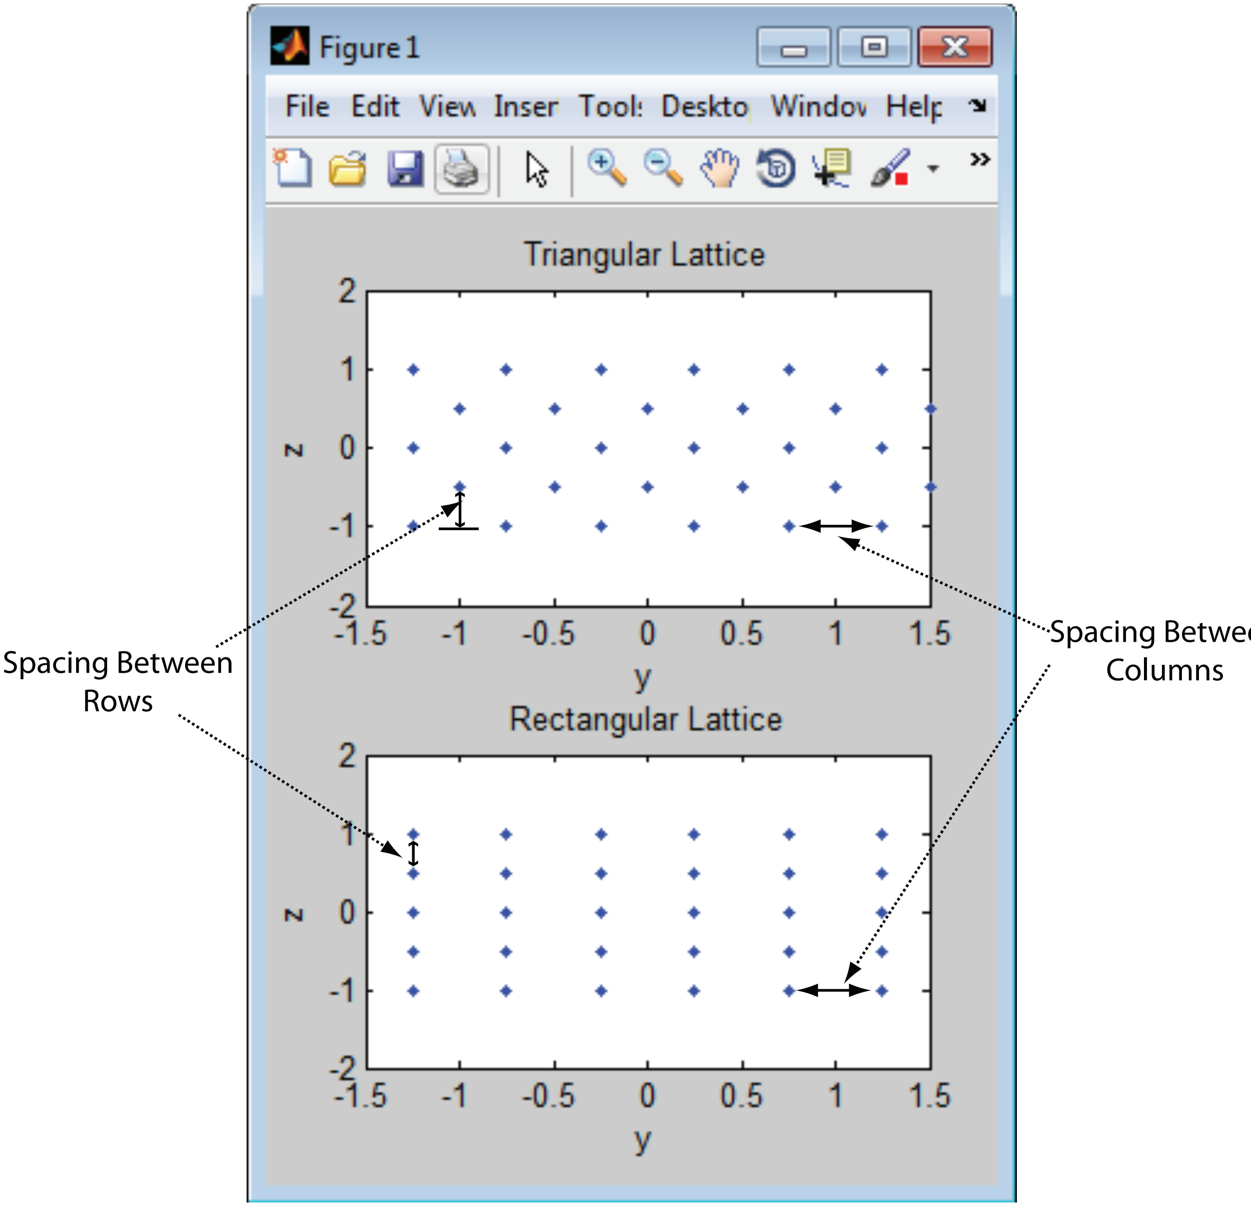
# More About

## Spacing Between Columns

The spacing between columns is the distance between adjacent elements in the same row.

## Spacing Between Rows

The spacing between rows is the distance along the column axis direction between adjacent rows.



Spacing Between Rows

Spacing Betwe Columns

# directivity

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Directivity of heterogeneous uniform rectangular array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` computes the “Directivity (dBi)” on page 1-935 of a heterogeneous uniform rectangular array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `H` — Heterogeneous uniform rectangular array

System object

Uniform rectangular array specified as a `phased.HeterogeneousURA` System object.

Example: `H = phased.HeterogeneousURA`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

**`ANGLE` — Angles for computing directivity**
1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### D — Directivity

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Heterogeneous Uniform Rectangular Array

Compute the directivity of a 9-element 3-by-3 heterogeneous URA consisting of short-dipole antenna elements. The three elements on the middle row are Y-directed while all the remaining elements are Z-directed.

Set the signal frequency to 1 GHz.

```
c = physconst('LightSpeed');
freq = 1e9;
lambda = c/freq;
```

Create the array of short-dipole antenna elements. The elements have frequency ranges from 0 to 10 GHz.

```
myElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[0 10e9],...
    'AxisDirection','Z');
myElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[0 10e9],...
    'AxisDirection','Y');
myArray = phased.HeterogeneousURA(...
    'ElementSet',{myElement1,myElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
```

Create the steering vector to point to 30 degrees azimuth and compute the directivity in the same direction as the steering vector.

```
ang = [30;0];
w = steervec(getElementPosition(myArray)/lambda,ang);
d = directivity(myArray,freq,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d = 11.1405
```

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta, \varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# collectPlaneWave

**System object:** phased.HeterogeneousURA
**Package:** phased

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

Y = collectPlaneWave(H,X,ANG) returns the received signals at the sensor array, H, when the input signals indicated by X arrive at the array from the directions specified in ANG.

Y = collectPlaneWave(H,X,ANG,FREQ), in addition, specifies the incoming signal carrier frequency in FREQ.

Y = collectPlaneWave(H,X,ANG,FREQ,C), in addition, specifies the signal propagation speed in C.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of X represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

## Output Arguments

**Y**

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

## Examples

### Create Received Signal at Heterogeneous URA

Simulate two received signals at a 2-by-2 element heterogeneous URA with two different cosine antenna patterns. The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0deg; degrees.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
array = phased.HeterogeneousURA(...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 2; 1 2]);
y = collectPlaneWave(array,randn(4,2),[10 30],1e8,physconst('LightSpeed'))
```

```
y = 4×4 complex

   0.8433 - 0.1314i   0.8433 - 0.1314i   0.8433 + 0.1314i   0.8433 + 0.1314i
   0.5632 + 0.1721i   0.5632 + 0.1721i   0.5632 - 0.1721i   0.5632 - 0.1721i
  -2.6683 + 0.3175i  -2.6683 + 0.3175i  -2.6683 - 0.3175i  -2.6683 - 0.3175i
   1.1895 - 0.1671i   1.1895 - 0.1671i   1.1895 + 0.1671i   1.1895 + 0.1671i
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array.

For further details, see [1].

# getElementNormal

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Normal vector to array elements

## Syntax

```
normvec = getElementNormal(sURA)
normvec = getElementNormal(sURA,elemidx)
```

## Description

`normvec = getElementNormal(sURA)` returns the normal vectors of the array elements of the `phased.URA` System object, `sURA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sURA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form`[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sURA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

## Input Arguments

### sURA — Heterogeneous uniform rectangular array

`phased.HeterogeneousURA` System object

Uniform line array, specified as a `phased.HeterogeneousURA` System object.

Example: `sULA = phased.HeterogeneousURA`

**elemidx — Element indices**

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

## Output Arguments

**normvec — Element normal vectors**

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*. You can determine element indices using the `viewArray` method.

## Examples

### URA Element Normals

Construct three 2-by-2 URA's with element normals along the *x*-, *y*-, and *z*-axes. Obtain the element positions and normal directions.

First, choose the array normal along the *x*-axis.

```
sURA1 = phased.URA('Size',[2,2],'ArrayNormal','x');
pos = getElementPosition(sURA1)
```

```
pos = 3×4

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
```

```
normvec = getElementNormal(sURA1)
normvec = 2×4

     0     0     0     0
     0     0     0     0
```

All elements lie in the *yz*-plane and the element normal vectors point along the *x*-axis *(0°,0°)*.

Next, choose the array normal along the *y*-axis.

```
sURA2 = phased.URA('Size',[2,2],'ArrayNormal','y');
pos = getElementPosition(sURA2)
```

```
pos = 3×4

   -0.2500   -0.2500    0.2500    0.2500
         0         0         0         0
    0.2500   -0.2500    0.2500   -0.2500
```

```
normvec = getElementNormal(sURA2)
```

```
normvec = 2×4

    90    90    90    90
     0     0     0     0
```

All elements lie in the *zx*-plane and the element normal vectors point along the *y*-axis *(90°,0°)*.

Finally, set the array normal along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sURA3 = phased.URA('Size',[2,2],'ArrayNormal','z');
pos = getElementPosition(sURA3)
```

```
pos = 3×4

   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
         0         0         0         0
```

```
normvec = getElementNormal(sURA3,[1,3])
normvec = 2×2

     0     0
    90    90
```

All elements lie in the *xy*-plane and the element normal vectors point along the *z*-axis *(0°,90°)*.

**Introduced in R2016a**

# getElementPosition

**System object:** phased.HeterogeneousURA
**Package:** phased

Positions of array elements

## Syntax

```
POS = getElementPosition(H)
POS = getElementPosition(H,ELEIDX)
```

## Description

POS = getElementPosition(H) returns the element positions of the HeterogeneousURA System object, H. POS is a 3-by-N matrix where N is the number of elements in H. Each column of POS defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

For details regarding the local coordinate system of the URA or heterogeneous URA, enter phased.URA.coordinateSystemInfo on the command line.

POS = getElementPosition(H,ELEIDX) returns the positions of the elements that are specified in the element index vector, ELEIDX. The element indices of a URA run down each column, then to the top of the next column to the right. For example, in a URA with 4 elements in each row and 3 elements in each column, the element in the third row and second column has an index value of 6. This syntax can use any of the input arguments in the previous syntax.

## Examples

### Element Positions of Heterogeneous URA

Construct a heterogeneous URA with a rectangular lattice, and obtain the element positions.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2; 2 1]);
pos = getElementPosition(array)
```

```
pos = 3×4

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
```

# getNumElements

**System object:** phased.HeterogeneousURA
**Package:** phased

Number of elements in array

## Syntax

```
N = getNumElements(H)
```

## Description

N = getNumElements(H) returns the number of elements, N, in the HeterogeneousURA System object H.

## Examples

### Find Number of Elements of Heterogeneous URA

Construct a Heterogeneous URA, and obtain the number of elements.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2; 2 1]);
N = getNumElements(array)
```

```
N = 4
```

# getTaper

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Array element tapers

## Syntax

`wts = getTaper(h)`

## Description

`wts = getTaper(h)` returns the tapers, `wts`, applied to each element of the phased heterogeneous uniform rectangular array (URA), `h`. Tapers are often referred to as weights.

## Input Arguments

### h — Uniform rectangular array

`phased.HeterogeneousURA` System object

Uniform rectangular array specified as a `phased.HeterogeneousURA` System object.

## Output Arguments

### `wts` — Array element tapers

*N*-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector. The dimension *N* is the number of elements in the array. The array tapers are returned in the same order as the element indices. The element indices of a URA run down each column, then to the top of the next column to the right.

# Examples

### Heterogeneous URA Array Element Tapering

Construct a 2-by-5 element heterogeneous URA with a Taylor window taper along each row. Then, show the array with the element taper shading.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 2 2 2 1 ; 1 2 2 2 1],...
    'Taper',[taylorwin(5)';taylorwin(5)']);
w = getTaper(array)
```

```
w = 10×1

# isPolarizationCapable

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

## Input Arguments

### h — Uniform rectangular array

Uniform rectangular array specified as `phased.HeterogeneousURA` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

## Examples

### Short-dipole Antenna Array Polarization

Show that an array of short-dipole antenna element supports polarization.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 2 1 ; 1 2 2 2 1]);
isPolarizationCapable(array)
```

```
ans = logical
   1
```

# pattern

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Plot heterogeneous URA directivity and power pattern

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-963 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sArray` — Heterogeneous URA

System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousURA` System object.

Example: `sArray= phased.HeterogeneousURA;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| 'Polarization' | Display |
|---|---|
| 'combined' | Combined *H* and *V* polarization components |
| 'H' | *H* polarization component |
| 'V' | *V* polarization component |

Example: `'V'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`. |

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `PAT` — Array pattern

*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

### `AZ_ANG` — Azimuth angles

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

### `EL_ANG` — Elevation angles

scalar | 1-by-*M* real-valued row vector

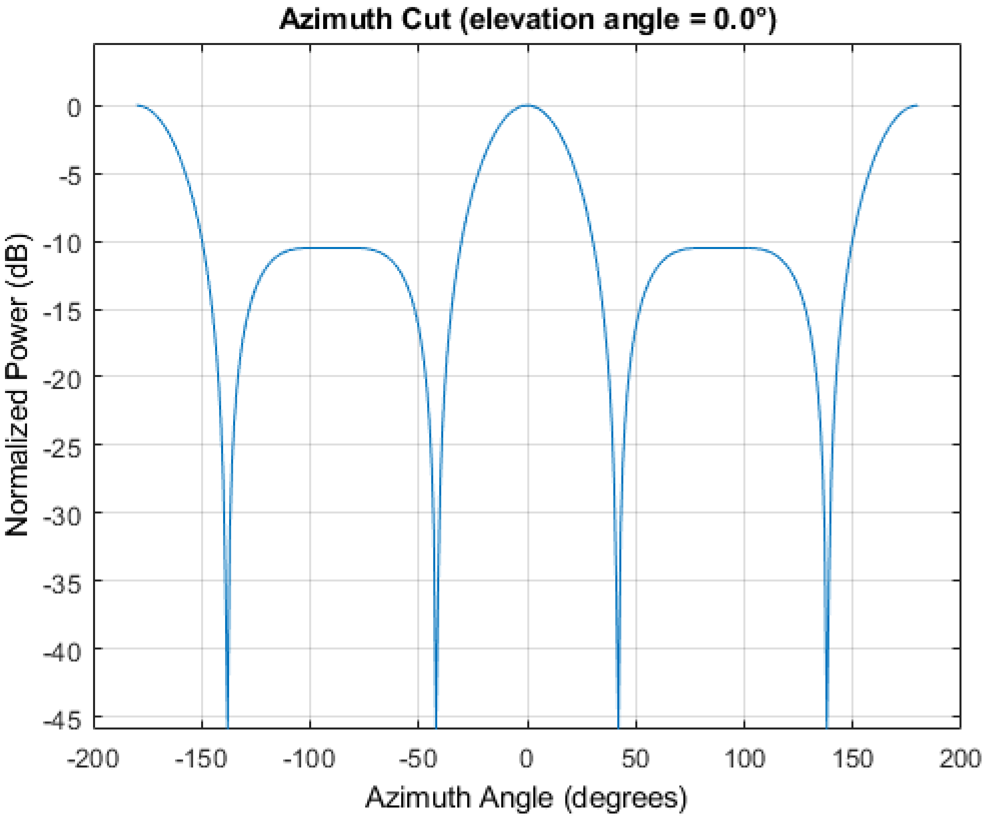
Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Azimuth Pattern and Directivity of Heterogeneous URA

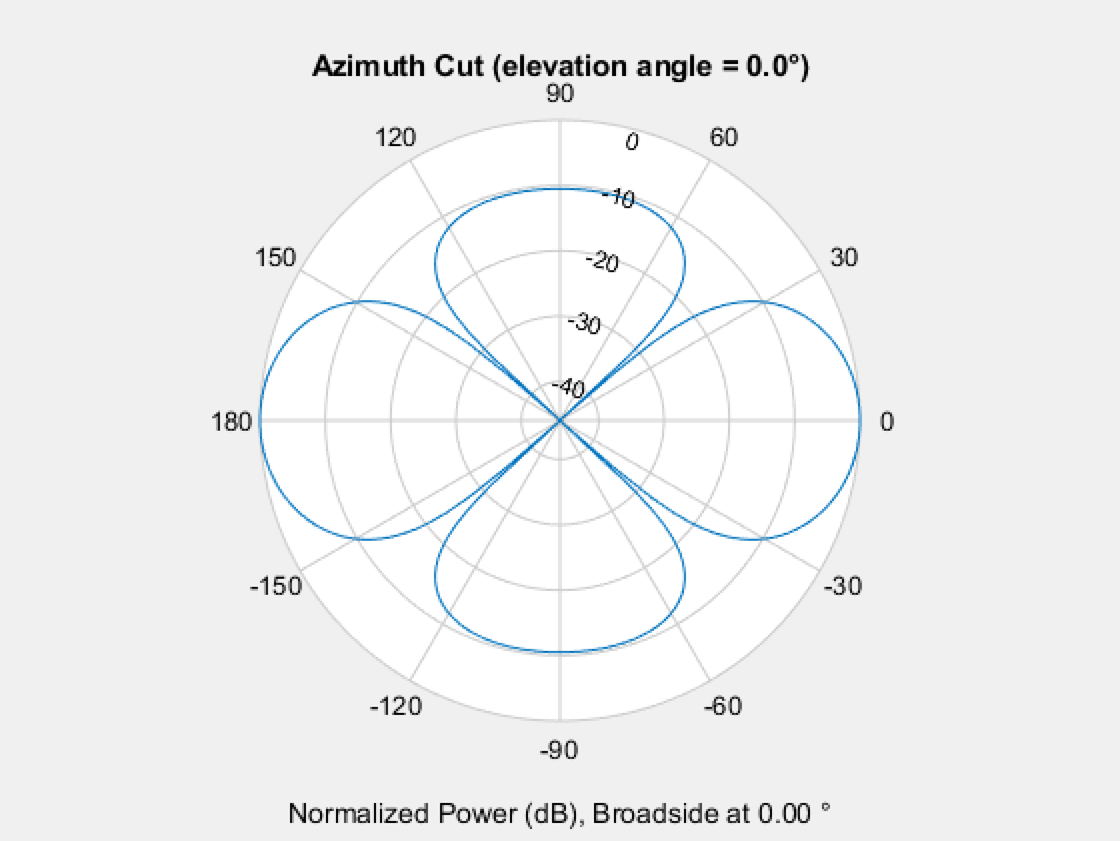
Construct a 3-by-3 heterogeneous URA of short-dipole antenna elements with a rectangular lattice. Then, plot the array's azimuth pattern at 300 MHz.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = 300e6;
c = physconst('LightSpeed');
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','powerdb',...
    'Normalize',true,...
    'Polarization','combined')
```



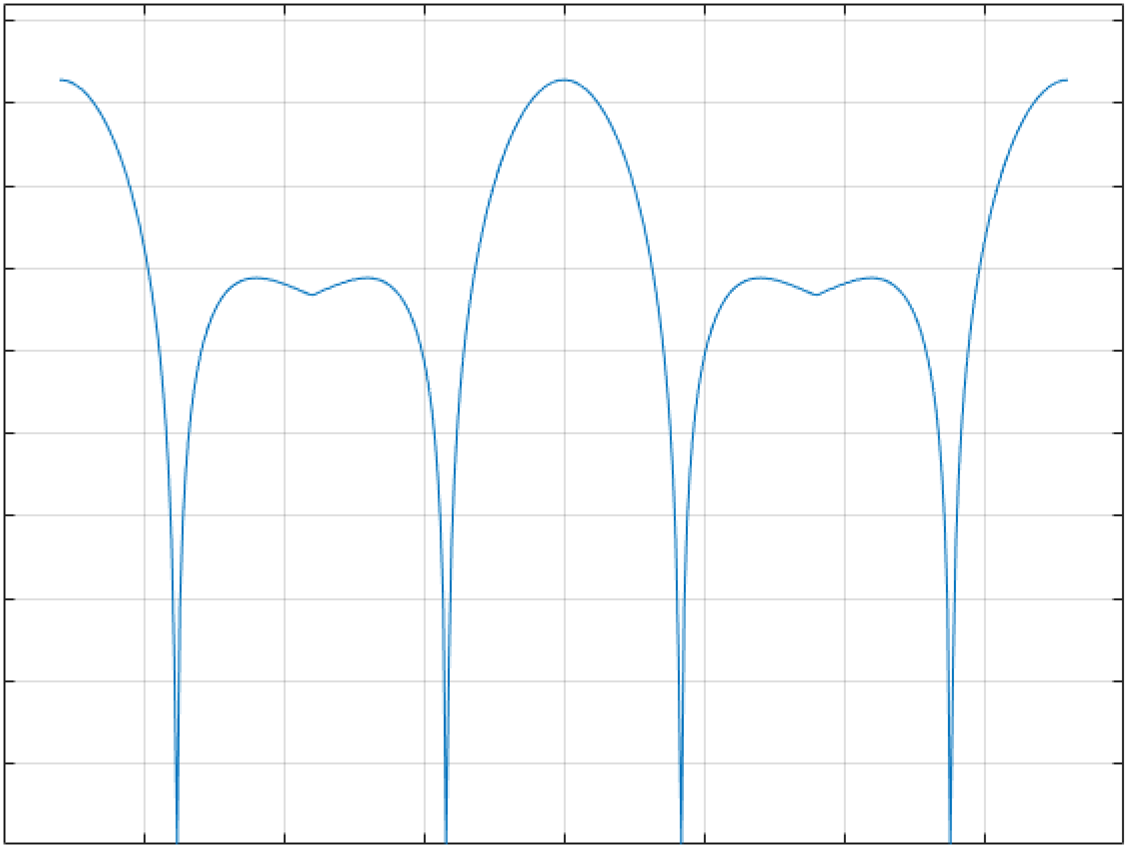
Plot the same result in polar form.

```
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Normalize',true,...
    'Polarization','combined')
```



Finally, plot the directivity.

```
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```

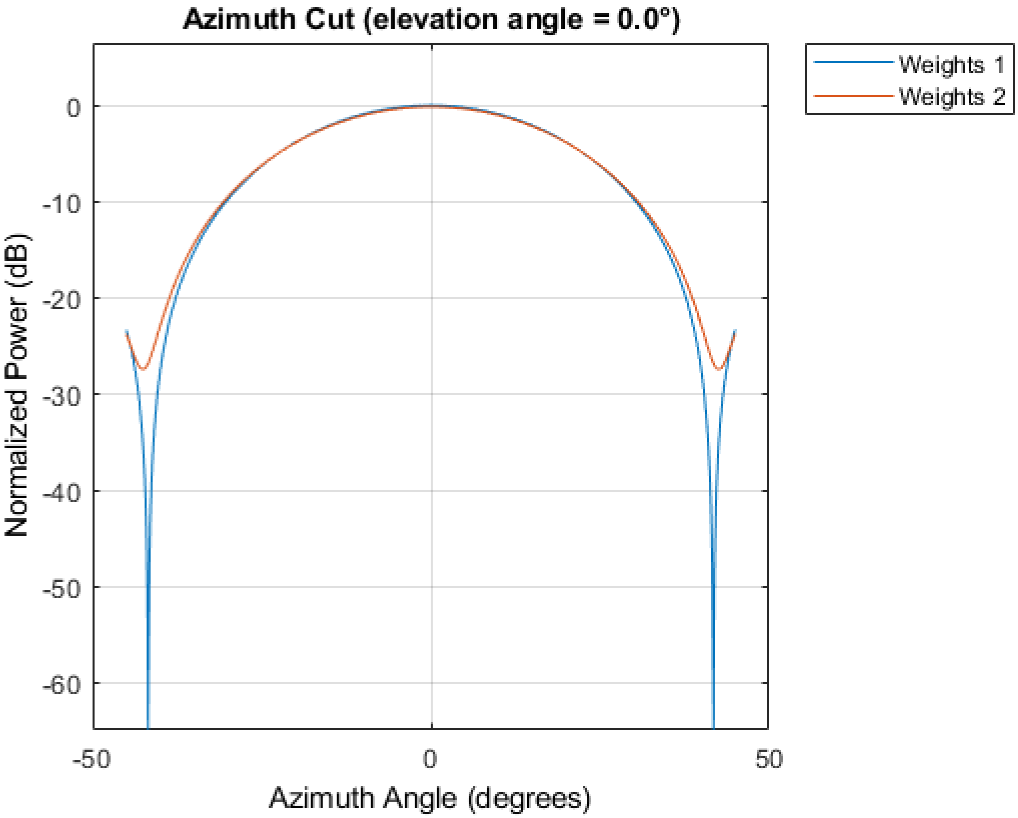


### Azimuth Pattern of Heterogeneous URA For Two Sets of Weights

Construct a square 3-by-3 heterogeneous URA composed of 9 short-dipole antenna elements with different orientations. Plot the array azimuth pattern from -45 degrees to 45 degrees in 0.1 degree increments. The `Weights` parameter lets you display the array pattern simultaneously for different sets of weights: in this case a uniform set of weights and a tapered set.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
```

```
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = [3e8];
c = physconst('LightSpeed');
wts1 = ones(9,1)/9;
wts2 = [.7,.7,.7,.7,1,.7,.7,.7,.7]';
wts2 = wts2/sum(wts2);
pattern(sArray,fc,[-45:0.1:45],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','powerdb',...
    'Weights',[wts1,wts2],...
    'Polarization','combined')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta, \varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| V argument | Propagation speed. This argument is used only for arrays. | 'PropagationSpeed' name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or <i>UV</i> space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.<br>Set the display axis using either the 'AzimuthAngles' or 'ElevationAngles' name-value pairs.</td></tr>

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.HeterogeneousURA
**Package:** phased

Plot heterogeneous URA directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**sArray — Heterogeneous URA**
System object

Heterogeneous URA, specified as a `phased.HeterogeneousURA` System object.

Example: `sArray= phased.HeterogeneousURA;`

**`FREQ` — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**`EL` — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Type — Displayed pattern type**
`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

**`PropagationSpeed` — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**`Weights` — Array weights**
*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

---

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Azimuth` — Azimuth angles**
`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

## Examples

### Azimuth Directivity of Heterogeneous URA

Construct a square 4-by-4 heterogeneous URA composed of a mix of crossed-dipole and short-dipole antenna elements with short dipoles in the center. Plot the array azimuth directivity for two different elevation angles. Set the operating frequency to 400 MHz.

```
sElement1 = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6]);
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
elemindices = ones(4,4);
elemindices(2:3,2:3) = 2;
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',elemindices);
fc = 400e6;
c = physconst('LightSpeed');
patternAzimuth(sArray,fc,[0 30],...
    'PropagationSpeed',c,...
    'Type','directivity')
```

# patternElevation

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Plot heterogeneous ULA directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

**`sArray` — Heterogeneous URA**
System object

Heterogeneous URA array, specified as a `phased.HeterogeneousURA` System object.

Example: `sArray= phased.HeterogeneousURA;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

**AZ — Azimuth angles for computing directivity and pattern**
1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Array weights

*M*-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

**Note** Use complex weights to steer the array response toward different directions. You can create weights using the `phased.SteeringVector` System object or you can compute your own weights. In general, you apply Hermitian conjugation before using

weights in any Phased Array System Toolbox function or System object such as `phased.Radiator` or `phased.Collector`. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

**`Elevation` — Elevation angles**
`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

**PAT — Array directivity or pattern**
*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Elevation Directivity of Heterogeneous URA

Construct a square 4-by-4 heterogeneous URA composed of a mix of crossed-dipole and short-dipole antenna elements with short dipoles in the center. Plot the array elevation directivity for two different azimuth angles. Set the operating frequency to 400 MHz.

```
sElement1 = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6]);
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
elemindices = ones(4,4);
elemindices(2:3,2:3) = 2;
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',elemindices);
fc = 400e6;
c = physconst('LightSpeed');
patternElevation(sArray,fc,[0 75],...
    'PropagationSpeed',c,...
    'Type','directivity')
```

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2015a**

# plotResponse

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Array object

**`FREQ`**

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no

response at frequencies outside that range. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

**V**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**CutAngle**

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

**Format**

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

**NormalizeResponse**

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### OverlayFreq

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `'None'`

### RespCut

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

### Unit

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimensions | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

**ElevationAngles**

Elevation angles for plotting array response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

**UGrid**

*U* coordinate values for plotting array response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

**VGrid**

*V* coordinate values for plotting array response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set VGrid and UGrid parameters simultaneously.

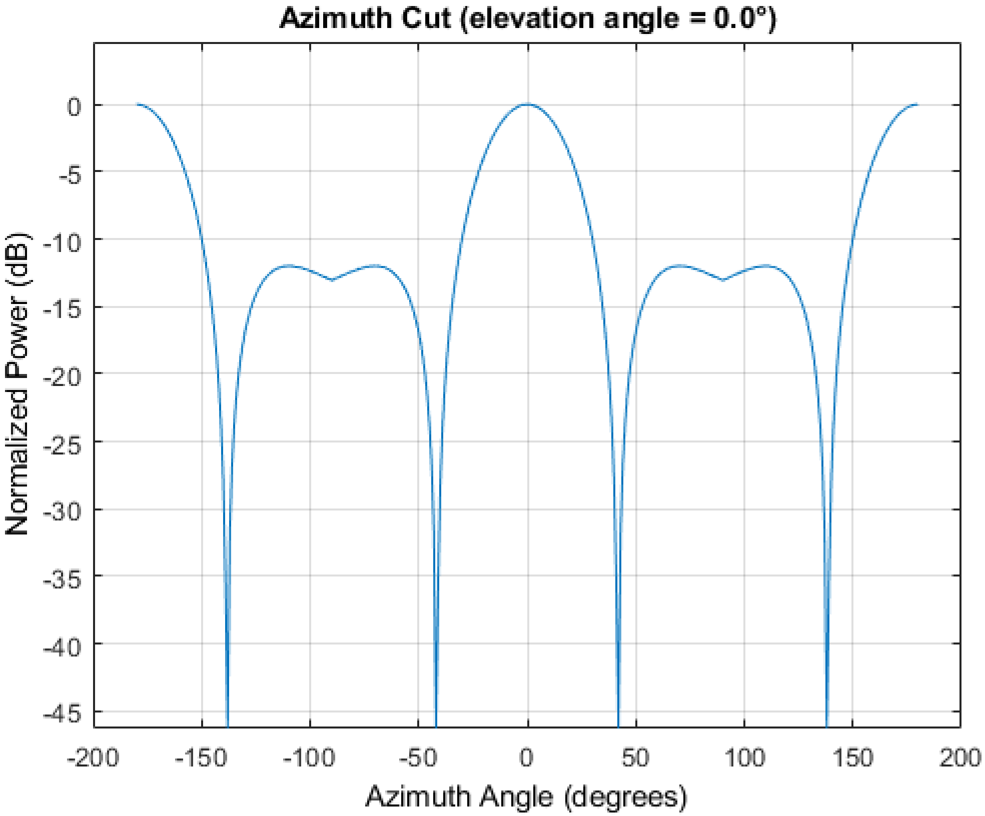
**Default:** [-1:0.01:1]

# Examples

### Azimuth Response and Directivity of Heterogeneous URA

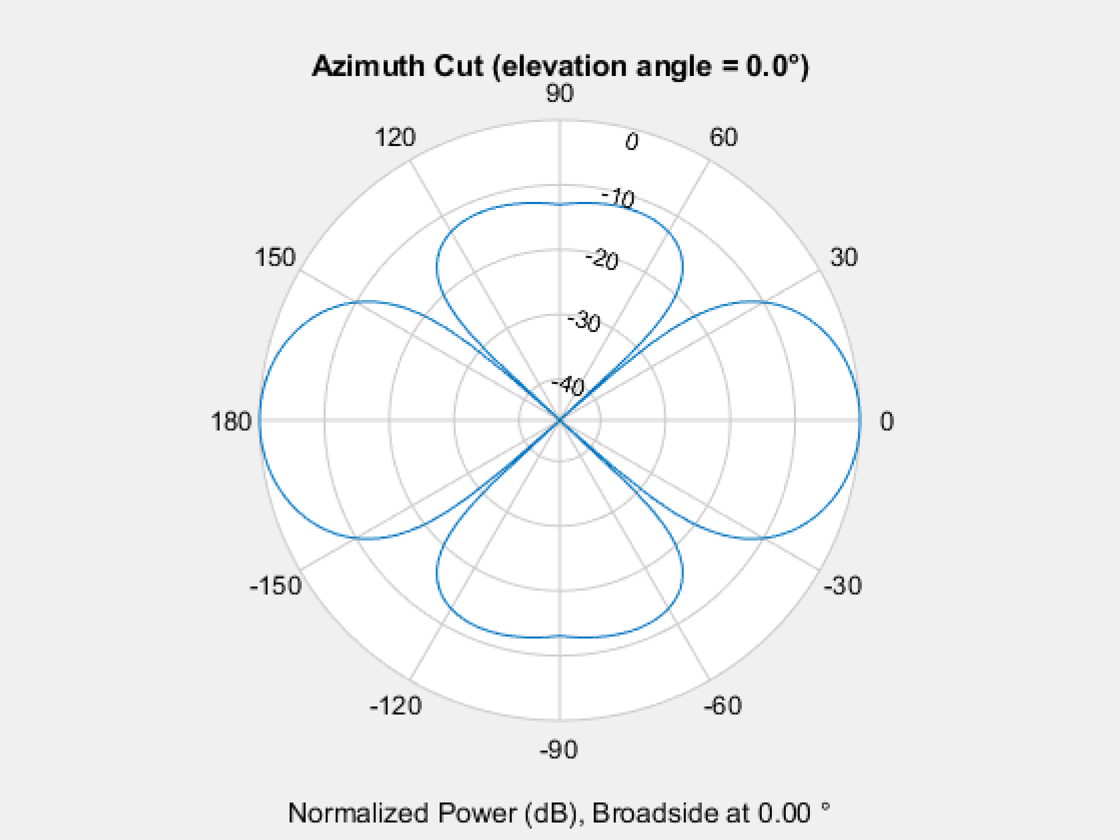
Construct a 3-by-3 heterogeneous URA with a rectangular lattice, then plot the array's azimuth response at 300 MHz.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = [3e8];
c = physconst('LightSpeed');
plotResponse(sArray,fc,c);
```



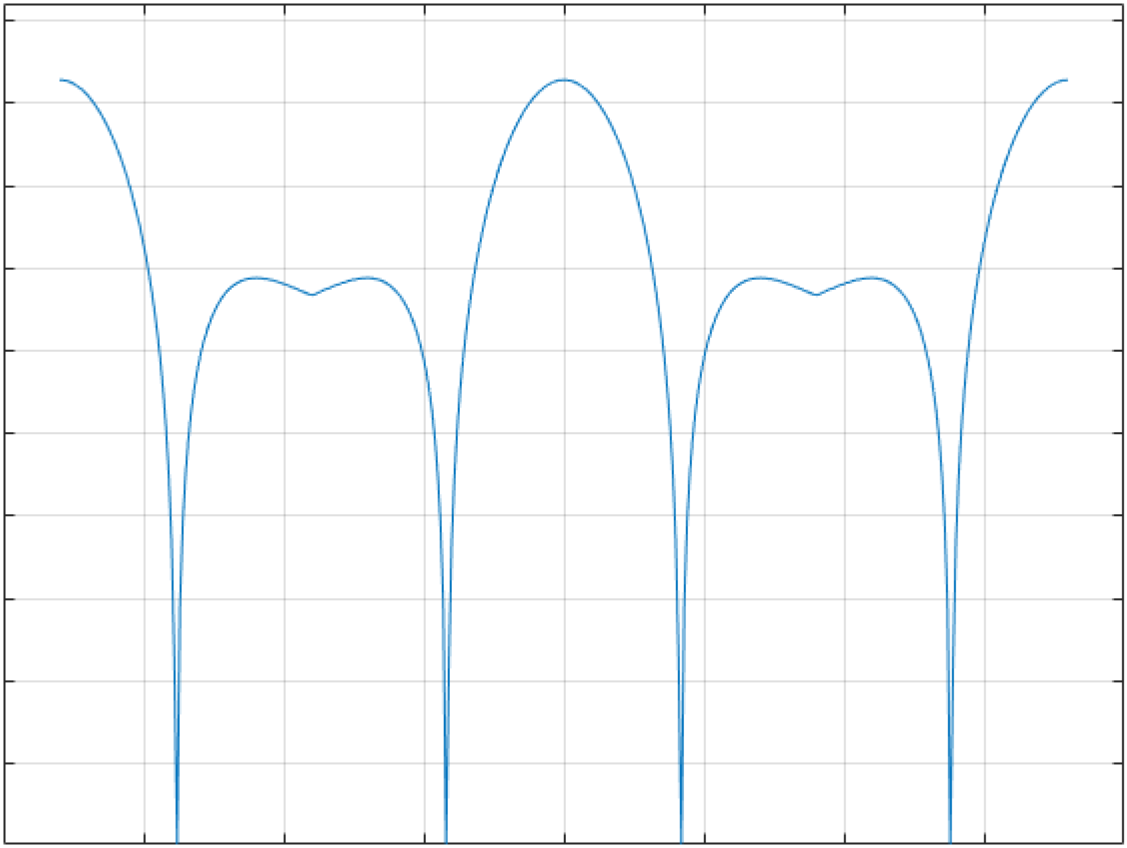
Plot the same result in polar form.

```
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar');
```



Finally, plot the directivity.

```
plotResponse(sArray,fc,c,'RespCut','Az','Unit','dbi');
```

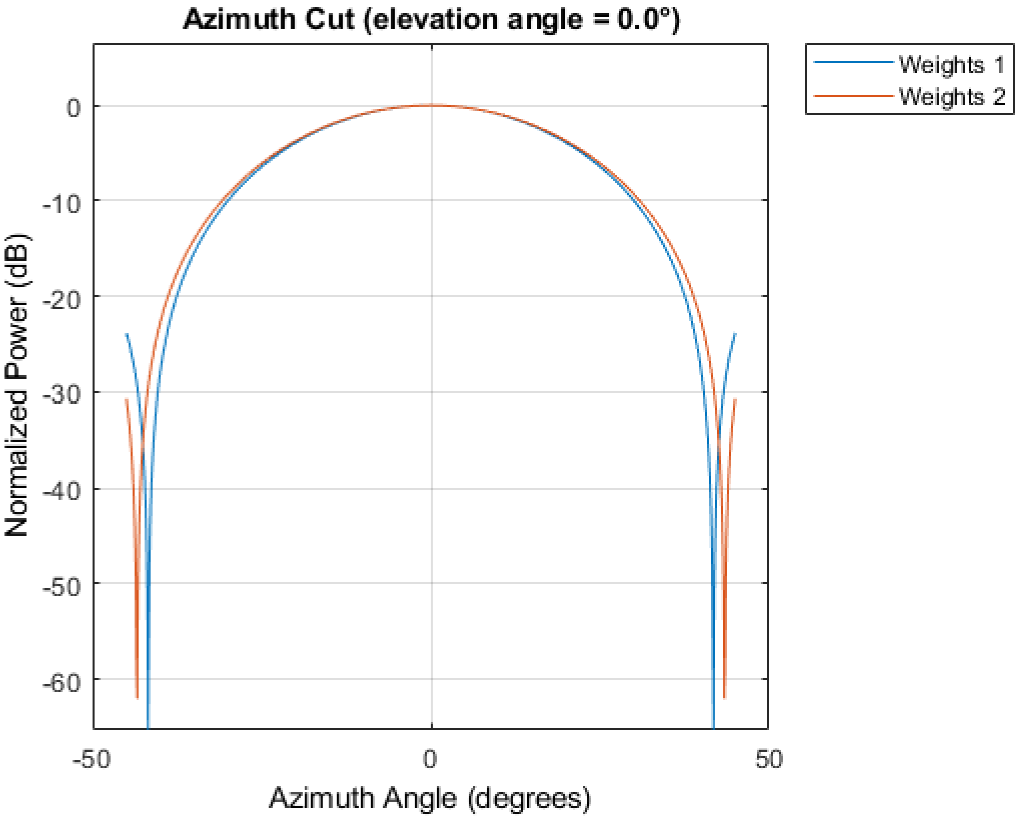


### Azimuth Responses of a Heterogeneous URA For Two Sets of Weights

Construct a square 3-by-3 heterogeneous URA composed of 9 short-dipole antenna elements with different orientations. Using the AzimuthAngles parameter, plot the array's azimuth response in the -45 degrees to 45 degrees in 0.1 degree increments. The `Weights` parameter lets you display the array's response simultaneously for different sets of weights: in this case a uniform set of weights and a tapered set.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
```

```
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = [3e8];
c = physconst('LightSpeed');
wts1 = ones(9,1)/9;
wts2 = [.7,.7,.7,.7,1,.7,.7,.7,.7]';
wts2 = wts2/sum(wts2);
plotResponse(sArray,fc,c,'RespCut','Az',...
    'Format','Line',...
    'AzimuthAngles',[-45:0.1:45],...
    'Weights',[wts1,wts2],'Unit','db');
```



## See Also

# step

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

Output responses of array elements

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array elements' responses `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Array object

### FREQ

Operating frequencies of array in hertz. FREQ is a row vector of length *L*. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

### ANG

Directions in degrees. ANG is either a 2-by-*M* matrix or a row vector of length *M*.

If ANG is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

## Output Arguments

### RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in ANG. *L* is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each

of the *L* pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

# Examples

### Response of 2-by-2 Heterogeneous URA of Cosine Antennas

Construct a 2-by-2 rectangular lattice heterogeneous URA of cosine antenna elements. Find the response of each element at 30 degrees azimuth and 0 degrees elevation. Assume the operating frequency is 1 GHz. Then, plot the array directivity.

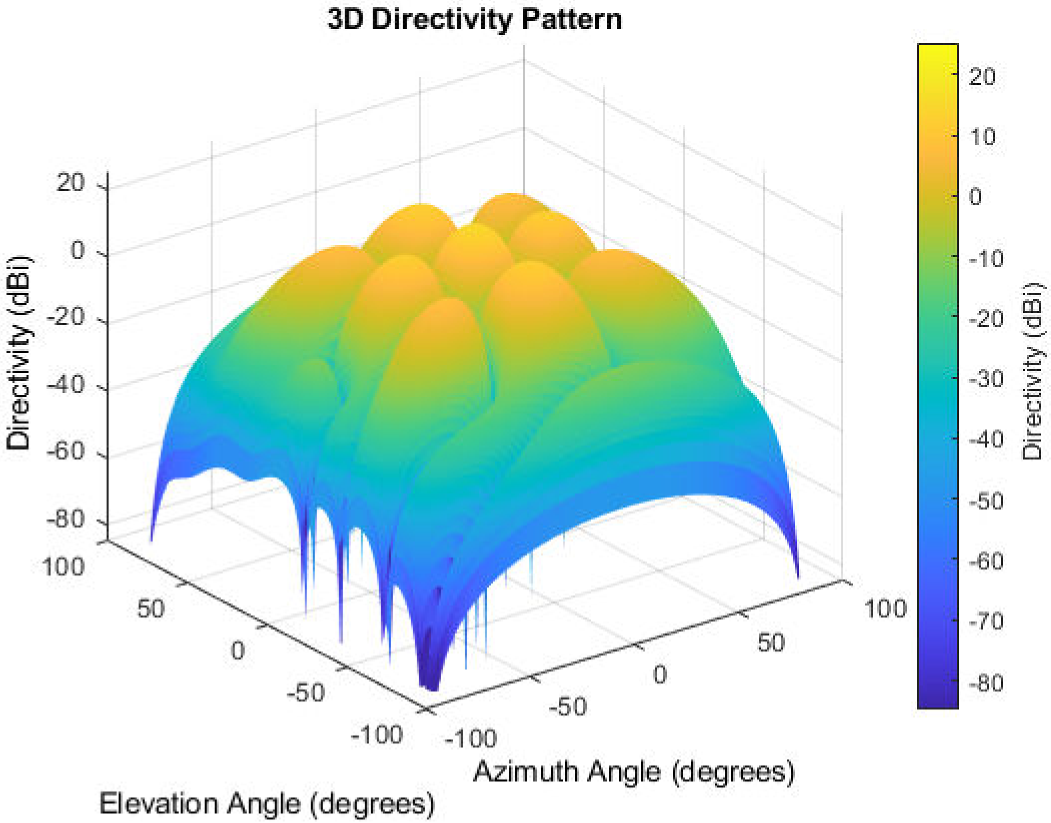
```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2; 2 1]);
fc = 1e9;
c = physconst('LightSpeed');
ang = [30;0];
resp = step(sArray,fc,ang)
```

```
resp = 4×1

    0.8059
    0.7719
    0.7719
    0.8059
```

Show the 3-D directivity pattern.

```
pattern(sArray,fc,[-180:180],[-90:90],...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```



## See Also

`phitheta2azel` | `uv2azel`

# viewArray

**System object:** `phased.HeterogeneousURA`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### ShowIndex

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

### ShowNormals

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

### ShowTaper

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

**Default:** `false`

### Title

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

### hPlot

Handle of array elements in figure window.

## Examples

### Geometry, Normal Directions, and Indices of Heterogeneous URA Elements

Display the element positions, normal directions, and indices for all elements of a 4-by-4 heterogeneous URA.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1; 1 2 2 1; 1 2 2 1; 1 1 1 1]);
viewArray(sArray,'ShowIndex','all','ShowNormal',true);
```

Phased Array Gallery

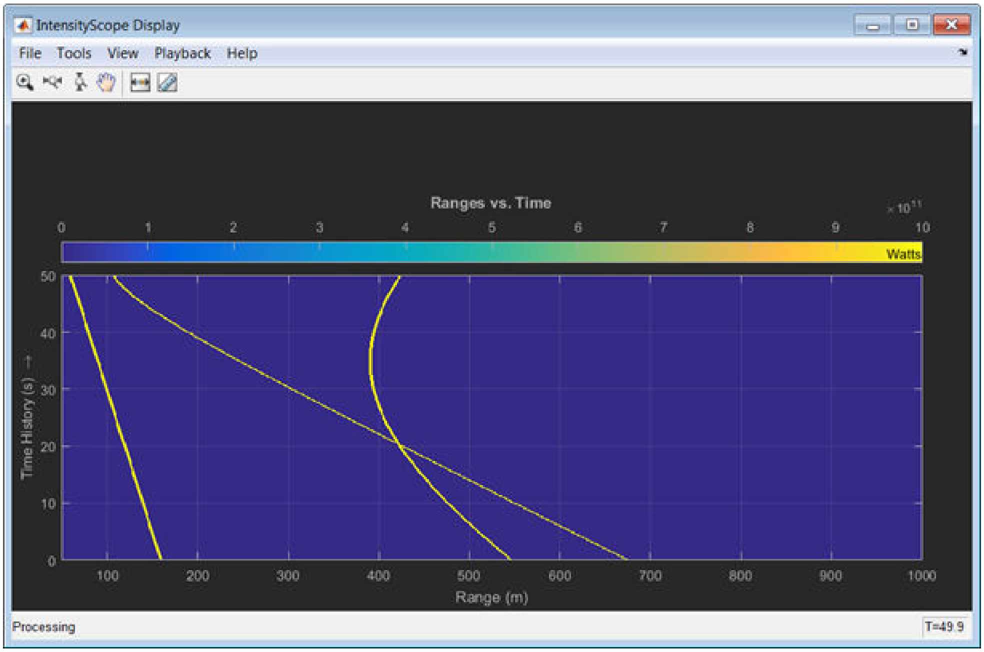
# phased.IntensityScope

**Package:** `phased`

Range-time-intensity (RTI) or Doppler-time-intensity (DTI) display

## Description

The `phased.IntensityScope` System object creates an intensity scope for viewing range-time-intensity (RTI) or Doppler-time-intensity (DTI) data. An intensity scope is a scrolling waterfall of intensity values as a function of time. Scan lines appear at the bottom of the display window and scroll off at the top. Each scan line represents signal intensity as a function of a parameter of interest, such as range or speed. You can also use this object to display angle-time-intensity data and spectral data. This figure shows an RTI display.



To create an intensity scope:

1. Define and set up the `phased.IntensityScope` System object. You can set any System object properties at this time or you can leave them at their default values. See “Construction” on page 1-1002 .
2. Call the `step` method to add intensity lines to the bottom of the display according to the properties of the `phased.IntensityScope` System object. Some properties are tunable and can be changed at any time. Non-tunable properties cannot be changed after the first call to `step`. Subsequent calls to `step` add more intensity lines.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`sIS = phased.IntensityScope` creates an intensity scope System object, `sIS`, having default property values.

`sIS = phased.IntensityScope(Name,Value)` returns an intensity scope System object, `sIS`, with each specified property `Name` set to a specified `Value`. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Properties

### Name — Window name

`'Intensity Scope'` (default) | character vector

Intensity scope window name, specified as a character vector. `Name` property and `Title` are different properties. The title appears inside the display window, above the data. The name appears in the title bar of the window.

Example: `'Range Intensity'`

Data Types: `char`

### XResolution — *X*-axis sample spacing

`1` (default) | positive real-valued scalar

X-axis sample spacing, specified as a positive real-valued scalar. This quantity determines the width of each horizontal bin of the scan line. The units depend on the interpretation of the data. For example, if you are creating an RTI display, then setting `XResolution` to `0.5` is interpreted as 0.5 meters.

Example: `0.5`

Data Types: `double`

### `XOffset` — *X*-axis offset

`0` (default) | real-valued scalar

X-axis offset, specified as a real-valued scalar. This quantity sets the value of the lowest bin of the scan line. The values of all other bins are equal to this value plus an integer multiple of `Xresolution`. The units depend upon the interpretation of the data. For example, if you are creating an RTI display, then setting `XOffset` to `100.0` is interpreted as 100 meters.

Example: `-0.1`

Data Types: `double`

### `Xlabel` — X-axis label

`''` (default) | character vector

*X*-axis label, specified as a character vector.

Example: `'Range (km)'`

Data Types: `char`

### `Title` — Title of display

`''` (default) | character vector

Title of the intensity scope display, specified as a character vector. `Title` property and `Name` are different properties. The title appears inside the display window, above the data. The name appears in the title bar of the window.

Example: `'Range vs Time'`

Data Types: `char`

### `TimeResolution` — Time resolution

`.001` (default) | positive real-valued scalar

Time resolution of intensity line(s), specified as a positive real-valued scalar. Units are seconds.

Example: `.0001`

Data Types: `double`

### `TimeSpan` — Time span of display window

0.1 (default) | positive real-valued scalar

Time span of intensity display, specified as a positive real-valued scalar. Units are seconds.

Example: `5.0`

Data Types: `double`

### `IntensityUnits` — Intensity units label

`'dB'` (default) | character vector

Intensity units label displayed in the color bar, specified as a character vector.

Example: `'Watts'`

Data Types: `char`

### `Position` — Location and size of intensity scope window

depends on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form `[left bottom width height]`. Units are in pixels.

- `left` and `bottom` specify the location of the bottom-left corner of the window.
- `width` and `height` specify the width and height of the window.

The default value of this property depends on the resolution of your display. This property is tunable.

Example: `[100 100 500 400]`

Data Types: `double`

## Methods

| | |
|---|---|
| hide | Hide intensity scope window |
| reset | Reset state of intensity scope System object |
| show | Show intensity scope window |
| step | Update intensity scope display |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### RTI Display of Moving Target

Use a `phased.IntensityScope` System object? to display the echo intensity of a moving target as a function of range and time.

Run the simulation for 5 seconds at 0.1 second steps. In the display, each horizontal scan line shows the intensities of radar echo at each time step.

```
nsteps = 50;
dt = .1;
timespan = nsteps*dt;
```

Simulate a target at a range of 320.0 km and a range rate of 2.0 km/s. Echoes are resolved into range bins of 1 km resolution. The range bins span from 50 to 1000 km.

```
rngres = 1.0;
rngmin = 50.0;
rngmax = 1000.0;
tgtrange = 320.0;
rangerate = 2.0;
rngscan = [rngmin:rngres:rngmax];
```

Set up the Intensity Scope using these properties.

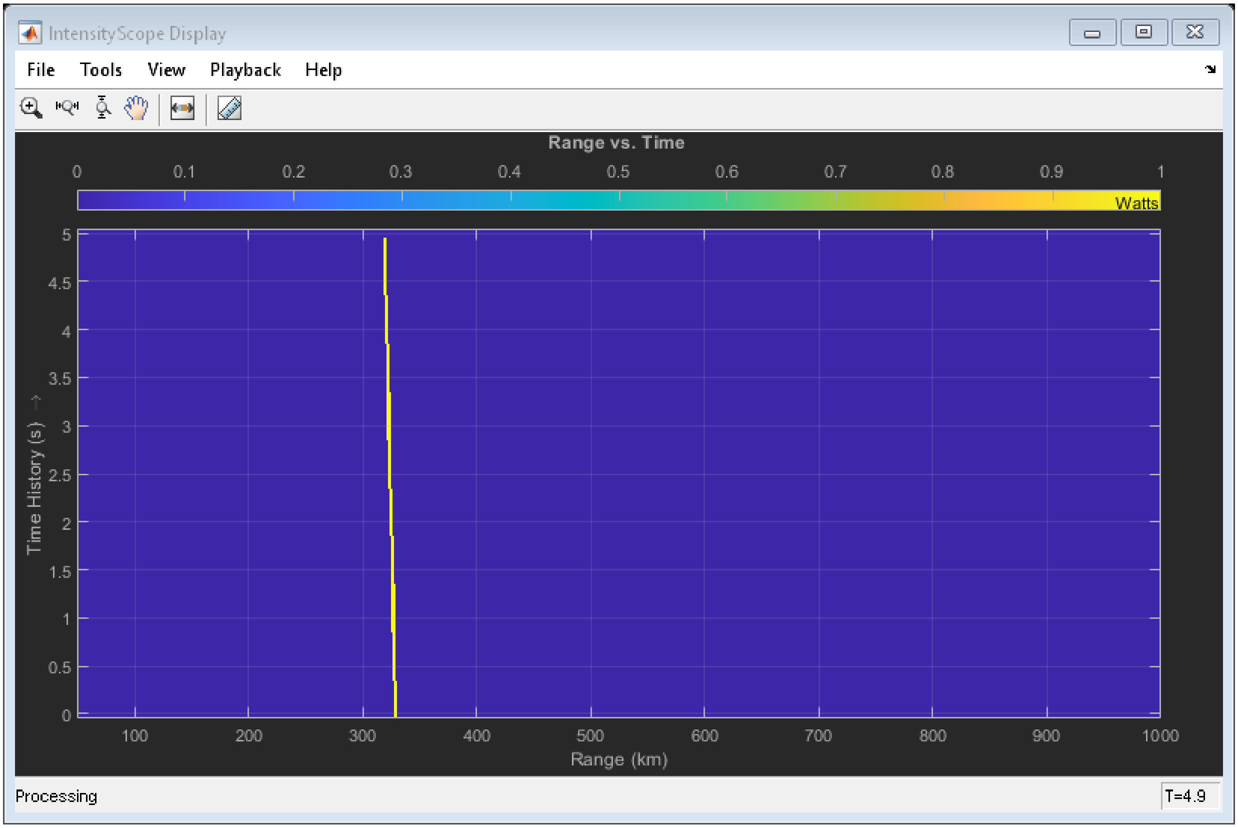
- Use the `XResolution` property to set the width of each scan line bin to the range resolution of 1 km.

- Use the XOffset property to set the value of the lowest range bin to the minimum range of 50 km.
- Use the TimeResolution property to set the value of the scan line time difference to 0.1 s.
- Use the TimeSpan property to set the height of the display window to the time duration of the simulation.
- Use the IntensityUnits property to set the display units to Watts.

```
scope = phased.IntensityScope('Name','IntensityScope Display',...
    'Title','Range vs. Time','XLabel','Range (km)',...
    'XResolution',rngres,'XOffset',rngmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts','Position',[100,100,800,450]);
```

Update the current target bin and create entries for two adjacent range bins. Each call to the step method creates a new scan line.

```
for k = 1:nsteps
    bin = floor((tgtrange - rngmin)/rngres) + 1;
    scanline = zeros(size(rngscan));
    scanline(bin+[-1:1]) = 1;
    scope(scanline.');
    tgtrange = tgtrange + dt*rangerate;
    pause(.1);
end
```



### RTI Display of Three Moving Targets

Use the `phased.IntensityScope` System object? to display the intensities of the echoes of three moving targets as functions of range and time.

### Create the Radar and Target System Objects

Set up the initial positions and velocities of the three targets. Use the `phased.Platform` System object? to model radar and target motions. The radar is stationary while the targets undergo constant velocity motion. The simulation runs for 500 steps at 0.1 second increments, giving a total simulation time of 50 seconds.

```
nsteps = 500;
dt = .1;
timespan = nsteps*dt;
x1 = [60,0,0]';
x2 = [60,-80,40]';
x3 = [300,0,-300]';
v1 = [2,0,0]';
v2 = [10,5,6]';
v3 = [-10,2,-4]';
platform = phased.Platform([0,0,0]',[0,0,0]');
targets = phased.Platform([x1,x2,x3],[v1,v2,v3]);
```

### Set Up Range Bins

Each echo is put into a range bin. The range bin resolution is 1 meter and the range is from 50 to 1000 meters.

```
rngres = 1.0;
rngmin = 50.0;
rngmax = 1000.0;
rngscan = [rngmin:rngres:rngmax];
```

### Create the Gain Function

Define a range-dependent gain function to enhance the display of targets at larger ranges. The gain function amplifies the returned echo for visualization purposes only.

```
rangegain = @(rng)(1e12*rng^4);
```

### Create the Intensity Scope

Set up the Intensity Scope using these properties.

- Use the `XResolution` property to set the width of each scan line bin to the range resolution of 1 km.
- Use the `XOffset` property to set the value of the lowest range bin to the minimum range of 50 km.
- Use the `TimeResolution` property to set the value of the scan line time difference to 0.1 s.
- Use the `TimeSpan` property to set the height of the display window to the time duration of the simulation.
- Use the `IntensityUnits` property to set the display units to `Watts`.

```
scope = phased.IntensityScope('Name','IntensityScope Display',...
    'Title','Ranges vs. Time','XLabel','Range (m)','XResolution',rngres,...
    'XOffset',rngmin,'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts','Position',[100,100,800,450]);
```

### Run Simulation Loop

1. In this loop, move the targets at constant velocity using the `step` method of the `phased.Platform` System object.
2. Compute the target ranges using the `rangeangle` function.
3. Compute the target range bins by quantizing the range values in integer multiples of `rangres`.
4. Fill each target range bin and neighboring bins with a simulated radar intensity value.
5. Add the signal from each target to the scan line.
6. Call the `step` method of the `phased.IntensityScope` System object to display the scan lines.

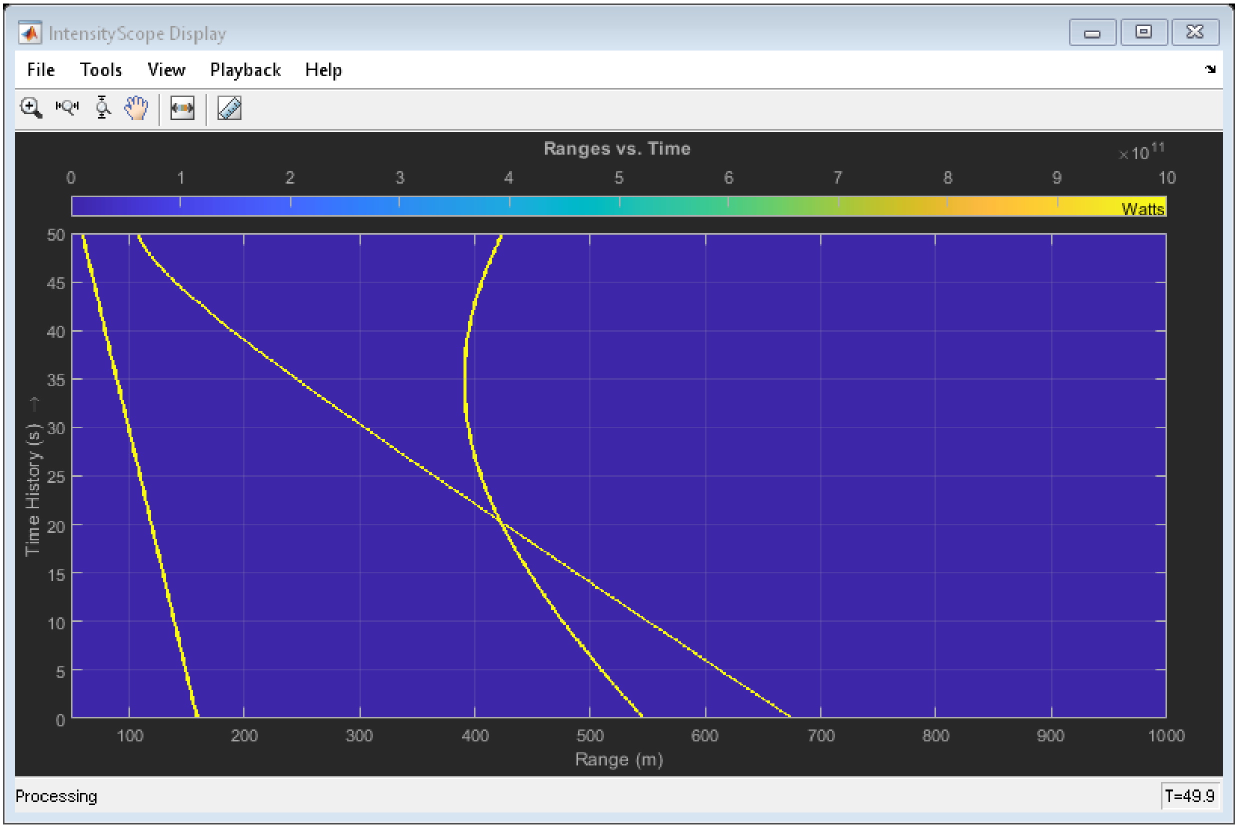
```
for k = 1:nsteps
    xradar = platform(dt);
    xtgts = targets(dt);
    [rngs] = rangeangle(xtgts,xradar);
    scanline = zeros(size(rngscan));

    rngindx = ceil((rngs(1) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(1))/(rngs(1)^4);

    rngindx = ceil((rngs(2) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(2))/(rngs(2)^4);

    rngindx = ceil((rngs(3) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(3))/(rngs(3)^4);

    scope(scanline.');
    pause(.1);
end
```



### RTI and DTI Displays in Full Radar Simulation

Use the `phased.IntensityScope` System object? to display the detection output of a complete radar system simulation. The radar scenario contains a stationary single-element monostatic radar and three moving targets.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

### Set Radar Operating Parameters

Set the probability of detection, probability of false alarm, maximum range, range resolution, operating frequency, transmitter gain, and target radar cross-section.

```
pd = 0.9;
pfa = 1e-6;
max_range = 5000;
range_res = 50;
fc = 10e9;
tx_gain = 20;
tgt_rcs = 1;
```

Choose the signal propagation speed to be the speed of light, and compute the signal wavelength corresponding to the operating frequency.

```
c = physconst('LightSpeed');
lambda = c/fc;
```

Compute the pulse bandwidth from the range resolution. Set the sampling rate, `fs`, to twice the pulse bandwidth. The noise bandwidth is also set to the pulse bandwidth. The radar integrates a number of pulses set by `num_pulse_int`. The duration of each pulse is the inverse of the pulse bandwidth.

```
pulse_bw = c/(2*range_res);
pulse_length = 1/pulse_bw;
fs = 2*pulse_bw;
noise_bw = pulse_bw;
num_pulse_int = 10;
```

Set the pulse repetition frequency to match the maximum range of the radar.

```
prf = c/(2*max_range);
```

### Compute Transmit Power

Use the Albersheim equation to compute the SNR required to meet the desired probability of detection and probability of false alarm. Then, use the radar equation to compute the power needed to achieve the required SNR.

```
snr_min = albersheim(pd, pfa, num_pulse_int);
peak_power = radareqpow(lambda,max_range,snr_min,pulse_length,...
    'RCS',tgt_rcs,'Gain',tx_gain);
```

### Create System Objects for the Model

Choose a rectangular waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',pulse_length,...
    'PRF',prf,'SampleRate',fs);
```

Set the receiver amplifier characteristics.

```
amplifier = phased.ReceiverPreamp('Gain',20,'NoiseFigure',0,...
    'SampleRate',fs,'EnableInputPort',true,'SeedSource','Property',...
    'Seed',2007);
transmitter = phased.Transmitter('Gain',tx_gain,'PeakPower',peak_power,...
    'InUseOutputPort',true);
```

Specify the radar antenna as a single isotropic antenna.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[5e9 15e9]);
```

Set up a monostatic radar platform.

```
radarplatform = phased.Platform('InitialPosition',[0; 0; 0],...
    'Velocity',[0; 0; 0]);
```

Set up the three target platforms using a single System object.

```
targetplatforms = phased.Platform(...
    'InitialPosition',[2000.66 3532.63 3845.04; 0 0 0; 0 0 0], ...
    'Velocity',[150 -150 0; 0 0 0; 0 0 0]);
```

Create the radiator and collector System objects.

```
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc);
```

Set up the three target RCS properties.

```
targets = phased.RadarTarget('MeanRCS',[1.6 2.2 1.05],'OperatingFrequency',fc);
```

Create System object to model two-way freespace propagation.

```
channels= phased.FreeSpace('SampleRate',fs,'TwoWayPropagation',true,...
    'OperatingFrequency',fc);
```

Define a matched filter.

```
MFcoef = getMatchedFilter(waveform);
filter = phased.MatchedFilter('Coefficients',MFcoef,'GainOutputPort',true);
```

### Create Range and Doppler Bins

Set up the fast-time grid. Fast time is the sampling time of the echoed pulse relative to the pulse transmission time. The range bins are the ranges corresponding to each bin of the fast time grid.

```
fast_time = unigrid(0,1/fs,1/prf,'[)');
range_bins = c*fast_time/2;
```

To compensate for range loss, create a time varying gain System Object?.

```
gain = phased.TimeVaryingGain('RangeLoss',2*fspl(range_bins,lambda),...
    'ReferenceLoss',2*fspl(max_range,lambda));
```

Set up Doppler bins. Doppler bins are determined by the pulse repetition frequency. Create an FFT System object for Doppler processing.

```
DopplerFFTbins = 32;
DopplerRes = prf/DopplerFFTbins;
fft = dsp.FFT('FFTLengthSource','Property',...
    'FFTLength',DopplerFFTbins);
```

### Create Data Cube

Set up a reduced data cube. Normally, a data cube has fast-time and slow-time dimensions and the number of sensors. Because the data cube has only one sensor, it is two-dimensional.

```
rx_pulses = zeros(numel(fast_time),num_pulse_int);
```

### Create IntensityScope System Objects

Create two `IntensityScope` System objects, one for Doppler-time-intensity and the other for range-time-intensity.

```
dtiscope = phased.IntensityScope('Name','Doppler-Time Display',...
    'XLabel','Velocity (m/sec)', ...
    'XResolution',dop2speed(DopplerRes,c/fc)/2, ...
    'XOffset',dop2speed(-prf/2,c/fc)/2,...
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','Mag');
rtiscope = phased.IntensityScope('Name','Range-Time Display',...
    'XLabel','Range (m)', ...
    'XResolution',c/(2*fs), ...
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','Mag');
```

### Run the Simulation Loop Over Multiple Radar Transmissions

Transmit 2000 pulses. Coherently process groups of 10 pulses at a time.

For each pulse:

1. Update the radar position and velocity `radarplatform`
2. Update the target positions and velocities `targetplatforms`
3. Create the pulses of a single wave train to be transmitted `transmitter`
4. Compute the ranges and angles of the targets with respect to the radar
5. Radiate the signals to the targets `radiator`
6. Propagate the pulses to the target and back `channels`
7. Reflect the signals off the target `targets`
8. Receive the signal `sCollector`
9. Amplify the received signal `amplifier`
10. Form data cube

For each set of 10 pulses in the data cube:

1. Match filter each row (fast-time dimension) of the data cube.
2. Compute the Doppler shifts for each row (slow-time dimension) of the data cube.

```
pri = 1/prf;
nsteps = 200;
for k = 1:nsteps
    for m = 1:num_pulse_int
        [ant_pos,ant_vel] = radarplatform(pri);
        [tgt_pos,tgt_vel] = targetplatforms(pri);
        sig = waveform();
        [s,tx_status] = transmitter(sig);
        [~,tgt_ang] = rangeangle(tgt_pos,ant_pos);
        tsig = radiator(s,tgt_ang);
        tsig = channels(tsig,ant_pos,tgt_pos,ant_vel,tgt_vel);
        rsig = targets(tsig);
        rsig = collector(rsig,tgt_ang);
        rx_pulses(:,m) = amplifier(rsig,~(tx_status>0));
    end
```

```
        rx_pulses = filter(rx_pulses);
        MFdelay = size(MFcoef,1) - 1;
        rx_pulses = buffer(rx_pulses((MFdelay + 1):end), size(rx_pulses,1));
        rx_pulses = gain(rx_pulses);
        range = pulsint(rx_pulses,'noncoherent');
        rtiscope(range);
        dshift = fft(rx_pulses.');
        dshift = fftshift(abs(dshift),1);
        dtiscope(mean(dshift,2));
        radarplatform(.05);
        targetplatforms(.05);
    end
```

All of the targets lie on the x-axis. Two targets are moving along the x-axis and one is stationary. Because the radar is at the origin, you can read the target speed directly from the Doppler-Time Display window. The values agree with the specified velocities of -150, 150, and 0 m/sec.

"Measure Intensity Levels Using the Intensity Scope"

**Introduced in R2016a**

# phased.RTIScope

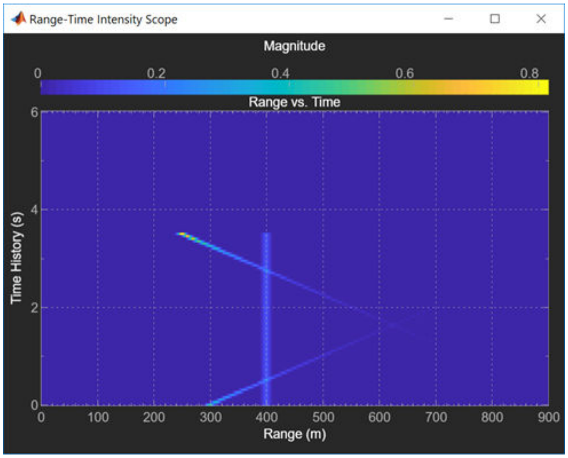
**Package:** phased

Range intensity scope

## Description

The phased.RTIScope System object creates a scrolling display of range response intensity as a function of time. Each row represents the range response for a pulse or FMCW signal. Sequential calls to the object add new rows to the bottom of the display window. Columns represent the responses at a specific range over all pulses. You can input two types of data - in-phased and quadrature (I/Q) data or response data.

- I/Q data – The input consists of fast-time I/Q samples for one or more pulses or FM sweeps. The scope computes the range response and adds it to the display. To use I/Q data, set the IQDataInput property to true. In this mode, you can set the properties shown in “Properties Applicable to I/Q Data” on page 1-1027.
- Response data – The data consists of the range response itself. The scope adds the range response to the display. For example, you can obtain the range response from a phased.RangeResponse object. To use response data, set the IQDataInput property to false. In this mode, you can set the properties shown in “Properties Applicable to Response Data” on page 1-1028.



To create and run a range-time intensity scope,

1. Create the `phased.RTIScope` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

## Syntax

```
scope = phased.RTIScope
scope = phased.phased.RTIScope(Name,Value)
```

### Description

`scope = phased.RTIScope` creates a range-time intensity scope System object, `scope`. This object displays the intensity of the range-time response for the input data.

`scope = phased.phased.RTIScope(Name,Value)` creates a range-time intensity scope, `scope`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose property names in quotes. For example,

```
scope = phased.RTIScope('IQInputData',true,'RangeMethod', ...
        'FFT','SampleRate',1e6,'TimeResolution,0.5,'TimeSpan',10. ...
        'RangeFFTLength',1024);
```

creates a scope object that uses FFT-based range processing for I/Q data having a sample rate of 1 MHz. The time resolution is 0.5 seconds and the time span is 10 seconds. The range FFT length is 1024 samples.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `Name` — Display caption

`'Range Time Intensity Scope'` (default) | character vector

Display caption, specified as a character vector. The caption appears in the title bar of the window.

Example: `'Multi-target Range Time Intensity Scope'`

**Tunable:** Yes

Data Types: `char`

### `Position` — Location and size of intensity scope window

depends on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form `[left bottom width height]`.

- `left` and `bottom` specify the location of the bottom-left corner of the window.
- `width` and `height` specify the width and height of the window.

Units are in pixels.

The default value of this property depends on the resolution of your display. By default, the window is positioned in the center of the screen, with a width and height of 800 and 450 pixels, respectively.

Example: `[100 100 500 400]`

**Tunable:** Yes

Data Types: `double`

### `IQDataInput` — Type of input data

`false` (default) | `true`

Type of input data, specified as `false` or `true`. When `true`, the object assumes that the input consists of I/Q sample data and further processing is required in the range domain. When `false`, the object assumes that the data is response data that has already been processed.

Data Types: `logical`

### `RangeLabel` — Range axis label

`'Range (m)'` (default) | character vector

Range-axis label, specified as a character vector.

Example: `'Range (km)'`

**Tunable:** Yes

Data Types: `char`

### `RangeResolution` — Range difference between samples

`1.0` (default) | positive scalar

Range distance between samples, specified as a positive scalar. This property defines the distance between columns of the scope. Units are in meters.

Data Types: `double`

### `RangeOffset` — Range offset

`0.0` (default) | positive scalar

Range offset, specified as a positive scalar. This property defines the range value of the first column of the display. Units are in meters.

Data Types: `double`

### `TimeResolution` — Time difference between rows

`0.001` (default) | positive scalar

Time interval between samples, specified as a positive scalar. This property defines the time interval between the rows of the scope. Units are in seconds.

Data Types: `double`

### `TimeSpan` — Time span of display

`0.100` (default) | positive scalar

Time span of the intensity display, specified as a positive scalar. Units are in seconds.

Data Types: `double`

### `IntensityUnits` — Response intensity units

`'db'` (default) | `'magnitude'` | `'power'`

Response intensity units, specified as a `'db'`, `'magnitude'`, or `'power'`.

Data Types: `char`

### `RangeMethod` — Range processing method

`'Matched filter'` (default) | `'FFT'`

Range-processing method, specified as `'Matched filter'` or `'FFT'`.

| | |
|---|---|
| `'Matched filter'` | The object applies a matched filter to the incoming signal. This approach is commonly used with pulsed signals, where the matched filter is a time-reversed replica of the transmitted signal. |
| `'FFT'` | Algorithm performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW continuous signals and linear FM pulsed signals. |

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

### `PropagationSpeed` — Signal propagation speed

`physconst('Lightspeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value of this property is the speed of light. See `physconst`. Units are in meters/second.

Example: `3e8`

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `SampleRate` — Sample rate

`1e6` (default) | positive scalar

Sample rate, specified as a positive scalar. Units are in Hz.

Example: `10e3`

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `SweepSlope` — FM sweep slope

`1e9` (default) | scalar

Slope of the linear FM sweep, specified as a scalar. Units are in Hz/sec.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `double`

### `DechirpInput` — Dechirp input signal

`false` (default) | `true`

Set this property to `true` to dechirp the input signal before performing range processing. `false` indicates that the input signal is already dechirped and no dechirp operation is necessary.

**Dependencies**

To enable this property, set the the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

### `RangeFFTLength` — FFT length used in range processing

`1024` (default) | positive integer

FFT length used for range processing, specified as a positive integer.

Example: `128`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `double`

### `ReferenceRangeCentered` — Set reference range at center of range span

`true` (default) | `false`

Set this property to `true` to set the reference range to the center of the range span. Set this property to `false` to set the reference range to the beginning of the range span.

#### Dependencies

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

# Usage

# Syntax

`scope(X)`

`scope(X,Xref)`

## Description

`scope(X)` adds new rows to the range-time intensity scope. The input `X` can be I/Q sample data or range response data depending on the value of the `IQDataInput` property.

`scope(X,Xref)` also specifies a reference signal to use for dechirping the input signal, `X`. This syntax applies when you set the `IQDataInput` property to `true`, the `RangeMethod` property to `'FFT'`, and the `DechirpInput` property to `true`. This syntax is most commonly used with FMCW signals. `Xref` is generally the transmitted signal.

`scope(X,coeff)` also specifies matched filter coefficients, `coeff`. This syntax applies when you set the `IQDataInput` property to `true` and the `RangeMethod` property to `'Matched Filter'`. This syntax is most commonly used with pulsed signals.

## Input Arguments

#### X — Input data

real-valued *N*-by-*M* matrix | complex-valued *N*-by-*M* matrix

Input data, specified as a complex-valued *N*-by-*M* matrix. The interpretation of the data depends on the setting of the `IQDataInput` property.

- When `IQDataInput` is `true`, the each column contains *N* fast-time I/Q samples for a pulse or FMCW sweep. *M* is the number of pulses in the case of pulsed signals or the number of dechirped frequency sweeps for FMCW signals. The scope computes and displays the range-response.

  - When `RangeMethod` is set to `'FFT'` and `DechirpInput` is `false`, `X` has previously been dechirped.
  - When `RangeMethod` is set to `'FFT'` and `DechirpInput` is `false`, `X` has not been previously dechirped. Use the syntax that includes `XREF` as input data.
  - When `RangeMethod` is set to `'MatchedFilter'`, `X` has not been matched filtered. Use the syntax that includes `COEF` as input data.
- When `IQDataInput` is `false`, the each column contains *N* response samples for a pulse or FMCW swee such as that produced by the `phased.RangeResponse`. *M* is the number of pulses in the case of pulsed signals or the number of dechirped frequency sweeps for FMCW signals. The scope only displays the range-response.

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Scope Objects

| | |
|---|---|
| show | Turn on visibility of scopes |
| hide | Turn off visibility of scope |
| isVisible | Visibility of scopes |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Display Range Time Intensity Map for Three Targets

Create a scrolling display of intensity at each range as function of time. The intensity is a combination of intensities from three simulated targets. One target starts at a range of 250 m and moves outward to 950 m. The second target starts at 1000 m and moves inward to 300 m. The third stays a 400 m. The intensities are computed using the inline function `rangePow`. The targets move in steps of 10 m but the `rangePow` function spreads the intensity over nearby range bins which are spaced every meter.

The inline function `rangePow` simulates a spread target return having an intensity falling off with the fourth power of range.

```
txpow = 200;
gain = 2e8;
std = 5;
rangePow = @(rngbins,range) ...
    gain.*exp(-0.5*((rngbins-range)./std).^2).* ...
    txpow./(range.^4)./(sqrt(2*pi).*std);
```

Create an RTI Scope to view intensity data.

```
scope = phased.RTIScope( ...
    'IQDataInput',false,...
    'Name','Range-Time Intensity Scope',...
    'Position',[560 375 560 420],...
    'RangeLabel','Range (m)', ...
    'RangeResolution',1, ...
    'TimeResolution',0.05,'TimeSpan',6, ...
    'IntensityUnits','magnitude');
```

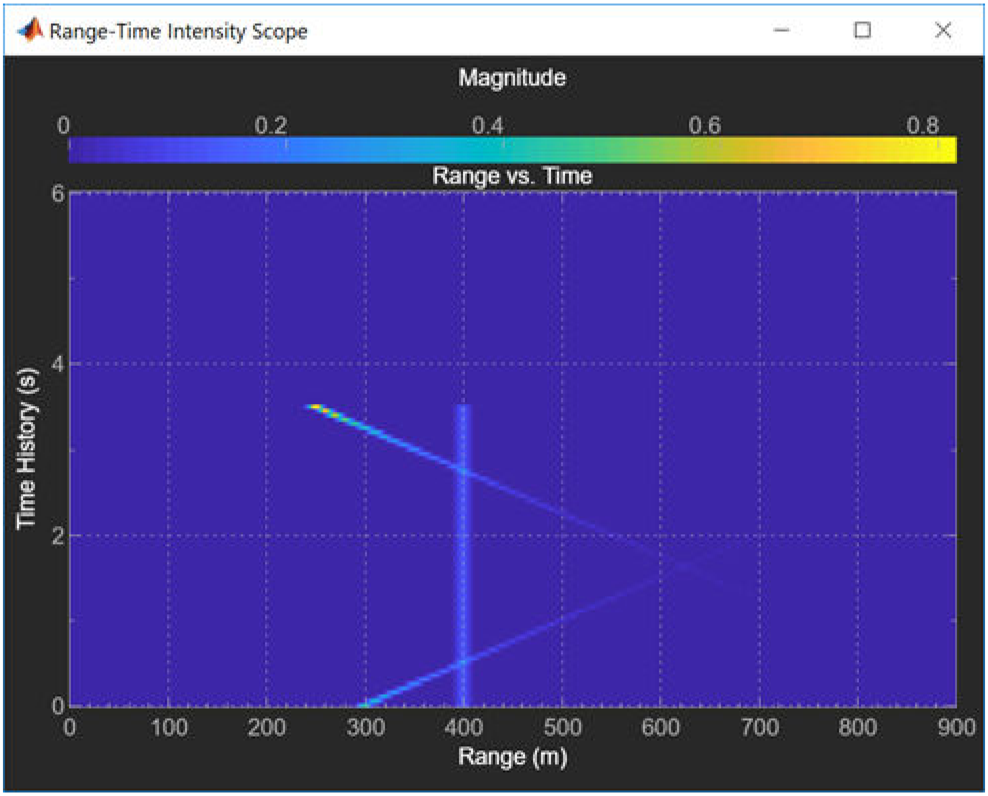
Create range bins for three targets.

```
rngbins = 0:900;
ranges(:,1) = 250:10:950;
ranges(:,2) = 1000:-10:300;
ranges(:,3) = 400;
```

Fill in all range bins by looping over all ranges and add each line at a time to the scope.

```
for k = 1:size(ranges,1)
    y = rangePow(rngbins,ranges(k,1)) + ...
```

```
        rangePow(rngbins,ranges(k,2)) + ...
        rangePow(rngbins,ranges(k,3));
    scope(y.');
    pause(.1);
end
```



# More About

## Properties Applicable to I/Q Data

These properties are applicable when `IQDataInput` is `true`.

| Properties | |
|---|---|
| Name | Position |
| RangeLabel | RangeResolution |
| RangeOffset | TimeResolution |
| TimeSpan | IntensityUnits |
| RangeMethod | PropagationSpeed |
| SampleRate | SweepSlope |
| DechirpInput | RangeFFTLength |
| ReferenceRangeCentered | |

## Properties Applicable to Response Data

These properties are applicable when `IQDataInput` is `false`.

| Properties | |
|---|---|
| Name | Position |
| RangeLabel | RangeResolution |
| RangeOffset | TimeResolution |
| TimeSpan | IntensityUnits |

**Introduced in R2019a**

# phased.DTIScope

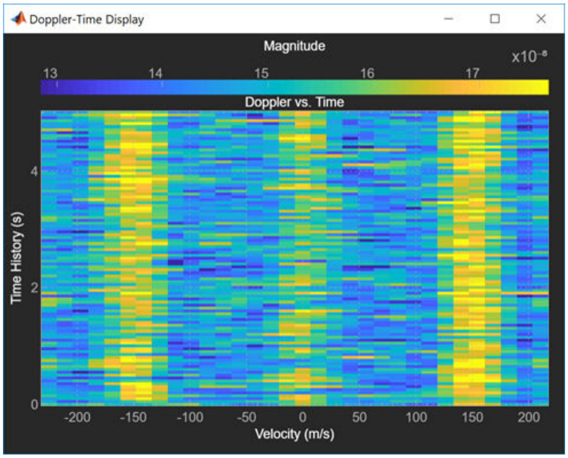
**Package:** phased

Doppler-time intensity scope

## Description

The phased.DTIScope System object creates a scrolling display of Doppler response intensity as a function of time. Each row represents the Doppler response for a pulse or FMCW signal. Sequential calls to the object add new rows to the bottom of the display window. Columns represent the responses at specific Doppler values as a function of time. You can input two types of data - in-phased and quadrature (I/Q) data or response data.

- I/Q data – The input consists of fast-time I/Q samples from one or more pulses or FM sweeps. The scope computes the Doppler response and adds it to the display. To use I/Q data, set the IQDataInput property to true. In this mode, you can set the properties listed in “Properties Applicable to I/Q Data” on page 1-1027.
- Response data – The data consists of the Doppler response itself as a function of time. The scope only adds the Doppler response to the display. For example, you can obtain Doppler responses from the phased.RangeDopplerResponse System object. To use response data, set the IQDataInput property to false. In this mode, you can set the properties listed in “Properties Applicable to Response Data” on page 1-1028.



To create and run a Doppler-time intensity scope,

1. Create the `phased.DTIScope` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

# Syntax

```
scope = phased.DTIScope
scope = phased.phased.DTIScope(Name,Value)
```

## Description

`scope = phased.DTIScope` creates a Doppler time intensity scope System object, `scope`. This object displays the Doppler-time response intensity of the input data.

`scope = phased.phased.DTIScope(Name,Value)` creates a Doppler-time intensity scope object, `scope`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose property names in quotes. For example,

```
scope = phased.DTIScope('IQInputData',false, ...
        'OperatingFrequency',1e6, ...
        'SampleRate',1e6,'DopplerOutput','Speed', ...
        'OperatingFrequency',10e6,'DopplerFFTLength',512);
```

creates a scope object that displays a 10-second time span of data using a Doppler FFT size of 512 for I/Q data. The Doppler output units are speed in meters per second.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### Name — Display caption

`Doppler Time Intensiy Scope'` (default) | character vector

Display caption, specified as a character vector. The caption appears in the title bar of the window.

Example: `'Multi-target Doppler Time Intensiy Scope'`

**Tunable:** Yes

Data Types: `char`

### `Position` — Location and size of intensity scope window

depends on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form `[left bottom width height]`.

- `left` and `bottom` specify the location of the bottom-left corner of the window.
- `width` and `height` specify the width and height of the window.

Units are in pixels.

The default value of this property depends on the resolution of your display. By default, the window is positioned in the center of the screen, with a width and height of 800 and 450 pixels, respectively.

Example: `[100 100 500 400]`

**Tunable:** Yes

Data Types: `double`

### `IQDataInput` — Type of input data

`false` (default) | `true`

Type of input data, specified as `true` or `false`. When `true`, the object assumes that the input consists of I/Q sample data and further processing is required in the Doppler domain. When `false`, the object assumes that the data is response data that has already been processed.

Data Types: `logical`

### `DopplerResolution` — Doppler interval between samples

`1.0` (default) | positive scalar

Doppler interval between samples, specified as a positive scalar. This property defines the Doppler frequency difference between the scope columns. Units are in Hz.

Data Types: `double`

### `DopplerOffset` — Doppler axis offset

`0.0` (default) | scalar

Doppler axis offset, specified as a scalar. This property apples a frequency offset to the Doppler axis. Units are in Hz.

Data Types: `double`

### `TimeResolution` — Time difference between rows

`0.001` (default) | positive scalar

Time interval between samples, specified as a positive scalar. This property defines the time duration between rows of scope. Units are in seconds.

Data Types: `double`

### `TimeSpan` — Time duration of display

`0.100` (default) | positive scalar

Time span of the intensity display, specified as a positive scalar. Units are in seconds.

Data Types: `double`

### `IntensityUnits` — Response Intensity units

`'db'` (default) | `'magnitude'` | `'power'`

Response intensity units, specified as a `'db'`, `'magnitude'`, or `'power'`.

Data Types: `char`

### `DopplerOutput` — Doppler output domain

`'Frequency'` (default) | `'Speed'`

Doppler output domain, specified as `'Frequency'` or `'Speed'`. If you set this property to `'Frequency'`, the Doppler domain is the Doppler shift. Units are in Hz. If you set this property to `'Speed''`, the Doppler domain is the corresponding radial speed. Units are in m/s.

Data Types: `char`

### `PropagationSpeed` — Signal propagation speed

`physconst('Lightspeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value of this property is the speed of light. See `physconst`. Units are in meters/second.

Example: `3e8`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `DopplerOutput` to `'Speed'`.

Data Types: `double`

### `DopplerFFTLength` — FFT length used in Doppler processing

`1024` (default) | positive integer

FFT length used in Doppler processing, specified as a positive integer.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

# Usage

# Syntax

```
scope(X)
```

## Description

`scope(X)` updates and displays the Doppler-time intensity scope for the input data, `X`. The input `X` can be I/Q sample data or Doppler response data depending on the value of the `IQDataInput` property.

## Input Arguments

**`X` — Input data**
complex-valued *K*-by-*L* matrix

Input data, specified as a complex-valued *K*-by-*L* matrix. The interpretation of the data depends on the value of the `IQDataInput` property.

- When `IQDataInput` is `true`, the input consists of received fast-time and slow-time data for each PRI pulse or FMCW sweep. *K* denotes the number of time samples. *L* is the number of pulses in the case of pulsed signals or the number of dechirped frequency sweeps for FMCW signals. The scope computes and displays the Doppler response.
- When `IQDataInput` is `false`, the input already consists of response data in the Doppler domain such as that produced, for example, by `phased.RangeDopplerResponse`. Each row contains the set of Doppler responses. Each response corresponds to an element of the `Dop` vector. The scope serves only as a display of the Doppler response.

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Scope Objects

| | |
|---|---|
| show | Turn on visibility of scopes |
| hide | Turn off visibility of scope |
| isVisible | Visibility of scopes |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Display Doppler-Time Intensity Map for Three Targets

Create a `phased.DTIScope` object to view a scrolling Doppler-Time Intensity map.

Load the example data.

```
load('RTIDTIExampleData.mat')
rx_pulses = zeros(numel(fast_time),num_pulse_int);
```

Create the DTI scope.

```
scope = phased.DTIScope('IQDataInput',false,...
    'DopplerOutput','Speed',...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'Name','Doppler-Time Display',...
    'DopplerResolution',DopplerRes, ...
    'DopplerOffset',-prf/2,...
    'TimeResolution',0.05,...
    'TimeSpan',5,...
    'IntensityUnits','magnitude',...
    'Position',[560 375 560 420]);
```

Obtain the pulse repetition interval, 33.3564 microsec.

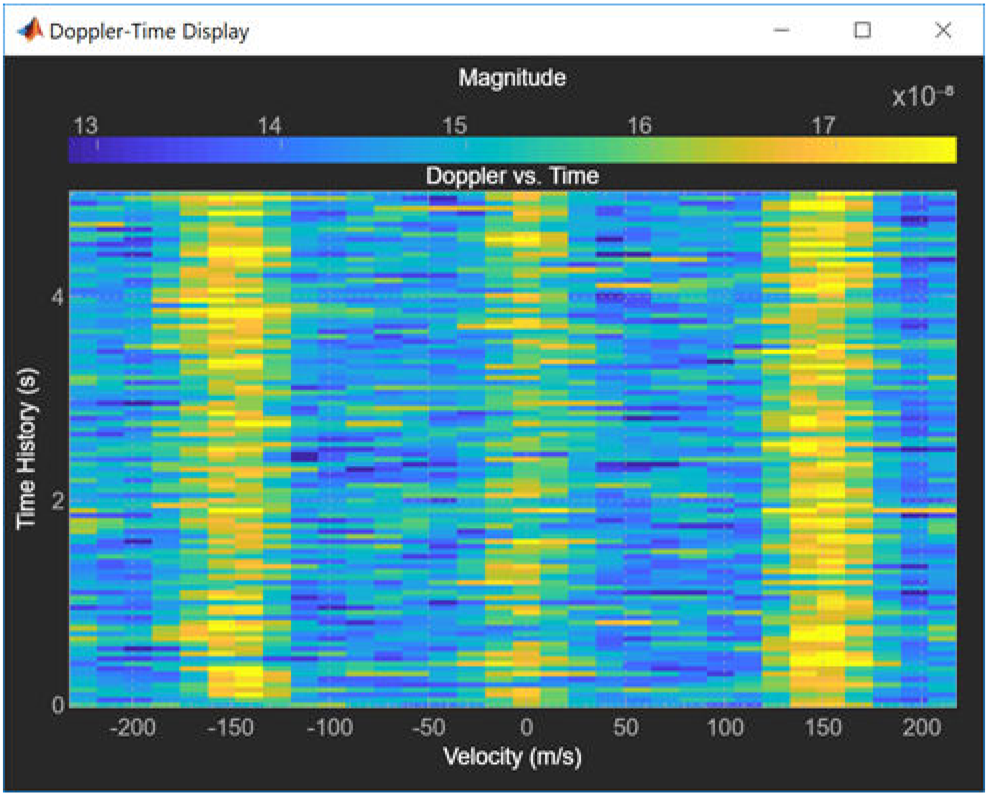
```
pri = 1/prf;
```

Transmit 2000 pulses and coherently process a train of 10 pulses at a time. There are 200 trains. After each pulse, move the target and radar platform. The radar reflects off three targets. The first moves along the *x*-axis at -150 m/sec. The second moves along the *x*-axis at +150 m/sec. The third target is stationary. After each pulse train, compute the Doppler response using an FFT.

```
nsteps = 200;
for k = 1:nsteps
    for m = 1:num_pulse_int
        [ant_pos,ant_vel] = radarplatform(pri);
        [tgt_pos,tgt_vel] = targetplatforms(pri);
        sig = waveform();
        [s,tx_status] = transmitter(sig);
        [~,tgt_ang] = rangeangle(tgt_pos,ant_pos);
        tsig = radiator(s,tgt_ang);
        tsig = channels(tsig,ant_pos,tgt_pos,ant_vel,tgt_vel);
        rsig = targets(tsig);
        rsig = collector(rsig,tgt_ang);
        rx_pulses(:,m) = preamplifier(rsig,~(tx_status>0));
    end

    rx_pulses = gain(rx_pulses);
    dshift = fft(rx_pulses.');
    dshift = fftshift(abs(dshift),1);
    scope(mean(dshift,2));

    pause(0.1)
    radarplatform(.05);
    targetplatforms(.05);
end
```



# More About

## Properties Applicable to I/Q Data

These properties are applicable when `IQDataInput` is `true`.

| Properties | |
|---|---|
| `Name` | `Position` |
| `DopplerResolution` | `DopplerOffset` |
| `TimeResolution` | `TimeSpan` |

| Properties | |
|---|---|
| IntensityUnits | DopplerOutput |
| PropagationSpeed | OperatingFrequency |
| DopplerFFTLength | |

### Properties Applicable to Response Data

These properties are applicable when `IQDataInput` is `false`.

| Properties | |
|---|---|
| Name | Position |
| DopplerResolution | DopplerOffset |
| TimeResolution | TimeSpan |
| IntensityUnits | DopplerOutput |
| PropagationSpeed | OperatingFrequency |

**Introduced in R2019a**

# hide

**System object:** phased.IntensityScope
**Package:** phased

Hide intensity scope window

## Syntax

```
hide(sIS)
```

## Description

hide(sIS) hides the display window of the phased.IntensityScope object, sIS.

## Input Arguments

### sIS — Intensity scope

phased.IntensityScope System object

Intensity scope, specified as a phased.IntensityScope System object.

Example: phased.IntensityScope

## Examples

### Hide and Show Intensity Scope

Create an angle-time-intensity scope. Use the phased.IntensityScope System object? to display simulated intensity as a function of the angular motion of a moving target. After five steps in the processing loop, use the hide method to hide the scope. At completion of the loop, use the show method to show the scope.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.%% Simulate data for 5 seconds with a time interval of 0.5 seconds between scan lines.

```
nsteps = 10;
dt = 0.5;
timespan = nsteps*dt;
```

### Set Up IntensityScope System Object

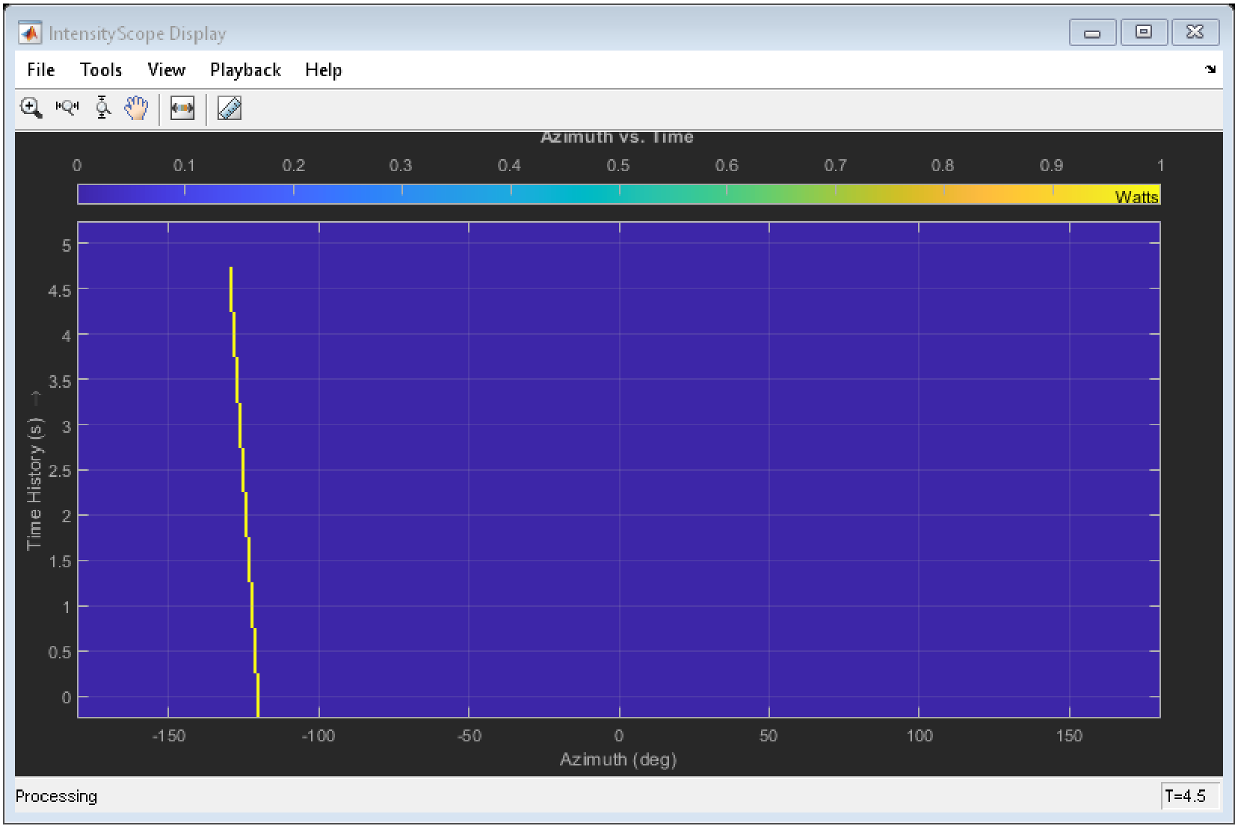
Create an angle-time-intensity scope having azimuth angle bins spanning ?180° to 180° with 1° resolution.

```
scanline = zeros(361,1);
angres = 1.0;
angmin = -180.0;
angmax = 180.0;
rtidisplay = phased.IntensityScope( ...
    'Name','IntensityScope Display',...
    'Title','Azimuth vs. Time',...
    'XLabel','Azimuth (deg)', ...
    'XResolution',angres,'XOffset',angmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts',...
    'Position',[100,100,800,450]);
```

### Loop Over Scan Updates

Simulate angular motion and fill the bin containing the current angular position of the signal. Hide the scope after the 5th step and show the scope at the end of the simulation.

```
for k = 1:nsteps
    ang = -130.0 + k;
    binindexdx = floor((ang - angmin)/angres) + 1;
    scanline(binindexdx) = 1;
    rtidisplay(scanline);
    scanline(binindexdx) = 0;
    if k == 5
        hide(rtidisplay)
    end
    pause(.1);
end
show(rtidisplay)
```



**Introduced in R2016a**

# reset

**System object:** `phased.IntensityScope`
**Package:** `phased`

Reset state of intensity scope System object

## Syntax

```
reset(sIS)
```

## Description

`reset(sIS)` resets the internal state of the `phased.IntensityScope` System object, `sIS`, to its initial value.

## Input Arguments

### `sIS` — Intensity scope

`phased.IntensityScope` System object

Intensity scope, specified as a `phased.IntensityScope` System object.

Example: `phased.IntensityScope`

**Introduced in R2016a**

# show

**System object:** phased.IntensityScope
**Package:** phased

Show intensity scope window

## Syntax

show(sIS)

## Description

show(sIS) shows the display window of the phased.IntensityScope object, sIS.

## Input Arguments

**sIS — Intensity scope**
phased.IntensityScope System object

Intensity scope, specified as a phased.IntensityScope System object.

Example: phased.IntensityScope

## Examples

### Hide and Show Intensity Scope

Create an angle-time-intensity scope. Use the phased.IntensityScope System object? to display simulated intensity as a function of the angular motion of a moving target. After five steps in the processing loop, use the hide method to hide the scope. At completion of the loop, use the show method to show the scope.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.%% Simulate data for 5 seconds with a time interval of 0.5 seconds between scan lines.

```
nsteps = 10;
dt = 0.5;
timespan = nsteps*dt;
```

### Set Up IntensityScope System Object

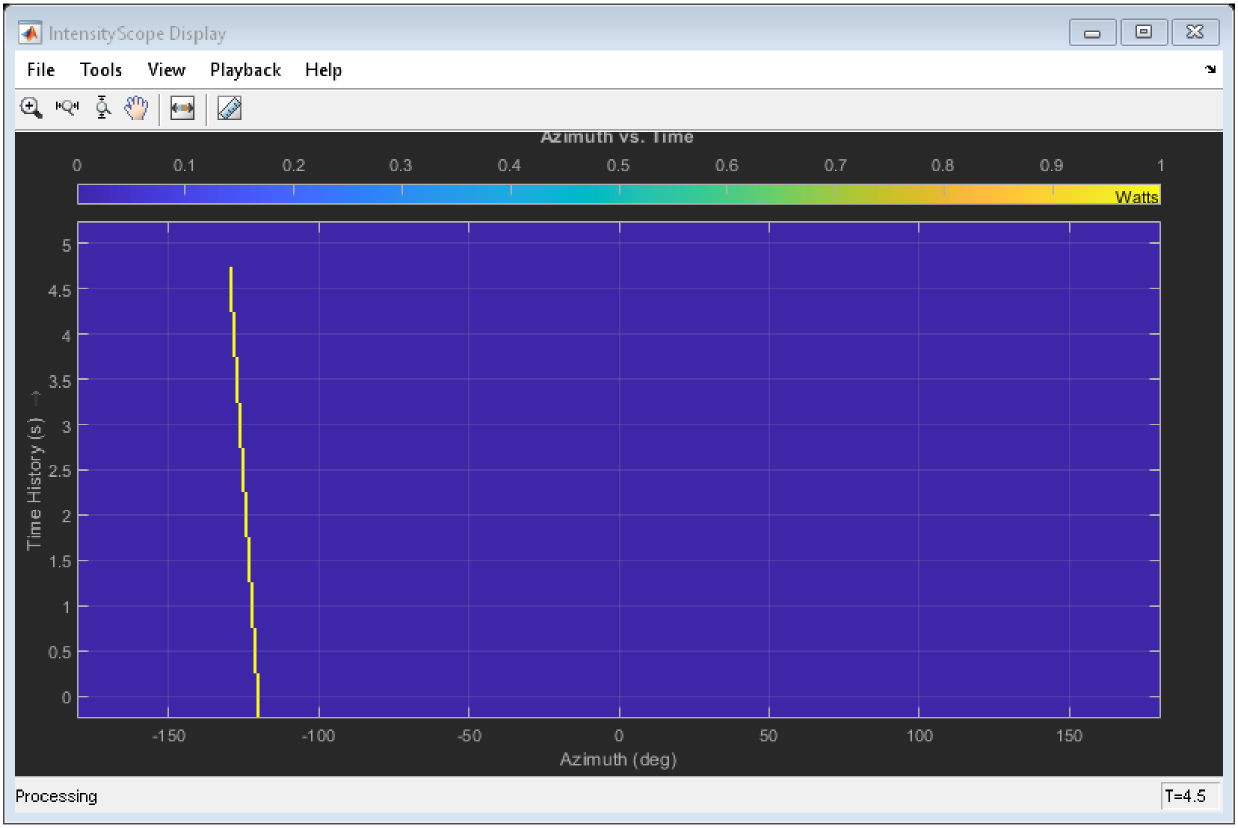
Create an angle-time-intensity scope having azimuth angle bins spanning ?180° to 180° with 1° resolution.

```
scanline = zeros(361,1);
angres = 1.0;
angmin = -180.0;
angmax = 180.0;
rtidisplay = phased.IntensityScope( ...
    'Name','IntensityScope Display',...
    'Title','Azimuth vs. Time',...
    'XLabel','Azimuth (deg)', ...
    'XResolution',angres,'XOffset',angmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts',...
    'Position',[100,100,800,450]);
```

### Loop Over Scan Updates

Simulate angular motion and fill the bin containing the current angular position of the signal. Hide the scope after the 5th step and show the scope at the end of the simulation.

```
for k = 1:nsteps
    ang = -130.0 + k;
    binindexdx = floor((ang - angmin)/angres) + 1;
    scanline(binindexdx) = 1;
    rtidisplay(scanline);
    scanline(binindexdx) = 0;
    if k == 5
        hide(rtidisplay)
    end
    pause(.1);
end
show(rtidisplay)
```



**Introduced in R2016a**

# step

**System object:** `phased.IntensityScope`
**Package:** `phased`

Update intensity scope display

## Syntax

```
step(sIS,data)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(sIS,data)` updates the intensity scope display with new scan lines from a real signal, `data`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `sIS` — Intensity scope display

`phased.IntensityScope` System object

Intensity scope display, specified as a `phased.IntensityScope` System object.

Example: `phased.IntensityScope`

**`data` — Displayed intensity values**
real-valued *N*-by-*M* matrix

Displayed intensity values, specified as a real-valued *N*-by-*M* matrix. The quantity *N* specifies the number of intensity bins in `data`. The quantity *M* specifies the number of intensity vectors in the data. Each column of the matrix creates a display line. Units are arbitrary. Specify the time interval between intensity vectors using the `TimeResolution` property.

Example: `[5.0;5.1;5.0;4.9]`

Data Types: `double`

# Examples

### RTI Display of Three Moving Targets

Use the `phased.IntensityScope` System object? to display the intensities of the echoes of three moving targets as functions of range and time.

### Create the Radar and Target System Objects

Set up the initial positions and velocities of the three targets. Use the `phased.Platform` System object? to model radar and target motions. The radar is stationary while the targets undergo constant velocity motion. The simulation runs for 500 steps at 0.1 second increments, giving a total simulation time of 50 seconds.

```
nsteps = 500;
dt = .1;
timespan = nsteps*dt;
x1 = [60,0,0]';
x2 = [60,-80,40]';
x3 = [300,0,-300]';
v1 = [2,0,0]';
v2 = [10,5,6]';
v3 = [-10,2,-4]';
platform = phased.Platform([0,0,0]',[0,0,0]');
targets = phased.Platform([x1,x2,x3],[v1,v2,v3]);
```

### Set Up Range Bins

Each echo is put into a range bin. The range bin resolution is 1 meter and the range is from 50 to 1000 meters.

```
rngres = 1.0;
rngmin = 50.0;
rngmax = 1000.0;
rngscan = [rngmin:rngres:rngmax];
```

### Create the Gain Function

Define a range-dependent gain function to enhance the display of targets at larger ranges. The gain function amplifies the returned echo for visualization purposes only.

```
rangegain = @(rng)(1e12*rng^4);
```

### Create the Intensity Scope

Set up the Intensity Scope using these properties.

- Use the `XResolution` property to set the width of each scan line bin to the range resolution of 1 km.
- Use the `XOffset` property to set the value of the lowest range bin to the minimum range of 50 km.
- Use the `TimeResolution` property to set the value of the scan line time difference to 0.1 s.
- Use the `TimeSpan` property to set the height of the display window to the time duration of the simulation.
- Use the `IntensityUnits` property to set the display units to `Watts`.

```
scope = phased.IntensityScope('Name','IntensityScope Display',...
    'Title','Ranges vs. Time','XLabel','Range (m)','XResolution',rngres,...
    'XOffset',rngmin,'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts','Position',[100,100,800,450]);
```

### Run Simulation Loop

1. In this loop, move the targets at constant velocity using the `step` method of the `phased.Platform` System object.
2. Compute the target ranges using the `rangeangle` function.

3 Compute the target range bins by quantizing the range values in integer multiples of `rangres`.

4 Fill each target range bin and neighboring bins with a simulated radar intensity value.

5 Add the signal from each target to the scan line.

6 Call the `step` method of the `phased.IntensityScope` System object to display the scan lines.

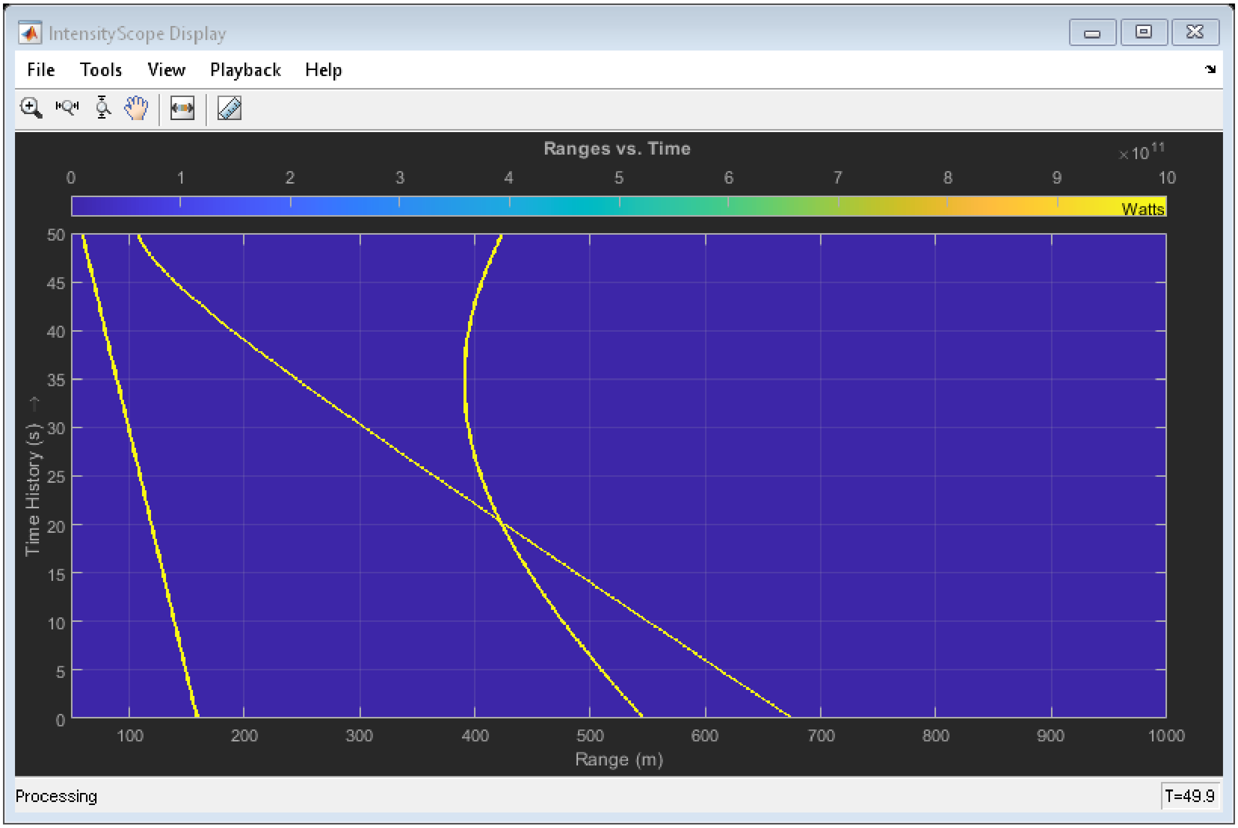
```
for k = 1:nsteps
    xradar = platform(dt);
    xtgts = targets(dt);
    [rngs] = rangeangle(xtgts,xradar);
    scanline = zeros(size(rngscan));

    rngindx = ceil((rngs(1) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(1))/(rngs(1)^4);

    rngindx = ceil((rngs(2) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(2))/(rngs(2)^4);

    rngindx = ceil((rngs(3) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(3))/(rngs(3)^4);

    scope(scanline.');
    pause(.1);
end
```



### RTI and DTI Displays in Full Radar Simulation

Use the `phased.IntensityScope` System object? to display the detection output of a complete radar system simulation. The radar scenario contains a stationary single-element monostatic radar and three moving targets.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

### Set Radar Operating Parameters

Set the probability of detection, probability of false alarm, maximum range, range resolution, operating frequency, transmitter gain, and target radar cross-section.

```
pd = 0.9;
pfa = 1e-6;
max_range = 5000;
range_res = 50;
fc = 10e9;
tx_gain = 20;
tgt_rcs = 1;
```

Choose the signal propagation speed to be the speed of light, and compute the signal wavelength corresponding to the operating frequency.

```
c = physconst('LightSpeed');
lambda = c/fc;
```

Compute the pulse bandwidth from the range resolution. Set the sampling rate, `fs`, to twice the pulse bandwidth. The noise bandwidth is also set to the pulse bandwidth. The radar integrates a number of pulses set by `num_pulse_int`. The duration of each pulse is the inverse of the pulse bandwidth.

```
pulse_bw = c/(2*range_res);
pulse_length = 1/pulse_bw;
fs = 2*pulse_bw;
noise_bw = pulse_bw;
num_pulse_int = 10;
```

Set the pulse repetition frequency to match the maximum range of the radar.

```
prf = c/(2*max_range);
```

### Compute Transmit Power

Use the Albersheim equation to compute the SNR required to meet the desired probability of detection and probability of false alarm. Then, use the radar equation to compute the power needed to achieve the required SNR.

```
snr_min = albersheim(pd, pfa, num_pulse_int);
peak_power = radareqpow(lambda,max_range,snr_min,pulse_length,...
    'RCS',tgt_rcs,'Gain',tx_gain);
```

### Create System Objects for the Model

Choose a rectangular waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',pulse_length,...
    'PRF',prf,'SampleRate',fs);
```

Set the receiver amplifier characteristics.

```
amplifier = phased.ReceiverPreamp('Gain',20,'NoiseFigure',0,...
    'SampleRate',fs,'EnableInputPort',true,'SeedSource','Property',...
    'Seed',2007);
transmitter = phased.Transmitter('Gain',tx_gain,'PeakPower',peak_power,...
    'InUseOutputPort',true);
```

Specify the radar antenna as a single isotropic antenna.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[5e9 15e9]);
```

Set up a monostatic radar platform.

```
radarplatform = phased.Platform('InitialPosition',[0; 0; 0],...
    'Velocity',[0; 0; 0]);
```

Set up the three target platforms using a single System object.

```
targetplatforms = phased.Platform(...
    'InitialPosition',[2000.66 3532.63 3845.04; 0 0 0; 0 0 0], ...
    'Velocity',[150 -150 0; 0 0 0; 0 0 0]);
```

Create the radiator and collector System objects.

```
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc);
```

Set up the three target RCS properties.

```
targets = phased.RadarTarget('MeanRCS',[1.6 2.2 1.05],'OperatingFrequency',fc);
```

Create System object to model two-way freespace propagation.

```
channels= phased.FreeSpace('SampleRate',fs,'TwoWayPropagation',true,...
    'OperatingFrequency',fc);
```

Define a matched filter.

```
MFcoef = getMatchedFilter(waveform);
filter = phased.MatchedFilter('Coefficients',MFcoef,'GainOutputPort',true);
```

### Create Range and Doppler Bins

Set up the fast-time grid. Fast time is the sampling time of the echoed pulse relative to the pulse transmission time. The range bins are the ranges corresponding to each bin of the fast time grid.

```
fast_time = unigrid(0,1/fs,1/prf,'[)');
range_bins = c*fast_time/2;
```

To compensate for range loss, create a time varying gain System Object?.

```
gain = phased.TimeVaryingGain('RangeLoss',2*fspl(range_bins,lambda),...
    'ReferenceLoss',2*fspl(max_range,lambda));
```

Set up Doppler bins. Doppler bins are determined by the pulse repetition frequency. Create an FFT System object for Doppler processing.

```
DopplerFFTbins = 32;
DopplerRes = prf/DopplerFFTbins;
fft = dsp.FFT('FFTLengthSource','Property',...
    'FFTLength',DopplerFFTbins);
```

### Create Data Cube

Set up a reduced data cube. Normally, a data cube has fast-time and slow-time dimensions and the number of sensors. Because the data cube has only one sensor, it is two-dimensional.

```
rx_pulses = zeros(numel(fast_time),num_pulse_int);
```

### Create IntensityScope System Objects

Create two `IntensityScope` System objects, one for Doppler-time-intensity and the other for range-time-intensity.

```
dtiscope = phased.IntensityScope('Name','Doppler-Time Display',...
    'XLabel','Velocity (m/sec)', ...
    'XResolution',dop2speed(DopplerRes,c/fc)/2, ...
    'XOffset',dop2speed(-prf/2,c/fc)/2,...
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','Mag');
rtiscope = phased.IntensityScope('Name','Range-Time Display',...
    'XLabel','Range (m)', ...
    'XResolution',c/(2*fs), ...
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','Mag');
```

### Run the Simulation Loop Over Multiple Radar Transmissions

Transmit 2000 pulses. Coherently process groups of 10 pulses at a time.

For each pulse:

1. Update the radar position and velocity `radarplatform`
2. Update the target positions and velocities `targetplatforms`
3. Create the pulses of a single wave train to be transmitted `transmitter`
4. Compute the ranges and angles of the targets with respect to the radar
5. Radiate the signals to the targets `radiator`
6. Propagate the pulses to the target and back `channels`
7. Reflect the signals off the target `targets`
8. Receive the signal `sCollector`
9. Amplify the received signal `amplifier`
10. Form data cube

For each set of 10 pulses in the data cube:

1. Match filter each row (fast-time dimension) of the data cube.
2. Compute the Doppler shifts for each row (slow-time dimension) of the data cube.

```
pri = 1/prf;
nsteps = 200;
for k = 1:nsteps
    for m = 1:num_pulse_int
        [ant_pos,ant_vel] = radarplatform(pri);
        [tgt_pos,tgt_vel] = targetplatforms(pri);
        sig = waveform();
        [s,tx_status] = transmitter(sig);
        [~,tgt_ang] = rangeangle(tgt_pos,ant_pos);
        tsig = radiator(s,tgt_ang);
        tsig = channels(tsig,ant_pos,tgt_pos,ant_vel,tgt_vel);
        rsig = targets(tsig);
        rsig = collector(rsig,tgt_ang);
        rx_pulses(:,m) = amplifier(rsig,~(tx_status>0));
    end
```

```
        rx_pulses = filter(rx_pulses);
        MFdelay = size(MFcoef,1) - 1;
        rx_pulses = buffer(rx_pulses((MFdelay + 1):end), size(rx_pulses,1));
        rx_pulses = gain(rx_pulses);
        range = pulsint(rx_pulses,'noncoherent');
        rtiscope(range);
        dshift = fft(rx_pulses.');
        dshift = fftshift(abs(dshift),1);
        dtiscope(mean(dshift,2));
        radarplatform(.05);
        targetplatforms(.05);
    end
```

All of the targets lie on the x-axis. Two targets are moving along the x-axis and one is stationary. Because the radar is at the origin, you can read the target speed directly from the Doppler-Time Display window. The values agree with the specified velocities of -150, 150, and 0 m/sec.

### Intensity Scope Display of Target Angular Motion

Use the `phased.IntensityScope` System object? to display the angular motions of moving targets as functions of time. Each horizontal line (scan line) shows the strength of radar echoes at different azimuth angles. Azimuth space is divided into azimuth bins and each bin is filled with a simulated value depending upon the position of the targets.

### Create Radar and Target System Objects

Set up the initial positions and velocities of the three targets. Use the `phased.Platform` System object? to model radar and target motions. The radar is stationary while the targets undergo constant velocity motion. The simulation runs for 200 steps at 0.5 second intervals, giving a total simulation time of 100 seconds.

```
nsteps = 200;
dt = 0.5;
timespan = nsteps*dt;
x1 = [60,0,0]';
x2 = [60,-80,40]';
x3 = [300,0,-300]';
x3 = [-300,0,-300]';

v1 = [2,0,0]';
v2 = [10,5,6]';
v3 = [-10,2,-4]';
radarplatform = phased.Platform([0,0,0]',[0,0,0]');
targets = phased.Platform([x1,x2,x3],[v1,v2,v3]);
```

### Set Up Azimuth Angle Bins

The signal for each echo is put into an angle bin and two adjacent bins. Bin resolution is 1 degree and the angle span is from -180 to 180 degrees.

```
angres = 1.0;
angmin = -180.0;
angmax = 180.0;
angscan = [angmin:angres:angmax];
na = length(angscan);
```

### Range Gain Function

Define a range-dependent gain function to enhance the display of targets at larger ranges. The gain function amplifies the returned echo for visualization purposes only.

```
rangegain = @(rng)(1e12*rng^4);
```

### Set Up Scope Viewer

The `XResolution` name-value pair specifies the width of each bin of the scan line. The `XOffset` sets the value of the lowest azimuth angle bin. The `TimeResolution` name-value pair specifies the time difference between scan lines. The `TimeSpan` name-value pair sets the height of the display window. A scan line is created with each call to the step method. Intensity units are amplitude units.

```
scope = phased.IntensityScope( ...
    'Name','IntensityScope Display',...
    'Title','Azimuth vs. Time',...
    'XLabel','Azimuth (deg)', ...
    'XResolution',angres,'XOffset',angmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts',...
    'Position',[100,100,800,450]);
```

### Update-Display Loop

1 In this loop, move the targets at constant velocity using the step method of the phased.Platform System object.
2 Compute the target ranges and azimuth angles using the rangeangle function.
3 Compute the azimuth angle bins by quantizing the azimuth angle values in integer multiples of angres.
4 Fill each target azimuth bin and neighboring bins with a simulated radar intensity value.
5 Call the phased.IntensityScope step method to display the scan line.

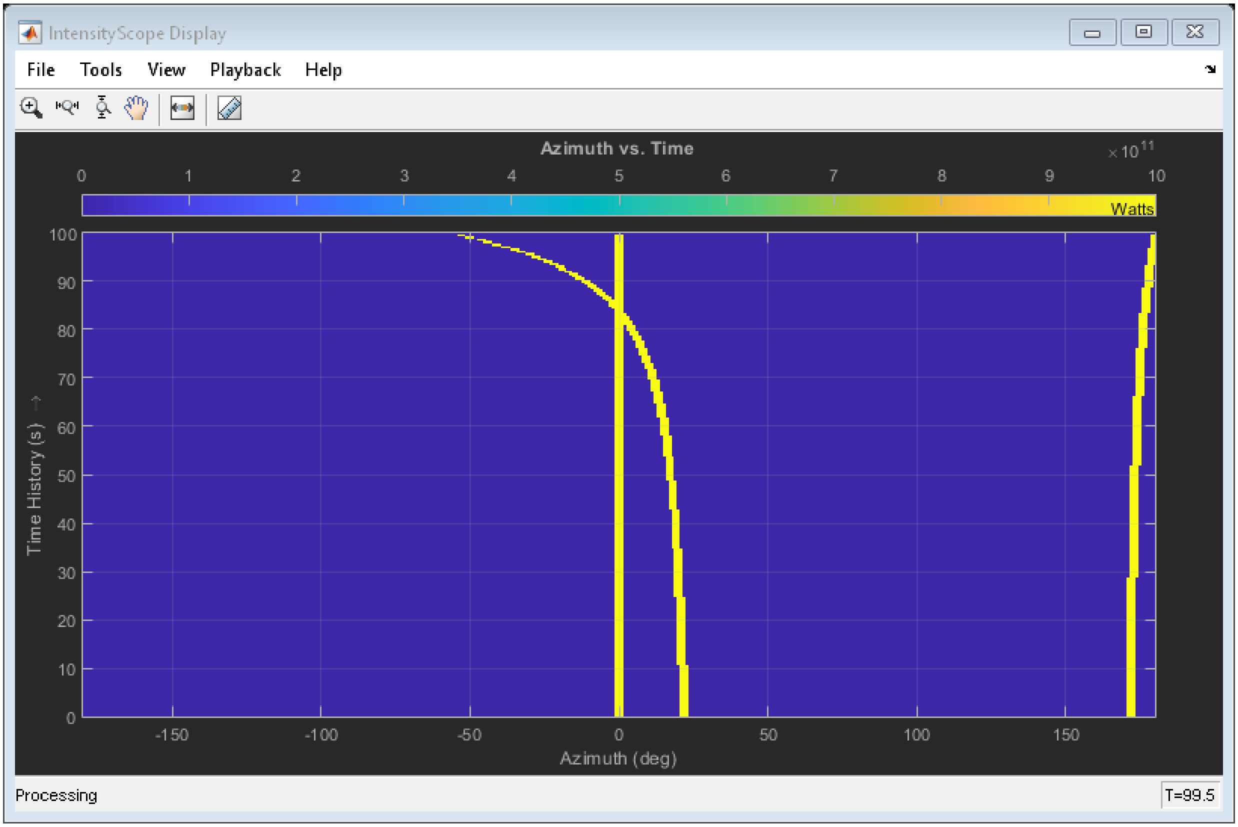
```
for k = 1:nsteps
    xradar = radarplatform(dt);
    xtgts = targets(dt);
    [rngs,angs] = rangeangle(xtgts,xradar);
    scanline = zeros(size(angscan));

    angindx = ceil((angs(1,1) - angmin)/angres) + 1;
    idx = angindx + [-1:1];
    idx(idx>na)=[];
    idx(idx<1)=[];
    scanline(idx) = rangegain(rngs(1))/(rngs(1)^4);

    angindx = ceil((angs(1,2) - angmin)/angres) + 1;
    idx = angindx + [-1:1];
    idx(idx>na)=[];
    idx(idx<1)=[];
    scanline(idx) = rangegain(rngs(2))/(rngs(2)^4);

    angindx = ceil((angs(1,3) - angmin)/angres) + 1;
    idx = angindx + [-1:1];
```

```
        idx(idx>na)=[];
        idx(idx<1)=[];
        scanline(idx) = rangegain(rngs(3))/(rngs(3)^4);
        scope(scanline.');
        pause(.1);
    end
```



**Introduced in R2016a**

# phased.IsoSpeedUnderwaterPaths

**Package:** `phased`

Isospeed multipath sonar channel

## Description

The `phased.IsoSpeedUnderwaterPaths` System object creates an underwater acoustic channel to propagate narrowband sound from point to point. The channel has finite constant depth with air-water and water-bottom interfaces. Both interfaces are planar and horizontal. Sound speed is constant throughout the channel. The object generates multiple propagation paths in the channel using the acoustical method of images (see [3]). Because sound speed is constant, all propagation paths are straight lines between the source, boundaries, and receiver. There is always one direct line-of-sight path. For each propagation path, the object outputs range-dependent time delay, gain, Doppler factor, reflection loss, and spreading loss. You can use the channel data as input to the multipath sound propagator, `phased.MultipathChannel`.

To model an isospeed channel :

1. Define and set up the channel. You can set `phased.IsoSpeedUnderwaterPaths` System object properties at construction time or leave them to their default values. See “Construction” on page 1-1061. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To create the multipath channel, call the `step` method of `phased.IsoSpeedUnderwaterPaths`. The output of the method depends on the properties of the `phased.IsoSpeedUnderwaterPaths` System object. You can change tunable properties at any time.

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`channel = phased.IsoSpeedUnderwaterPaths` creates an isospeed multipath underwater channel System object, `channel`.

`channel = phased.IsoSpeedUnderwaterPaths(Name,Value)` creates an isospeed multipath underwater channel System object, `channel`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `ChannelDepth` — Channel depth

`100` (default) | positive scalar

Channel depth, specified as a positive scalar. Units are in meters.

Example: `250.0`

Data Types: `double`

### `PropagationSpeed` — Underwater sound propagation speed

`1520.0` (default) | positive scalar

Underwater sound propagation speed, specified as a positive scalar. Units are in meter per second. The default value is a commonly-used underwater sound propagation speed.

Example: `1502.0`

Data Types: `double`

### `NumPathsSource` — Source of number of propagation paths

`'Auto'` (default) | `'Property'`

The source of the number of propagation paths, specified as `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the object automatically determines the number of paths based on spreading and reflection losses. If you set this property to `'Property'`, you specify the number of paths using the `NumPaths` property.

When `NumPathsSource` is set to `'Auto'`, only paths having a total loss greater than 20 dB below the direct path loss are returned.

Example: `'Property'`

Data Types: `char`

### `NumPaths` — Number of propagation paths

`10` (default) | positive integer

The number of propagation paths, specified as a positive integer between 1 and 51, inclusive.

Example: `11`

#### Dependencies

To enable this property, set the `NumPathsSource` property to `'Property'`.

Data Types: `double`

### `CoherenceTime` — Channel coherence time

`0` (default) | nonnegative scalar

Channel coherence time, specified as a nonnegative scalar. Coherence time is a measure of the temporal stability of the channel. The object keeps a record of cumulative step time. When the cumulative step time exceeds the coherence time, propagation paths are recomputed and the cumulative step time is reset to zero. If you set this quantity to zero, the propagation paths are update at each call to `step`. Units are in seconds.

Example: `5.0`

Data Types: `double`

### `BottomLoss` — Bottom reflection loss

`6` (default) | nonnegative scalar

Bottom reflection loss, specified as a nonnegative scalar. This value applies to each bottom reflection of a path. Units are in dB.

Example: `10`

Data Types: `double`

### `LossFrequencies` — Absorption loss frequencies

`[1:100]*1000` (default) | positive real-valued vector

Frequencies for which to compute absorption loss, specified as a positive real-valued vector. Units are in Hz.

Example: `[1000:100:3000]`

Data Types: `double`

### `TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in `step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

## Methods

| | |
|---|---|
| step | Create propagation paths in an isospeed multipath sound channel |
| reset | Reset state of System object |

| **Common to All System Objects** | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Create One-Way Multipath Underwater Sound Channel

Create a 5-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the receiver is moving along the *x*-axis towards the source at 20 kph. Assume one-way propagation.

```
speed = -20*1000/3600;
numpaths = 5;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
```

```
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
pathmat = channelpaths(srcpos,rcvpos,srcvel,rcvvel,tstep);
disp(pathmat)
```

```
    0.3356    0.3556    0.4687    0.3507    0.3791
    1.0000   -1.0000   -0.3162    0.3162   -0.3162
   54.1847   54.6850   57.0766   54.5652   55.2388
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

### Create Two-Way Multipath Underwater Sound Channel

Create a 7-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the target is moving along the *x*-axis towards the source at 20 kph. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5,...
    'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
[pathmat,dop,aloss,tgtangs,srcangs] = channelpaths(srcpos,tgtpos,srcvel,tgtvel,tstep);
disp(pathmat)
```

```
    0.6712    0.7112    0.9374    1.0354    0.7014    0.7581    1.0152
    1.0000    1.0000    0.1000    0.1000    0.1000    0.1000    0.0100
  108.3693  109.3699  114.1531  115.8772  109.1304  110.4775  115.5355
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

### Propagate Sound in Channel Having Unknown Number of Paths

Create an underwater sound channel and plot the combined received signal. Automatically find the number of paths. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

```
speed = -20*1000/3600;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses. The propagator outputs 51 paths output but some paths can contain `Nan` values.

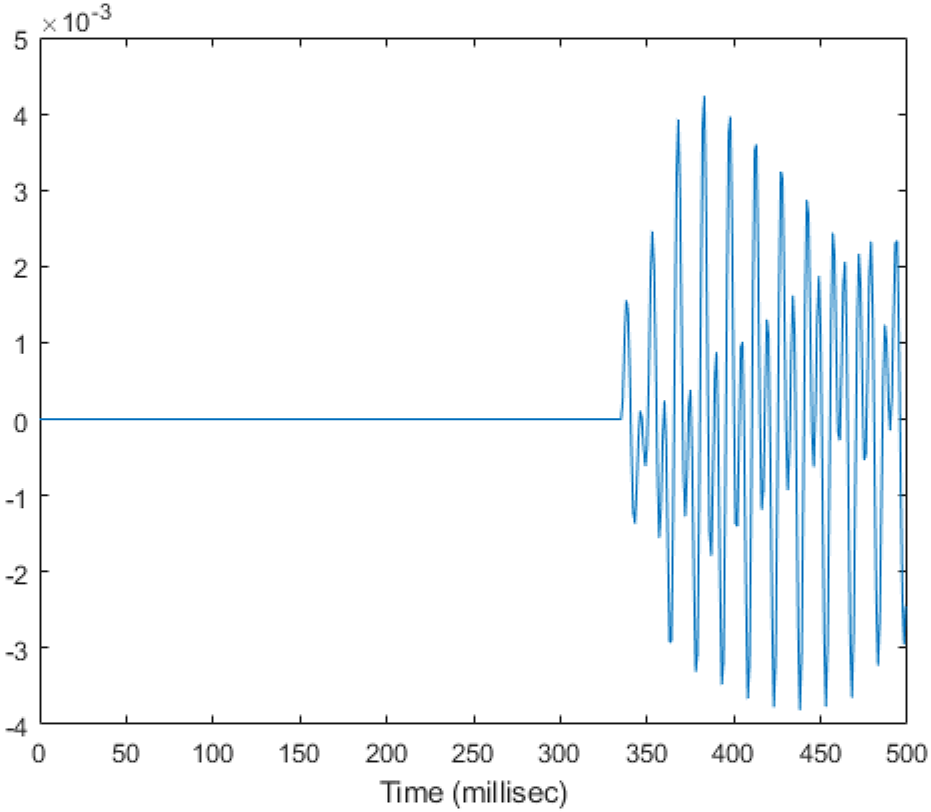
```
[pathmat,dop,absloss,rcvangs,srcangs] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create of a 100 Hz signal with 500 samples. Assume that all the paths have the same signal. Use a `phased.MultipathChannel` System object to propagate the signals to the receiver. `phased.MultipathChannel` accepts as input all paths produced by `phased.IsoSpeedUnderwaterPaths` but ignores paths that have `NaN` values.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
numpaths = size(pathmat,2);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



### Doppler Stretching of Sonar Signal

Compare the duration of a propagated signal from a stationary sonar to that of a moving sonar. The moving sonar has a radial velocity of 25 m/s away from the target. In each case, propagate the signal along a single path. Assume one-way propagation.

Define the sonar system parameters: maximum unambiguous range, required range resolution, operating frequency, and propagation speed.

```
maxrange = 5000.0;
rngres = 10.0;
fc = 20.0e3;
csound = 1520.0;
```

Use a rectangular waveform for the transmitted signal.

```
prf = csound/(2*maxrange);
pulseWidth = 8*rngres/csound;
pulseBW = 1/pulseWidth;
fs = 80*pulseBW;
waveform = phased.RectangularWaveform('PulseWidth',pulseWidth,'PRF',prf, ...
    'SampleRate',fs);
```

Specify the sonar positions.

```
sonarplatform1 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;0;0]);
sonarplatform2 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;-25;0]);
```

Specify the target position.

```
targetplatform = phased.Platform('InitialPosition',[0;500;-60],'Velocity',[0;0;0]);
```

Define the underwater path and propagation channel objects.

```
paths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',100, ...
    'CoherenceTime',0,'NumPathsSource','Property','NumPaths',1, ...
    'PropagationSpeed',csound);
propagator = phased.MultipathChannel('SampleRate',fs,'OperatingFrequency',fc);
```

Create the transmitted waveform.

```
wav = waveform();
nsamp = size(wav,1);
rxpulses = zeros(nsamp,2);
t = (0:nsamp-1)/fs;
```

Transmit the signal and then receive the echo at the stationary sonar.

```
[pathmat,dop,aloss,~,~] = paths(sonarplatform1.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform1.InitialVelocity, ...
    targetplatform.InitialVelocity,1/prf);
rxpulses(:,1) = propagator(wav,pathmat,dop,aloss);
```

Transmit and receive at the moving sonar.

```
[pathmat,dop,aloss,~,~] = paths(sonarplatform2.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform2.Velocity, ...
    targetplatform.Velocity,1/prf);
rxpulses(:,2) = propagator(wav,pathmat,dop,aloss);
```

Plot the received pulses.

```
plot(abs(rxpulses))
xlim([490 650])
ylim([0 1.65e-3])
legend('Stationary sonar','Moving sonar')
xlabel('Received Sample Time (sec)')
ylabel('Integrated Received Pulses')
```

The signal received at the moving sonar has increased in duration compared to the stationary sonar.

# step

**System object:** `phased.IsoSpeedUnderwaterPaths`
**Package:** `phased`

Create propagation paths in an isospeed multipath sound channel

## Syntax

```
pathmat = step(channel,srcpos,destpos,srcvel,destvel,T)
[pathmat,dop,aloss,destang,srcang] = step(channel,srcpos,destpos,
srcvel,destvel,T)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`pathmat = step(channel,srcpos,destpos,srcvel,destvel,T)` returns the propagation paths matrix, `pathmat`, for a multipath underwater acoustic channel. The matrix describes one or two-way propagation from the signal source position, `srcpos`, to the signal destination position, `destpos`. The velocity of the signal source is specified in `srcvel` and the velocity of the signal destination is specified in `destvel`. `T` is the step time interval.

When you use this method for one-way propagation, `srcpos` refers to the origin of the signal and `destpos` to the receiver. One-way propagation modeling is useful for passive sonar and underwater communications.

When you use this method for two-way propagation, `destpos` now refers to the reflecting target, not the sonar receiver. A two-way path consists of a one-way path from source to target and then along an identical one-way path from target to receiver (which is collocated with the source). Two-way propagation modeling is useful for active sonar systems.

[pathmat,dop,aloss,destang,srcang] = step(channel,srcpos,destpos, srcvel,destvel,T) also returns the Doppler factor, dop, the frequency dependent absorption loss, aloss, the receiver arrival angles, destang, and the srcang transmitting angles.

When you use this method for two-way propagation, destang now refers to the reflecting target, not the sonar receiver.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Input Arguments

**channel — Isospeed underwater channel path**
phased.IsoSpeedUnderwaterPaths System object

Isospeed underwater channel paths, specified as a phased.IsoSpeedUnderwaterPaths System object.

Example: phased.IsoSpeedUnderwaterPaths

**srcpos — Source of sonar signals**
real-valued 3-by-1 column vector

Source of the sonar signal, specified as a real-valued 3-by-1 column vector. Position units are meters.

Example: [1000;100;500]

Data Types: double

### `destpos` — Destination of signal

real-valued 3-by-1 column vector

Destination position of the signal, specified as a real-valued 3-by-1 column vector. Position units are in meters.

Example: `[0;0;0]`

Data Types: `double`

### `srcvel` — Velocity of signal source

real-valued 3-by-1 column vector

Velocity of signal source, specified as a real-valued 3-by-1 column vector. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

### `destvel` — Velocity of signal destination

real-valued 3-by-1 column vector

Velocity of signal destination, specified as a real-valued 3-by-1 column vector. Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

### `T` — Elapsed time of current step

positive scalar

Elapsed time of current step, specified as a positive scalar. Time units are in seconds.

Example: `0.1`

Data Types: `double`

## Output Arguments

### `pathmat` — Propagation paths matrix

real-valued 3-by-*N* matrix

Propagation paths matrix, returned as a real-valued 3-by-*N* matrix. *N* is the number of paths in the channel. Each column represents a path. When you set `NumPathsSource` to `'Auto'`, *N* is 51. In this case, any columns filled with `NaN` do not correspond to found paths. The matrix rows represent:

| Row | Data |
|---|---|
| 1 | Propagation delays for each path. Units are in seconds. |
| 2 | Total reflection coefficient for each path. Units are dimensionless |
| 3 | Spreading loss for each path. Units are in dB. |

Except for the direct path, paths consists of alternating surface and bottom reflections. The losses for multiple reflections are multiplied. Bottom loss per reflection is specified by the `BottomLoss` property. The loss at the surface is *–1* indicating no loss, but only a 180° phase change. This is because the air-water interface surface is a pressure-release surface.

Data Types: `double`

**dop — Doppler factor**
real-valued *N*-by-1 row vector

Doppler factor, returned as a real-valued *N*-by-1 row vector where *N* is the number of paths. The Doppler factor multiplies the transmitted frequency to produce the Doppler-shifted received frequency for each path. The Doppler shift is defined as the difference between the transmitted frequency and the received frequency. The Doppler factor also defines the time compression or expansion of a signal. Units are dimensionless.

Data Types: `double`

**`aloss` — Frequency-dependent absorption loss**
real-valued *K*-by-*(N+1)* matrix

Frequency-dependent absorption loss, returned as a real-valued *K*-by-*(N+1)* matrix. *K* is the number of frequencies specified in the `LossFrequencies` property. *N* is the number of paths returned. The first column of `aloss` contains the absorption loss frequencies in Hz. You specify the frequencies using the `LossFrequencies` property. The remaining columns contain the absorption losses for each frequency. There is one column for each path. Units are in dB.

Data Types: `double`

### destang — Angles of paths at destination

real-valued 2-by-*N* matrix

Angles of paths at destination, returned as a real-valued 2-by-*N* matrix. Each column contains the direction of the received path with respect to the destination position as azimuth and elevation, `[az;el]`. Units are in degrees.

Data Types: `double`

### srcang — Angles of paths from source

real-valued 2-by-*N* matrix

Angles of paths from source, returned as a real-valued 2-by-*N* matrix. Each column contains the direction of the transmitted path with respect to the source position as azimuth and elevation, `[az;el]`. Units are in degrees.

Data Types: `double`

## Examples

### Create One-Way Multipath Underwater Sound Channel

Create a 5-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the receiver is moving along the *x*-axis towards the source at 20 kph. Assume one-way propagation.

```
speed = -20*1000/3600;
numpaths = 5;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
pathmat = channelpaths(srcpos,rcvpos,srcvel,rcvvel,tstep);
disp(pathmat)
```

```
    0.3356    0.3556    0.4687    0.3507    0.3791
    1.0000   -1.0000   -0.3162    0.3162   -0.3162
   54.1847   54.6850   57.0766   54.5652   55.2388
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

### Create Two-Way Multipath Underwater Sound Channel

Create a 7-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the target is moving along the *x*-axis towards the source at 20 kph. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5,...
    'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
[pathmat,dop,aloss,tgtangs,srcangs] = channelpaths(srcpos,tgtpos,srcvel,tgtvel,tstep);
disp(pathmat)
```

```
    0.6712    0.7112    0.9374    1.0354    0.7014    0.7581    1.0152
    1.0000    1.0000    0.1000    0.1000    0.1000    0.1000    0.0100
  108.3693  109.3699  114.1531  115.8772  109.1304  110.4775  115.5355
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

### Automatically Find the Number of Paths

Create an underwater sound channel and display the propagation paths which are found automatically. Assume the source is stationary and the receiver is moving along the *x*-axis towards the source at 20 kph. Assume two-way propagation.

```
speed = -20*1000/3600;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5,'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtpos = [speed;0;0];
[pathmat,dop,aloss,rcvangs,srcangs] = channelpaths(srcpos,tgtpos,srcvel,tgtpos,tstep);
```

Display the first 7 columns of `pathmat`. Some columns are filled with |NaN|s.

```
disp(pathmat(:,1:7))
```

```
    0.2107    0.2107       NaN       NaN       NaN       NaN       NaN
    1.0000    1.0000       NaN       NaN       NaN       NaN       NaN
   88.1753   88.1753       NaN       NaN       NaN       NaN       NaN
```

Select the column indices of the valid paths from the entire matrix.

```
idx = find(~isnan(pathmat(1,:)))
```

```
idx = 1×4

     1     2    27    28
```

Display the valid paths information.

```
validpaths = pathmat(:,idx)
```

```
validpaths = 3×4

    0.2107    0.2107    0.3159    0.3159
    1.0000    1.0000    0.3162    0.3162
   88.1753   88.1753   95.2131   95.2131
```

The first row contains the time delays in seconds. The second row contains the bottom reflected loss coefficients, and the third row contains the spreading losses.

**Introduced in R2017a**

# reset

**System object:** `phased.IsoSpeedUnderwaterPaths`
**Package:** `phased`

Reset state of System object

## Syntax

```
reset(channel)
```

## Description

`reset(channel)` resets the internal state of the `phased.IsoSpeedUnderwaterPaths` object, `channel`. This method resets the coherence time clock.

## Input Arguments

### `channel` — Isospeed underwater channel path

`phased.IsoSpeedUnderwaterPaths` System object

Isospeed underwater channel paths, specified as a `phased.IsoSpeedUnderwaterPaths` System object.

Example: `phased.IsoSpeedUnderwaterPaths`

**Introduced in R2017a**

# phased.IsotropicAntennaElement

**Package:** `phased`

Isotropic antenna element

## Description

The `IsotropicAntennaElement` object creates an antenna element with an isotropic response pattern. This antenna object does not support polarization.

To compute the response of the antenna element for specified directions:

1. Define and set up your isotropic antenna element. See "Construction" on page 1-1080.
2. Call `step` to compute the antenna response according to the properties of `phased.IsotropicAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.IsotropicAntennaElement` creates an isotropic antenna system object, `H`. The object models an antenna element whose response is 1 in all directions.

`H = phased.IsotropicAntennaElement(Name,Value)` creates an isotropic antenna object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

**`FrequencyRange`**

Operating frequency range

Specify the antenna element operating frequency range (in Hz) as a 1-by-2 row vector in the form of `[LowerBound HigherBound]`. The antenna element has zero response outside the specified frequency range.

**Default:** `[0 1e20]`

**`BackBaffled`**

Baffle the back of antenna element

Set this property to `true` to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond +/– 90 degrees from the broadside (0 degrees azimuth and elevation) are 0.

When the value of this property is `false`, the back of the antenna element is not baffled.

**Default:** `false`

## Methods

| | |
|---|---|
| directivity | Directivity of isotropic antenna element |
| isPolarizationCapable | Polarization capability |
| pattern | Plot isotropic antenna element directivity and patterns |
| patternAzimuth | Plot isotropic antenna element directivity or pattern versus azimuth |
| patternElevation | Plot isotropic antenna element directivity or pattern versus elevation |
| plotResponse | Plot response pattern of antenna |
| step | Output response of antenna element |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

## Examples

### Plot Isotropic Antenna Element Response

Create an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz. The operating frequency is 1 GHz. Find the response of the antenna at boresight. Then, plot the polar-pattern elevation response of the antenna.

```
antenna = phased.IsotropicAntennaElement( ...
    'FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
```

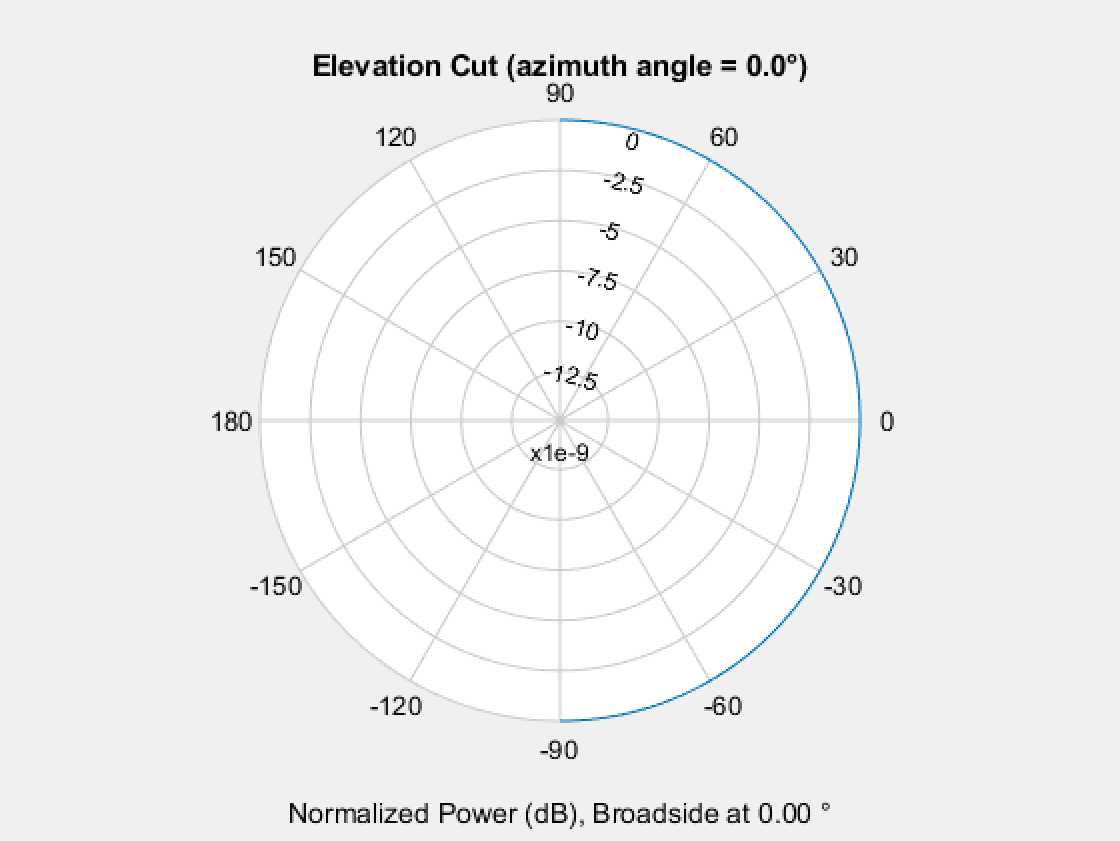
Obtain the response at boresight.

```
resp = antenna(fc,[0;0])
```

```
resp = 1
```

Plot the response pattern.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Normalize',true)
```



# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# directivity

**System object:** `phased.IsotropicAntennaElement`
**Package:** `phased`

Directivity of isotropic antenna element

## Syntax

`D = directivity(H,FREQ,ANGLE)`

## Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-1088 of an isotropic antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

## Input Arguments

### `H` — Isotropic antenna element

System object

Isotropic antenna element specified as a `phased.IsotropicAntennaElement` System object.

Example: `H = phased.IsotropicAntennaElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

### `D` — Directivity

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Isotropic Antenna Element

Compute the directivity of an isotropic antenna element in different directions.

Create an isotropic antenna element system object.

```
myAnt = phased.IsotropicAntennaElement();
```

First, select the angles of interest to be constant elevation angle at zero degrees. The seven azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation). Set the frequency to 1 GHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1e9;
```

Compute the directivity along the constant elevation cut.

```
d = directivity(myAnt,freq,ang)
```

```
d = 7×1

     0
     0
     0
     0
     0
     0
     0
```

Next choose the desired angles of interest to be at constant azimuth angle at zero degrees. All elevation angles are centered around boresight. The five elevation angles range from -20 to +20 degrees. Set the desired frequency to 1 GHz.

```
ang = [0,0,0,0,0; -20,-10,0,10,20];
freq = 1e9;
```

Compute the directivity along the constant azimuth cut.

```
d = directivity(myAnt,freq,ang)
```

```
d = 5×1

     0
     0
     0
     0
     0
```

For an isotropic antenna, the directivity is independent of direction.

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** `phased.IsotropicAntennaElement`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the `phased.IsotropicAntennaElement` System object supports polarization. An antenna element supports polarization if it can create or respond to polarized fields. This object does not support polarization.

## Input Arguments

### h — Isotropic antenna element

Isotropic antenna element specified as a `phased.IsotropicAntennaElement` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. Since the `phased.IsotropicAntennaElement` object does not support polarization, `flag` is always returned as `false`.

# Examples

### Isotropic Antenna Does Not Support Polarization

Create an isotropic antenna element using the `phased.IsotropicAntennaElement` System object™ and show that it does not support polarization.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[1.0,10]*1e9);
isPolarizationCapable(antenna)
```

```
ans = logical
   0
```

The returned value `0` shows that the antenna element does not support polarization.

# pattern

**System object:** `phased.IsotropicAntennaElement`
**Package:** `phased`

Plot isotropic antenna element directivity and patterns

## Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-1101 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sElem` — Isotropic antenna element

System object

Isotropic antenna element, specified as a `phased.IsotropicAntennaElement` System object.

Example: `sElem = phased.IsotropicAntennaElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

**EL — Elevation angles**
`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`CoordinateSystem` — Plotting coordinate system**
`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

## Output Arguments

### PAT — Element pattern

*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

**AZ_ANG — Azimuth angles**

scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**

scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

# Examples

### Plot Pattern and Directivity of Isotropic Antenna

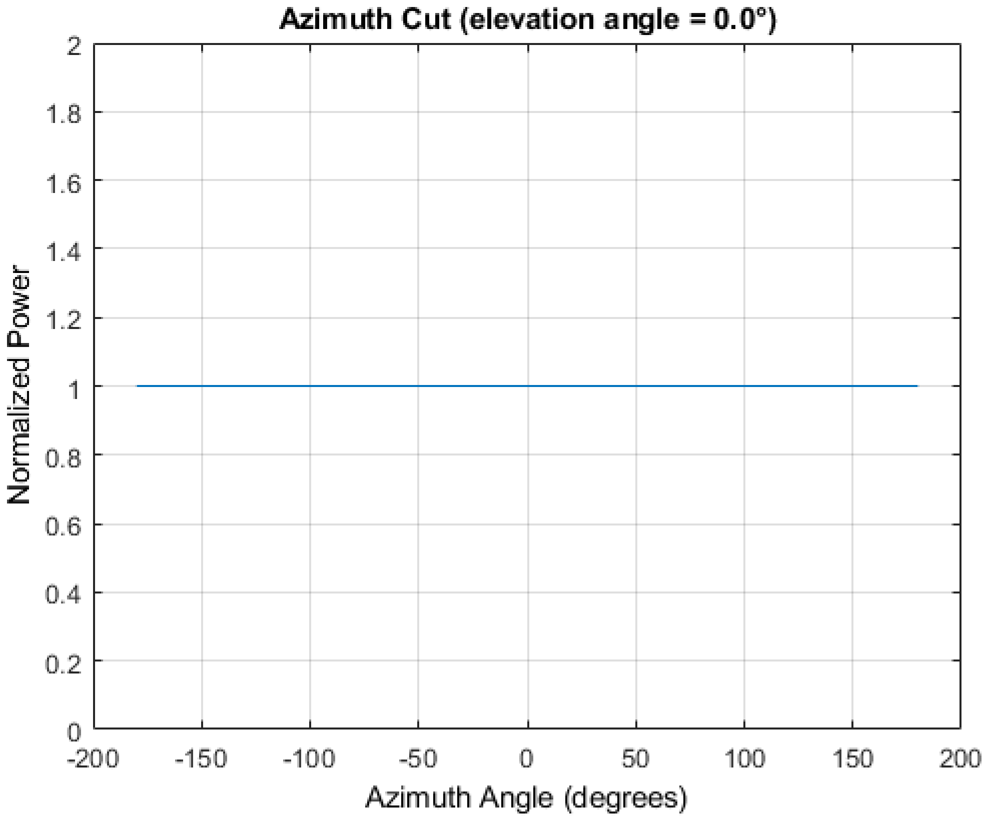
Create an isotropic antenna element. The, plot the power pattern and the directivity.

First, create the antenna.

```
sIso = phased.IsotropicAntennaElement;
```

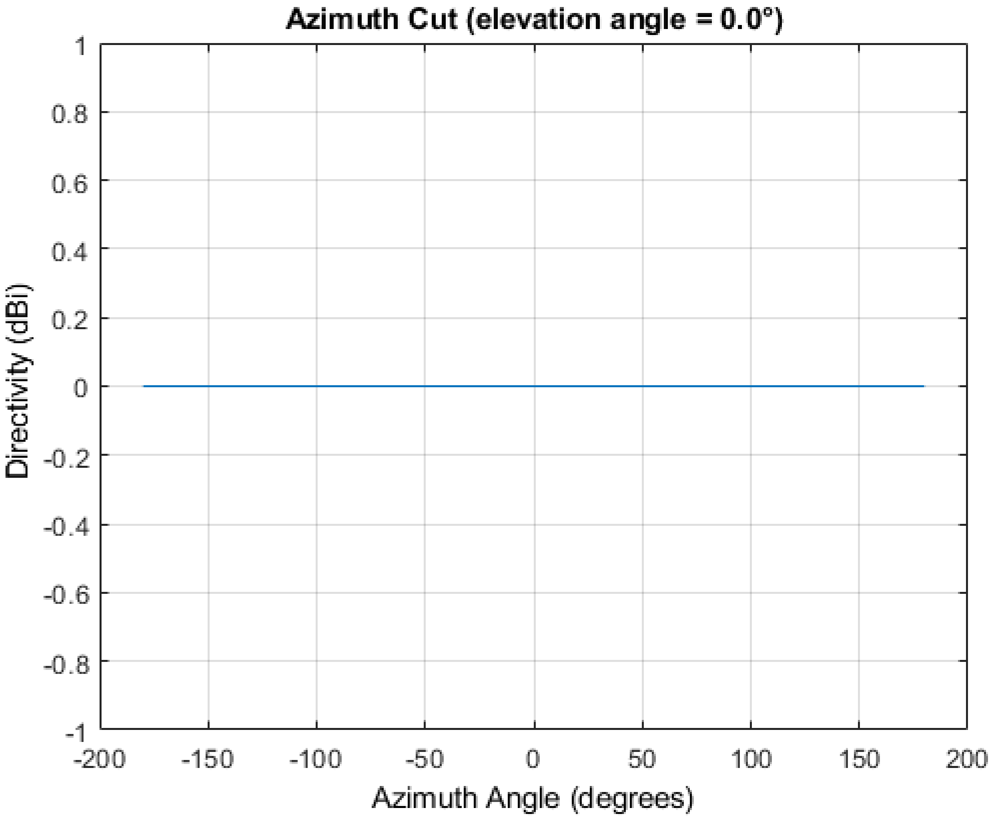
Draw an azimuth cut of the power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz.

```
fc = 1e9;
pattern(sIso,fc,[-180:180],0,...
    'Type','power',...
    'CoordinateSystem','rectangular')
```



Draw the same azimuth cut of the antenna directivity.

```
pattern(sIso,fc,[-180:180],0,...
    'Type','directivity',...
    'CoordinateSystem','rectangular')
```



### Elevation-Cut of Isotropic Antenna Pattern

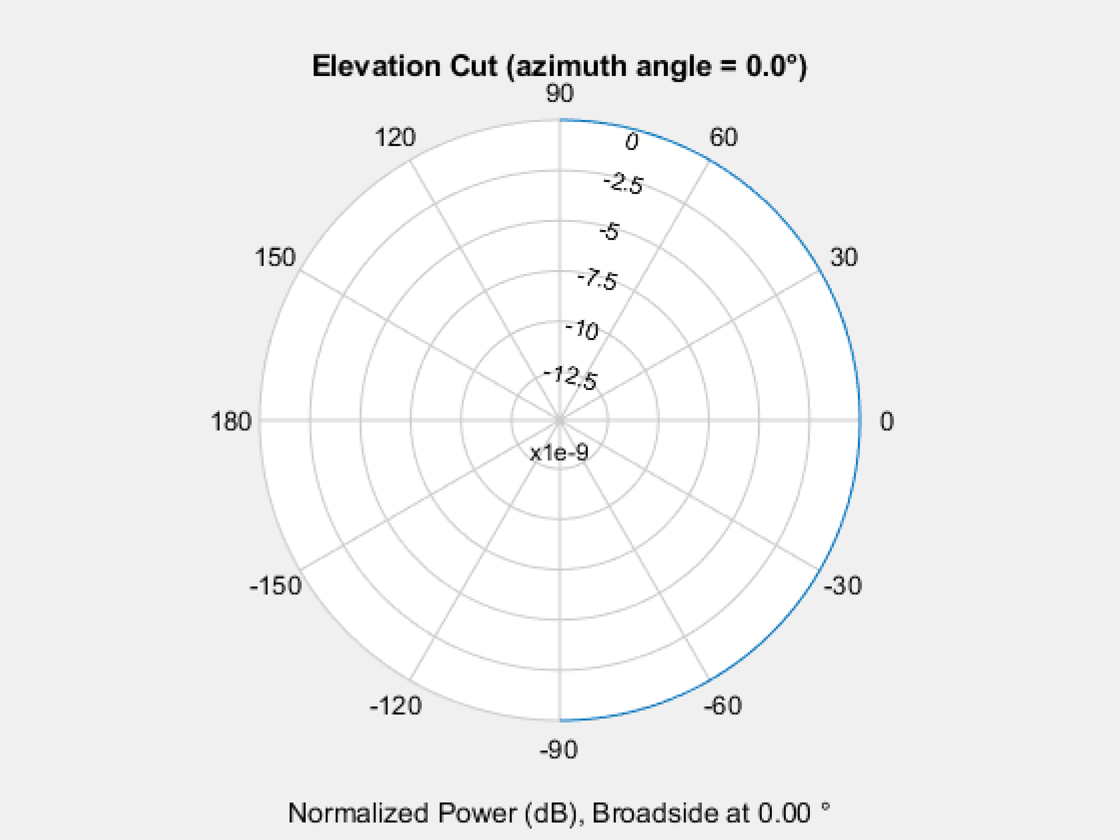
Construct an isotropic antenna operating in the frequency range from 800 MHz to 1.2 GHz. Compute the response at boresight at 1 GHz. Display the power pattern of the antenna at 1 GHz.

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
resp = step(sIso,fc,[0;0])
```

```
resp = 1
```

Plot the elevation power pattern of the antenna in polar coordinates.

```
pattern(sIso,fc,0,[-90:90],...
    'Type','powerdb',...
    'CoordinateSystem','polar')
```



### 3-D Isotropic Antenna Pattern

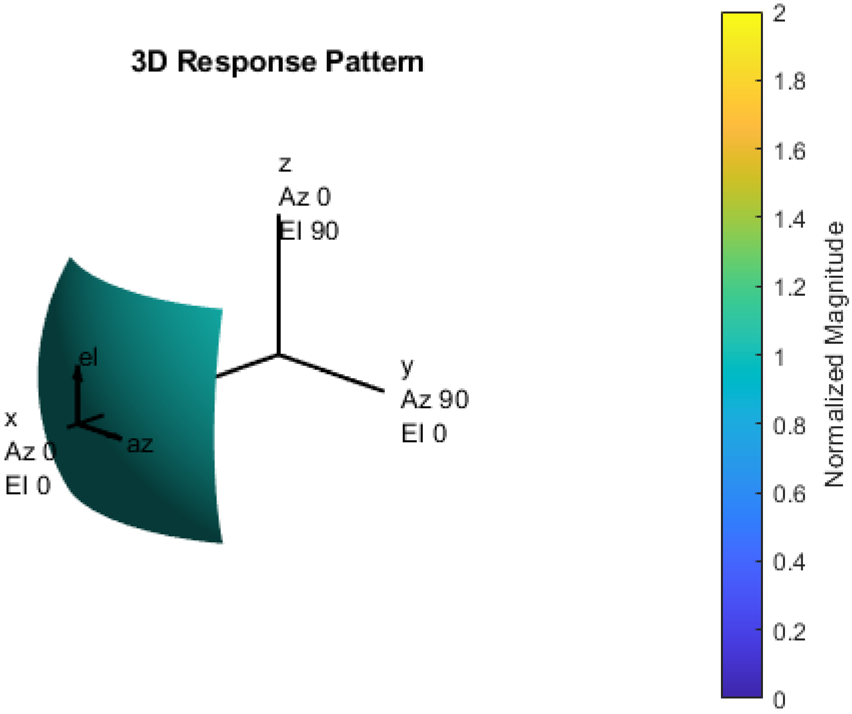
Construct an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz. Then plot the 3-D antenna field pattern.

Construct the antenna element.

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[800e6 1.2e9]);
```

Plot the 3-D magnitude pattern of the antenna at 1 GHz from -30 to 30 degrees in both azimuth and elevation in 0.1 degree increments.

```
fc = 1e9;
pattern(sIso,fc,[-30:0.1:30],[-30:0.1:30],...
    'Type','efield',...
    'CoordinateSystem','polar')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>

## See Also

patternAzimuth | patternElevation

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.IsotropicAntennaElement
**Package:** phased

Plot isotropic antenna element directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

patternAzimuth(sElem,FREQ) plots the 2-D element directivity pattern versus azimuth (in dBi) for the element sElem at zero degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(sElem,FREQ,EL), in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(sElem,FREQ,EL,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

**sElem — Isotropic antenna element**
System object

Isotropic antenna element, specified as a `phased.IsotropicAntennaElement` System object.

Example: `sElem = phased.IsotropicAntennaElement;`

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Azimuth — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

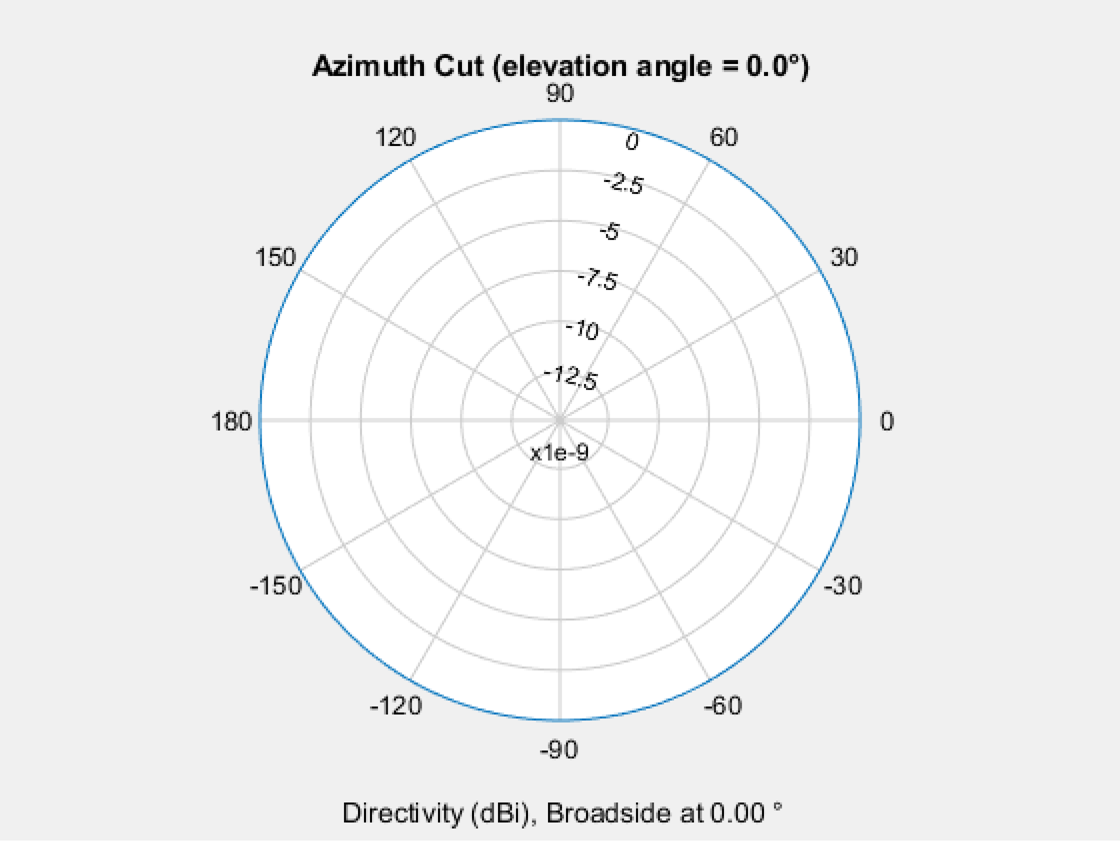
# Examples

### Restricted Azimuth Directivity Pattern of Isotropic Antenna Element

Plot an azimuth cut of the directivity of an isotropic antenna element at 0 and then at 30 degrees elevation. Assume the operating frequency is 500 MHz.

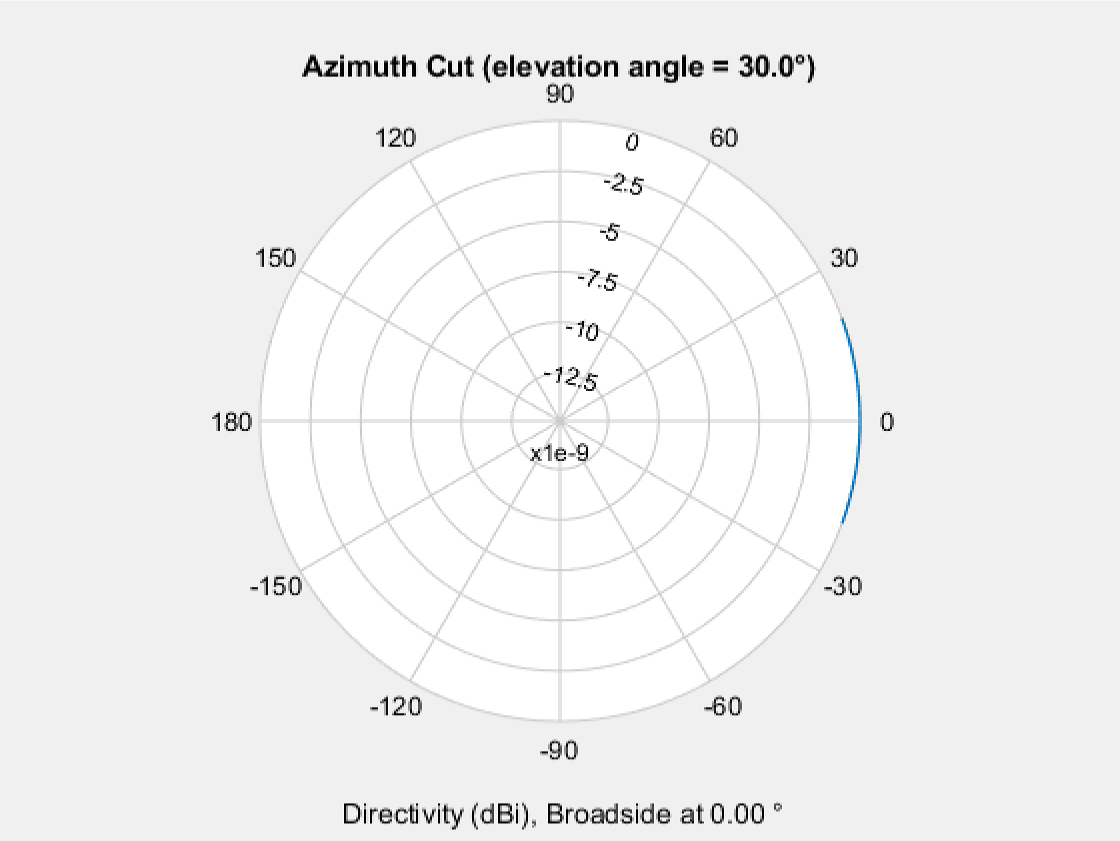
Create the antenna element.

```
fc = 500e6;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
patternAzimuth(sIso,fc,0)
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(sIso,fc,30,'Azimuth',[-20:20])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternElevation`

**Introduced in R2015a**

# patternElevation

**System object:** `phased.IsotropicAntennaElement`
**Package:** `phased`

Plot isotropic antenna element directivity or pattern versus elevation

## Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

## Input Arguments

**`sElem` — Isotropic antenna element**
System object

Isotropic antenna element, specified as a `phased.IsotropicAntennaElement` System object.

Example: `sElem = phased.IsotropicAntennaElement;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Elevation — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

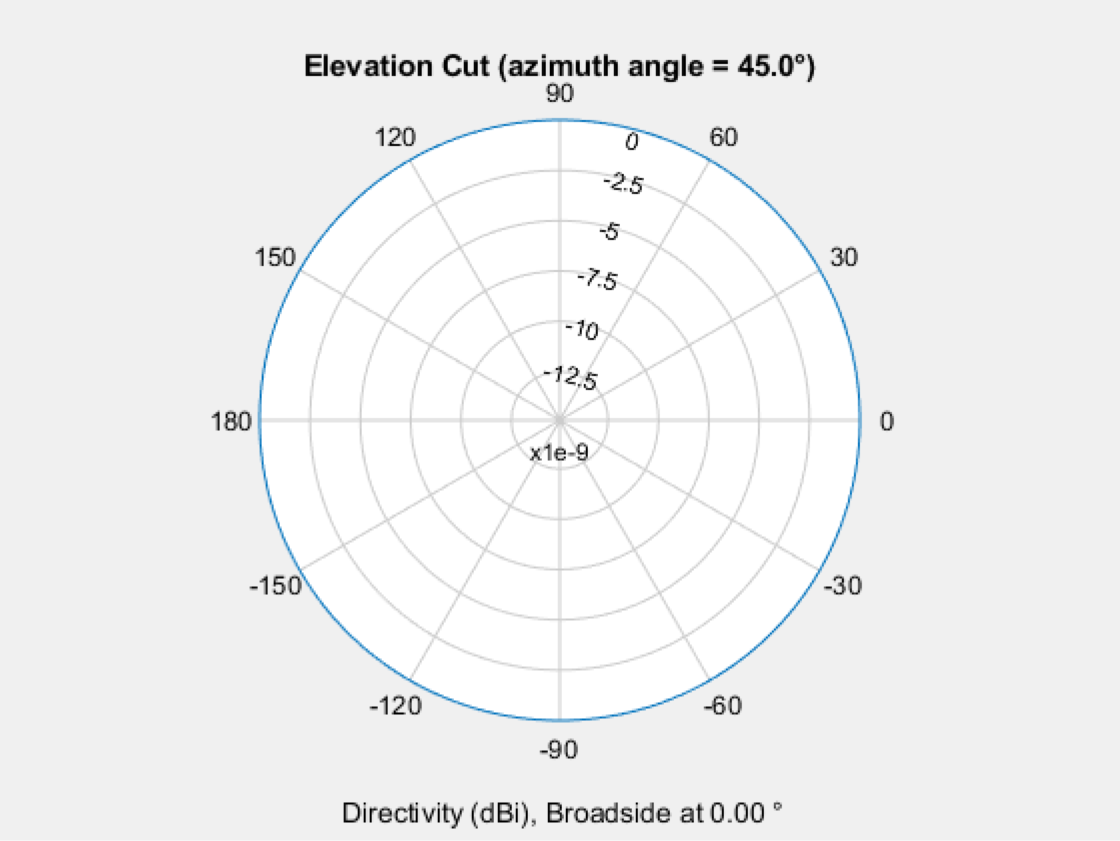
## Examples

### Restricted Elevation Directivity Pattern of Isotropic Antenna Element

Plot an elevation cut of directivity of an isotropic antenna element at 45 degrees azimuth. Assume the operating frequency is 500 MHz.

Create the antenna element.

```
fc = 500e6;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
patternElevation(sIso,fc,45)
```



Plot a reduced range of elevation angles using the `Elevation` parameter.

```
patternElevation(sIso,fc,45,'Elevation',[-20:20])
```

# plotResponse

**System object:** `phased.IsotropicAntennaElement`
**Package:** `phased`

Plot response pattern of antenna

## Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

### H

Element System object

### FREQ

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CutAngle`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

### `Format`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

### `NormalizeResponse`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### `OverlayFreq`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the antenna response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| db | power pattern in dB scale |
| mag | field pattern |
| pow | power pattern |
| dbi | directivity |

**Default:** 'db'

**AzimuthAngles**

Azimuth angles for plotting element response, specified as a row vector. The AzimuthAngles parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'Az' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the AzimuthAngles and ElevationAngles parameters simultaneously.

**Default:** [-180:180]

**ElevationAngles**

Elevation angles for plotting element response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

**UGrid**

*U* coordinate values for plotting element response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

**VGrid**

*V* coordinate values for plotting element response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid

should be between –1 and 1 and should be specified in nondecreasing order. You can set the VGrid and UGrid parameters simultaneously.

**Default:** [-1:0.01:1]

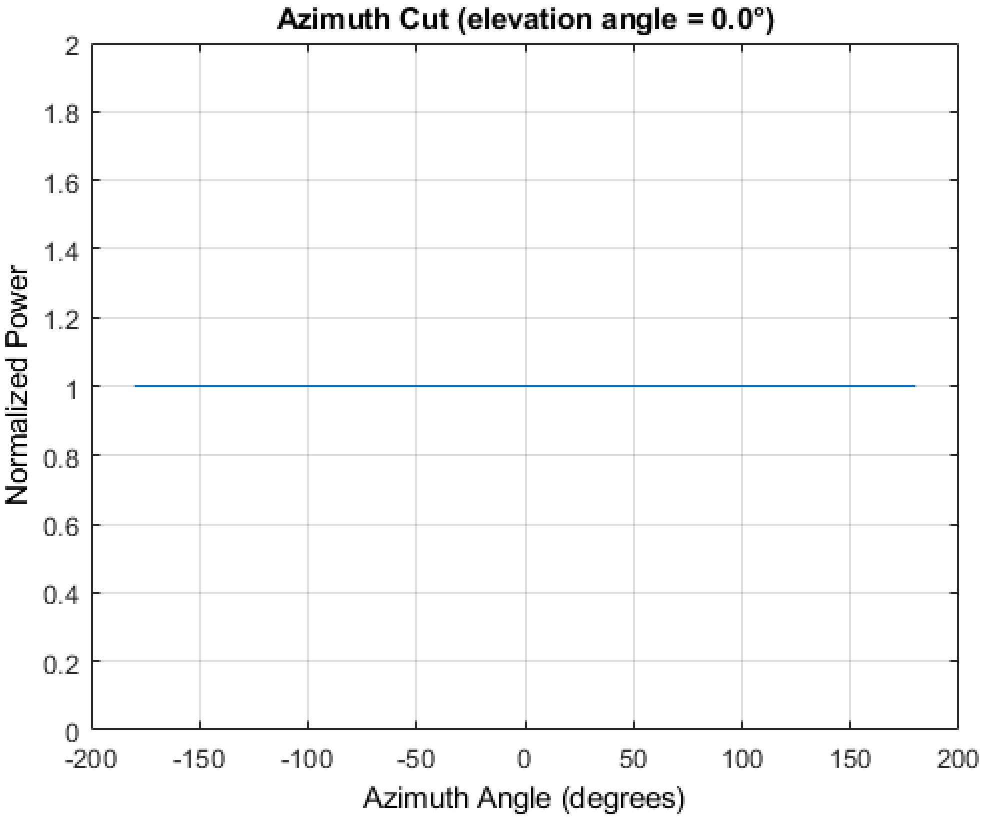
## Examples

### Plot Response and Directivity of Isotropic Antenna

This example shows how to plot the response and the directivity of an isotropic antenna element.

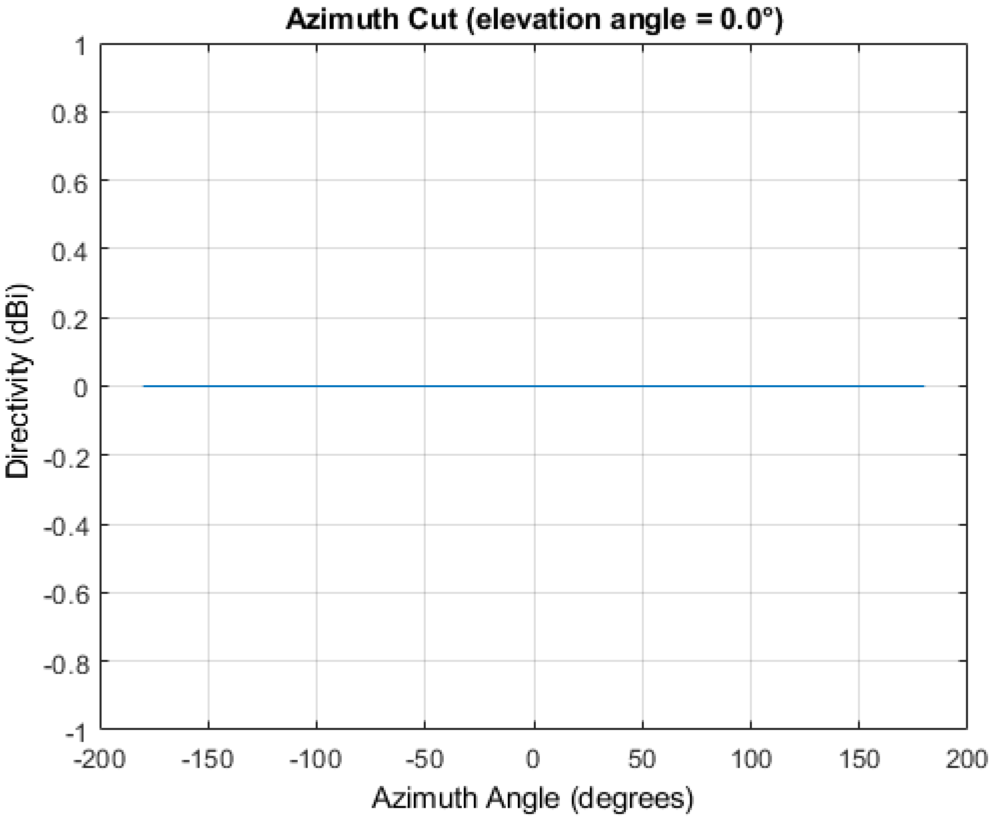
Draw a line plot of an azimuth cut of the response of an isotropic antenna along 0 degrees elevation. Assume the operating frequency is 1 GHz.

```
sIso = phased.IsotropicAntennaElement;
plotResponse(sIso,1e9,'Unit','pow');
```



Draw an azimuth cut of the antenna directivity.

```
plotResponse(sIso,1e9,'Unit','dbi');
```



### Plot Elevation-Cut of Isotropic Antenna Response

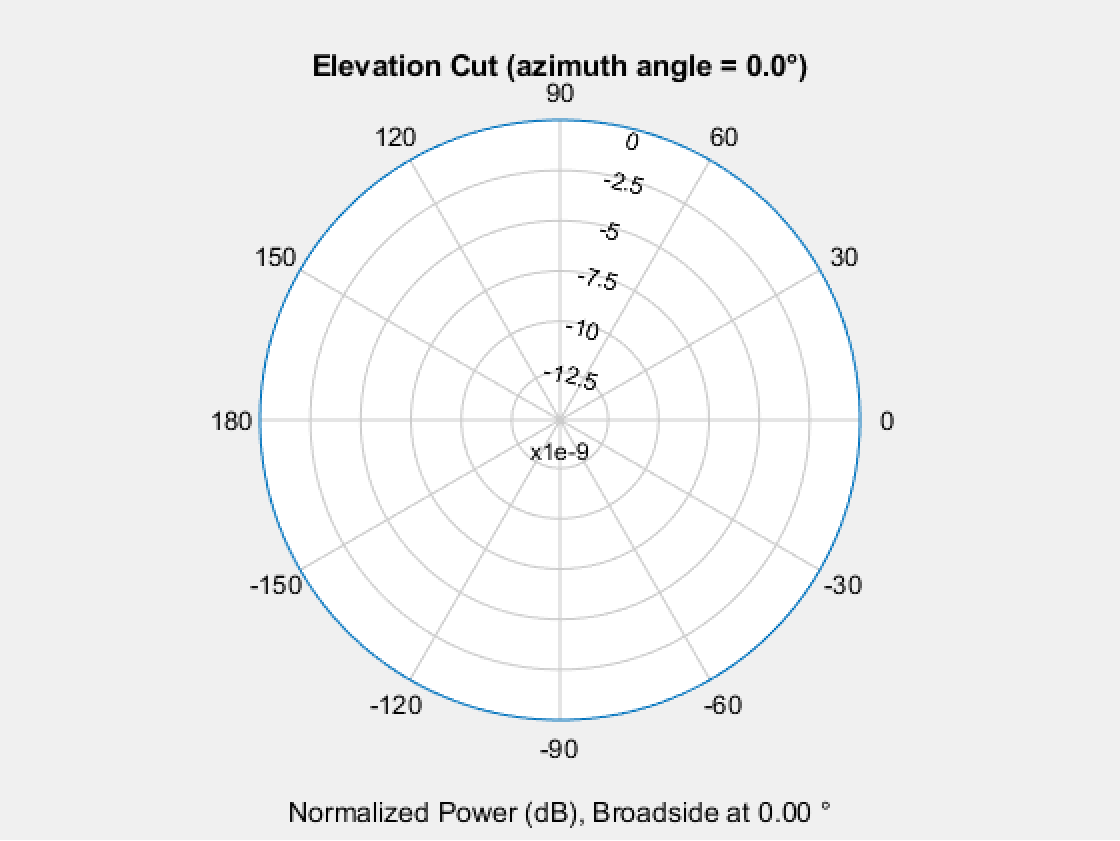
Construct an isotropic antenna operating in the frequency range from 800 MHz to 1.2 GHz. Find the response of the antenna at boresight at 1 GHz.

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
resp = step(sIso,fc,[0;0])
```

```
resp = 1
```

Plot the polar-form of the elevation response of the antenna.

```
plotResponse(sIso,fc,'RespCut','El','Format','Polar');
```



### Plot 3-D Response

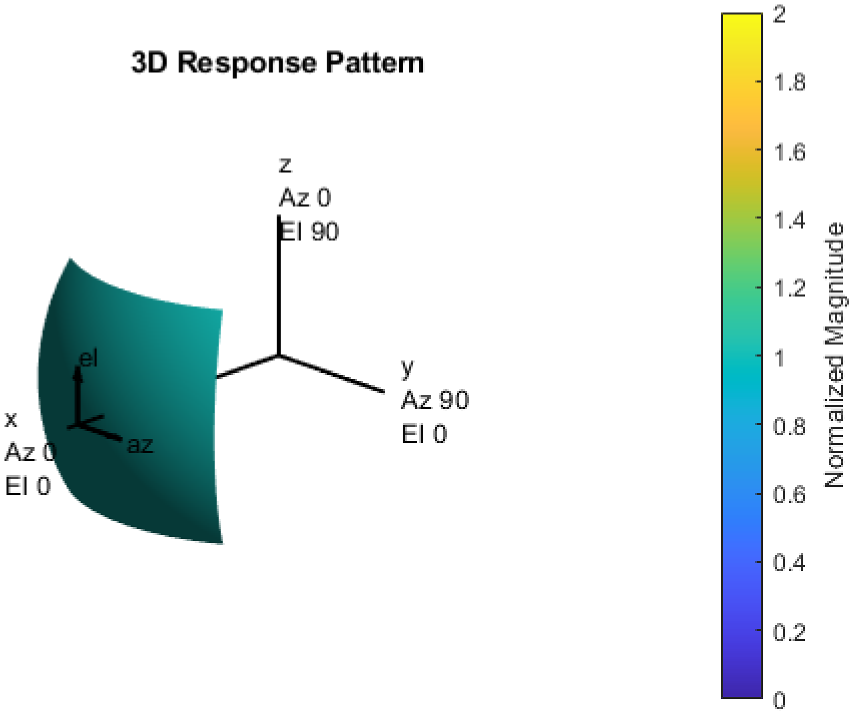
This example shows how to construct an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz and how to plot its response.

Construct the antenna element.

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[0.8e9 1.2e9]);
```

Plot the 3-D response of the antenna at 1 GHz from -30 to 30 degrees in both azimuth and elevation at 0.1 degree increments.

```
fc = 1e9;
plotResponse(sIso,fc,'RespCut','3D','Format','Polar',...
    'Unit','mag','AzimuthAngles',[-30:.1:30],...
    'ElevationAngles',[-30:.1:30]);
```



## See Also

# step

**System object:** `phased.IsotropicAntennaElement`
**Package:** `phased`

Output response of antenna element

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna's voltage response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`H`**

Antenna element object.

### FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

### ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction’s azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

## Output Arguments

### RESP

Voltage response of antenna element specified as an *M*-by-*L*, complex-valued matrix. In this matrix, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.

## Examples

### Plot Isotropic Antenna Element Response

Create an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz. The operating frequency is 1 GHz. Find the response of the antenna at boresight. Then, plot the polar-pattern elevation response of the antenna.

```
antenna = phased.IsotropicAntennaElement( ...
    'FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
```

Obtain the response at boresight.

```
resp = antenna(fc,[0;0])
```

```
resp = 1
```

Plot the response pattern.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb','Normalize',true)
```

phitheta2azel | uv2azel

# phased.IsotropicHydrophone

**Package:** phased

Isotropic hydrophone

## Description

The phased.IsotropicHydrophone System object creates an isotropic hydrophone for sonar applications. An isotropic hydrophone has the same response in all signal directions. The response is the output voltage of the hydrophone per unit sound pressure. The response of a hydrophone is also called its sensitivity. You can specify the response using the VoltageSensitivity property.

To compute the response of a hydrophone for specified directions:

1. Define and set up an isotropic hydrophone System object. See "Construction" on page 1-1132.
2. Call step to compute the response according to the properties of phased.IsotropicHydrophone.

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

hydrophone = phased.IsotropicHydrophone creates an isotropic hydrophone System object, hydrophone.

hydrophone = phased.IsotropicHydrophone(Name,Value) creates an isotropic hydrophone System object, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### FrequencyRange — Operating frequency range of hydrophone

`[0 100e6]` (default) | real-valued 1-by-2 vector

Operating frequency range of hydrophone, specified as a real-valued 1-by-2 row vector of the form `[LowerBound HigherBound]`. This property defines the frequency range over which the hydrophone has a response. The hydrophone element has zero response outside this frequency range. Units are in Hz.

Example: `[0 1000]`

Data Types: `double`

### VoltageSensitivity — Voltage sensitivity of hydrophone

`-120` (default) | scalar | real-valued 1-by-*K* row vector

Voltage sensitivity of hydrophone, specified as a scalar or real-valued 1-by-*K* row vector. When you specify the voltage sensitivity as a scalar, that value applies to the entire frequency range specified by `FrequencyRange`. When you specify the voltage sensitivity as a vector, the frequency range is divided into K-1 equal intervals. The sensitivity values are assigned to the interval end points. The `step` method interpolates the voltage sensitivity for any frequency inside the frequency range. Units are in dB//1V/µPa. See “Hydrophone Sensitivity” on page 1-1137 for more details.

Example: `10`

Data Types: `double`

### BackBaffled — Backbaffle hydrophone element

`false` (default) | `true`

Backbaffle hydrophone element, specified as `false` or `true`. Set this property to `true` to backbaffle the hydrophone. When the hydrophone is backbaffled, the hydrophone response for all azimuth angles beyond ±90° from broadside are zero. Broadside is defined as 0° azimuth and 0° elevation.

When the value of this property is `false`, the hydrophone is not backbaffled.

## Methods

| | |
|---|---|
| directivity | Directivity of isotropic hydrophone |
| isPolarizationCapable | Polarization capability |
| pattern | Plot isotropic hydrophone directivity and patterns |
| patternAzimuth | Plot isotropic hydrophone directivity and response patterns versus azimuth |
| patternElevation | Plot isotropic hydrophone directivity and response patterns versus elevation |
| step | Voltage sensitivity of isotropic hydrophone |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Single Frequency Response and Pattern of Isotropic Hydrophone

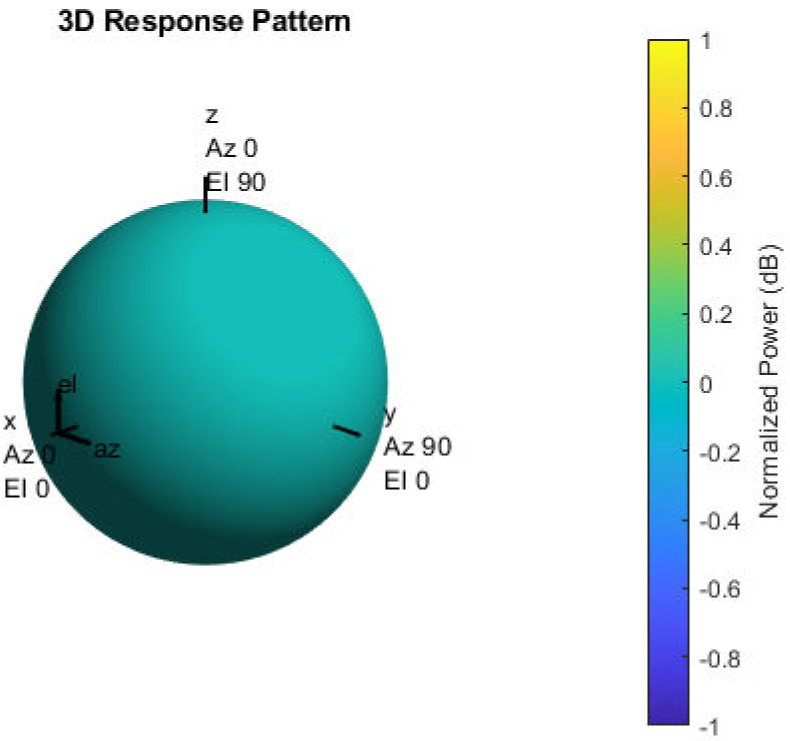
Examine the response and patterns of an isotropic hydrophone operating between 1 kHz and 10 kHz.

Set up the hydrophone parameters. Obtain the voltage sensitivity at five different elevation angles: -30�, -15�, 0�, 15� and 30�. All elevation angles are at 0&deg;. The sensitivities are computed at the signal frequency of 2 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3);
fc = 2e3;
resp = hydrophone(fc,[0 0 0 0 0;-30 -15 0 15 30]);
```

Draw a 3-D plot of the voltage sensitivity.

```
pattern(hydrophone,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb')
```



### Response and Pattern of Isotropic Hydrophone at Multiple Frequencies

Examine the response and patterns of an isotropic hydrophone at three different frequencies. The hydrophone operates between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

Set up the hydrophone parameters and obtain the voltage sensitivity at 45° azimuth and 30° elevation. Compute the sensitivities at the signal frequencies of 2, 5, and 7 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3, ...
    'VoltageSensitivity',[-100 -90 -100]);
```

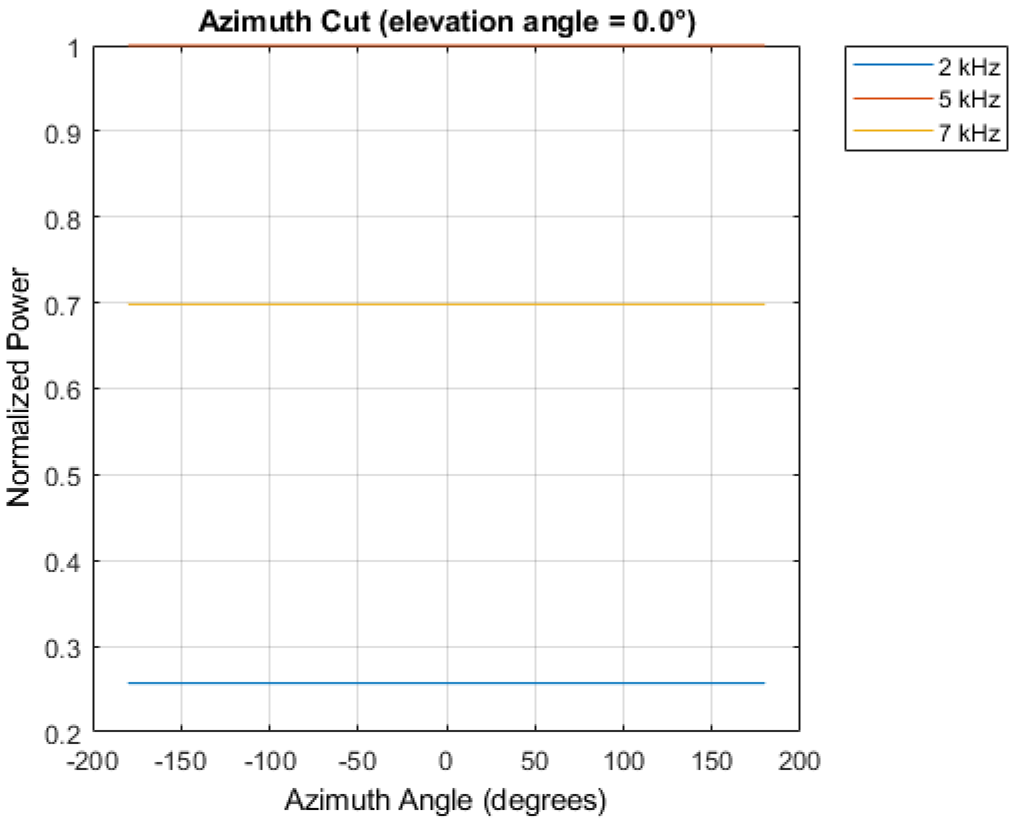
```
fc = [2e3 5e3 7e3];
resp = hydrophone(fc,[45;30])
```

```
resp = 1×3

   14.8051   29.2202   24.4152
```

Draw a 2-D plot of the voltage sensitivity as a function of azimuth.

```
pattern(hydrophone,fc,[-180:180],0,'CoordinateSystem','rectangular',...
    'Type','power')
```



# More About

## Hydrophone Sensitivity

Hydrophone sensitivity measures the response of a hydrophone to input sound pressure.

Hydrophone voltage sensitivity is the open circuit voltage (OCV) at the output of a hydrophone for a given input sound intensity. Another term for hydrophone sensitivity is open circuit receiving response (OCRR). Specifically, OCRR is the voltage generated by a hydrophone per µPa of sound intensity. OCRR is generally a function of frequency. If the sound intensity level (SIL) is expressed in dB//µPa and the output voltage is expressed in dB//1V, then OCRR is expressed in dB//1V/µPa. The output voltage of a hydrophone is related to the input sound level by

$$VdB = SIL + OCRR.$$

Consider a hydrophone that has OCRR = –160 dB//1V/µPa at 10 kHz. Assume that the SIL at the hydrophone due to a nearby ship is 120 dB//µPa. Then, the output voltage of the hydrophone is

$$VdB = SIL + OCRR = 120 \text{ dB} + (-160) \text{ dB} = -40 \text{ dB//1V}.$$

In linear units,

$$V = 10^{VdB/10} = 100 \ \mu V.$$

Directivity of isotropic hydrophone

## Syntax

```
D = directivity(hydrophone,FREQ,ANGLE)
```

## Description

`D = directivity(hydrophone,FREQ,ANGLE)` returns the “Directivity” on page 1-1142 of the isotropic hydrophone, `hydrophone`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

## Input Arguments

### `hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

### `D` — Directivity

*M*-by-*L* matrix

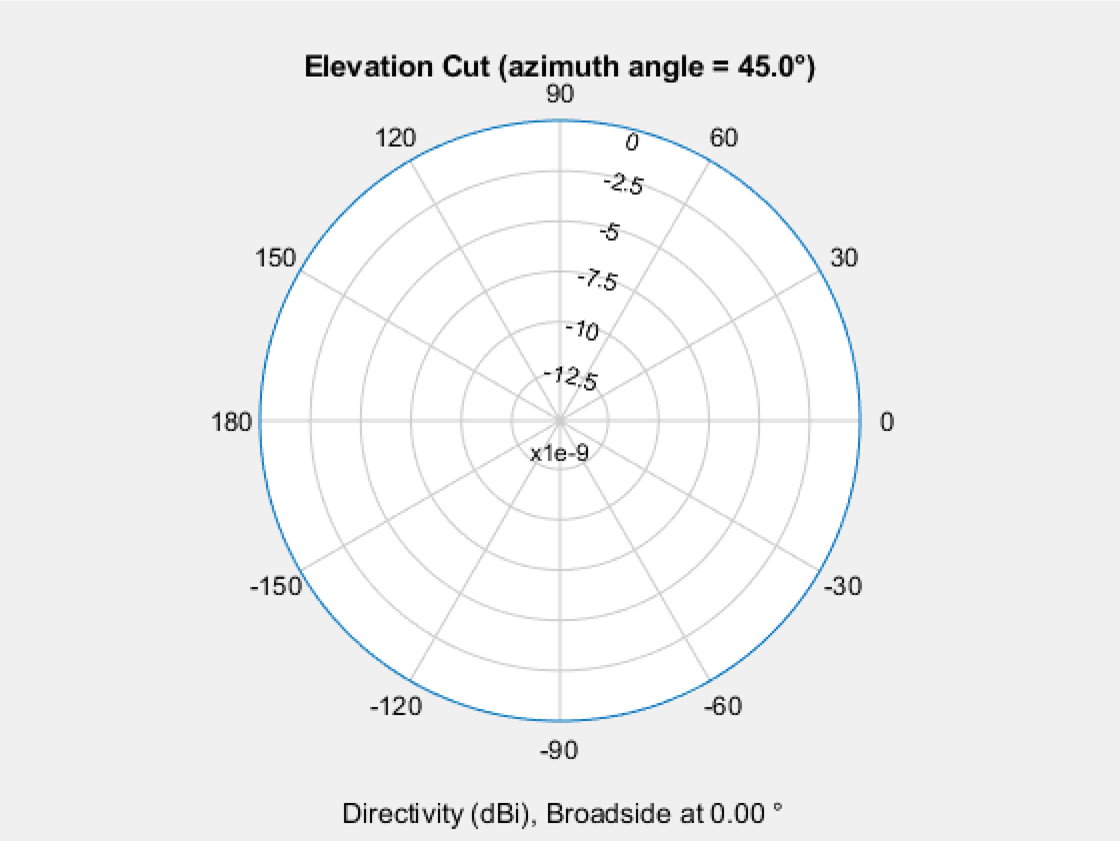
Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Isotropic Hydrophone

Compute the directivity of an isotropic hydrophone in different directions. Assume the signal frequency is 3 kHz. First, set up the hydrophone parameters.

```
fc = 3e3;
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1,10]*1e3, ...
    'VoltageSensitivity',[-100,-90,-100]);
patternElevation(hydrophone,fc,45)
```



First, select the angles of interest to be constant elevation angle at zero degrees. The five azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation).

```
ang = [-20,-10,0,10,20; 0,0,0,0,0];
```

Compute the directivity along the constant elevation cut.

```
d = directivity(hydrophone,fc,ang)
```

```
d = 5×1

     0
     0
     0
     0
     0
```

The directivity of an isotropic hydrophone is zero in every direction.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2017a**

# isPolarizationCapable

**System object:** `phased.IsotropicHydrophone`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(hydrophone)
```

## Description

`flag = isPolarizationCapable(hydrophone)` returns a Boolean value, `flag`, indicating whether the `phased.IsotropicHydrophone` supports polarization. An element supports polarization if it can create or respond to polarized fields. This hydrophone does not support polarization.

## Input Arguments

### `hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

## Output Arguments

### `flag` — Polarization-capability flag

`true` | `false`

Polarization-capability returned as a Boolean value `true` if the hydrophone supports polarization or `false` if it does not. Because the `phased.IsotropicHydrophone` object does not support polarization, `flag` is always returned as `false`.

**Introduced in R2017a**

# pattern

**System object:** `phased.IsotropicHydrophone`
**Package:** `phased`

Plot isotropic hydrophone directivity and patterns

## Syntax

```
pattern(hydrophone,FREQ)
pattern(hydrophone,FREQ,AZ)
pattern(hydrophone,FREQ,AZ,EL)
pattern(___,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern(___)
```

## Description

`pattern(hydrophone,FREQ)` plots the 3D directivity pattern (in dBi) for the hydrophone, `hydrophone`. The operating frequency is specified in `FREQ`.

`pattern(hydrophone,FREQ,AZ)` plots the directivity pattern at the specified azimuth angle.

`pattern(hydrophone,FREQ,AZ,EL)` plots the directivity pattern at specified azimuth and elevation angles.

`pattern(___,Name,Value)` plots the directivity pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern(___)` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

## Input Arguments

**hydrophone — Isotropic hydrophone**
phased.IsotropicHydrophone System object

Isotropic hydrophone, specified as a phased.IsotropicHydrophone System object.

Example: phased.IsotropicHydrophone

**FREQ — Frequency for computing directivity and patterns**
positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

**AZ — Azimuth angles**
[-180:180] (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: [-45:2:45]

Data Types: double

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.

- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the sensors are polarization-capable and when the 'Type' parameter is not set to 'directivity'. This table shows the meaning of the display options.

| 'Polarization' | Display |
|---|---|
| 'combined' | Combined *H* and *V* polarization components |
| 'H' | *H* polarization component |

| 'Polarization' | Display |
|---|---|
| 'V' | *V* polarization component |

Example: 'V'

Data Types: char

## Output Arguments

**PAT — Element pattern**
*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

### Single Frequency Response and Pattern of Isotropic Hydrophone

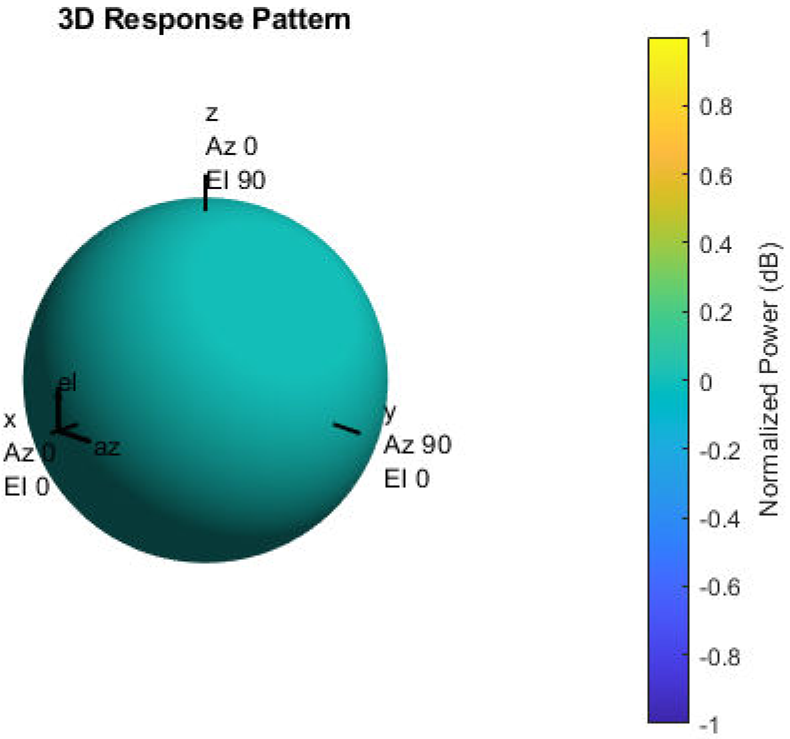
Examine the response and patterns of an isotropic hydrophone operating between 1 kHz and 10 kHz.

Set up the hydrophone parameters. Obtain the voltage sensitivity at five different elevation angles: -30�, -15�, 0�, 15� and 30�. All elevation angles are at 0&deg;. The sensitivities are computed at the signal frequency of 2 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3);
fc = 2e3;
resp = hydrophone(fc,[0 0 0 0 0;-30 -15 0 15 30]);
```

Draw a 3-D plot of the voltage sensitivity.

```
pattern(hydrophone,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb')
```



### Response and Pattern of Isotropic Hydrophone at Multiple Frequencies

Examine the response and patterns of an isotropic hydrophone at three different frequencies. The hydrophone operates between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

Set up the hydrophone parameters and obtain the voltage sensitivity at 45° azimuth and 30° elevation. Compute the sensitivities at the signal frequencies of 2, 5, and 7 kHz.

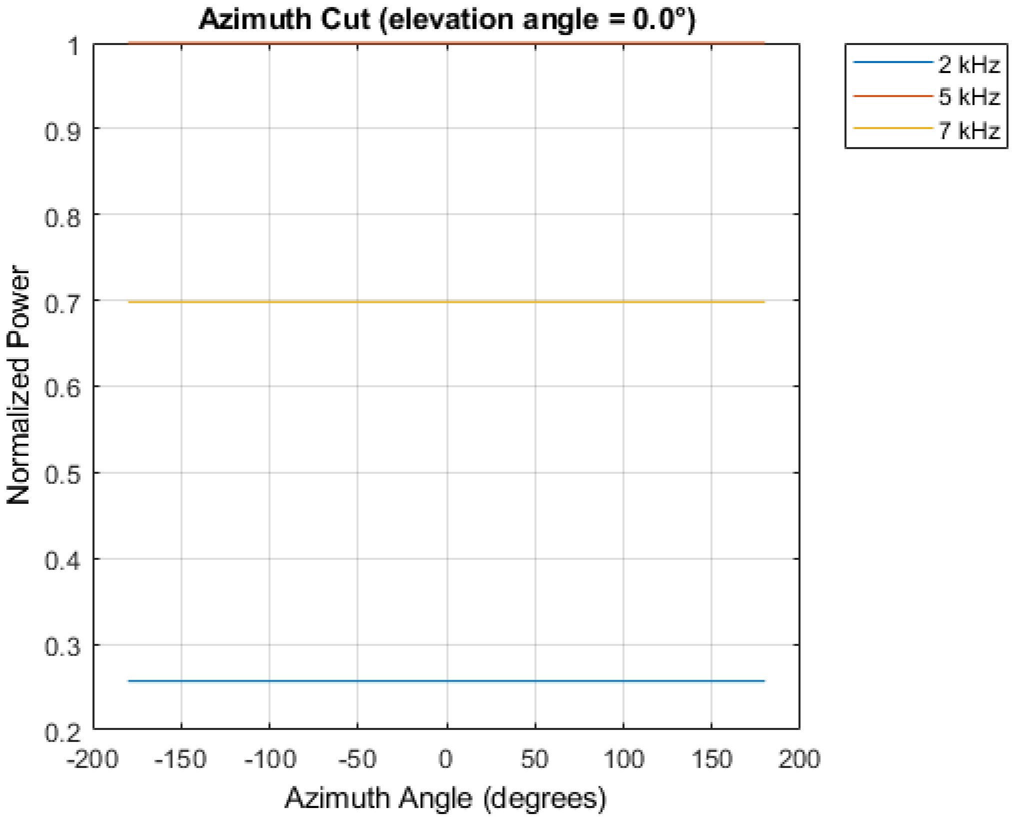
```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3, ...
    'VoltageSensitivity',[-100 -90 -100]);
fc = [2e3 5e3 7e3];
resp = hydrophone(fc,[45;30])
```

```
resp = 1×3

   14.8051   29.2202   24.4152
```

Draw a 2-D plot of the voltage sensitivity as a function of azimuth.

```
pattern(hydrophone,fc,[-180:180],0,'CoordinateSystem','rectangular',...
    'Type','power')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Plot isotropic hydrophone directivity and response patterns versus azimuth

## Syntax

```
patternAzimuth(hydrophone,FREQ)
patternAzimuth(hydrophone,FREQ,EL)
patternAzimuth(hydrophone,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

patternAzimuth(hydrophone,FREQ) plots the 2-D element directivity pattern versus azimuth (in dBi) for the element hydrophone at zero degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(hydrophone,FREQ,EL), in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(hydrophone,FREQ,EL,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

**hydrophone — Isotropic hydrophone**
phased.IsotropicHydrophone System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Azimuth — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

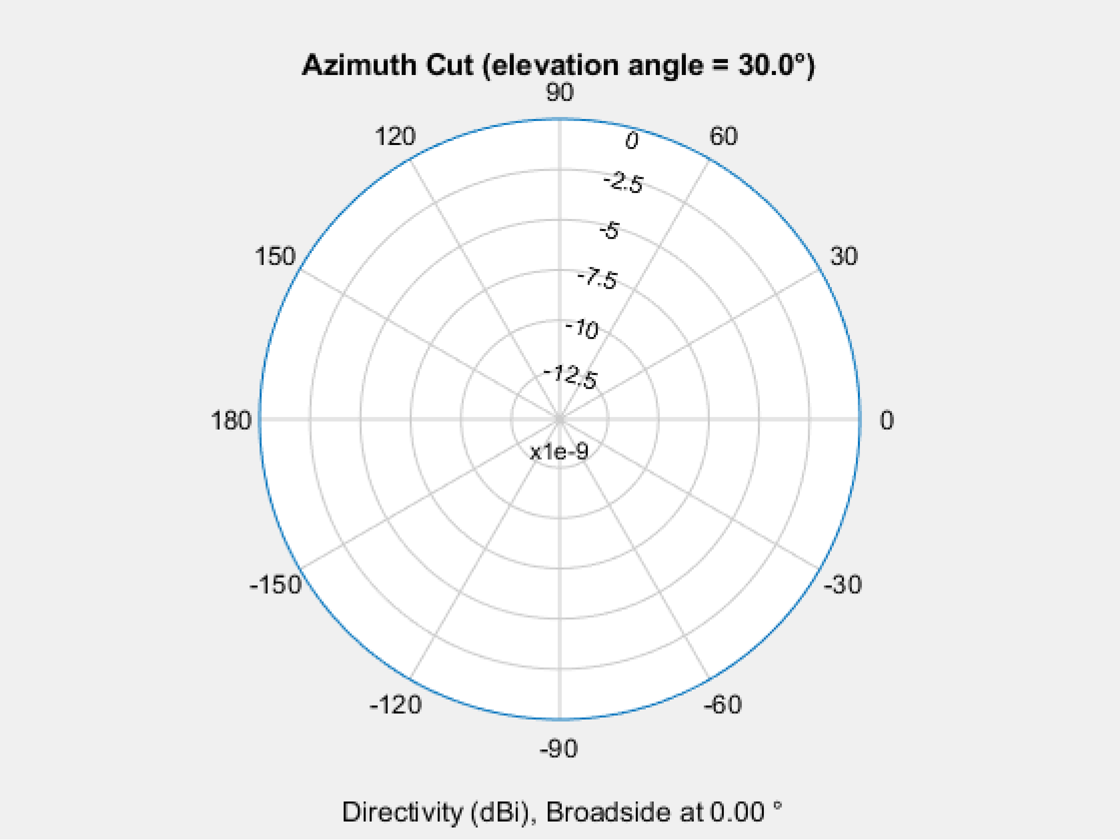
## Examples

### Azimuth Pattern of Isotropic Hydrophone

Examine the azimuth pattern of an isotropic hydrophone at 30° elevation. The frequency range is between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

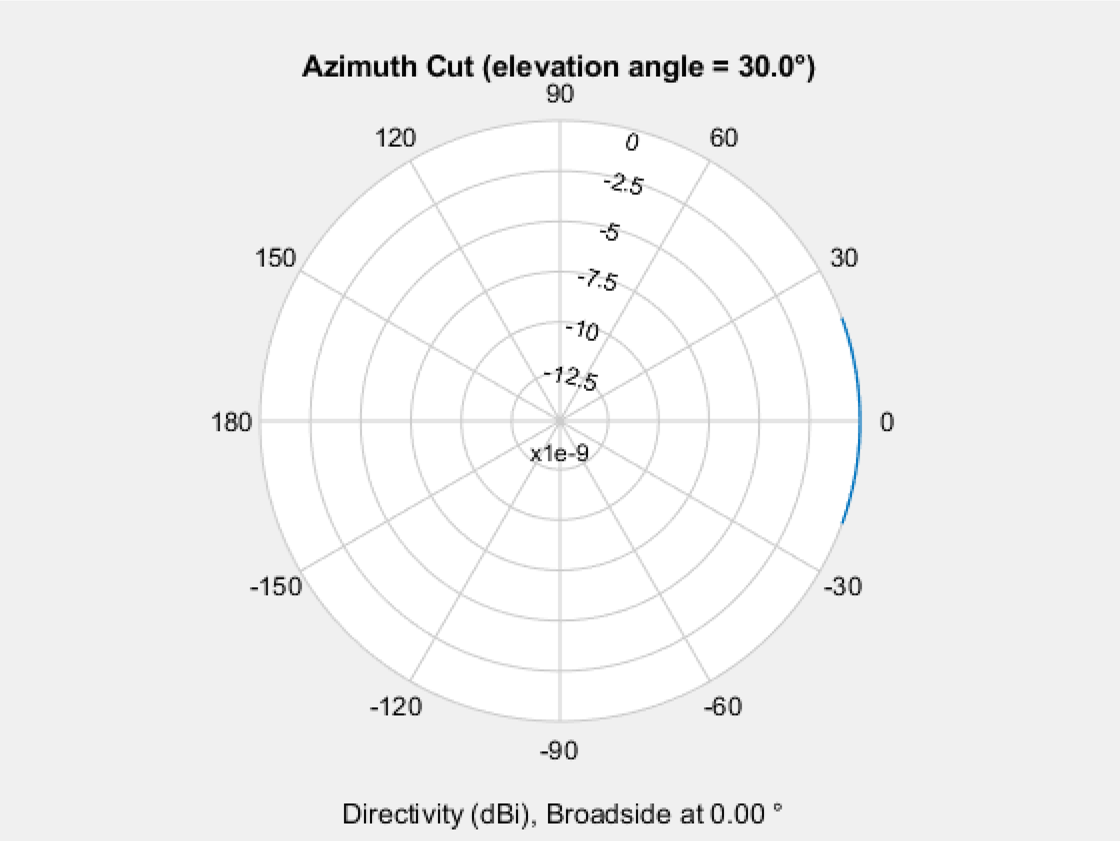
First, set up the hydrophone parameters.

```
fc = 3e3;
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1,10]*1e3, ...
    'VoltageSensitivity',[-100,-90,-100]);
patternAzimuth(hydrophone,fc,30)
```



Plot a smaller range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(hydrophone,fc,30,'Azimuth',[-20:20])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Plot isotropic hydrophone directivity and response patterns versus elevation

## Syntax

```
patternElevation(hydrophone,FREQ)
patternElevation(hydrophone,FREQ,AZ)
patternElevation(hydrophone,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(hydrophone,FREQ) plots the 2-D element directivity pattern versus elevation (in dBi) for the element hydrophone at zero degrees azimuth angle. The argument FREQ specifies the operating frequency.

patternElevation(hydrophone,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(hydrophone,FREQ,AZ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**hydrophone — Isotropic hydrophone**
phased.IsotropicHydrophone System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

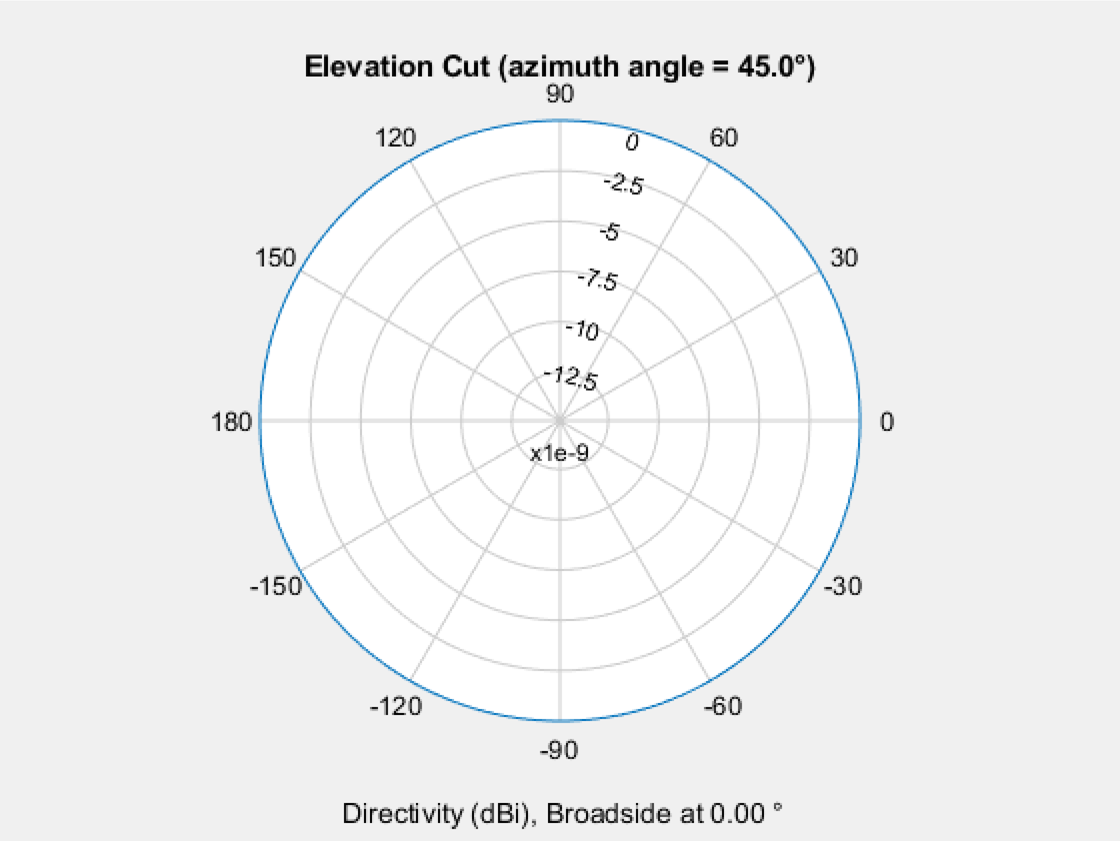
Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

# Examples

### Elevation Pattern of Isotropic Hydrophone

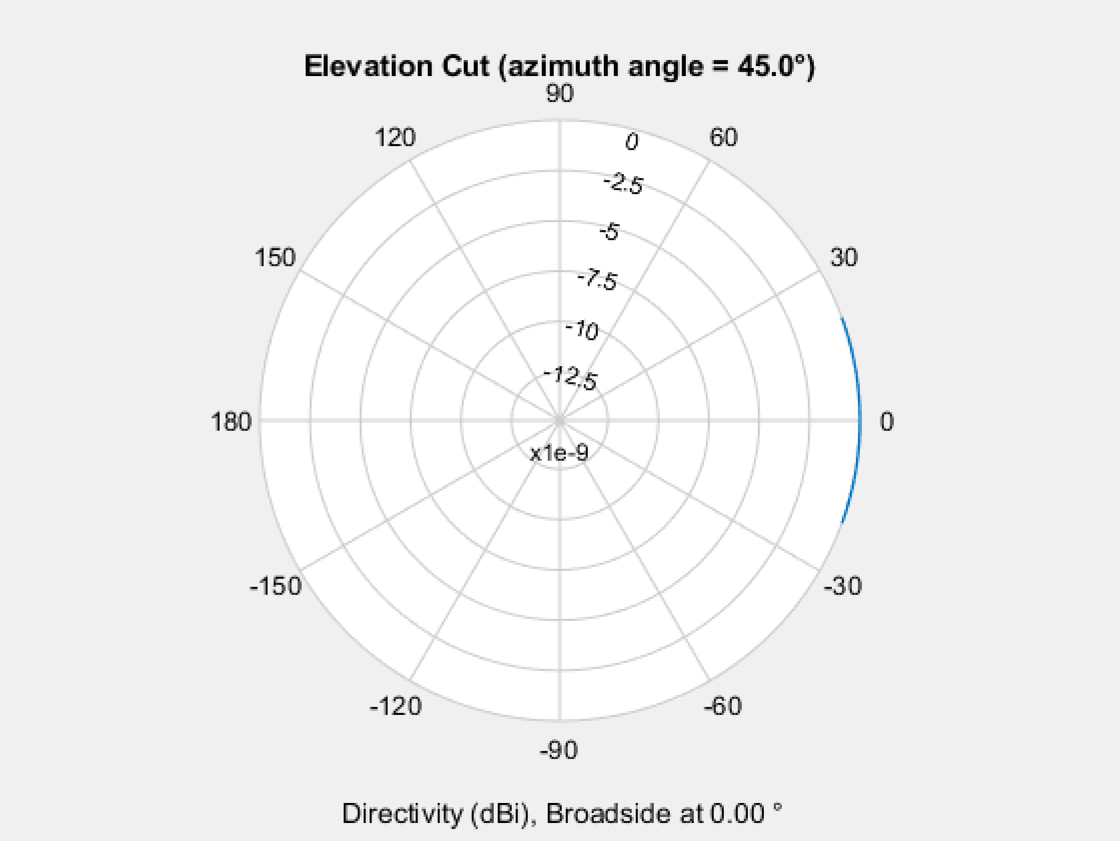
Plot an elevation cut of directivity of an isotropic hydrophone at 45° azimuth. Assume the signal frequency is 3 kHz. First, set up the hydrophone parameters.

```
fc = 3e3;
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1,10]*1e3, ...
    'VoltageSensitivity',[-100,-90,-100]);
patternElevation(hydrophone,fc,45)
```



Plot a smaller range of elevation angles using the `Elevation` parameter.

```
patternElevation(hydrophone,fc,45,'Elevation',-20:20)
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified

direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta, \varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternAzimuth`

**Introduced in R2017a**

# step

**System object:** `phased.IsotropicHydrophone`
**Package:** `phased`

Voltage sensitivity of isotropic hydrophone

## Syntax

```
resp = step(hydrophone,freq,ang)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`resp = step(hydrophone,freq,ang)` returns the voltage sensitivity for the hydrophone at the specified operating frequencies and in the specified directions of arriving signals.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### hydrophone — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

#### `freq` — Voltage sensitivity frequencies

positive real scalar | real-valued 1-by-*L* vector of positive values

Voltage sensitivity frequencies of hydrophone, specified as a positive real scalar or a real-valued 1-by-*L* vector of positive values. Units are in Hz.

Data Types: `double`

#### `ang` — Direction of arriving signals

real-valued 1-by-*M* row vector | real-valued 2-by-*M* matrix

Direction of arriving signals, specified as a real-valued 1-by-*M* row vector or 2-by-*M* matrix. When `ang` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth;elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

When `ang` is a 1-by-*M* row vector, each element specifies the azimuth angle of the arriving signal. In this case, the corresponding elevation angle is assumed to be zero.

Data Types: `double`

## Output Arguments

#### `resp` — Voltage sensitivity of hydrophone

Voltage sensitivity of hydrophone, returned as a real-valued *M*-by-*L* matrix. *M* represents the number of angles specified in `ang`, and *L* represents the number of frequencies specified in `freq`. Units are in V/Pa.

## Examples

### Single Frequency Response and Pattern of Isotropic Hydrophone

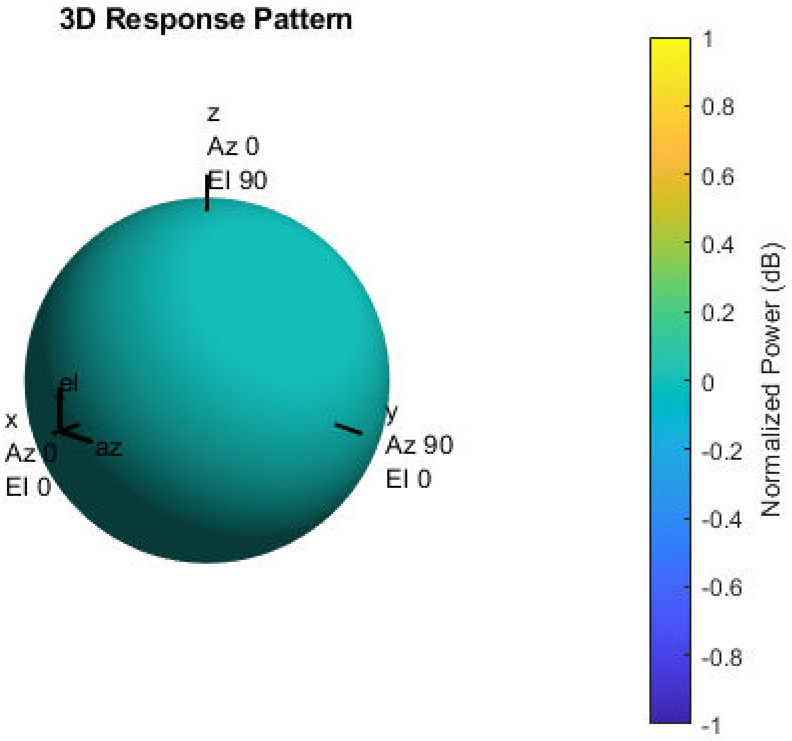
Examine the response and patterns of an isotropic hydrophone operating between 1 kHz and 10 kHz.

Set up the hydrophone parameters. Obtain the voltage sensitivity at five different elevation angles: -30�, -15�, 0�, 15� and 30�. All elevation angles are at 0&deg;. The sensitivities are computed at the signal frequency of 2 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3);
fc = 2e3;
resp = hydrophone(fc,[0 0 0 0 0;-30 -15 0 15 30]);
```

Draw a 3-D plot of the voltage sensitivity.

```
pattern(hydrophone,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb')
```



### Response and Pattern of Isotropic Hydrophone at Multiple Frequencies

Examine the response and patterns of an isotropic hydrophone at three different frequencies. The hydrophone operates between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

Set up the hydrophone parameters and obtain the voltage sensitivity at 45° azimuth and 30° elevation. Compute the sensitivities at the signal frequencies of 2, 5, and 7 kHz.

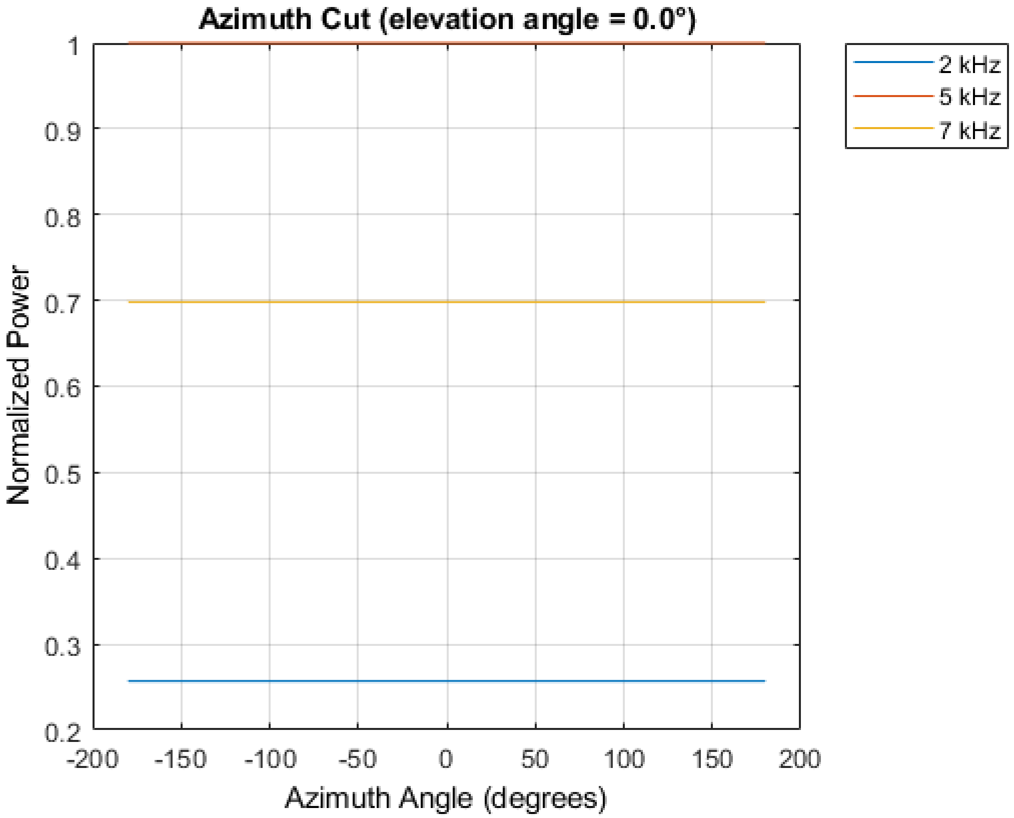
```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3, ...
    'VoltageSensitivity',[-100 -90 -100]);
fc = [2e3 5e3 7e3];
resp = hydrophone(fc,[45;30])
```

```
resp = 1×3

   14.8051   29.2202   24.4152
```

Draw a 2-D plot of the voltage sensitivity as a function of azimuth.

```
pattern(hydrophone,fc,[-180:180],0,'CoordinateSystem','rectangular',...
    'Type','power')
```



## Algorithms

The total sensitivity of a hydrophone is a combination of its frequency sensitivity and spatial sensitivity. `phased.IsotropicHydrophone` calculates both sensitivities using nearest neighbor interpolation, and then multiplies the sensitivities to form the total sensitivity.

# phased.IsotropicProjector

**Package:** phased

Isotropic projector

## Description

The phased.IsotropicProjector System object creates an isotropic sound projector for sonar applications. An isotropic projector has the same response in all directions. The response is the radiated sound intensity per unit input voltage to the projector. You can adjust the response using the VoltageResponse property.

To compute the response of a projector for specified directions:

1. Define and set up an isotropic projector System object. See “Construction” on page 1-1172.
2. Call step to compute the response according to the properties of phased.IsotropicProjector.

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

projector = phased.IsotropicProjector creates an isotropic projector System object, projector.

projector = phased.IsotropicProjector(Name,Value) creates an isotropic projector System object, projector, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### FrequencyRange — Operating frequency range of projector

[0 100e6] (default) | real-valued 1-by-2 vector

Operating frequency range of projector, specified as a 1-by-2 row vector in the form of [LowerBound HigherBound]. The projector defines the nonzero response range over which the hydrophone has a response. The projector has zero response outside this frequency range. Units are Hz.

Example: [0 10e3]

Data Types: double

### VoltageResponse — Voltage response of projector

120 (default) | scalar | real-valued 1-by-*K* row vector

Voltage response of projector, specified as a scalar or real-valued 1-by-*K* row vector. When you specify voltage response as a scalar, that value applies to the entire frequency range specified by FrequencyRange. When you specify the voltage sensitivity as a vector, the frequency range is divided into K-1 equal intervals. The response values are assigned to the interval end points. Then, the step method interpolates the voltage response for any frequency inside the frequency range. Units are in dB ref: 1 µPa/V. See “Projector Voltage Response” on page 1-1177 for more details.

Example: 10

Data Types: double

### BackBaffled — Backbaffle response of projector

false (default) | true

Backbaffle response of projector, specified as false or true. Set this property to true to backbaffle the projector response. When the projector is backbaffled, the projector response for all azimuth angles beyond ±90° from broadside are zero. Broadside is defined as 0° azimuth and 0° elevation.

When the value of this property is false, the projector is not backbaffled.

## Methods

| | |
|---|---|
| directivity | Directivity of isotropic projector |

| patternElevation | Plot isotropic projector directivity and response patterns versus elevation |
| step | Voltage response of isotropic projector |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Response and Pattern of Isotropic Projector at Single Frequency

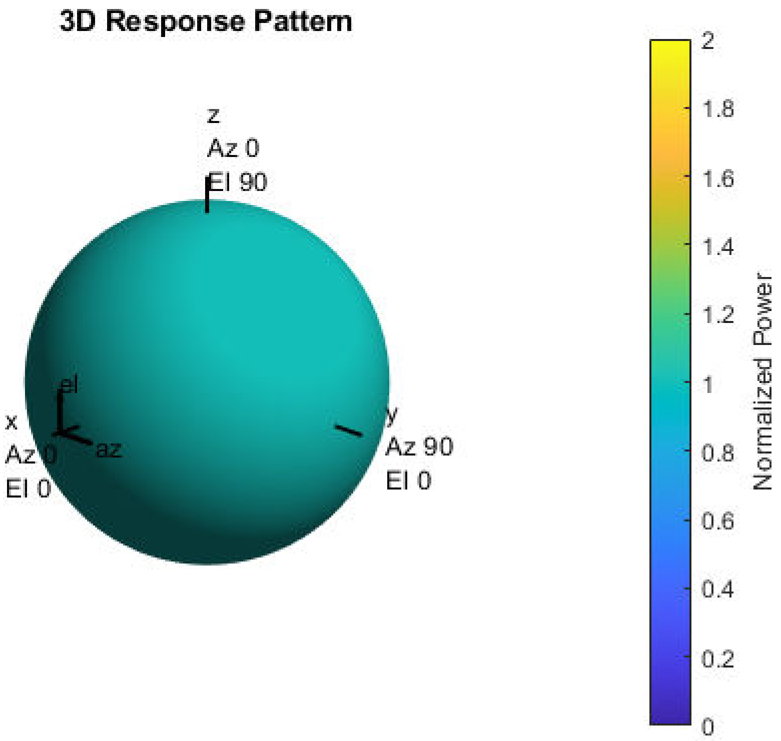
Examine the response and patterns of an isotropic projector operating between 1 kHz and 10 kHz.

Set the projector parameters and obtain the voltage response at five different elevation angles: -30°, -15°, 0°, 15° and 30&deg. All elevation angles at 0° azimuth angle. The voltage response is computed at 2 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3);
fc = 2e3;
resp = projector(fc,[0,0,0,0,0;-30,-15,0,15,30]);
```

Draw a 3-D plot of the voltage response.

```
pattern(projector,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','power')
```



### Response and Pattern of Isotropic Projector at Multiple Frequencies

Examine the response and patterns of an isotropic projector at three different frequencies. The projector operates between 1 kHz and 10 kHz. Specify the voltage response as a vector.

Set up the projector parameters, and obtain the voltage response at 45° azimuth and 30° elevation. Compute the responses at signal frequencies of 2, 5, and 7 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1 10]*1e3, ...
    'VoltageResponse',[90 95 100 95 90]);
```

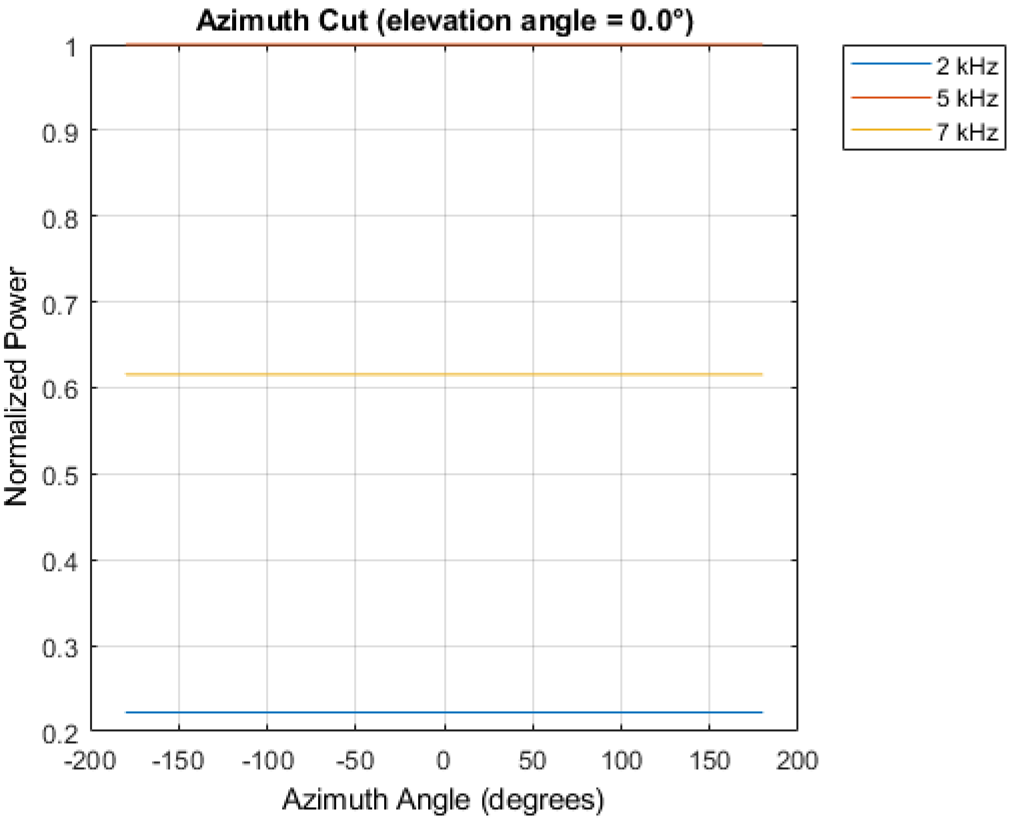
```
fc = [2e3 5e3 7e3];
resp = projector(fc,[45;30]);
resp

resp = 1×3

    0.0426    0.0903    0.0708
```

Next, draw a 2-D plot of the voltage response as a function of azimuth

```
pattern(projector,fc,[-180:180],0,'CoordinateSystem','rectangular', ...
    'Type','power')
```



# More About

## Projector Voltage Response

The voltage response of a projector relates the transmitted sound intensity to the input voltage.

For a sound projector, the transmitting voltage response (TVR) is the sound intensity in µPa per volt, when measured at one meter from the projector. TVR is generally a function of frequency. If the sound intensity level (SIL) is expressed in dB//µPa and the output voltage (VdB) is expressed in dB//1V, then TVR is expressed in dB//µPa/1V. The output sound pressure level of a hydrophone is related to the input voltage level by

$$SIL = TVR + VdB.$$

Consider a projector that has TVR = 160 dB//µPa/1V at 10 kHz. If the projector input voltage is 200 V, then the VdB is 23 dB and the sound intensity level (SIL) at one meter is

$$SIL = TVR + VdB = 160 + 23 = 173 \quad dB//\mu Pa.$$

**Package:** phased

Directivity of isotropic projector

## Syntax

```
D = directivity(projector,FREQ,ANGLE)
```

## Description

D = directivity(projector,FREQ,ANGLE) returns the “Directivity” on page 1-1182 of the isotropic projector, projector, at frequencies specified by FREQ and in the directions specified by ANGLE.

## Input Arguments

### projector — Isotropic projector

phased.IsotropicProjector System object

Isotropic projector, specified as a phased.IsotropicProjector System object.

Example: phased.IsotropicProjector

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

### `D` — Directivity

*M*-by-*L* matrix

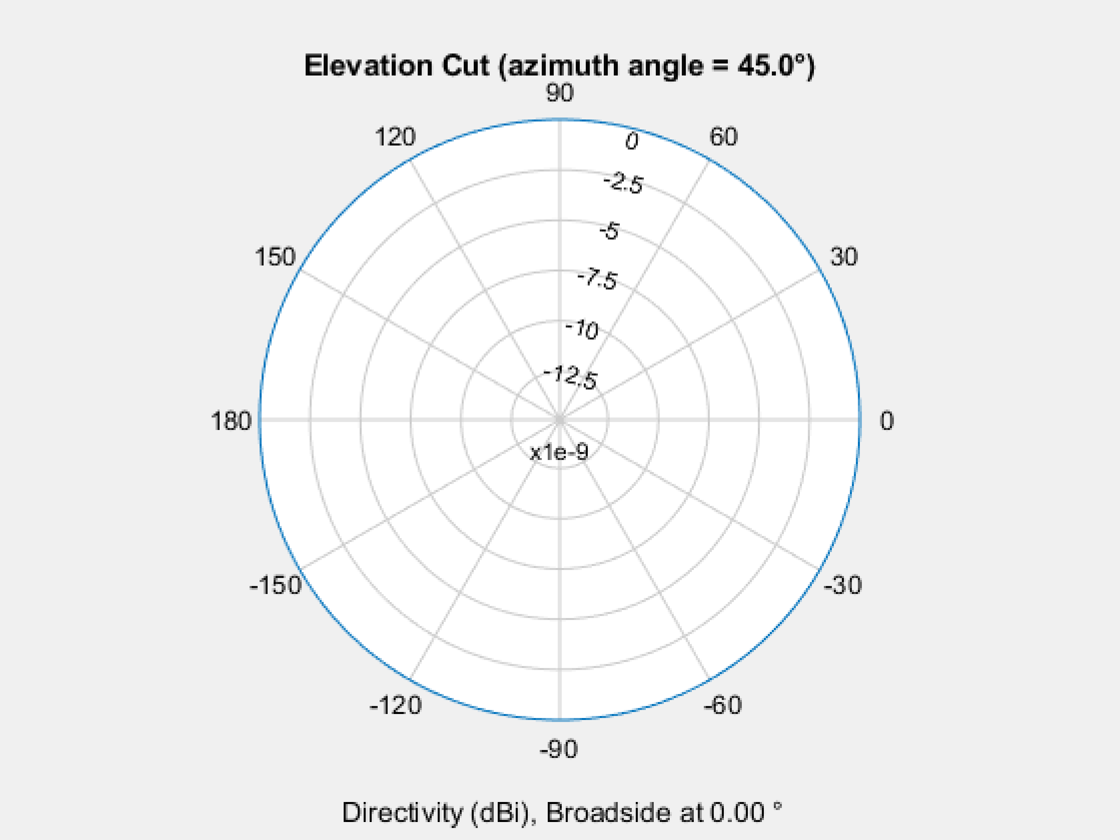
Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Isotropic Projector

Compute the directivity of an isotropic projector in different directions. Assume the signal frequency is 3 kHz. First, set the projector parameters.

```
fc = 3e3;
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3, ...
    'VoltageResponse',[100,110,120,110,100]);
patternElevation(projector,fc,45)
```



Select the angles of interest to be constant elevation angle at zero degrees. The five azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation).

```
ang = [-20,-10,0,10,20; 0,0,0,0,0];
```

Compute the directivity along the constant elevation cut.

```
d = directivity(projector,fc,ang)
```

```
d = 5×1

     0
     0
     0
     0
     0
```

The directivity of an isotropic projector is zero in every direction.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** phased.IsotropicProjector
**Package:** phased

Polarization capability

## Syntax

```
flag = isPolarizationCapable(projector)
```

## Description

`flag = isPolarizationCapable(projector)` returns a Boolean value, `flag`, indicating whether the `phased.IsotropicProjector` supports polarization. An element supports polarization if it can create or respond to polarized fields. This projector does not support polarization.

## Input Arguments

**`projector` — Isotropic projector**
`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

## Output Arguments

**`flag` — Polarization-capability flag**
`true` | `false`

Polarization-capability returned as a Boolean value `true` if the projector supports polarization or `false` if it does not. Because the `phased.IsotropicProjector` object does not support polarization, `flag` is always returned as `false`.

**Introduced in R2017a**

# pattern

**System object:** phased.IsotropicProjector
**Package:** phased

Plot isotropic projector directivity and patterns

## Syntax

```
pattern(projector,FREQ)
pattern(projector,FREQ,AZ)
pattern(projector,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

pattern(projector,FREQ) plots the 3D directivity pattern (in dBi) for the projector specified in projector. The operating frequency is specified in FREQ.

pattern(projector,FREQ,AZ) plots the projector directivity pattern at the specified azimuth angle.

pattern(projector,FREQ,AZ,EL) plots the projector directivity pattern at specified azimuth and elevation angles.

pattern( ___ ,Name,Value) plots the projector pattern with additional options specified by one or more Name,Value pair arguments.

[PAT,AZ_ANG,EL_ANG] = pattern( ___ ) returns the projector pattern in PAT. The AZ_ANG output contains the coordinate values corresponding to the rows of PAT. The EL_ANG output contains the coordinate values corresponding to the columns of PAT. If the 'CoordinateSystem' parameter is set to 'uv', then AZ_ANG contains the *U* coordinates of the pattern and EL_ANG contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

## Input Arguments

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### AZ — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Normalize` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize`' and a Boolean. Set this parameter to `true` to display a normalized pattern. This parameter does not apply when you set `'Type'` to `'directivity'`. Directivity patterns are already normalized.

Data Types: `logical`

### `PlotStyle` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Data Types: `char`

### `Polarization` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| `'Polarization'` | Display |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

## Output Arguments

**PAT — Element pattern**
*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

### Response and Pattern of Isotropic Projector at Single Frequency

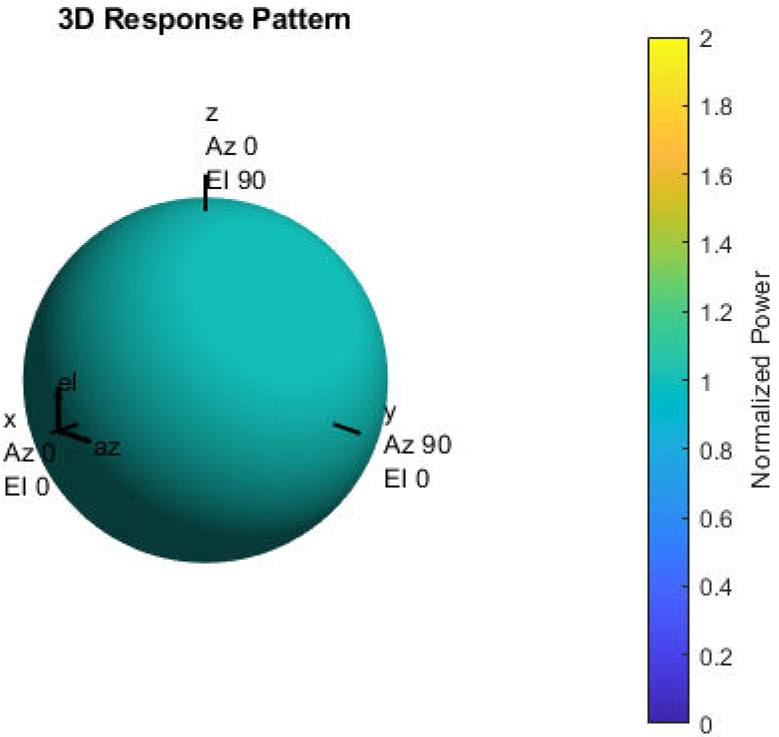
Examine the response and patterns of an isotropic projector operating between 1 kHz and 10 kHz.

Set the projector parameters and obtain the voltage response at five different elevation angles: -30°, -15°, 0°, 15° and 30&deg. All elevation angles at 0° azimuth angle. The voltage response is computed at 2 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3);
fc = 2e3;
resp = projector(fc,[0,0,0,0,0;-30,-15,0,15,30]);
```

Draw a 3-D plot of the voltage response.

```
pattern(projector,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','power')
```



### Response and Pattern of Isotropic Projector at Multiple Frequencies

Examine the response and patterns of an isotropic projector at three different frequencies. The projector operates between 1 kHz and 10 kHz. Specify the voltage response as a vector.

Set up the projector parameters, and obtain the voltage response at 45° azimuth and 30° elevation. Compute the responses at signal frequencies of 2, 5, and 7 kHz.

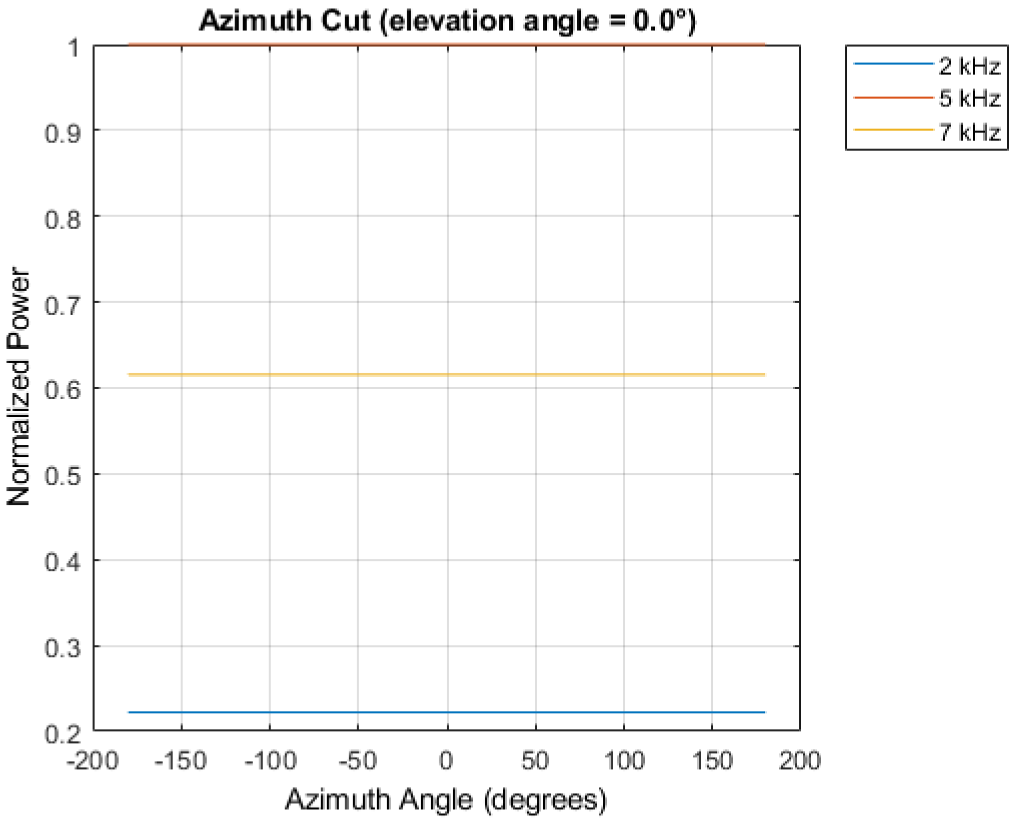
```
projector = phased.IsotropicProjector('FrequencyRange',[1 10]*1e3, ...
    'VoltageResponse',[90 95 100 95 90]);
fc = [2e3 5e3 7e3];
resp = projector(fc,[45;30]);
resp
```

```
resp = 1×3

    0.0426    0.0903    0.0708
```

Next, draw a 2-D plot of the voltage response as a function of azimuth

```
pattern(projector,fc,[-180:180],0,'CoordinateSystem','rectangular', ...
    'Type','power')
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Plot isotropic projector directivity and response patterns versus azimuth

## Syntax

```
patternAzimuth(projector,FREQ)
patternAzimuth(projector,FREQ,EL)
patternAzimuth(projector,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

patternAzimuth(projector,FREQ) plots the 2-D element directivity pattern versus azimuth (in dBi) for the projector, projector, at zero-degrees elevation angle. The argument FREQ specifies the operating frequency.

patternAzimuth(projector,FREQ,EL), in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by EL. When EL is a vector, multiple overlaid plots are created.

patternAzimuth(projector,FREQ,EL,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternAzimuth( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Azimuth' parameter and the EL input argument.

## Input Arguments

**projector — Isotropic projector**
phased.IsotropicProjector System object

Isotropic projector, specified as a phased.IsotropicProjector System object.

Example: phased.IsotropicProjector

**FREQ — Frequency for computing directivity and pattern**
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, FREQ must lie within the range of values specified by the FrequencyRange or the FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: 1e8

Data Types: double

**EL — Elevation angles**
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: [0,10,20]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Azimuth — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

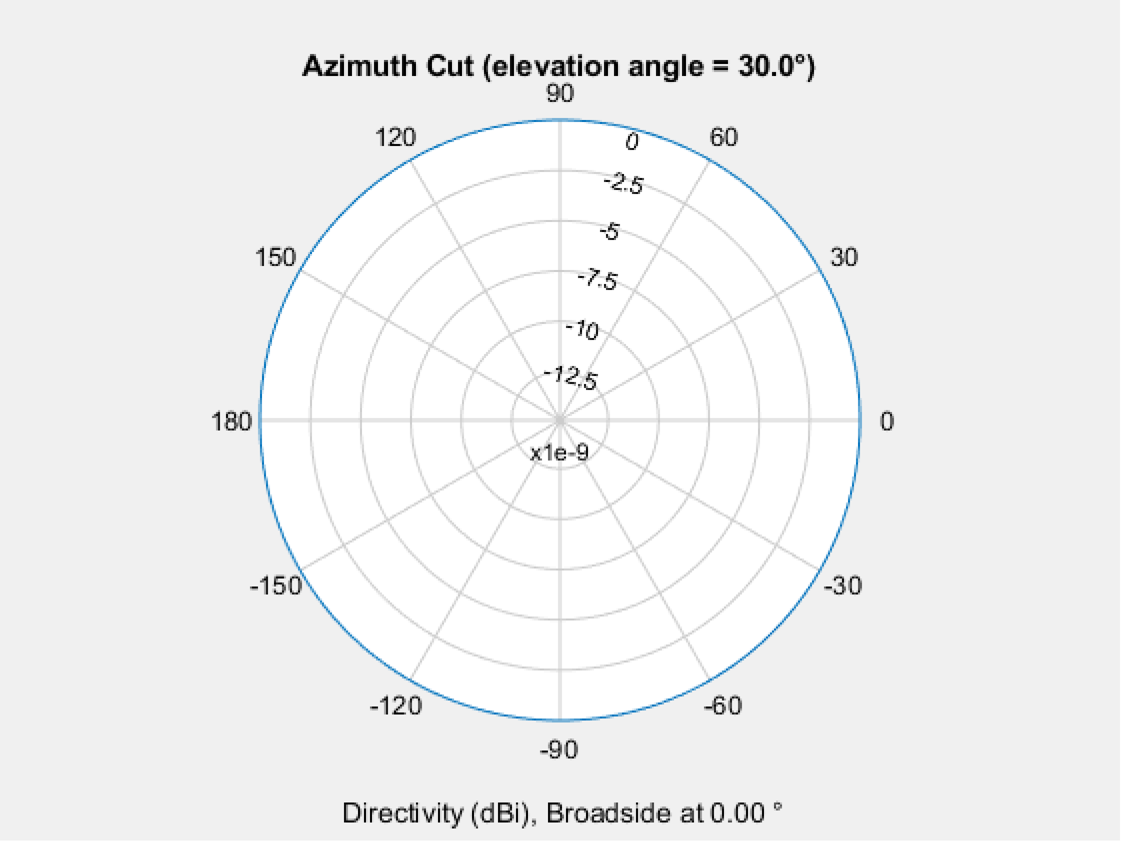
## Examples

### Azimuth Pattern of Isotropic Projector

Examine the azimuth pattern of an isotropic projector at 30° elevation. The frequency range is between 1 kHz and 10 kHz. Specify the voltage response as a scalar.

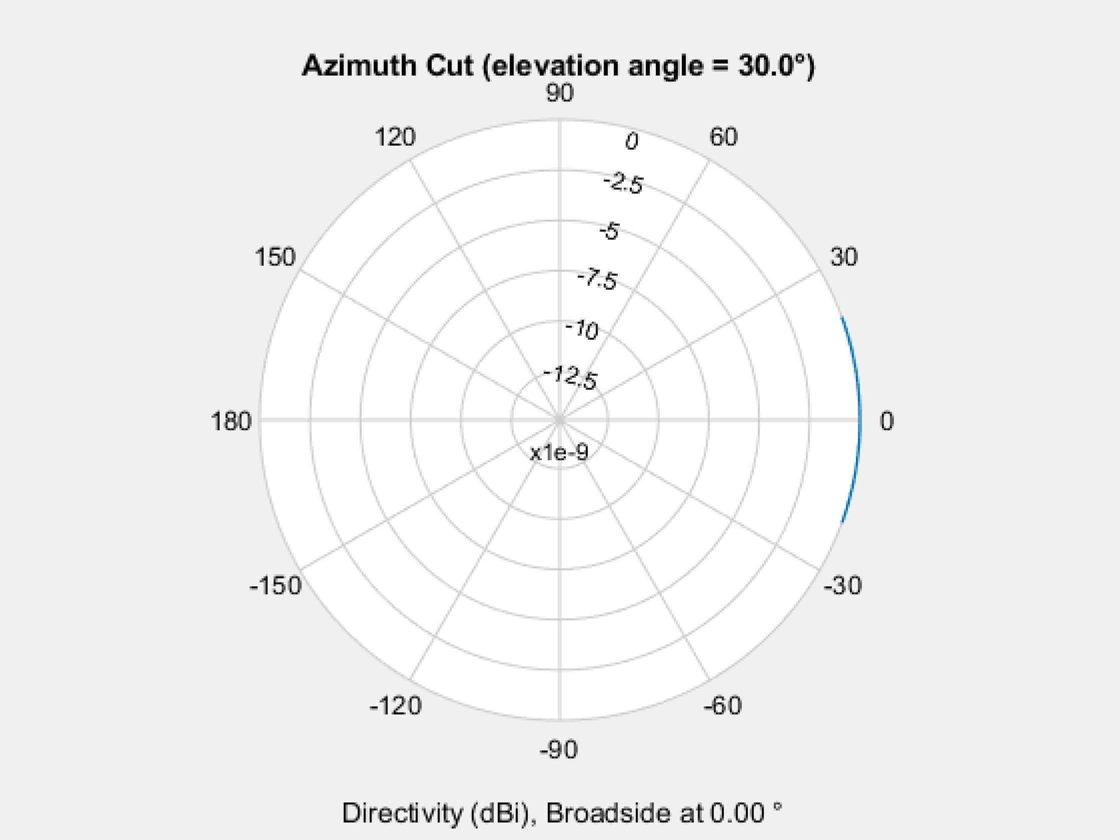
Set the projector parameters.

```
fc = 3e3;
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3, ...
    'VoltageResponse',-115);
patternAzimuth(projector,fc,30)
```



Plot a smaller range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(projector,fc,30,'Azimuth',[-20:20])
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2017a**

# patternElevation

**System object:** phased.IsotropicProjector
**Package:** phased

Plot isotropic projector directivity and response patterns versus elevation

## Syntax

```
patternElevation(projector,FREQ)
patternElevation(projector,FREQ,AZ)
patternElevation(projector,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(projector,FREQ) plots the 2D element directivity pattern versus elevation (in dBi) for the projector, projector, at zero-degrees azimuth angle. The argument FREQ specifies the operating frequency.

patternElevation(projector,FREQ,AZ), in addition, plots the 2D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(projector,FREQ,AZ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**projector — Isotropic projector**
phased.IsotropicProjector System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Elevation — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

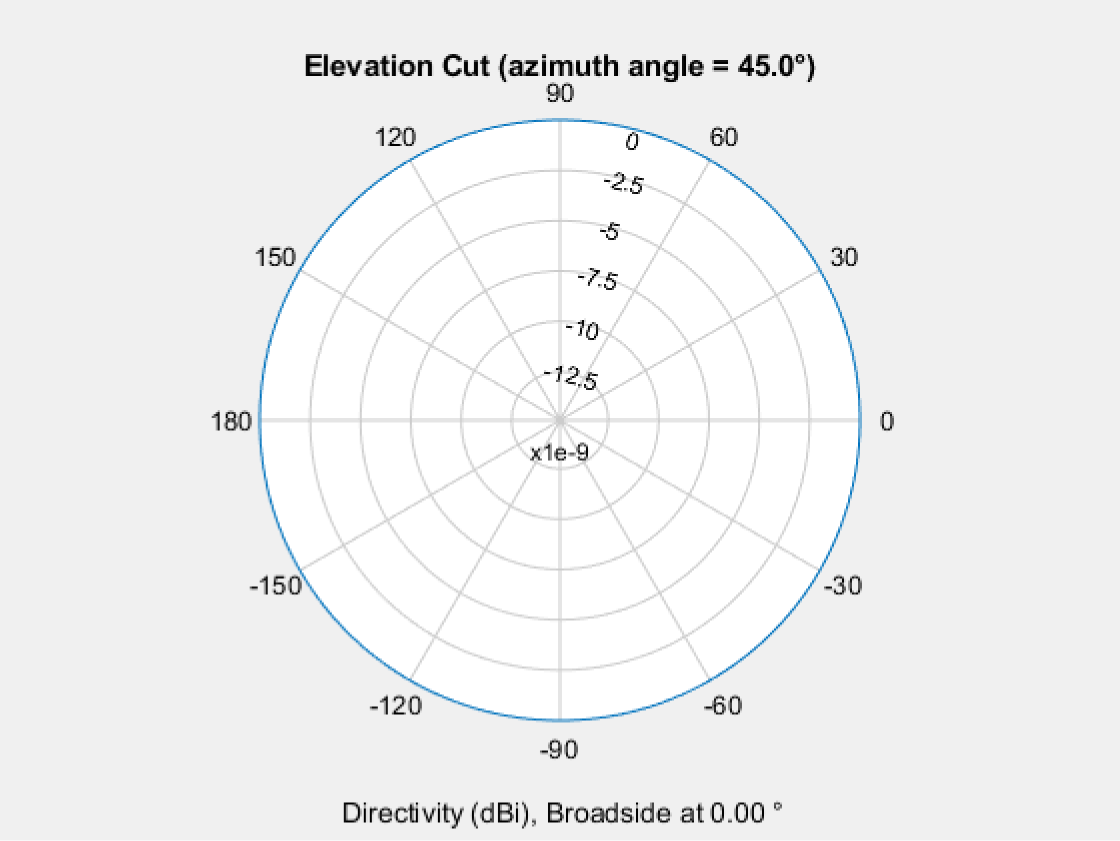
# Examples

### Elevation Pattern of Isotropic Projector

Plot an elevation cut of the directivity of an isotropic projector at 45° azimuth. Assume the signal frequency is 3 kHz.

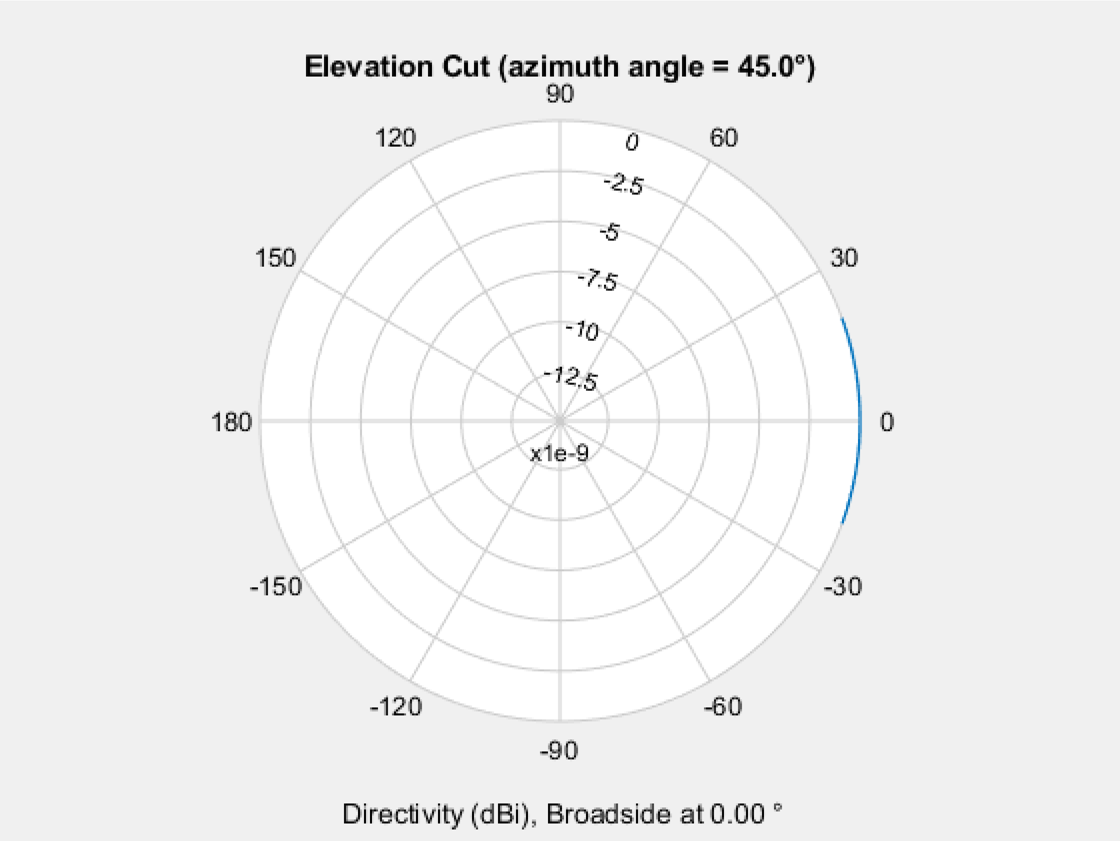
Create the isotropic projector object and call the pattern object function.

```
fc = 3e3;
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3, ...
    'VoltageResponse',70);
patternElevation(projector,fc,45)
```



Plot a smaller range of elevation angles using the `Elevation` parameter.

```
patternElevation(projector,fc,45,'Elevation',-20:20)
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

`pattern` | `patternAzimuth`

**Introduced in R2017a**

# step

**System object:** `phased.IsotropicProjector`
**Package:** `phased`

Voltage response of isotropic projector

## Syntax

```
resp = step(projector,freq,ang)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`resp = step(projector,freq,ang)` returns the voltage response for the projector at the specified operating frequencies and in the specified directions of arriving signals.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `projector` — Isotropic projector

`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

**`freq` — Voltage response frequencies**
positive real scalar | real-valued 1-by-*L* vector of positive values

Voltage response frequencies of projector, specified as a positive real scalar or a real-valued 1-by-*L* vector of positive values. Units are in Hz.

Data Types: `double`

**`ang` — Direction of arriving signals**
real-valued 1-by-*M* row vector | real-valued 2-by-*M* matrix

Direction of arriving signals, specified as a real-valued 1-by-*M* row vector or 2-by-*M* matrix. When `ang` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth;elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

When `ang` is a 1-by-*M* row vector, each element specifies the azimuth angle of the arriving signal. In this case, the corresponding elevation angle is assumed to be zero.

Data Types: `double`

## Output Arguments

**`resp` — Voltage response of projector**
real-valued *M*-by-*L* matrix

Voltage response of projector, returned as a real-valued *M*-by-*L* matrix. *M* represents the number of angles specified in `ang`, and *L* represents the number of frequencies specified in `freq`. Units are in V/Pa.

## Examples

### Response and Pattern of Isotropic Projector at Single Frequency

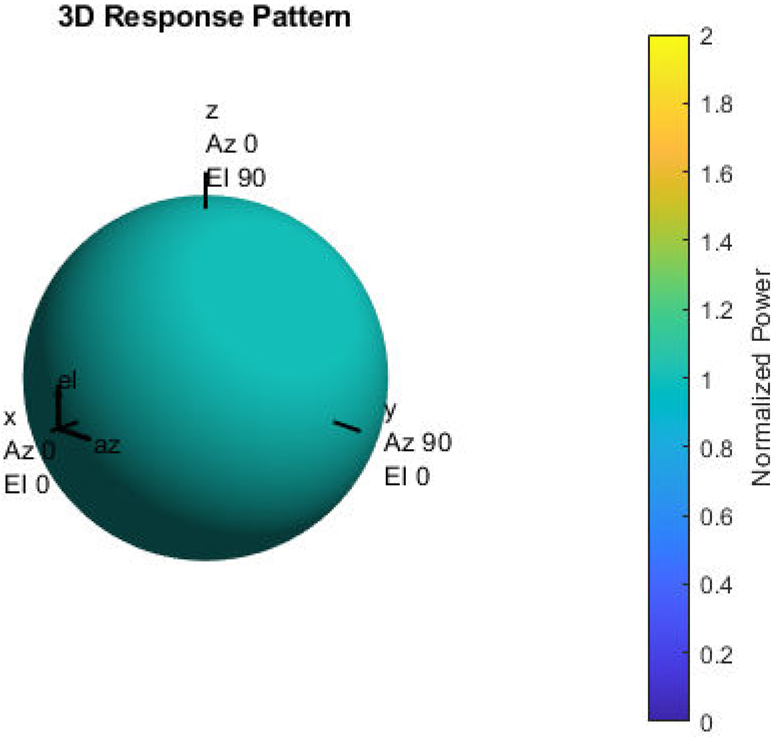
Examine the response and patterns of an isotropic projector operating between 1 kHz and 10 kHz.

Set the projector parameters and obtain the voltage response at five different elevation angles: -30°, -15°, 0°, 15° and 30&deg. All elevation angles at 0° azimuth angle. The voltage response is computed at 2 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3);
fc = 2e3;
resp = projector(fc,[0,0,0,0,0;-30,-15,0,15,30]);
```

Draw a 3-D plot of the voltage response.

```
pattern(projector,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','power')
```



### Response and Pattern of Isotropic Projector at Multiple Frequencies

Examine the response and patterns of an isotropic projector at three different frequencies. The projector operates between 1 kHz and 10 kHz. Specify the voltage response as a vector.

Set up the projector parameters, and obtain the voltage response at 45° azimuth and 30° elevation. Compute the responses at signal frequencies of 2, 5, and 7 kHz.

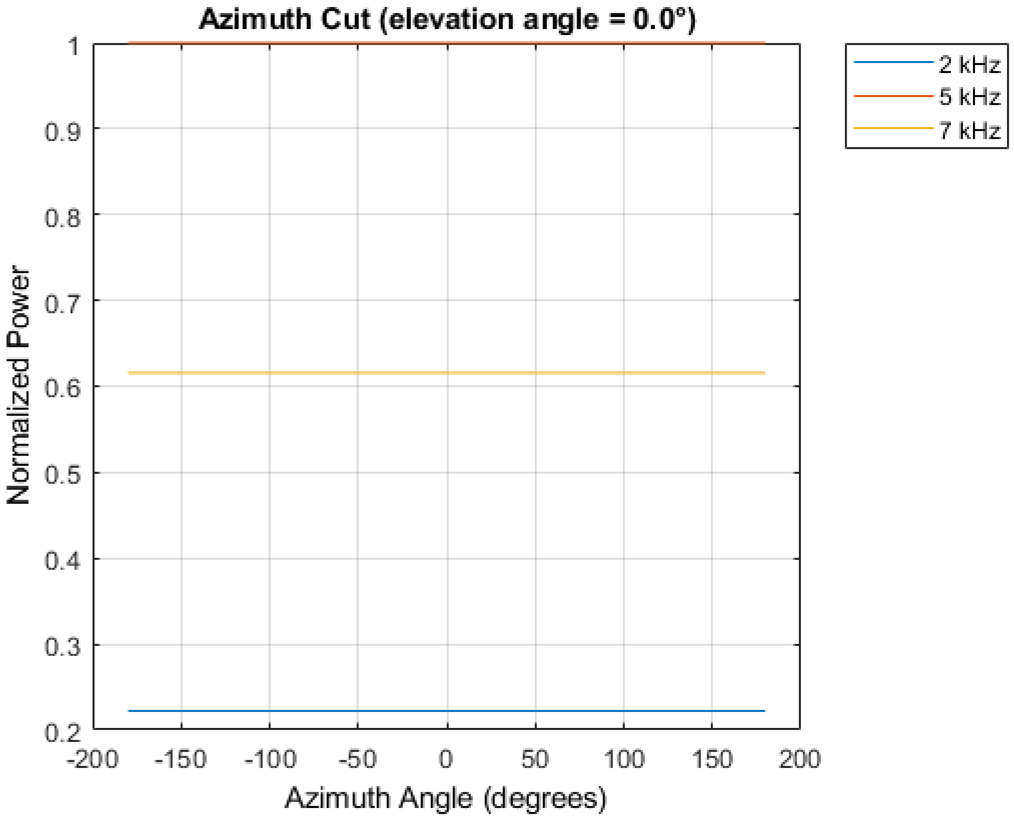
```
projector = phased.IsotropicProjector('FrequencyRange',[1 10]*1e3, ...
    'VoltageResponse',[90 95 100 95 90]);
fc = [2e3 5e3 7e3];
resp = projector(fc,[45;30]);
resp
```

```
resp = 1×3

    0.0426    0.0903    0.0708
```

Next, draw a 2-D plot of the voltage response as a function of azimuth

```
pattern(projector,fc,[-180:180],0,'CoordinateSystem','rectangular', ...
    'Type','power')
```



## Algorithms

The total response of a projector is a combination of its frequency response and spatial response. `phased.IsotropicProjector` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

# phased.LCMVBeamformer

**Package:** `phased`

Narrowband LCMV beamformer

## Description

The phased.LCMVBeamformer object implements a narrowband linear-constraint minimum-variance (LCMV) beamformer for a sensor array. The LCMV beamformer belongs to the family of constrained optimization beamformers.

To beamform signals arriving at a sensor array:

1. Create the `phased.LCMVBeamformer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
beamformer = phased.LCMVBeamformer
beamformer = phased.LCMVBeamformer(Name,Value)
```

### Description

`beamformer = phased.LCMVBeamformer` creates an LCMV beamformer System object, `beamformer`, with default property values.

`beamformer = phased.LCMVBeamformer(Name,Value)` creates an LCMV beamformer with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `beamformer = phased.LCMVBeamformer('Constraint',[1;1])` sets the constraint matrix.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `Constraint` — Constraint matrix

`[1;1]` (default) | complex-valued *N*-by-*K* matrix

Constraint matrix, specified as a complex-valued *N*-by-*K* matrix. Each column of the matrix represents a constraint. *N* is the number of elements in the sensor array and *K* is the number of constraints. *K* must be less than or equal to *N*, $K \leq N$.

Example: `[1 1i;1 1i]`

Data Types: `single` | `double`
Complex Number Support: Yes

### `DesiredResponse` — Desired response

`1` (default) | complex-valued *K*-by-1 vector

Desired response of the LCMV beamformer, specified as a complex-valued *K*-by-1 vector, where *K* is the number of constraints in the Constraint property. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the `Constraint` property. A value of one creates a distortionless response and a value of zero creates a null response.

Example: `[1;0]`

Data Types: `single` | `double`
Complex Number Support: Yes

### `DiagonalLoadingFactor` — Diagonal loading factor

`0` (default) | nonnegative scalar

Diagonal loading factor, specified as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample size is small. A small sample size can lead to an inaccurate estimate of the covariance matrix. Diagonal loading also provides robustness due to steering vector errors. The diagonal loading technique adds a positive scalar multiple of the identity matrix to the sample covariance matrix.

**Tunable:** Yes

Data Types: `single` | `double`

### `TrainingInputPort` — Enable training data input

`false` (default) | `true`

Enable training data input, specified as `false` or `true`. When you set this property to `true`, use the training data input argument, `XT`, when running the object. Set this property to `false` to use the input data, `X`, as the training data.

Data Types: `logical`

### `WeightsOutputPort` — Enable beamforming weights output

`false` (default) | `true`

Enable the output of beamforming weights, specified as `false` or `true`. To obtain the beamforming weights, set this property to `true` and use the corresponding output argument, `W`. If you do not want to obtain the weights, set this property to `false`.

Data Types: `logical`

## Usage

## Syntax

```
Y = beamformer(X)
Y = beamformer(X,XT)
[Y,W] = beamformer(___)
```

## Description

`Y = beamformer(X)` performs LCMV beamforming on the input array data, `X`, and returns the beamformed output in `Y`.

`Y = beamformer(X,XT)` uses `XT` as training data to calculate the beamforming weights. To use this syntax, set the TrainingInputPort property to `true`.

`[Y,W] = beamformer( ___ )` returns the beamforming weights `W`. To use this syntax, set the WeightsOutputPort property to `true`.

## Input Arguments

### X — Array element data

complex-valued *M*-by-*N* matrix

Array element data, specified as an*M*-by-*N* matrix where *N* is the number of elements in the sensor array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1 0.5 2.6; 2 -0.2 0]`

Data Types: `single` | `double`

### XT — Training data

complex-valued *P*-by-*N* matrix

Training data, specified as a *P*-by-*N* matrix. *N* is the number of elements of the sensor array. *P* is the length of the training data and must be greater than *N*.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[1 0.5 2.6; 2 -0.2 0; 3 -2 -1]`

**Dependencies**

To enable this argument, set the `TrainingInputPort` property to `true`.

Data Types: `single` | `double`

## Output Arguments

### Y — Beamformed output

complex-valued *M*-by-1 vector

Beamformed output, returned as a complex-valued *M*-by-1 vector.

Data Types: `single` | `double`

### `W` — Beamformer weights

complex-valued *N*-by-1 vector

Beamformer weights, returned as a complex-valued *N*-by-1 vector. *N* is the number of elements in the sensor array.

#### Dependencies

To enable this argument, set the WeightsOutputPort property to `true`.

Data Types: `single` | `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### LCMV Beamformer with One Constraint

Apply an LCMV beamformer to a 5-element ULA of isotropic sensor elements, preserving the signal from a desired direction. The operating frequency is 300 MHz.

Simulate a low-frequency sinusoid signal in gaussian noise.

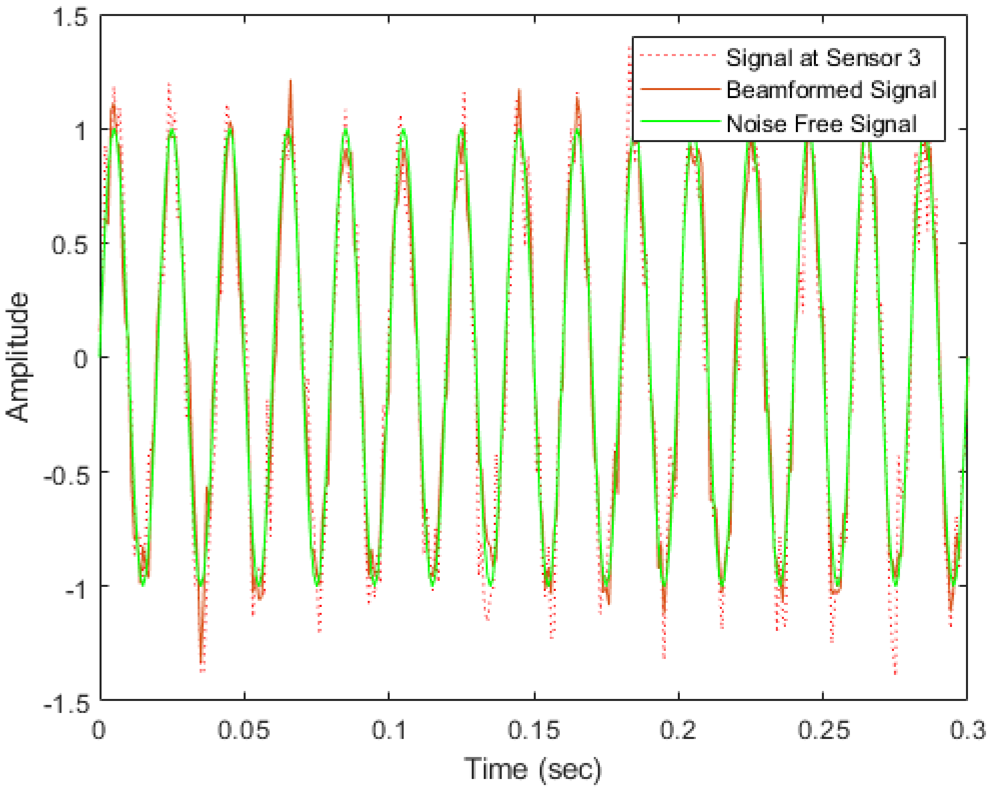
```
f = 50;
t = (0:.001:.3)';
x = sin(2*pi*f*t);
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
incidentAngle = [45;0];
antenna = phased.IsotropicAntennaElement('FrequencyRange',[20 20e8]);
array = phased.ULA('NumElements',5,'ElementSpacing',lambda/2,...
    'Element',antenna);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.2*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Beamform the array.

```
steervec = phased.SteeringVector('SensorArray',array,...
    'PropagationSpeed',c);
beamformer = phased.LCMVBeamformer('Constraint',steervec(fc,incidentAngle),'DesiredResp
y = beamformer(rx);
```

Plot the original and beamformed signals.

```
plot(t,real(rx(:,3)),'r:',t,real(y),t,real(x(:,3)),'g')
xlabel('Time (sec)')
ylabel('Amplitude')
legend('Signal at Sensor 3','Beamformed Signal','Noise Free Signal')
```



### Nulling with LCMV Beamformer

This example shows how to use an LCMV beamformer to point a null of the array response in the direction of an interfering source. The array is a 10-element uniform linear array (ULA). By default, the ULA elements are isotropic antennas created by the `phased.IsotropicAntennaElement` System object™. Set the frequency range of the antenna elements so that the carrier frequency lies within the operating range. The carrier frequency is 1 GHz.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
```

```
array = phased.ULA('NumElements',10,'ElementSpacing',lambda/2);
array.Element.FrequencyRange = [8e8 1.2e9];
```

Simulate a test signal using a simple rectangular pulse.

```
t = linspace(0,0.3,300)';
testsig = zeros(size(t));
testsig(201:205) = 1;
```

Assume the rectangular pulse is incident on the ULA from an angle of 30° azimuth and 0° elevation. Use the `collectPlaneWave` function of the ULA System object to simulate reception of the pulse waveform from the incident angle.

```
angle_of_arrival = [30;0];
x = collectPlaneWave(array,testsig,angle_of_arrival,fc);
```

The signal `x` is a matrix with ten columns. Each column represents the received signal at one of the array elements.

Construct a conventional phase-shift beamformer. Set the `WeightsOutputPort` property to `true` to output the spatial filter weights.

```
convbeamformer = phased.PhaseShiftBeamformer('SensorArray',array,...
    'OperatingFrequency',1e9,'Direction',angle_of_arrival,...
    'WeightsOutputPort',true);
```

Add complex-valued white Gaussian noise to the signal `x`. Set the default random number stream for reproducible results.

```
rng default
npower = 0.5;
x = x + sqrt(npower/2)*(randn(size(x)) + 1i*randn(size(x)));
```

Create an interference source using the `phased.BarrageJammer` System object. Specify the barrage jammer to have an effective radiated power of 10 W. The interference signal from the barrage jammer is incident on the ULA from an angle of 120° azimuth and 0° elevation. Use the `collectPlaneWave` function of the ULA System object to simulate reception of the jammer signal.

```
jammer = phased.BarrageJammer('ERP',10,'SamplesPerFrame',300);
jamsig = jammer();
jammer_angle = [120;0];
jamsig = collectPlaneWave(array,jamsig,jammer_angle,fc);
```

Add complex-valued white Gaussian noise to simulate noise contributions not directly associated with the jamming signal. Again, set the default random number stream for reproducible results. This noise power is 0 dB below the jammer power. Beamform the signal using a conventional beamformer.

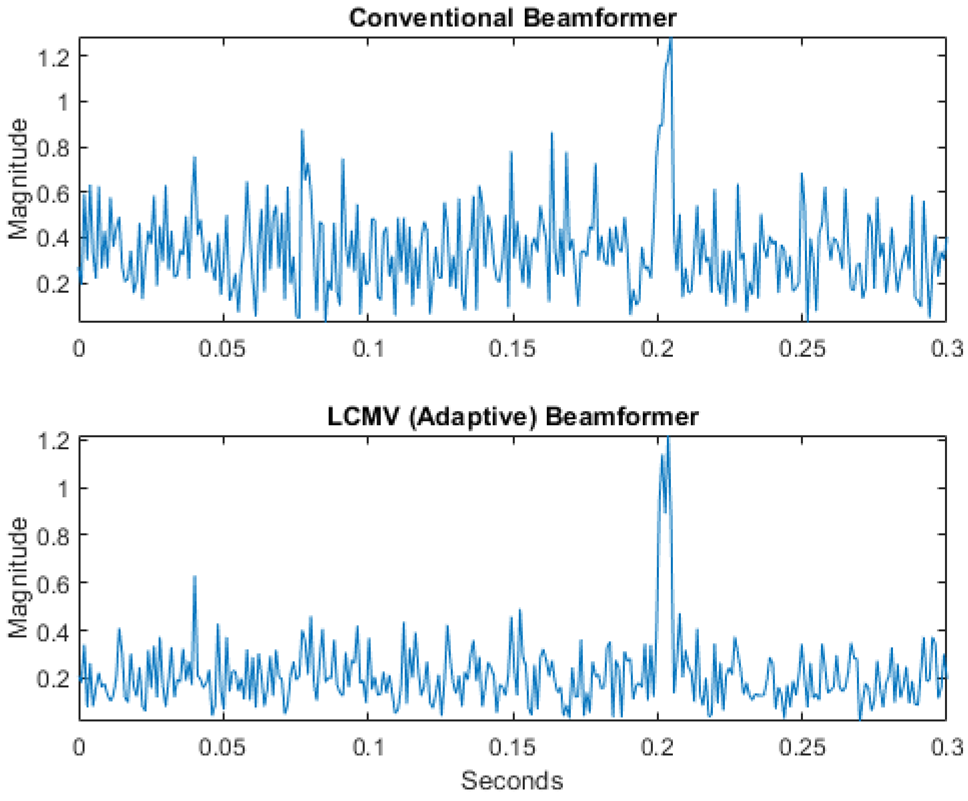
```
noisePwr = 1e-5;
rng(2008);
noise = sqrt(noisePwr/2)*...
    (randn(size(jamsig)) + 1j*randn(size(jamsig)));
jamsig = jamsig + noise;
rxsig = x + jamsig;
[yout,w] = convbeamformer(rxsig);
```

Implement the adaptive LCMV beamformer using the same ULA array. Use the target-free data, `jamsig`, as training data. Output the beamformed signal and the beamformer weights.

```
steeringvector = phased.SteeringVector('SensorArray',array,...
    'PropagationSpeed',physconst('LightSpeed'));
LCMVbeamformer = phased.LCMVBeamformer('DesiredResponse',1,...
    'TrainingInputPort',true,'WeightsOutputPort',true);
LCMVbeamformer.Constraint = steeringvector(fc,angle_of_arrival);
LCMVbeamformer.DesiredResponse = 1;
[yLCMV,wLCMV] = LCMVbeamformer(rxsig,jamsig);
```

Plot the conventional beamformer output and the adaptive beamformer output.

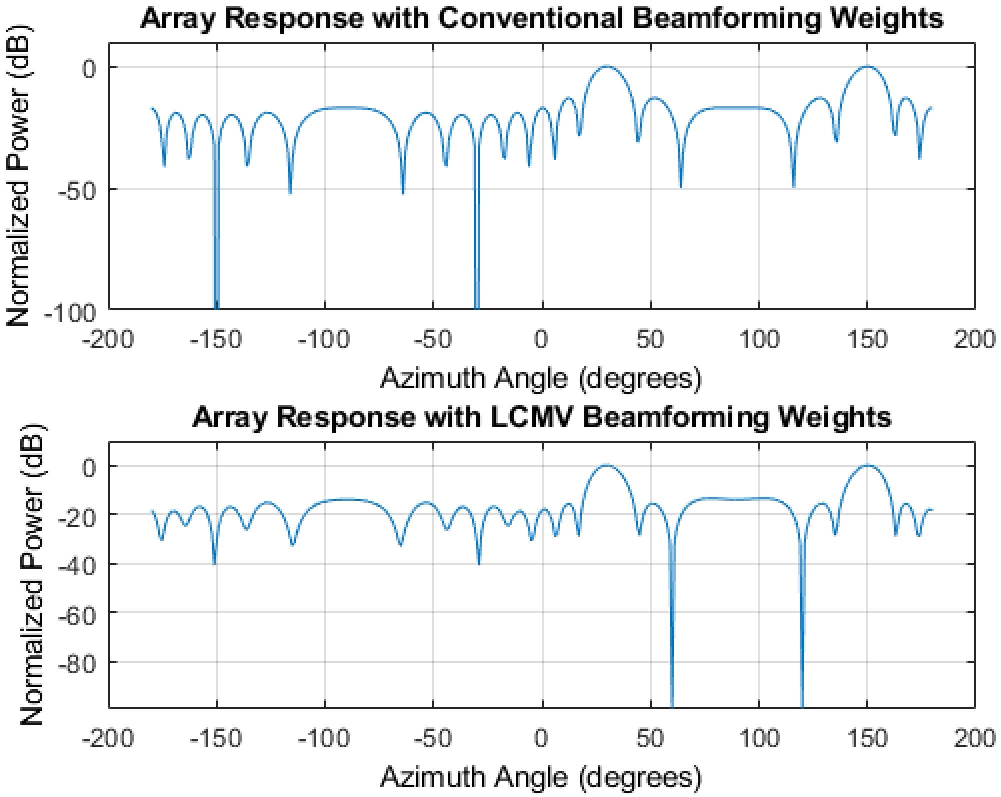
```
subplot(211)
plot(t,abs(yout))
axis tight
title('Conventional Beamformer')
ylabel('Magnitude')
subplot(212)
plot(t,abs(yLCMV))
axis tight
title('LCMV (Adaptive) Beamformer')
xlabel('Seconds')
ylabel('Magnitude')
```



The adaptive beamformer significantly improves the SNR of the rectangular pulse at 0.2 s.

Using conventional and LCMV weights, plot the responses for each beamformer.

```
subplot(211)
pattern(array,fc,[-180:180],0,'PropagationSpeed',physconst('LightSpeed'),...
    'CoordinateSystem','rectangular','Type','powerdb','Normalize',true,...
    'Weights',w)
title('Array Response with Conventional Beamforming Weights');
subplot(212)
pattern(array,fc,[-180:180],0,'PropagationSpeed',physconst('LightSpeed'),...)
    'CoordinateSystem','rectangular','Type','powerdb','Normalize',true,...
    'Weights',wLCMV)
title('Array Response with LCMV Beamforming Weights');
```



The adaptive beamform places a null at the arrival angle of the interference signal, 120°.

# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If

the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

## Topics

“Adaptive Beamforming”

**Introduced in R2012a**

# step

**System object:** `phased.LCMVBeamformer`
**Package:** `phased`

Perform LCMV beamforming

## Syntax

```
Y = step(H,X)
Y = step(H,X,XT)
[Y,W] = step(___)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs LCMV beamforming on the input, `X`, and returns the beamformed output in `Y`. `X` is an M-by-N matrix where N is the number of elements of the sensor array. `Y` is a column vector of length M.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,XT)` uses `XT` as the training samples to calculate the beamforming weights. This syntax is available when you set the `TrainingInputPort` property to `true`. `XT` is a P-by-N matrix, where N is the number of elements of the sensor array. P must be greater than N.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

[Y,W] = step(____) returns the beamforming weights W. This syntax is available when you set the WeightsOutputPort property to true. W is a column vector of length N, where N is the number of elements in the sensor array.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Examples

### LCMV Beamformer with One Constraint

Apply an LCMV beamformer to a 5-element ULA of isotropic sensor elements, preserving the signal from a desired direction. The operating frequency is 300 MHz.

Simulate a low-frequency sinusoid signal in gaussian noise.

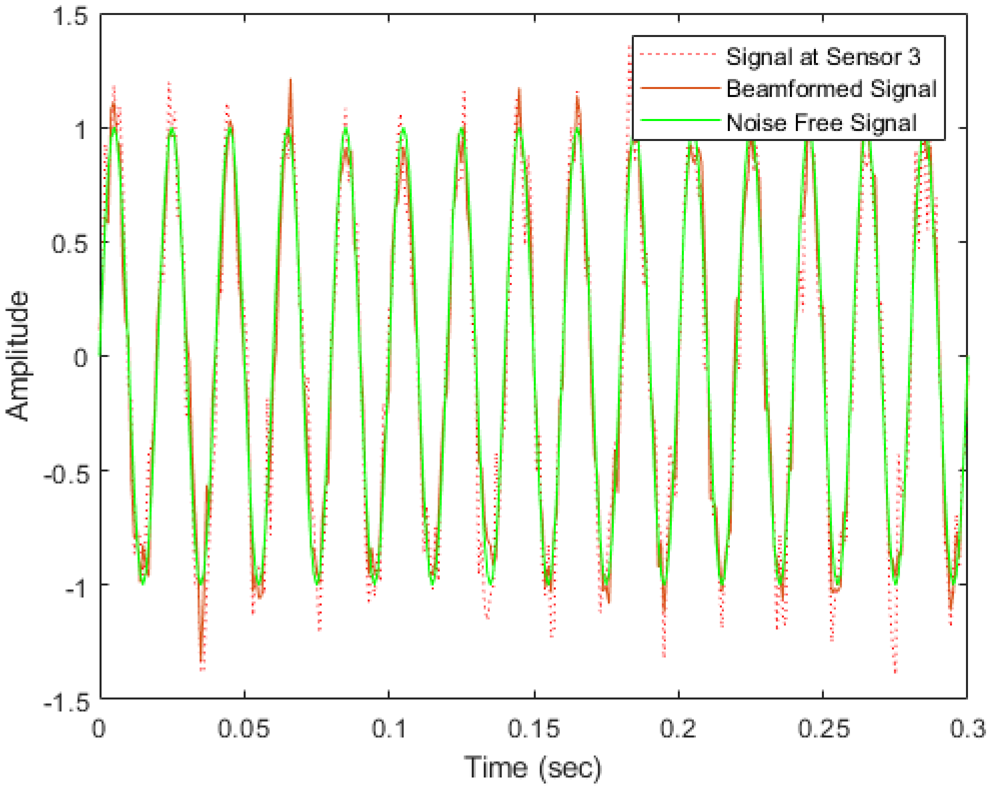
```
f = 50;
t = (0:.001:.3)';
x = sin(2*pi*f*t);
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
incidentAngle = [45;0];
antenna = phased.IsotropicAntennaElement('FrequencyRange',[20 20e8]);
array = phased.ULA('NumElements',5,'ElementSpacing',lambda/2,...
    'Element',antenna);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.2*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Beamform the array.

```
steervec = phased.SteeringVector('SensorArray',array,...
    'PropagationSpeed',c);
beamformer = phased.LCMVBeamformer('Constraint',steervec(fc,incidentAngle),'DesiredResp
y = beamformer(rx);
```

Plot the original and beamformed signals.

```
plot(t,real(rx(:,3)),'r:',t,real(y),t,real(x(:,3)),'g')
xlabel('Time (sec)')
ylabel('Amplitude')
legend('Signal at Sensor 3','Beamformed Signal','Noise Free Signal')
```



# phased.LinearFMWaveform

**Package:** phased

Linear FM pulse waveform

## Description

The LinearFMWaveform object creates a linear FM pulse waveform.

To obtain waveform samples:

1. Define and set up your linear FM waveform. See “Construction” on page 1-1227.
2. Call step to generate the linear FM waveform samples according to the properties of phased.LinearFMWaveform. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations. When the only argument to the step method is the System object itself, replace y = step(obj) by y = obj().

## Construction

H = phased.LinearFMWaveform creates a linear FM pulse waveform System object, H. The object generates samples of a linear FM pulse waveform.

H = phased.LinearFMWaveform(Name,Value) creates a linear FM pulse waveform object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

**Default:** `1e6`

### `DurationSpecification`

Method to set pulse duration

Method to set pulse duration (pulse width), specified as `'Pulse width'` or `'Duty cycle'`. This property determines how you set the pulse duration. When you set this property to `'Pulse width'`, then you set the pulse duration directly using the `PulseWidth` property. When you set this property to `'Duty cycle'`, you set the pulse duration from the values of the `PRF` and `DutyCycle` properties. The pulse width is equal to the duty cycle divided by the *PRF*.

**Default:** `'Pulse width'`

### `PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

**Default:** `50e-6`

### `DutyCycle`

Waveform duty cycle

Waveform duty cycle, specified as a scalar from 0 through 1, inclusive. This property applies when you set the `DurationSpecification` property to `'Duty cycle'`. The pulse width is the value of the `DutyCycle` property divided by the value of the `PRF` property.

**Default:** `0.5`

### PRF

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The*PRF* must satisfy these restrictions:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of `PRF` must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* using property settings alone or using property settings in conjunction with the `prfidx` input argument of the `step` method.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties only. You can
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an argument specifying an index into the *PRF* vector.

In all cases, the number of output samples is fixed when you set the `OutputFormat` property to `'Samples'`. When you use a varying *PRF* and set the `OutputFormat` property to `'Pulses'`, the number of samples can vary.

**Default:** `10e3`

**`PRFSelectionInputPort`**

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property. When you set this property to `true`, you pass an index argument into the `step` method to select a value from the PRF vector.

**Default:** `false`

**`SweepBandwidth`**

FM sweep bandwidth

Specify the bandwidth of the linear FM sweeping (in hertz) as a positive scalar. The default value corresponds to 100 kHz.

**Default:** `1e5`

**`SweepDirection`**

FM sweep direction

Specify the direction of the linear FM sweep as one of `'Up'` or `'Down'`.

**Default:** `'Up'`

**`SweepInterval`**

Location of FM sweep interval

If you set this property value to `'Positive'`, the waveform sweeps in the interval between *0* and *B*, where *B* is the `SweepBandwidth` property value. If you set this property value to `'Symmetric'`, the waveform sweeps in the interval between *–B/2* and *B/2*.

**Default:** `'Positive'`

**`Envelope`**

Envelope function

Specify the envelope function as one of `'Rectangular'` or `'Gaussian`'.

**Default:** `'Rectangular'`

### `OutputFormat`

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

**Default:** `'Pulses'`

### `NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

### `NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

**Default:** `1`

### `PRFOutputPort`

Set this property to `true` to output the PRF for the current pulse using a `step` method argument.

#### Dependencies

This property can be used only when the `OutputFormat` property is set to `'Pulses'`.

**Default:** `false`

## Methods

| | |
|---|---|
| bandwidth | Bandwidth of linear FM waveform |
| getMatchedFilter | Matched filter coefficients for waveform |
| getStretchProcessor | Create stretch processor for waveform |
| plot | Plot linear FM pulse waveform |
| reset | Reset states of the linear FM waveform object |
| step | Samples of linear FM pulse waveform |

## Examples

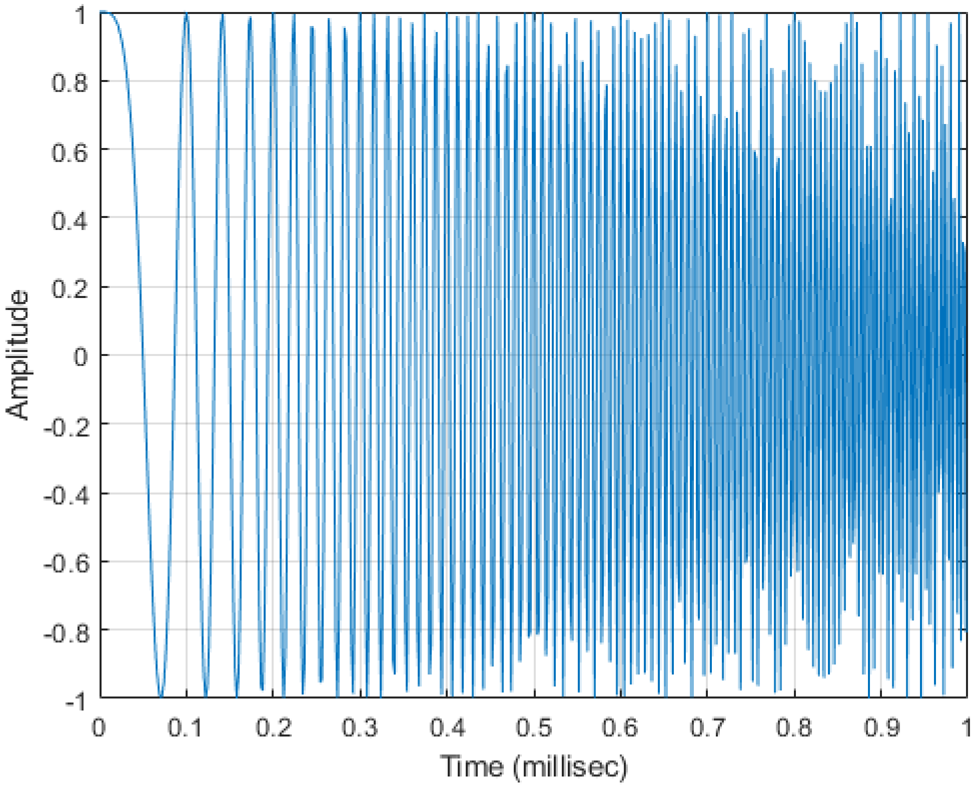
### Plot LFM Waveform and Spectrum

Create and plot an upsweep linear FM pulse waveform. The sample rate is 500 kHz, the sweep bandwidth is 200 kHz and the pulse width is 1 millisecond (equal to the pulse repetition interval).

```
fs = 500e3;
sLFM = phased.LinearFMWaveform('SampleRate',fs,...
    'SweepBandwidth',200e3,...
    'PulseWidth',1e-3,'PRF',1e3);
```

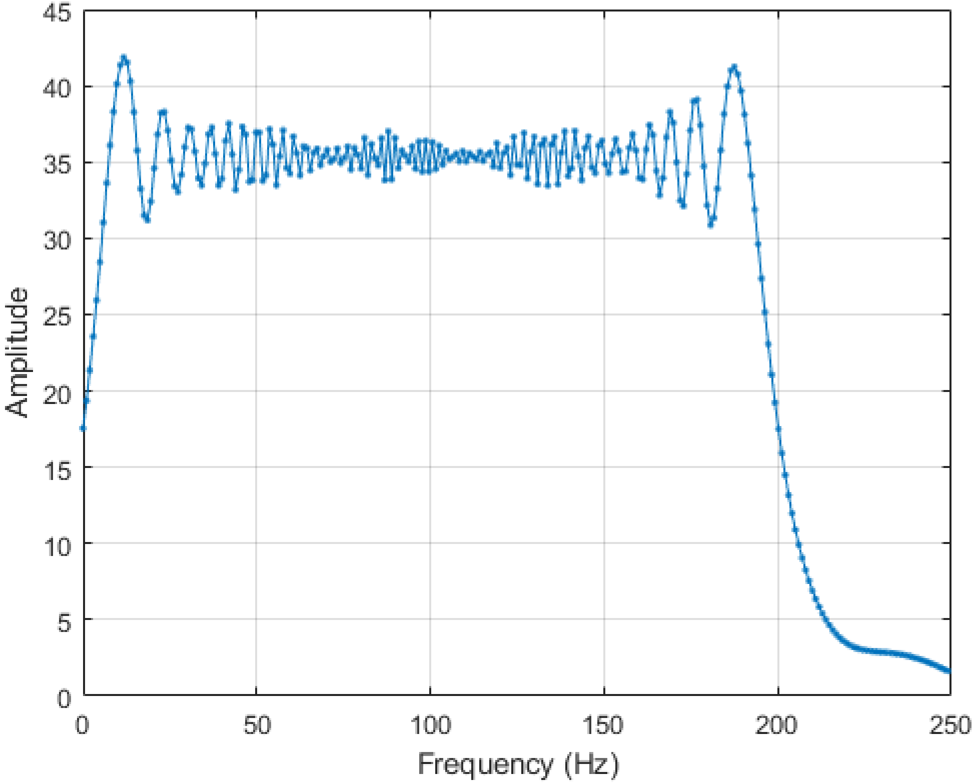
Obtain and then plot the real part of the LFM waveform.

```
lfmwav = step(sLFM);
nsamp = size(lfmwav,1);
t = [0:(nsamp-1)]/fs;
plot(t*1000,real(lfmwav))
xlabel('Time (millisec)')
ylabel('Amplitude')
grid
```



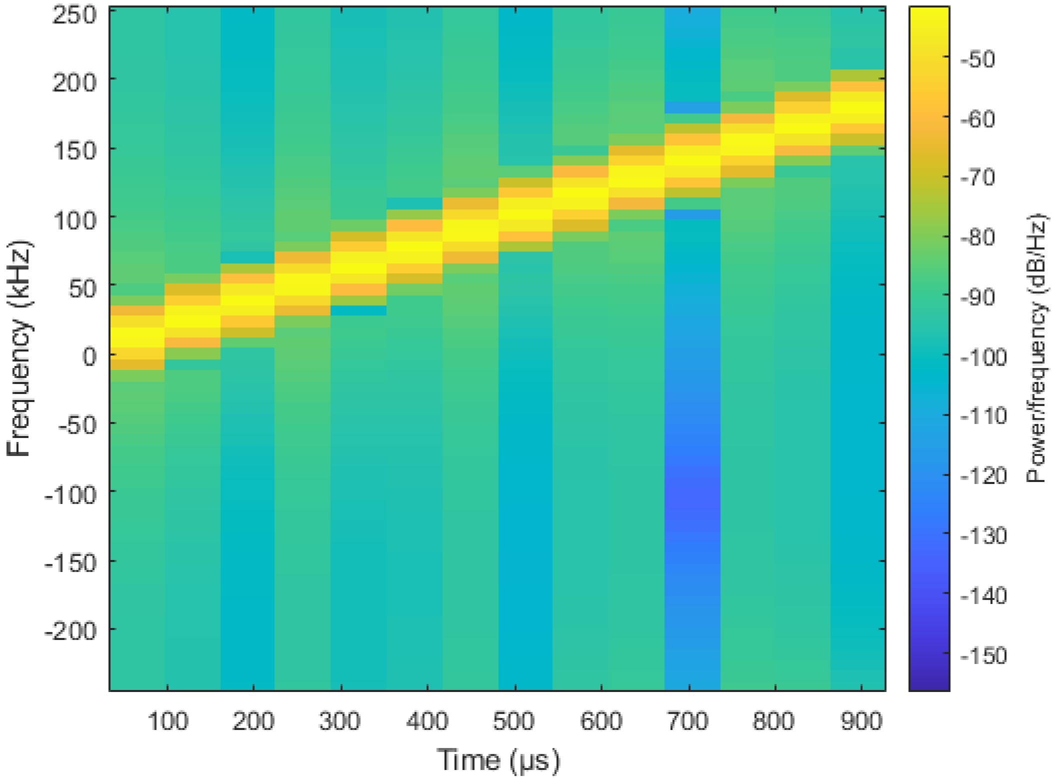
Plot the Fourier transform of the complex signal.

```
nfft = 2^nextpow2(nsamp);
Z = fft(lfmwav,nfft);
fr = [0:(nfft/2-1)]/nfft*fs;
plot(fr/1000,abs(Z(1:nfft/2)),'.-')
xlabel('Frequency (Hz)')
ylabel('Amplitude')
grid
```



Plot a spectrogram of the function with window size of 64 samples and 50% overlap.

```
nfft1 = 64;
nov = floor(0.5*nfft1);
spectrogram(lfmwav,hamming(nfft1),nov,nfft1,fs,'centered','yaxis')
```



This plot shows the increasing frequency of the signal.

### Topics

Waveform Analysis Using the Ambiguity Function

**Introduced in R2012a**

# bandwidth

**System object:** `phased.LinearFMWaveform`
**Package:** `phased`

Bandwidth of linear FM waveform

## Syntax

```
BW = bandwidth(H)
```

## Description

`BW = bandwidth(H)` returns the bandwidth (in hertz) of the pulses for the linear FM pulse waveform `H`. The bandwidth equals the value of the `SweepBandwidth` property.

## Input Arguments

### `H`

Linear FM pulse waveform object.

## Output Arguments

### `BW`

Bandwidth of the pulses, in hertz.

## Examples

### Compute Linear FM Bandwidth

Determine the bandwidth of a linear FM pulse waveform. The default value for an LFM waveform is 100 kHz.

```
waveform = phased.LinearFMWaveform;
bw = bandwidth(waveform)
```

```
bw = 100000
```

# getMatchedFilter

**System object:** `phased.LinearFMWaveform`
**Package:** `phased`

Matched filter coefficients for waveform

## Syntax

```
Coeff = getMatchedFilter(H)
```

## Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the linear FM waveform object `H`. `Coeff` is a column vector.

## Examples

### Matched Filter Coefficients of Linear FM Waveform

Get the matched filter coefficients for a linear FM pulse.

```
waveform = phased.LinearFMWaveform('PulseWidth',5e-05,...
    'SweepBandwidth',1e5,'OutputFormat','Pulses');
coeff = getMatchedFilter(waveform);
stem(real(coeff))
title('Matched filter coefficients, real part')

# getStretchProcessor

**System object:** `phased.LinearFMWaveform`
**Package:** `phased`

Create stretch processor for waveform

## Syntax

```
HS = getStretchProcessor(H)
HS = getStretchProcessor(H,refrng)
HS = getStretchProcessor(H,refrng,rngspan)
HS = getStretchProcessor(H,refrng,rngspan,v)
```

## Description

`HS = getStretchProcessor(H)` returns the stretch processor for the waveform, `H`. `HS` is set up so the reference range corresponds to 1/4 of the maximum unambiguous range of a pulse. The range span corresponds to 1/10 of the distance traveled by the wave within the pulse width. The propagation speed is the speed of light.

`HS = getStretchProcessor(H,refrng)` specifies the reference range.

`HS = getStretchProcessor(H,refrng,rngspan)` specifies the range span. The reference interval is centered at `refrng`.

`HS = getStretchProcessor(H,refrng,rngspan,v)` specifies the propagation speed.

## Input Arguments

### `H`

Linear FM pulse waveform object.

**refrng**

Reference range, in meters, as a positive scalar.

**Default:** 1/4 of the maximum unambiguous range of a pulse

**rngspan**

Length of the interval of ranges of interest, in meters, as a positive scalar. The center of the interval is the range value specified in the `refrng` argument.

**Default:** 1/10 of the distance traveled by the wave within the pulse width

**v**

Propagation speed, in meters per second, as a positive scalar.

**Default:** Speed of light

# Output Arguments

**HS**

Stretch processor as a `phased.StretchProcessor` System object.

# Examples

### Detect a Target Using Stretch Processing

Use stretch processing to locate a target at a range of 4950 m.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Simulate the signal.

```
waveform = phased.LinearFMWaveform;
x = waveform();
```

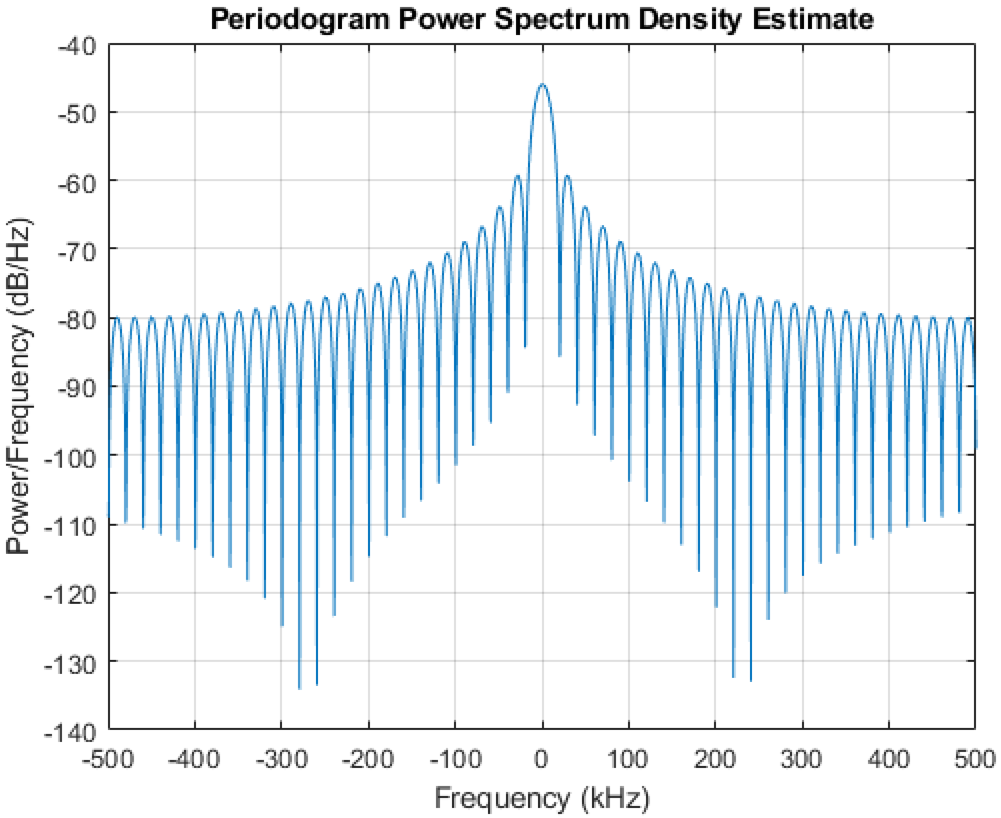
```
c = physconst('LightSpeed');
rng = 4950.0;
num_samples = round(rng/(c/(2*waveform.SampleRate)));
x = circshift(x,num_samples);
```

Perform stretch processing.

```
stretchproc = getStretchProcessor(waveform,5000,200,c);
y = stretchproc(x);
```

Plot the spectrum of the resulting signal.

```
[Pxx,F] = periodogram(y,[],2048,stretchproc.SampleRate,'centered');
plot(F/1000,10*log10(Pxx))
grid
xlabel('Frequency (kHz)')
ylabel('Power/Frequency (dB/Hz)')
title('Periodogram Power Spectrum Density Estimate')
```



Detect the range.

```
[~,rngidx] = findpeaks(pow2db(Pxx/max(Pxx)),'MinPeakHeight',-5);
rngfreq = F(rngidx);
rng = stretchfreq2rng(rngfreq,stretchproc.SweepSlope,stretchproc.ReferenceRange,c)
```

```
rng = 4.9634e+03
```

# plot

**System object:** `phased.LinearFMWaveform`
**Package:** `phased`

Plot linear FM pulse waveform

## Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

## Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

## Input Arguments

### `Hwav`

Waveform object. This variable must be a scalar that represents a single waveform object.

### **`LineSpec`**

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

**Default:** `'b'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **`PlotType`**

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

**Default:** `'real'`

### **`PulseIdx`**

Index of the pulse to plot. This value must be a scalar.

**Default:** `1`

# Output Arguments

### **`h`**

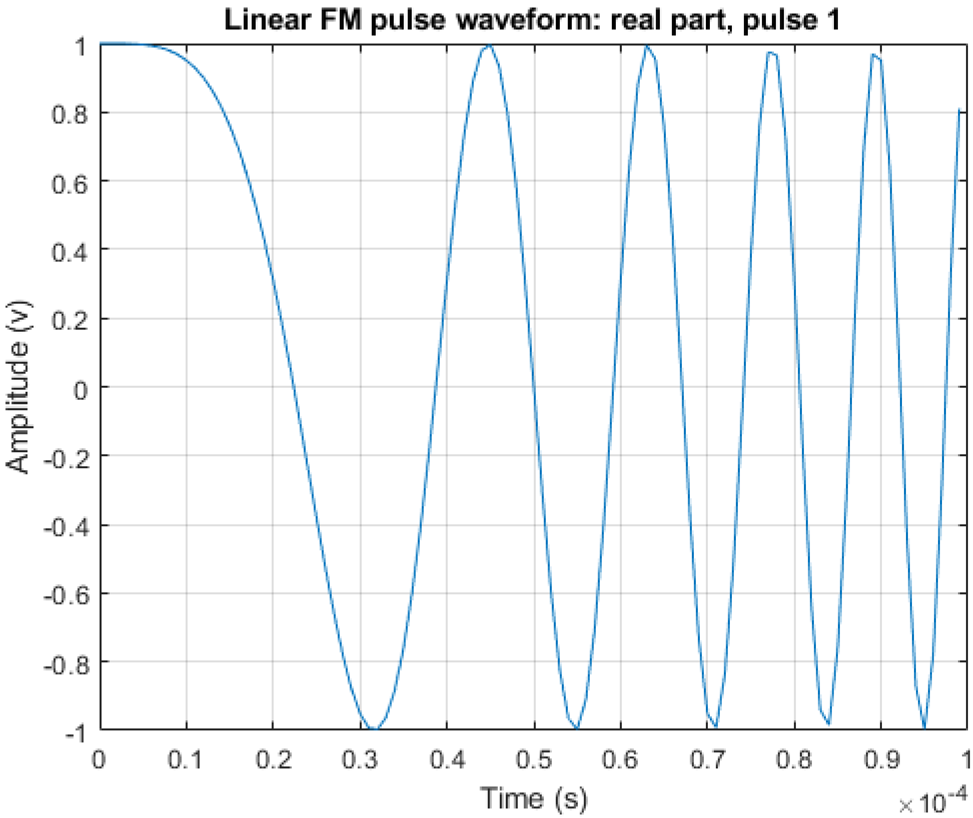
Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

# Examples

### Plot Linear FM Pulse

Create and plot an upsweep linear FM pulse waveform.

```
waveform = phased.LinearFMWaveform('SweepBandwidth',1e5,'PulseWidth',1e-4);
plot(waveform);
```



# reset

**System object:** `phased.LinearFMWaveform`
**Package:** `phased`

Reset states of the linear FM waveform object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `LinearFMWaveform` object, `H`. Afterward, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

# step

**System object:** phased.LinearFMWaveform
**Package:** phased

Samples of linear FM pulse waveform

## Syntax

```
Y = step(sLFM)
Y = step(sLFM,prfidx)
[Y,PRF] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations. When the only argument to the step method is the System object itself, replace y = step(obj) by y = obj().

Y = step(sLFM) returns samples of the linear FM pulse in a column vector Y.

Y = step(sLFM,prfidx), uses the prfidx index to select the PRF from the predefined vector of values specified by in the PRF property. This syntax applies when you set the PRFSelectionInputPort property to true.

[Y,PRF] = step( ___ ) also returns the current pulse repetition frequency, PRF. To enable this syntax, set the PRFOutputPort property to true and set the OutputFormat property to 'Pulses'.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

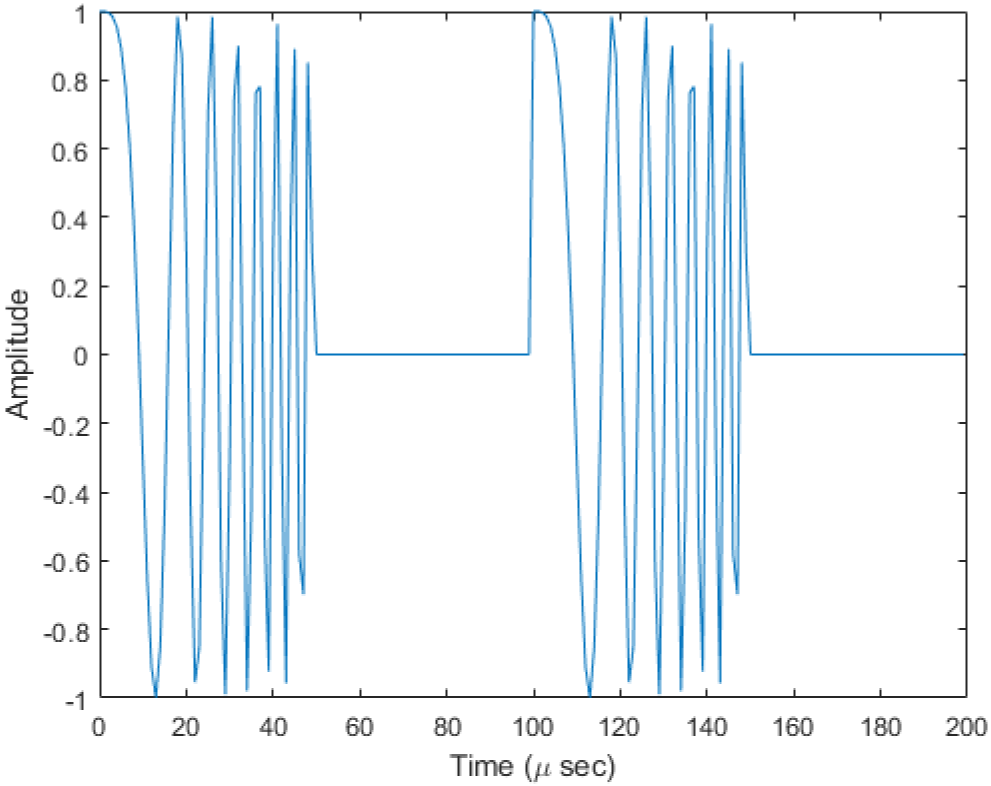
### Create Linear FM Pulses

Construct a linear FM waveform having a sweep bandwidth of 300 kHz, a sample rate of 1 MHz, a pulse width of 50 microseconds, and a pulse repetition frequency of 10 kHz. Generate two pulses.

```
sLFM = phased.LinearFMWaveform('SweepBandwidth',3e5,...
    'OutputFormat','Pulses','SampleRate',1e6,...
    'PulseWidth',50e-6,'PRF',10e3,'NumPulses',2);
```

Obtain and plot the linear FM waveform.

```
wav = step(sLFM);
numpulses = size(wav,1);
t = [0:(numpulses-1)]/sLFM.SampleRate;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```



### Create Linear FM Pulses with Variable PRF

Construct six linear FM waveform pulses having a sweep bandwidth of 300 kHz, a sample rate of 1 MHz, a pulse width of 50 microseconds, and a duty cycle of 20%. Vary the pulse repetition frequency.

Set the sample rate and PRF. The ratio of sample rate to PRF must be an integer.

```
fs = 1e6;
PRF = [10000,25000];
sLFM = phased.LinearFMWaveform('SweepBandwidth',3e5,...
    'OutputFormat','Pulses','SampleRate',fs,...
    'DurationSpecification','Duty Cycle','DutyCycle',.2,...
    'PRF',PRF,'NumPulses',1,'PRFSelectionInputPort',true);
```

Obtain and plot the linear FM waveforms. For the first three calls to the step method, set the PRF to 10kHz using the PRF index. For the next three calls, set the PRF to 25 kHz.

```
wav = [];
for n = 1:6
    idx = floor((n-1)/3)+1;
    wav1 = step(sLFM,idx);
    wav = [wav;wav1];
end
nsamps = size(wav,1);
t = [0:(nsamps-1)]/sLFM.SampleRate;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')

# phased.LOSChannel

**Package:** `phased`

Narrowband LOS propagation channel

## Description

The `phased.LOSChannel` models the propagation of narrowband electromagnetic signals through a line-of-sight (LOS) channel from a source to a destination. In an LOS channel, propagation paths are straight lines from point to point. The propagation model in the LOS channel includes free-space attenuation in addition to attenuation due to atmospheric gases, rain, fog, and clouds. You can use `phased.LOSChannel` to model the propagation of signals between multiple points simultaneously.

While the System object works for all frequencies, the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only. The attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.LOSChannel` System object applies range-dependent time delays to the signals, as well as gains or losses. When either the source or destination is moving, the System object applies Doppler shifts.

Like the `phased.FreeSpace` System object, the `phased.LOSChannel` System object supports two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your LOS channel using the “Construction” on page 1-1256 procedure. You can set the System object properties during construction or leave them at their default values. Some properties are tunable and can be changed at any time.
2. Call the `step` method to compute the propagated signal using the properties of the `phased.LOSChannel` System object.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`sLOS = phased.LOSChannel` creates an LOS attenuating propagation channel System object, `sLOS`.

`sLOS = phased.LOSChannel(Name,Value)` creates a System object, `sLOS`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

## Properties

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

### `Temperature` — Ambient temperature
`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `DryAirPressure` — Atmospheric dry air pressure
`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `WaterVapourDensity` — Atmospheric water vapor density
`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m$^3$.

Example: `7.4`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m$^3$. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

#### Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

### `TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in `step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

### `SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

### `MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

### `MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

#### Dependencies

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

## Methods

| | |
|---|---|
| reset | Reset states of System object |
| step | Propagate signal in LOS channel |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

# Examples

### Propagate Polarized Wave in LOS Channel

Propagate a polarized electromagnetic wave radiating from a short-dipole antenna element. The dipole is rotated 30° around the *y*-axis. Set the orientation of the local axis to coincide with the dipole. Assume the dipole radiates at 30.0 GHz. Propagate the signal toward a target approximately 10 km away.

Create the short-dipole antenna element and radiator System objects. Set the `Polarization` property to `'Combined'` to generate polarized waves.

```
freq = 30.0e9;
c = physconst('LightSpeed');
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 40e9], ...
    'AxisDirection','Z');
radiator = phased.Radiator('Sensor',antenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',freq, ...
    'Polarization','Combined', ...
    'WeightsInputPort',false);
```

Create a signal to radiate. The signal envelope consists of several cycles of a 4 kHz sinusoid with amplitude set to unity. Set the sampling frequency to 1 MHz.

```
fsig = 4.0e3;
fs = 1.0e6;
t = [1:1000]/fs;
signal = sin(2*pi*fsig*t');
laxes = roty(30)*eye(3,3);
```

Use a `phased.FreeSpace` System object to propagate the field from the origin to the destination in free space.

```
fschannel = phased.FreeSpace('PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'TwoWayPropagation',false,...
    'SampleRate',fs);
```

Use a `phased.LOSChannel` System object to propagate the field from the origin to the destination in the LOS channel. Attenuation is due to atmospheric gases and fog.

```
loschannel = phased.LOSChannel('PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'TwoWayPropagation',false,...
    'SampleRate',fs,'SpecifyAtmosphere',true,'LiquidWaterDensity',0.5);
```

Set the signal origin, signal origin velocity, signal destination, and signal destination velocity.

```
source_pos = [0;0;0];
target_pos = [10000;200;0];
source_vel = [0;0;0];
target_vel = [0;0;0];
[~,radiatingAngles] = rangeangle(target_pos,source_pos,laxes);
```

Radiate the signal towards the target. The radiated signal is a `struct` containing the polarized field.

```
rad_sig = radiator(signal,radiatingAngles,laxes);
```

Propagate the signals to the target in free space.

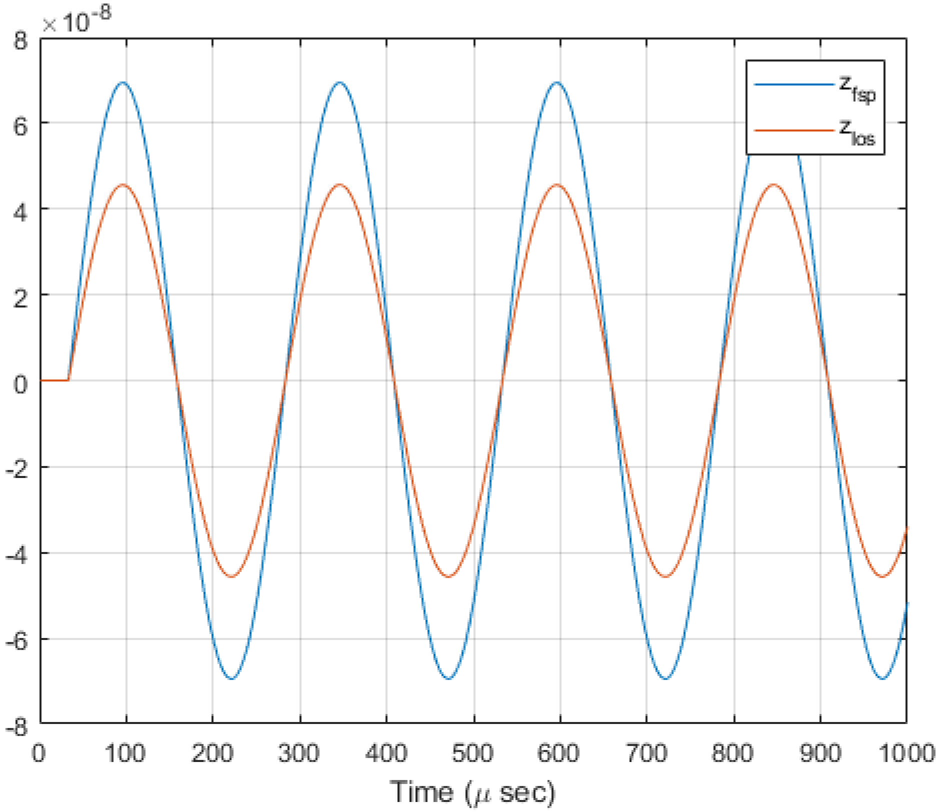
```
prop_sig = fschannel(rad_sig,source_pos,target_pos,...
    source_vel,target_vel);
```

Propagate the signals to the target in the LOS channel.

```
prop_att_sig = loschannel(rad_sig,source_pos,target_pos,...
    source_vel,target_vel);
```

Plot the z-components of both the free-space and LOS-channel-propagated signals.

```
plot(1e6*t,real(prop_sig.Z),1e6*t,real(prop_att_sig.Z))
grid
xlabel('Time (\mu sec)')
legend('z_{fsp}','z_{los}')
```



The LOS channel signal is attenuated as compared to the free-space signal.

# More About

## Path Attenuation or Loss

Attenuation or path loss in the LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- $L_{fsp}$ is the free space path attenuation

- $L_g$ is the atmospheric path attenuation
- $L_c$ is the fog and cloud path attenuation
- $L_r$ is the rain path attenuation

Each path attenuation is in magnitude units, not in dB.

## Free-space Time Delay and Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity $\tau$ is the signal delay and $L_{fsp}$ is the free-space path loss. The delay $\tau$ is given by $R/c$, where $R$ is the propagation distance and $c$ is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \leq \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is $v/\lambda$ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity $v$ is the relative speed of the destination with respect to the origin.

For more details on free-space channel propagation, see [5].

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. The ITU model *Recommendation ITU-R P.676-10:*

*Attenuation by atmospheric gases* is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f)\,.$$

The quantity *N"()* is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, *F(f)*$_\mathrm{i}$, multiplied by a spectral line strength, *S*$_\mathrm{i}$. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7}\left(\frac{300}{T}\right)^3 \exp\left[a_2(1 - \left(\frac{300}{T}\right)\right]P\,.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2(1 - \left(\frac{300}{T}\right)\right]W\,.$$

*P* is the dry air pressure, *W* is the water vapor partial pressure, and *T* is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, *W*, is related to the water vapor density, ρ, by

$$W = \frac{\rho T}{216.7}\,.$$

The total atmospheric pressure is *P* + *W*.

For each oxygen line, $S_i$ depends on two parameters, $a_1$ and $a_2$. Similarly, each water vapor line depends on two parameters, $b_1$ and $b_2$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, $R$. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog* is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where $M$ is the liquid water density in gm/m$^3$. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m$^3$).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where $r$ is the rain rate in mm/hr. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, $R$. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1 + \frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

# reset

**System object:** `phased.LOSChannel`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(sLOS)
```

## Description

`reset(sLOS)` resets the internal state of the `phased.LOSChannel` System object, `sLOS`. If `SeedSource` is a property of this System object and has the value `'Property'`, then this method resets the random number generator state.

## Input Arguments

**`sLOS` — LOS channel**
`phased.LOSChannel` System object

LOS channel, specified as a `phased.LOSChannel` System object.

Example: `phased.LOSChannel`

**Introduced in R2016a**

# step

**System object:** `phased.LOSChannel`
**Package:** `phased`

Propagate signal in LOS channel

## Syntax

```
prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a narrowband signal, `sig`, propagates through a line-of-sight (LOS) channel from a source located at the `origin_pos` position to a destination at the `dest_pos` position. Only one of the `origin_pos` or `dest_pos` arguments can specify multiple positions. The other must contain a single position. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must match the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagating through an LOS channel can be polarized or nonpolarized. For nonpolarized fields, the propagating signal field, `sig`, is a vector or matrix. For polarized fields, `sig` is an array of structures. The structure elements represent an electric field vector in Cartesian form.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `sLOS` — LOS channel

`phased.LOSChannel` System object

LOS channel, specified as a `phased.LOSChannel` System object.

Example: `phased.LOSChannel`

### `sig` — Narrowband signal

*M*-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Narrowband signal, specified as a matrix or `struct` array, depending on whether is signal or polarized or nonpolarized. The quantity *M* is the number of samples in the signal, and *N* is the number of LOS channels. Each channel corresponds to a source-destination pair.

- Narrowband nonpolarized scalar signal. Specify `sig` as an *M*-by-*N* complex-valued matrix. Each column contains one signal propagated along the line-of-sight path.

  The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.
- Narrowband polarized signal. Specify `sig` as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` represents a polarized signal propagated along the line-of-sight path. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`

Complex Number Support: Yes

### origin_pos — Signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

### dest_pos — Signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

### origin_vel — Velocities of signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

### dest_vel — Velocities of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

## Output Arguments

### prop_sig — Narrowband propagated signal

*M*-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Narrowband signal, returned as a matrix or `struct` array, depending on whether signal is polarized or nonpolarized. The quantity *M* is the number of samples in the signal and *N* is the number of narrowband LOS channels. Each channel corresponds to a source-destination pair.

- Narrowband nonpolarized scalar signal. `prop_sig` is an *M*-by-*N* complex-valued matrix.
- Narrowband polarized scalar signal. `prop_sig` is a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The `prop_sig` output contains signal samples arriving at the signal destination within the current time frame. The current time frame is the time frame of the input signals to `step`. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output might not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

## Examples

### Propagate Signal in LOS Channel

Propagate a sinusoidal signal in a line of sight (LOS) channel from a radar at *(1000,0,0)* meters to a target at *(10000,4000,500)* meters in medium fog specified by the liquid water density of 0.05 $g/m^3$. Assume that the radar and the target are stationary. The signal carrier frequency is 10 GHz. The signal frequency is 500 Hz and the sample rate is 8.0 kHz.

Set up the transmitted signal.

```
fs = 8.0e3;
dt = 1/fs;
fsig = 500.0;
fc = 10.0e9;
t = [0:dt:.01];
sig = sin(2*pi*fsig*t);
```

Set the liquid water density and specify the LOS channel System object™.

```
lwd = 0.05;
sLOS = phased.LOSChannel('SampleRate',fs,'SpecifyAtmosphere',true,...
    'LiquidWaterDensity',lwd,'OperatingFrequency',fc);
```

Set the origin and destination of the signal.

```
xradar = [1000,0,0].';
vradar = [0,0,0].';
xtgt = [10000,4000,500].';
vtgt = [0,0,0].';
```

Propagate the signal from origin to destination and plot the result.

```
prog_sig = step(sLOS,sig.',xradar,xtgt,vradar,vtgt);
plot(t*1000,real(prog_sig))
grid
xlabel('Time (milliseconds)')
ylabel('Amplitude')
```

**Introduced in R2016a**

# phased.MatchedFilter

**Package:** phased

Matched filter

## Description

The MatchedFilter object implements matched filtering of an input signal.

To compute the matched filtered signal:

1. Define and set up your matched filter. See “Construction” on page 1-1276.
2. Call step to perform the matched filtering according to the properties of phased.MatchedFilter. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.MatchedFilter creates a matched filter System object, H. The object performs matched filtering on the input data.

H = phased.MatchedFilter(Name,Value) creates a matched filter object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `CoefficientsSource`

Source of matched filter coefficients

Specify whether the matched filter coefficients come from the `Coefficients` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| `'Property'` | The `Coefficients` property of this object specifies the coefficients. |
| `'Input port'` | An input argument in each invocation of `step` specifies the coefficients. |

**Default:** `'Property'`

### `Coefficients`

Matched filter coefficients

Specify the matched filter coefficients as a column vector. This property applies when you set the `CoefficientsSource` property to `'Property'`. This property is tunable.

**Default:** `[1;1]`

### `SpectrumWindow`

Window for spectrum weighting

Specify the window used for spectrum weighting using one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`. Spectrum weighting is often used with linear FM waveform to reduce the sidelobes in the time domain. The object computes the window length internally, to match the FFT length.

**Default:** `'None'`

### `CustomSpectrumWindow`

User-defined window for spectrum weighting

Specify the user-defined window for spectrum weighting using a function handle or a cell array. This property applies when you set the `SpectrumWindow` property to `'Custom'`.

If CustomSpectrumWindow is a function handle, the specified function takes the window length as the input and generates appropriate window coefficients.

If CustomSpectrumWindow is a cell array, then the first cell must be a function handle. The specified function takes the window length as the first input argument, with other additional input arguments if necessary, and generates appropriate window coefficients. The remaining entries in the cell array are the additional input arguments to the function, if any.

**Default:** @hamming

### SpectrumRange

Spectrum window coverage region

Specify the spectrum region on which the spectrum window is applied as a 1-by-2 vector in the form of [StartFrequency EndFrequency] (in hertz). This property applies when you set the SpectrumWindow property to a value other than 'None'.

Note that both StartFrequency and EndFrequency are measured in baseband. That is, they are within [-Fs/2 Fs/2], where Fs is the sample rate that you specify in the SampleRate property. StartFrequency cannot be larger than EndFrequency.

**Default:** [0 1e5]

### SampleRate

Coefficient sample rate

Specify the matched filter coefficients sample rate (in hertz) as a positive scalar. This property applies when you set the SpectrumWindow property to a value other than 'None'.

**Default:** 1e6

### SidelobeAttenuation

Window sidelobe attenuation level

Specify the sidelobe attenuation level (in decibels) of a Chebyshev or Taylor window as a positive scalar. This property applies when you set the SpectrumWindow property to 'Chebyshev' or 'Taylor'.

**Default:** `30`

### `Beta`

Kaiser window parameter

Specify the parameter that affects the Kaiser window sidelobe attenuation as a nonnegative scalar. Please refer to `kaiser` for more details. This property applies when you set the `SpectrumWindow` property to `'Kaiser'`.

**Default:** `0.5`

### `Nbar`

Number of nearly constant sidelobes in Taylor window

Specify the number of nearly constant level sidelobes adjacent to the mainlobe in a Taylor window as a positive integer. This property applies when you set the `SpectrumWindow` property to `'Taylor'`.

**Default:** `4`

### `GainOutputPort`

Output gain

To obtain the matched filter gain, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the matched filter gain, set this property to `false`.

**Default:** `false`

## Methods

| | |
|---|---|
| step | Perform matched filtering |

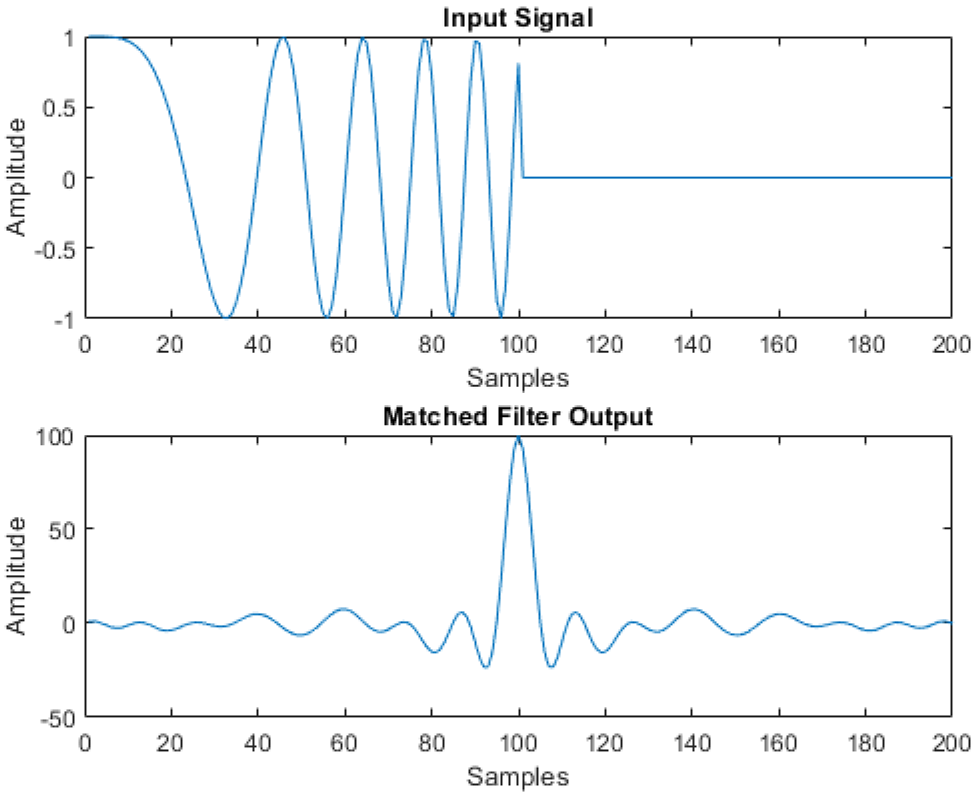
| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Matched Filter for Linear FM Waveform

Construct a matched filter for a linear FM waveform.

```
waveform = phased.LinearFMWaveform('PulseWidth',1e-4,'PRF',5e3);
x = waveform();
filter = phased.MatchedFilter( ...
    'Coefficients',getMatchedFilter(waveform));
y = filter(x);
subplot(2,1,1),plot(real(x))
xlabel('Samples')
ylabel('Amplitude')
title('Input Signal')
subplot(2,1,2),plot(real(y))
xlabel('Samples')
ylabel('Amplitude')
title('Matched Filter Output')
```

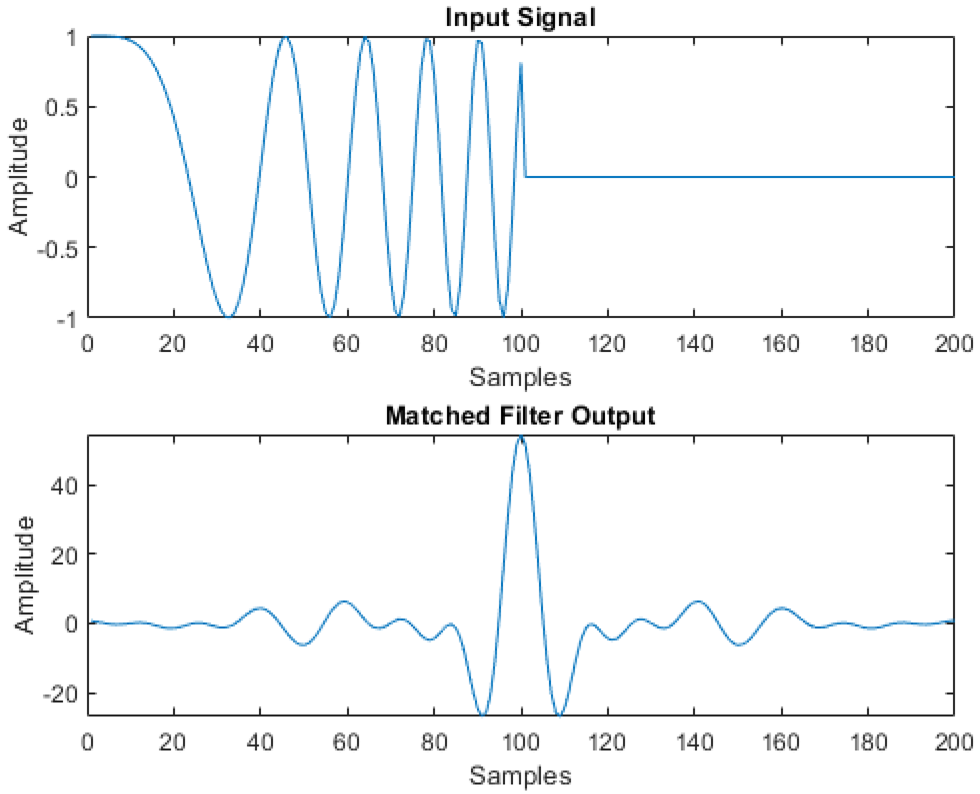


### Matched Filter Using Hamming Window

Apply a matched filter, using a Hamming window to do spectrum weighting.

```
waveform = phased.LinearFMWaveform('PulseWidth',1e-4,'PRF',5e3);
x = waveform();
filter = phased.MatchedFilter( ...
    'Coefficients',getMatchedFilter(waveform), ...
    'SpectrumWindow','Hamming');
y = filter(x);
subplot(2,1,1)
```

```
plot(real(x))
xlabel('Samples')
ylabel('Amplitude')
title('Input Signal')
subplot(2,1,2)
plot(real(y))
xlabel('Samples')
ylabel('Amplitude')
title('Matched Filter Output')
```



Input Signal

Matched Filter Output

### Matched Filter with Custom Window

Apply a matched filter, using a custom Gaussian window for spectrum weighting.

```
waveform = phased.LinearFMWaveform('PulseWidth',1e-4,'PRF',5e3);
x = waveform();
filter = phased.MatchedFilter( ...
    'Coefficients',getMatchedFilter(waveform), ...
    'SpectrumWindow','Custom', ...
    'CustomSpectrumWindow',{@gausswin,2.5});
y = filter(x);
subplot(2,1,1)
plot(real(x))
xlabel('Samples')
ylabel('Amplitude')
title('Input Signal')

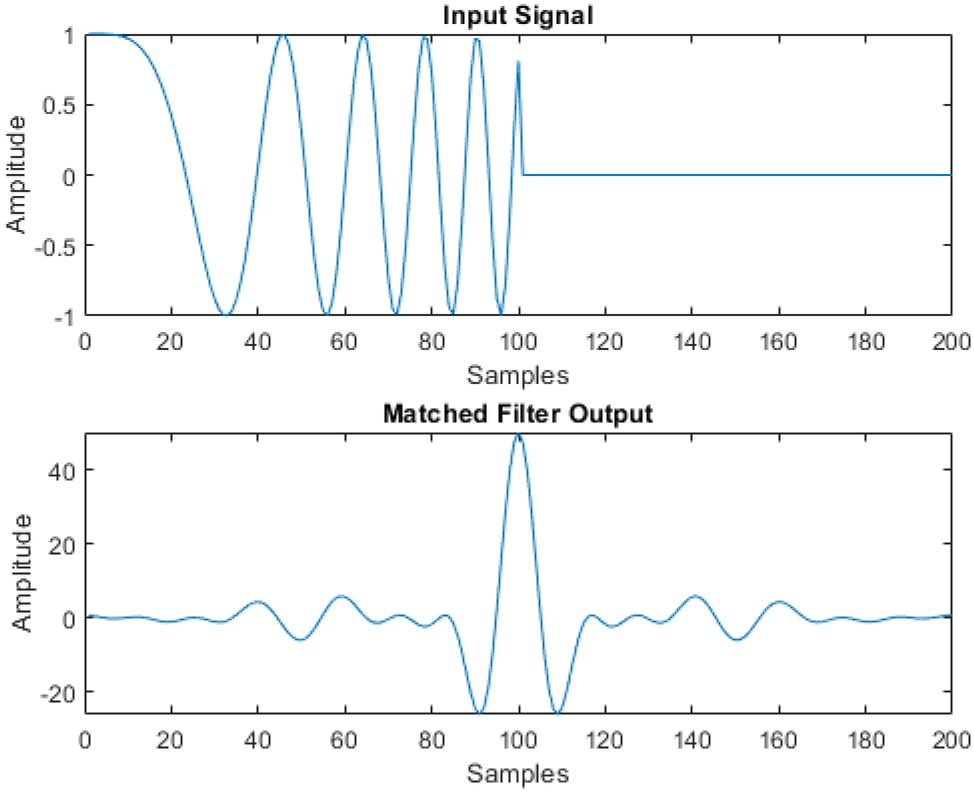
title('Matched Filter Output')
```



## Algorithms

The filtering operation uses the overlap-add method.

Spectrum weighting produces a transfer function

$$H'(F) = w(F)H(F)$$

where $w(F)$ is the window and $H(F)$ is the original transfer function.

For further details on matched filter theory, see [1]or [2].

**Introduced in R2012a**

# step

**System object:** phased.MatchedFilter
**Package:** phased

Perform matched filtering

## Syntax

```
Y = step(H,X)
Y = step(H,X,COEFF)
[Y,GAIN] = step( ___ )
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) applies the matched filtering to the input X and returns the filtered result in Y. The filter is applied along the first dimension. Y and X have the same dimensions. The initial transient is removed from the filtered result.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Y = step(H,X,COEFF) uses the input COEFF as the matched filter coefficients. This syntax is available when you set the CoefficientsSource property to 'Input port'.

[Y,GAIN] = step( ___ ) returns additional output GAIN as the gain (in decibels) of the matched filter. This syntax is available when you set the GainOutputPort property to true.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

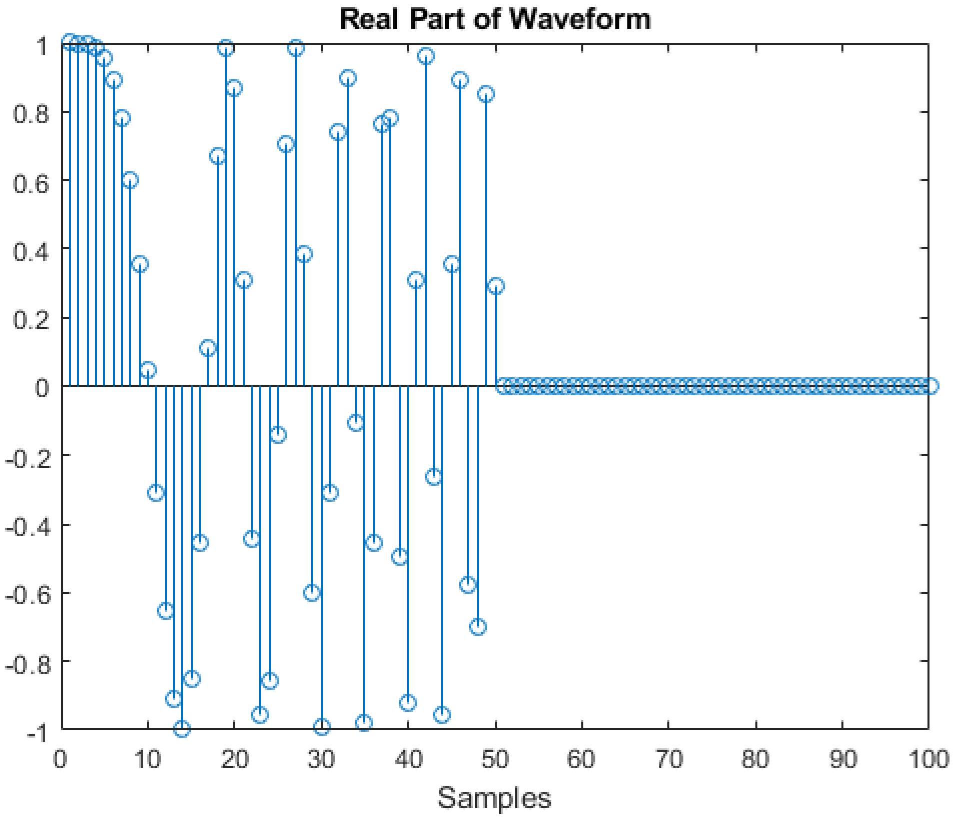
### Match Filter Linear FM Waveform

Construct a linear FM waveform with a sweep bandwidth of 300 kHz and a pulse width of 50 µs. Obtain the matched filter coefficients using the `getMatchedFilter` method. Then, use the `step` to match-filter the waveform.

```
waveform = phased.LinearFMWaveform('SweepBandwidth',3e5,...
    'OutputFormat','Pulses','SampleRate',1e6,...
    'PulseWidth',50e-6,'PRF',1e4);
wav = waveform();
```

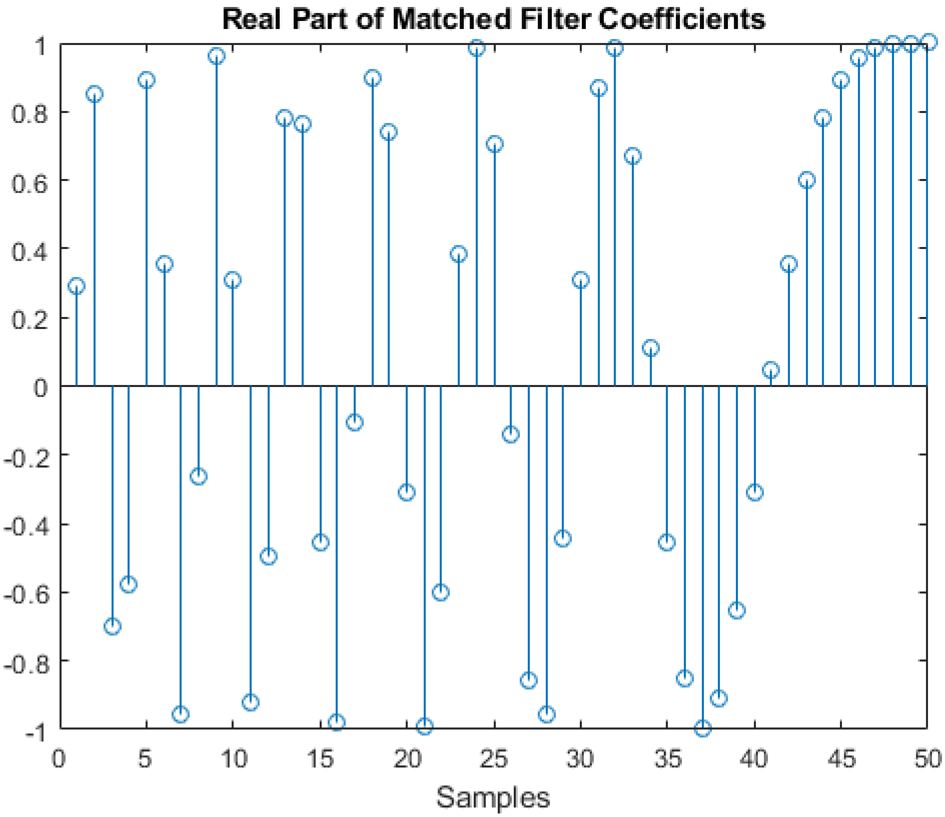
Plot the entire waveform. The length of the waveform is the pulse repetition interval (100 samples).

```
stem(real(wav))
xlabel('Samples')
title('Real Part of Waveform')
```



Obtain the matched filter coefficients for the linear FM waveform. The length of the matched filter coefficients is the length of the pulse.

```
mfcoeffs = getMatchedFilter(waveform);
stem(real(mfcoeffs))
xlabel('Samples')
title('Real Part of Matched Filter Coefficients')
```



Use `phased.MatchedFilter` `step` method to obtain the matched filter output.

```
filter = phased.MatchedFilter('Coefficients',mfcoeffs);
mfoutput = filter(wav);
stem(real(mfoutput))
xlabel('Samples')
title('Real Part of Matched Filter Output')
```

# phased.MonopulseEstimator

**Package:** `phased`

Amplitude monopulse direction finding

## Description

The phased.MonopulseEstimator System object implements a target direction estimator using the amplitude monopulse technique with arbitrary array geometry. The object works with the sum and difference channels that are output from the `phased.MonopulseFeed` System object or your own sum-difference channel generator. The output is an estimate of the target direction in azimuth and elevation. You can use the object for target direction estimation and target tracking.

To create a monopulse estimator:

1. Create the `phased.MonopulseEstimator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
estimator = phased.MonopulseEstimator
estimator = phased.MonopulseEstimator(Name,Value)
```

### Description

`estimator = phased.MonopulseEstimator` creates a monopulse estimator System object, `estimator`, with default property values.

`estimator = phased.MonopulseEstimator(Name,Value)` creates an estimator with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN). Enclose each property name in single quotes.

Example: `estimator = phased.MonopulseEstimator('SensorArray',phased.URA,'OperatingFrequency',300e6,'Coverage','Azimuth')` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The estimator estimates azimuth from the sum channel and azimuth difference channel. The estimator operates at 300 MHz.

**Note** You can also create a `phased.MonopulseEstimator` object from a `phased.MonopulseFeed` object using the `getMonopulseEstimator` object function.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### SensorArray — Sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox array

Sensor array, specified as an array System object belonging to Phased Array System Toolbox. The sensor array can contain subarrays.

Example: `phased.URA`

### PropagationSpeed — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `Coverage` — Monopulse coverage

`'3D'` (default) | `'Azimuth'`

Coverage of monopulse estimator, specified as `'3D'` or `'Azimuth'`. When you set this property to `'3D'`, the monopulse estimator uses the sum channel and both azimuth and elevation difference channels. When you set this property to `'Azimuth'`, the estimator uses the sum channel and the azimuth difference channel.

### `SquintAngle` — Squint angle

`10` (default) | scalar | real-valued 2-by-1 vector

Squint angle, specified as a scalar or real-valued 2-by-1 vector. The squint angle is the separation angle or angles between the sum beam and the beams along the azimuth and elevation directions.

- When you set the `Coverage` property to `'Azimuth'`, set the `SquintAngle` property to a scalar.
- When you set the `Coverage` property to `'3D'`, you can specify the squint angle as either a scalar or vector. If you set the `SquintAngle` property to a scalar, then the squint angle is the same along both the azimuth and elevation directions. If you set the `SquintAngle` property to a 2-by-1 vector, its elements specify the squint angle along the azimuth and elevation directions.

Example: `[20;5]`

### `OutputFormat` — Output direction format

`'Angle'` (default) | `'Angle offset'`

Format of direction output, specified as `'Angle'` or `'Angle offset'`. When you set this property to `'Angle'`, the output angles are in the direction of the target. When you set this property to `'Angle offset'`, the output is the angle offset from the array steering direction.

**SumDifferenceRatioOutputPort — Enable sum-difference ratio output**
false (default) | true

Set this property to true to output the ratio of the sum and difference channels in the azimuth and elevation directions. Set this property to false to not output the ratios. The ratio is often used as an error control signal.

Data Types: logical

# Usage

# Syntax

```
angest = estimator(sumchan,diffazchan,steervec)
angest = estimator(sumchan,diffazchan,diffelchan,steervec)
[angest,dratio] = estimator( ___ )
```

## Description

angest = estimator(sumchan,diffazchan,steervec) returns the estimated target angle, angest, derived from the sum channel signal, sumchan, and the azimuth difference channel signal, diffazchan. steervec specifies the array steering direction. To use this syntax, set the Coverage property to 'Azimuth'.

angest = estimator(sumchan,diffazchan,diffelchan,steervec) also specifies the elevation difference channel signal, diffelchan. To use this syntax, set the Coverage property to '3D'.

[angest,dratio] = estimator( ___ ) also returns the sum and difference ratio, dratio. To use this syntax, set the SumDifferenceRatioOutputPort property to true.

You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of the enabling properties. For example:

```
[angest,dratio] = estimator(X,steervec)
```

## Input Arguments

### `sumchan` — Sum-channel signal

complex-valued *N*-by-1 column vector

Sum-channel signal, specified as a complex-valued *N*-by-1 column vector. *N* is the number of snapshots in the signal.

Data Types: `double`
Complex Number Support: Yes

### `diffazchan` — Azimuth difference-channel signal

complex-valued *N*-by-1 column vector

Azimuth difference-channel signal, specified as a complex-valued *N*-by-1 column vector. *N* is the number of snapshots in the signal.

Data Types: `double`
Complex Number Support: Yes

### `diffelchan` — Elevation difference-channel signal

complex-valued *N*-by-1 column vector

Elevation difference-channel signal, specified as a complex-valued *N*-by-1 column vector. *N* is the number of snapshots in the signal.

#### Dependencies

To enable this output argument, set the `Coverage` property to `'3D'`.

Data Types: `double`
Complex Number Support: Yes

### `steervec` — Array steering direction

scalar | real-valued 2-by-1 column vector

Array steering direction, specified as a scalar or real-valued 2-by-1 column vector.

- When you set the `Coverage` property to `'Azimuth'`, the steering direction is a scalar and represents the azimuth steering angle.
- When you set the `Coverage` property to `'3D'`, the steering vector has the form `[azimuthAngle; elevationAngle]`, where `azimuthAngle` is the azimuth steering angle and `elevationAngle` is the elevation steering angle.

Units are in degrees. Azimuth angles lie between –180° and 180°, inclusive and elevation angles must lie between –90° and 90°, inclusive.

Example: `[40;10]`

Data Types: `double`

## Output Arguments

### `angest` — Estimated direction of target

real-valued 1-by-*N* vector | real-valued 2-by-*N* matrix

Estimated direction of target, returned as a real-valued 1-by-*N* vector or real-valued 2-by-*N* matrix. *N* is the number of snapshots in the signal. Units are in degrees.

- When you set the `Coverage` property to `'Azimuth'`, `angest` is a real-valued 1-by-*N* vector. The elements contain the estimated target direction azimuth angle at each signal snapshot.
- When you set the `Coverage` property to `'3D'`, `angest` is a real-valued 2-by-*N* matrix. Each column contains the estimated target direction in the form `[azimuthAngle;elevationAngle]`, where `azimuthAngle` is the estimated azimuth angle, and `elevationAngle` is the estimated elevation angle.

If you set the `OutputFormat` property to `'Angle offset'`, each element of the vector or matrix represent an offset from the steering vector direction.

Data Types: `double`

### `dratio` — Ratio of sum and difference channels

real-valued 1-by-*N* vector | real-valued 2-by-*N* matrix

Ratio of sum and difference channels, returned as a real-valued 1-by-*N* vector or real-valued 2-by-*N* matrix. *N* is the number of snapshots in the signal. Units are in degrees.

- When you set the `Coverage` property to `'Azimuth'`, `dratio` is a real-valued 1-by-*N* vector. The elements contain the ratio of the sum to azimuth difference channel at each signal snapshot.
- When you set the `Coverage` property to `'3D'`, `dratio` is a real-valued 2-by-*N* matrix. The elements of the first row contain the ratio of the sum to azimuth difference channel at each signal snapshot. The elements of the second row contain the ratio of the sum to elevation difference channel at each signal snapshot.

#### Dependencies

To enable this output argument, set the `SumDifferenceRatioOutputPort` property to `true`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Create Sum and Difference Channels for URA

After creating sum and difference channels, determine the direction of a target at approximately 24 degrees azimuth and 40 degrees elevation with respect to a 5-by-5 uniform rectangular array.

Create a monopulse feed system based on a URA.

```
fc = 200e6;
c = physconst('LightSpeed');
lambda = c/fc;
array = phased.URA('Size',[5 5],'ElementSpacing',lambda/2);
feed = phased.MonopulseFeed('SensorArray',array,'OperatingFrequency', ...
    fc,'Coverage','3D','AngleOutputPort',true);
```

Create a signal using a steering vector.

```
steervector = phased.SteeringVector('SensorArray',array);
x = steervector(feed.OperatingFrequency,[24;40]).';
```

Obtain the sum and difference channels and the estimated target angle.

```
[sumch,azch,elch,est_dir] = feed(x,[30;35]);
disp(est_dir)
```

```
   24.3705
   41.1997
```

Use a derived `phased.MonopulseEstimator` object to also obtain the target angle.

```
estimator = getMonopulseEstimator(feed);
est_dir = estimator(sumch,azch,elch,[30;35])
```

```
est_dir = 2×1

   24.3705
   41.1997
```

### Find Direction of Target

Determine the direction of a target using monopulse processing of signals arriving on a URA. The target echo is first detected before applying monopulse processing.

```
array = phased.URA('Size',4);
collect = phased.Collector('Sensor',array);
feed = phased.MonopulseFeed('SensorArray',array,'Coverage','3D');
estimator = phased.MonopulseEstimator('SensorArray',array,'Coverage','3D');

% Create a 100-sample random source signal with a single spike to simulate
% an echo.
x = sqrt(0.01/2)*(randn(100,1)+1i*randn(100,1));
x(20) = 1;
targetangle = [31;9];
rx = collect(x,targetangle);
```

Point the monopulse in a different direction from the target. Then, create the sum and difference angles.

```
steerangle = [30;10];
[sumch,azch,elch] = feed(rx,steerangle);

% Detect the target by finding the peak of the sum channel.
[~,idx] = max(abs(sumch));

% Estimate the arrival angle using a monopulse estimator.
est_dir = estimator(sumch(idx),azch(idx),elch(idx),steerangle)
```

```
est_dir = 2×1

   31.1307
    9.0132
```

# phased.MonopulseFeed

**Package:** `phased`

Creates sum and difference channels

## Description

The phased.MonopulseFeed System object implements a monopulse feed system for the amplitude sum and difference monopulse tracker. This object combines received signals from an arbitrary array to form sum and difference channels. You can use this object as a feed for the `phased.MonopulseEstimator` System object.

To create a monopulse feed system:

1. Create the `phased.MonopulseFeed` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
feed = phased.MonopulseFeed
feed = phased.MonopulseFeed(Name,Value)
```

### Description

`feed = phased.MonopulseFeed` creates a monopulse feed System object, `feed`, with default property values.

`feed = phased.MonopulseFeed(Name,Value)` creates a feed system with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN). Enclose each property name in single quotes.

Example: `feed = phased.MonopulseFeed('SensorArray',phased.URA,'OperatingFrequency',300e6,'Coverage','Azimuth')` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The feed forms only the sum channel and azimuth difference channel. The feed system operates at 300 MHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**SensorArray — Sensor array**
`phased.ULA` array with default property values (default) | Phased Array System Toolbox array

Sensor array, specified as an array System object belonging to Phased Array System Toolbox. The sensor array can contain subarrays.

Example: `phased.URA`

**PropagationSpeed — Signal propagation speed**
`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

**OperatingFrequency — Operating frequency**
`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `Coverage` — Monopulse coverage

`'3D'` (default) | `'Azimuth'`

Coverage directions of monopulse feed, specified as `'3D'` or `'Azimuth'`. When you set this property to `'3D'`, the monopulse feed forms the sum channel and both azimuth and elevation difference channels. When you set this property to `'Azimuth'`, the monopulse feed forms the sum channel and the azimuth difference channel.

Example: `'Azimuth'`

### `SquintAngle` — Squint angle

`10` (default) | scalar | real-valued 2-by-1 vector

Squint angle, specified as a scalar or real-valued 2-by-1 vector. The squint angle is the separation angle or angles between the sum beam and the beams along the azimuth and elevation directions.

- When you set the `Coverage` property to `'Azimuth'`, set the `SquintAngle` property to a scalar.
- When you set the `Coverage` property to `'3D'`, you can specify the squint angle as either a scalar or vector. If you set the `SquintAngle` property to a scalar, then the squint angle is the same along both the azimuth and elevation directions. If you set the `SquintAngle` property to a 2-by-1 vector, its elements specify the squint angle along the azimuth and elevation directions.

Example: `[20;5]`

### `AngleOutputPort` — Enable angle estimate output

`false` (default) | `true`

Enable angle estimate output, specified as `false` or `true`. Set this property to `true` to output the angle estimate in addition to sum and difference channels. Set this property to `false` to only output sum and difference channels.

Data Types: `logical`

# Usage

# Syntax

```
[sumchan,diffazchan] = feed(X,steervec)
[sumchan,diffazchan,diffelchan] = feed(X,steervec)
[___,angest] = feed(X,steervec)
```

## Description

`[sumchan,diffazchan] = feed(X,steervec)` returns the sum channel signal, `sumchan`, and the azimuth difference channel signal, `diffazchan`, computed from the input signal, `X`. `steervec` specifies the array steering direction. To use this syntax, set the `Coverage` property to `'Azimuth'`.

`[sumchan,diffazchan,diffelchan] = feed(X,steervec)` also returns the elevation difference channel signal, `diffelchan`. To use this syntax, set the `Coverage` property to `'3D'`.

`[___,angest] = feed(X,steervec)` also returns the estimated direction angle, `angest`. To use this syntax, set the `AngleOutputPort` property to `true`.

## Input Arguments

**`X` — Input signal**
complex-valued M-by-N matrix | -by-*N* matrix

Input signal, specified as a complex-valued *M*-by-*N* matrix, where *M* is the number of samples or snapshots of data, and *N* is the number of array elements. If the array contains subarrays, then *N* is the number of subarrays.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

**`steervec` — Array steering direction**
scalar | real-valued 2-by-1 column vector

Array steering direction, specified as a scalar or real-valued 2-by-1 column vector.

- When you set the `Coverage` property to `'Azimuth'`, the steering direction is a scalar and represents the azimuth steering angle.
- When you set the `Coverage` property to `'3D'`, the steering vector has the form `[azimuthAngle; elevationAngle]`, where `azimuthAngle` is the azimuth steering angle and `elevationAngle` is the elevation steering angle.

Units are in degrees. Azimuth angles lie between –180° and 180°, inclusive and elevation angles must lie between –90° and 90°, inclusive.

Example: `[40;10]`

Data Types: `double`

You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of the enabling properties. For example,

```
array = phased.URA('Size',[5 5]);
feed = phased.MonopulseFeed('SensorArray',array,'Coverage','3D', ...
       'AngleOutputPort',true);
[sumch,dazch,delch,angest] = feed(X,steervec);
```

## Output Arguments

### `sumchan` — Sum-channel signal

complex-valued *M*-by-*1* column vector

Sum-channel signal, returned as a complex-valued *M*-by-1 column vector, where *M* is the number of rows of `X`.

Data Types: `double`
Complex Number Support: Yes

### `diffazchan` — Azimuth difference-channel signal

complex-valued *M*-by-*1* column vector

Azimuth difference-channel signal, returned as a complex-valued *M*-by-1 column vector, where *M* is the number of rows of `X`.

Data Types: `double`
Complex Number Support: Yes

**`diffelchan` — Elevation difference-channel signal**
complex-valued *M*-by-*1* column vector

Elevation difference-channel signal, returned as a complex-valued *M*-by-1 column vector, where *M* is the number of rows of `X`.

**Dependencies**

To enable this output argument, set the `Coverage` property to `'3D'`.

Data Types: `double`
Complex Number Support: Yes

**`angest` — Estimated direction of target**
real-valued 2-by-1 vector

Estimated direction of target, returned as a real-valued 2-by-1 vector in the form `[azimuth,elevation]`. Units are in degrees.

**Dependencies**

To enable this output argument, set the `AngleOutputPort` property to `true`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to phased.MonopulseFeed

| | |
|---|---|
| getMonopulseEstimator | Create monopulse estimator from monopulse feed |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

## Examples

### Create Sum and Difference Channels for URA

After creating sum and difference channels, determine the direction of a target at approximately 24 degrees azimuth and 40 degrees elevation with respect to a 5-by-5 uniform rectangular array.

Create a monopulse feed system based on a URA.

```
fc = 200e6;
c = physconst('LightSpeed');
lambda = c/fc;
array = phased.URA('Size',[5 5],'ElementSpacing',lambda/2);
feed = phased.MonopulseFeed('SensorArray',array,'OperatingFrequency', ...
    fc,'Coverage','3D','AngleOutputPort',true);
```

Create a signal using a steering vector.

```
steervector = phased.SteeringVector('SensorArray',array);
x = steervector(feed.OperatingFrequency,[24;40]).';
```

Obtain the sum and difference channels and the estimated target angle.

```
[sumch,azch,elch,est_dir] = feed(x,[30;35]);
disp(est_dir)
```

```
   24.3705
   41.1997
```

Use a derived `phased.MonopulseEstimator` object to also obtain the target angle.

```
estimator = getMonopulseEstimator(feed);
est_dir = estimator(sumch,azch,elch,[30;35])
```

```
est_dir = 2×1

   24.3705
   41.1997
```

## Input Arguments

**`feed` — Monopulse feed**
`phased.MonopulseFeed` System object

Monopulse feed, specified as a System object.

## Output Arguments

**`estimator` — Monopulse estimator**
`phased.MonopulseEstimator` System object

Monopulse estimator, returned as a `phased.MonopulseEstimator` System object.

MFSK waveform

## Description

The multiple frequency shift keying (MFSK) waveform is used in automotive radar to improve simultaneous range and Doppler estimation of multiple targets. The `MFSKWaveform` System object creates the baseband representation of an MFSK waveform. An MFSK waveform consists of two interleaved sequences of increasing frequencies, as described in “Algorithms” on page 1-1316.

To obtain waveform samples:

1. Define and set up the MFSK waveform. See “Construction” on page 1-1312.
2. Call `step` to generate the MFSK waveform samples according to the properties of `phased.MFSKWaveform`. The behavior of `step` is specific to each object in the toolbox. The output of the `step` method is controlled by the `OutputFormat` property, which has no effect on the properties of the waveform.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

## Construction

`sMFSK = phased.MFSKWaveform` creates an MFSK waveform System object, `sMFSK`.

`sMFSK = phased.MFSKWaveform(Name,Value)` creates an MFSK waveform object, `sMFSK`, with additional properties specified by one or more `Name-Value pair` arguments. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

## Properties

### `SampleRate` — Sample rate

1e6 (default) | positive scalar

Sample rate of the signal, specified as a positive scalar. Units are hertz.

Example: 96e6

Data Types: `double`

### `SweepBandwidth` — MFSK sweep bandwidth

1e5 (default) | positive scalar

MFSK sweep bandwidth, specified as a positive scalar. Units are in hertz. The sweep bandwidth is the difference between the highest and lowest frequencies of either sequence.

Example: 9e7

Data Types: `double`

### `StepTime` — Duration of frequency step

1e-4 (default) | positive scalar

Time duration of each frequency step, specified as a positive scalar in seconds.

Example: 0.2e-3

Data Types: `double`

### `StepsPerSweep` — Total number of frequency steps

64 (default) | even positive integer

Total number of frequency steps in a sweep, specified as an even positive integer.

Example: 16

Data Types: `double`

### `FrequencyOffset` — Chirp offset frequency

1000 (default) | real scalar

Chirp offset frequency, specified as a real scalar. Units are in hertz. The offset determines the frequency translation between the two sequences.

Example: 500

Data Types: `double`

### `OutputFormat` — Output signal grouping

`'Steps'` (default) | `'Sweeps'` | `'Samples'`

Output signal grouping, specified as one of `'Steps'`, `'Sweeps'`, or `'Samples'`. This property has no effect on the waveform but determines the output form of the `step` method.

- `'Steps'` — The output consists of all samples contained in an integer number of frequency steps, `NumSteps`.
- `'Samples'` — The output consists of an integer number of samples, `NumSamples`.
- `'Sweeps'` — The output consists of all samples contained in an integer number of sweeps, `NumSweeps`.

Example: `'Samples'`

Data Types: `char`

### `NumSamples` — Number of samples in output

1 (default) | positive integer

Number of samples in output, specified as a positive integer. This property applies only when you set `OutputFormat` to `'Samples'`.

Example: 200

Data Types: `double`

### `NumSteps` — Number of frequency steps in output

1 (default) | positive integer

Number of frequency steps in output, specified as a positive integer. This property applies only when you set `OutputFormat` to `'Steps'`.

Example: 10

Data Types: `double`

### `NumSweeps` — Number of sweeps in output

1 (default) | positive integer

Number of sweeps in output, specified as a positive integer. This property applies only when you set `OutputFormat` to `'Sweeps'`.

Example: 5

Data Types: `double`

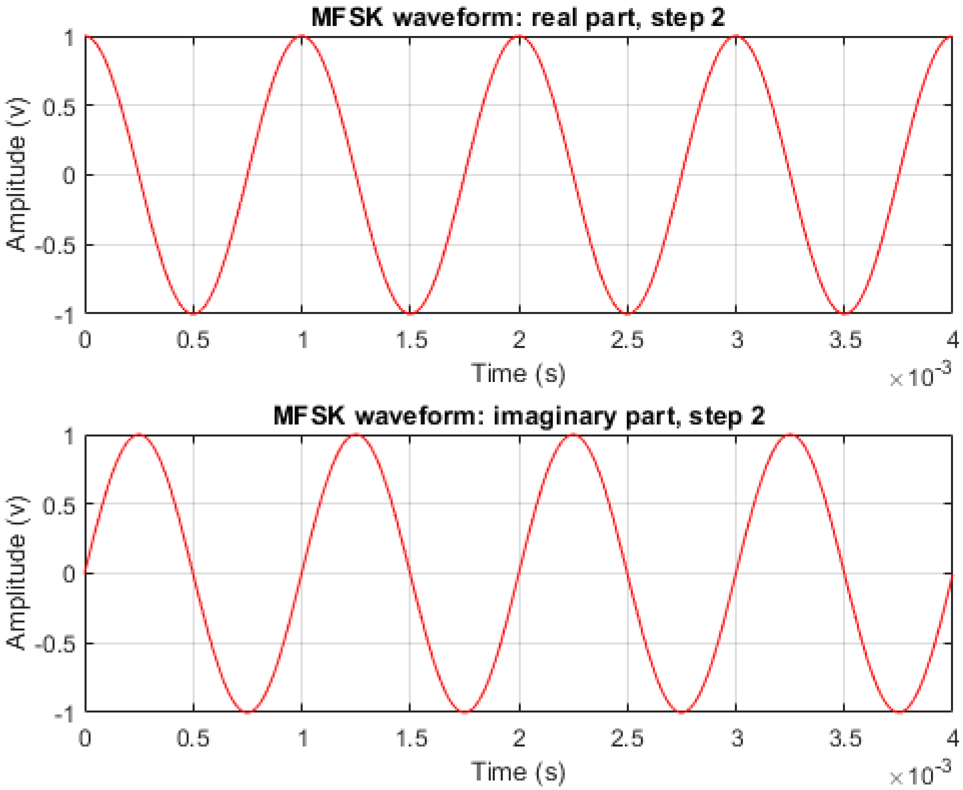
### Plot MFSK Waveform

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps with a step time of 4 milliseconds. Set the frequency offset to 1 kHz. There are 4000 samples per step.

```
fs = 1e6;
fsweep = 1e5;
tstep = 4e-3;
numsteps = 52;
foffset = 1000;
noutputsteps = 4;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Steps',...
    'NumSteps',noutputsteps);
```

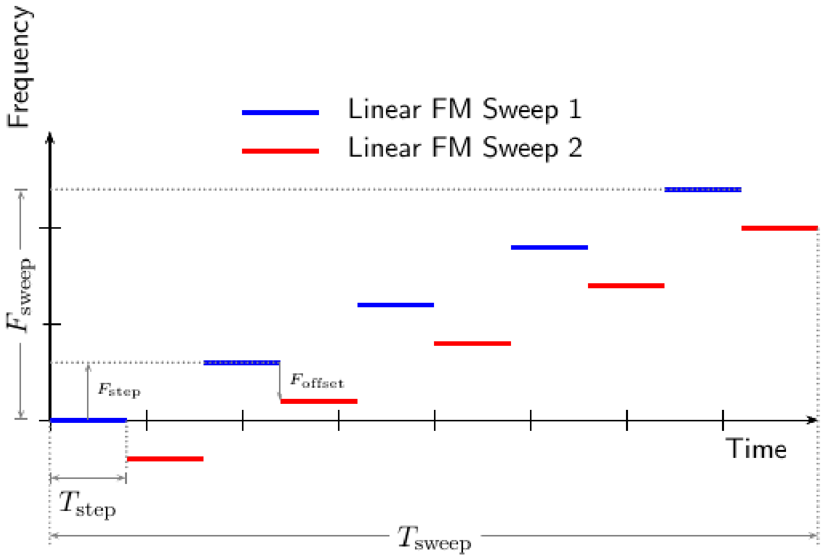
Plot the real and imaginary components of the second step of the waveform using the `plot` method. Set the plot color to red.

```
plot(sMFSK,'PlotType','complex','StepIdx',2,'r')
```



## Algorithms

An MFSK waveform consists of two interleaved stepped-frequency sequences, as shown in this time-frequency diagram.



Each sequence is a set of continuous waveform (CW) signals increasing in frequency. The offset, $F_{\text{offset}}$, between the two sequences is constant and can be positive or negative. A complete waveform consists of an even number of steps, $N$, of equal duration, $T_{\text{step}}$. Then, each sequence consists of $N/2$ steps. The sweep frequency, $F_{\text{sweep}}$, is the difference between the lowest and highest frequency of either sequence. $F_{\text{sweep}}$ is always positive, indicating increasing frequency. The frequency difference between successive steps of each sequence is given by

$$F_{\text{step}} = F_{\text{sweep}}/(N/2-1).$$

The lowest frequency of the first sequence is always 0 hertz and corresponds to the carrier frequency of the bandpass signal. The lowest frequency of the second sequence can be positive or negative and is equal to $F_{\text{offset}}$. Negative frequencies correspond to bandpass frequencies that are lower than the carrier frequency. The duration of the waveform is given by $T_{\text{sweep}} = N *T_{\text{step}}$. The System object properties corresponding to the signal parameters are

| Signal Parameter | Property |
|---|---|
| $F_{\text{sweep}}$ | 'SweepBandwidth' |
| $T_{\text{step}}$ | 'StepTime' |
| $N$ | 'StepsPerSweep' |
| $F_{\text{offset}}$ | 'FrequencyOffset' |

# plot

**System object:** `phased.MFSKWaveform`
**Package:** `phased`

Plot continuous MFSK waveform

## Syntax

```
plot(sMFSK)
plot(sMFSK,Name,Value)
plot(sMFSK,Name,Value,LineSpec)
h = plot( ___ )
```

## Description

`plot(sMFSK)` plots the real part of the waveform specified by `sMFSK`.

`plot(sMFSK,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(sMFSK,Name,Value,LineSpec)` specifies the same line color, line style, or marker options that are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

## Input Arguments

### sMFSK — MFSK waveform

MFSK waveform System object

MFSK waveform, specified as a `phased.MFSKWaveform` System object.

Example: `sMFSK = phased.MFSKWaveform;`

### LineSpec — Plot style

`'b'` (default) | character vector

Plot style, specified as a character vector. You can specify the same line color, style, or marker options that are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Example: `'k.'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `PlotType` — Waveform component to plot

`'real'` (default) | `'imag'` | `'complex'`

Waveform component to plot, specified as the comma-separated pair consisting of `'PlotType'` and one of the following:

- `'real'` — Plots the real part of the waveform
- `'imag'` — Plots the imaginary part of the waveform
- `'complex'` — Plots both parts of the waveform

Example: `'PlotType','complex'`

### `StepIdx` — Index of step

1 (default) | positive integer

Index of the step to plot, specified as the comma-separated pair consisting of `'StepIdx'` and a positive integer. If you specify a `'StepIdx'` value greater than `'StepsPerSweep'`, the frequency corresponds to the `mod('StepIdx','StepsPerSweep') value`.

# Output Arguments

### h — Plot handle

double

Plot handle(s) to the line or lines in the figure, returned as a double. When `PlotType` is set to `'complex'`, `h` is a 2-by-1 column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

## Examples

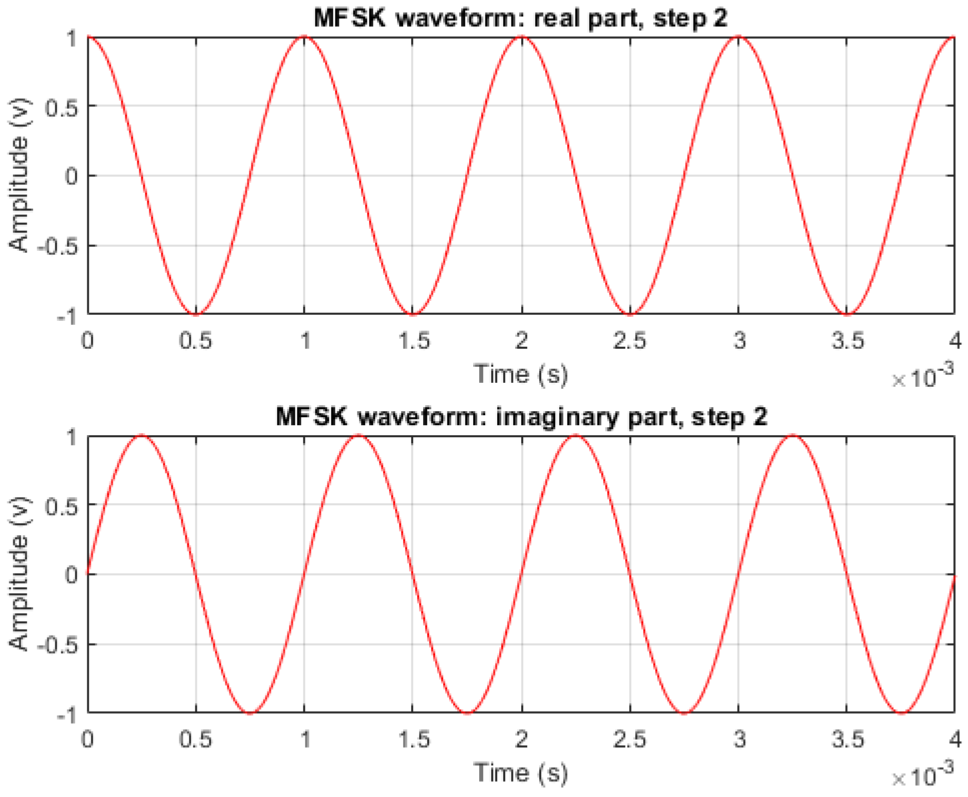
### Plot MFSK Waveform

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps with a step time of 4 milliseconds. Set the frequency offset to 1 kHz. There are 4000 samples per step.

```
fs = 1e6;
fsweep = 1e5;
tstep = 4e-3;
numsteps = 52;
foffset = 1000;
noutputsteps = 4;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Steps',...
    'NumSteps',noutputsteps);
```

Plot the real and imaginary components of the second step of the waveform using the `plot` method. Set the plot color to red.

```
plot(sMFSK,'PlotType','complex','StepIdx',2,'r')
```



**Introduced in R2015a**

# reset

**System object:** `phased.MFSKWaveform`
**Package:** `phased`

Reset states of the MFSK waveform object

## Syntax

```
reset(sMFSK)
```

## Description

`reset(sMFSK)` resets the internal states of the `phased.MFSKWaveform` object, `sMFSK`, to their initial values.

## Input Arguments

### `sMFSK` — MFSK waveform

System object

MFSK waveform, specified as a `phased.MFSKWaveform` System object.

Example: `sMFSK= phased.MFSKWaveform;`

**Introduced in R2015a**

# step

**System object:** `phased.MFSKWaveform`
**Package:** `phased`

Samples of continuous MFSK waveform

## Syntax

```
Y = step(sMFSK)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sMFSK)` returns samples of the MFSK waveform in a *N*-by-1 complex valued column vector, `Y`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

**`sMFSK` — MFSK waveform**
System object

MFSK waveform, specified as a `phased.MFSKWaveform` System object.

Example: `sMFSK= phased.MFSKWaveform;`

## Output Arguments

### Y — Output samples

*N*-by-1 complex valued vector

Output samples of MFSK waveform, returned as an *N*-by-1 complex valued vector. When the `step` method reaches the end of the waveform, the output samples wrap around from the start of the waveform, yielding a periodic waveform.

## Examples

### Construct MFSK Step Output

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps, with a step time of 4 milliseconds. Set the frequency offset to 1 kHz. There are 4000 samples per step.

```
fs = 1e6;
fsweep = 1e5;
tstep = 40e-4;
numsteps = 52;
foffset = 1000;
noutputsteps = 4;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Steps',...
    'NumSteps',noutputsteps);
```

Call the step method to retrieve the samples for the four steps.

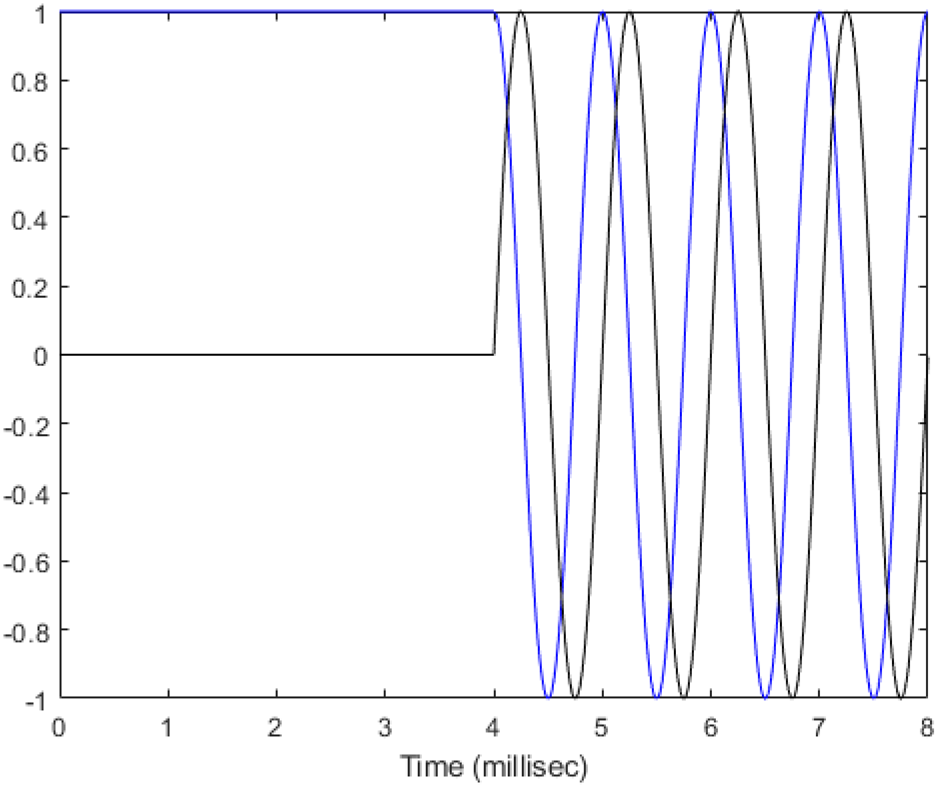
```
z = step(sMFSK);
```

Plot the real and imaginary parts of the first two steps.

```
samplesperstep = fs*tstep;
disp(samplesperstep)

        4000

idx = [1:2*samplesperstep]';
time = idx/fs*1000;
plot(time,real(z(idx)),'b',time,imag(z(idx)),'k');
xlabel('Time (millisec)')
```

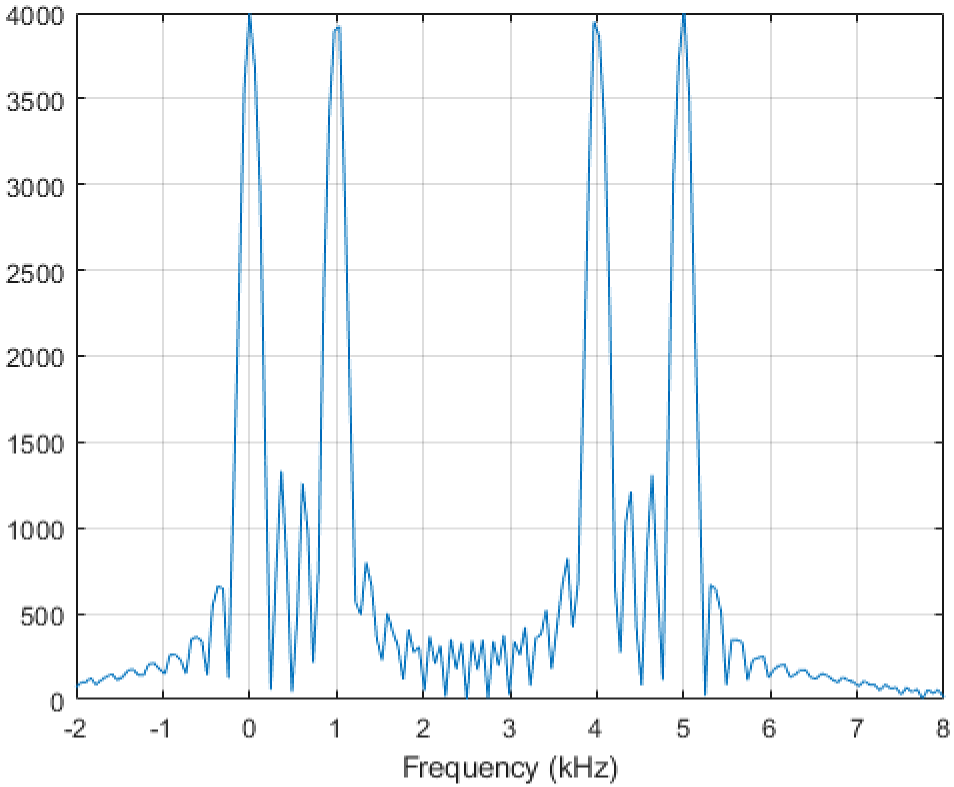


Compute the FFT of all the data.

```
n = size(z,1);
nfft = 2^ceil(log2(n));
Y = fftshift(fft(z,nfft));
```

Plot the magnitudes of the spectrum.

```
fmax = fs/2;
ft = [-nfft/2:nfft/2-1]*fmax/(nfft/2);
figure(2);
hp = plot(ft/1000,abs(Y));
axis([-2,8,-1,4000]);
xlabel('Frequency (kHz)')
grid
```



The plot shows two pairs of peaks. The first pair lies at 0 Hz and 1000 Hz. The second pair lies at 4000 Hz and 5000 Hz. The frequency offset is 1000 Hz.

Compute the frequency increase to the second pair off peaks.

```
fdelta = fsweep/(numsteps/2-1);
disp(fdelta)

        4000
```

The increase agrees with the location of the second pair of peaks in the FFT spectrum.

### MFSK Samples per Sweep

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps with a step time of 400 microseconds. Set the frequency offset to 1 kHz. Find the number of samples returned when the `OutputFormat` property is set to return the samples for one sweep.

```
fs = 1e6;
fsweep = 1e5;
tstep = 40e-4;
numsteps = 52;
foffset = 1000;
noutputsweeps = 1;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Sweeps',...
    'NumSweeps',noutputsweeps);
```

Call the `step` method to retrieve the samples for the four steps.

```
z = step(sMFSK);
```

Count the number of samples in a sweep.

```
samplespersweep = fs*tstep*numsteps;
disp(samplespersweep)

      208000
```

Verify that this value agrees with the number of samples returned by the `step` method.

```
disp(size(z))
```

```
    208000           1
```

**Introduced in R2015a**

# phased.MVDRBeamformer

**Package:** `phased`

Narrowband minimum-variance distortionless-response beamformer

## Description

The phased.MVDRBeamformer System object implements a narrowband minimum-variance distortionless-response (MVDR) beamformer. The MVDR beamformer is also called the Capon beamformer. An MVDR beamformer belongs to the family of constrained optimization beamformers.

To beamform signals arriving at an array:

1. Create the `phased.MVDRBeamformer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
beamformer = phased.MVDRBeamformer
beamformer = phased.MVDRBeamformer(Name,Value)
```

### Description

`beamformer = phased.MVDRBeamformer` creates an MVDR beamformer System object, `beamformer`, with default property values.

`beamformer = phased.MVDRBeamformer(Name,Value)` creates an MVDR beamformer with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `beamformer = phased.MVDRBeamformer('SensorArray',phased.URA,'OperatingFrequency',300e6)` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The beamformer has an operating frequency of 300 MHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `SensorArray` — Sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox array

Sensor array, specified as an array System object belonging to Phased Array System Toolbox. The sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `single` | `double`

### `DiagonalLoadingFactor` — Diagonal loading factor

`0` (default) | nonnegative scalar

Diagonal loading factor, specified as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample size is small. A small sample size can lead to an inaccurate estimate of the covariance matrix. Diagonal loading also provides robustness due to steering vector errors. The diagonal loading technique adds a positive scalar multiple of the identity matrix to the sample covariance matrix.

**Tunable:** Yes

Data Types: `single` | `double`

### `TrainingInputPort` — Enable training data input

`false` (default) | `true`

Enable training data input, specified as `false` or `true`. When you set this property to `true`, use the training data input argument, XT, when running the object. Set this property to `false` to use the input data, X, as the training data.

Data Types: `logical`

### `DirectionSource` — Source of beamforming direction

`'Property'` (default) | `'Input port'`

Source of beamforming direction, specified as `'Property'` or `'Input port'`. Specify whether the beamforming direction comes from the `Direction` property of this object or from the input argument, ANG. Values of this property are:

| | |
|---|---|
| `'Property'` | Specify the beamforming direction using the `Direction` property. |
| `'Input port'` | Specify the beamforming direction using the input argument, ANG. |

Data Types: `char`

### `Direction` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 vector or a real-valued 2-by-*L* matrix. For a matrix, each column specifies a different beamforming direction. Each column has the form `[AzimuthAngle;ElevationAngle]`. Azimuth angles must lie between –180° and 180° and elevation angles must lie between –90° and 90°. All angles are defined with respect to the local coordinate system of the array. Units are in degrees.

Example: `[40;30]`

**Dependencies**

To enable this property, set the `DirectionSource` property to `'Property'`.

Data Types: `single` | `double`

### `NumPhaseShifterBits` — Number of phase shifter quantization bits

`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights, specified as a nonnegative integer. A value of zero indicates that no quantization is performed.

Example: 5

Data Types: `single` | `double`

### `WeightsOutputPort` — Enable beamforming weights output

`false` (default) | `true`

Enable the output of beamforming weights, specified as `false` or `true`. To obtain the beamforming weights, set this property to `true` and use the corresponding output argument, `W`. If you do not want to obtain the weights, set this property to `false`.

Data Types: `logical`

# Usage

# Syntax

```
Y = beamformer(X)
Y = beamformer(X,XT)
Y = beamformer(X,ANG)
```

```
Y = beamformer(X,XT,ANG)
[Y,W] = beamformer( ___ )
```

## Description

`Y = beamformer(X)` performs MVDR beamforming on the input signal, `X`, and returns the beamformed output in `Y`. This syntax uses `X` as training samples to calculate the beamforming weights.

`Y = beamformer(X,XT)` uses `XT` as training samples to calculate the beamforming weights. To use this syntax, set the TrainingInputPort property to `true`.

`Y = beamformer(X,ANG)` uses `ANG` as the beamforming direction. To use this syntax, set the DirectionSource property to `'Input port'`.

`Y = beamformer(X,XT,ANG)` combines all input arguments. To use this syntax, set the `TrainingInputPort` property to `true` and set the DirectionSource property to `'Input port'`.

`[Y,W] = beamformer( ___ )` returns the beamforming weights, `W`. To use this syntax, set the WeightsOutputPort property to `true`.

## Input Arguments

### X — Input signal

complex-valued *M*-by-*N* matrix

Input signal, specified as a complex-valued *M*-by-*N* matrix. *N* is the number of array elements. If the sensor array contains subarrays, *N* is the number of subarrays. If you set TrainingInputPort to `false`, *M* must be larger than *N*; otherwise, *M* can be any positive integer.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`
Complex Number Support: Yes

### XT — Training data

complex-valued *P*-by-*N* matrix

Training data, specified as a complex-valued *P*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. *P* must be larger than *N*.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[1 0.5 2.6; 2 -0.2 0; 3 -2 -1]`

#### Dependencies

To enable this argument, set the TrainingInputPort property to `true`.

Data Types: `single` | `double`
Complex Number Support: Yes

### `ANG` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 column vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 column vector, or 2-by-*L* matrix. *L* is the number of beamforming directions. Each column has the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees. Each azimuth angle must lie between –180° and 180°, and each elevation angle must lie between –90° and 90°.

Example: `[40;10]`

#### Dependencies

To enable this argument, set the DirectionSource property to `'Input port'`.

Data Types: `single` | `double`

## Output Arguments

### `Y` — Beamformed output

complex-valued *M*-by-*L* matrix

Beamformed output, returned as a complex-valued *M*-by-*L* matrix, where *M* is the number of rows of X and *L* is the number of beamforming directions.

Data Types: `single` | `double`
Complex Number Support: Yes

#### `W` — Beamforming weights

complex-valued *N*-by-*L* matrix.

Beamforming weights, returned as a complex-valued *N*-by-*L* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. *L* is the number of beamforming directions.

**Dependencies**

To enable this output, set the WeightsOutputPort property to `true`.

Data Types: `single` | `double`
Complex Number Support: Yes

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### MVDR Beamforming

Apply an MVDR beamformer to a 5-element ULA. The incident angle of the signal is 45 degrees in azimuth and 0 degree in elevation. The signal frequency is .01 hertz. The carrier frequency is 300 MHz.

```
t = [0:.1:200]';
fr = .01;
xm = sin(2*pi*fr*t);
```

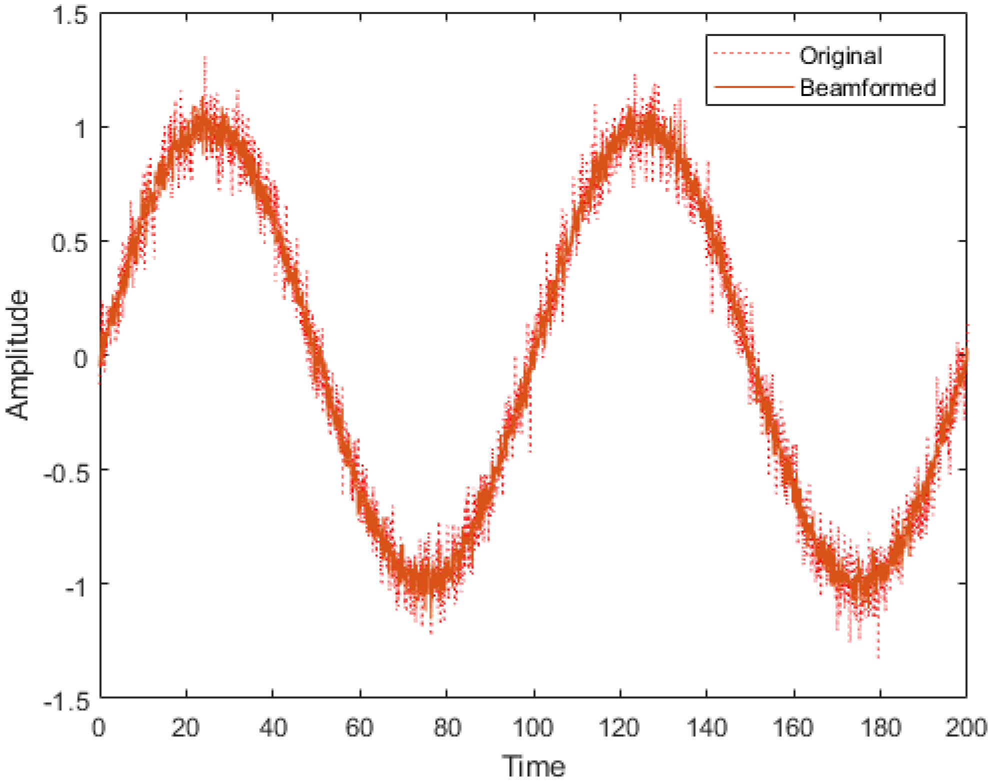
```
c = physconst('LightSpeed');
fc = 300e6;
rng('default');
incidentAngle = [45;0];
array = phased.ULA('NumElements',5,'ElementSpacing',0.5);
x = collectPlaneWave(array,xm,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Compute the beamforming weights

```
beamformer = phased.MVDRBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'OperatingFrequency',fc,...
    'Direction',incidentAngle,'WeightsOutputPort',true);
[y,w] = beamformer(rx);
```

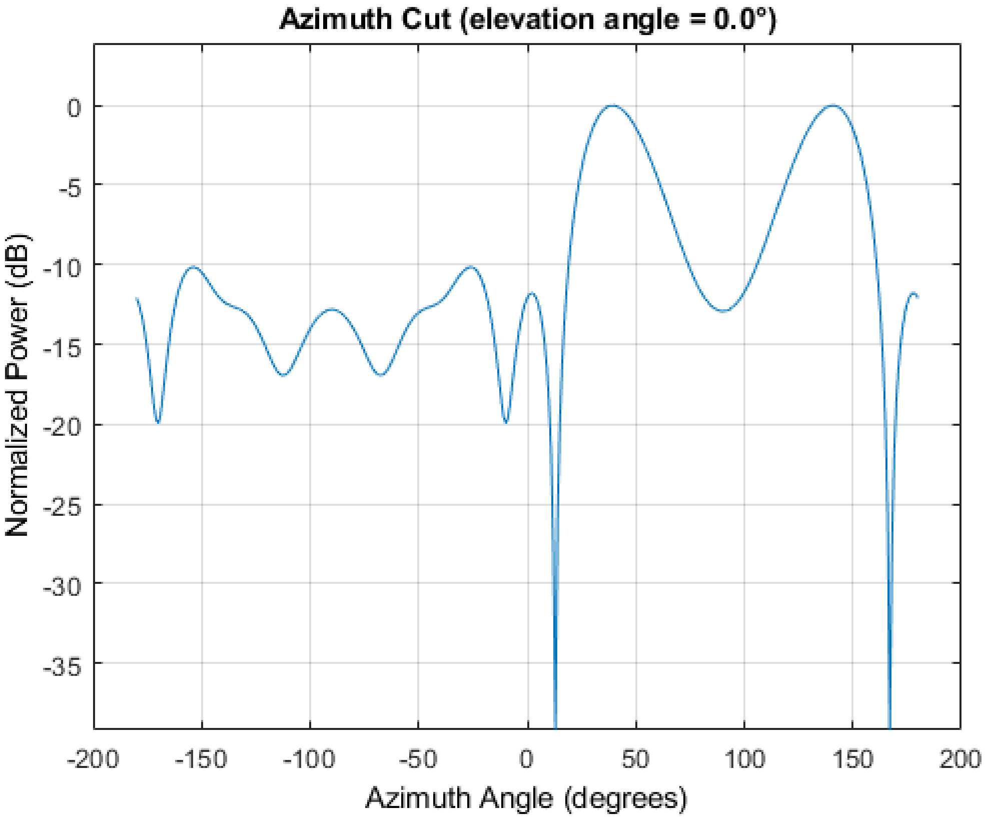
Plot the signals

```
plot(t,real(rx(:,3)),'r:',t,real(y))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the array response pattern using the MVDR weights

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,...
    'Weights',w,'CoordinateSystem','rectangular',...
    'Type','powerdb');
```



# Algorithms

## MVDR Beamforming

The MVDR beamformer maximizes the signal to noise ratio.

Start with a signal arriving at the elements of an array. Assume that *X* is a complex-valued *N*-by-*M* data matrix representing the arrival of signals at an array. *N* is the number of sensors in the array and *M* is the number of samples or snapshots per signal. For mathematical convenience, this matrix is the transpose of the matrix specified in the X argument. Each row of *X* represents a time series of data for the corresponding array. The signal-to-noise ratio of a signal is given here.

$$SNR = \frac{\left|w^H s\right|^2}{w^H R_{I+N} w}$$

Properly, the covariance matrix in the denominator is the covariance matrix for the noise and any interferers. You can vary the scale of *w* without affecting the SNR. Therefore, you can choose the normalization for *w* so that The MVDR estimator weights for beamforming are $w = R^{-1}v/v^H Rv$ where *R* is the data covariance matrix $R = E[xx^H]$.

### Diagonal Loading

Diagonal loading provides beamformer robustness due to small sample size and steering vector errors.

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Package:** `phased`

MVDR (Capon) spatial spectrum estimator for ULA

## Description

The `MVDREstimator` object computes a minimum variance distortionless response (MVDR) spatial spectrum estimate for a uniform linear array. This DOA estimator is also referred to as a Capon DOA estimator.

To estimate the spatial spectrum:

1. Define and set up your MVDR spatial spectrum estimator. See “Construction” on page 1-1343.
2. Call `step` to estimate the spatial spectrum according to the properties of `phased.MVDREstimator`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.MVDREstimator` creates an MVDR spatial spectrum estimator System object, `H`. The object estimates the incoming signal's spatial spectrum using a narrowband MVDR beamformer for a uniform linear array (ULA).

`H = phased.MVDREstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

# Properties

### SensorArray

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

**Default:** `phased.ULA` with default property values

### PropagationSpeed

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Default:** Speed of light

### OperatingFrequency

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

**Default:** `3e8`

### NumPhaseShifterBits

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Default:** `0`

### ForwardBackwardAveraging

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

**Default:** `false`

### `SpatialSmoothing`

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of element by 1. The maximum value of this property is M–2, where M is the number of sensors.

**Default:** `0`, indicating no spatial smoothing

### `ScanAngles`

Scan angles

Specify the scan angles (in degrees) as a real vector. The angles are broadside angles and must be between –90 and 90, inclusive. You must specify the angles in ascending order.

**Default:** `-90:90`

### `DOAOutputPort`

Enable DOA output

To obtain the signal's direction of arrival (DOA), set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the DOA, set this property to `false`.

**Default:** `false`

### `NumSignals`

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This property applies when you set the `DOAOutputPort` property to true.

**Default:** `1`

# Examples

### Estimate DOA of Two Signals Using MVDR

First, estimate the DOAs of two signals received by a standard 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and −5° in elevation. Then, plot the MVDR spatial spectrum.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the signals with added noise. Then, create the ULA System object™.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150.0e6;
x = collectPlaneWave(array,[x1 x2],[10 20;60 -5]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Construct MVDR estimator System object.

```
estimator = phased.MVDREstimator('SensorArray',array,...
    'OperatingFrequency',fc,'DOAOutputPort',true,'NumSignals',2);
```

Estimate the DOAs.

```
[y,doas] = estimator(x + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas = 1×2

    9.5829   60.3813
```

Plot the spectrum.

```
plotSpectrum(estimator)
```

Plot spatial spectrum

## Syntax

```
plotSpectrum(estimator)
plotSpectrum(estimator,Name,Value)
hl = plotSpectrum( ___ )
```

## Description

`plotSpectrum(estimator)` plots the spatial spectrum resulting from the most recent execution of the object.

`plotSpectrum(estimator,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`hl = plotSpectrum( ___ )` returns the line handle in the figure.

## Input Arguments

**`H`**

Spatial spectrum estimator object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### NormalizeResponse

Set this value to `true` to plot the normalized spectrum. Setting this value to `false` plots the spectrum without normalization.

**Default:** `false`

### Title

Character vector to use as figure title.

**Default:** `''`

### Unit

Plot units, specified as `'db'`, `'mag'`, or `'pow'`.

**Default:** `'db'`

Reset states of MVDR spatial spectrum estimator object

## Syntax

`reset(H)`

## Description

`reset(H)` resets the states of the `MVDREstimator` object, `H`.

# step

**System object:** phased.MVDREstimator
**Package:** phased

Perform spatial spectrum estimation

## Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Y = step(H,X) estimates the spatial spectrum from X using the estimator H. X is a matrix whose columns correspond to channels. Y is a column vector representing the magnitude of the estimated spatial spectrum.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

[Y,ANG] = step(H,X) returns additional output ANG as the signal's direction of arrival (DOA) when the DOAOutputPort property is true. ANG is a row vector of the estimated broadside angles (in degrees).

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# phased.MVDREstimator2D

**Package:** phased

2-D MVDR (Capon) spatial spectrum estimator

## Description

The MVDREstimator2D object computes a 2-D minimum variance distortionless response (MVDR) spatial spectrum estimate. This DOA estimator is also referred to as a Capon estimator.

To estimate the spatial spectrum:

1. Define and set up your 2-D MVDR spatial spectrum estimator. See “Construction” on page 1-1357.
2. Call step to estimate the spatial spectrum according to the properties of phased.MVDREstimator2D. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.MVDREstimator2D creates a 2-D MVDR spatial spectrum estimator System object, H. The object estimates the signal’s spatial spectrum using a narrowband MVDR beamformer.

H = phased.MVDREstimator2D(Name,Value) creates object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

**Default:** `phased.ULA` with default property values

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz. You can specify this property as single or double precision.

**Default:** `3e8`

### `NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed. You can specify this property as single or double precision.

**Default:** `0`

### ForwardBackwardAveraging

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

**Default:** `false`

### AzimuthScanAngles

Azimuth scan angles (degrees)

Specify the azimuth scan angles (in degrees) as a real vector. The angles must be between –180 and 180, inclusive. You must specify the angles in ascending order. You can specify this property as single or double precision.

**Default:** `-90:90`

### ElevationScanAngles

Elevation scan angles

Specify the elevation scan angles (in degrees) as a real vector or scalar. The angles must be between –90 and 90, inclusive. You must specify the angles in ascending order. You can specify this property as single or double precision.

**Default:** `0`

### DOAOutputPort

Enable DOA output

To obtain the signal's direction of arrival (DOA), set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the DOA, set this property to `false`.

**Default:** `false`

### NumSignals

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This property applies when you set the `DOAOutputPort` property to `true`. You can specify this property as single or double precision.

**Default:** 1

## Methods

## Examples

### Estimate DOA of Two Signals Arriving at URA

Estimate the DOAs of two signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is −37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° degrees in elevation. Then, plot the spatial spectrum.

Create the arriving signals.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[-37 0;17 20]',fc);
```

Add noise.

```
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create the MVDR DOA estimator and estimate the DOAs.

```
estimator = phased.MVDREstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:50,...
    'ElevationScanAngles',-30:30);
[~,doas] = estimator(x + noise);
```

Plot the spectrum.

```
plotSpectrum(estimator)
```

Reset states of 2-D MVDR spatial spectrum estimator object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `MVDREstimator2D` object, `H`.

# step

**System object:** `phased.MVDREstimator2D`
**Package:** `phased`

Perform spatial spectrum estimation

## Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the spatial spectrum from `X` using the estimator `H`. `X` is a matrix whose columns correspond to channels. `Y` is a matrix representing the magnitude of the estimated 2-D spatial spectrum. The row dimension of `Y` is equal to the number of angles in the `ElevationScanAngles` and the column dimension of `Y` is equal to the number of angles in the `AzimuthScanAngles` property. You can specify the argument, `X`, as single or double precision.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`[Y,ANG] = step(H,X)` returns additional output `ANG` as the signal's direction of arrival (DOA) when the `DOAOutputPort` property is `true`. `ANG` is a two-row matrix where the first row represents estimated azimuth and the second row represents estimated elevation (in degrees).

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Examples

# phased.MultipathChannel

**Package:** `phased`

Propagate signals in multipath channel

## Description

The `phased.MultipathChannel` System object propagates a signal through a multipath channel. To run the object, you must provide characteristics for each path: time delay, gain, Doppler factor, reflection loss, and spreading loss.

For sonar applications, you can use the `phased.IsoSpeedUnderwaterPaths` System object to generate channel path characteristics. You can also supply these characteristics independently.

To model signal propagation through a multipath channel:

1. Define and set up the propagator. You can set `phased.MultipathChannel` properties at construction time or leave them to their default values. See "Construction" on page 1-1372. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the propagated signal, call the `step` method of `phased.MultipathChannel`. The output of the `step` method depends on the properties of the `phased.MultipathChannel` System object. You can change tunable properties at any time.

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`propagator = phased.MultipathChannel` creates a signal propagator System object for a multipath underwater channel.

`propagator = phased.MultipathChannel(Name,Value)` creates a signal propagator System object with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

# Properties

### `OperatingFrequency` — Signal carrier frequency

`20e3` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `10000`

Data Types: `double`

### `SampleRate` — Signal sample rate

`1e3` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `3e3`

Data Types: `double`

### `MaximumDelaySource` — Source of maximum delay

`'Auto'` (default) | `'Property'`

Source of the maximum delay value, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the channel automatically allocates enough memory to simulate the propagation delay. When you set this property to `'Property'`, you can specify the maximum delay by using the `MaximumDelay` property. Signals arriving after the maximum delay are ignored.

### `MaximumDelay` — Maximum signal delay

`1` (default) | positive scalar

Maximum signal delay, specified as a positive scalar. Delays greater than this value are ignored. Units are in seconds.

#### Dependencies

To enable this property, set the `MaximumDelaySource` property to `'Property'`.

Data Types: `double`

#### `InterpolationMethod` — Interpolation method to implement fractional delay

`'Linear'` (default) | `'Oversample'`

Interpolation method used to implement signal fractional delay and doppler time-dilation and compression, specified as `'Linear'` or `'Oversample'`. When this property is set to `'Linear'`, the input signal is linearly interpolated directly onto a uniform grid to propagate the signal. When this property is set to `'Oversample'`, the input signal is resampled to a higher rate before linear interpolation. For broadband signals, oversampling preserves spectral shape.

Data Types: `char`

## Methods

| | |
|---|---|
| step | Propagate signal through multipath sound channel |
| reset | Reset state of System object |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### One-Way Signal Propagation in Multipath Underwater Sound Channel

Create a five-path underwater sound channel and compute the propagation path matrix, the Doppler factor, and the absorption loss. Assume that the source is stationary and the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

Create the channel and specify the source and receiver locations and velocities.

```
numpaths = 5;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [100;0;-50];
speed = -20*1000/3600;
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses.

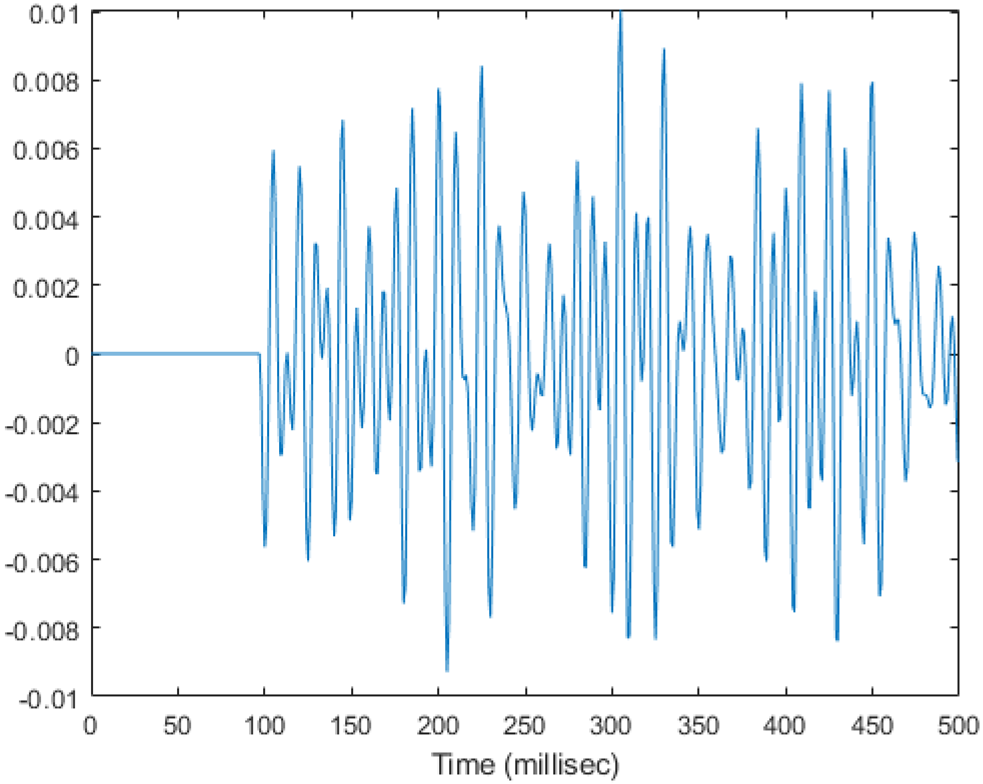
```
[pathmat,dop,absloss] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create 500 samples of a 100 Hz signal. Assume all the paths have the same signal. Propagate the signals to the receiver.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



### Two-Way Signal Propagation in Multipath Underwater Sound Channel

Create a seven-path underwater sound channel and display the propagation path matrix. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
csound = 1515.0;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200, ...
    'PropagationSpeed',csound,'BottomLoss',10,'NumPathsSource','Property', ...
    'NumPaths',numpaths,'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
```

Obtain the path matrix, Doppler factor, loss, and target reflection and transmit angles.

```
[pathmat,dop,aloss,tgtangs,srcangs] = channel(srcpos,tgtpos,srcvel,tgtvel,tstep);
```

Create a 100 Hz signal with 500 samples. Assume that all the paths have the same signal but with different amplitudes. Then, propagate the signals to the target and back. You can use the angle information to calculate any angular dependence of the source and target responses. Each channel can have a different amplitude. This example uses a simple cosine model.

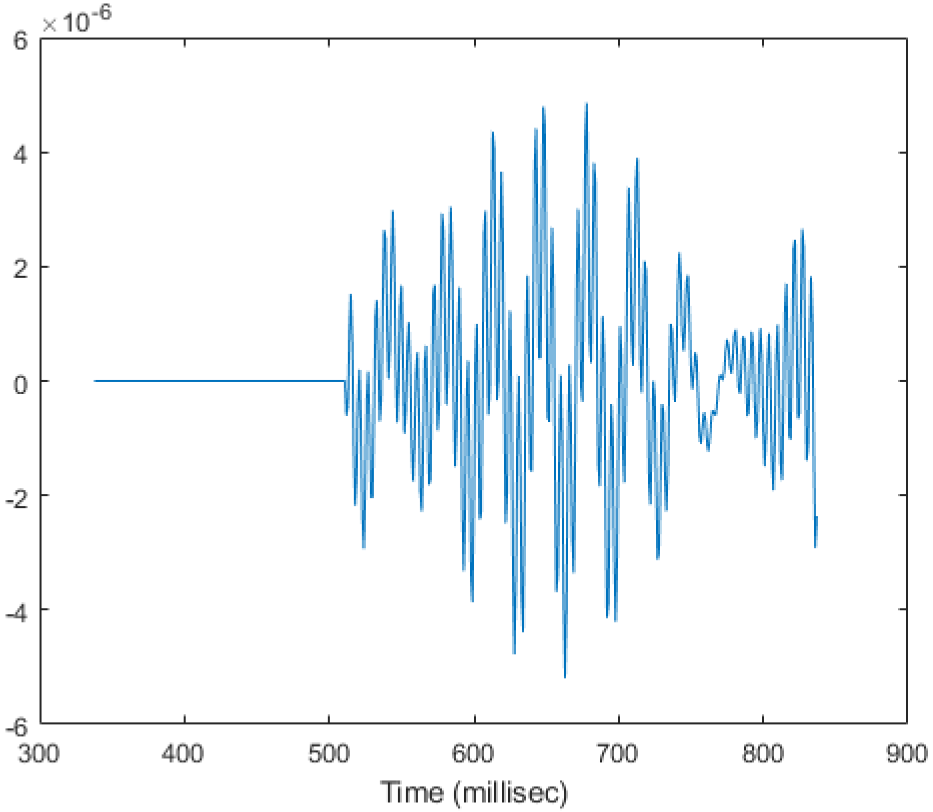
```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
ampsrc = cosd(srcangs(2,:));
amptgt = cosd(tgtangs(2,:));
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
amptotal = ampsrc.^2.*amptgt;
sig = bsxfun(@times,amptotal,sig);
```

Because of the finite propagation delay, the first call to the propagator does not return the signal. Call `propagator` twice to obtain the returned signal.

```
propsig = propagator(sig,pathmat,dop,aloss);
propsig = propagator(sig,pathmat,dop,aloss);
```

Plot the real part of the coherent sum of the propagated signals. Compute the round trip time.

```
rng = rangeangle(srcpos,tgtpos);
tr = rng/csound;
plot((t+tr)*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



### Propagate Sound in Channel Having Unknown Number of Paths

Create an underwater sound channel and plot the combined received signal. Automatically find the number of paths. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

```
speed = -20*1000/3600;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5);
tstep = 1;
```

```
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses. The propagator outputs 51 paths output but some paths can contain `Nan` values.

```
[pathmat,dop,absloss,rcvangs,srcangs] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create of a 100 Hz signal with 500 samples. Assume that all the paths have the same signal. Use a `phased.MultipathChannel` System object to propagate the signals to the receiver. `phased.MultipathChannel` accepts as input all paths produced by `phased.IsoSpeedUnderwaterPaths` but ignores paths that have `NaN` values.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
numpaths = size(pathmat,2);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```

### Doppler Stretching of Sonar Signal

Compare the duration of a propagated signal from a stationary sonar to that of a moving sonar. The moving sonar has a radial velocity of 25 m/s away from the target. In each case, propagate the signal along a single path. Assume one-way propagation.

Define the sonar system parameters: maximum unambiguous range, required range resolution, operating frequency, and propagation speed.

```
maxrange = 5000.0;
rngres = 10.0;
```

```
fc = 20.0e3;
csound = 1520.0;
```

Use a rectangular waveform for the transmitted signal.

```
prf = csound/(2*maxrange);
pulseWidth = 8*rngres/csound;
pulseBW = 1/pulseWidth;
fs = 80*pulseBW;
waveform = phased.RectangularWaveform('PulseWidth',pulseWidth,'PRF',prf, ...
    'SampleRate',fs);
```

Specify the sonar positions.

```
sonarplatform1 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;0;0]);
sonarplatform2 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;-25;0]);
```

Specify the target position.

```
targetplatform = phased.Platform('InitialPosition',[0;500;-60],'Velocity',[0;0;0]);
```

Define the underwater path and propagation channel objects.

```
paths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',100, ...
    'CoherenceTime',0,'NumPathsSource','Property','NumPaths',1, ...
    'PropagationSpeed',csound);
propagator = phased.MultipathChannel('SampleRate',fs,'OperatingFrequency',fc);
```

Create the transmitted waveform.

```
wav = waveform();
nsamp = size(wav,1);
rxpulses = zeros(nsamp,2);
t = (0:nsamp-1)/fs;
```

Transmit the signal and then receive the echo at the stationary sonar.

```
[pathmat,dop,aloss,~,~] = paths(sonarplatform1.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform1.InitialVelocity, ...
    targetplatform.InitialVelocity,1/prf);
rxpulses(:,1) = propagator(wav,pathmat,dop,aloss);
```

Transmit and receive at the moving sonar.

```
[pathmat,dop,aloss,~,~] = paths(sonarplatform2.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform2.Velocity, ...
    targetplatform.Velocity,1/prf);
rxpulses(:,2) = propagator(wav,pathmat,dop,aloss);
```

Plot the received pulses.

```
plot(abs(rxpulses))
xlim([490 650])
ylim([0 1.65e-3])
legend('Stationary sonar','Moving sonar')
xlabel('Received Sample Time (sec)')
ylabel('Integrated Received Pulses')
```

The signal received at the moving sonar has increased in duration compared to the stationary sonar.

# step

**System object:** `phased.MultipathChannel`
**Package:** `phased`

Propagate signal through multipath sound channel

## Syntax

```
propsig = step(propagator,sig,pathmat,dop,aloss)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`propsig = step(propagator,sig,pathmat,dop,aloss)` returns a signal, `propsig`, propagated through a multipath channel. `sig` is the input signal to the channel. The `pathmat` matrix contains the path time delay, the total reflection coefficient, and the spreading loss. `dop` specifies the Doppler factor and `aloss` specifies the frequency-dependent absorption loss. The matrix can describe one-way or two-way propagation from the signal source position to the signal destination position.

- When you use this method for one-way propagation, the source refers to the origin of the signal and the destination refers to the receiver. You can use one-way propagation modeling to model passive sonar and underwater communications.
- When you use this method for two-way propagation, the destination refers to the reflecting target, not the sonar receiver. A two-way path consists of a two identical one-way paths from source to target and back to receiver (collocated with the source). You can use two-way propagation to model active sonar systems.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Input Arguments

### `propagator` — Multipath channel propagator

`phased.MultipathChannel` System object

Multipath channel propagator, specified as a `phased.MultipathChannel` System object.

Example: `phased.MultipathChannel`

### `sig` — Channel input signal

complex-valued *M*-by-*N* matrix

Channel input signal, specified as a complex-valued *M*-by-*N* matrix. *M* is the number of samples in the signal and *N* is the number of paths.

Data Types: `double`

### `pathmat` — Propagation paths matrix

real-valued 3-by-*N* matrix

Propagation paths matrix, specified as a real-valued 3-by-*N* matrix. *N* is the number of paths in the channel. Each column represents a path. The matrix rows represent:

| Row | Data |
|---|---|
| 1 | Propagation delays for each path. Units are in seconds. |
| 2 | Total reflection coefficient for each path. Units are dimensionless |
| 3 | Spreading loss for each path. Units are in dB. |

Except for the direct path, paths consist of alternating surface and bottom reflections. The losses for multiple reflections at the boundaries are multiplied. When you use phased.IsoSpeedUnderwaterPaths to create a path matrix, some of the columns can contain NaN values. phased.MultipathChannel ignores these paths.

Data Types: double

**dop — Doppler factor**
real-valued *N*-by-1 row vector

Doppler factor, specified as a real-valued *N*-by-1 row vector where *N* is the number of paths. The Doppler factor multiplies the transmitted frequency to produce the Doppler-shifted frequency for each path. The factor also defines the time contraction or dilation of a signal. Units are dimensionless.

Data Types: double

**aloss — Frequency-dependent absorption loss**
real-valued *K*-by-*N*+1 matrix

Frequency-dependent absorption loss, specified as a real-valued *K*-by-*N*+1 matrix. *K* is the number of frequencies and *N* is the number of paths. The first column of aloss contains the absorption-loss frequencies in Hz. The remaining columns contain the absorption losses for the corresponding frequency. Units are in dB.

Data Types: double

# Output Arguments

**propsig — Channel output signal**
complex-valued *M*-by-*N* matrix

Channel output signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the number of samples in the signal and *N* is the number of paths. The output is the signal propagated through the channel. propsig has the same dimensions as the input signal, sig.

# Examples

### One-Way Signal Propagation in Multipath Underwater Sound Channel

Create a five-path underwater sound channel and compute the propagation path matrix, the Doppler factor, and the absorption loss. Assume that the source is stationary and the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

Create the channel and specify the source and receiver locations and velocities.

```
numpaths = 5;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [100;0;-50];
speed = -20*1000/3600;
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses.

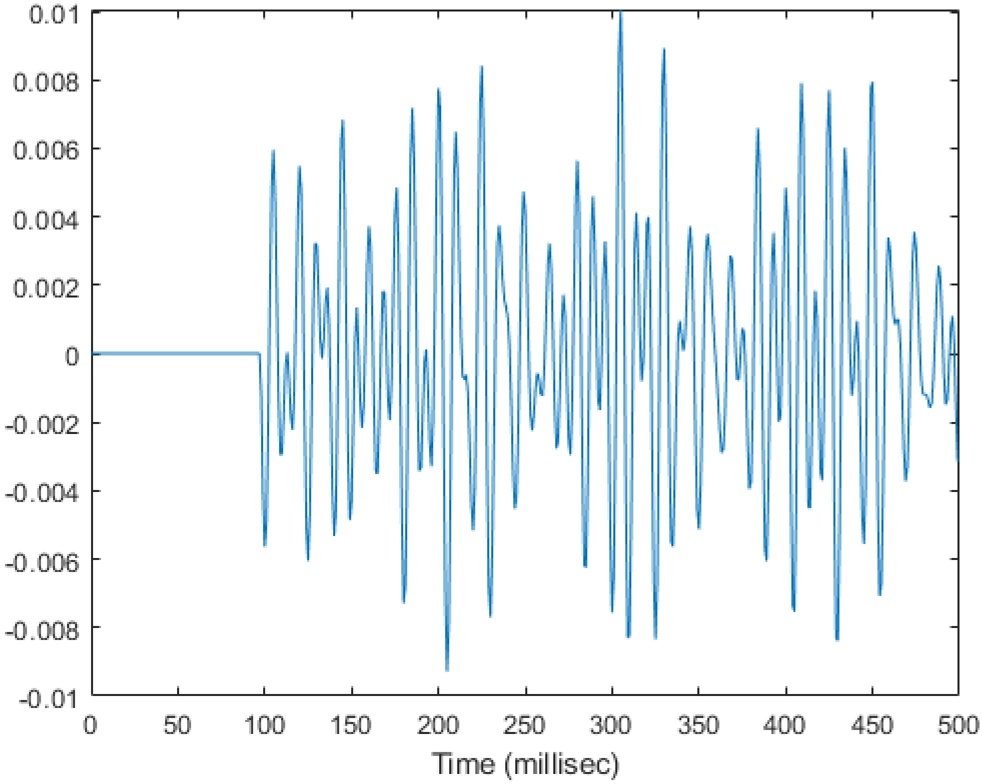
```
[pathmat,dop,absloss] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create 500 samples of a 100 Hz signal. Assume all the paths have the same signal. Propagate the signals to the receiver.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



### Two-Way Signal Propagation in Multipath Underwater Sound Channel

Create a seven-path underwater sound channel and display the propagation path matrix. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
csound = 1515.0;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200, ...
    'PropagationSpeed',csound,'BottomLoss',10,'NumPathsSource','Property', ...
    'NumPaths',numpaths,'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
```

Obtain the path matrix, Doppler factor, loss, and target reflection and transmit angles.

```
[pathmat,dop,aloss,tgtangs,srcangs] = channel(srcpos,tgtpos,srcvel,tgtvel,tstep);
```

Create a 100 Hz signal with 500 samples. Assume that all the paths have the same signal but with different amplitudes. Then, propagate the signals to the target and back. You can use the angle information to calculate any angular dependence of the source and target responses. Each channel can have a different amplitude. This example uses a simple cosine model.

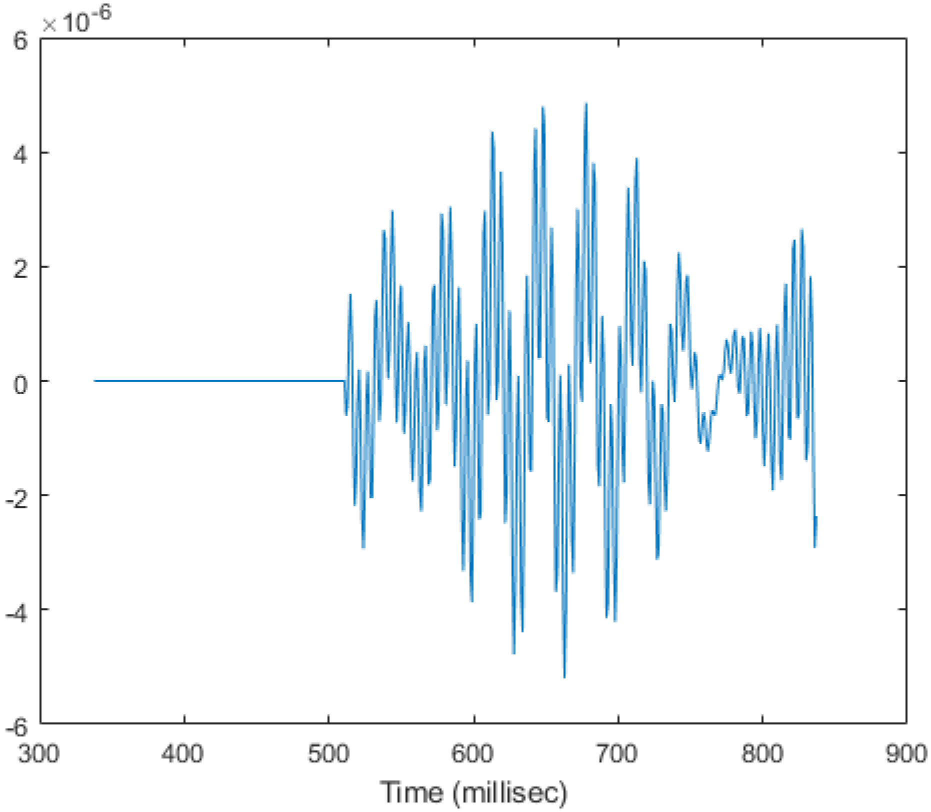
```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
ampsrc = cosd(srcangs(2,:));
amptgt = cosd(tgtangs(2,:));
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
amptotal = ampsrc.^2.*amptgt;
sig = bsxfun(@times,amptotal,sig);
```

Because of the finite propagation delay, the first call to the propagator does not return the signal. Call `propagator` twice to obtain the returned signal.

```
propsig = propagator(sig,pathmat,dop,aloss);
propsig = propagator(sig,pathmat,dop,aloss);
```

Plot the real part of the coherent sum of the propagated signals. Compute the round trip time.

```
rng = rangeangle(srcpos,tgtpos);
tr = rng/csound;
plot((t+tr)*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



### Propagate Sound in Channel Having Unknown Number of Paths

Create an underwater sound channel and plot the combined received signal. Automatically find the number of paths. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

```
speed = -20*1000/3600;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5);
tstep = 1;
```

```
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses. The propagator outputs 51 paths output but some paths can contain Nan values.

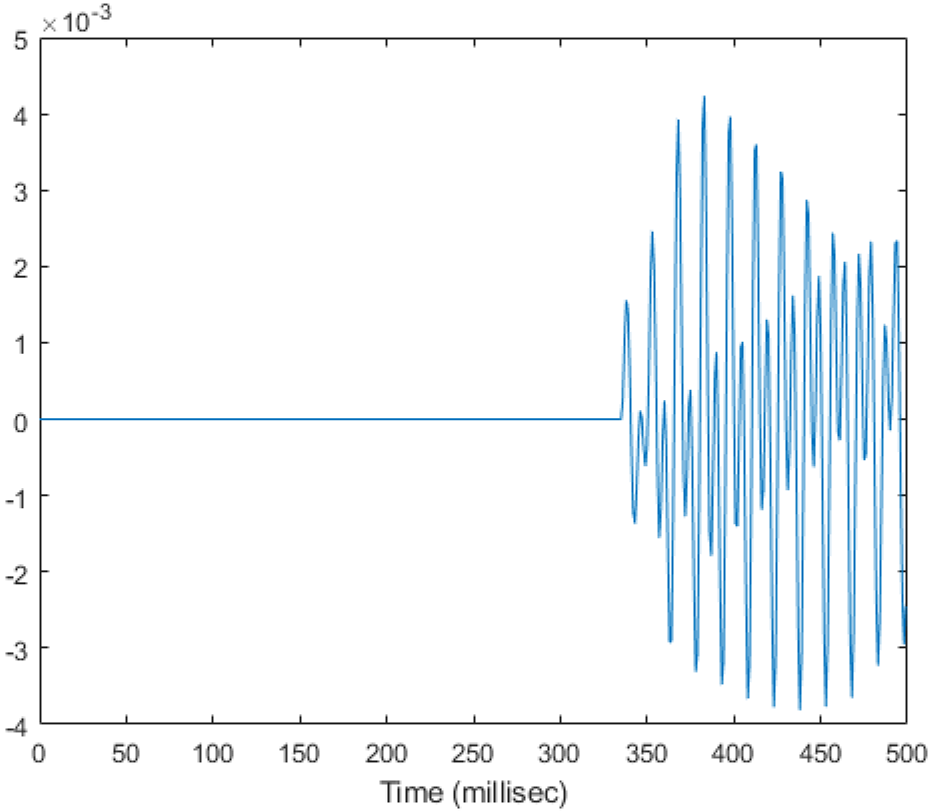
```
[pathmat,dop,absloss,rcvangs,srcangs] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create of a 100 Hz signal with 500 samples. Assume that all the paths have the same signal. Use a phased.MultipathChannel System object to propagate the signals to the receiver. phased.MultipathChannel accepts as input all paths produced by phased.IsoSpeedUnderwaterPaths but ignores paths that have NaN values.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
numpaths = size(pathmat,2);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



**Introduced in R2017a**

# reset

**System object:** phased.MultipathChannel
**Package:** phased

Reset state of System object

## Syntax

```
reset(propagator)
```

## Description

`reset(propagator)` resets the internal state of the `phased.MultipathChannel` object, `propagator`.

## Input Arguments

### `propagator` — Multipath channel

`phased.MultipathChannel` System object

Multipath channel, specified as a `phased.MultipathChannel` System object.

Example: `phased.MultipathChannel`

**Introduced in R2017a**

# phased.MUSICEstimator

**Package:** phased

Estimate direction of arrival using narrowband MUSIC algorithm for ULA

## Description

The phased.MUSICEstimator System object implements the narrowband multiple signal classification (MUSIC) algorithm for uniform linear arrays (ULA). MUSIC is a high-resolution direction-finding algorithm capable of resolving closely-spaced signal sources. The algorithm is based on eigenspace decomposition of the sensor spatial covariance matrix.

To estimate directions of arrival (DOA):

1. Define and set up a phased.MUSICEstimator System object. See “Construction” on page 1-1394.
2. Call the step method to estimate the DOAs according to the properties of phased.MUSICEstimator.

**Note** Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

estimator = phased.MUSICEstimator creates a MUSIC DOA estimator System object, estimator.

estimator = phased.MUSICEstimator(Name,Value) creates a System object, estimator, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

**SensorArray — ULA sensor array**
phased.ULA System object (default)

ULA sensor array, specified as a phased.ULA System object. If you do not specify any name-value pair properties for the ULA sensor array, the default properties of the array are used.

**PropagationSpeed — Signal propagation speed**
physconst('LightSpeed') (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by physconst('LightSpeed').

Example: 3e8

Data Types: single | double

**OperatingFrequency — Operating frequency**
300e6 (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: 1e9

Data Types: single | double

**ForwardBackwardAveraging — Enable forward-backward averaging**
false (default) | true

Enable forward-backward averaging, specified as false or true. Set this property to true to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Data Types: logical

**ScanAngles — Broadside scan angles**
[-90:90] (default) | real-valued *K*-length vector

Broadside scan angles, specified as a real-valued vector. Units are in degrees. Broadside angles are between the search direction and the ULA array axis. The angles lie between –90° and 90°, inclusive. Specify the angles in increasing value.

Example: [-20:20]

Data Types: single | double

### DOAOutputPort — Enable directions of arrival output

false (default) | true

Option to enable directions-of-arrival (DOA) output, specified as false or true. To obtain the DOA of signals, set this property to true. The DOAs are returned in the second output argument when the object is executed.

Data Types: logical

### NumSignalsSource — Source of number of signals

'Auto' (default) | 'Property'

Source of the number of arriving signals, specified as 'Auto' or 'Property'.

- 'Auto' — The System object estimates the number of arriving signals using the method specified in the NumSignalsMethod property.
- 'Property' — Specify the number of arriving signals using the NumSignals property.

Data Types: char

### NumSignalsMethod — Method used to estimate number of arriving signals

'AIC' (default) | 'MDL'

Method used to estimate the number of arriving signals, specified as 'AIC' or 'MDL'.

- 'AIC' — Akaike Information Criterion
- 'MDL' — Minimum Description Length criterion

#### Dependencies

To enable this property, set NumSignalsSource to 'Auto'.

Data Types: char

### NumSignals — Number of arriving signals

1 (default) | positive integer

Number of arriving signals for DOA estimation, specified as a positive integer.

Example: 3

**Dependencies**

To enable this property, set `NumSignalsSource` to `'Property'`.

Data Types: `single` | `double`

### `SpatialSmoothing` — Enable spatial smoothing

0 (default) | nonnegative integer

Option to enable spatial smoothing, specified as a nonnegative integer. Use spatial smoothing to compute the arrival directions of coherent signals. A value of zero specifies no spatial smoothing. A positive value represents the number of subarrays used to compute the smoothed (averaged) source covariance matrix. Each increment in this value lets you handle one additional coherent source, but reduces the effective number of array elements by one. The length of the smoothing aperture, $L$, depends on the array length, $M$, and the averaging number, $K$, by $L = M - K + 1$. The maximum value of $K$ is $M - 2$.

Example: 5

Data Types: `double`

## Methods

| | |
|---|---|
| plotSpectrum | Plot MUSIC spectrum |
| reset | Reset states of System object |
| step | Estimate direction of arrival using MUSIC |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Plot MUSIC Spectrum of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of 1 meter. Then plot the MUSIC spectrum.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the ULA array. The antenna operating frequency is 150 MHz.

```
fc = 150.0e6;
array = phased.ULA('NumElements',10,'ElementSpacing',1.0);
```

Create the arriving signals at the ULA. The true direction of arrival of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

```
fs = 8000.0;
t = (0:1/fs:1).';
sig1 = cos(2*pi*t*300.0);
sig2 = cos(2*pi*t*400.0);
sig = collectPlaneWave(array,[sig1 sig2],[10 20; 60 -5]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

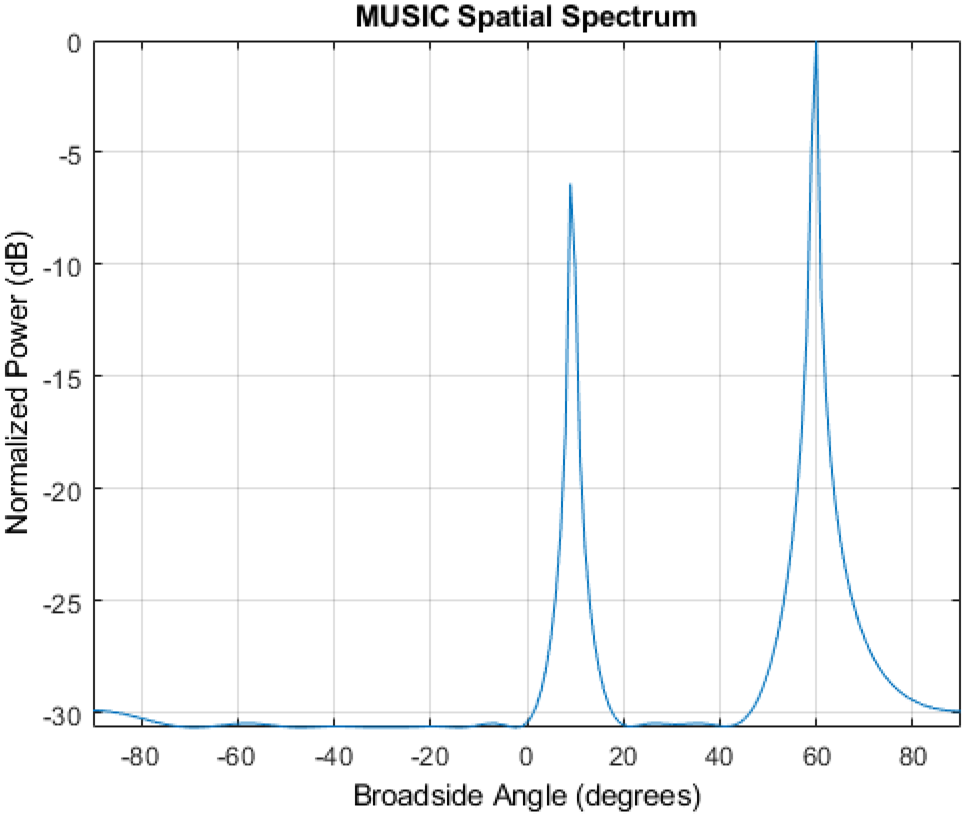
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignalsSource','Property',...
    'NumSignals',2);
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas = 1×2

    9.5829   60.3813
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



### Compute DOA of Two Nearby Signals Using MUSIC

First, estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of one-half wavelength.Then, plot the spatial spectrum.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

The antenna operating frequency is 150 MHz. The arrival directions of the two signals are separated by 2°. The direction of the first signal is 30° azimuth and 0° elevation. The direction of the second signal is 32° azimuth and 0° elevation. Estimate the number of signals using the Minimum Description Length (MDL) criterion.

Create the signals arriving at the ULA.

```
fs = 8000;
t = (0:1/fs:1).';
f1 = 300.0;
f2 = 600.0;
sig1 = cos(2*pi*t*f1);
sig2 = cos(2*pi*t*f2);
fc = 150.0e6;
c = physconst('LightSpeed');
lam = c/fc;
array = phased.ULA('NumElements',10,'ElementSpacing',0.5*lam);
sig = collectPlaneWave(array,[sig1 sig2],[30 0; 32 0]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

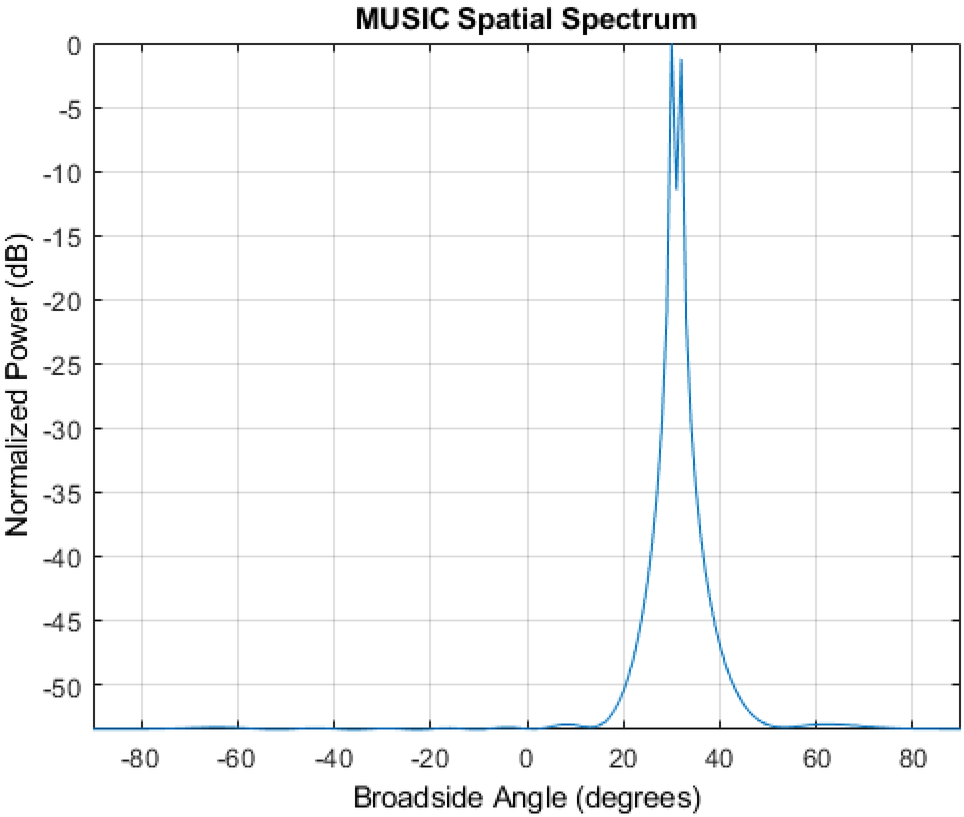
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,'DOAOutputPort',true,...
    'NumSignalsSource','Auto','NumSignalsMethod','MDL');
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[0 0])
```

```
doas = 1×2

   30.0000   32.0000
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



# Algorithms

## MUSIC Algorithm

MUSIC is a high-resolution direction-finding algorithm that estimates directions of arrival (DOA) of signals at an array from the covariance matrix of array sensor data. MUSIC belongs to the subspace-decomposition family of direction-finding algorithms. Unlike conventional beamforming, MUSIC can resolve closely spaced signal sources.

Based on eigenspace decomposition of the sensor covariance matrix, MUSIC divides the observation space into orthogonal signal and noise subspaces. Eigenvectors corresponding to the largest eigenvalues span the signal subspace. Eigenvectors corresponding to the smaller eigenvalues span the noise subspace. Because arrival (or steering) vectors lie in the signal subspace, they are orthogonal to the noise subspace. For ULAs, arrival vectors are functions of the broadside direction angles of the sources. The algorithm searches a grid of arrival angles to find the arrival vectors that have zero or small projections into the noise subspace. These angles are the directions of the sources.

MUSIC requires that the number of source signals is known. If the number of specified sources does not match the actual number of sources, the algorithm degrades. Generally, you must provide an estimate of the number of sources or use one of the built-in source number estimation methods. For a description of the methods used to estimate the number of sources, see the `aictest` or `mdltest` functions.

In place of the true sensor covariance matrix, the algorithm computes the sample covariance matrix from the sensor data. MUSIC applies to noncoherent signals but can be extended to coherent signals using spatial smoothing and/or forward-backward averaging techniques. For a high-level description of the algorithm, see “MUSIC Super-Resolution DOA Estimation”.

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# plotSpectrum

**System object:** phased.MUSICEstimator
**Package:** phased

Plot MUSIC spectrum

## Syntax

```
plotSpectrum(estimator)
output_args = method(estimator,Name,Value)
lh = plotSpectrum(___)
```

## Description

plotSpectrum(estimator) plots the MUSIC spectrum computed by the most recent step method execution for the phased.MUSICEstimator System object, estimator.

output_args = method(estimator,Name,Value) plots the MUSIC spatial spectrum with additional options specified by one or more Name,Value pair arguments.

lh = plotSpectrum(___) returns the line handle to the figure.

## Input Arguments

### estimator — MUSIC estimator

phased.MUSICEstimator System object.

MUSIC estimator, specified as a phased.MUSICEstimator System object

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Unit` — Units used for plotting

`'db'` (default) | `'mag'` | `'pow'`

Units used for plotting, specified as the comma-separated pair consisting of `'Unit'` and `'db'`, `'mag'`, or `'pow'`.

Data Types: `char`

### `NormalizeResponse` — Plot normalized spectrum

`false` (default) | `true`

Plot a normalized spectrum, specified as the comma-separated pair consisting of `'NormalizedResponse'` and `false` or `true`. Normalization sets the magnitude of the largest spectrum value to one.

Data Types: `char`

### `Title` — Title of plot

`'MUSIC Spatial Spectrum'` (default) | character vector

Title of plot, specified as a comma-separated pair consisting of `'Title'` and a character vector.

Example: `true`

Data Types: `char`

## Output Arguments

### `lh` — Line handle of plot

line handle

Line handle of plot.

## Examples

### Plot MUSIC Spectrum of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of 1 meter. Then plot the MUSIC spectrum.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the ULA array. The antenna operating frequency is 150 MHz.

```
fc = 150.0e6;
array = phased.ULA('NumElements',10,'ElementSpacing',1.0);
```

Create the arriving signals at the ULA. The true direction of arrival of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

```
fs = 8000.0;
t = (0:1/fs:1).';
sig1 = cos(2*pi*t*300.0);
sig2 = cos(2*pi*t*400.0);
sig = collectPlaneWave(array,[sig1 sig2],[10 20; 60 -5]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

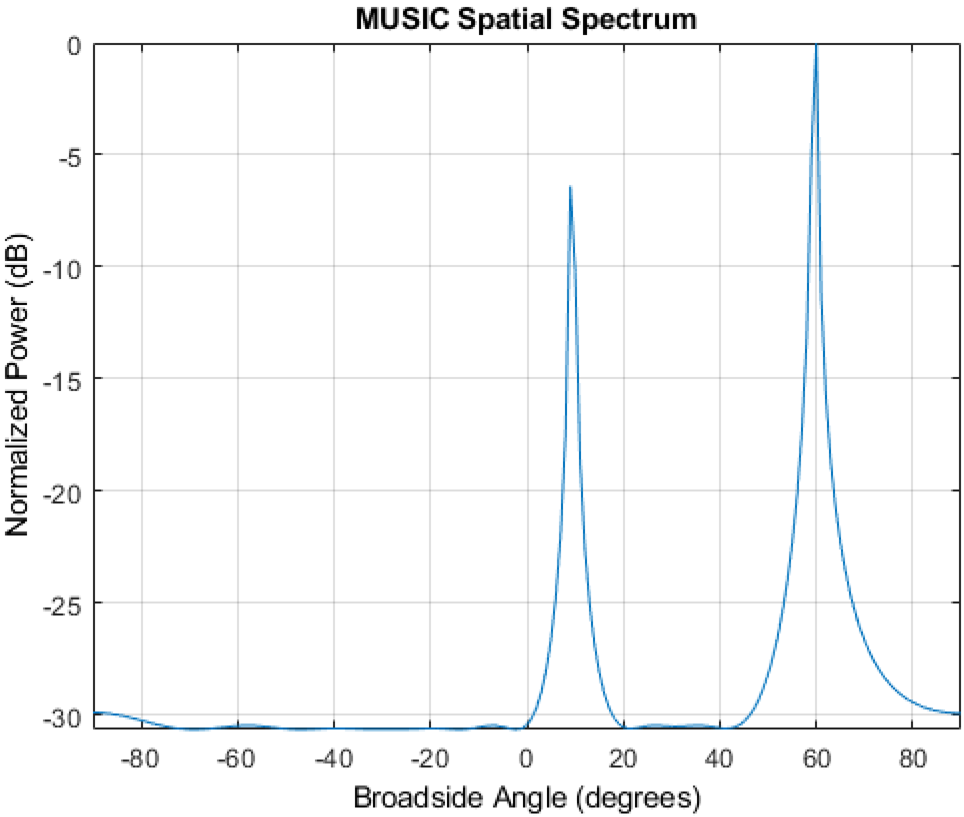
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignalsSource','Property',...
    'NumSignals',2);
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas = 1×2

    9.5829   60.3813
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



**Introduced in R2016b**

# reset

**System object:** `phased.MUSICEstimator`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(estimator)
```

## Description

`reset(estimator)` resets the internal state of the `phased.MUSICEstimator` System object, `estimator`.

## Input Arguments

### `estimator` — MUSIC estimator

`phased.MUSICEstimator` System object

MUSIC estimator, specified as a `phased.MUSICEstimator` System object.

**Introduced in R2016b**

# step

**System object:** `phased.MUSICEstimator`
**Package:** `phased`

Estimate direction of arrival using MUSIC

## Syntax

```
spectrum = step(estimator,X)
[spectrum,doa] = step(estimator,X)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`spectrum = step(estimator,X)` returns the MUSIC spectrum for a signal specified by `X`.

`[spectrum,doa] = step(estimator,X)` also returns the signal broadside directions of arrival, `doa`. To use this syntax, set the `DOAOutputPort` property to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `estimator` — MUSIC estimator

`phased.MUSICEstimator` System object

MUSIC estimator, specified as a `phased.MUSICEstimator` System object.

Example: `phased.MUSICEstimator`

### `X` — Received signal

*M*-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) contained in the signal, and *N* is the number of sensor elements in the array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

### `spectrum` — MUSIC spatial spectrum

nonnegative, real-valued *K*-length column vector

MUSIC spatial spectrum, returned as a non-negative, real-valued *K*-length column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the `ScanAngles` property.

### `doa` — Directions of arrival

real-valued *L*-length row vector

Directions of arrival of the signals, returned as a real-valued *L*-length row vector. The direction of arrival angle is the angle between the source direction and the array axis or broadside angle. Angle units are in degrees. *L* is the number of signals specified by the `NumSignals` property or computed using the method specified by the `NumSignalsMethod` property.

**Dependencies**

To enable this output argument, set the `DOAOutputPort` property to `true`.

# Examples

### Plot MUSIC Spectrum of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of 1 meter. Then plot the MUSIC spectrum.

**Note:** You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the ULA array. The antenna operating frequency is 150 MHz.

```
fc = 150.0e6;
array = phased.ULA('NumElements',10,'ElementSpacing',1.0);
```

Create the arriving signals at the ULA. The true direction of arrival of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

```
fs = 8000.0;
t = (0:1/fs:1).';
sig1 = cos(2*pi*t*300.0);
sig2 = cos(2*pi*t*400.0);
sig = collectPlaneWave(array,[sig1 sig2],[10 20; 60 -5]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignalsSource','Property',...
    'NumSignals',2);
[y,doas] = estimator(sig + noise);

# phased.MUSICEstimator2D

**Package:** `phased`

Estimate 2D direction of arrival using narrowband MUSIC algorithm

## Description

The `phased.MUSICEstimator2D` System object implements the narrowband multiple signal classification (MUSIC) algorithm for 2-D planar or 3-D arrays such as a uniform rectangular array (URA). MUSIC is a high-resolution direction-finding algorithm capable of resolving closely-spaced signal sources. The algorithm is based on the eigenspace decomposition of the sensor covariance matrix.

To estimate directions of arrival (DOA):

1. Define and set up a `phased.MUSICEstimator2D` System object. See "Construction" on page 1-1415.
2. Call the `step` method to estimate the DOAs according to the properties of `phased.MUSICEstimator2D`.

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`estimator = phased.MUSICEstimator2D` creates a MUSIC DOA estimator System object, `estimator`.

`estimator = phased.MUSICEstimator2D(Name,Value)` creates a System object, `estimator`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### SensorArray — Sensor array

phased.ULA array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object.

Example: phased.URA

### PropagationSpeed — Signal propagation speed

physconst('LightSpeed') (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by physconst('LightSpeed').

Example: 3e8

Data Types: single | double

### OperatingFrequency — Operating frequency

300e6 (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: 1e9

Data Types: single | double

### ForwardBackwardAveraging — Enable forward-backward averaging

false (default) | true

Enable forward-backward averaging, specified as false or true. Set this property to true to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Data Types: logical

### AzimuthScanAngles — Azimuth scan angles

[-90:90] (default) | real-valued row vector

Azimuth scan angles, specified as a or real-valued row vector. Angle units are in degrees. The angle values must lie between –180° and 180°, inclusive, and be in ascending order.

Example: `[-30:20]`

Data Types: `single` | `double`

### `ElevationScanAngles` — Elevation scan angles

`0` (default) | real-valued row vector

Elevation scan angles, specified as a real-valued row vector. Angle units are in degrees. The angle values must lie between –90° and 90°, inclusive, and be in ascending order.

Example: `[-70:75]`

Data Types: `single` | `double`

### `DOAOutputPort` — Enable directions of arrival output

`false` (default) | `true`

Option to enable directions-of-arrival (DOA) output, specified as `false` or `true`. To obtain the DOA of signals, set this property to `true`. The DOAs are returned in the second output argument when the object is executed.

Data Types: `logical`

### `NumSignalsSource` — Source of number of signals

`'Auto'` (default) | `'Property'`

Source of the number of arriving signals, specified as `'Auto'` or `'Property'`.

- `'Auto'` — The System object estimates the number of arriving signals using the method specified in the `NumSignalsMethod` property.
- `'Property'` — Specify the number of arriving signals using the `NumSignals` property.

Data Types: `char`

### `NumSignalsMethod` — Method used to estimate number of arriving signals

`'AIC'` (default) | `'MDL'`

Method used to estimate the number of arriving signals, specified as `'AIC'` or `'MDL'`.

- `'AIC'` — Akaike Information Criterion
- `'MDL'` — Minimum Description Length criterion

#### Dependencies

To enable this property, set `NumSignalsSource` to `'Auto'`.

Data Types: `char`

### `NumSignals` — Number of arriving signals

`1` (default) | positive integer

Number of arriving signals for DOA estimation, specified as a positive integer.

Example: `3`

#### Dependencies

To enable this property, set `NumSignalsSource` to `'Property'`.

Data Types: `single` | `double`

## Methods

| | |
|---|---|
| plotSpectrum | Plot 2-D MUSIC spectrum |
| reset | Reset states of System object |
| step | Estimate direction of arrival using 2-D MUSIC |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Estimate DOAs of Two Signals

Assume that two sinusoidal waves of frequencies 450 Hz and 600 Hz strike a URA from two different directions. Signals arrive from -37° azimuth, 0° elevation and 17° azimuth, 20° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 150 MHz and the signal sampling frequency is 8 kHz.

```
f1 = 450.0;
f2 = 600.0;
```

```
doa1 = [-37;0];
doa2 = [17;20];
fc = 150e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8000;
```

Create the URA with default isotropic elements. Set the frequency response range of the elements.

```
array = phased.URA('Size',[11 11],'ElementSpacing',[lam/2 lam/2]);
array.Element.FrequencyRange = [50.0e6 500.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(array,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:.5:50,...
    'ElevationScanAngles',-30:.5:30);
[~,doas] = estimator(x + noise)
```

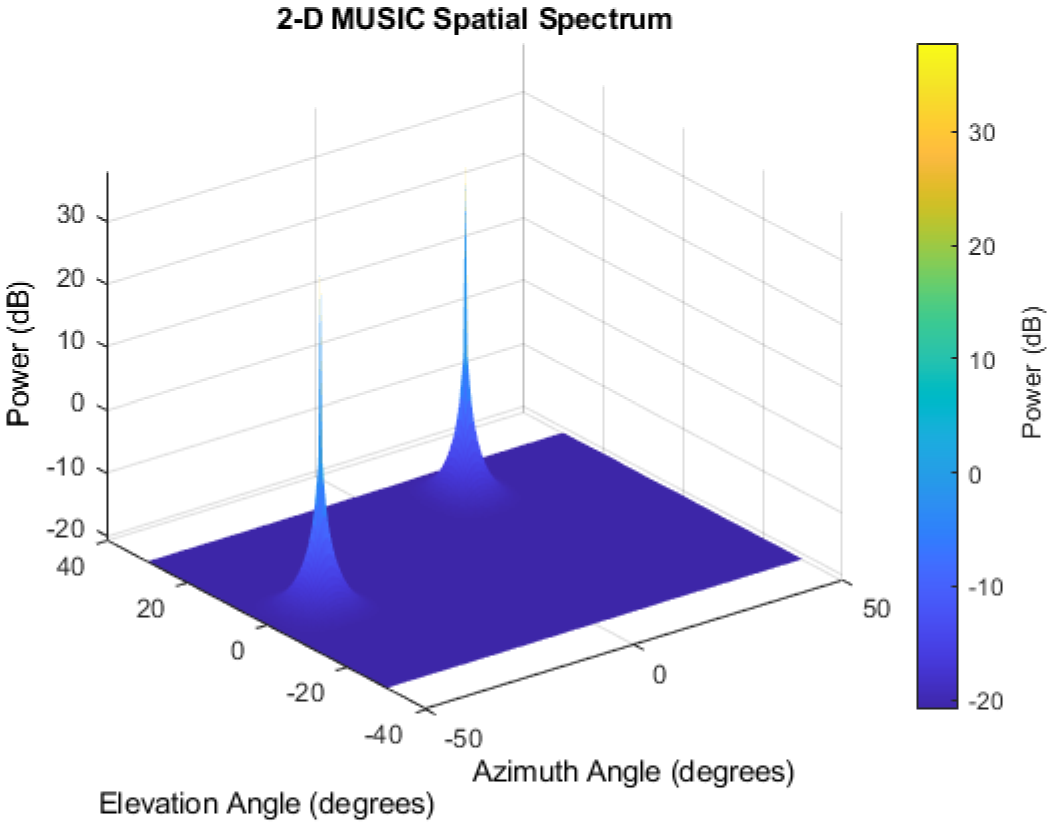
```
doas = 2×2

   -37    17
     0    20
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```



### Estimate DOAs of Two Signals at Disk Array

Assume that two sinusoidal waves of frequencies 1.6 kHz and 1.8 kHz strike a disk array from two different directions. The spacing between elements of the disk is 1/2 wavelength. Signals arrive from -31° azimuth, -11° elevation and 35° azimuth, 55° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 300 MHz and the signal sampling frequency is 8 kHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
f1 = 1.6e3;
f2 = 1.8e3;
doa1 = [-31;-11];
doa2 = [35;55];
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8.0e3;
```

Create a conformal array with default isotropic elements. First, create a URA to get the element positions.

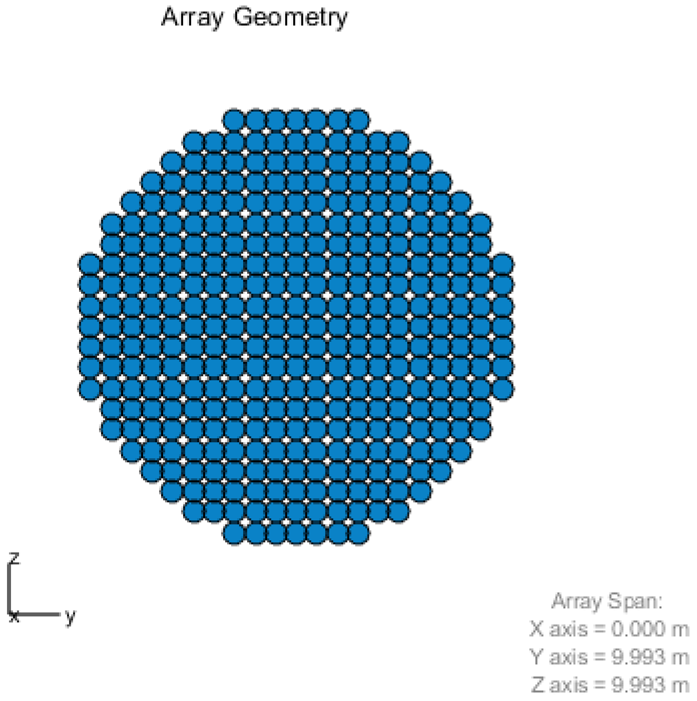
```
uraarray = phased.URA('Size',[21 21],'ElementSpacing',[lam/2 lam/2]);
pos = getElementPosition(uraarray);
```

Extract a subset of these to form an inscribed disk.

```
radius = 10.5*lam/2;
pos(:,sum(pos.^2) > radius^2) = [];
```

Then, create the conformal array using these positions.

```
confarray = phased.ConformalArray('ElementPosition',pos);
viewArray(confarray)
```



Set the frequency response range of the elements.

```
confarray.Element.FrequencyRange = [50.0e6 600.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1.5).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(confarray,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',confarray,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-60:.1:60,...
    'ElevationScanAngles',-60:.1:60);
[~,doas] = estimator(x + noise)
```

```
doas = 2×2

    35   -31
    55   -11
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```

# Algorithms

## MUSIC Algorithm

MUSIC stands for *MUltiple SIgnal Classification*. MUSIC is a high-resolution direction-finding algorithm that estimates directions of arrival (DOA) of signals at an array from the covariance matrix of array sensor data. MUSIC belongs to the subspace-decomposition family of direction-finding algorithms. Unlike conventional beamforming, MUSIC can resolve closely-spaced signal sources.

Based on eigenspace decomposition of the sensor covariance matrix, MUSIC divides the observation space into orthogonal signal and noise subspaces. Eigenvectors corresponding to the largest eigenvalues span the signal subspace. Eigenvectors corresponding to the smaller eigenvalues span the noise subspace. Because arrival (or steering) vectors lie in the signal subspace, they are orthogonal to the noise subspace. The arrival vectors depend on the direction of arrival of a signals. For a 2-D or 3-D array. the directions are determined by the azimuth and elevation of the sources. By searching over a grid of arrival angles, the algorithm finds those arrival vectors whose projection into the noise subspace is zero or at least very small.

MUSIC requires that the number of source signals is known. The algorithm degrades if the number of specified sources does not match the actual number of sources. Generally, you must provide an estimate of the number of sources or use one of the built-in source number estimation methods. For a description of the methods used to estimate the number of sources, see the `aictest` or `mdltest` functions.

In place of the true sensor covariance matrix, the algorithm computes the sample covariance matrix from the sensor data. MUSIC applies to noncoherent signals but can be extended to coherent signals using forward-backward averaging techniques. For a high-level description of the algorithm, see “MUSIC Super-Resolution DOA Estimation”.

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

Plot 2-D MUSIC spectrum

## Syntax

```
plotSpectrum(estimator)
output_args = method(estimator,Name,Value)
lh = plotSpectrum( ___ )
```

## Description

plotSpectrum(estimator) plots the 2-D MUSIC spatial spectrum computed by the most recent step method execution for the phased.MUSICEstimator2D, estimator.

output_args = method(estimator,Name,Value) plots the 2-D MUSIC spatial spectrum with additional options specified by one or more Name,Value pair arguments.

lh = plotSpectrum( ___ ) returns the line handle to the figure.

## Input Arguments

**estimator — 2-D MUSIC estimator**
phased.MUSICEstimator2D System object

2-D MUSIC estimator, specified as a phased.MUSICEstimator2D System object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Unit` — Units used for plotting

`'db'` (default) | `'mag'` | `'pow'`

Units used for plotting, specified as the comma-separated pair consisting of `'Unit'` and `'db'`, `'mag'`, or `'pow'`.

Example:

Data Types: `char`

### `NormalizeResponse` — Plot normalized spectrum

`false` (default) | `true`

Plot a normalized spectrum, specified as the comma-separated pair consisting of `'NormalizedResponse'` and `false` or `true`. Normalization sets the magnitude of the largest spectrum value to one.

Example: `true`

Data Types: `char`

### `Title` — Title of plot

`'2D MUSIC Spatial Spectrum'` (default) | character vector

Title of plot, specified as a comma-separated pair consisting of `'Title'` and a character vector.

Example: `true`

Data Types: `char`

## Output Arguments

### `lh` — Line handle of plot

line handle

Line handle of plot.

## Examples

### Estimate DOAs of Two Signals

Assume that two sinusoidal waves of frequencies 450 Hz and 600 Hz strike a URA from two different directions. Signals arrive from -37° azimuth, 0° elevation and 17° azimuth, 20° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 150 MHz and the signal sampling frequency is 8 kHz.

```
f1 = 450.0;
f2 = 600.0;
doa1 = [-37;0];
doa2 = [17;20];
fc = 150e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8000;
```

Create the URA with default isotropic elements. Set the frequency response range of the elements.

```
array = phased.URA('Size',[11 11],'ElementSpacing',[lam/2 lam/2]);
array.Element.FrequencyRange = [50.0e6 500.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(array,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:.5:50,...
    'ElevationScanAngles',-30:.5:30);
[~,doas] = estimator(x + noise)
```

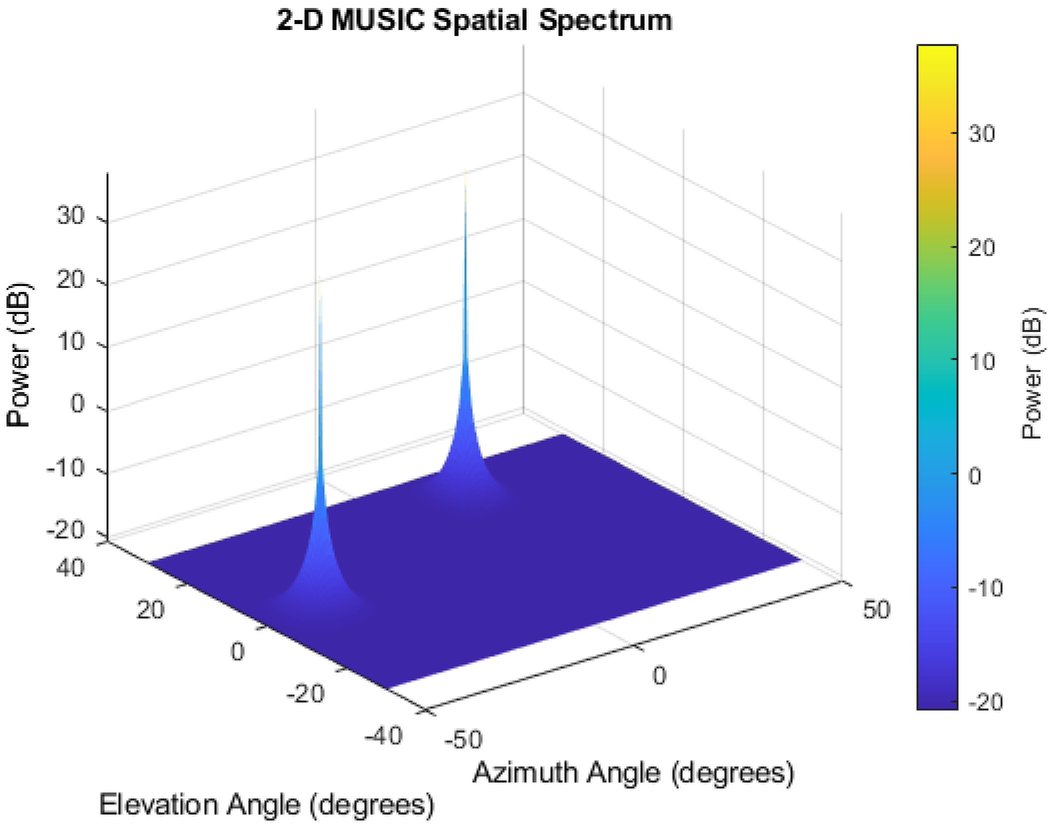
```
doas = 2×2
```

```
   -37    17
     0    20
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```



**Introduced in R2016b**

# reset

**System object:** `phased.MUSICEstimator2D`
**Package:** `phased`

Reset states of System object

## Syntax

```
reset(estimator)
```

## Description

`reset(estimator)` resets the internal state of the `phased.MUSICEstimator2D` System object, `estimator`.

## Input Arguments

**`estimator` — 2-D MUSIC estimator**
`phased.MUSICEstimator2D` System object

2-D MUSIC estimator, specified as a `phased.MUSICEstimator2D` System object.

**Introduced in R2016b**

# step

**System object:** `phased.MUSICEstimator2D`
**Package:** `phased`

Estimate direction of arrival using 2-D MUSIC

## Syntax

```
spectrum = step(estimator,X)
[spectrum,doa] = step(estimator,X)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`spectrum = step(estimator,X)` returns the 2-D MUSIC spectrum of a signal specified in `X`.

`[spectrum,doa] = step(estimator,X)` also returns the signal directions of arrival angles, `doa`. To use this syntax, set the `DOAOutputPort` property to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `estimator` — 2-D MUSIC estimator

`phased.MUSICEstimator2D` System object

2-D MUSIC estimator, specified as a `phased.MUSICEstimator2D` System object.

### `X` — Received signal

*M*-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) contained in the signal and *N* is the number of sensor elements in the array.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `single` | `double`
Complex Number Support: Yes

## Output Arguments

### `spectrum` — 2-D MUSIC spatial spectrum

nonnegative, real-valued *K*-length column vector

2-D MUSIC spatial spectrum, returned as a nonnegative, real-valued *K*-length column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the `AzimuthScanAngles` and `ElevationScanAngles` properties.

### doa — Directions of arrival

real-valued 2-by-*L* matrix

Directions of arrival of the signals, returned as a real-valued 2-by-*L* matrix. The direction of arrival angle is defined by the azimuth and elevation angles of the source with respect to the array local coordinate system. The first row of the matrix contains the azimuth angles and the second row contains the elevation angles. Angle units are in degrees. *L* is the number of signals specified by the NumSignals property or derived using the method specified by the NumSignalsMethod property.

**Dependencies**

To enable this output argument, set the DOAOutputPort property to true.

# Examples

### Estimate DOAs of Two Signals

Assume that two sinusoidal waves of frequencies 450 Hz and 600 Hz strike a URA from two different directions. Signals arrive from -37° azimuth, 0° elevation and 17° azimuth, 20° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 150 MHz and the signal sampling frequency is 8 kHz.

```
f1 = 450.0;
f2 = 600.0;
doa1 = [-37;0];
doa2 = [17;20];
fc = 150e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8000;
```

Create the URA with default isotropic elements. Set the frequency response range of the elements.

```
array = phased.URA('Size',[11 11],'ElementSpacing',[lam/2 lam/2]);
array.Element.FrequencyRange = [50.0e6 500.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(array,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:.5:50,...
    'ElevationScanAngles',-30:.5:30);
[~,doas] = estimator(x + noise)
```

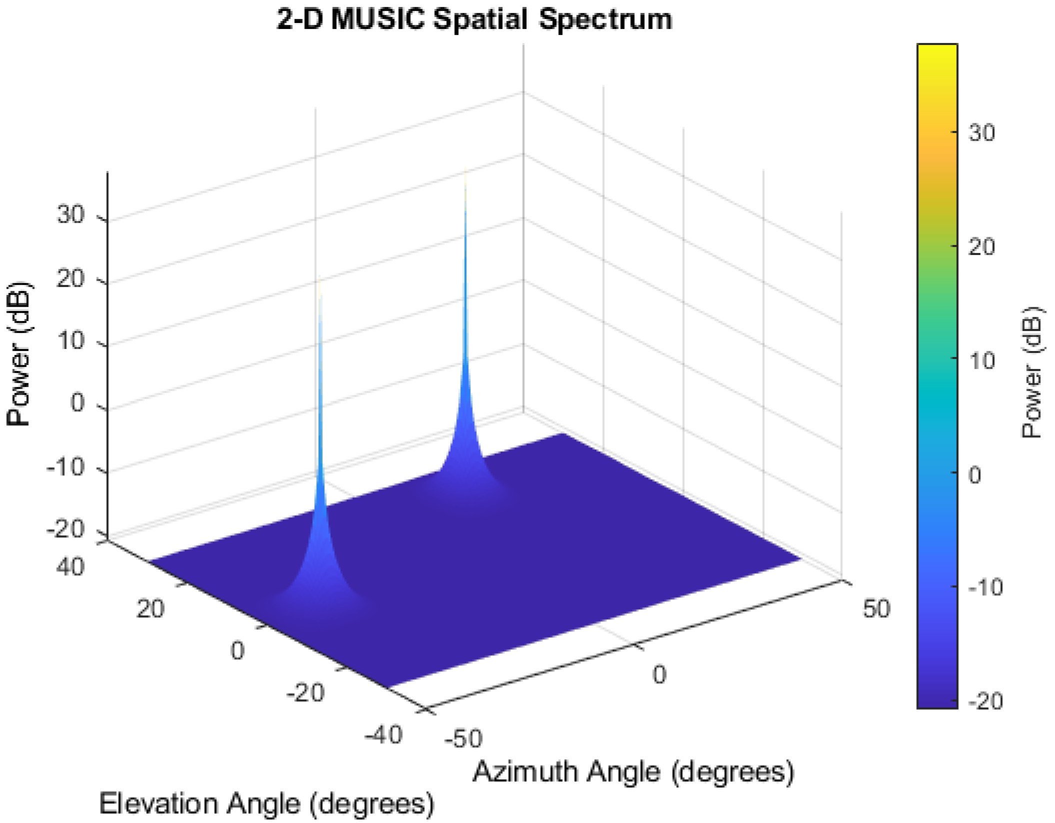
```
doas = 2×2

   -37    17
     0    20
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```



### Estimate DOAs of Two Signals at Disk Array

Assume that two sinusoidal waves of frequencies 1.6 kHz and 1.8 kHz strike a disk array from two different directions. The spacing between elements of the disk is 1/2 wavelength. Signals arrive from -31° azimuth, -11° elevation and 35° azimuth, 55° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 300 MHz and the signal sampling frequency is 8 kHz.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
f1 = 1.6e3;
f2 = 1.8e3;
doa1 = [-31;-11];
doa2 = [35;55];
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8.0e3;
```

Create a conformal array with default isotropic elements. First, create a URA to get the element positions.

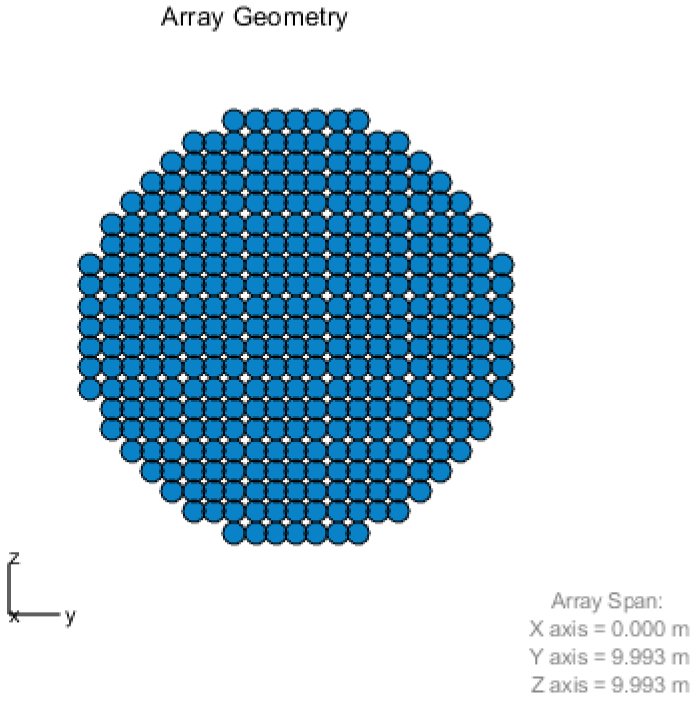
```
uraarray = phased.URA('Size',[21 21],'ElementSpacing',[lam/2 lam/2]);
pos = getElementPosition(uraarray);
```

Extract a subset of these to form an inscribed disk.

```
radius = 10.5*lam/2;
pos(:,sum(pos.^2) > radius^2) = [];
```

Then, create the conformal array using these positions.

```
confarray = phased.ConformalArray('ElementPosition',pos);
viewArray(confarray)
```



Set the frequency response range of the elements.

```
confarray.Element.FrequencyRange = [50.0e6 600.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1.5).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(confarray,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',confarray,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-60:.1:60,...
    'ElevationScanAngles',-60:.1:60);
[~,doas] = estimator(x + noise)
```

```
doas = 2×2

    35   -31
    55   -11
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```

**Introduced in R2016b**

# phased.OmnidirectionalMicrophoneElement

**Package:** phased

Omnidirectional microphone

## Description

The OmnidirectionalMicrophoneElement object models an omnidirectional microphone with an equal response in all directions.

To compute the response of the microphone element for specified directions:

1. Define and set up your omnidirectional microphone element. See “Construction” on page 1-1441.
2. Call step to estimate the microphone response according to the properties of phased.OmnidirectionalMicrophoneElement. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

H = phased.OmnidirectionalMicrophoneElement creates an omnidirectional microphone system object, H, that models an omnidirectional microphone element whose response is 1 in all directions.

H = phased.OmnidirectionalMicrophoneElement(Name,Value) creates an omnidirectional microphone object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### `FrequencyRange`

Operating frequency range

Specify the operating frequency range (in Hz) of the microphone element as a 1x2 row vector in the form of `[LowerBound HigherBound]`. The microphone element has no response outside the specified frequency range.

**Default:** `[0 1e20]`

### `BackBaffled`

Baffle the back of microphone element

Set this property to `true` to baffle the back of the microphone element. In this case, the microphone responses to all azimuth angles beyond +/– 90 degrees from the broadside (0 degree azimuth and elevation) are 0.

When the value of this property is `false`, the back of the microphone element is not baffled.

**Default:** `false`

## Methods

| | |
|---|---|
| directivity | Directivity of omnidirectional microphone element |
| isPolarizationCapable | Polarization capability |
| pattern | Plot omnidirectional microphone element directivity and patterns |
| patternAzimuth | Plot omnidirectional microphone element directivity or pattern versus azimuth |
| patternElevation | Plot omnidirectional microphone element directivity or pattern versus elevation |
| plotResponse | Plot response pattern of microphone |
| step | Output response of microphone |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

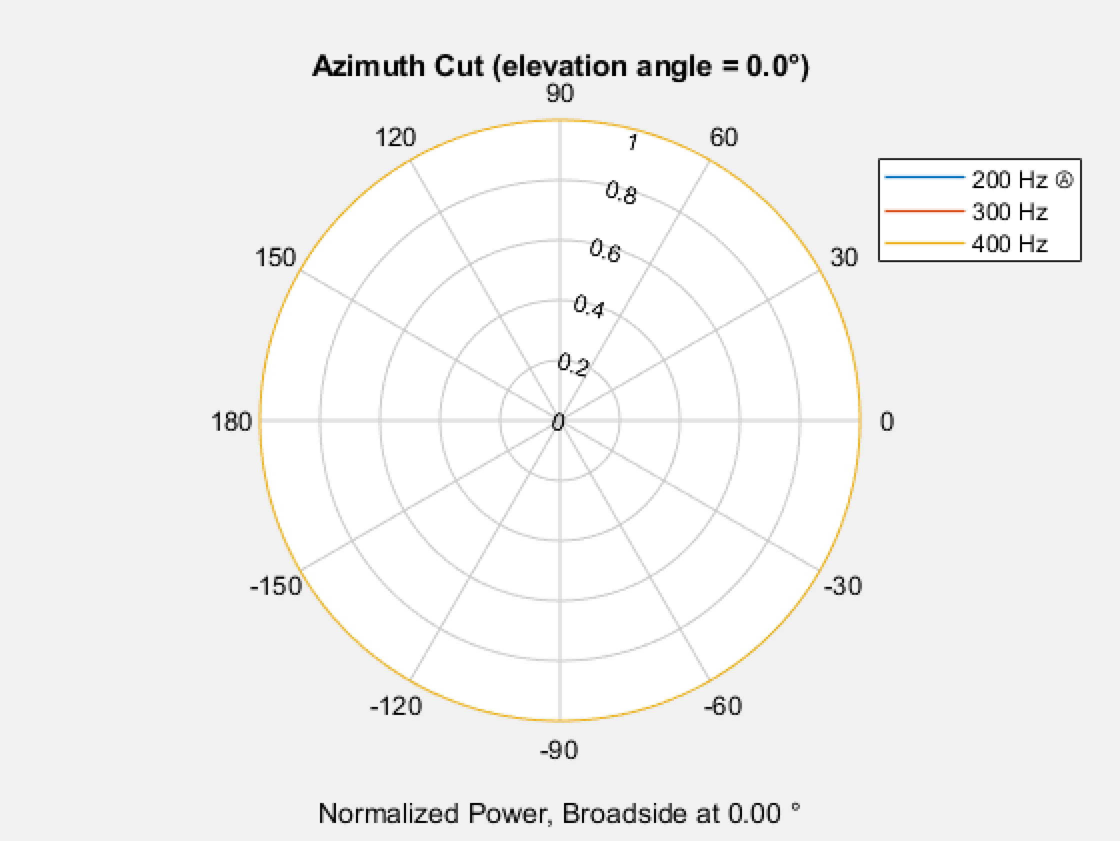
### Display Omni-Directional Microphone Pattern

Create an omnidirectional microphone. Find the microphone response at 200, 300, and 400 Hz for the incident angle 0° azimuth and 0° elevation. Then, plot the azimuth response of the microphone at three frequencies.

```
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 2e3]);
fc = [200 300 400];
ang = [0;0];
resp = microphone(fc,ang);
```

Plot the response pattern. Response patterns for all three frequencies are the same.

```
pattern(microphone,fc,[-180:180],0,'CoordinateSystem','polar','Type','power');
```



# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**Introduced in R2012a**

# directivity

**System object:** `phased.OmnidirectionalMicrophoneElement`
**Package:** `phased`

Directivity of omnidirectional microphone element

## Syntax

`D = directivity(H,FREQ,ANGLE)`

## Description

`D = directivity(H,FREQ,ANGLE)` returns the “Directivity (dBi)” on page 1-1449 of an omnidirectional microphone element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

## Input Arguments

### H — Omnidirectional Microphone Element

System object

Omnidirectional microphone element specified as a `phased.OmnidirectionalMicrophoneElement` System object.

Example: `H = phased.OmnidirectionalMicrophoneElement`

### FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –`Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –`Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: `[45 60; 0 10]`

Data Types: `double`

## Output Arguments

### `D` — Directivity

*M*-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix. Each row corresponds to one of the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

## Examples

### Directivity of Omnidirectional Microphone Element

Compute the directivity of an omnidirectional microphone element for several different directions.

Create the omnidirectional microphone element system object.

```
myMic = phased.OmnidirectionalMicrophoneElement();
```

Select the angles of interest at constant elevation angle set equal to zero degrees. Select seven azimuth angles centered at boresight (zero degrees azimuth and zero degrees elevation). Finally, set the desired frequency to 1 kHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1000;
```

Compute the directivity along the constant elevation cut.

```
d = directivity(myMic,freq,ang)
```

```
d = 7×1

     0
     0
     0
     0
     0
     0
     0
```

Next select the angles of interest to be at constant azimuth angle at zero degrees. All elevation angles are centered around boresight. The five elevation angles range from -20 to +20 degrees. Set the desired frequency to 1 GHz.

```
ang = [0,0,0,0,0; -20,-10,0,10,20];
freq = 1000;
```

Compute the directivity along the constant azimuth cut.

```
d = directivity(myMic,freq,ang)
```

```
d = 5×1

     0
     0
     0
     0
     0
```

For an omnidirectional microphone, the directivity is independent of direction.

# More About

## Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# isPolarizationCapable

**System object:** `phased.OmnidirectionalMicrophoneElement`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(microphone)
```

## Description

`flag = isPolarizationCapable(microphone)` returns a Boolean value, `flag`, indicating whether the `phased.OmnidirectionalMicrophoneElement` supports polarization. An element supports polarization if it can create or respond to polarized fields. This microphone element, as all microphone elements, does not support polarization.

## Input Arguments

### `microphone` — Omni-directional microphone element

Omni-directional microphone element specified as a `phased.OmnidirectionalMicrophoneElement` System object

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the microphone element supports polarization or `false` if it does not. Because the `phased.OmnidirectionalMicrophoneElement` object does not support polarization, `flag` is always returned as `false`.

# Examples

### Omnidirectional Microphone Element Does Not Support Polarization

Determine whether a `phased.OmnidirectionalMicrophoneElement` microphone element supports polarization.

```
microphone = phased.OmnidirectionalMicrophoneElement;
isPolarizationCapable(microphone)
```

```
ans = logical
   0
```

The returned value `0` shows that the omnidirectional microphone element does not support polarization.

# pattern

**System object:** `phased.OmnidirectionalMicrophoneElement`
**Package:** `phased`

Plot omnidirectional microphone element directivity and patterns

## Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern(___,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern(___)
```

## Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern(___,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern(___)` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-1462 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

### `sElem` — Omnidirectional microphone element

System object

Omnidirectional microphone element, specified as a `phased.OmnidirectionalMicrophoneElement` System object.

Example: `sElem = phased.OmnidirectionalMicrophoneElement;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

### `AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

## Output Arguments

### PAT — Element pattern

*N*-by-*M* real-valued matrix

Element pattern, returned as an *N*-by-*M* real-valued matrix. The pattern is a function of azimuth and elevation. The rows of PAT correspond to the azimuth angles in the vector specified by EL_ANG. The columns correspond to the elevation angles in the vector specified by AZ_ANG.

**AZ_ANG — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in AZ. The columns of PAT correspond to the values in AZ_ANG. Units are in degrees.

**EL_ANG — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in EL. The rows of PAT correspond to the values in EL_ANG. Units are in degrees.

## Examples

### Magnitude and Directivity Patterns of Omnidirectional Microphone

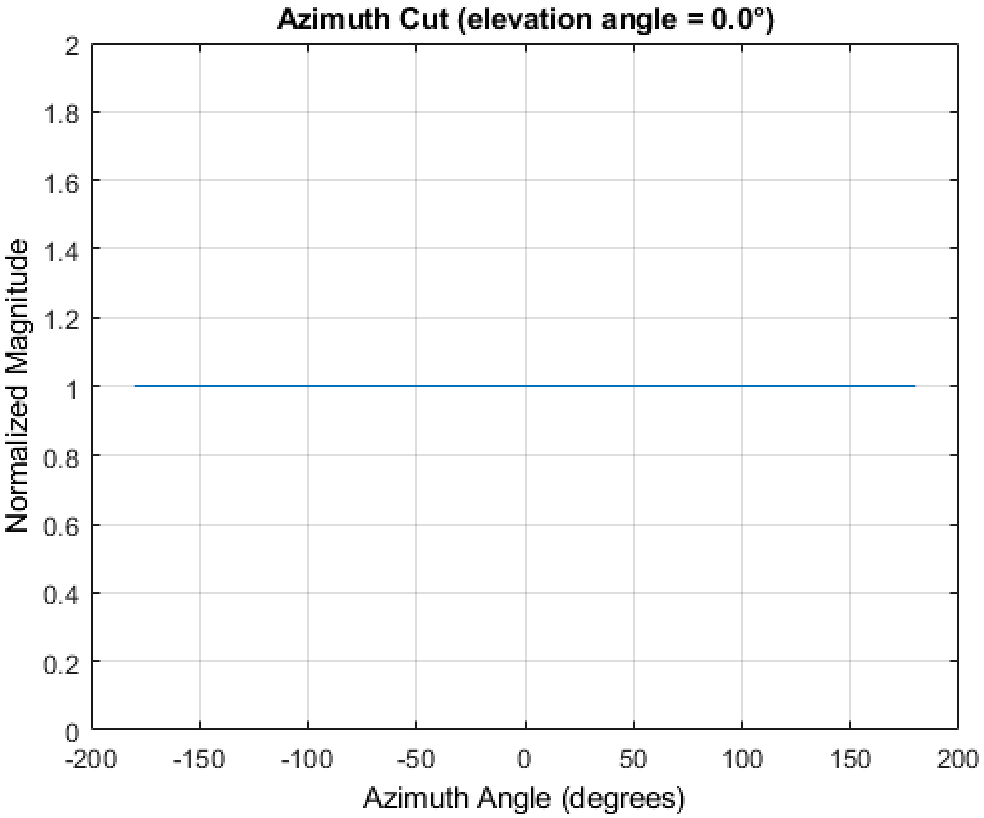
Construct an omnidirectional microphone and plot the magnitude and directivity patterns. The microphone operating frequency spans the range 20 to 20000 Hz.

Construct the omnidirectional microphone.

```
sOmni = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

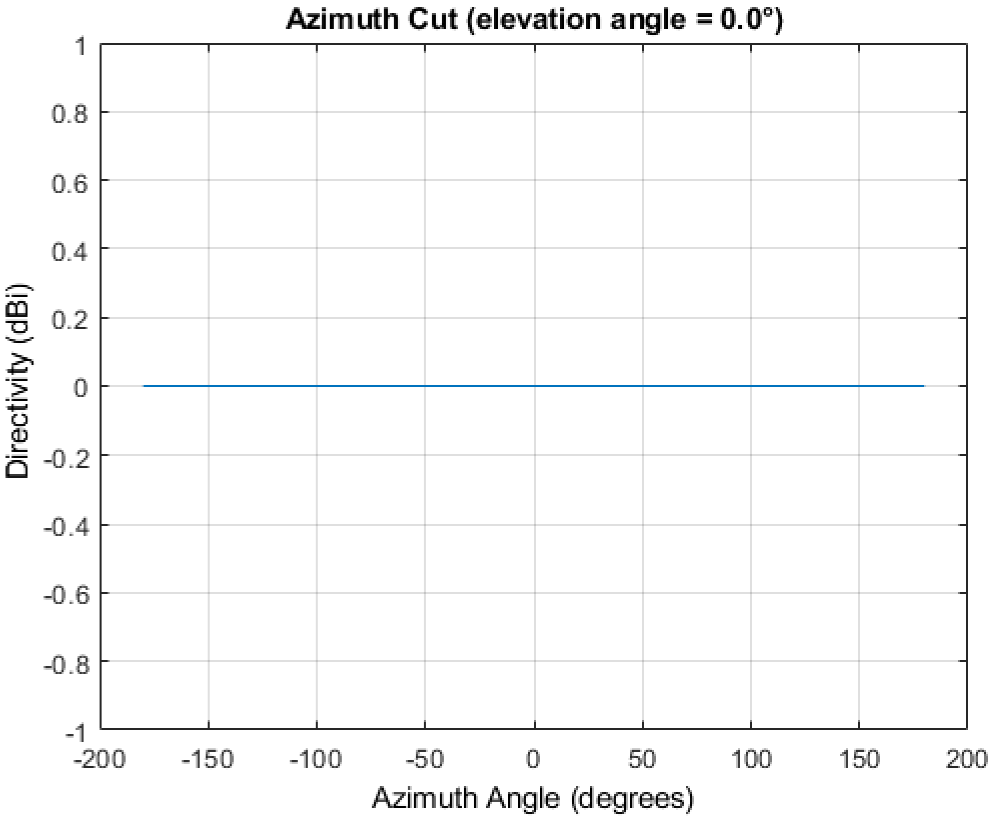
Plot the microphone magnitude pattern at 200 Hz.

```
fc = 200;
pattern(sOmni,fc,[-180:180],0,...
    'CoordinateSystem','rectangular',...
    'Type','efield')
```



Plot the microphone directivity.

```
pattern(sOmni,fc,[-180:180],0,...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```



The directivity is 0 dbi as expected for an omnidirectional element.

### 3-D Magnitude Pattern of Omnidirectional Microphone

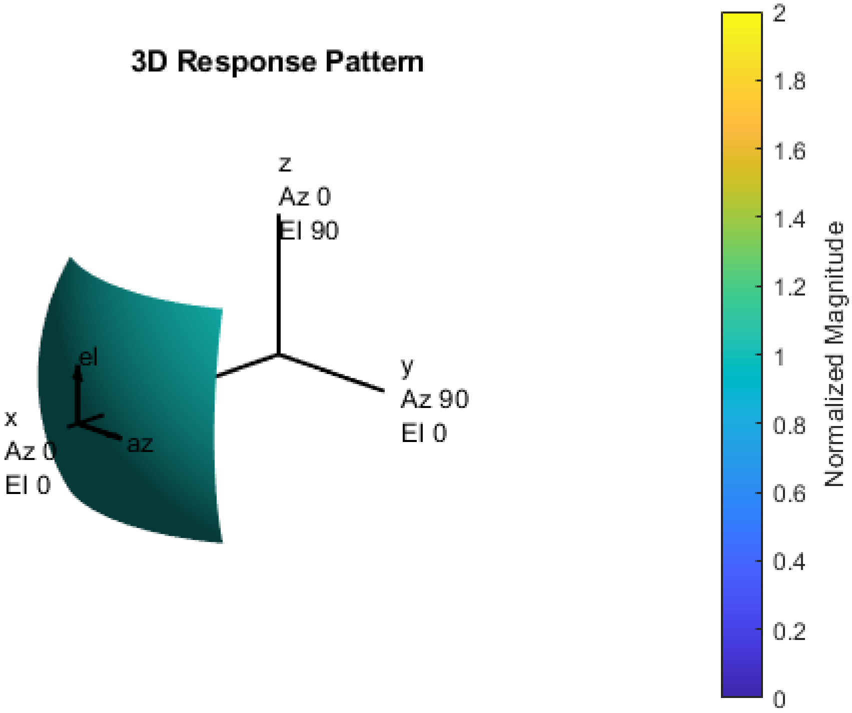
Construct an omnidirectional microphone with response in the frequency range 20-20000 Hz. Then, plot the 3-D magnitude pattern over a range of angles.

Construct the microphone element.

```
sOmin = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

Plot the 3-D pattern at 500 Hz between -30 to 30 degrees in both azimuth and elevation in 0.1 degree increments.

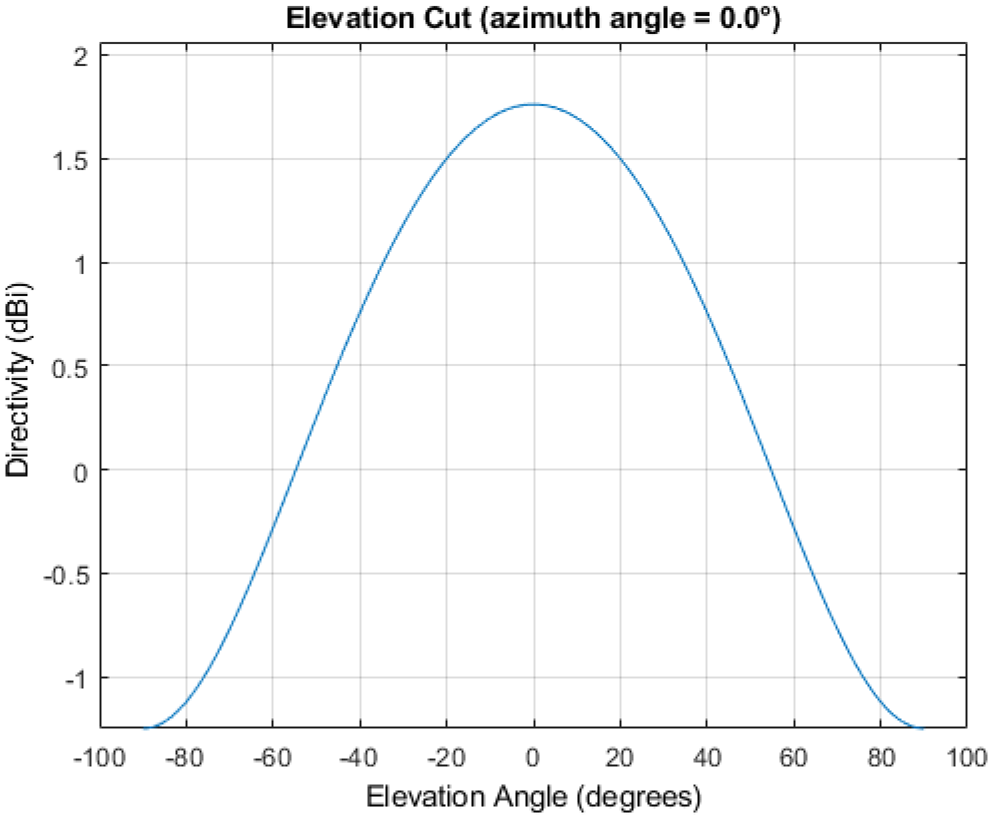
```
fc = 500;
pattern(sOmin,fc,[-30:0.1:30],[-30:0.1:30],...
    'CoordinateSystem','polar',...
    'Type','efield')
```



### Plot Directivity of Crossed-Dipole Antenna

Create a crossed-dipole antenna. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Then, plot the directivity at a constant azimuth of 0˚.

```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[1e9 2e9]);
fc = 1.5e9;
pattern(antenna,fc,0,-90:90,'Type','directivity', ...
    'CoordinateSystem','rectangular')
```



The directivity is maximum at 0˚ elevation and attains a value of approximately 1.75 dB.

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi\frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>

`patternAzimuth` | `patternElevation`

**Introduced in R2015a**

# patternAzimuth

**System object:** `phased.OmnidirectionalMicrophoneElement`
**Package:** `phased`

Plot omnidirectional microphone element directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**`sElem` — Omnidirectional microphone element**
System object

Omnidirectional microphone element, specified as a `phased.OmnidirectionalMicrophoneElement` System object.

Example: `sElem = phased.OmnidirectionalMicrophoneElement;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### Azimuth — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

# Examples

### Azimuth Pattern of Omnidirectional Microphone Element

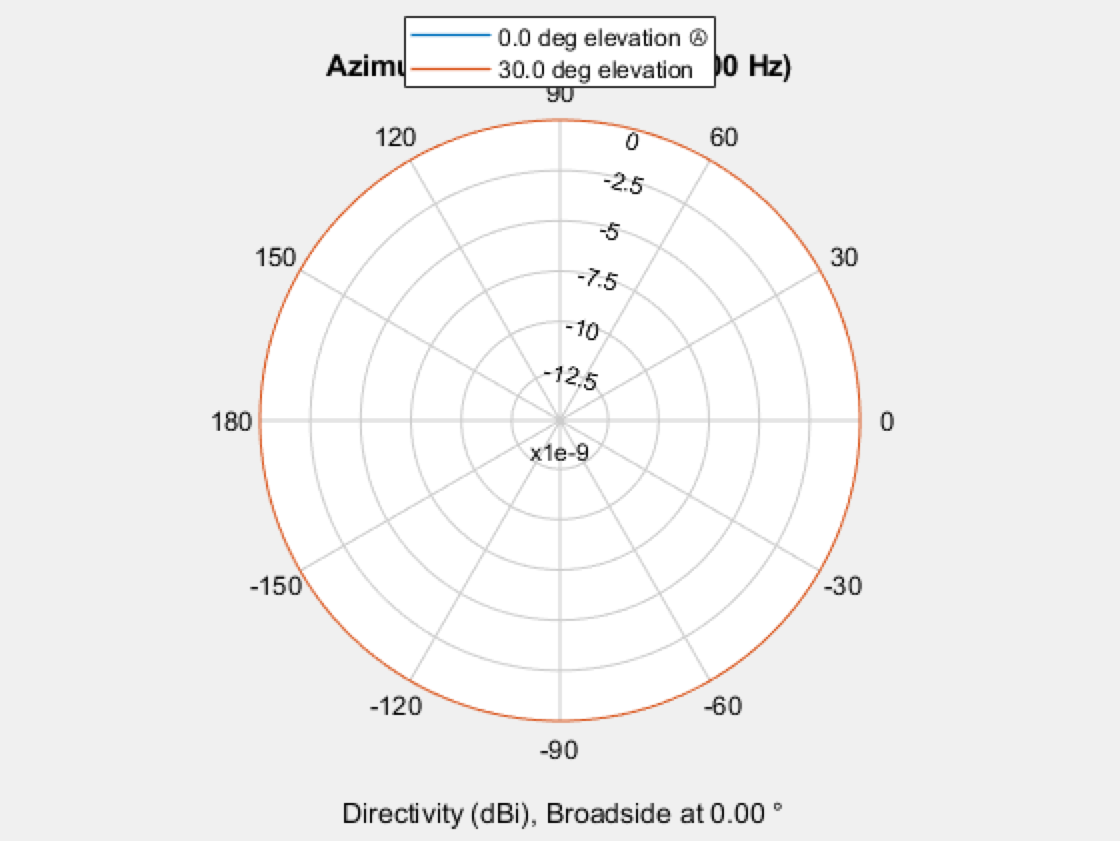
Create an omnidirectional microphone element. Plot an azimuth cut of the directivity at 0 and 30 degrees elevation. Assume an operating frequency of 500 Hz.

Create the microphone element.

```
sOmni = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[100,900]);
fc = 500;
```

Plot the azimuth pattern.

```
patternAzimuth(sOmni,fc,[0 30])
```



Because of the omnidirectionality of the microphone, the two patterns coincide.

Plot a reduced range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(sOmni,fc,[0 30],'Azimuth',[-20:20])
```

Plot omnidirectional microphone element directivity or pattern versus elevation

## Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(sElem,FREQ) plots the 2-D element directivity pattern versus elevation (in dBi) for the element sElem at zero degrees azimuth angle. The argument FREQ specifies the operating frequency.

patternElevation(sElem,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(sElem,FREQ,AZ,Name,Value) plots the element pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the element pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

**sElem — Omnidirectional microphone element**
System object

Omnidirectional microphone element, specified as a `phased.OmnidirectionalMicrophoneElement` System object.

Example: `sElem = phased.OmnidirectionalMicrophoneElement;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### `Elevation` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

## Output Arguments

### PAT — Element directivity or pattern

*P*-by-*N* real-valued matrix

Element directivity or pattern, returned as an *P*-by-*N* real-valued matrix. The dimension *P* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

## Examples

### Elevation Pattern of Omnidirectional Microphone Element

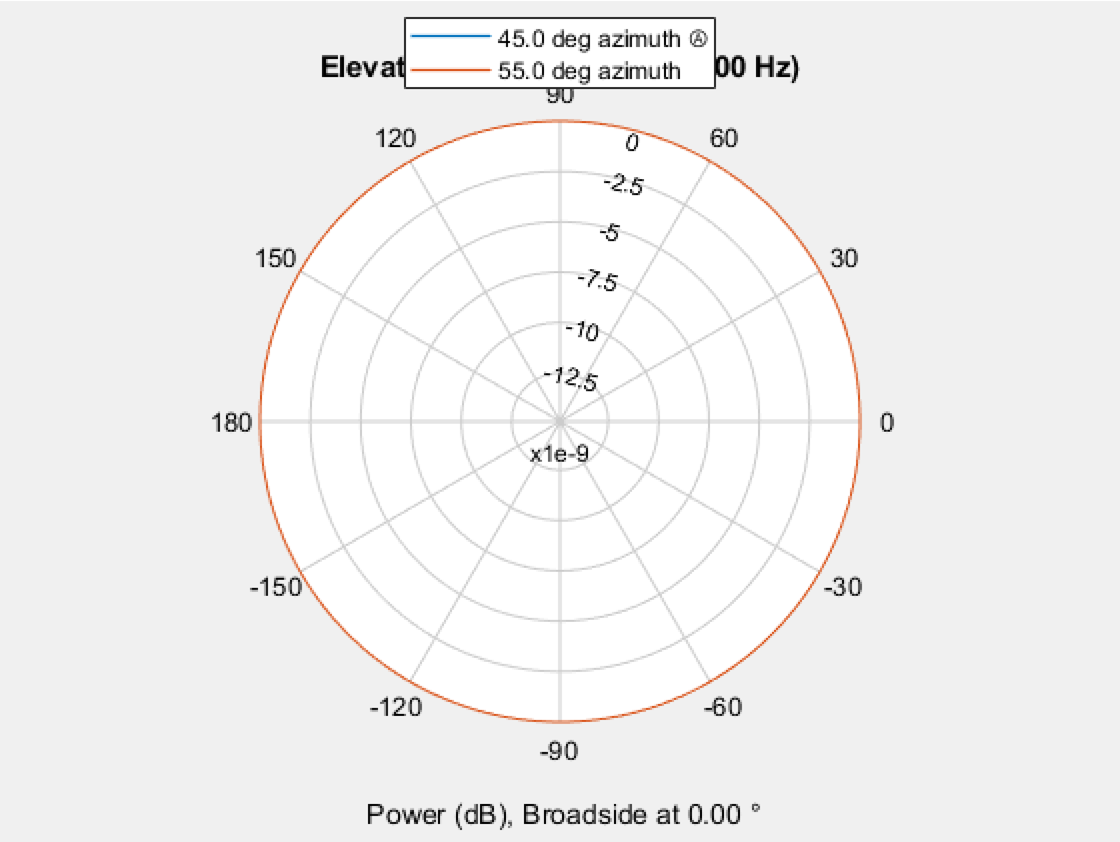
Construct an omnidirectional microphone element. Plot an elevation cut of the power 45 and 55 degrees azimuth. Assume the operating frequency is 500 Hz.

Create the microphone element.

```
fc = 500;
sOmni = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[100,900]);
```

Display the power pattern.

```
patternElevation(sOmni,fc,[45 55],'Type','powerdb')
```



Because of the omnidirectionality, the two plots coincide.

Plot a reduced range of elevation angles using the `Elevation` parameter.

```
patternElevation(sOmni,fc,[45 55],...
    'Elevation',[-20:20],...
    'Type','powerdb')
```

# plotResponse

**System object:** `phased.OmnidirectionalMicrophoneElement`
**Package:** `phased`

Plot response pattern of microphone

## Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Element System object

**`FREQ`**

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### CutAngle

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

**Default:** `0`

### Format

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

**Default:** `'Line'`

### NormalizeResponse

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `true`

### OverlayFreq

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the antenna response pattern. The allowable values are |'None' | 'Combined' | 'H' | 'V' | where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** 'None'

### RespCut

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

### Unit

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| db | power pattern in dB scale |
| mag | field pattern |
| pow | power pattern |
| dbi | directivity |

**Default:** 'db'

### AzimuthAngles

Azimuth angles for plotting element response, specified as a row vector. The AzimuthAngles parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'Az' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the AzimuthAngles and ElevationAngles parameters simultaneously.

**Default:** [-180:180]

### ElevationAngles

Elevation angles for plotting element response, specified as a row vector. The ElevationAngles parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the RespCut parameter is set to 'El' or '3D' and the Format parameter is set to 'Line' or 'Polar'. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the RespCut parameter to '3D', you can set the ElevationAngles and AzimuthAngles parameters simultaneously.

**Default:** [-90:90]

### UGrid

*U* coordinate values for plotting element response, specified as a row vector. The UGrid parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to 'U' or '3D'. The values of UGrid should be between –1 and 1 and should be specified in nondecreasing order. You can set the UGrid and VGrid parameters simultaneously.

**Default:** [-1:0.01:1]

### VGrid

*V* coordinate values for plotting element response, specified as a row vector. The VGrid parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the Format parameter is set to 'UV' and the RespCut parameter is set to '3D'. The values of VGrid

should be between –1 and 1 and should be specified in nondecreasing order. You can set the VGrid and UGrid parameters simultaneously.

**Default:** [-1:0.01:1]

## Examples

### Plot Response and Directivity of Omnidirectional Microphone

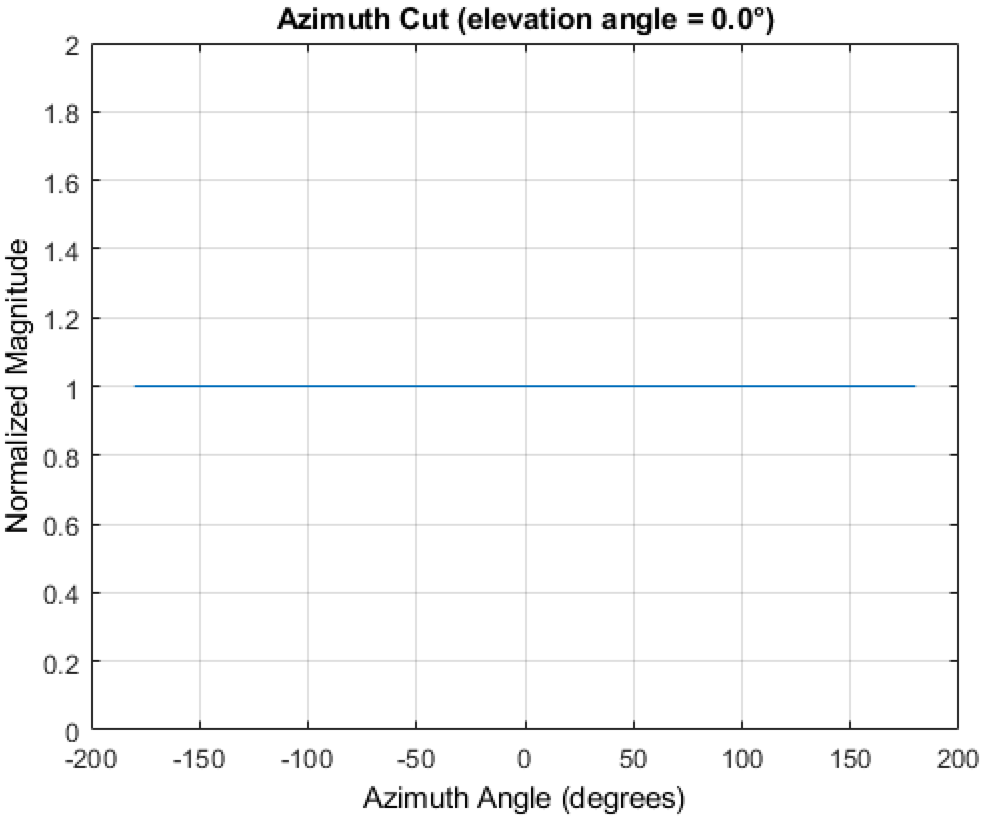
This example shows how to construct an omnidirectional microphone and how to plot its response and directivity. The microphone operating frequency spans the range 20 to 20000 Hz.

Construct the omnidirectional microphone.

```
sOmni = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

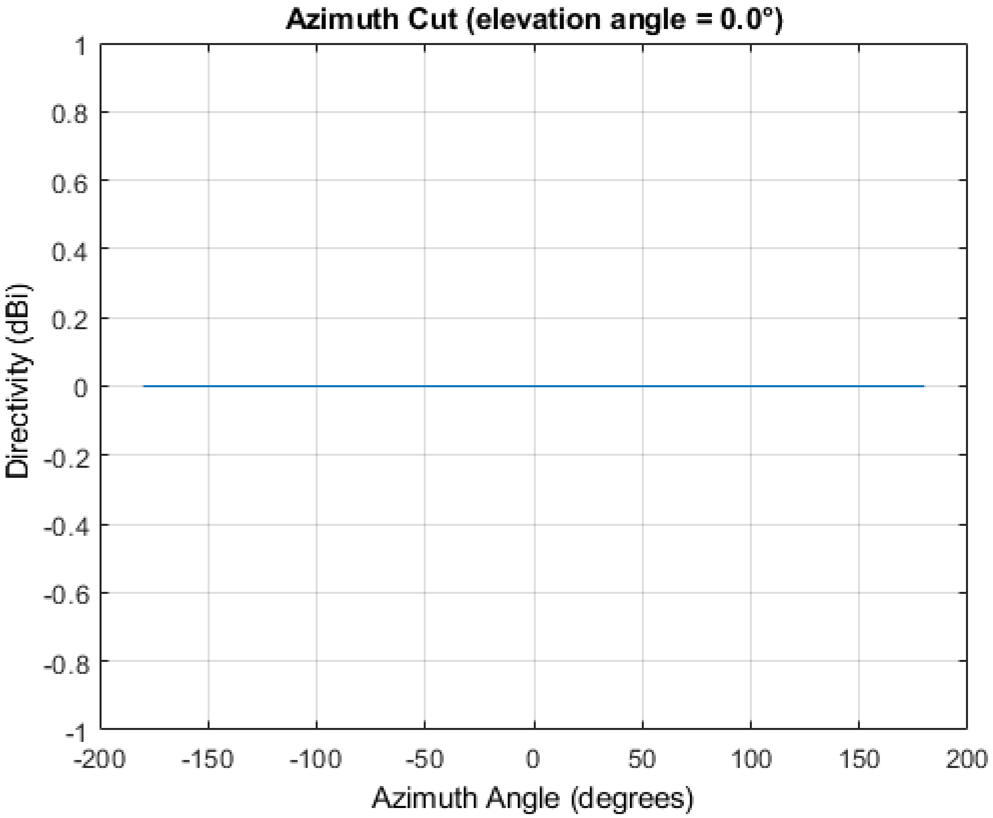
Plot the microphone response at 200 Hz.

```
fc = 200;
plotResponse(sOmni,fc,'Unit','mag');
```



Plot the microphone directivity.

```
plotResponse(sOmni,fc,'Unit','dbi');
```



### Plot 3-D Response of Omnidirectional Microphone

This example shows how to construct an omnidirection microphone with response in the frequency range 20 - 20000 Hz and how to plot its 3-D response over a range of angles.

Construct the microphone element.

```
sOmin = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

Plot the 3-D response at 500 Hz. Show the response between -30 to 30 degrees in both azimuth and elevation in 0.1 degree increments.

```
plotResponse(sOmin,500,'Format','Polar',...
    'RespCut','3D','Unit','mag',...
    'AzimuthAngles',[-30:0.1:30],...
    'ElevationAngles',[-30:0.1:30]);
```

**System object:** `phased.OmnidirectionalMicrophoneElement`
**Package:** `phased`

Output response of microphone

## Syntax

```
RESP = step(H,FREQ,ANG)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the microphone's magnitude response, `RESP`, at frequencies specified in `FREQ` and directions specified in `ANG`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Microphone object.

**FREQ**

Frequencies in hertz. FREQ is a row vector of length L.

**ANG**

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction’s azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

## Output Arguments

**RESP**

Response of microphone. RESP is an M-by-L matrix that contains the responses of the microphone element at the M angles specified in ANG and the L frequencies specified in FREQ.

## Examples

### Display Omni-Directional Microphone Pattern

Create an omnidirectional microphone. Find the microphone response at 200, 300, and 400 Hz for the incident angle 0° azimuth and 0° elevation. Then, plot the azimuth response of the microphone at three frequencies.

```
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 2e3]);
fc = [200 300 400];
ang = [0;0];
resp = microphone(fc,ang);
```

Plot the response pattern. Response patterns for all three frequencies are the same.

```
pattern(microphone,fc,[-180:180],0,'CoordinateSystem','polar','Type','power');
```

# phased.PartitionedArray

**Package:** `phased`

Phased array partitioned into subarrays

## Description

The `PartitionedArray` object represents a phased array that is partitioned into one or more subarrays.

To obtain the response of the subarrays in a partitioned array:

1. Define and set up your partitioned array. See “Construction” on page 1-1493.
2. Call `step` to compute the response of the subarrays according to the properties of `phased.PartitionedArray`. The behavior of `step` is specific to each object in the toolbox.

You can also specify a `PartitionedArray` object as the value of the `SensorArray` or `Sensor` property of objects that perform beamforming, steering, and other operations.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.PartitionedArray` creates a partitioned array System object, `H`. This object represents an array that is partitioned into subarrays.

`H = phased.PartitionedArray(Name,Value)` creates a partitioned array object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `Array`

Sensor array

Sensor array, specified as any array System object belonging to Phased Array System Toolbox.

**Default:** `phased.ULA('NumElements',4)`

### `SubarraySelection`

Subarray definition matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the number of elements in the array. Each row of the matrix corresponds to a subarray and each entry in the row indicates whether or not an element belongs to the subarray. When the entry is zero, the element does not belong to the subarray. A nonzero entry represents a complex-valued weight applied to the corresponding element. Each row must contain at least one nonzero entry.

The phase center of each subarray is at the subarray geometric center. The `SubarraySelection` and `Array` properties determine the geometric center.

**Default:** `[1 1 0 0; 0 0 1 1]`

### `SubarraySteering`

Subarray steering method

Specify the method of subarray steering as either `'None'` | `'Phase'` | `'Time'` | `'Custom'`.

- When you set this property to `'Phase'`, a phase shifter is used to steer the subarray. Use the `STEERANG` argument of the `step` method to define the steering direction.
- When you set this property to `'Time'`, subarrays are steered using time delays. Use the `STEERANG` argument of the `step` method to define the steering direction.
- When you set this property to `'Custom'`, subarrays are steered by setting independent weights for all elements in each subarray. Use the `WS` argument of the `step` method to define the weights for all subarrays.

**Default:** `'None'`

### `PhaseShifterFrequency`

Subarray phase shifter frequency

Specify the operating frequency of phase shifters that perform subarray steering. The property value is a positive scalar in hertz. This property applies when you set the `SubarraySteering` property to `'Phase'`.

**Default:** `300e6`

### `NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

**Default:** `0`

## Methods

| | |
|---|---|
| directivity | Directivity of partitioned array |
| collectPlaneWave | Simulate received plane waves |
| getElementPosition | Positions of array elements |
| getNumElements | Number of elements in array |
| getNumSubarrays | Number of subarrays in array |
| getSubarrayPosition | Positions of subarrays in array |
| isPolarizationCapable | Polarization capability |
| pattern | Plot partitioned array directivity, field, and power patterns |
| patternAzimuth | Plot partitioned array directivity or pattern versus azimuth |
| patternElevation | Plot partitioned array directivity or pattern versus elevation |
| plotResponse | Plot response pattern of array |
| step | Output responses of subarrays |
| viewArray | View array geometry |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Azimuth Response of Partitioned ULA

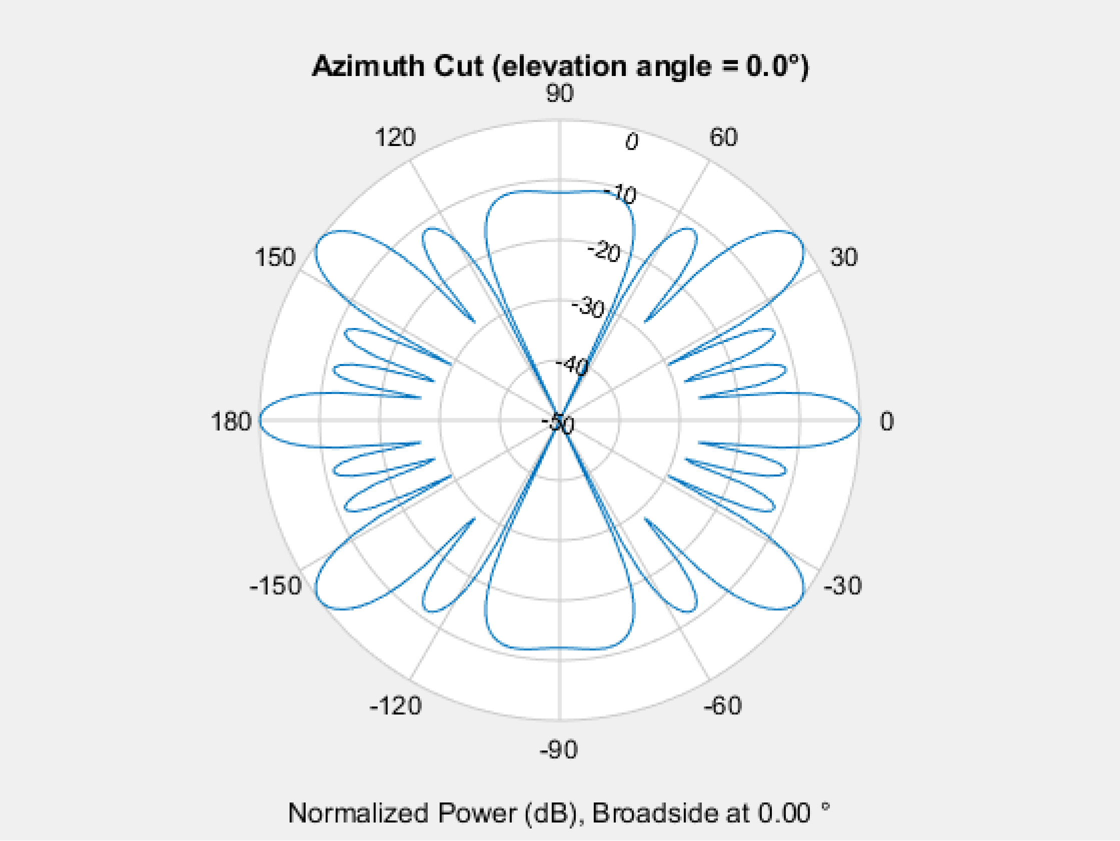
Plot the azimuth response of a 4-element ULA partitioned into two 2-element ULA's. The element spacing is one-half wavelength.

Create the ULA, and partition it into two 2-element ULA's.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
    'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
fc = 1e9;
pattern(sPA,fc,[-180:180],0,'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Normalize',true)
```



### Response of Subarrays of Partitioned ULA

Create a 4-element ULA. Then partition the ULA into two 2-element ULAs. Then, calculate the response at boresight of a 4-element ULA partitioned into two 2-element ULAs.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
   'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Calculate the response at 1 GHz. The signal propagation speed is the speed of light.

```
fc = 1e9;
resp = step(sPA,fc,[0;0],physconst('LightSpeed'))
```

```
resp = 2×1

     2
     2
```

### Subarray Element Weights for Partitioned Array

Create a partitioned URA array with three subarrays of different sizes. The subarrays have 8, 16, and 32 elements. Use different sets of subarray element weights for each subarray.

Create a 4-by-56 element URA.

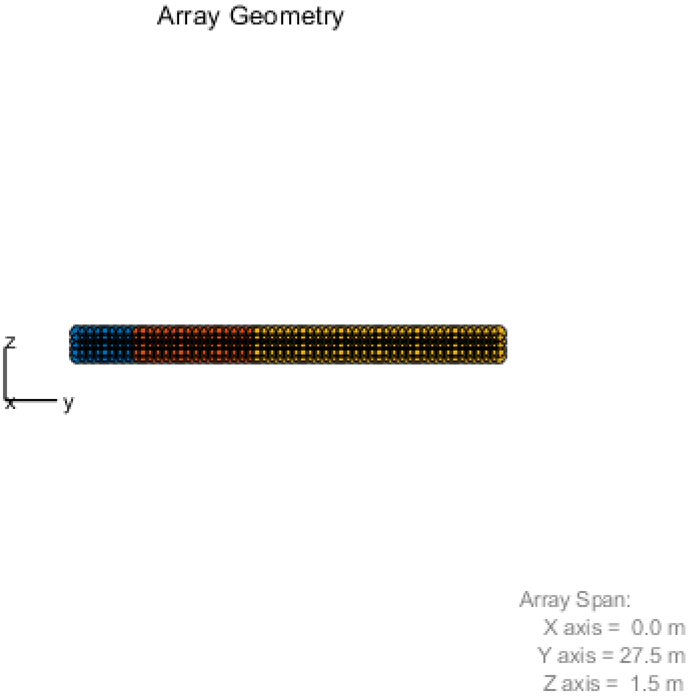
```
antenna = phased.IsotropicAntennaElement;
fc = 300e6;
c = physconst('LightSpeed');
lambda = c/fc;
n1 = 2^3;
n2 = 2^4;
n3 = 2^5;
nrows = 4;
ncols = n1 + n2 + n3;
array = phased.URA('Element',antenna,'Size',[nrows,ncols]);
```

Select the three subarrays by setting the selection matrix.

```
sel1 = zeros(nrows,ncols);
sel2 = sel1;
sel3 = sel1;
sel = zeros(3,nrows*ncols);
for r = 1:nrows
    sel1(r,1:n1) = 1;
    sel2(r,(n1+1):(n1+n2)) = 1;
    sel3(r,((n1+n2)+1):ncols) = 1;
end
sel(1,:) = sel1(:);
sel(2,:) = sel2(:);
sel(3,:) = sel3(:);
```

Create the partitioned array.

```
partarray = phased.PartitionedArray('Array',array, ...
    'SubarraySelection',sel,'SubarraySteering','Custom');
viewArray(partarray,'ShowSubarray','All');
```



Set weights for each subarray and get the response of each subarray. Put the weights in a cell array.

```
wts1 = ones(nrows*n1,1);
wts2 = 1.5*ones(nrows*n2,1);
wts3 = 3*ones(nrows*n3,1);
resp = partarray(fc,[30;0],c,{wts1,wts2,wts3})
```

```
resp = 3×1 complex

   0.0246 + 0.0000i
   0.0738 - 0.0000i
   0.2951 - 0.0000i
```

# directivity

**System object:** `phased.PartitionedArray`
**Package:** `phased`

Directivity of partitioned array

## Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

## Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity" on page 1-1507 of a partitioned array of antenna or microphone elements, `H`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `H` — Partitioned array

System object

Partitioned array, specified as a `phased.PartitionedArray` System object.

Example: `H = phased.PartitionedArray;`

### `FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, FREQ must lie within the range of values specified by the FrequencyRange or FrequencyVector property of the element. Otherwise, the element produces no response and the directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.
- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

### ANGLE — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis. See “Azimuth and Elevation Angles”.

Example: [45 60; 0 10]

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### `PropagationSpeed` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### `Weights` — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

| `Weights` dimension | `FREQ` dimension | Purpose |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `‘Weights’` for the corresponding frequency in the `FREQ` argument. |

Example: `'Weights',ones(N,M)`

Data Types: `double`

### `SteerAngle` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

**`ElementWeights` — Weights applied to elements within subarray**
`1` (default) | complex-valued $N_{SE}$-by-$N$ matrix | 1-by-$N$ cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array. Weights are applied to the individual elements within a subarray. Subarrays can have different dimensions and sizes.

If `ElementWeights` is a complex-valued $N_{SE}$-by-$N$ matrix, $N_{SE}$ is the number of elements in the largest subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray. Only the first $K$ entries in each column are applied as weights where $K$ is the number of elements in the corresponding subarray.

If `ElementWeights` is a 1-by-$N$ cell array. Each cell contains a complex-valued column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray.

**Dependencies**

To enable this name-value pair, set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**D — Directivity**
$M$-by-$L$ matrix

Directivity, returned as an $M$-by-$L$ matrix. Each row corresponds to one of the $M$ angles specified by `ANGLE`. Each column corresponds to one of the $L$ frequency values specified in FREQ. Directivity units are in dBi where dBi is defined as the gain of an element relative to an isotropic radiator.

# Examples

### Directivity of Partitioned Array

Compute the directivity of a partitioned array formed from a single 20-element ULA with elements spaced one-quarter wavelength apart. The subarrays are then phase-steered towards 30 degrees azimuth. The directivities are computed at azimuth angles from 0 to 60 degrees.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
angsteer = [30;0];
ang = [0:10:60;0,0,0,0,0,0,0];
```

Create a partitioned ULA array using the SubarraySelection property.

```
myArray = phased.PartitionedArray('Array',...
    phased.ULA(20,lambda/4),'SubarraySelection',...
    [ones(1,10) zeros(1,10);zeros(1,10) ones(1,10)],...
    'SubarraySteering','Phase','PhaseShifterFrequency',fc);
```

Create the steering vector and compute the directivity.

```
myStv = phased.SteeringVector('SensorArray',myArray,...
    'PropagationSpeed',c);
d = directivity(myArray,fc,ang,'PropagationSpeed',c,'Weights',...
    step(myStv,fc,angsteer),'SteerAngle',angsteer)
```

```
d = 7×1

   -7.5778
   -4.7676

    0.9714
   -3.5575
  -10.8439
```

# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# collectPlaneWave

**System object:** phased.PartitionedArray
**Package:** phased

Simulate received plane waves

## Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

## Description

Y = collectPlaneWave(H,X,ANG) returns the received signals at the sensor array, H, when the input signals indicated by X arrive at the array from the directions specified in ANG.

Y = collectPlaneWave(H,X,ANG,FREQ), in addition, specifies the incoming signal carrier frequency in FREQ.

Y = collectPlaneWave(H,X,ANG,FREQ,C), in addition, specifies the signal propagation speed in C.

## Input Arguments

### H

Array object.

### X

Incoming signals, specified as an M-column matrix. Each column of X represents an individual incoming signal.

**ANG**

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

**FREQ**

Carrier frequency of signal in hertz. FREQ must be a scalar.

**Default:** 3e8

**C**

Propagation speed of signal in meters per second.

**Default:** Speed of light

## Output Arguments

**Y**

Received signals. Y is an N-column matrix, where N is the number of subarrays in the array H. Each column of Y is the received signal at the corresponding subarray, with all incoming signals combined.

## Examples

### Plane Waves Received at Array Containing Subarrays

Simulate the received signal at a 16-element ULA partitioned into four 4-element ULAs.

Create a 16-element ULA, and partition it into 4-element ULAs.

```
ula = phased.ULA('NumElements',16);
array = phased.PartitionedArray('Array',ula,...
   'SubarraySelection',....
   [1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0;...
    0 0 0 0 1 1 1 1 0 0 0 0 0 0 0 0;...
    0 0 0 0 0 0 0 0 1 1 1 1 0 0 0 0;...
    0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1]);
```

Simulate received signals from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
sig = collectPlaneWave(array,randn(4,2),[10 30],1.0e8,physconst('LightSpeed'))
```

```
sig = 4×4 complex

  -0.0710 - 0.4765i   0.6616 - 0.4676i   0.6616 + 0.4676i  -0.0710 + 0.4765i
   2.1529 - 1.6304i   1.0607 + 0.4802i   1.0607 - 0.4802i   2.1529 + 1.6304i
  -0.6074 + 2.0037i  -2.3274 + 1.1797i  -2.3274 - 1.1797i  -0.6074 - 2.0037i
   0.0547 - 0.7644i   0.9768 - 0.6037i   0.9768 + 0.6037i   0.0547 + 0.7644i
```

## Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array and only models the array factor among subarrays. Therefore, the result does not depend on whether the subarray is steered.

# getElementPosition

**System object:** `phased.PartitionedArray`
**Package:** `phased`

Positions of array elements

## Syntax

```
POS = getElementPosition(H)
```

## Description

`POS = getElementPosition(H)` returns the element positions in the array `H`.

## Input Arguments

### `H`

Partitioned array object.

## Output Arguments

### `POS`

Element positions in array. `POS` is a 3-by-N matrix, where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

## Examples

### Element Positions in Partitioned Array

Obtain the positions of the six elements in a partitioned array.

```
array = phased.PartitionedArray('Array',phased.URA('Size',[2 3]),...
    'SubarraySelection',[1 0 1 0 1 0; 0 1 0 1 0 1]);
pos = getElementPosition(array)
```

```
pos = 3×6

getElementPosition

# isPolarizationCapable

**System object:** `phased.PartitionedArray`
**Package:** `phased`

Polarization capability

## Syntax

```
flag = isPolarizationCapable(h)
```

## Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all its constituent sensor elements support polarization.

## Input Arguments

### h — Partitioned array

Partitioned array specified as a `phased.PartitionedArray` System object.

## Output Arguments

### `flag` — Polarization-capability flag

Polarization-capability flag returned as a Boolean value. This value is `true`, if the array supports polarization or `false`, if it does not.

## Examples

### Partitioned Array of Short-Dipole Antenna Elements Supports Polarization

Determine whether a partitioned array of `phased.ShortDipoleAntennaElements` supports polarization.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
ulaarray = phased.ULA(4,'Element',antenna);
partitionedarray = phased.PartitionedArray('Array',ulaarray,...
     'SubarraySelection',[1 1 0 0; 0 0 1 1]);
isPolarizationCapable(partitionedarray)
```

```
ans = logical
   1
```

The returned value `1` shows that this array supports polarization.

# pattern

**System object:** phased.PartitionedArray
**Package:** phased

Plot partitioned array directivity, field, and power patterns

## Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

## Description

pattern(sArray,FREQ) plots the 3-D array directivity pattern (in dBi) for the array specified in sArray. The operating frequency is specified in FREQ.

pattern(sArray,FREQ,AZ) plots the array directivity pattern at the specified azimuth angle.

pattern(sArray,FREQ,AZ,EL) plots the array directivity pattern at specified azimuth and elevation angles.

pattern( ___ ,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

[PAT,AZ_ANG,EL_ANG] = pattern( ___ ) returns the array pattern in PAT. The AZ_ANG output contains the coordinate values corresponding to the rows of PAT. The EL_ANG output contains the coordinate values corresponding to the columns of PAT. If the 'CoordinateSystem' parameter is set to 'uv', then AZ_ANG contains the *U* coordinates of the pattern and EL_ANG contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

**Note** This method replaces the `plotResponse` method. See “Convert plotResponse to pattern” on page 1-1532 for guidelines on how to use `pattern` in place of `plotResponse`.

## Input Arguments

**`sArray` — Partitioned array**
System object

Partitioned array, specified as a `phased.PartitionedArray` System object.

Example: `sArray= phased.PartitionedArray;`

**`FREQ` — Frequency for computing directivity and patterns**
positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

**`AZ` — Azimuth angles**
`[-180:180]` (default) | 1-by-*N* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

### EL — Elevation angles

`[-90:90]` (default) | 1-by-*M* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. The elevation angle is positive when measured towards the *z*-axis.

Example: `[-75:1:70]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `CoordinateSystem` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

### Type — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

### Normalize — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. This parameter does not apply when you set 'Type' to 'directivity'. Directivity patterns are already normalized.

Data Types: logical

### PlotStyle — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Data Types: char

### Polarization — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the

sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options.

| **'Polarization'** | **Display** |
|---|---|
| `'combined'` | Combined *H* and *V* polarization components |
| `'H'` | *H* polarization component |
| `'V'` | *V* polarization component |

Example: `'V'`

Data Types: `char`

**PropagationSpeed — Signal propagation speed**
speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

**Weights — Subarray weights**
1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights`' and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

| **Weights dimension** | **FREQ dimension** | **Purpose** |
|---|---|---|
| *N*-by-1 complex-valued column vector | Scalar or 1-by-*L* row vector | Applies a set of weights for the single frequency or for all *L* frequencies. |
| *N*-by-*L* complex-valued matrix | 1-by-*L* row vector | Applies each of the *L* columns of `‘Weights’` for the corresponding frequency in the `FREQ` argument. |

Example: `'Weights',ones(N,M)`

Data Types: `double`

### `SteerAngle` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

### `ElementWeights` — Weights applied to elements within subarray

`1` (default) | complex-valued $N_{SE}$-by-$N$ matrix | 1-by-$N$ cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array. Weights are applied to the individual elements within a subarray. Subarrays can have different dimensions and sizes.

If `ElementWeights` is a complex-valued $N_{SE}$-by-$N$ matrix, $N_{SE}$ is the number of elements in the largest subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray. Only the first $K$ entries in each column are applied as weights where $K$ is the number of elements in the corresponding subarray.

If `ElementWeights` is a 1-by-$N$ cell array. Each cell contains a complex-valued column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray.

**Dependencies**

To enable this name-value pair, set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

## Output Arguments

**`PAT` — Array pattern**
*M*-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

**`AZ_ANG` — Azimuth angles**
scalar | 1-by-*N* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `AZ`. The columns of `PAT` correspond to the values in `AZ_ANG`. Units are in degrees.

**`EL_ANG` — Elevation angles**
scalar | 1-by-*M* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `EL`. The rows of `PAT` correspond to the values in `EL_ANG`. Units are in degrees.

## Examples

### Azimuth Response of Partitioned ULA

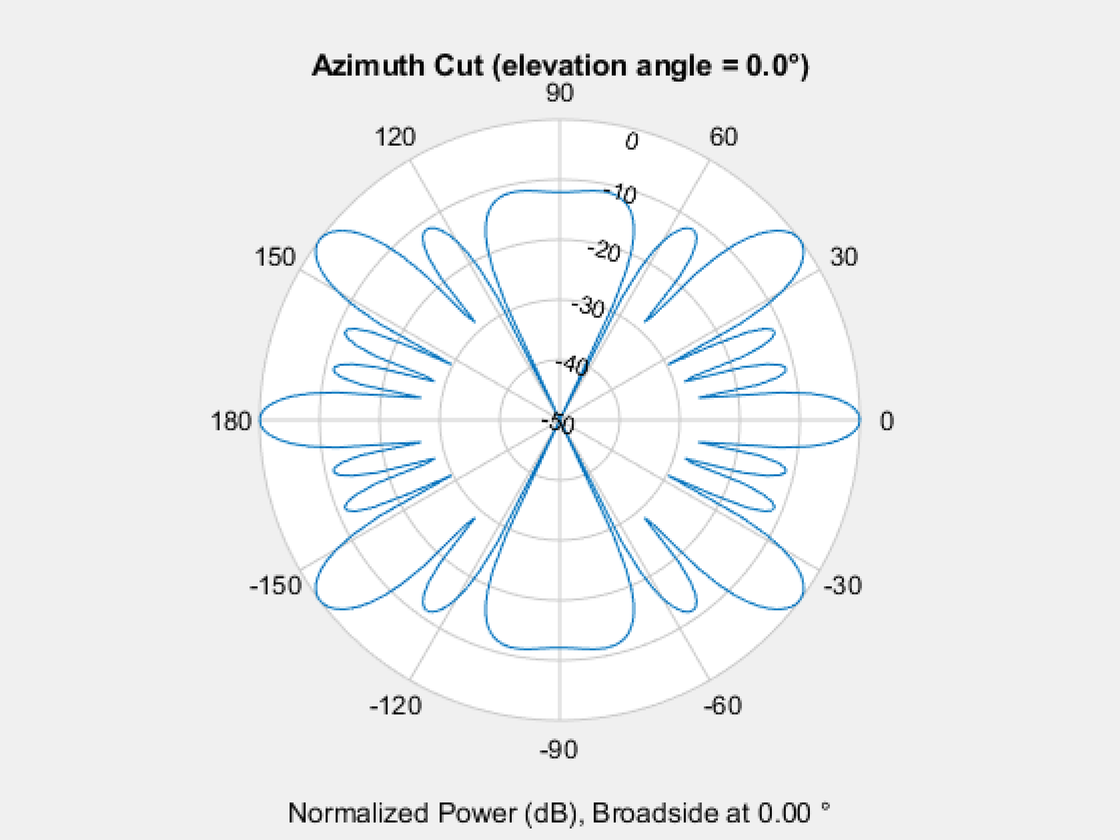
Plot the azimuth response of a 4-element ULA partitioned into two 2-element ULA's. The element spacing is one-half wavelength.

Create the ULA, and partition it into two 2-element ULA's.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
    'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
fc = 1e9;
pattern(sPA,fc,[-180:180],0,'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Normalize',true)
```



### Plot Pattern and Directivity of Partitioned URA Over Restricted Range of Angles

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot an azimuth cut from -50 to 50 degrees for different two sets of weights. For partitioned arrays, weights are applied to the subarrays instead of the elements.

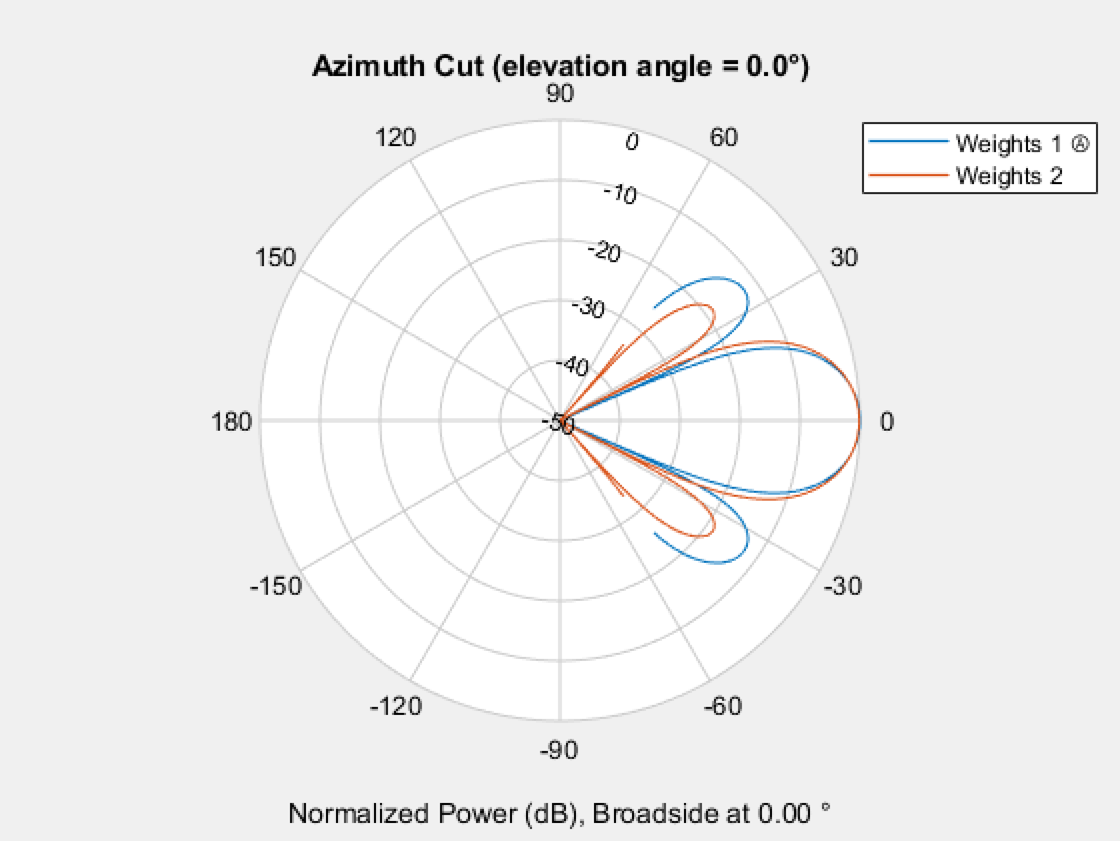
### Create partitioned array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
sPA = phased.PartitionedArray('Array',sURA,...
    'SubarraySelection',subarraymap);
```

### Plot power pattern

Plot the response of the array at 5 GHz over the restricted range of azimuth angles.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
pattern(sPA,fc,[-50:0.1:50],0,...
    'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Weights',wts)
```

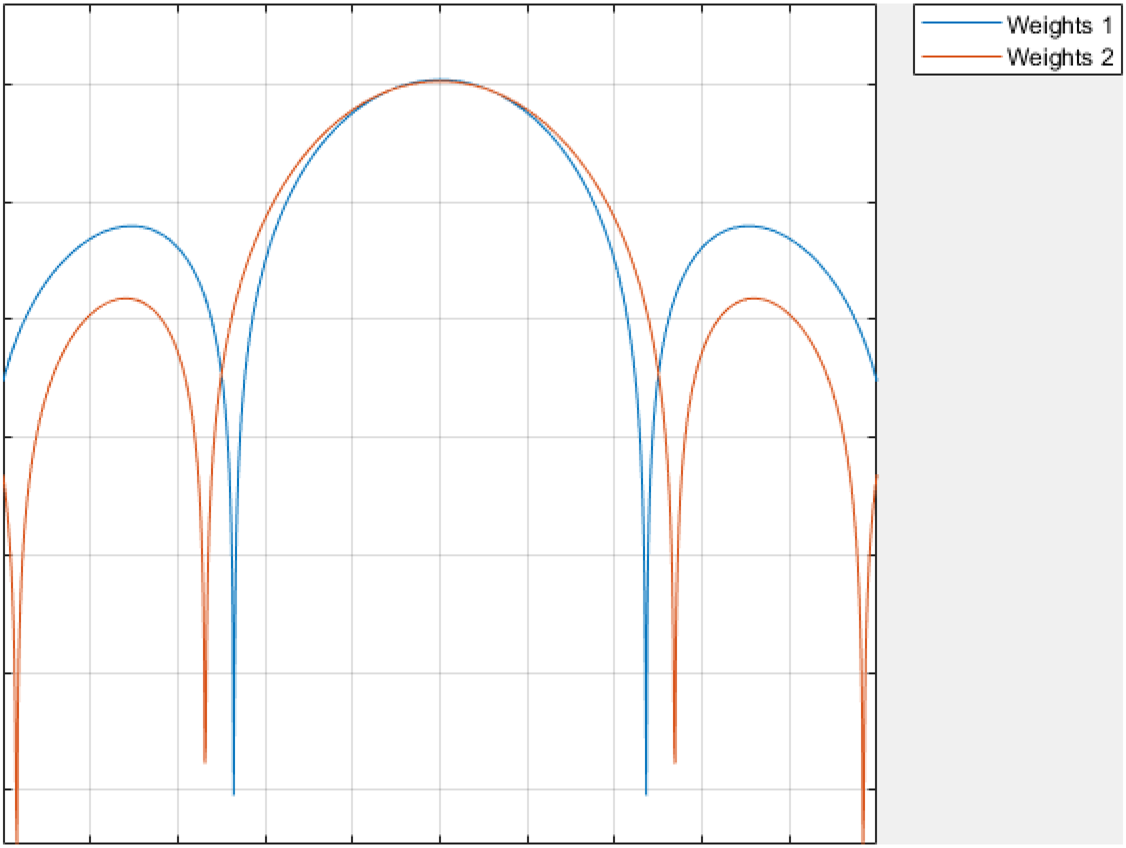


The plot of the response shows the broadening of the main lobe and the reduction of the strength of the sidelobes caused by the weight tapering.

### Plot directivity

Plot an azimuth cut of the directivity of the array at 5 GHz over the restricted range of azimuth angles for the two different sets of weights.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
pattern(sPA,fc,[-50:0.1:50],0,...
    'Type','directivity',...
    'CoordinateSystem','rectangular',...
    'Weights',wts)
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

## Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `H` argument | Antenna, microphone, or array System object. | `H` argument (no change) |
| `FREQ` argument | Operating frequency. | `FREQ` argument (no change) |

| plotResponse Inputs | plotResponse Description | pattern Inputs |
|---|---|---|
| `V` argument | Propagation speed. This argument is used only for arrays. | `'PropagationSpeed'` name-value pair. This parameter is only used for arrays. |

<table>

**Introduced in R2015a**

# patternAzimuth

**System object:** phased.PartitionedArray
**Package:** phased

Plot partitioned array directivity or pattern versus azimuth

## Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

## Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addition, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

## Input Arguments

**sArray — Partitioned array**
System object

Partitioned array, specified as a `phased.PartitionedArray` System object.

Example: `sArray= phased.PartitionedArray;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Subarray weights

*M*-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### SteerAngle — Subarray steering angle

[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of 'SteerAngle' and a scalar or a 2-by-1 column vector.

If 'SteerAngle' is a 2-by-1 column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If 'SteerAngle' is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the 'SubarraySteering' property of the System object is set to 'Phase' or 'Time'.

Example: 'SteerAngle',[20;30]

Data Types: double

### ElementWeights — Weights applied to elements within subarray

1 (default) | complex-valued $N_{SE}$-by-$N$ matrix | 1-by-$N$ cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array. Weights are applied to the individual elements within a subarray. Subarrays can have different dimensions and sizes.

If ElementWeights is a complex-valued $N_{SE}$-by-$N$ matrix, $N_{SE}$ is the number of elements in the largest subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray. Only the first $K$ entries in each column are applied as weights where $K$ is the number of elements in the corresponding subarray.

If ElementWeights is a 1-by-$N$ cell array. Each cell contains a complex-valued column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray.

#### Dependencies

To enable this name-value pair, set the SubarraySteering property of the array to 'Custom'.

Data Types: double
Complex Number Support: Yes

### Azimuth — Azimuth angles

[-180:180] (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of 'Azimuth' and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: 'Azimuth',[-90:2:90]

Data Types: double

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the 'Azimuth' name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the EL input argument.

## Examples

### Plot Azimuth Directivity of Partitioned URA

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot the azimuth directivity. For partitioned arrays, weights are applied to the subarrays instead of the elements.

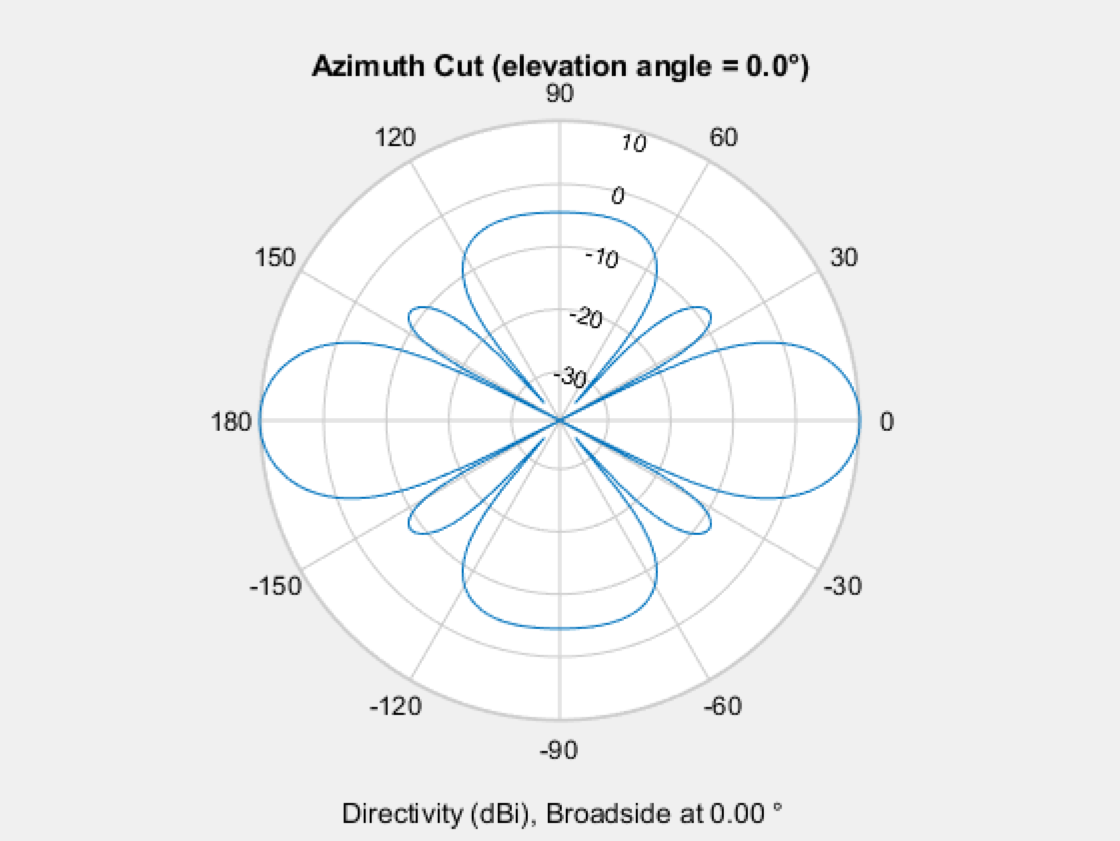
### Create partitioned array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
sPA = phased.PartitionedArray('Array',sURA,...
    'SubarraySelection',subarraymap);
```

### Plot azimuth directivity pattern

Plot the response of the array at 5 GHz

```
fc = 5e9;
wts = [0.862,1.23,0.862]';
patternAzimuth(sPA,fc,0,...
    'Type','directivity',...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Weights',wts)
```



## More About

### Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta, \varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\text{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

**Introduced in R2015a**

# patternElevation

**System object:** phased.PartitionedArray
**Package:** phased

Plot partitioned array directivity or pattern versus elevation

## Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

## Description

patternElevation(sArray,FREQ) plots the 2-D array directivity pattern versus elevation (in dBi) for the array sArray at zero degrees azimuth angle. When AZ is a vector, multiple overlaid plots are created. The argument FREQ specifies the operating frequency.

patternElevation(sArray,FREQ,AZ), in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by AZ. When AZ is a vector, multiple overlaid plots are created.

patternElevation(sArray,FREQ,AZ,Name,Value) plots the array pattern with additional options specified by one or more Name,Value pair arguments.

PAT = patternElevation( ___ ) returns the array pattern. PAT is a matrix whose entries represent the pattern at corresponding sampling points specified by the 'Elevation' parameter and the AZ input argument.

## Input Arguments

### sArray — Partitioned array

System object

Partitioned array, specified as a `phased.PartitionedArray` System object.

Example: `sArray= phased.PartitionedArray;`

### FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for `phased.CustomAntennaElement` and `phased.CustomMicrophoneElement`, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

### AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Type — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

### PropagationSpeed — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

### Weights — Subarray weights

*M*-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

### `SteerAngle` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

### `ElementWeights` — Weights applied to elements within subarray

`1` (default) | complex-valued $N_{SE}$-by-$N$ matrix | 1-by-$N$ cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array. Weights are applied to the individual elements within a subarray. Subarrays can have different dimensions and sizes.

If `ElementWeights` is a complex-valued $N_{SE}$-by-$N$ matrix, $N_{SE}$ is the number of elements in the largest subarray and $N$ is the number of subarrays. Each column of the matrix specifies the weights for the corresponding subarray. Only the first $K$ entries in each column are applied as weights where $K$ is the number of elements in the corresponding subarray.

If `ElementWeights` is a 1-by-$N$ cell array. Each cell contains a complex-valued column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray.

#### Dependencies

To enable this name-value pair, set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

### Elevation — Elevation angles

[-90:90] (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of 'Elevation' and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: 'Elevation',[-90:2:90]

Data Types: double

## Output Arguments

### PAT — Array directivity or pattern

*L*-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the 'Elevation' name-value pair argument. The dimension *N* is the number of azimuth angles determined by the AZ argument.

## Examples

### Plot Elevation Directivity of Partitioned URA

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot the directivity for elevation angles from -45 to 45 degrees. For partitioned arrays, weights are applied to the subarrays instead of the elements.

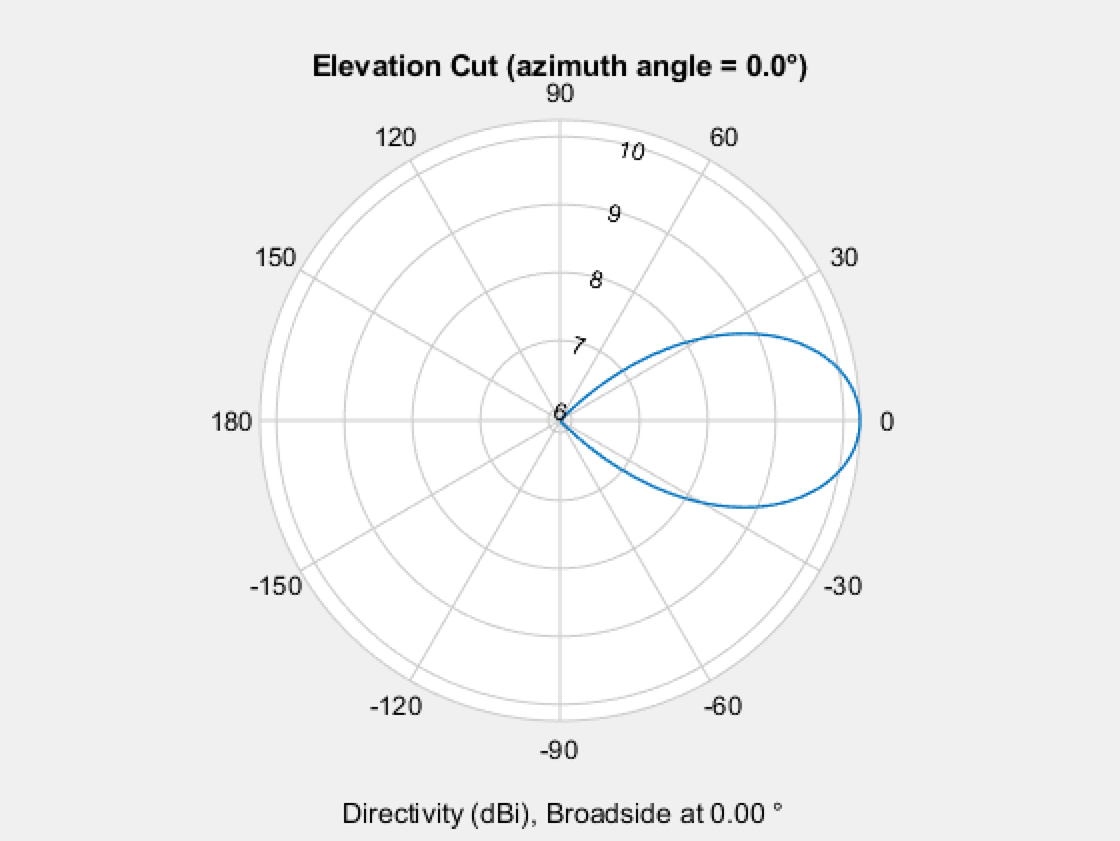
### Create partitioned array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
sPA = phased.PartitionedArray('Array',sURA,...
    'SubarraySelection',subarraymap);
```

### Plot elevation directivity pattern

Plot the response of the array at 5 GHz

```
fc = 5e9;
wts = [0.862,1.23,0.862]';
azimangle = 0;
patternElevation(sPA,fc,azimangle,...
    'Type','directivity',...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Elevation',[-45:45],...
    'Weights',wts)
```



# More About

## Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements.

Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta, \varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction $(\theta,\varphi)$ and $P_{\mathrm{total}}$ is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element Directivity” and “Array Directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

# plotResponse

**System object:** `phased.PartitionedArray`
**Package:** `phased`

Plot response pattern of array

## Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

**`H`**

Array object.

**`FREQ`**

Operating frequency in hertz. Typical values are within the range specified by a property of `H.Array.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range. If FREQ is a nonscalar row vector, the plot shows multiple frequency responses on the same axes.

**V**

Propagation speed in meters per second.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CutAngle**

Cut angle specified as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

**Default:** 0

**Format**

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

**Default:** 'Line'

**NormalizeResponse**

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

**Default:** true

**OverlayFreq**

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, then FREQ must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and `RespCut` is not `'3D'`.

**Default:** `true`

### Polarization

Specify the polarization options for plotting the array response pattern. The allowable values are |`'None' | 'Combined' | 'H' | 'V'` | where:

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

**Default:** `'None'`

### RespCut

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

### SteerAng

Subarray steering angle. `SteerAng` can be either a 2-element column vector or a scalar.

If `SteerAng` is a 2-element column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `SteerAng` is a scalar, it specifies the azimuth angle. In this case, the elevation angle is assumed to be 0.

This option is applicable only if the `SubarraySteering` property of `H` is `'Phase'` or `'Time'`.

**Default:** `[0;0]`

### `Unit`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

| Unit value | Plot type |
|---|---|
| `db` | power pattern in dB scale |
| `mag` | field pattern |
| `pow` | power pattern |
| `dbi` | directivity |

**Default:** `'db'`

### `Weights`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of subarrays in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

| Weights Dimension | FREQ Dimension | Purpose |
|---|---|---|
| *N*-by-1 column vector | Scalar or 1-by-*M* row vector | Apply one set of weights for the same single frequency or all *M* frequencies. |
| *N*-by-*M* matrix | Scalar | Apply all of the *M* different columns in `Weights` for the same single frequency. |
| | 1-by-*M* row vector | Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`. |

### `AzimuthAngles`

Azimuth angles for plotting subarray response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

**Default:** `[-180:180]`

**`ElevationAngles`**

Elevation angles for plotting subarray response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

**Default:** `[-90:90]`

**`UGrid`**

*U* coordinate values for plotting subarray response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

**`VGrid`**

*V* coordinate values for plotting subarray response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U/V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

**Default:** `[-1:0.01:1]`

# Examples

### Azimuth Response of Partitioned ULA

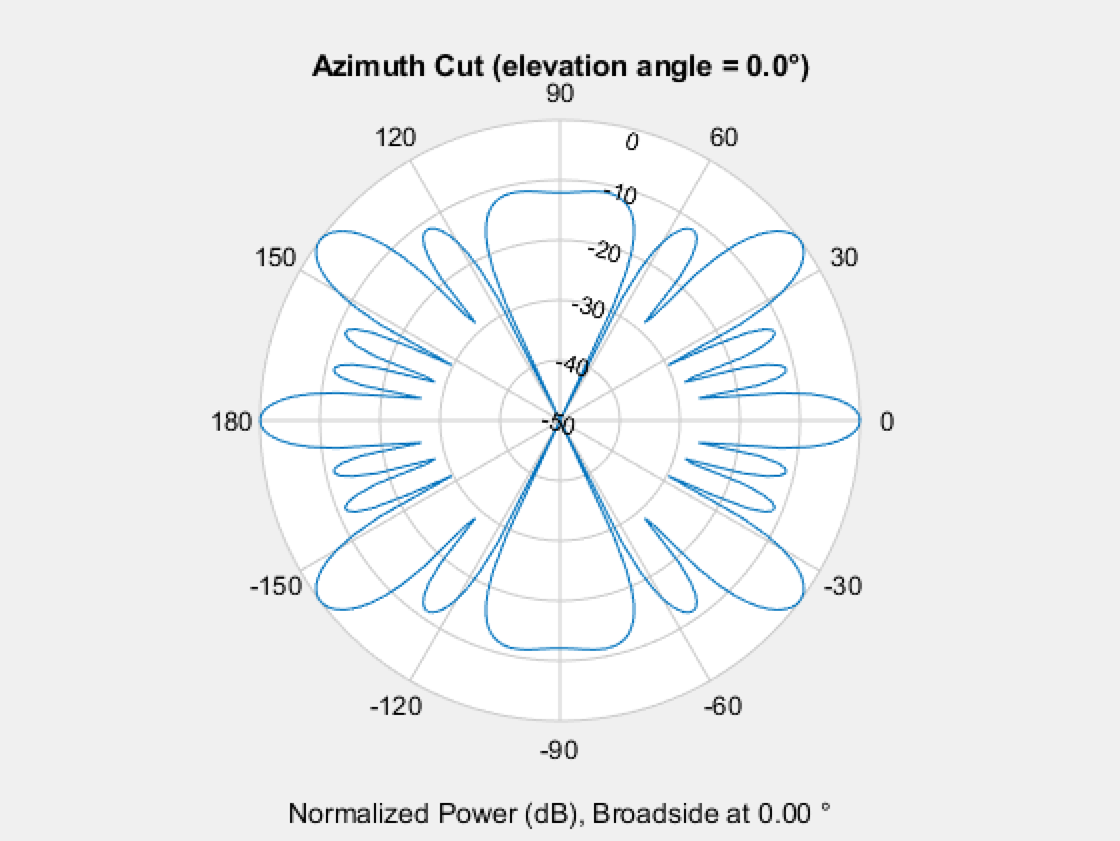
Plot the azimuth response of a 4-element ULA partitioned into two 2-element ULA's. The element spacing is one-half wavelength.

Create the ULA, and partition it into two 2-element ULA's.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
    'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
fc = 1e9;
pattern(sPA,fc,[-180:180],0,'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Normalize',true)
```



### Plot Response and Directivity of Partitioned URA Over Restricted Range of Angles

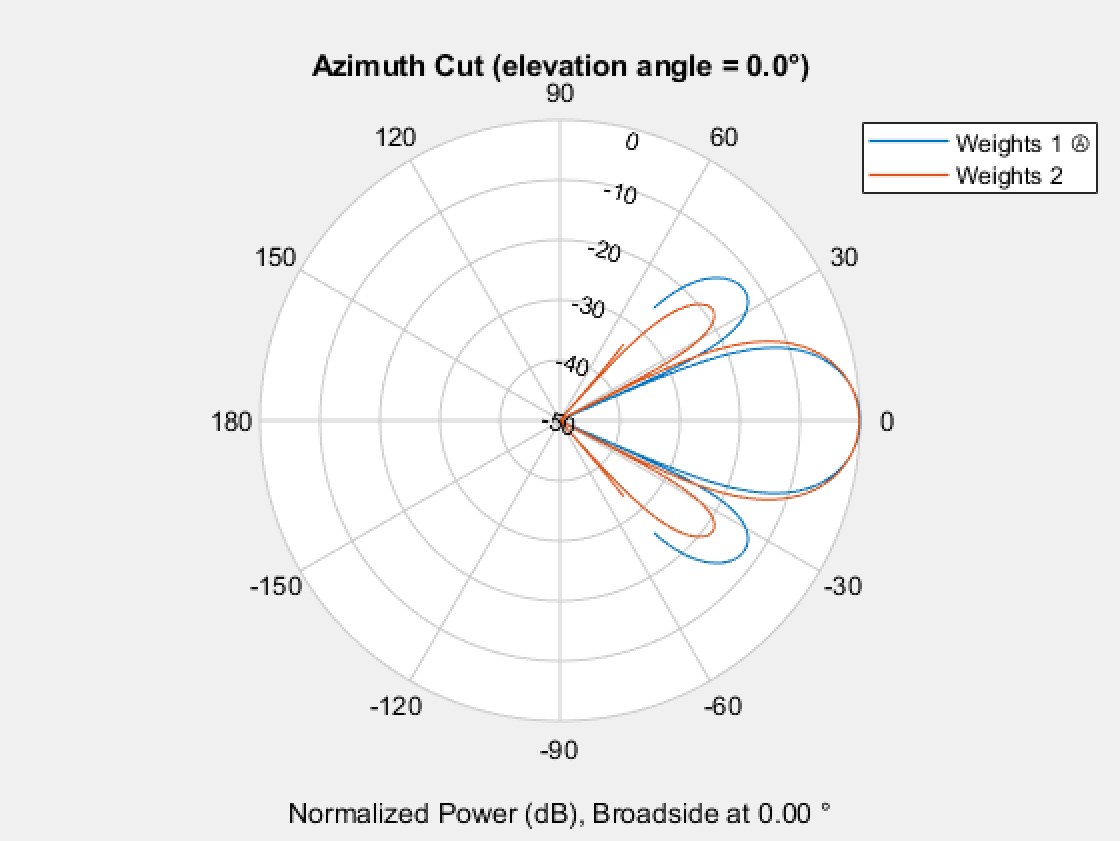
Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot an azimuth cut from -50 to 50 degrees for different two sets of weights. For partitioned arrays, weights are applied to the subarrays instead of the elements.

Set up the partitioned array.

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
s_iso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
s_ura = phased.URA('Element',s_iso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
s_pa = phased.PartitionedArray('Array',s_ura,...
    'SubarraySelection',subarraymap);
```

Plot the response of the array at 5 GHz over the restricted range of azimuth angles.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
plotResponse(s_pa,fc,c,'RespCut','Az',...
    'AzimuthAngles',[-50:0.1:50],...
    'Unit','db','Format','Polar',...
    'Weights',wts);
```



The plot of the response shows the broadening of the main lobe and the reduction of the strength of the sidelobes caused by the weight tapering.

Next, plot an azimuth cut of the directivity of the array at 5 GHz over the restricted range of azimuth angles for the two different sets of weights.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
plotResponse(s_pa,fc,c,'RespCut','Az',...
    'AzimuthAngles',[-50:0.1:50],...
    'Unit','dbi',...
    'Weights',wts);
```

# step

**System object:** `phased.PartitionedArray`
**Package:** `phased`

Output responses of subarrays

## Syntax

```
RESP = step(H,FREQ,ANG,V)
RESP = step(H,FREQ,ANG,V,STEERANGLE)
RESP = step(H,FREQ,ANG,V,WS)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG,V)` returns the responses `RESP` of the subarrays in the array, at operating frequencies specified in `FREQ` and directions specified in `ANG`. The phase center of each subarray is at its geometric center. `V` is the propagation speed. The elements within each subarray are connected to the subarray phase center using an equal-path feed.

`RESP = step(H,FREQ,ANG,V,STEERANGLE)` uses `STEERANGLE` as the subarray's steering direction. This syntax is available when you set the `SubarraySteering` property to either `'Phase'` or `'Time'`.

`RESP = step(H,FREQ,ANG,V,WS)` uses `WS` as the subarray element weights. This syntax is available when you set the `SubarraySteering` property to `'Custom'`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# Input Arguments

**H**

Partitioned array object.

**FREQ**

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of `H.Array.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

**ANG**

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

**V**

Propagation speed in meters per second. This value must be a scalar.

**STEERANGLE**

Subarray steering direction. `STEERANGLE` can be either a 2-element column vector or a scalar.

If `STEERANGLE` is a 2-element column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If STEERANGLE is a scalar, it specifies the direction’s azimuth angle. In this case, the elevation angle is assumed to be 0.

### WS

Subarray element weights

Subarray element weights, specified as a complex-valued $N_{SE}$-by-$N$ matrix or 1-by-$N$ cell array where $N$ is the number of subarrays.

Subarrays do not have to have the same dimensions and sizes. In this case, you specify subarray weights as

- an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.
- a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray.

#### Dependencies

To enable this argument, set the SubarraySteering to 'Custom'.

## Output Arguments

### RESP

Voltage responses of the subarrays of a phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions $N$-by-$M$-by-$L$. The size $N$ represents the number of subarrays in the phased array, $M$ represents the number of angles specified in ANG, and $L$ represents the number of frequencies specified in FREQ. For a particular subarray, each column of RESP contains the responses of the subarray for the corresponding direction specified in ANG. Each of the $L$ pages of RESP contains the responses of the subarrays for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field RESP.H

represents the array’s horizontal polarization response while RESP.V represents the array’s vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. The size *N* represents the number of subarrays in the phased array, *M* represents the number of angles specified in ANG, and *L* represents the number of frequencies specified in FREQ. For a particular subarray, each column of RESP contains the responses of the subarray for the corresponding direction specified in ANG. Each of the *L* pages of RESP contains the responses of the subarrays for the corresponding frequency specified in FREQ.

# Examples

### Response of Subarrays in Partitioned ULA

Calculate the response at boresight of a 4-element ULA partitioned into two 2-element ULAs.

**Note:** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

Set up the partitioned array.

```
hula = phased.ULA('NumElements',4,'ElementSpacing',0.5);
partitionedarray = phased.PartitionedArray('Array',hula,...
   'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Calculate the response of the subarrays at boresight. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
resp = partitionedarray(1.0e9,[0;0],physconst('Lightspeed'))
```

```
resp = 2×1

     2
     2
```

### Subarray Element Weights for Partitioned Array

Create a partitioned URA array with three subarrays of different sizes. The subarrays have 8, 16, and 32 elements. Use different sets of subarray element weights for each subarray.

Create a 4-by-56 element URA.

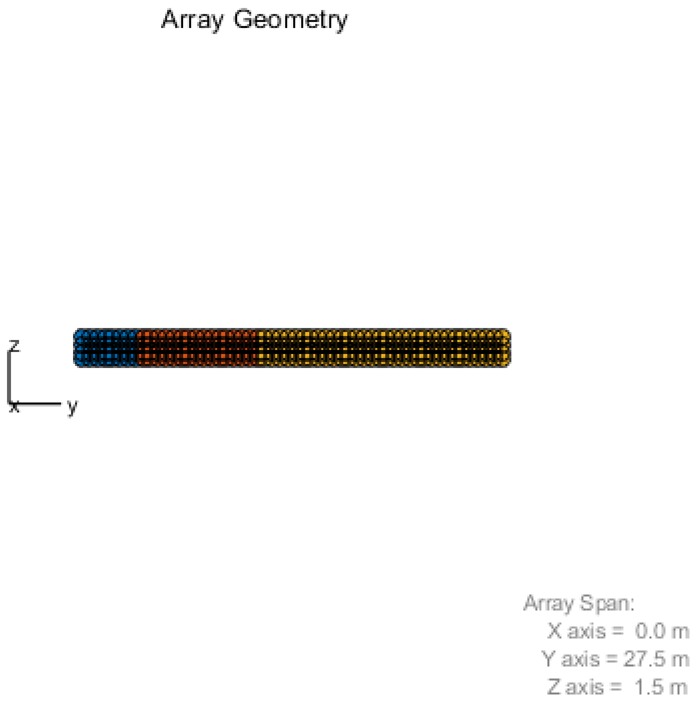
```
antenna = phased.IsotropicAntennaElement;
fc = 300e6;
c = physconst('LightSpeed');
lambda = c/fc;
n1 = 2^3;
n2 = 2^4;
n3 = 2^5;
nrows = 4;
ncols = n1 + n2 + n3;
array = phased.URA('Element',antenna,'Size',[nrows,ncols]);
```

Select the three subarrays by setting the selection matrix.

```
sel1 = zeros(nrows,ncols);
sel2 = sel1;
sel3 = sel1;
sel = zeros(3,nrows*ncols);
for r = 1:nrows
    sel1(r,1:n1) = 1;
    sel2(r,(n1+1):(n1+n2)) = 1;
    sel3(r,((n1+n2)+1):ncols) = 1;
end
sel(1,:) = sel1(:);
sel(2,:) = sel2(:);
sel(3,:) = sel3(:);
```

Create the partitioned array.

```
partarray = phased.PartitionedArray('Array',array, ...
    'SubarraySelection',sel,'SubarraySteering','Custom');
viewArray(partarray,'ShowSubarray','All');
```



Set weights for each subarray and get the response of each subarray. Put the weights in a cell array.

```
wts1 = ones(nrows*n1,1);
wts2 = 1.5*ones(nrows*n2,1);
wts3 = 3*ones(nrows*n3,1);
resp = partarray(fc,[30;0],c,{wts1,wts2,wts3})
```

```
resp = 3×1 complex

   0.0246 + 0.0000i
   0.0738 - 0.0000i
   0.2951 - 0.0000i
```

## See Also

`phitheta2azel` | `uv2azel`

# viewArray

**System object:** `phased.PartitionedArray`
**Package:** `phased`

View array geometry

## Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray(___)
```

## Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray(___)` returns the handles of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

## Input Arguments

**`H`**

Array object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**ShowIndex**

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show indices of all elements of the array or `'None'` to suppress indices.

**Default:** `'None'`

**ShowNormals**

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

**Default:** `false`

**ShowTaper**

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color. The default value is `false`.

**Default:** `false`

**ShowSubarray**

Vector specifying the indices of subarrays to highlight in the figure. Each number in the vector must be an integer between 1 and the number of subarrays. You can also specify the value `'All'` to highlight all subarrays of the array or `'None'` to suppress the subarray highlighting. The highlighting uses different colors for different subarrays, and white for elements that occur in multiple subarrays.

**Default:** `'All'`

**Title**

Character vector specifying the title of the plot.

**Default:** `'Array Geometry'`

## Output Arguments

**hPlot**

Handles of array elements in figure window.

## Examples

### Highlight Overlapped Subarrays

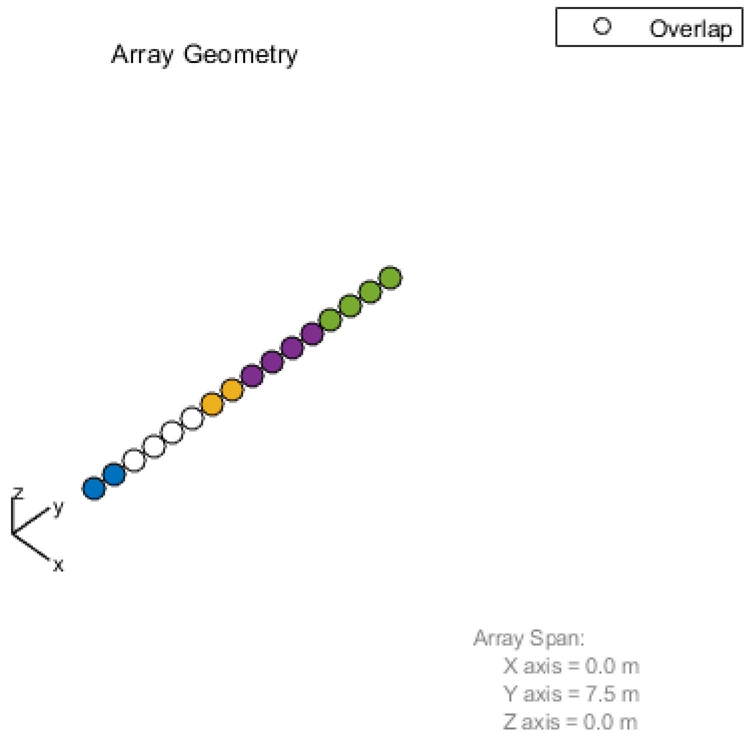
Display the geometry of a uniform linear array having overlapped subarrays.

Create a 16-element ULA that has five 4-element subarrays. Some elements occur in more than one subarray.

```
h = phased.ULA(16);
ha = phased.PartitionedArray('Array',h,...
    'SubarraySelection',...
    [1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0;...
    0 0 1 1 1 1 0 0 0 0 0 0 0 0 0 0;...
    0 0 0 0 1 1 1 1 0 0 0 0 0 0 0 0;...
    0 0 0 0 0 0 0 0 1 1 1 1 0 0 0 0;...
    0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1]);
```

Display the geometry of the array, highlighting all subarrays.

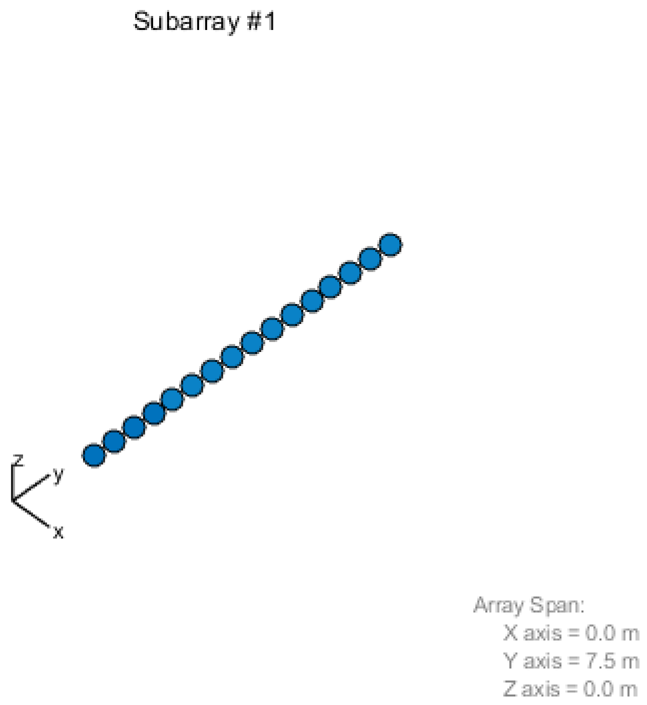
```
viewArray(ha);
```



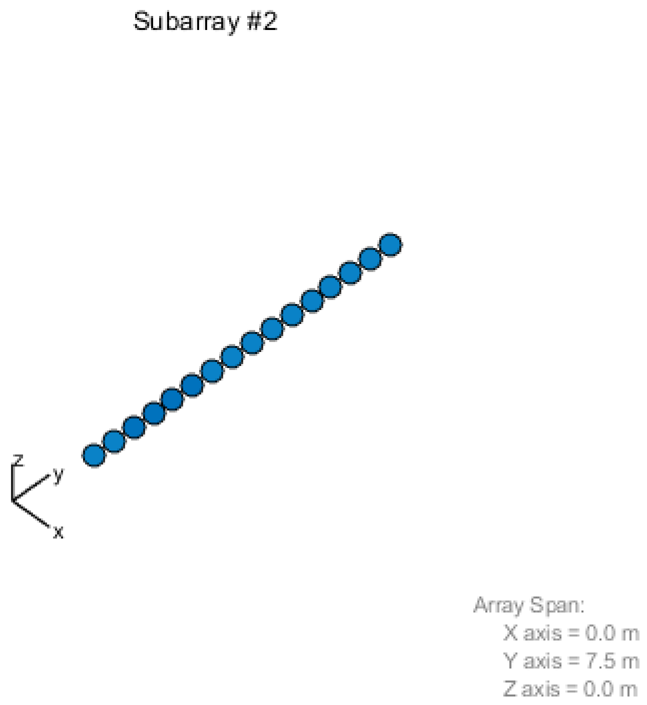
Each color other than white represents a different subarray. White represents elements that occur in multiple subarrays.

Examine the overlapped subarrays by creating separate figures that highlight the first, second, and third subarrays. In each figure, dark blue represents the highlighted elements.

```
for idx = 1:3
    figure;
    viewArray(ha,'ShowSubarray',idx,...
        'Title',['Subarray #' num2str(idx)]);
end
```



Subarray #1
z
y
x
Array Span:
X axis = 0.0 m
Y axis = 7.5 m
Z axis = 0.0 m



Subarray #2
z
y
x
Array Span:
X axis = 0.0 m
Y axis = 7.5 m
Z axis = 0.0 m

# phased.PhaseCodedWaveform

**Package:** phased

Phase-coded pulse waveform

## Description

The PhaseCodedWaveform object creates a phase-coded pulse waveform.

To obtain waveform samples:

1. Define and set up your phase-coded pulse waveform. See "Construction" on page 1-1578.
2. Call step to generate the phase-coded pulse waveform samples according to the properties of phased.PhaseCodedWaveform. The behavior of step is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations. When the only argument to the step method is the System object itself, replace y = step(obj) by y = obj().

## Construction

H = phased.PhaseCodedWaveform creates a phase-coded pulse waveform System object, H. The object generates samples of a phase-coded pulse.

H = phased.PhaseCodedWaveform(Name,Value) creates a phase-coded pulse waveform object, H, with additional options specified by one or more Name,Value pair arguments. Name is a property name on page 1-1579, and Value is the corresponding value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1,…,NameN,ValueN.

## Properties

### `SampleRate`

Sample rate

Specify the sample rate in hertz as a positive scalar. The default value of this property corresponds to 1 MHz. The value of this property must satisfy these constraints:

- `(SampleRate./PRF)` is a scalar or vector that contains only integers — the number of samples in a pulse must be an integer.
- `(SampleRate*ChipWidth)` is an integer value — the number of samples in a chip must be an integer.

**Default:** `1e6`

### `Code`

Phase code type

Specify the phase code type used in phase modulation. Valid values are:

- `'Barker'`
- `'Frank'`
- `'P1'`
- `'P2'`
- `'P3'`
- `'P4'`
- `'Px'`
- `'Zadoff-Chu'`

**Default:** `'Frank'`

### `ChipWidth`

Time duration of each chip

Specify the time duration of each chip in a phase-coded waveform as a positive scalar. Units are seconds. For this waveform, the pulse duration is equal to the product of the chip width and number of chips.

The value of this property must satisfy these constraints:

- `ChipWidth` is less than or equal to `(1./(NumChips*PRF))` — the total time duration of all chips cannot exceed the duration of the pulse.
- `(SampleRate*ChipWidth)` is an integer value — the number of samples in a chip must be an integer.

**Default:** `1e-5`

**`NumChips`**

Number of chips

Specify the number of chips per pulse in a phase-coded waveform as a positive integer. The value of this property must be less than or equal to `(1./(ChipWidth*PRF))` — the total time duration of all chips cannot exceed the pulse repetition interval.

The table shows additional constraints on the number of chips for different code types.

| If the `Code` property is ... | Then the `NumChips` property must be... |
|---|---|
| `'Frank'`, `'P1'`, or `'Px'` | A perfect square |
| `'P2'` | An even number that is a perfect square |
| `'Barker'` | 2, 3, 4, 5, 7, 11, or 13 |

**Default:** `4`

**`SequenceIndex`**

Zadoff-Chu sequence index

Specify the sequence index used in Zadoff-Chu code as a positive integer. This property applies only when you set the `Code` property to `'Zadoff-Chu'`. The value of `SequenceIndex` must be relatively prime to the value of the `NumChips` property.

**Default:** `1`

**`PRF`**

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval, *PRI*, is the inverse of the pulse repetition frequency, *PRF*. The*PRF* must satisfy these restrictions:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of PRF must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

You can select the value of *PRF* using property settings alone or using property settings in conjunction with the `prfidx` input argument of the `step` method.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties only. You can
  - implement a constant *PRF* by specifying PRF as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying PRF as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying PRF as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an argument specifying an index into the *PRF* vector.

In all cases, the number of output samples is fixed when you set the `OutputFormat` property to `'Samples'`. When you use a varying *PRF* and set the `OutputFormat` property to `'Pulses'`, the number of samples can vary.

**Default:** `10e3`

### PRFSelectionInputPort

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the PRF property. When you set this property to `true`, you pass an index argument into the `step` method to select a value from the PRF vector.

**Default:** `false`

### `OutputFormat`

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

**Default:** `'Pulses'`

### `NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

**Default:** `100`

### `NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

**Default:** `1`

### `PRFOutputPort`

Set this property to `true` to output the PRF for the current pulse using a `step` method argument.

#### Dependencies

This property can be used only when the `OutputFormat` property is set to `'Pulses'`.

**Default:** `false`

## Methods

| | |
|---|---|
| bandwidth | Bandwidth of phase-coded waveform |
| getMatchedFilter | Matched filter coefficients for waveform |
| plot | Plot phase-coded pulse waveform |
| reset | Reset states of phase-coded waveform object |
| step | Samples of phase-coded waveform |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

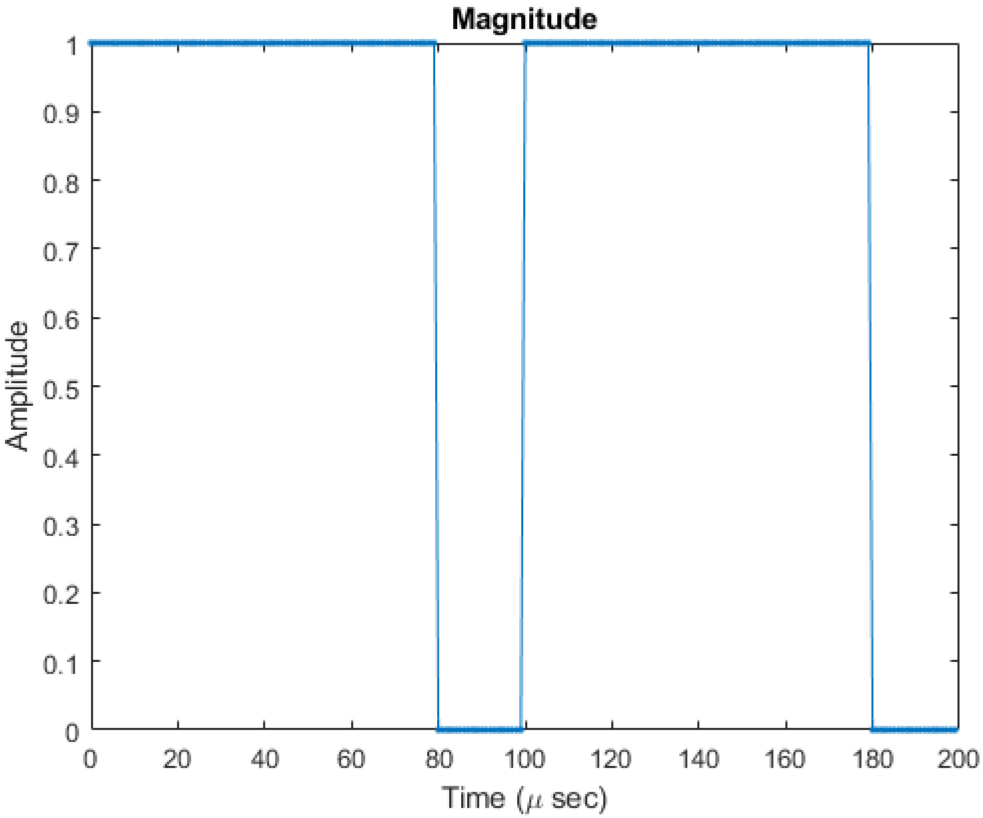
### Plot Phase-Coded Waveform and Spectrum

Create and plot a two-pulse phase-coded waveform that uses the Zadoff-Chu code.

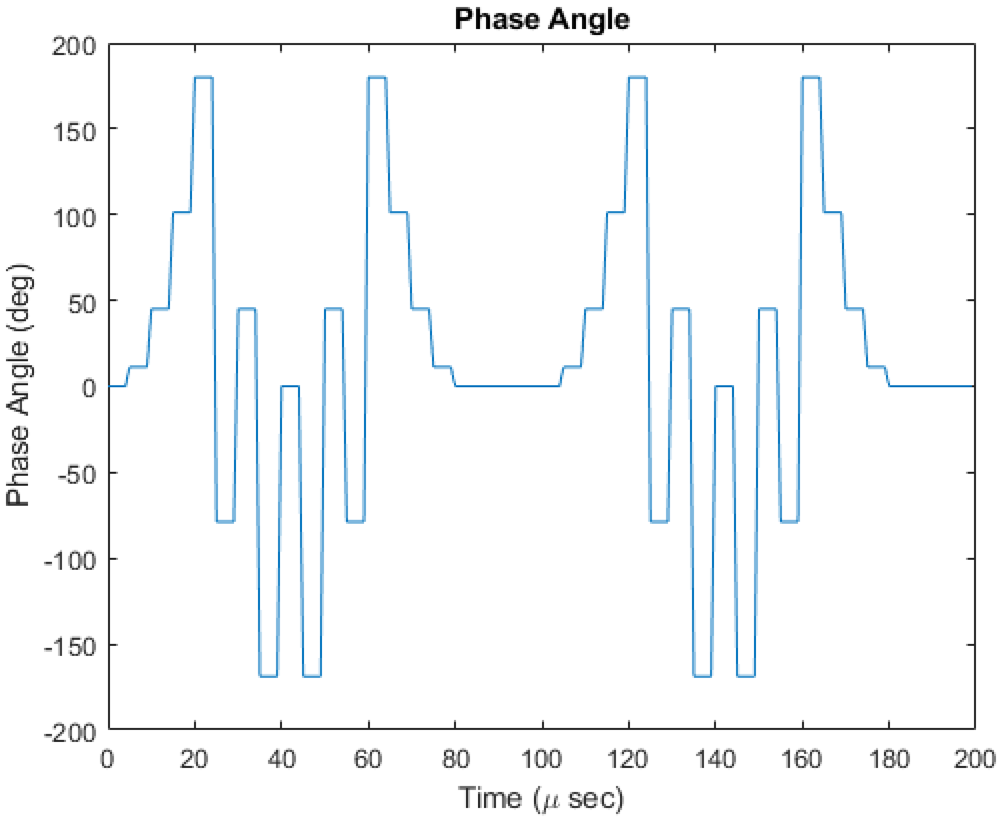
```
sPCW = phased.PhaseCodedWaveform('Code','Zadoff-Chu',...
    'ChipWidth',5e-6,'NumChips',16,...
    'OutputFormat','Pulses','NumPulses',2);
fs = sPCW.SampleRate;
```

Generate signal samples and plot the magnitude and phase of the waveforms.

```
wav = step(sPCW);
nsamp = size(wav,1);
t = [0:(nsamp-1)]/fs;
plot(t*1e6,abs(wav),'.-')
title('Magnitude')
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```

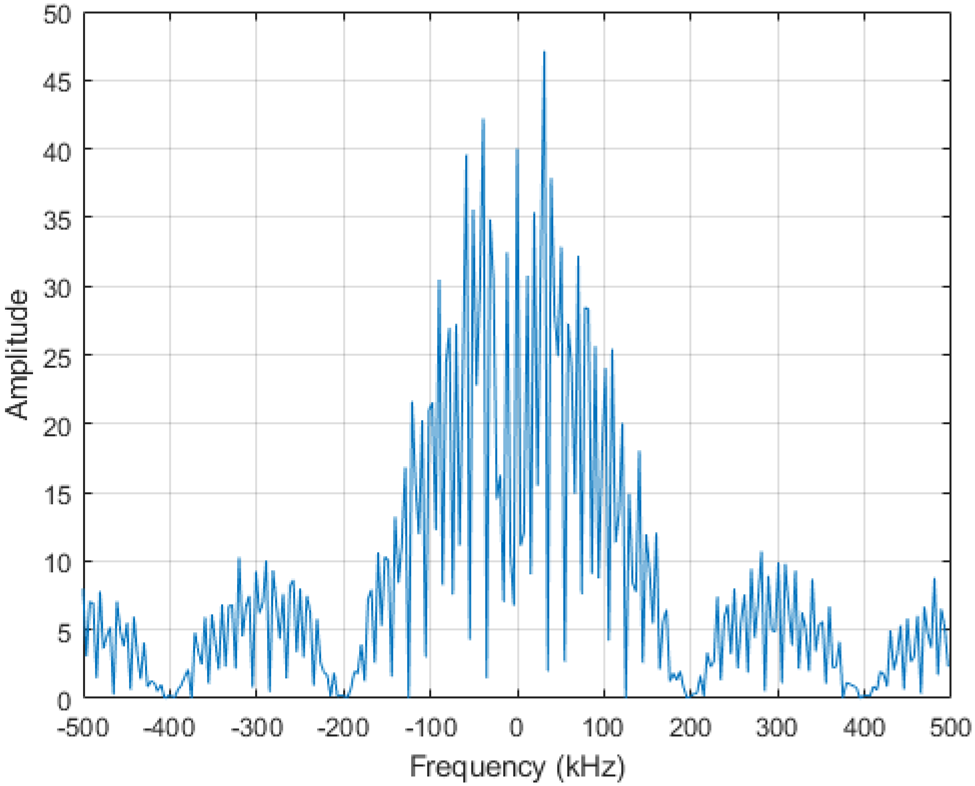


```
plot(t*1e6,180/pi*angle(wav))
title('Phase Angle')
xlabel('Time (\mu sec)')
ylabel('Phase Angle (deg)')
```



Plot the spectrum.

```
nsamp = size(wav,1);
nfft = 2^nextpow2(nsamp);
Z = fft(wav,nfft);
fr = [0:(nfft-1)]/nfft*fs;
fr = fr - fs/2;
plot(fr/1000,abs(fftshift(Z)))
xlabel('Frequency (kHz)')
ylabel('Amplitude')
grid
```



## Algorithms

A 2-chip Barker code can use [1 –1] or [1 1] as the sequence of amplitudes. This software implements [1 –1].

A 4-chip Barker code can use [1 1 –1 1] or [1 1 1 –1] as the sequence of amplitudes. This software implements [1 1 –1 1].

A Zadoff-Chu code can use a clockwise or counterclockwise sequence of phases. This software implements the latter, such as $\pi \cdot f(k) \cdot$ SequenceIndex/NumChips instead of

$-\pi \cdot f(k) \cdot \text{SequenceIndex/NumChips}$. In these expressions, $k$ is the index of the chip and $f(k)$ is a function of $k$.

For further details, see [1].

### Topics

Waveform Analysis Using the Ambiguity Function
“Phase-Coded Waveforms”

**Introduced in R2012a**

# bandwidth

**System object:** `phased.PhaseCodedWaveform`
**Package:** `phased`

Bandwidth of phase-coded waveform

## Syntax

```
bw = bandwidth(waveform)
```

## Description

`bw = bandwidth(waveform)` returns the bandwidth (in hertz) of the pulses for the phase-coded pulse waveform, `waveform`. The bandwidth value is the reciprocal of the chip width.

## Input Arguments

**`waveform`**

Phase-coded waveform object.

## Output Arguments

**`bw`**

Bandwidth of the pulses, in hertz.

## Examples

### Phase-Coded Waveform Bandwidth

Determine the bandwidth of a Frank phased-coded waveform.

```
waveform = phased.PhaseCodedWaveform;
bw = bandwidth(waveform)
```

```
bw = 1.0000e+05
```

# getMatchedFilter

**System object:** `phased.PhaseCodedWaveform`
**Package:** `phased`

Matched filter coefficients for waveform

## Syntax

```
Coeff = getMatchedFilter(H)
```

## Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the phase-coded waveform object, `H`. `Coeff` is a column vector.

## Input Arguments

**`H`**

Phase-coded waveform object.

## Output Arguments

**`Coeff`**

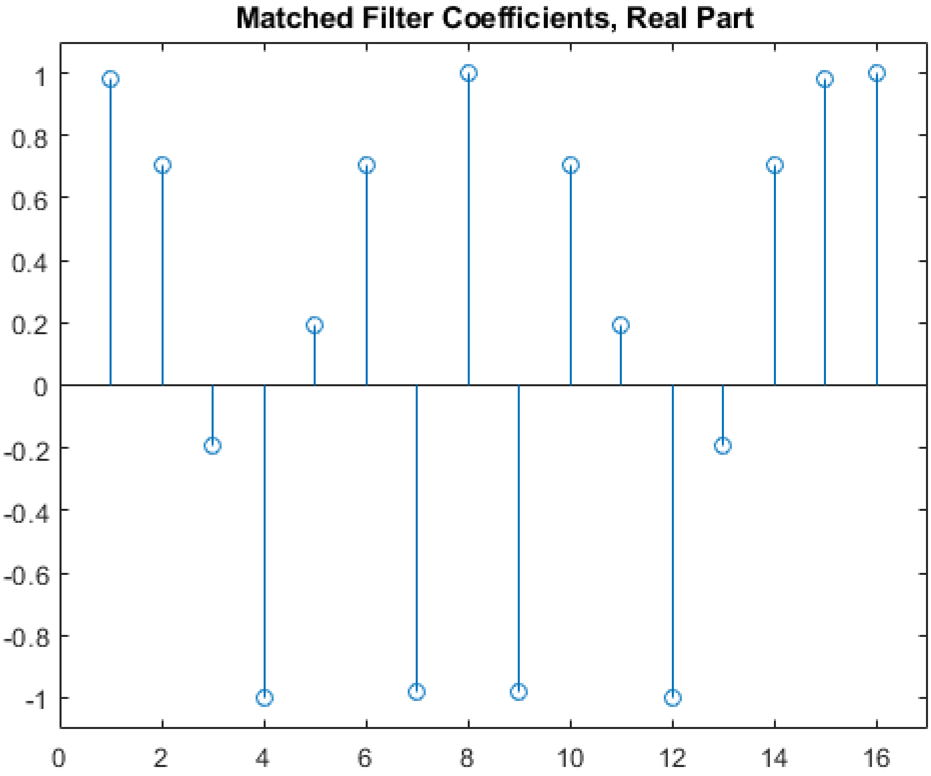
Column vector containing coefficients of the matched filter for `H`.

## Examples

### Matched-Filter Coefficients for Pulse-Coded Waveform

Obtain the matched filter coefficients for a phase-coded pulse waveform that uses the Zadoff-Chu code.

```
waveform = phased.PhaseCodedWaveform('Code','Zadoff-Chu','ChipWidth',1e-6, ...
    'NumChips',16,'OutputFormat','Pulses','NumPulses',2);
coeff = getMatchedFilter(waveform);
stem(real(coeff))
title('Matched Filter Coefficients, Real Part')
axis([0 17 -1.1 1.1])
```



# plot

**System object:** `phased.PhaseCodedWaveform`
**Package:** `phased`

Plot phase-coded pulse waveform

## Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

## Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

## Input Arguments

### Hwav

Waveform object. This variable must be a scalar that represents a single waveform object.

### LineSpec

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

**Default:** `'b'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### PlotType

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

**Default:** `'real'`

### PulseIdx

Index of the pulse to plot. This value must be a scalar.

**Default:** `1`

# Output Arguments

### h

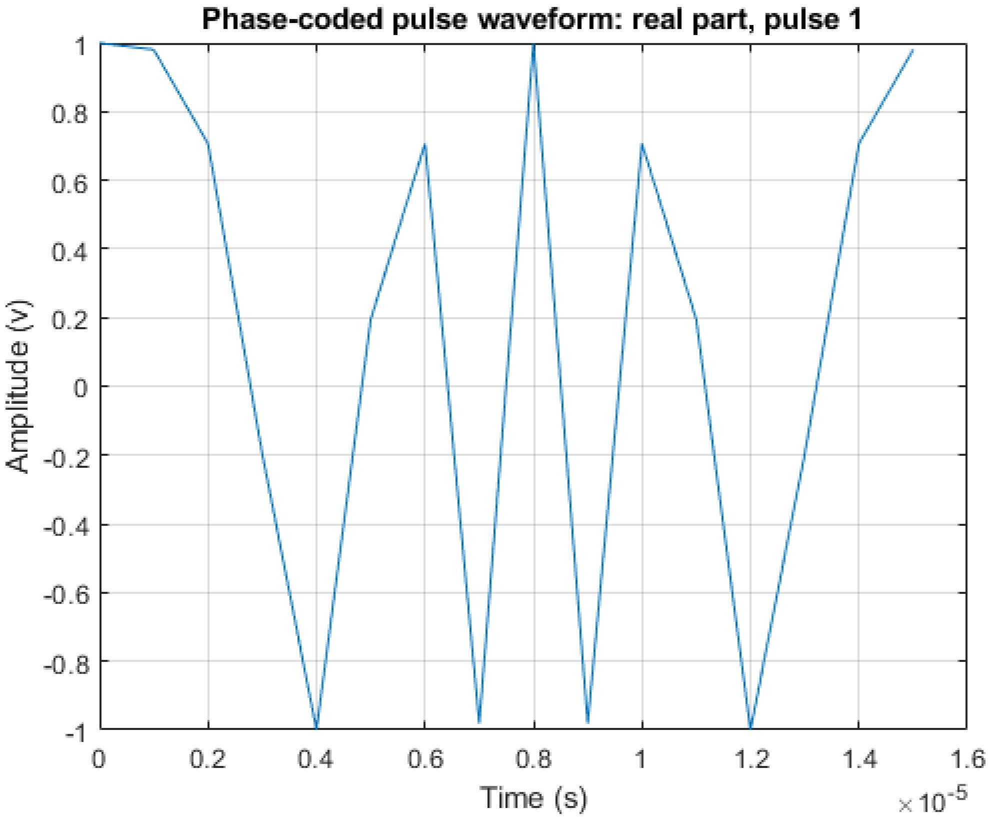
Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

# Examples

### Plot Pulse-Coded Waveform

Create and plot a phase-coded pulse waveform that uses the Zadoff-Chu code.

```
waveform = phased.PhaseCodedWaveform('Code','Zadoff-Chu','ChipWidth',1e-6, ...
    'NumChips',16,'OutputFormat','Pulses','NumPulses',2);
plot(waveform)
```



# reset

**System object:** `phased.PhaseCodedWaveform`
**Package:** `phased`

Reset states of phase-coded waveform object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `PhaseCodedWaveform` object, `H`. Afterward, the next call to `step` restarts the phase sequence from the beginning. Also, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

# step

**System object:** phased.PhaseCodedWaveform
**Package:** phased

Samples of phase-coded waveform

## Syntax

```
Y = step(sPCW)
Y = step(sPCW,prfidx)
```

## Description

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations. When the only argument to the step method is the System object itself, replace y = step(obj) by y = obj().

Y = step(sPCW) returns samples of the phase-coded pulse in a column vector, Y.

Y = step(sPCW,prfidx), uses the prfidx index to select the PRF from the predefined vector of values specified by in the PRF property. This syntax applies when you set the PRFSelectionInputPort property to true.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### sPCW

Phase-coded waveform object.

## Output Arguments

### Y

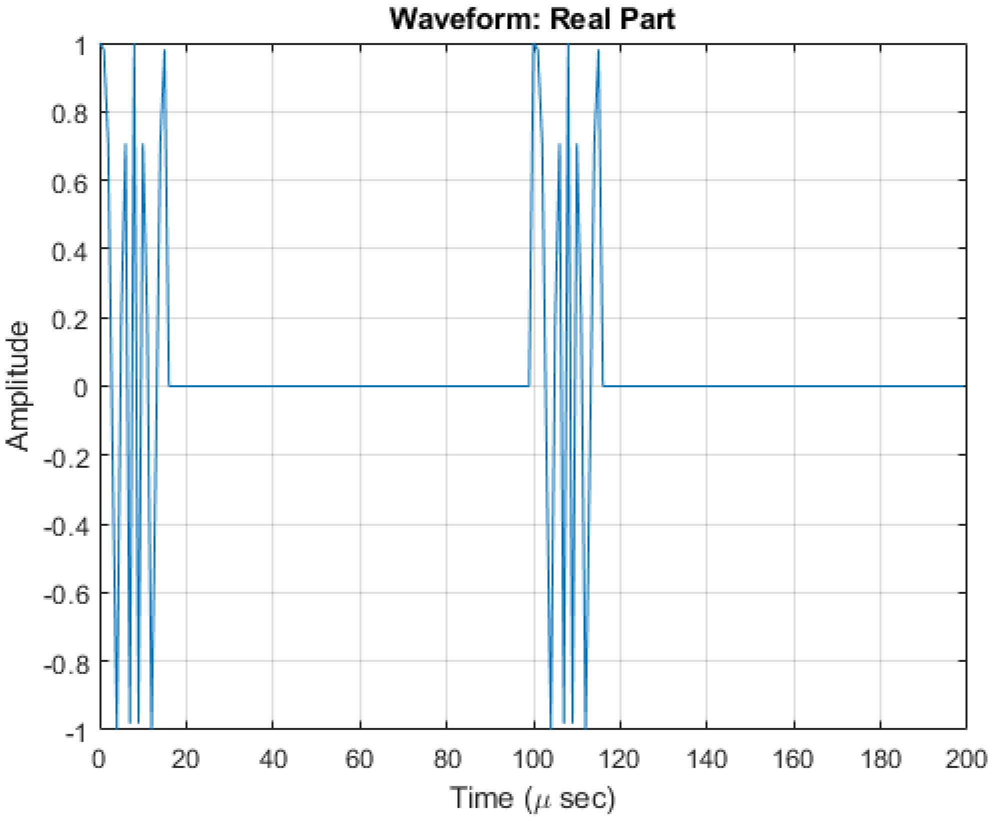
Column vector containing the waveform samples.

## Examples

### Create Pulse Coded Waveform

Generate samples of two pulses of a phase-coded pulse waveform that uses the Zadoff-Chu code.

```
sPCW = phased.PhaseCodedWaveform('Code','Zadoff-Chu',...
    'ChipWidth',1e-6,'NumChips',16,...
    'OutputFormat','Pulses','NumPulses',2);
wav = step(sPCW);
fs = sPCW.SampleRate;
nsamps = size(wav,1);
t = [0:(nsamps-1)]/fs;
plot(t*1e6,real(wav))
title('Waveform: Real Part')
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



### Create Phase-Coded Waveform with Variable PRF

Create and plot two-pulse phase-coded waveforms that uses the Zadoff-Chu code. Set the sample rate to 1 MHz, a chip width of 5 microseconds, 16 chips per pulse. Vary the pulse repetition frequency.

```
fs = 1e6;
PRF = [5000,10000];
waveform = phased.PhaseCodedWaveform('SampleRate',fs,...
    'Code','Zadoff-Chu','PRFSelectionInputPort',true,...
    'ChipWidth',5e-6,'NumChips',16,'PRF',PRF,...
    'OutputFormat','Pulses','NumPulses',2);
```

Obtain and plot the phase-coded waveforms. For the first call to the `step` method, set the PRF to 10kHz using the PRF index. For the next call, set the PRF to 25 kHz. For the final call, set the PRF to 10kHz.

```
wav = [];
wav1 = waveform(1);
wav = [wav; wav1];
wav1 = waveform(2);
wav = [wav; wav1];
wav1 = waveform(1);
wav = [wav; wav1];
nsamps = size(wav,1);
t = [0:(nsamps-1)]/fs;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```

# phased.PhaseShiftBeamformer

**Package:** `phased`

Narrowband phase shift beamformer

## Description

The phased.PhaseShiftBeamformer object implements a narrowband phase-shift beamformer. A phase-shift beamformer approximates a time-delay beamformer for narrowband signals by phase-shifting the arriving signal. A phase shift beamformer belongs to the family of conventional beamformers.

To beamform signals arriving at an array:

1. Create the `phased.PhaseShiftBeamformer` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
beamformer = phased.PhaseShiftBeamformer
beamformer = phased.PhaseShiftBeamformer(Name,Value)
```

### Description

`beamformer = phased.PhaseShiftBeamformer` creates a phase-shift beamformer System object, `beamformer`, with default property values.

`beamformer = phased.PhaseShiftBeamformer(Name,Value)` creates a phase-shift beamformer with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `beamformer = phased.PhaseShiftBeamformer('SensorArray',phased.URA,'OperatingFrequency',300e6)` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The beamformer has an operating frequency of 300 MHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `SensorArray` — Sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox array

Sensor array, specified as an array System object belonging to Phased Array System Toolbox. The sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `single` | `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: 1e9

Data Types: single | double

### DirectionSource — Source of beamforming direction

'Property' (default) | 'Input port'

Source of beamforming direction, specified as 'Property' or 'Input port'. Specify whether the beamforming direction comes from the Direction property of this object or from the input argument, ANG. Values of this property are:

| | |
|---|---|
| 'Property' | Specify the beamforming direction using the Direction property. |
| 'Input port' | Specify the beamforming direction using the input argument, ANG. |

Data Types: char

### Direction — Beamforming directions

[0;0] (default) | real-valued 2-by-1 vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 vector or a real-valued 2-by-*L* matrix. For a matrix, each column specifies a different beamforming direction. Each column has the form [AzimuthAngle;ElevationAngle]. Azimuth angles must lie between –180° and 180° and elevation angles must lie between –90° and 90°. All angles are defined with respect to the local coordinate system of the array. Units are in degrees.

Example: [40;30]

#### Dependencies

To enable this property, set the DirectionSource property to 'Property'.

Data Types: single | double

### NumPhaseShifterBits — Number of phase shifter quantization bits

0 (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights, specified as a nonnegative integer. A value of zero indicates that no quantization is performed.

Example: 5

Data Types: single | double

**WeightsNormalization — Approach for normalizing beamformer weights**
'Distortionless' (default) | 'Preserve power'

If you set this property value to 'Distortionless', the gain in the beamforming direction is 0 dB. If you set this property value to 'Preserve power', the norm of the weights is unity.

Example: 'Preserve power'

Data Types: char

**WeightsOutputPort — Enable beamforming weights output**
false (default) | true

Enable the output of beamforming weights, specified as false or true. To obtain the beamforming weights, set this property to true and use the corresponding output argument, W. If you do not want to obtain the weights, set this property to false.

Data Types: logical

# Usage

# Syntax

```
Y = beamformer(X)
Y = beamformer(X,ANG)
[Y,W] = beamformer( ___ )
```

## Description

Y = beamformer(X) performs phase-shift beamforming on the input signal, X, and returns the beamformed output in Y. To use this syntax, set DirectionSource to 'Property' and set the beamforming direction using the Direction property.

Y = beamformer(X,ANG) uses the ANG input argument to set the beamforming direction. To use this syntax, set the DirectionSource property to 'Input port'.

`[Y,W] = beamformer( ___ )` returns the beamforming weights, `W`. To use this syntax, set the WeightsOutputPort property to `true`.

## Input Arguments

### `X` — Input signal

complex-valued *M*-by-*N* matrix

Input signal, specified as a complex-valued *M*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of array elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`
Complex Number Support: Yes

### `ANG` — Beamforming directions

`[0;0]` (default) | real-valued 2-by-1 column vector | real-valued 2-by-*L* matrix

Beamforming directions, specified as a real-valued 2-by-1 column vector, or 2-by-*L* matrix. *L* is the number of beamforming directions. Each column has the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees. Each azimuth angle must lie between –180° and 180°, and each elevation angle must lie between –90° and 90°.

Example: `[40;10]`

#### Dependencies

To enable this argument, set the DirectionSource property to `'Input port'`.

Data Types: `single` | `double`

## Output Arguments

### `Y` — Beamformed output

complex-valued *M*-by-*L* matrix

Beamformed output, returned as a complex-valued *M*-by-*L* matrix, where *M* is the number of rows of `X` and *L* is the number of beamforming directions.

Data Types: `single` | `double`

Complex Number Support: Yes

### `W` — Beamforming weights

complex-valued *N*-by-*L* matrix.

Beamforming weights, returned as a complex-valued *N*-by-*L* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. *L* is the number of beamforming directions.

#### Dependencies

To enable this output, set the DirectionSource property to `true`.

Data Types: `single` | `double`
Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

## Examples

### Phase-Shift ULA Beamformer

Apply phase-shift beamforming to a sinewave signal received by a 7-element ULA. The beamforming direction is 45° azimuth and 0° elevation. Assume the array operates at 300 MHz. Specify the beamforming direction using the `Direction` property.

Simulate the signal.

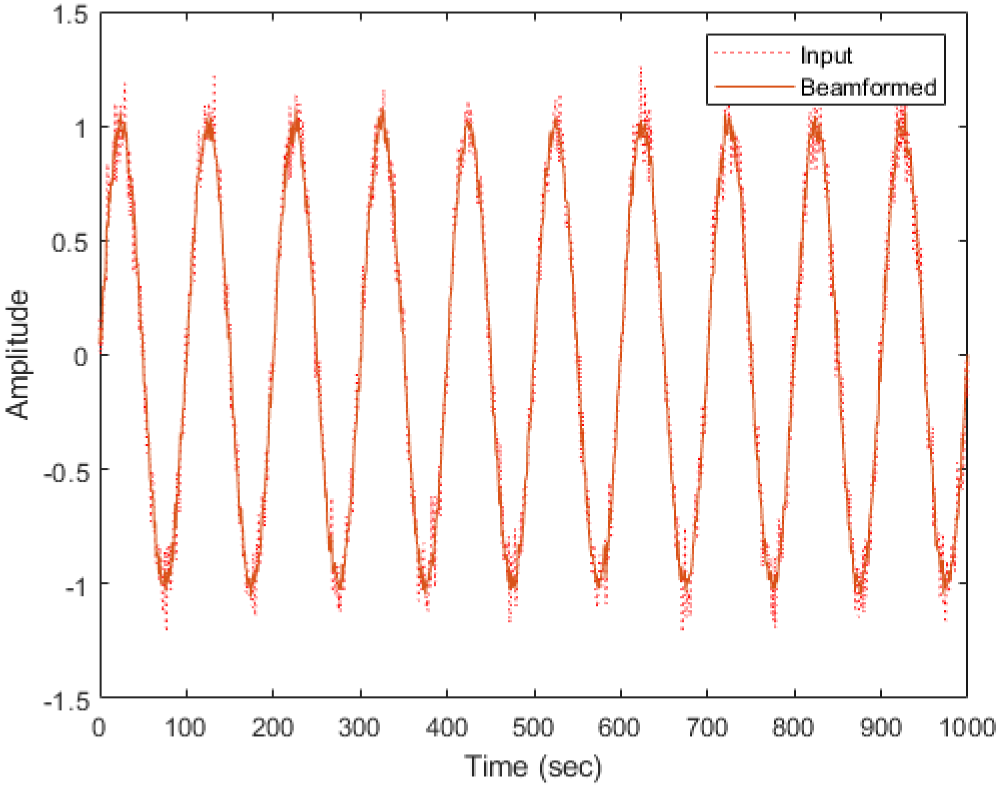
```
t = (0:1000)';
fsignal = 0.01;
x = sin(2*pi*fsignal*t);
c = physconst('Lightspeed');
fc = 300e6;
incidentAngle = [45;0];
array = phased.ULA('NumElements',7);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Set up a phase-shift beamformer and then beamform the input data.

```
beamformer = phased.PhaseShiftBeamformer('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,...
    'Direction',incidentAngle,'WeightsOutputPort',true);
[y,w] = beamformer(rx);
```

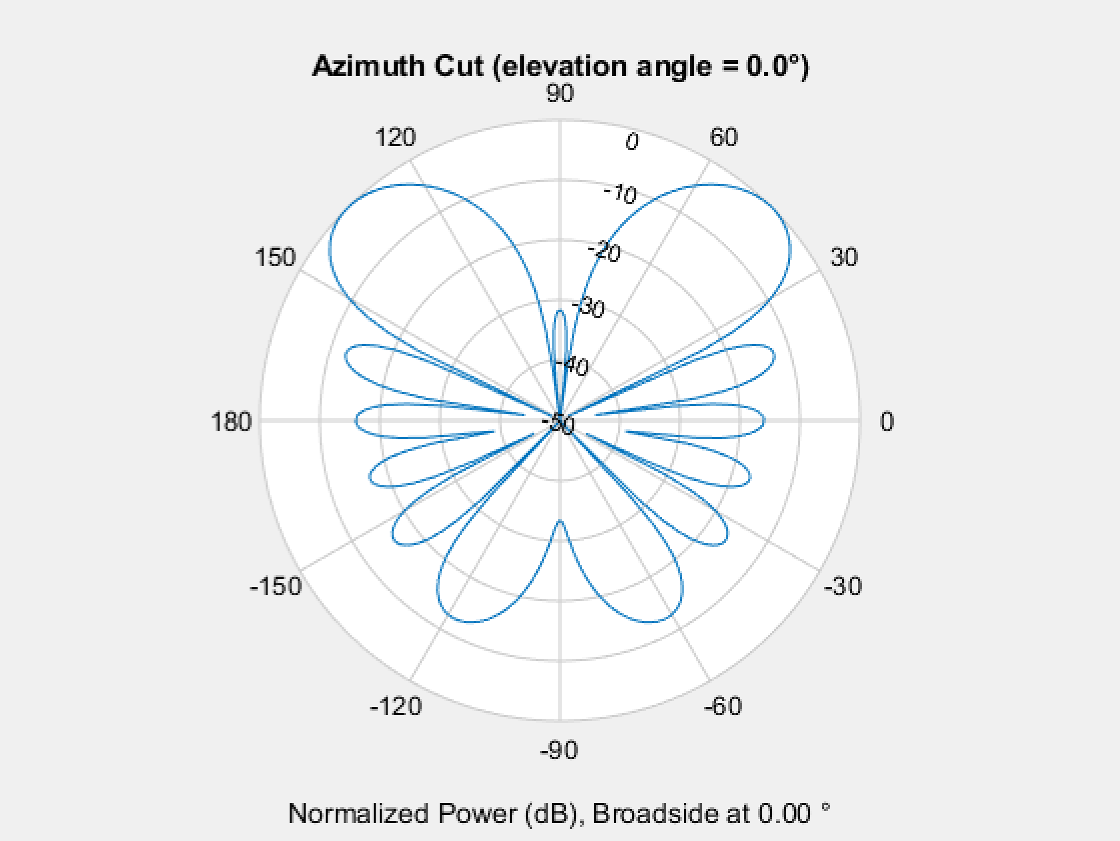
Plot the original signal at the middle element and the beamformed signal.

```
plot(t,real(rx(:,4)),'r:',t,real(y))
xlabel('Time (sec)')
ylabel('Amplitude')
legend('Input','Beamformed')
```



Plot the array response pattern after applying the weights.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'Type',...
    'powerdb','CoordinateSystem','polar','Weights',w)
```



### Phase-Shift Beamformer Using ULA

Apply phase-shift beamforming to the signal received by a 5-element ULA. The beamforming direction is 45° azimuth and 0° elevation. Assume the array operates at 300 MHz. Specify the beamforming direction using an input port.

Simulate a sinewave signal arriving at the array.

```
t = (0:1000)';
fsignal = 0.01;
x = sin(2*pi*fsignal*t);
```

```
c = physconst('LightSpeed');
fc = 300e6;
incidentAngle = [45;0];
array = phased.ULA('NumElements',5);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Construct the phase-shift beamformer and then beamform the input data.

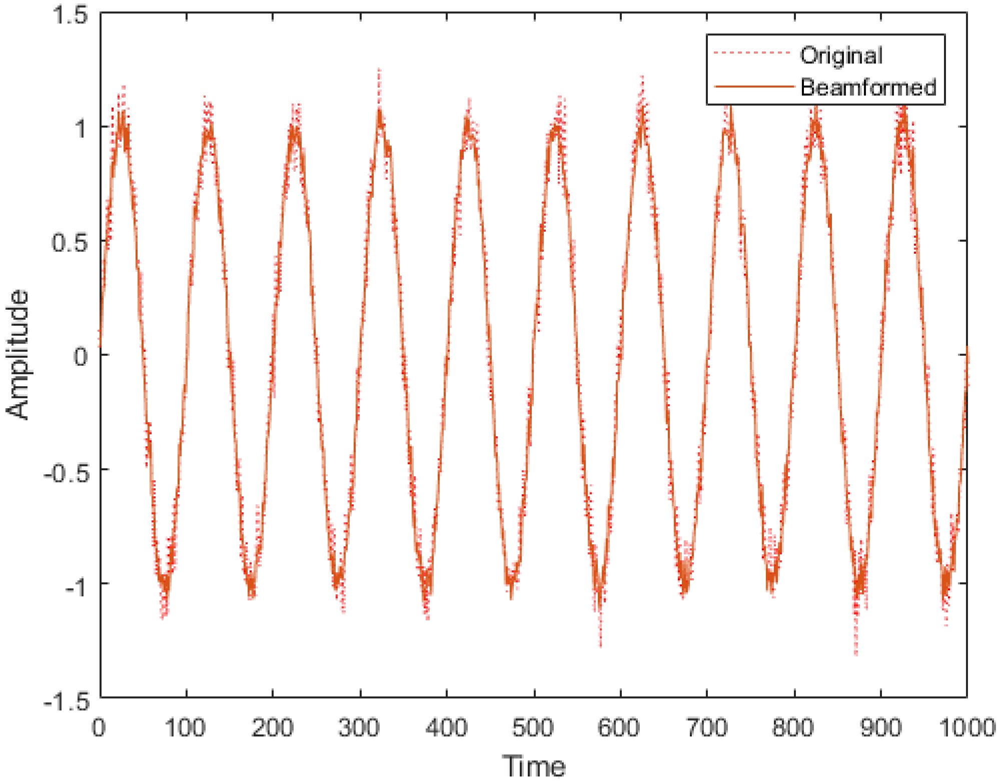
```
beamformer = phased.PhaseShiftBeamformer('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,...
    'DirectionSource','Input port','WeightsOutputPort',true);
```

Obtain the beamformed signal and the beamformer weights.

```
[y,w] = beamformer(rx,incidentAngle);
```

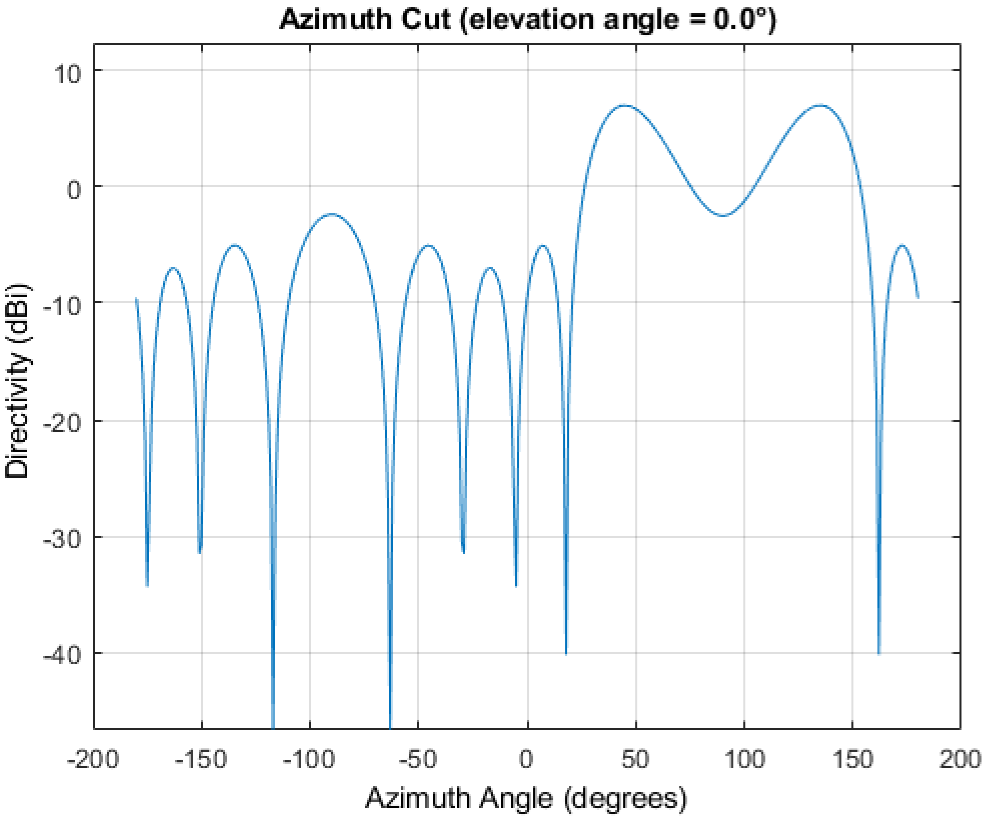
Plot the original signal at the middle element and the beamformed signal.

```
plot(t,real(rx(:,3)),'r:',t,real(y))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the array response pattern after applying the weights.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','rectangular','We
```



## Algorithms

### Phase Shift Beamforming

The phase shift beamformer uses the conventional delay-and-sum beamforming algorithm. The beamformer assumes the signal is narrowband, so a phase shift can approximate the required delay. The beamformer preserves the incoming signal power.

For more details, see [1].

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

**Introduced in R2012a**

# step

**System object:** `phased.PhaseShiftBeamformer`
**Package:** `phased`

Perform phase shift beamforming

## Syntax

```
Y = step(H,X)
Y = step(H,X,ANG)
[Y,W] = step(___)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs phase shift beamforming on the input, `X`, and returns the beamformed output in `Y`.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`.

`[Y,W] = step(___)` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### H

Beamformer object.

### X

Input signal, specified as an *M*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

### ANG

Beamforming directions, specified as a two-row matrix. Each column has the form [AzimuthAngle; ElevationAngle], in degrees. Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees.

## Output Arguments

### Y

Beamformed output. `Y` is an *M*-by-*L* matrix, where *M* is the number of rows of `X` and *L* is the number of beamforming directions.

### W

Beamforming weights. `W` is an *N*-by-*L* matrix, where *L* is the number of beamforming directions. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements.

## Examples

### Phase-Shift Beamformer Using ULA

Apply phase-shift beamforming to the signal received by a 5-element ULA. The beamforming direction is 45° azimuth and 0° elevation. Assume the array operates at 300 MHz. Specify the beamforming direction using an input port.

Simulate a sinewave signal arriving at the array.

```
t = (0:1000)';
fsignal = 0.01;
x = sin(2*pi*fsignal*t);
c = physconst('LightSpeed');
fc = 300e6;
incidentAngle = [45;0];
array = phased.ULA('NumElements',5);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Construct the phase-shift beamformer and then beamform the input data.

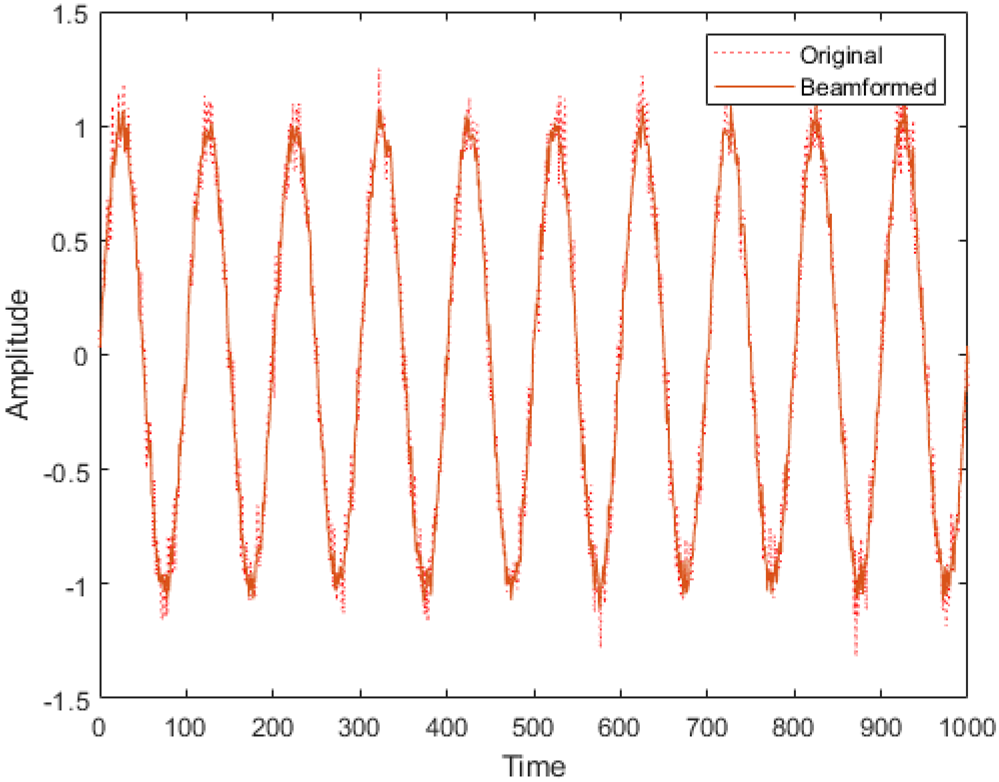
```
beamformer = phased.PhaseShiftBeamformer('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,...
    'DirectionSource','Input port','WeightsOutputPort',true);
```

Obtain the beamformed signal and the beamformer weights.

```
[y,w] = beamformer(rx,incidentAngle);
```

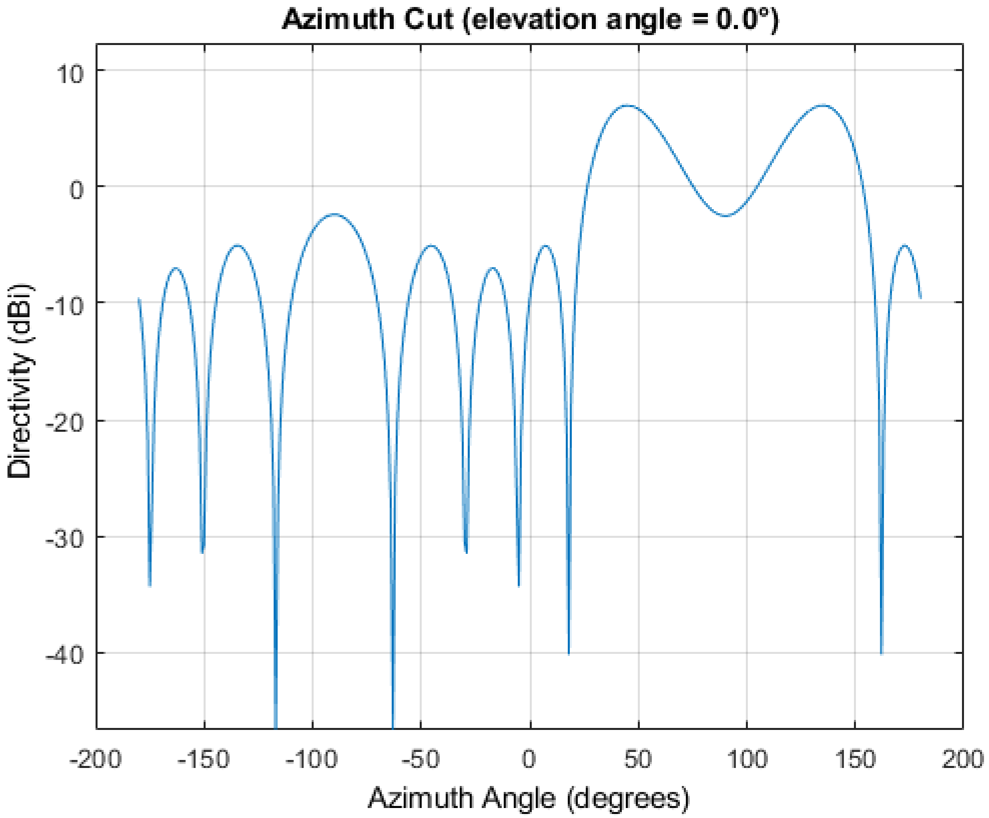
Plot the original signal at the middle element and the beamformed signal.

```
plot(t,real(rx(:,3)),'r:',t,real(y))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the array response pattern after applying the weights.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','rectangular','We
```



## Algorithms

The phase shift beamformer uses the conventional delay-and-sum beamforming algorithm. The beamformer assumes the signal is narrowband, so a phase shift can approximate the required delay. The beamformer preserves the incoming signal power.

For further details, see [1].

# phased.Platform

**Package:** `phased`

Model platform motion

## Description

The `phased.Platform` System object models the translational motion of one or more platforms in space. A platform can be a target such as a vehicle or airplane, or a sonar or radar transmitter and receiver. The model assumes that the platform undergoes translational motion at constant velocity or constant acceleration during each simulation step. Positions and velocities are always defined in the global coordinate system.

To model a moving platform:

1. Define and set up your platform using the “Construction” on page 1-1621 procedure.
2. Repeatedly call the `step` method to move the platform along a path determined by the `phased.Platform` properties.

   The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`sPlat = phased.Platform` creates a platform System object, `sPlat`. The object models a stationary platform with position at the origin and velocity set to zero.

`sPlat = phased.Platform(Name,Value)` creates an object, `sPlat`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

sPlat = phased.Platform(pos,vel,Name,Value) creates a platform object, sPlat, with InitialPosition set to pos and Velocity set to vel. Other specified property Names are set to specified Values. The pos and vel arguments are value-only. Value-only arguments do not require a specified Name but are interpreted according to their argument positions. To specify any value-only argument, specify all preceding value-only arguments.

The motion model is either a constant velocity, a constant acceleration, or a custom trajectory. You can choose one of two motion models using the MotionModel property.

| MotionModel Value | Usage |
|---|---|
| 'Velocity' | If you set the VelocitySource property to 'Property', the platform moves with constant velocity determined by the Velocity property. You can specify the InitialPosition property or leave it to its default value. You can change the tunable Velocity property at any simulation step.<br>When you set the VelocitySource property to 'Input port', you can input instantaneous velocity as an argument to the step method. Specify the initial position using the InitialPosition property or leave it as a default value. |

| MotionModel Value | Usage |
|---|---|
| 'Acceleration' | When you set the AccelerationSource property to 'Property', the platform moves with constant acceleration determined by the Acceleration property. You can specify the InitialPosition and InitialVelocity properties or leave them to their defaults. You can change the tunable Acceleration property at any simulation step.<br>When you set the AccelerationSource property to 'Input port', you can input instantaneous acceleration as an argument to the step method. Specify the InitialPosition and InitialVelocity properties or leave them as their defaults. |
| 'Custom' | Specify the platform motion using a series of waypoints in the CustomTrajectory property. |

# Properties

**MotionModel**

Object motion model

Object motion model, specified as 'Velocity', 'Acceleration', or 'Custom'. When you set this property to 'Velocity', the platform follows a constant velocity trajectory during each simulation step. When you set this property to 'Acceleration', the platform follows a constant acceleration trajectory during each simulation step. When you set the property to 'Custom', the platform motion follows a sequence of waypoints specified by the CustomTrajectory property. The object performs a piecewise cubic interpolation on the waypoints to derive the position and velocity at each time step.

**Default:** 'Velocity'

### `InitialPosition`

Initial position of platform

Initial position of platform, specified as a real-valued 3-by-1 column vector in the form of `[x;y;z]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms. Each column takes the form `[x;y;z]`. Position units are meters.

**Default:** `[0;0;0]`

### `InitialVelocity`

Initial velocity of platform

Initial velocity of platform, specified as a real-valued 3-by-1 column vector in the form of `[vx;vy;vz]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms. Each column taking the form `[vx;vy;vz]`. Velocity units are meters per second.

This property only applies when you set the `MotionModel` property to `'Velocity'` and the `VelocitySource` to `'Input port'`, or when you set the `MotionModel` property to `'Acceleration'`.

**Default:** `[0;0;0]`

### `VelocitySource`

Source of velocity data

Source of velocity data, specified as one of `'Property'` or `'Input port'`. When you set the value of this property to `'Property'`, use `Velocity` property to set the velocity. When you set this property to `'Input port'`, use an input argument of the `step` method to set the velocity.

This property applies when you set the `MotionModel` property to `'Velocity'`.

**Default:** `'Property'`

### `Velocity`

Current velocity of platform

Specify the current velocity of the platform as a 3-by-1 real-valued column vector in the form of `[vx;vy;vz]` or a 3-by-*N* real-valued matrix for multiple platforms. Each column taking the form `[vx;vy;vz]`. Velocity units are meters/sec. The dimension *N* is the number of platforms.

This property applies when you set the `MotionModel` property to `'Velocity'` and the `VelocitySource` to `'Property'`. This property is tunable.

**Default:** `[0;0;0]`

**`AccelerationSource`**

Source of acceleration data

Source of acceleration data, specified as one of `'Property'` or `'Input port'`. When you set the value of this property to `'Property'`, specify the acceleration using the `Acceleration` property. When you set this property to `'Input port'`, use an input argument of the `step` method to set the acceleration.

This property applies when you set the `MotionModel` property to `'Acceleration'`.

**Default:** `'Property'`

**`Acceleration`**

Acceleration of platform

Specify the current acceleration of the platform as a real-valued 3-by-1 column vector in the form `[ax;ay;az]` or a real-valued 3-by-*N* matrix with each column taking the form `[ax;ay;az]`. The dimension *N* is the number of platforms. Acceleration units are meters/sec/sec.

This property applies when you set the `MotionModel` property to `'Acceleration'` and `AccelerationSource` to `'Property'`. This property is tunable.

**Default:** `[0;0;0]`

**`CustomTrajectory`**

Custom trajectory waypoints.

Custom trajectory waypoints, specified as a real-valued *M*-by-*L* matrix, or *M*-by-*L*-by-*N* array. *M* is the number of waypoints. *L* is either 4 or 7.

- When *L* is 4, the first column indicates the times at which the platform position is measured. The 2nd through 4th columns are position measurements in x, y, and z coordinates. The velocity is derived from the position measurements.
- When L is 7, the 5th through seventh columns in the matrix are velocity measurements in x, y, and z coordinates.

When you set the `CustomTrajectory` property to a three-dimensional array, the number of pages, *N*, represent the number of platforms. Time units are in seconds, position units are in meters, and velocity units are in meters per second.

To enable this property, set the `MotionModel` property to `'Custom'`.

### ScanMode

Mechanical scanning mode

Mechanical scan mode for platform, specified as `'None'`, `'Circular''`, or `'Sector'`, where `'None'` is the default. When you set the `ScanMode` property to `'Circular'`, the platform scan clockwise 360 degrees continuously in the azimuthal direction of the platform orientation axes. When you set the `ScanMode` property to `'Sector'`, the platform scans clockwise in the azimuthal direction in the platform orientation axes within a range specified by the `AzimuthSpan` property. When the platform scan reaches the span limits, the scan reverses direction and scans back to the other scan limit. Scanning happens within the orientation axes of the platform.

### InitialScanAngle

Initial scan angle of platform

Initial scan angle of platform, specified as a 1-by-*N* vector where *N* is the number of platforms. The scanning occurs in the local coordinate system of the platform. The `InitialOrientationAxes` specifies the original local coordinate system. At the start of the simulation, the orientation axes specified by the `InitialOrientationAxes` are rotated by the angle specified in the `InitialScanAngle` property. The default value is zero. Units are in degrees. This property applies when you set the `ScanMode` property to `'Circular'` or `'Sector'`.

Example: [30 40]

### AzimuthSpan

Azimuth span

The azimuth angle span, specified as an *N*-by-2 matrix where *N* is the number of platforms. Each row of the matrix specifies the scan range of the corresponding platform in the form `[ScanAngleLowerBound ScanAngleHigherBound]`. The default value is `[-60 60]`. Units are in degrees. To enable this property, set the `ScanMode` to `'Sector'`.

**`AzimuthScanRate`**

Azimuth scan rate

Azimuth scan rate, specified as a 1-by-*N* vector where *N* is the number of platforms. Each entry in the vector is the azimuth scan rate for the corresponding platform. The default value is 10 degrees/second. Units are in degrees/second. To enable this property, set the `ScanMode` property to `'Circular'` or `'Sector'`.

**`InitialOrientationAxes`**

Initial orientation axes of platform

Initial orientation axes of platform, specified as a 3-by-3 real-valued orthonormal matrix for a single platform or as a 3-by-3-by-*N* real-valued matrix for multiple platforms. The dimension *N* is the number of platforms. When the orientation matrix is 3-by-3, the three columns represent the axes of the local coordinate system *(xyz)*. When the orientation matrix is 3-by-3-by-*N*, for each *page* index, the resulting 3-by-3 matrix represents the axes of a local coordinate system.

**Default:** `[1 0 0;0 1 0;0 0 1]`

**`OrientationAxesOutputPort`**

Output orientation axes

To obtain the instantaneous orientation axes of the platform, set this property to `true` and use the corresponding output argument when invoking `step`. If you do not want to obtain the orientation axes of the platform, set this property to `false`.

**Default:** `false`

## Methods

| | |
|---|---|
| reset | Reset platform to initial position |
| step | Output current position, velocity, and orientation axes of platform |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Simulate motion of a platform

Create a platform at the origin having a velocity of (100,100,0) meters per second. Simulate the motion of the platform for two time steps, assuming the time elapsed for each step is one second. The position of the platform is updated after each step.

```
sPlat = phased.Platform([0; 0; 0],[100; 100; 0]);
T = 1;
```

At the first call to step, the position is at its initial value.

```
[pos,v] = step(sPlat,T);
pos
```

```
pos = 3×1

     0
     0
     0
```

At the second call to step, the position changes.

```
[pos,v] = step(sPlat,T);
pos
```

```
pos = 3×1

   100
   100
     0
```

### Model Motion of Circling Airplane

Start with an airplane moving at 150 kmph in a circle of radius 10 km and descending at the same time at a rate of 20 m/sec. Compute the motion of the airplane from its instantaneous acceleration as an argument to the `step` method. Set the initial orientation of the platform to the identity, coinciding with the global coordinate system.

#### Set up the scenario

Specify the initial position and velocity of the airplane. The airplane has a ground range of 10 km and an altitude of 20 km.

```
range = 10000;
alt = 20000;
initPos = [cosd(60)*range;sind(60)*range;alt];
originPos = [1000,1000,0]';
originVel = [0,0,0]';
vs = 150.0;
phi = atan2d(initPos(2)-originPos(2),initPos(1)-originPos(1));
phi1 = phi + 90;
vx = vs*cosd(phi1);
vy = vs*sind(phi1);
initVel = [vx,vy,-20]';
platform = phased.Platform('MotionModel','Acceleration',...
    'AccelerationSource','Input port','InitialPosition',initPos,...
    'InitialVelocity',initVel,'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',eye(3));
relPos = initPos - originPos;
relVel = initVel - originVel;
rel2Pos = [relPos(1),relPos(2),0]';
rel2Vel = [relVel(1),relVel(2),0]';
r = sqrt(rel2Pos'*rel2Pos);
accelmag = vs^2/r;
unitvec = rel2Pos/r;
accel = -accelmag*unitvec;
T = 0.5;
N = 1000;
```

### Compute the trajectory

Specify the acceleration of an object moving in a circle in the *x*-*y* plane. The acceleration is v^2/r towards the origin.

```
posmat = zeros(3,N);
r1 = zeros(N);
v = zeros(N);
for n = 1:N
    [pos,vel,oax] = platform(T,accel);
    posmat(:,n) = pos;
    vel2 = vel(1)^2 + vel(2)^2;
    v(n) = sqrt(vel2);
    relPos = pos - originPos;
    rel2Pos = [relPos(1),relPos(2),0]';
    r = sqrt(rel2Pos'*rel2Pos);
    r1(n) = r;
    accelmag = vel2/r;
    accelmag = vs^2/r;
    unitvec = rel2Pos/r;
    accel = -accelmag*unitvec;
end
```

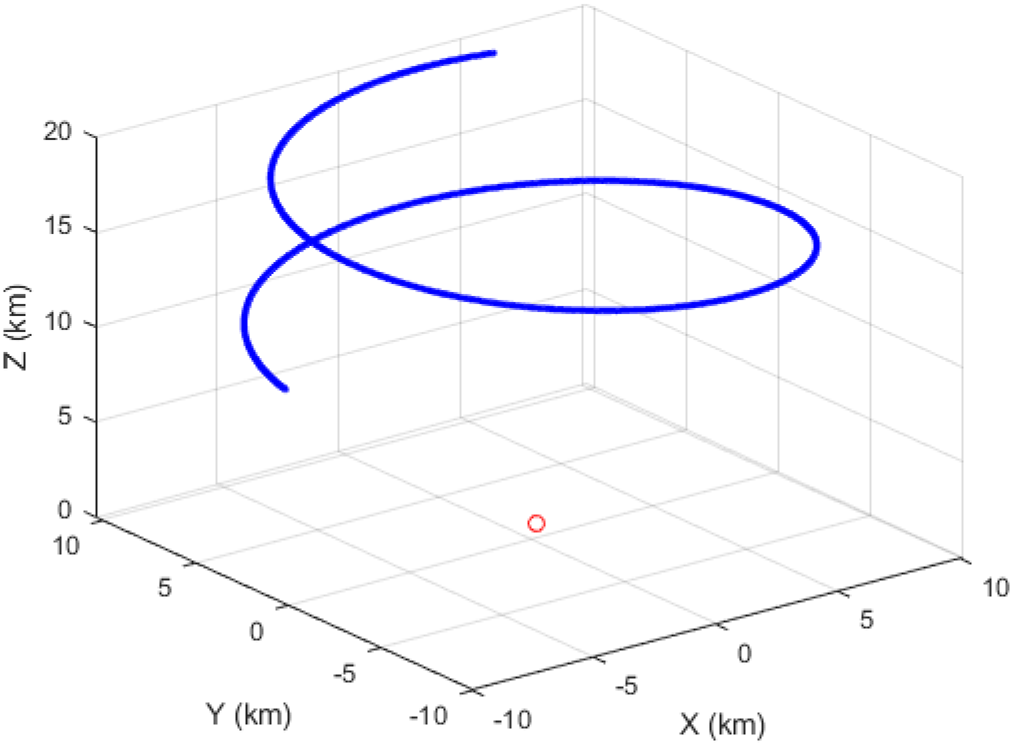
Display the final orientation of the local coordinate system.

```
disp(oax)
```

```
   -0.3658   -0.9307   -0.0001
    0.9307   -0.3658   -0.0010
    0.0009   -0.0005    1.0000
```

### Plot the trajectory and the origin position

```
posmat = posmat/1000;
figure(1)
plot3(posmat(1,:),posmat(2,:),posmat(3,:),'b.')
hold on
plot3(originPos(1)/1000,originPos(2)/1000,originPos(3)/1000,'ro')
xlabel('X (km)')
ylabel('Y (km)')
zlabel('Z (km)')
grid
hold off
```



## Define Platform Motion Using Waypoints

This example shows

Create waypoints from parabolic motion.

```
x0 = 100;
y0 = -150;
z0 = 0;
vx = 5;
vy = 10;
vz = 0;
```

```
ax = 1;
ay = -1;

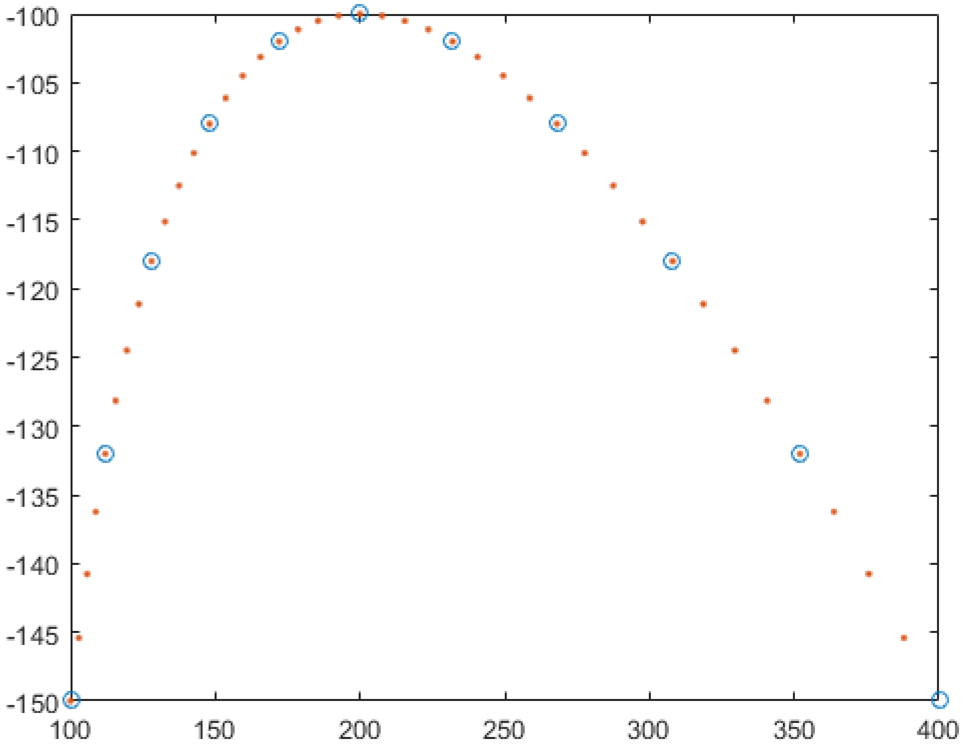
t = [0:2:20];
x = x0 + vx*t + ax/2*t.^2;
y = y0 + vy*t + ay/2*t.^2;
z = z0*ones(size(t));
wpts = [t.' x.' y.' z.'];
```

Create a platform object with motion determined using waypoints.

```
pltfm = phased.Platform('MotionModel','Custom','CustomTrajectory',wpts);
tstep = .5;
nsteps = 40;
X = [];
```

Advance the platform in time steps of one half second;.

```
for k = 1:nsteps
    [pos,vel] = pltfm(tstep);
    X = [X;pos'];
end
plot(x,y,'o'); hold on
plot(X(:,1),X(:,2),'.')
hold off;
```



# More About

## Platform Orientation

A platform has an associated local coordinate system defined by three orthonormal axis vectors. The direction and magnitude of the velocity vector can change with each call to the `step` method. When the platform undergoes curvilinear motion, the orientation of the local coordinate system axes rotates with the motion of the platform. The change of direction of the velocity vector defines a rotation matrix. The same rotation matrix is then used to rotate the local coordinate system as well. When the velocity vector maintains a constant direction, the rotation matrix is the identity matrix. The initial orientation of the local coordinate system is specified using the `InitialOrientationAxes` property. When you specify multiple platforms, each platform rotates independently.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### Topics

“Motion Modeling in Phased Array Systems”

**Introduced in R2012a**

# reset

**System object:** `phased.Platform`
**Package:** `phased`

Reset platform to initial position

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the initial position of the `Platform` object, `H`.

# step

**System object:** `phased.Platform`
**Package:** `phased`

Output current position, velocity, and orientation axes of platform

## Syntax

```
[Pos,Vel] = step(sPlat,T)
[Pos,Vel] = step(sPlat,T,V)
[Pos,Vel] = step(sPlat,T,A)
[Pos,Vel,Laxes] = step(___)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Pos,Vel] = step(sPlat,T)` returns the current position, `Pos`, and velocity, `Vel`, of the platform. The method then updates the position and velocity. When the `MotionModel` property is set to `'Velocity'` and the `VelocitySource` property is set to `'Property'`, the position is updated using the equation *Pos = Pos + Vel*T* where *T* specifies the elapsed time (in seconds) for the current step. When the `MotionModel` property is set to `'Acceleration'` and the `AccelerationSource` property is set to `'Property'`, the position and velocity are updated using the equations *Pos = Pos + Vel*T + 1/2Acl*T^2* and *Vel = Vel + Acl*T* where *T* specifies the elapsed time (in seconds) for the current step.

`[Pos,Vel] = step(sPlat,T,V)` returns the current position, `Pos`, and the current velocity, `Vel`, of the platform. The method then updates the position and velocity using the equation *Pos = Pos + Vel*T* where *T* specifies the elapsed time (in seconds) for the current step. This syntax applies when you set the `MotionModel` property to `'Velocity'` and the `VelocitySource` property to `'Input port'`.

`[Pos,Vel] = step(sPlat,T,A)` returns the current position, `Pos`, and the current velocity, `Vel`, of the platform. The method then updates the position and velocity using the equations *Pos = Pos + Vel*T + 1/2Acl*T^2* and *Vel = Vel + Acl*T* where *T* specifies the elapsed time (in seconds) for the current step. This syntax applies when you set the `MotionModel` property to `'Acceleration'` and the `AccelerationSource` property to `'Input port'`.

`[Pos,Vel,Laxes] = step( ___ )` returns the additional output `Laxes` as the platform's orientation axes when you set the `OrientationAxesOutputPort` property to `true`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### sPlat

Platform

Platform, specified as a `phased.Platform` System object.

### T

Step time

Step time, specified as a real-valued scalar. Units are seconds

### V

Platform velocity

Platform velocity, specified as a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. This argument applies when you set the `MotionModel` property to

`'Velocity'` and the `VelocitySource` property to `'Input port'`. Units are meters per second.

### `A`

Platform acceleration

Platform acceleration, specified as a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. This argument applies when you set the `MotionModel` property to `'Acceleration'` and the `AccelerationSource` property to `'Input port'`. Units are meters per second-squared.

## Output Arguments

### `Pos`

Current platform position

Current position of platform, specified as a real-valued 3-by-1 column vector in the form of `[x;y;z]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. Each column takes the form `[x;y;z]`. Units are meters.

### `Vel`

Current platform velocity

Current velocity of platform, specify as a real-valued 3-by-1 column vector in the form of `[vx;vy;vz]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. Each column taking the form `[vx;vy;vz]`. Velocity units are meters per second.

### `Laxes`

Current platform orientation axes

Current platform orientation axes, returned as real-valued 3-by-3-by-*N* matrix where *N* is the number of platforms to model. Each 3-by-3 submatrix is an orthonormal matrix. This output is enabled when you set the `OrientationAxesOutputPort` property to `true`. The current platform axes rotate around the normal vector to the path of the platform.

## Examples

### Simulate motion of two platforms

Create two moving platforms. The first platform, starting at the origin, has a velocity of (100,100,0) meters per second. The second starts at (1000,0,0) meters and has a velocity of (0,200,0) meters per second. Next, specify different local coordinate axes for each platform defined by rotation matrices. Setting the `OrientationAxesOutputPort` property to `true` lets you retrieve the local coordinate axes at each step.

Set up the platform object.

```
pos0 = [[0;0;0],[1000;0;0]];
vel0 = [[100;100;0],[0;200;0]];
R1 = rotx(30);
R2 = roty(45);
laxes(:,:,1) = R1;
laxes(:,:,2) = R2;
sPlat = phased.Platform(pos0,vel0,...
    'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',laxes);
```

Simulate the motion of the platform for two time steps, assuming the time elapsed for each step is one second. The position of the platform is updated after each step.

```
T = 1;
```

At the first step, the position and velocity equal the initial values.

```
[pos,v,lax] = step(sPlat,T);
pos
```

```
pos = 3×2

           0        1000
           0           0
           0           0
```

```
lax
```

```
lax = 
lax(:,:,1) =
    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660

lax(:,:,2) =

    0.7071         0    0.7071
         0    1.0000         0
   -0.7071         0    0.7071
```

At the second step, the position is updated.

```
[pos,v,lax] = step(sPlat,T);
pos
```

```
pos = 3×2

         100        1000
         100         200
           0           0
```

```
lax
```

```
lax =
lax(:,:,1) =

    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660

lax(:,:,2) =

    0.7071         0    0.7071
         0    1.0000         0
   -0.7071         0    0.7071
```

### Free Falling Accelerating Platform

Find the trajectory of a platform which starts with some initial upward velocity but accelerates downward with a constant gravitational acceleration of -9.8 m/sec/sec. Update the platform position and velocity every two seconds.

Construct the platform System object™.

```
platform = phased.Platform('MotionModel','Acceleration','InitialPosition',[2000,100,300
    'InitialVelocity',[300,150,20]','AccelerationSource','Property','Acceleration',[0,0
T = 2;
N = 100;
```

Call the step method for 100 time samples.

```
posmat = zeros(3,N);
for n = 1:N
    [pos,vel] = platform(T);
    posmat(:,n) = pos;
end
```

Plot the trajectory.

```
plot3(posmat(1,:),posmat(2,:),posmat(3,:),'b.')
axis equal
xlabel('m')
ylabel('m')
zlabel('m')
grid

# phased.PulseCompressionLibrary

**Package:** phased

Create a library of pulse compression specifications

## Description

The phased.PulseCompressionLibrary System object creates a pulse compression library. The library contains sets of parameters that describe pulse compression operations performed on received signals to generate their range response. You can use this library to perform matched filtering or stretch processing. This object can process waveforms created by the phased.PulseWaveformLibrary object.

To make a pulse compression library

1. Create the phased.PulseCompressionLibrary object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
complib = phased.PulseCompressionLibrary()
complib = phased.PulseCompressionLibrary(Name,Value)
```

### Description

complib = phased.PulseCompressionLibrary() System object creates a pulse compression library, complib, with default property values.

complib = phased.PulseCompressionLibrary(Name,Value) creates a pulse compression library with each property Name set to a specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `complib = phased.PulseCompressionLibrary('SampleRate',1e9,'WaveformSpecification',{{'Rectangular','PRF',1e4,'PulseWidth',100e-6}, {'SteppedFM','PRF',1e4}},'ProcessingSpecification', {{'MatchedFilter','SpectumWindow','Hann'}, {'MatchedFilter','SpectrumWindow','Taylor'}})` creates a library with two matched filters. One is matched to a rectangular waveform and the other to a stepped FM waveform. The matched filters use a Hann window and a Taylor window, respectively.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `SampleRate` — Waveform sample rate

`1e6` (default) | positive scalar

Waveform sample rate, specified as a positive scalar. All waveforms have the same sample rate. Units are in hertz.

Example: `100e3`

Data Types: `double`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### WaveformSpecification — Pulse waveforms

`{{'Rectangular','PRF',10e3,'PulseWidth',100e-6},{'LinearFM','PRF',1e4,'PulseWidth',50e-6,'SweepBandwidth',1e5,'SweepDirection','Up','SweepInterval','Positive'}}` (default) | cell array

Pulse waveforms, specified as a cell array. Each cell of the array contains the specification of one waveform.

```
{{Waveform 1 Specification},{Waveform 2 Specification},{Waveform 3 Specification}, ...}
```

Each waveform specification is also a cell array containing the parameters of the waveform. The entries in a specification cell are the pulse identifier and a set of name-value pairs specific to that waveform.

```
{PulseIdentifier,Name1,Value1,Name2,Value2, ...}
```

This System object supports four built-in waveforms and also lets you specify custom waveforms. For the built-in waveforms, the waveform specifier consists of a waveform identifier followed by several name-value pairs setting the properties of the waveform. For the custom waveforms, the waveform specifier consists of a handle to a user-define waveform function and the functions input arguments.

#### Waveform Types

| Pulse Type | Pulse Identifier | Waveform Arguments |
|---|---|---|
| Linear FM | `'LinearFM'` | “Linear FM Waveform Arguments” on page 1-1647 |
| Phase coded | `'PhaseCoded'` | “Phase-Coded Waveform Arguments” on page 1-1649 |
| Rectangular | `'Rectangular'` | “Rectangular Waveform Arguments” on page 1-1651 |
| Stepped FM | `'SteppedFM'` | “Stepped FM Waveform Arguments” on page 1-1652 |
| Custom | *Function handle* | “Custom Waveform Arguments” on page 1-1675 |

Example: `{{'Rectangular','PRF',10e3,'PulseWidth',100e-6},{'Rectangular','PRF',100e3,'PulseWidth',20e-6}}`

Data Types: `cell`

**ProcessingSpecification — Pulse compression descriptions**
`{{'MatchedFilter','SpectrumWindow','None'},{'StretchProcessor','RangeSpan',200,'ReferenceRange',5e3,'RangeWindow','None'}}` (default) | cell array

Pulse compression descriptions, specified as a cell array of processing specifications. Each cell defines a different processing specification. Each processing specification is itself a cell array containing the processing type and processing arguments.

```
{{Processing 1 Specification},{Processing 2 Specification},{Processing 3 Specification}, ...}
```

Each processing specification indicates which type of processing to apply to a waveform and the arguments needed for processing.

```
{ProcessType,Name,Value,...}
```

The value of `ProcessType` is either `'MatchedFilter'` or `'StretchProcessor'`.

- `'MatchedFilter'` – The name-value pair arguments are

  - `'Coefficients'`,`coeff` – specifies the matched filter coefficients, `coeff`, as a column vector. When not specified, the coefficients are calculated from the `WaveformSpecification` property. For the Stepped FM waveform containing multiple pulses, `coeff` corresponds to each pulse until the pulse index, `idx` changes.
  - `'SpectrumWindow'`,`sw` – specifies the spectrum weighting window, `sw`, applied to the waveform. Window values are one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, and `'Taylor'`. The default value is `'None'`.
  - `'SidelobeAttenuation'`,`slb` – specifies the sidelobe attenuation window, `slb`, of the Chebyshev or Taylor window as a positive scalar. The default value is 30. This parameter applies when you set `'SpectrumWindow'` to `'Chebyshev'` or `'Taylor'`.
  - `'Beta'`,`beta` – specifies the parameter, `beta`, that determines the Kaiser window sidelobe attenuation as a nonnegative scalar. The default value is 0.5. This parameter applies when you set `'SpectrumWindow'` to `'Kaiser'`.
  - `'Nbar'`,`nbar` – specifies the number of nearly constant level sidelobes, `nbar`, next to the main lobe in a Taylor window as a positive integer. The default value is 4. This parameter applies when you set `'SpectrumWindow'` to `'Taylor'`.
  - `'SpectrumRange'`,`sr` – specifies the spectrum region, `sr`, on which the spectrum window is applied as a 1-by-2 vector having the form `[StartFrequency EndFrequency]`. The default value is [0 1.0e5]. This parameter applies when you set the `'SpectrumWindow'` to any value other than 'None'. Units are in Hz.

Both `StartFrequency` and `EndFrequency` are measured in the baseband region [-*Fs*/2 *Fs*/2]. *Fs* is the sample rate specified by the `SampleRate` property. `StartFrequency` cannot be larger than `EndFrequency`.

- `'StretchProcessor'` – The name-value pair arguments are

  - `'ReferenceRange'`,`refrng` – specifies the center of the ranges of interest, `refrng`, as a positive scalar. The `refrng` must be within the unambiguous range of one pulse. The default value is 5000. Units are in meters.
  - `'RangeSpan'`,`rngspan` – specifies the span of the ranges of interest. `rngspan`, as a positive scalar. The range span is centered at the range value specified in the `'ReferenceRange'` parameter. The default value is 500. Units are in meters.
  - `'RangeFFTLength'`,`len` – specifies the FFT length in the range domain, `len`, as a positive integer. If not specified, the default value is same as the input data length.
  - `'RangeWindow'`,`rw` specifies the window used for range processing, `rw`, as one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, and `'Taylor'`. The default value is `'None'`.

Example: `'StretchProcessor'`

Data Types: `string` | `struct`

## Linear FM Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```
{'LinearFM','PRF',1e4,'PulseWidth',50e-6,'SweepBandwidth',1e5,...
'SweepDirection','Up','SweepInterval','Positive'}
```

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See "Pulse Repetition Frequency Restrictions" on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### `PulseWidth` — Pulse duration

`5e-5` (default) | positive scalar

Pulse duration, specified as a positive scalar. Units are in seconds. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `100e-6`

Data Types: `double`

### `DutyCycle` — Pulse duty cycle

`0.5` | positive scalar

Pulse duty cycle, specified as a positive scalar greater than zero and less than or equal to one. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `0.7`

Data Types: `double`

### `SweepBandwidth` — Bandwidth of the FM sweep

`1e5` (default) | positive scalar

Bandwidth of the FM sweep, specified as a positive scalar. Units are in hertz.

Example: `100e3`

Data Types: `double`

### `SweepDirection` — Bandwidth of the FM sweep

`'Up'` (default) | `'Down'`

Direction of the FM sweep, specified as `'Up'` or `'Down'`. `'Up'` corresponds to increasing frequency. `'Down'` corresponds to decreasing frequency.

Data Types: `char`

### `SweepInterval` — FM sweep interval

`'Positive'` (default) | `'Symmetric'`

FM sweep interval, specified as `'Positive'` or `'Symmetric'`. If you set this property value to `'Positive'`, the waveform sweeps the interval between 0 and $B$, where $B$ is the `SweepBandwidth` argument value. If you set this property value to `'Symmetric'`, the waveform sweeps the interval between $-B/2$ and $B/2$.

Example: `'Symmetric'`

Data Types: `char`

### `Envelope` — Envelope function

`'Rectangular'` (default) | `'Gaussian'`

Envelope function, specified as `'Rectangular'` or `'Gaussian'`.

Example: `'Gaussian'`

Data Types: `char`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Phase-Coded Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `{'PhaseCoded','PRF',1e4,'Code','Zadoff-Chu', 'SequenceIndex',3,'ChipWidth',5e-6,'NumChips',8}`

### `PRF` — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See “Pulse Repetition Frequency Restrictions” on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### `Code` — Type of phase modulation code

`'Frank'` (default) | `'P1'` | `'P2''Px'` | `'Zadoff-Chu'` | `'P3'` | `'P4'` | `'Barker'`

Type of phase modulation code, specified as 'Frank', 'P1', 'P2', 'Px', 'Zadoff-Chu', 'P3', 'P4', or 'Barker'.

Example: 'P1'

Data Types: char

### SequenceIndex — Zadoff-Chu sequence index

1 (default) | positive integer

Sequence index used for the Zadoff-Chu code, specified as a positive integer. The value of SequenceIndex must be relatively prime to the value of NumChips.

Example: 3

#### Dependencies

To enable this name-value pair, set the Code property to 'Zadoff-Chu'.

Data Types: double

### ChipWidth — Chip duration

1e-5 (default) | positive scalar

Chip duration, specified as a positive scalar. Units are in seconds. See “Chip Restrictions” on page 1-1685 for restrictions on chip sizes.

Example: 30e-3

Data Types: double

### NumChips — Number of chips in waveform

4 (default) | positive integer

Number of chips in waveform, specified as a positive integer. See “Chip Restrictions” on page 1-1685 for restrictions on chip sizes.

Example: 3

Data Types: double

### FrequencyOffset — Frequency offset of pulse

0 (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Rectangular Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `{'Rectangular','PRF',10e3,'PulseWidth',100e-6}`

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See “Pulse Repetition Frequency Restrictions” on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### `PulseWidth` — Pulse duration

`5e-5` (default) | positive scalar

Pulse duration, specified as a positive scalar. Units are in seconds. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `100e-6`

Data Types: `double`

### `DutyCycle` — Pulse duty cycle

`0.5` | positive scalar

Pulse duty cycle, specified as a positive scalar greater than zero and less than or equal to one. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `0.7`

Data Types: `double`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Stepped FM Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `{'SteppedFM','PRF',10e-4}`

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See "Pulse Repetition Frequency Restrictions" on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### PulseWidth — Pulse duration

`5e-5` (default) | positive scalar

Pulse duration, specified as a positive scalar. Units are in seconds. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `100e-6`

Data Types: `double`

### DutyCycle — Pulse duty cycle

`0.5` | positive scalar

Pulse duty cycle, specified as a positive scalar greater than zero and less than or equal to one. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `0.7`

Data Types: `double`

### `NumSteps` — Number of frequency steps in waveform

`5` (default) | positive integer

Number of frequency steps in waveform, specified as a positive integer.

Example: `3`

Data Types: `double`

### `FrequencyStep` — Linear frequency step size

`20e3` (default) | positive scalar

Linear frequency step size, specified as a positive scalar.

Example: `100.0`

Data Types: `double`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Custom Waveform Arguments

You can create a custom waveform from a user-defined function. The first input argument of the function must be the sample rate. For example, specify a hyperbolic waveform function,

```
function wav = HyperbolicFM(fs,prf,pw,freq,bw,fcent),
```

where `fs` is the sample rate and `prf`, `pw`, `freq`, `bw`, and `fcent` are other waveform arguments. The function must have at least one output argument, `wav`, to return the samples of each pulse. This output must be a column vector. There can be other outputs returned following the waveform samples.

Then, create a waveform specification using a function handle instead of the waveform identifier. The first cell in the waveform specification must be a function handle. The remaining cells contain all function input arguments except the sample rate. Specify all input arguments in the order they are passed into the function.

```
waveformspec = {@HyperbolicFM,prf,pw,freq,bw,fcent}
```

See “Add Custom Waveform to Pulse Waveform Library” on page 1-1682 for an example that uses a custom waveform.

# Usage

# Syntax

```
[Y,rng] = pulselib(X,idx)
```

## Description

`[Y,rng] = pulselib(X,idx)` returns samples of a compressed pulse waveform, `Y`, specified by its index, `idx`, in the library. `RNG` denotes the ranges corresponding to `Y`.

## Input Arguments

### X — Input signal

complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Input signal, specified as a complex-valued *K*-by-*L* matrix, complex-valued *K*-by-*N* matrix, or a complex-valued *K*-by-*N*-by-*L* array. *K* denotes the number of fast time samples, *L* the number of pulses, and *N* is the number of channels. Channels can be array elements or beams.

Data Types: `double`

### idx — Index of processing specification in pulse compression library

positive integer

Index of the processing specification in the pulse compression library, specified as a positive integer.

Data Types: `double`

## Output Arguments

### Y — Output signal

complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Output signal, returned as a complex-valued *M*-by-*L* matrix, complex-valued *M*-by-*N* matrix, or a complex-valued *M*-by-*N*-by-*L* array. *M* denotes the number of fast time samples, *L* the number of pulses, and *N* is the number of channels. Channels can be array elements or beams. The number of dimensions of `Y` matches the number of dimensions of `X`.

When matched filtering is performed, *M* is equal to the number of rows in `X`. When stretch processing is performed and you specify a value for the `RangeFFTLength` name-value pair, *M* is set to the value of `RangeFFTLength`. When you do not specify `RangeFFTLength`, *M* is equal to the number of rows in `X`.

Data Types: `double`

### `rng` — Sample range

real-valued length-*M* vector

Sample ranges, returned as a real-valued length-*M* vector where *M* is the number of rows of `Y`. Elements of this vector denote the ranges corresponding to the rows of `Y`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to phased.PulseCompressionLibrary

| | |
|---|---|
| plotResponse | Plot range response from pulse compression library |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |

| | |
|---|---|
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

## Examples

### Range Processing of Two Waveforms

Create a rectangular waveform and a linear FM waveform. Use the processing methods in the pulse compression library to range-process the waveforms. Use matched filtering for the rectangular waveform and stretch processing for the linear FM waveform.

Create two waveforms using the `phased.PulseWaveformLibrary` System object. The sampling frequency is 1 MHz and the pulse repetition frequency for both waveforms is 1 kHz . The pulse width is also the same at 50 microsec.

```
fs = 1.0e6;
prf = 1e3;
pw = 50e-6;
waveform1 = {'Rectangular','PRF',prf,'PulseWidth',pw};
waveform2 = {'LinearFM','PRF',prf,'PulseWidth',pw,...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
pulselib = phased.PulseWaveformLibrary('WaveformSpecification',...
    {waveform1,waveform2},'SampleRate',fs);
```

Retrieve the waveforms for processing by the pulse compression library.

```
rectwav = pulselib(1);
lfmwav = pulselib(2);
```

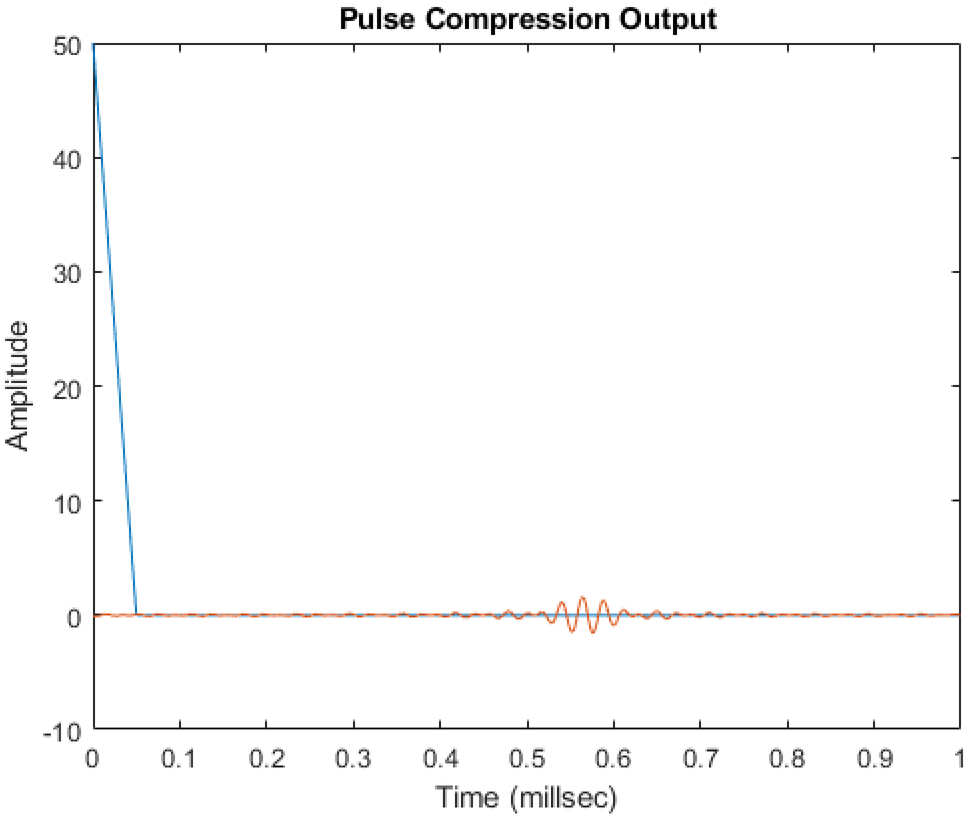
Create the compression processing library using the `phased.PulseCompressionLibrary` System object with two processing specifications. The first processing specification is matched filtering and the second is stretch processing.

```
mf = getMatchedFilter(pulselib,1);
procspec1 = {'MatchedFilter','Coefficients',mf};
procspec2 = {'StretchProcessor','ReferenceRange',5000,...
    'RangeSpan',200,'RangeWindow','Hamming'};
comprlib = phased.PulseCompressionLibrary( ...,
    'WaveformSpecification',{waveform1,waveform2}, ...
    'ProcessingSpecification',{procspec1,procspec2}, ...
    'SampleRate',fs,'PropagationSpeed',physconst('Lightspeed'));
```

Process both waveforms.

```
rect_out = comprlib(rectwav,1);
lfm_out = comprlib(lfmwav,2);
nsamp = fs/prf;
t = [0:(nsamp-1)]/fs;

plot(t*1000,real(rect_out))
hold on
plot(t*1000,real(lfm_out))
hold off
title('Pulse Compression Output')
xlabel('Time (millsec)')
ylabel('Amplitude')
```



### Range Response of Three Targets

Plot the range response of an LFM signal hitting three targets. The ranges are 2000, 4000, and 5500 meters. Assume the radar maximum range is 10 km. Set the pulse repetition interval from the maximum range.

Create the pulse waveform.

```
rmax = 10.0e3;
c = physconst('Lightspeed');
pri = 2*rmax/c;
```

```
fs = 1e6;
pri = ceil(pri*fs)/fs;
prf = 1/pri;
nsamp = pri*fs;
rxdata = zeros(nsamp,1);
t1 = 2*2000/c;
t2 = 2*4000/c;
t3 = 2*5500/c;
idx1 = floor(t1*fs);
idx2 = floor(t2*fs);
idx3 = floor(t3*fs);
lfm = phased.LinearFMWaveform('PulseWidth',10/fs,'PRF',prf, ...
    'SweepBandwidth',(30*fs)/40);
w = lfm();
```

Imbed the waveform part of the pulse into the received signal.

```
x = w(1:11);
rxdata(idx1:idx1+10) = x;
rxdata(idx2:idx2+10) = x;
rxdata(idx3:idx3+10) = x;
```

Create the pulse waveform library.

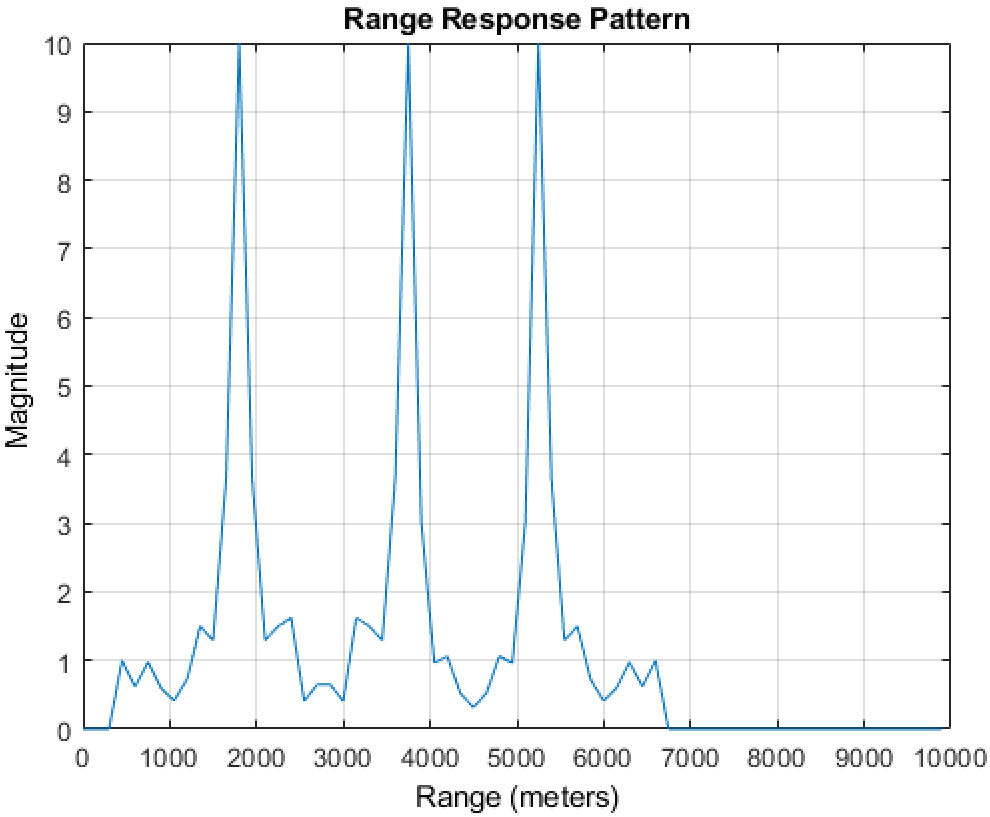
```
w1 = {'LinearFM','PulseWidth',10/fs,'PRF',prf,...
    'SweepBandwidth',(30*fs)/40};
wavlib = phased.PulseWaveformLibrary('SampleRate',fs,'WaveformSpecification',{w1});
wav = wavlib(1);
```

Generate the range response signal.

```
p1 = {'MatchedFilter','Coefficients',getMatchedFilter(wavlib,1),'SpectrumWindow','None
idx = 1;
complib = phased.PulseCompressionLibrary( ...
    'WaveformSpecification',{w1},...
    'ProcessingSpecification',{p1},...
    'SampleRate',fs,...
    'PropagationSpeed',c);
y = complib(rxdata,1);
```

Plot range response of processed data

```
plotResponse(complib,rxdata,idx,'Unit','mag');
```



# More About

## Pulse Repetition Frequency Restrictions

The PRF property must satisfy these restrictions:

- The product of PRF and PulseWidth must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval.

- The ratio of SampleRate to PRF must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

### Chip Restrictions

The values of the ChipWidth and NumChips properties must satisfy these constraints:

- The product of PRF, ChipWidth, and NumChips must be less than or equal to one. This condition expresses the requirement that the sum of the durations of all chips is less than one pulse repetition interval.
- The product of SampleRate and ChipWidth must be an integer. This condition expresses the requirement that the number of samples in a chip must be an integer.

The table shows additional constraints on the number of chips for different code types.

| If the Code Property Is ... | Then the NumChips Property Must Be... |
|---|---|
| 'Frank', 'P1', or 'Px' | A perfect square. |
| 'P2' | An even number that is a perfect square. |
| 'Barker' | 2, 3, 4, 5, 7, 11, or 13 |

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The plotResponse object function is not supported for code generation.

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# plotResponse

**Package:** phased

Plot range response from pulse compression library

## Syntax

```
plotResponse(complib,X,idx)
plotResponse( ___ ,pulseidx)
plotResponse( ___ ,'Unit',unit)
```

## Description

plotResponse(complib,X,idx) plots the range response of the input waveform, X, using the idx processing specification.

plotResponse( ___ ,pulseidx) also specifies the index, pulseidx, of the pulse to plot.

plotResponse( ___ ,'Unit',unit) plots the response in the units specified by unit.

## Examples

### Range Response of Three Targets

Plot the range response of an LFM signal hitting three targets. The ranges are 2000, 4000, and 5500 meters. Assume the radar maximum range is 10 km. Set the pulse repetition interval from the maximum range.

Create the pulse waveform.

```
rmax = 10.0e3;
c = physconst('Lightspeed');
pri = 2*rmax/c;
```

```
fs = 1e6;
pri = ceil(pri*fs)/fs;
prf = 1/pri;
nsamp = pri*fs;
rxdata = zeros(nsamp,1);
t1 = 2*2000/c;
t2 = 2*4000/c;
t3 = 2*5500/c;
idx1 = floor(t1*fs);
idx2 = floor(t2*fs);
idx3 = floor(t3*fs);
lfm = phased.LinearFMWaveform('PulseWidth',10/fs,'PRF',prf, ...
    'SweepBandwidth',(30*fs)/40);
w = lfm();
```

Imbed the waveform part of the pulse into the received signal.

```
x = w(1:11);
rxdata(idx1:idx1+10) = x;
rxdata(idx2:idx2+10) = x;
rxdata(idx3:idx3+10) = x;
```

Create the pulse waveform library.

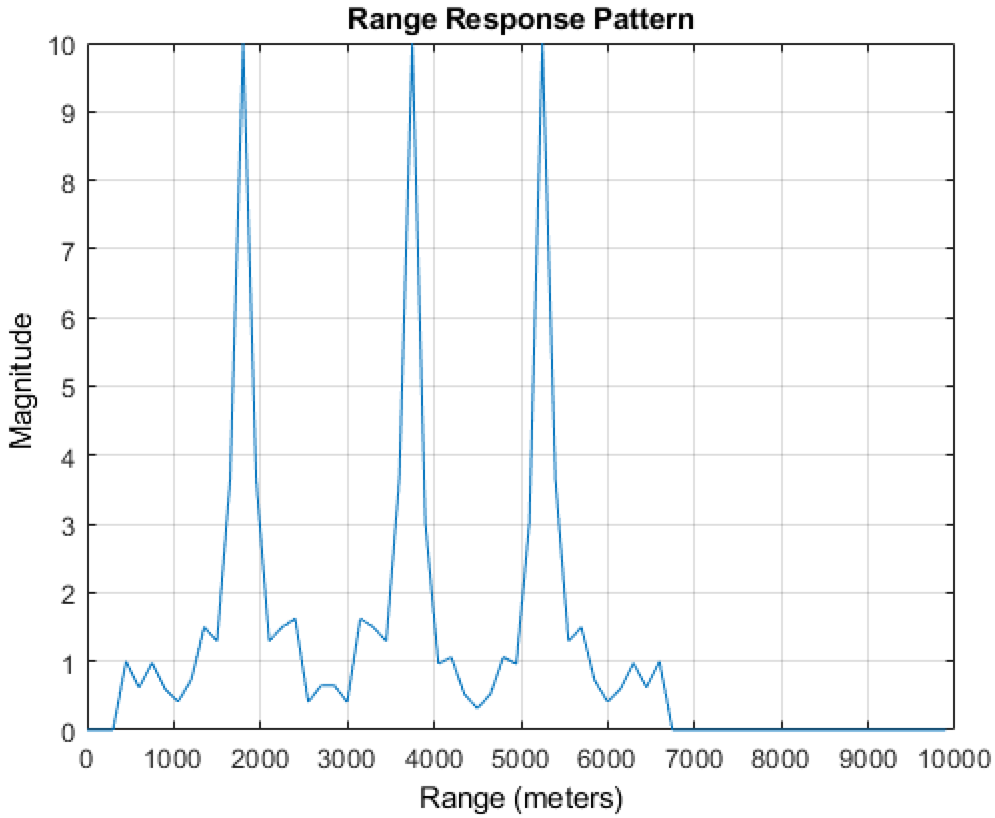
```
w1 = {'LinearFM','PulseWidth',10/fs,'PRF',prf,...
    'SweepBandwidth',(30*fs)/40};
wavlib = phased.PulseWaveformLibrary('SampleRate',fs,'WaveformSpecification',{w1});
wav = wavlib(1);
```

Generate the range response signal.

```
p1 = {'MatchedFilter','Coefficients',getMatchedFilter(wavlib,1),'SpectrumWindow','None
idx = 1;
complib = phased.PulseCompressionLibrary( ...
    'WaveformSpecification',{w1},...
    'ProcessingSpecification',{p1},...
    'SampleRate',fs,...
    'PropagationSpeed',c);
y = complib(rxdata,1);
```

Plot range response of processed data

```
plotResponse(complib,rxdata,idx,'Unit','mag');
```



## Input Arguments

### `complib` — Pulse compression library

`phased.PulseCompressionLibrary` System object

Pulse compression library, specified as a `phased.PulseCompressionLibrary` System object.

### X — Input signal

complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Input signal, specified as a complex-valued *K*-by-*L* matrix, complex-valued *K*-by-*N* matrix, or a complex-valued *K*-by-*N*-by-*L* array. *K* denotes the number of fast time samples, *L* the number of pulses, and *N* is the number of channels. Channels can be array elements or beams.

Data Types: `double`

### `idx` — Index of processing specification in pulse compression library

positive integer

Index of processing specification in the pulse waveform library, specified as a positive integer.

Example: `3`

Data Types: `double`

### `pulseidx` — Stepped FM waveform subpulse

`1` (default) | `positive integer`

Stepped FM waveform subpulse, specified as a positive integer. This index selects which subpulses of a stepped-FM waveform to plot. This argument only applies to stepped-FM waveforms.

Example: `5`

Data Types: `double`

### `unit` — Plot units

`'db'` (default) | `'mag'` | `'pow'`

Plot units, specified as `'db'`, `'mag'`, or `'pow'`. who

- `'db'` – plot the response power in dB.
- `'mag'` – plot the magnitude of the response.
- `'pow'` – plot the response power.

Example: `'mag'`

Data Types: `char` | `string`

**Introduced in R2018b**

# phased.PulseWaveformLibrary

**Package:** `phased`

Create a library of pulse waveforms

## Description

The `phased.PulseWaveformLibrary` System object creates a library of pulse waveforms. The waveforms in the library can be of different types or be of the same type with different parameters. You can use this library to transmit different kinds of pulses during a simulation.

To make a waveform library

1. Create the `phased.PulseWaveformLibrary` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
pulselib = phased.PulseWaveformLibrary
pulselib = phased.PulseWaveformLibrary(Name,Value)
```

### Description

`pulselib = phased.PulseWaveformLibrary` System object creates a library of pulse waveforms, `pulselib`, with default property values. The default consists of a rectangular waveform and a linear FM waveform.

`pulselib = phased.PulseWaveformLibrary(Name,Value)` creates a pulse waveform library with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `pulselib = phased.PulseWaveformLibrary('SampleRate',1e9,'WaveformSpecification',{{'Rectangular','PRF',1e4,'PulseWidth',100e-6},{'SteppedFM','PRF',1e4}})` creates a library containing one rectangular waveform and one stepped-FM waveform, both sampled at 1 GHz.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `SampleRate` — Waveform sample rate

`1e6` (default) | positive scalar

Waveform sample rate, specified as a positive scalar. All waveforms have the same sample rate. Units are in hertz.

Example: `100e3`

Data Types: `double`

### `WaveformSpecification` — Pulse waveforms

`{{'Rectangular','PRF',10e3,'PulseWidth',100e-6},{'LinearFM','PRF',1e4,'PulseWidth',50e-6,'SweepBandwidth',1e5,'SweepDirection','Up','SweepInterval','Positive'}}` (default) | cell array

Pulse waveforms, specified as a cell array. Each cell of the array contains the specification of one waveform.

```
{{Waveform 1 Specification},{Waveform 2 Specification},{Waveform 3 Specification}, ...}
```

Each waveform specification is also a cell array containing the parameters of the waveform. The entries in a specification cell are the pulse identifier and a set of name-value pairs specific to that waveform.

```
{PulseIdentifier,Name1,Value1,Name2,Value2, ...}
```

This System object supports four built-in waveforms and also lets you specify custom waveforms. For the built-in waveforms, the waveform specifier consists of a waveform identifier followed by several name-value pairs setting the properties of the waveform. For the custom waveforms, the waveform specifier consists of a handle to a user-define waveform function and the functions input arguments.

### Waveform Types

| Waveform type | Waveform identifier | Waveform arguments |
|---|---|---|
| Linear FM | `'LinearFM'` | "Linear FM Waveform Arguments" on page 1-1669 |
| Phase coded | `'PhaseCoded'` | "Phase-Coded Waveform Arguments" on page 1-1671 |
| Rectangular | `'Rectangular'` | "Rectangular Waveform Arguments" on page 1-1673 |
| Stepped FM | `'SteppedFM'` | "Stepped FM Waveform Arguments" on page 1-1674 |
| Custom | *Function handle* | "Custom Waveform Arguments" on page 1-1675 |

Example: `{{'Rectangular','PRF',10e3,'PulseWidth',100e-6},{'Rectangular','PRF',100e3,'PulseWidth',20e-6}}`

Data Types: `cell`

## Linear FM Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```
{'LinearFM','PRF',1e4,'PulseWidth',50e-6,'SweepBandwidth',1e5,...
'SweepDirection','Up','SweepInterval','Positive'}
```

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See "Pulse Repetition Frequency Restrictions" on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

**`PulseWidth` — Pulse duration**
`5e-5` (default) | positive scalar

Pulse duration, specified as a positive scalar. Units are in seconds. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `100e-6`

Data Types: `double`

**`DutyCycle` — Pulse duty cycle**
`0.5` | positive scalar

Pulse duty cycle, specified as a positive scalar greater than zero and less than or equal to one. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `0.7`

Data Types: `double`

**`SweepBandwidth` — Bandwidth of the FM sweep**
`1e5` (default) | positive scalar

Bandwidth of the FM sweep, specified as a positive scalar. Units are in hertz.

Example: `100e3`

Data Types: `double`

**`SweepDirection` — Bandwidth of the FM sweep**
`'Up'` (default) | `'Down'`

Direction of the FM sweep, specified as `'Up'` or `'Down'`. `'Up'` corresponds to increasing frequency. `'Down'` corresponds to decreasing frequency.

Data Types: `char`

**`SweepInterval` — FM sweep interval**
`'Positive'` (default) | `'Symmetric'`

FM sweep interval, specified as `'Positive'` or `'Symmetric'`. If you set this property value to `'Positive'`, the waveform sweeps the interval between 0 and *B*, where *B* is the `SweepBandwidth` argument value. If you set this property value to `'Symmetric'`, the waveform sweeps the interval between –*B*/2 and *B*/2.

Example: `'Symmetric'`

Data Types: `char`

### `Envelope` — Envelope function

`'Rectangular'` (default) | `'Gaussian'`

Envelope function, specified as `'Rectangular'` or `'Gaussian'`.

Example: `'Gaussian'`

Data Types: `char`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Phase-Coded Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `{'PhaseCoded','PRF',1e4,'Code','Zadoff-Chu',`
`'SequenceIndex',3,'ChipWidth',5e-6,'NumChips',8}`

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See “Pulse Repetition Frequency Restrictions” on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### `Code` — Type of phase modulation code

`'Frank'` (default) | `'P1'` | `'P2''Px'` | `'Zadoff-Chu'` | `'P3'` | `'P4'` | `'Barker'`

Type of phase modulation code, specified as `'Frank'`, `'P1'`, `'P2'`, `'Px'`, `'Zadoff-Chu'`, `'P3'`, `'P4'`, or `'Barker'`.

Example: `'P1'`

Data Types: `char`

### `SequenceIndex` — `Zadoff-Chu` sequence index

`1` (default) | positive integer

Sequence index used for the `Zadoff-Chu` code, specified as a positive integer. The value of `SequenceIndex` must be relatively prime to the value of `NumChips`.

Example: `3`

#### Dependencies

To enable this name-value pair, set the `Code` property to `'Zadoff-Chu'`.

Data Types: `double`

### `ChipWidth` — Chip duration

`1e-5` (default) | positive scalar

Chip duration, specified as a positive scalar. Units are in seconds. See “Chip Restrictions” on page 1-1685 for restrictions on chip sizes.

Example: `30e-3`

Data Types: `double`

### `NumChips` — Number of chips in waveform

`4` (default) | positive integer

Number of chips in waveform, specified as a positive integer. See “Chip Restrictions” on page 1-1685 for restrictions on chip sizes.

Example: `3`

Data Types: `double`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Rectangular Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `{'Rectangular','PRF',10e3,'PulseWidth',100e-6}`

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See “Pulse Repetition Frequency Restrictions” on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### `PulseWidth` — Pulse duration

`5e-5` (default) | positive scalar

Pulse duration, specified as a positive scalar. Units are in seconds. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `100e-6`

Data Types: `double`

### `DutyCycle` — Pulse duty cycle

`0.5` | positive scalar

Pulse duty cycle, specified as a positive scalar greater than zero and less than or equal to one. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `0.7`

Data Types: `double`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Stepped FM Waveform Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `{'SteppedFM','PRF',10e-4}`

### PRF — Pulse repetition frequency

`1e4` (default) | positive scalar

Pulse repetition frequency (PRF), specified as a positive scalar. Units are in hertz. See “Pulse Repetition Frequency Restrictions” on page 1-1685 for restrictions on the PRF.

Example: `20e3`

Data Types: `double`

### `PulseWidth` — Pulse duration

`5e-5` (default) | positive scalar

Pulse duration, specified as a positive scalar. Units are in seconds. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `100e-6`

Data Types: `double`

### `DutyCycle` — Pulse duty cycle

`0.5` | positive scalar

Pulse duty cycle, specified as a positive scalar greater than zero and less than or equal to one. You cannot specify both `PulseWidth` and `DutyCycle`.

Example: `0.7`

Data Types: `double`

### `NumSteps` — Number of frequency steps in waveform

`5` (default) | positive integer

Number of frequency steps in waveform, specified as a positive integer.

Example: `3`

Data Types: `double`

### `FrequencyStep` — Linear frequency step size

`20e3` (default) | positive scalar

Linear frequency step size, specified as a positive scalar.

Example: `100.0`

Data Types: `double`

### `FrequencyOffset` — Frequency offset of pulse

`0` (default) | scalar

Frequency offset of pulse, specified as a scalar. The frequency offset shifts the frequency of the generated pulse waveform. Units are in hertz.

Example: `100e3`

Data Types: `double`

## Custom Waveform Arguments

You can create a custom waveform from a user-defined function. The first input argument of the function must be the sample rate. For example, specify a hyperbolic waveform function,

```
function wav = HyperbolicFM(fs,prf,pw,freq,bw,fcent),
```

where `fs` is the sample rate and `prf`, `pw`, `freq`, `bw`, and `fcent` are other waveform arguments. The function must have at least one output argument, `wav`, to return the samples of each pulse. This output must be a column vector. There can be other outputs returned following the waveform samples.

Then, create a waveform specification using a function handle instead of the waveform identifier. The first cell in the waveform specification must be a function handle. The remaining cells contain all function input arguments except the sample rate. Specify all input arguments in the order they are passed into the function.

```
waveformspec = {@HyperbolicFM,prf,pw,freq,bw,fcent}
```

See “Add Custom Waveform to Pulse Waveform Library” on page 1-1682 for an example that uses a custom waveform.

# Usage

# Syntax

```
waveform = pulselib(idx)
```

## Description

`waveform = pulselib(idx)` returns samples of a waveform, `waveform`, specified by its index, `idx`, in the library.

## Input Arguments

**`idx` — Index of the waveform in the waveform library**
positive integer

Index of the waveform in the waveform library, specified as a positive integer.

Example: 2

Data Types: `double`

## Output Arguments

**`waveform` — Waveform samples**
complex-valued vector

Waveform samples, returned as a complex-valued vector.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to phased.PulseWaveformLibrary

| | |
|---|---|
| getMatchedFilter | Matched filter coefficients for pulse waveform |
| plot | Plot waveform from waveform library |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Obtain and Plot Phase-Coded Waveform from Waveform Library

Construct a waveform library consisting of three waveforms. The library contains a rectangular, a linear FM, and a phase-coded waveform. Then, obtain and plot the real and imaginary parts of the phase-coded waveform.

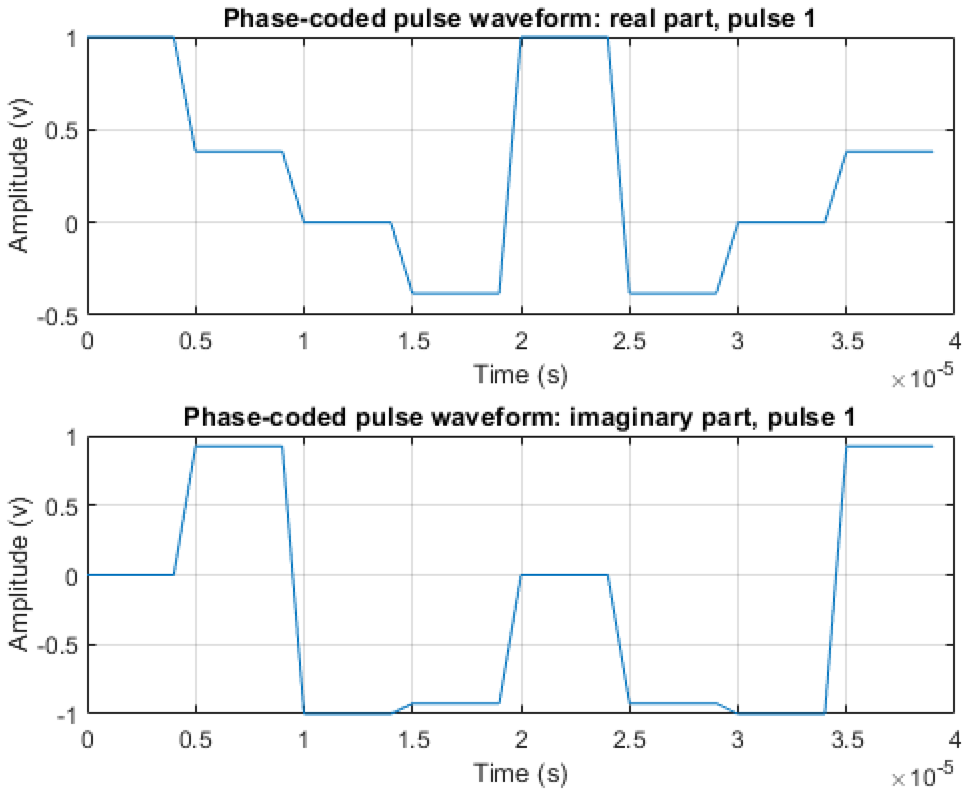
```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth', 50e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',50e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'PhaseCoded','PRF',1e4,'Code','Zadoff-Chu', ...
    'SequenceIndex',3,'ChipWidth',5e-6,'NumChips',8};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
```

Extract the waveform from the library.

```
wav3 = wavlib(3);
```

Plot the waveform using the `plot` method.

```
plot(wavlib,3,'PlotType','complex')
```



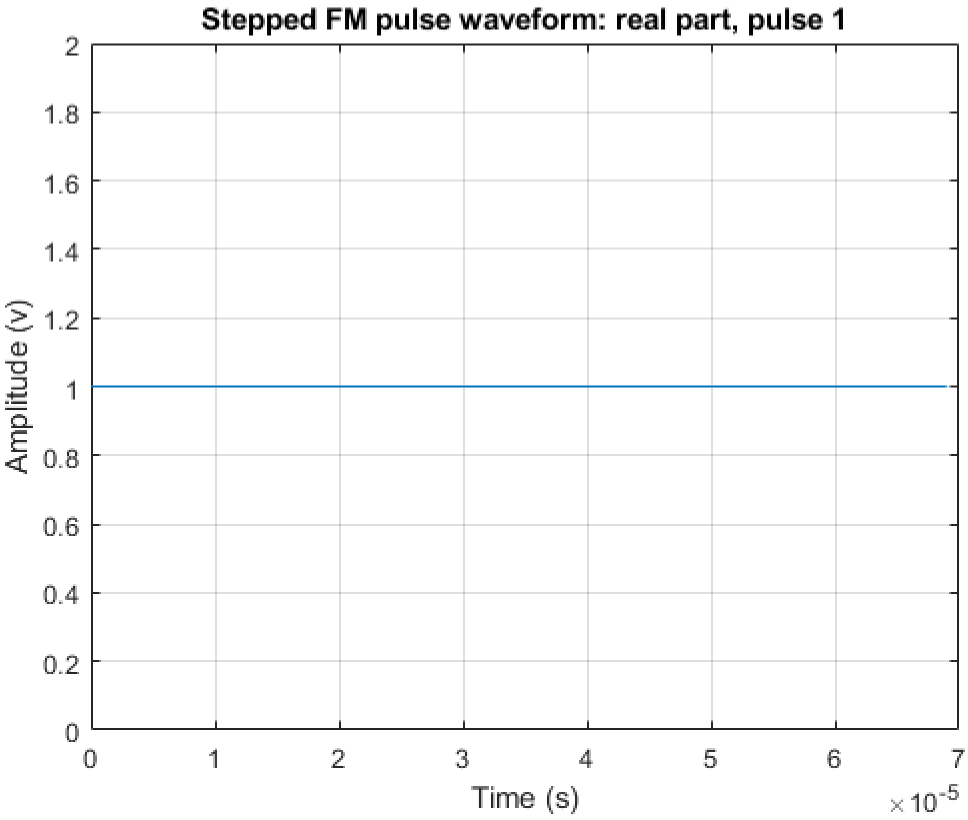
### Plot Stepped FM Waveform

Construct a waveform library consisting of three waveforms. The library contains one rectangular, one linear FM, and one stepped-FM waveforms. Then, plot the real parts of the first three pulses of the stepped-fm waveform.

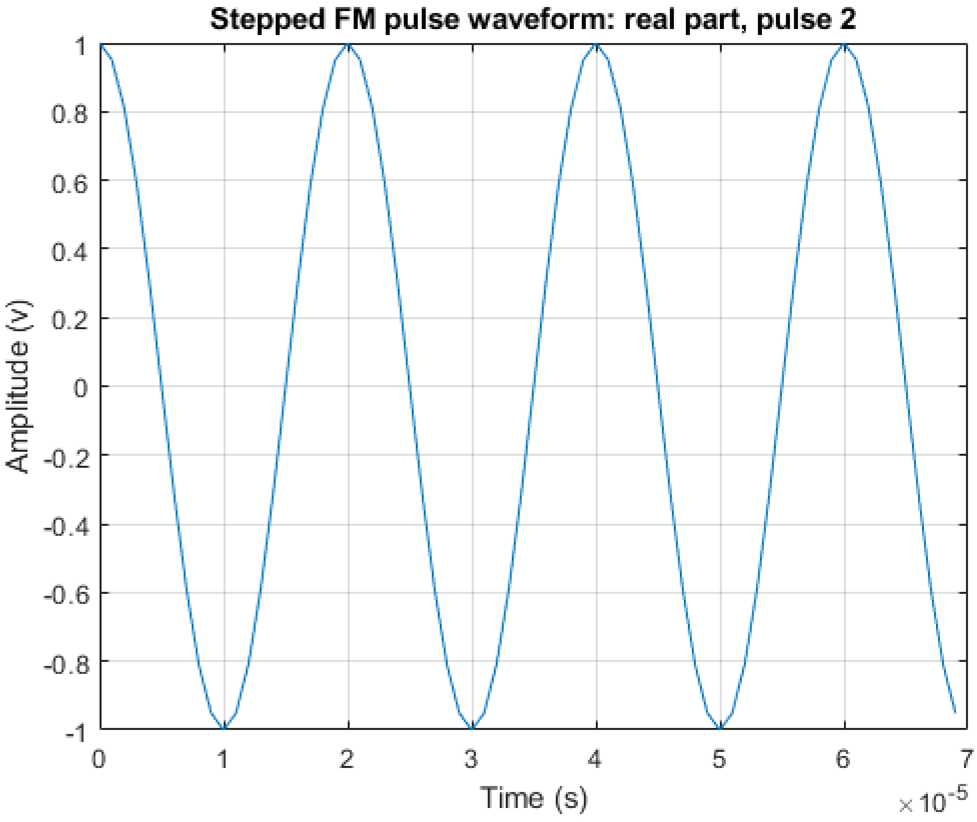
```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth',70e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',70e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'SteppedFM','PRF',1e4,'PulseWidth', 70e-6,'NumSteps',5, ...
    'FrequencyStep',50000,'FrequencyOffset',0};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
```

Plot the first three pulses of the waveform using the `plot` method.

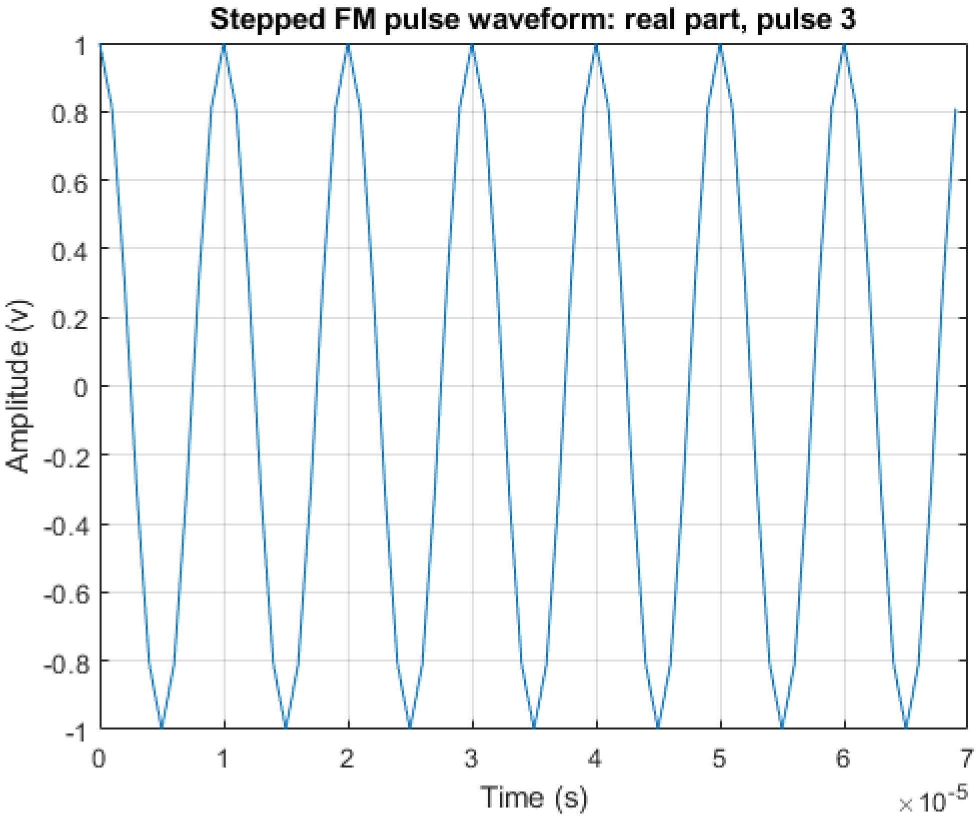
```
plot(wavlib,3,'PulseIdx',1)
```



```
plot(wavlib,3,'PulseIdx',2)
```



```
plot(wavlib,3,'PulseIdx',3)
```



### Plot Matched Filter Coefficients of Two Pulses

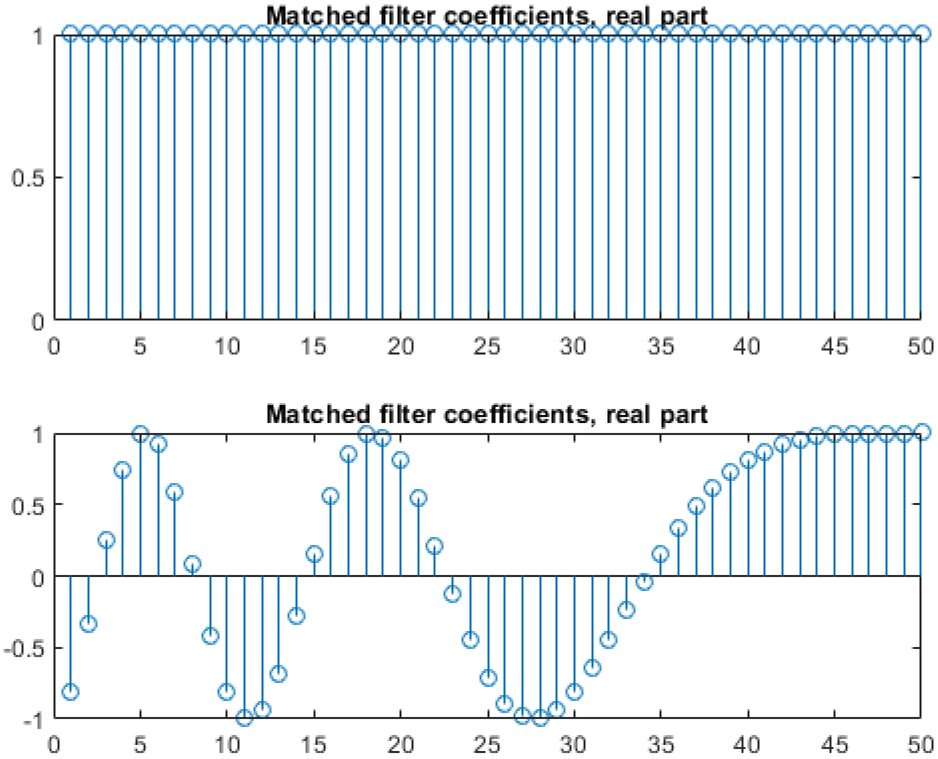
This example shows how to put two waveforms into a waveform library and how to extract and plot their matched filter coefficients.

Create a pulse library consisting of a rectangular and a linear FM waveform.

```
waveform1 = {'Rectangular','PRF',10e3 'PulseWidth',50e-6};
waveform2 = {'LinearFM','PRF',10e3,'PulseWidth',50e-6,'SweepBandwidth',1e5, ...
    'SweepDirection','Up','SweepInterval', 'Positive'};
pulsesib = phased.PulseWaveformLibrary('SampleRate',1e6,...
    'WaveformSpecification',{waveform1,waveform2});
```

Retrieve the matched filter coefficients for each waveform and plot their real parts.

```
coeff1 = getMatchedFilter(pulsesib,1,1);
subplot(2,1,1)
stem(real(coeff1))
title('Matched filter coefficients, real part')
coeff2 = getMatchedFilter(pulsesib,2,1);
subplot(2,1,2)
stem(real(coeff2))
title('Matched filter coefficients, real part')
```



Matched filter coefficients, real part

Matched filter coefficients, real part

### Add Custom Waveform to Pulse Waveform Library

Define a custom hyperbolic FM waveform and add it to a `phased.PulseWaveformLibrary` System object together with a linear FM waveform. Plot the hyperbolic waveform.

Specify the hyperbolic FM waveform parameters. The pulse width is 75 ms and the pulse repetition interval is 100 ms. The center frequency is 500 Hz and the bandwidth is 400 Hz.

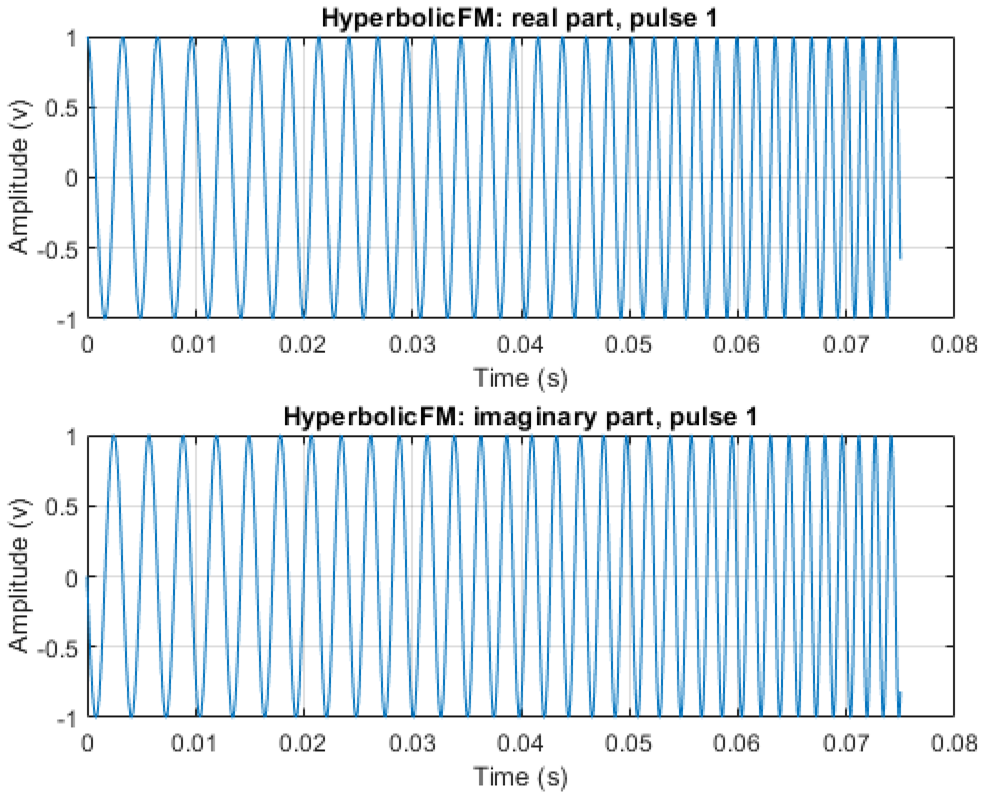
```
fs = 50e3;
pri = 0.1;
prf = 1/pri;
freq = 1000;
pw = 0.075;
bw = 400.0;
fcent = 500.0;
```

Create a pulse waveform library consisting of a hyperbolic FM waveform and a linear FM waveform.

```
pulselib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{{@HyperbolicFM,prf,pw,freq,bw,fcent}, ...
    {'LinearFM','PRF',prf,'PulseWidth',pw, ...
    'SweepBandwidth',bw,'SweepDirection','Up',...
    'SweepInterval','Positive'}});
```

Plot the complex hyperbolic FM waveform.

```
plot(pulselib,1,'PlotType','complex')
```



Define the Hyperbolic FM waveform function.

```
function y = HyperbolicFM(fs,prf,pw,freq,bw,fcent)
pri = 1/prf;
t = [0:1/fs:pri]';
idx = find(t <= pw);
fl = fcent - bw/2;
fh = fcent + bw/2;
y = zeros(size(t));
arg = 2*pi*fl*fh/bw*pw*log(1.0 - bw*t(idx)/fh/pw);
y(idx) = exp(1i*arg);
end
```

# More About

## Pulse Repetition Frequency Restrictions

The PRF property must satisfy these restrictions:

- The product of PRF and PulseWidth must be less than or equal to one. This condition expresses the requirement that the pulse width is less than one pulse repetition interval.
- The ratio of SampleRate to PRF must be an integer. This condition expresses the requirement that the number of samples in one pulse repetition interval is an integer.

## Chip Restrictions

The values of the ChipWidth and NumChips properties must satisfy these constraints:

- The product of PRF, ChipWidth, and NumChips must be less than or equal to one. This condition expresses the requirement that the sum of the durations of all chips is less than one pulse repetition interval.
- The product of SampleRate and ChipWidth must be an integer. This condition expresses the requirement that the number of samples in a chip must be an integer.

The table shows additional constraints on the number of chips for different code types.

| If the Code Property Is ... | Then the NumChips Property Must Be... |
|---|---|
| 'Frank', 'P1', or 'Px' | A perfect square |
| 'P2' | An even number that is a perfect square |
| 'Barker' | 2, 3, 4, 5, 7, 11, or 13 |

# getMatchedFilter

**Package:** phased

Matched filter coefficients for pulse waveform

## Syntax

```
coeff = getMatchedFilter(pulselib,idx)
coeff = getMatchedFilter(pulselib,idx,pidx)
```

## Description

coeff = getMatchedFilter(pulselib,idx) returns matched filter coefficients, coeff, for the waveform specified by the index, idx, in the waveform library, pulselib.

coeff = getMatchedFilter(pulselib,idx,pidx) also specifies the pulse index, pidx, of a stepped FM waveform.

## Examples

### Plot Matched Filter Coefficients of Two Pulses

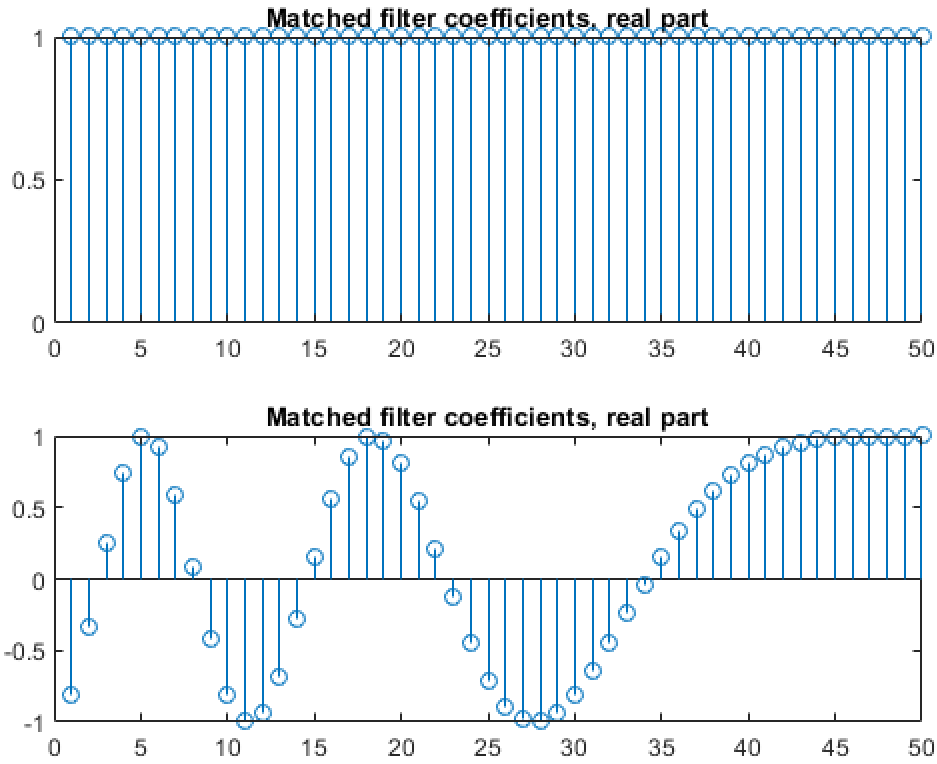
This example shows how to put two waveforms into a waveform library and how to extract and plot their matched filter coefficients.

Create a pulse library consisting of a rectangular and a linear FM waveform.

```
waveform1 = {'Rectangular','PRF',10e3 'PulseWidth',50e-6};
waveform2 = {'LinearFM','PRF',10e3,'PulseWidth',50e-6,'SweepBandwidth',1e5, ...
    'SweepDirection','Up','SweepInterval', 'Positive'};
pulsesib = phased.PulseWaveformLibrary('SampleRate',1e6,...
    'WaveformSpecification',{waveform1,waveform2});
```

Retrieve the matched filter coefficients for each waveform and plot their real parts.

```
coeff1 = getMatchedFilter(pulsesib,1,1);
subplot(2,1,1)
stem(real(coeff1))
title('Matched filter coefficients, real part')
coeff2 = getMatchedFilter(pulsesib,2,1);
subplot(2,1,2)
stem(real(coeff2))
title('Matched filter coefficients, real part')
```



## Input Arguments

### `pulselib` — Waveform library

`phased.PulseWaveformLibrary` System object

Pulse waveform library, specified as a `phased.PulseWaveformLibrary` System object.

### `idx` — Waveform index

`1` (default) | positive integer

Waveform index, specified as a positive integer. The index specifies which waveform coefficients to return.

Data Types: `double`

### `pidx` — Pulse index

`1` (default) | positive integer

Pulse index, specified as a positive integer. The index specifies which pulse matched-filter coefficients to return. This argument applies only to stepped FM waveforms.

Data Types: `double`

## Output Arguments

### `coeff` — Matched filter coefficients

complex-valued vector | complex-valued matrix

Matched filter coefficients, specified as a complex-valued vector or complex-valued matrix. For the stepped FM pulse, the output is a complex-valued matrix. Each matrix column corresponds to a step in the waveform. For all other waveforms, the output is a column vector.

Data Types: `double`

## See Also

**Introduced in R2018a**

# plot

**Package:** `phased`

Plot waveform from waveform library

## Syntax

```
plot(pulselib,idx)
plot(pulselib,idx,'PlotType',Type)
plot( ___ ,'PulseIdx',pidx)
plot( ___ ,LineSpec)
hndl = plot( ___ )
```

## Description

`plot(pulselib,idx)` plots the real part of the waveform specified by `idx` belonging to the pulse waveform library, `pulselib`.

`plot(pulselib,idx,'PlotType',Type)` also specifies whether to plot the real and/or imaginary parts of the waveform using the (`'PlotType'`,`Type`) name-value pair argument.

`plot( ___ ,'PulseIdx',pidx)` also specifies the index, `pidx`, of the pulse to plot using the (`'PulseIdx'`,`pidx`) name-value pair argument.

`plot( ___ ,LineSpec)` specifies the line color, line style, or marker options. These options are the same options found in the MATLAB `plot` function. When both real and imaginary plots are specified, the `LineSpec` applies to both subplots. This argument is always the last input to the method.

`hndl = plot( ___ )` returns the line handle, `hndl`, in the figure.

## Examples

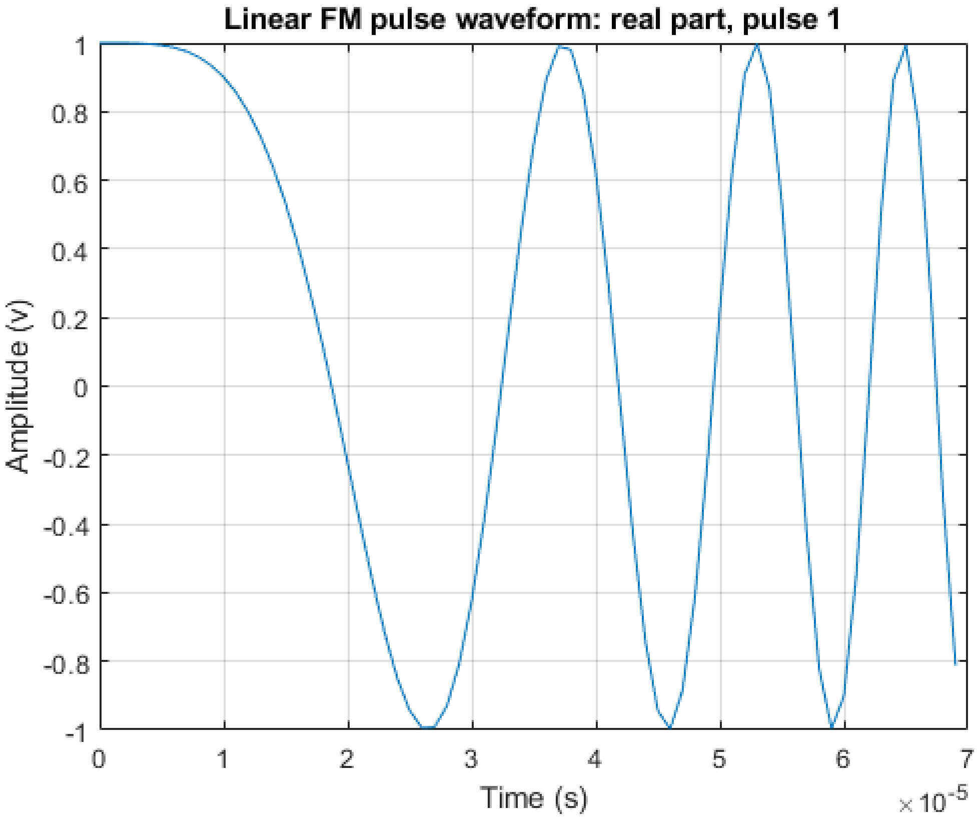
### Plot Linear FM Waveform

Construct a waveform library consisting of three waveforms. The library contains one rectangular, one linear FM, and one stepped-FM waveforms. Then, plot the linear fm waveform.

```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth',70e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',70e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'SteppedFM','PRF',1e4,'PulseWidth', 70e-6,'NumSteps',5, ...
    'FrequencyStep',50000,'FrequencyOffset',0};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
```

Plot the waveform using the `plot` method.

```
plot(wavlib,2)
```



### Obtain and Plot Phase-Coded Waveform from Waveform Library

Construct a waveform library consisting of three waveforms. The library contains a rectangular, a linear FM, and a phase-coded waveform. Then, obtain and plot the real and imaginary parts of the phase-coded waveform.

```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth', 50e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',50e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'PhaseCoded','PRF',1e4,'Code','Zadoff-Chu', ...
```

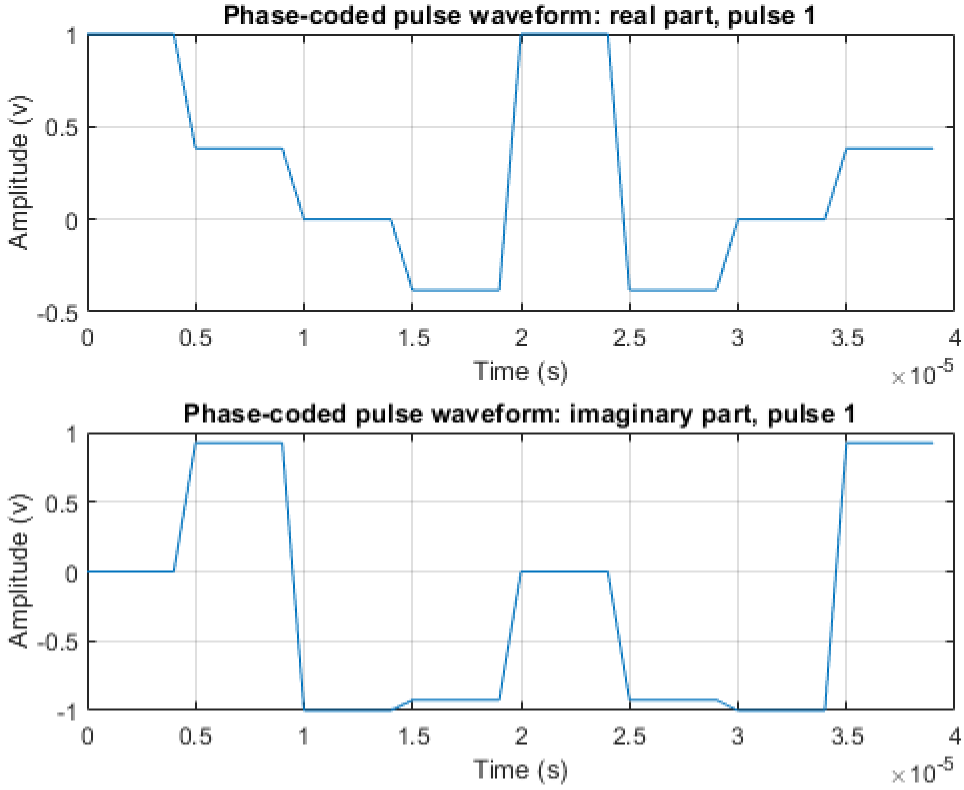
```
    'SequenceIndex',3,'ChipWidth',5e-6,'NumChips',8};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
```

Extract the waveform from the library.

```
wav3 = wavlib(3);
```

Plot the waveform using the `plot` method.

```
plot(wavlib,3,'PlotType','complex')
```



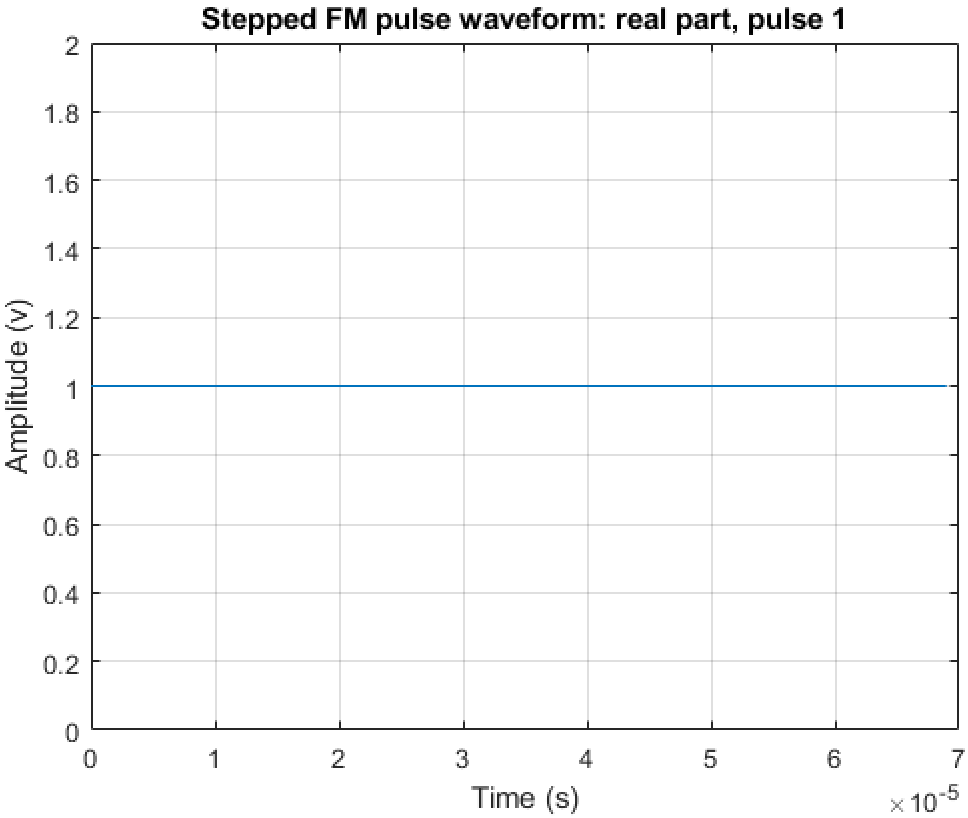
### Plot Stepped FM Waveform

Construct a waveform library consisting of three waveforms. The library contains one rectangular, one linear FM, and one stepped-FM waveforms. Then, plot the real parts of the first three pulses of the stepped-fm waveform.

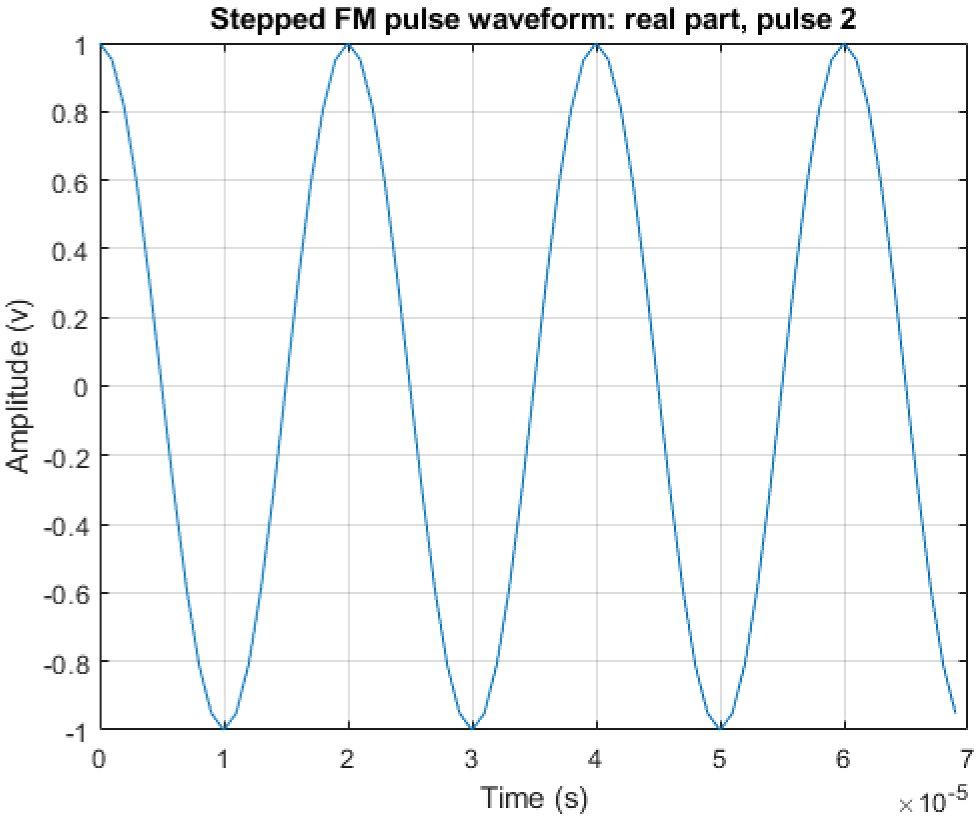
```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth',70e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',70e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'SteppedFM','PRF',1e4,'PulseWidth', 70e-6,'NumSteps',5, ...
    'FrequencyStep',50000,'FrequencyOffset',0};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
```

Plot the first three pulses of the waveform using the `plot` method.

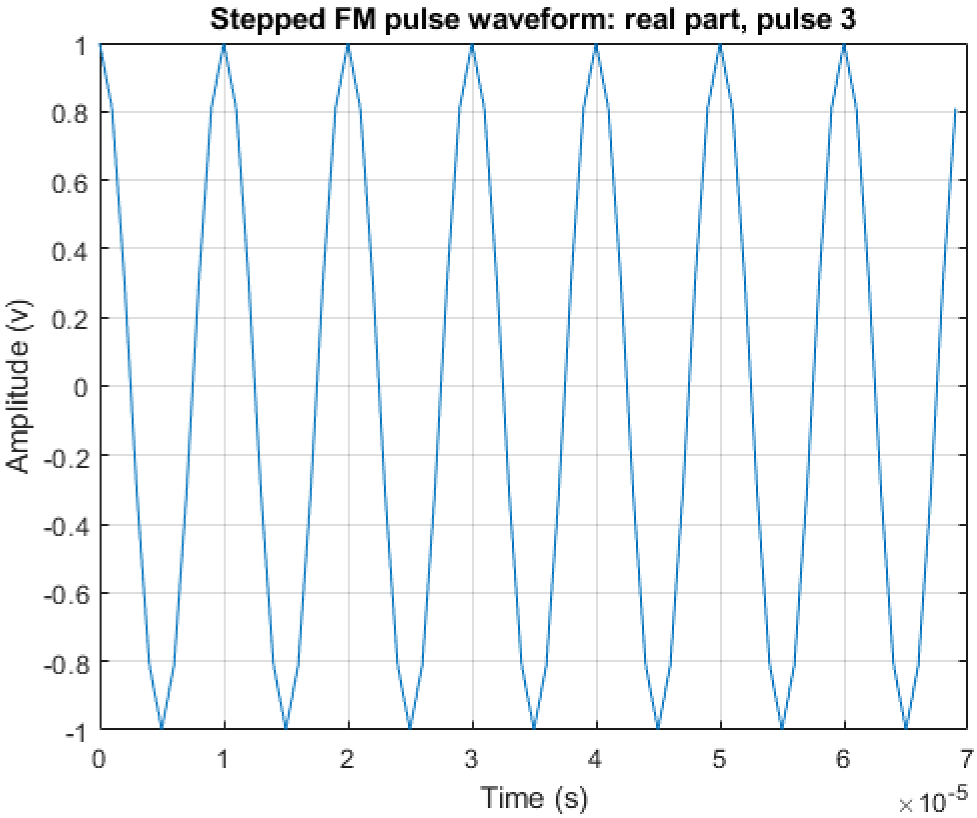
```
plot(wavlib,3,'PulseIdx',1)
```



```
plot(wavlib,3,'PulseIdx',2)
```



```
plot(wavlib,3,'PulseIdx',3)
```



### Plot Linear FM Waveform With Dotted Lines

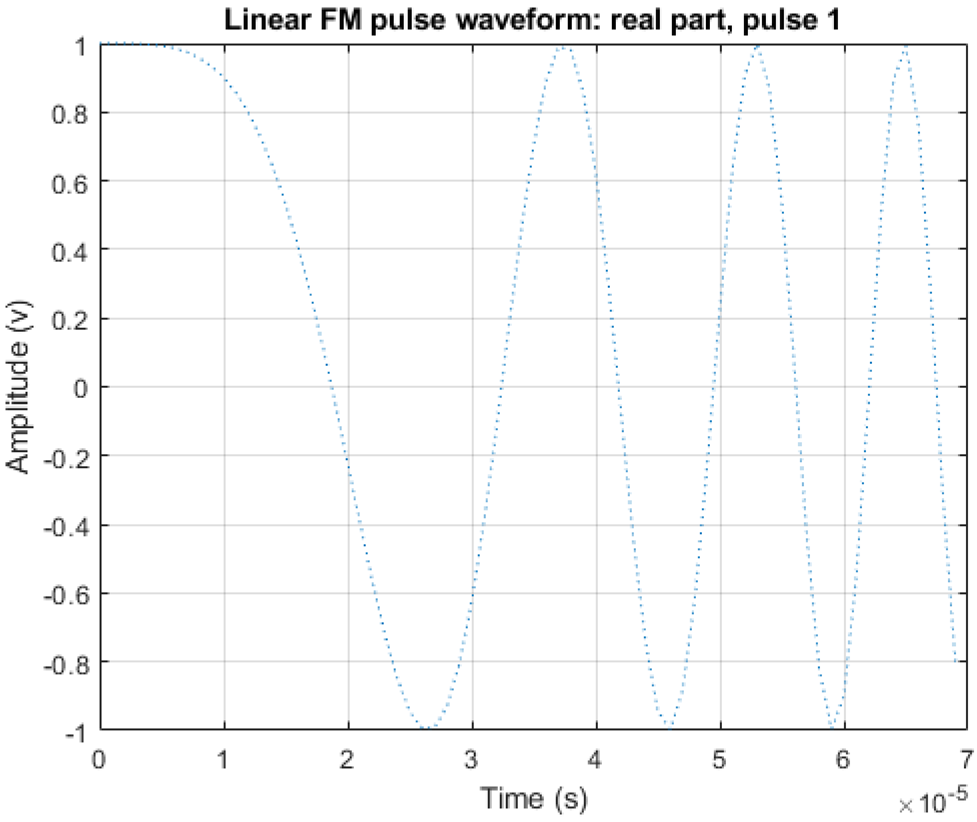
Construct a waveform library consisting of three waveforms. The library contains one rectangular, one linear FM, and one stepped-FM waveforms. Then, plot the linear fm waveform.

```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth',70e-6};
waveform2 = {'LinearFM','PRF',1e4,'PulseWidth',70e-6, ...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'SweepInterval', 'Positive'};
waveform3 = {'SteppedFM','PRF',1e4,'PulseWidth', 70e-6,'NumSteps',5, ...
```

```
    'FrequencyStep',50000,'FrequencyOffset',0};
fs = 1e6;
wavlib = phased.PulseWaveformLibrary('SampleRate',fs, ...
    'WaveformSpecification',{waveform1,waveform2,waveform3});
```

Plot the waveform using the `plot` method.

```
plot(wavlib,2,':')
```



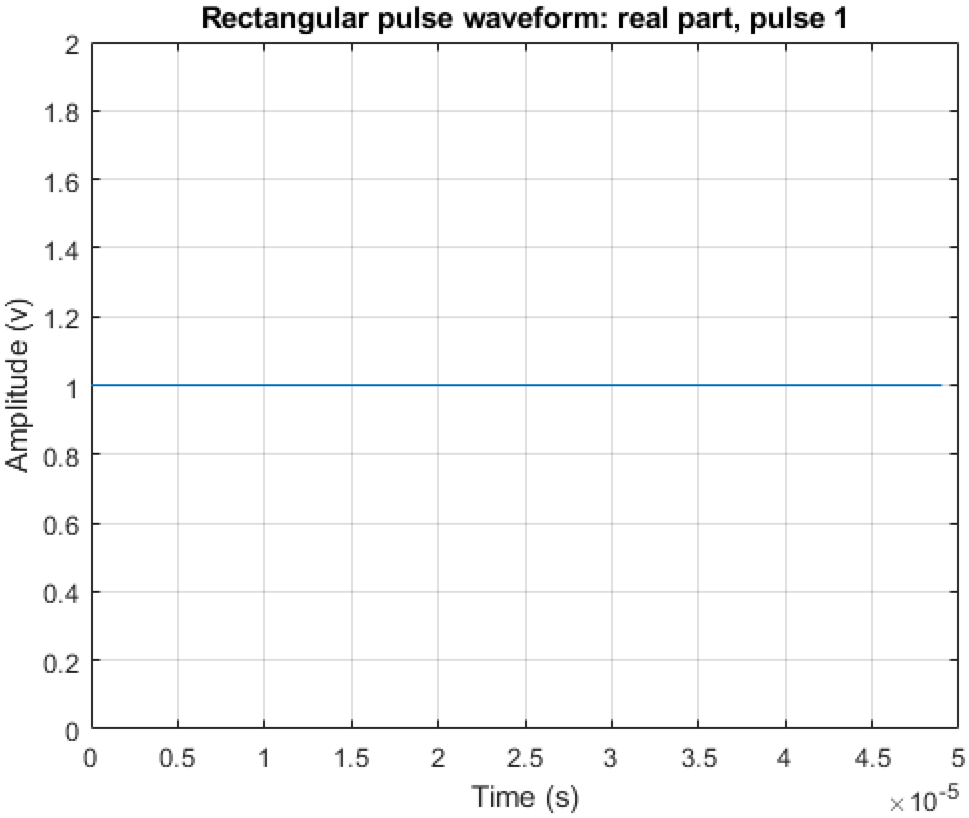
### Obtain Line Handle of Waveform Plot

Construct a waveform library consisting of two rectangular waveforms. Then, plot the real part of each waveform and obtain the handle to the second plot.

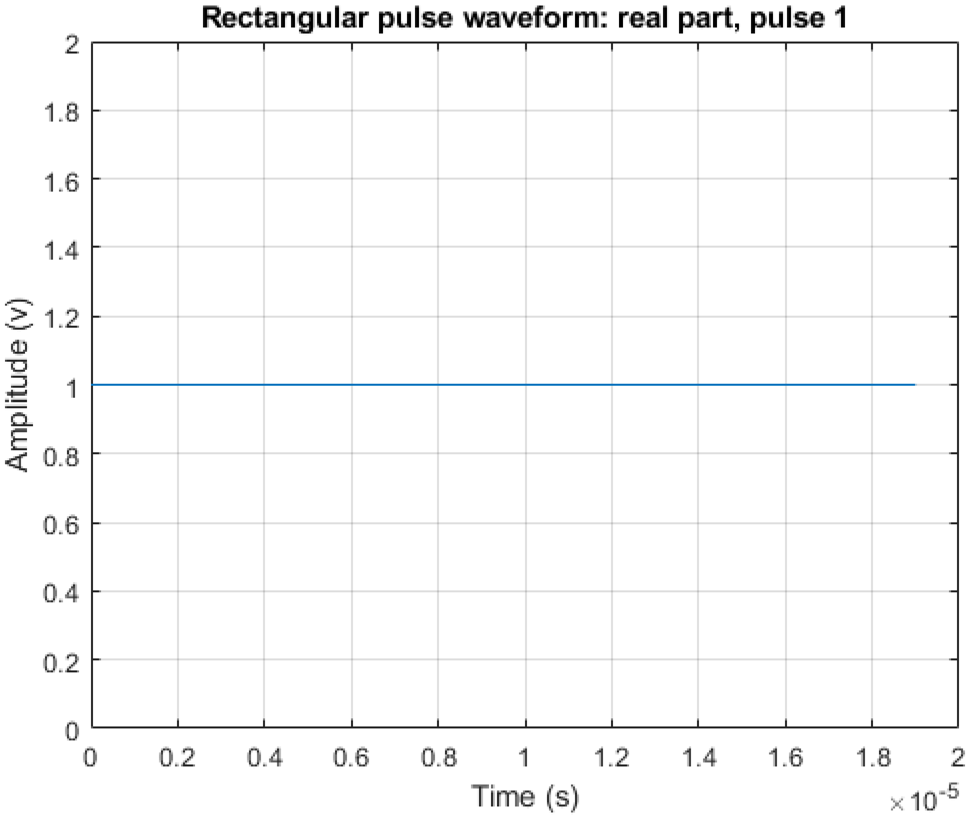
```
waveform1 = {'Rectangular','PRF',1e4,'PulseWidth',50.0e-6};
waveform2 = {'Rectangular','PRF',2e4,'PulseWidth',20.0e-6};
fs = 1e6;
pulselib = phased.PulseWaveformLibrary('SampleRate',fs,'WaveformSpecification', ...
    {waveform1,waveform2});
```

Plot the waveforms using the `plot` method.

```
hndl1 = plot(pulselib,1);
```



```
hndl2 = plot(pulselib,2)
```



```
hndl2 = 
  Line with properties:

              Color: [0 0.4470 0.7410]
          LineStyle: '-'
          LineWidth: 0.5000
             Marker: 'none'
         MarkerSize: 6
    MarkerFaceColor: 'none'
              XData: [1x20 double]
              YData: [1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1]
              ZData: [1x0 double]
  Show all properties
```

## Input Arguments

**`pulselib` — Waveform library**
`phased.PulseWaveformLibrary` System object

Waveform library, specified as a `phased.PulseWaveformLibrary` System object.

**`idx` — Index of waveform in pulse waveform library**
positive integer

Index of waveform in pulse waveform library, specified as a positive integer.

Example: `3`

Data Types: `double`

**`Type` — Plot type**
`'real'` (default) | `'imag'` | `'complex'`

Plot type, specified as `'real'`, `'imag'`,or `'complex'`. Use this argument in the `'Type'` name-value pair.

Data Types: `char` | `string`

**`pidx` — Index of plot to pulse**
`1` (default) | positive integer

Index of plot to pulse, specified as a positive integer. Use this argument in the `'PulseIdx'` name-value pair. This argument only affects the stepped-FM waveform.

Data Types: `double`

**`LineSpec` — Line color, style, and marker options**
`'b'` (default) | character vector

Line color, style, and marker options, specified as a character vector. These options are the same as in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Example: `'ko'`

Data Types: `char`

### Name-Value Pair Arguments

Example: `'PlotType','imag'`

**`PlotType` — Plot real or imaginary components of waveform**
`'real'` (default) | `'imag'` | `'complex'`

Components of waveform, specified as `'real'`, `'imag'`, or `'complex'`.

Example: `'complex'`

Data Types: `char`

**`PulseIdx` — Plot stepped FM waveform subpulse**
`1` (default) | `positive integer`

Plot stepped FM waveform subpulse, specified as a positive integer. This argument only affects the stepped-FM waveform.

Example: `5`

Data Types: `double`

## Output Arguments

**`hndl` — Handles of lines in figure**
scalar | 2-by-1 real-valued vector

Handle of lines in figure, returned as a scalar or 2-by-1 real-valued vector. For the case when both real and imaginary plots are specified, the vector includes handles to the lines in both subplots, in the form of `[RealLineHandle;ImagLineHandle]`.

# phased.RadarTarget

**Package:** phased

Radar target

## Description

The RadarTarget System object models how a signal is reflected from a radar target. The quantity that determines the response of a target to incoming signals is called the radar target cross-section (RCS). While all electromagnetic radar signals are polarized, you can sometimes ignore polarization and process them as if they were scalar signals. To ignore polarization, specify the EnablePolarization property as false. To utilize polarization, specify the EnablePolarization property as true. For non-polarized processing, the radar cross section is encapsulated in a single scalar quantity called the MeanRCS. For polarized processing, specify the radar cross-section as a 2-by-2 scattering matrix in the ScatteringMatrix property. For both polarization processing types, there are several Swerling models available that can generate random fluctuations in the RCS. Choose these models using the Model property. The SeedSource and Seed properties control the random fluctuations.

The properties that you can use to model the radar cross-section or scattering matrix depend upon the polarization type.

| EnablePolarization Value | Use These Properties |
|---|---|
| false | • MeanRCSSource<br>• MeanRCS |
| true | • ScatteringMatrixSource<br>• ScatteringMatrix<br>• Mode |

To compute the signal reflected from a radar target:

1 Define and set up your radar target. See “Construction” on page 1-1704.

2 Call `step` to compute the reflected signal according to the properties of `phased.RadarTarget`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.RadarTarget` creates a radar target System object, `H`, that computes the reflected signal from a target.

`H = phased.RadarTarget(Name,Value)` creates a radar target object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

## Properties

### `EnablePolarization`

Allow polarized signals

Set this property to `true` to allow the target to simulate the reflection of polarized radiation. Set this property to `false` to ignore polarization.

**Default:** `false`

### `Mode`

Target scattering mode

Target scattering mode specified as one of `'Monostatic'` or `'Bistatic'`. If you set this property to `'Monostatic'`, the reflected signal direction is opposite to its incoming direction. If you set this property to `'Bistatic'`, the reflected direction of the signal differs from its incoming direction. This property applies when you set the `EnablePolarization` property to `true`.

**Default:** `'Monostatic'`

### ScatteringMatrixSource

Sources of mean scattering matrix of target

Source of mean scattering matrix of target specified as one of `'Property'` or `'Input port'`. If you set the `ScatteringMatrixSource` property to `'Property'`, the target's mean scattering matrix is determined by the value of the `ScatteringMatrix` property. If you set this property to `'Input port'`, the mean scattering matrix is determined by an input argument of the `step` method. This property applies only when you set the `EnablePolarization` property to `true`. When the `EnablePolarization` property is set to `false`, use the `MeanRCSSource` property instead, together with the `MeanRCS` property, if needed.

**Default:** `'Property'`

### ScatteringMatrix

Mean radar scattering matrix for polarized signal

Mean radar scattering matrix specified as a complex–valued 2-by-2 matrix. This matrix represents the mean value of the target's radar cross-section. Units are in square meters. The matrix has the form `[s_hh s_hv;s_vh s_vv]`. In this matrix, the component `s_hv` specifies the complex scattering response when the input signal is vertically polarized and the reflected signal is horizontally polarized. The other components are defined similarly. This property applies when you set the `ScatteringMatrixSource` property to `'Property'` and the `EnablePolarization` property to `true`. When the `EnablePolarization` property is set to `false`, use the `MeanRCS` property instead, together with the `MeanRCSSource` property. This property is tunable.

**Default:** `[1 0;0 1i]`

### MeanRCSSource

Source of mean radar cross section

Specify whether the mean RCS value of the target comes from the `MeanRCS` property of this object or from an input argument in `step`. Values of this property are:

| | |
|---|---|
| 'Property' | The MeanRCS property of this object specifies the mean RCS value(s). |
| 'Input port' | An input argument in each invocation of step specifies the mean RCS value. |

When EnablePolarization property is set to true, use the ScatteringMatrixSource property together with the ScatteringMatrix property.

**Default:** 'Property'

### MeanRCS

Mean radar cross section

Specify the mean value of the target's radar cross section as a nonnegative scalar or as a 1-by-*M* real-valued, nonnegative row vector. Units are in square meters. Using a vector lets you simultaneously process multiple targets. The quantity *M* is the number of targets. This property is used when MeanRCSSource is set to 'Property'. This property is tunable.

When EnablePolarization property is set to true, use the ScatteringMatrix property together with the ScatteringMatrixSource.

**Default:** 1

### Model

Target statistical model

Specify the statistical model of the target as one of 'Nonfluctuating', 'Swerling1', 'Swerling2', 'Swerling3', or 'Swerling4'. If you set this property to a value other than 'Nonfluctuating', you must use the UPDATERCS input argument when invoking step. You can set the mean value of the radar cross-section model by specifying MeanRCS or use its default value.

**Default:** 'Nonfluctuating'

### PropagationSpeed

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

**Default:** Speed of light

### OperatingFrequency

Signal carrier frequency

Specify the carrier frequency of the signal you are reflecting from the target, as a scalar in hertz.

**Default:** 3e8

### SeedSource

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

| | |
|---|---|
| 'Auto' | The default MATLAB random number generator produces the random numbers. Use 'Auto' if you are using this object with Parallel Computing Toolbox software. |
| 'Property' | The object uses its own private random number generator to produce random numbers. The Seed property of this object specifies the seed of the random number generator. Use 'Property' if you want repeatable results and are not using this object with Parallel Computing Toolbox software. |

The random numbers are used to model random RCS values. This property applies when the Model property is 'Swerling1', 'Swerling2','Swerling3', or 'Swerling4'.

**Default:** 'Auto'

### Seed

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}$–1. This property applies when you set the SeedSource property to 'Property'.

**Default:** 0

## Methods

| | |
|---|---|
| reset | Reset states of radar target object |
| step | Reflect incoming signal |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Compute Reflected Signal from a Non-fluctuating Radar Target

Create a simple signal and compute the value of the reflected signal from a target having a radar cross section of $10m^2$. Set the radar cross section using the `MeanRCS` property. Set the radar operating frequency to 600 MHz.

```
x = ones(10,1);
target = phased.RadarTarget('Model','Nonfluctuating',...
        'MeanRCS',10,...
        'OperatingFrequency',600e6);
y = target(x);
disp(y(1:3))
```

```
   22.4355
   22.4355
   22.4355
```

This value agrees with the formula $y = \sqrt{G}x$ where

$$G = 4\pi\sigma/\lambda^2$$

## Algorithms

For a narrowband nonpolarized signal, the reflected signal, $Y$, is

$$Y = \sqrt{G} \cdot X,$$

where:

- $X$ is the incoming signal.
- $G$ is the target gain factor, a dimensionless quantity given by

  $$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, $X$, is replaced by a vector signal, $(E_H, E_V)$, with horizontal and vertical components. The scattering matrix, $S$, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see Mott, [1] or Richards, [2] .

“Radar Target”

**Introduced in R2012a**

# reset

**System object:** `phased.RadarTarget`
**Package:** `phased`

Reset states of radar target object

## Syntax

```
reset(H)
```

## Description

`reset(H)` resets the states of the `RadarTarget` object, `H`. This method resets the random number generator state if the `SeedSource` property is applicable and has the value `'Property'`.

# step

**System object:** `phased.RadarTarget`
**Package:** `phased`

Reflect incoming signal

## Syntax

```
Y = step(H,X)
Y = step(H,X,MEANRCS)
Y = step(H,X,UPDATERCS)
Y = step(H,X,MEANRCS,UPDATERCS)

Y = step(H,X,ANGLE_IN,LAXES)
Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES)
Y = step(H,X,ANGLE_IN,LAXES,SMAT)
Y = step(H,X,ANGLE_IN,LAXES,UPDATESMAT)
Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES,SMAT,UPDATESMAT)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` returns the reflected signal `Y` due to the incident signal `X`. The argument `X` is a complex-valued *N*-by-*1* column vector or *N*-by-*M* matrix. The value *M* is the number of signals. Each signal corresponds to a different target. The value *N* is the number of samples in each signal. Use this syntax when you set the `Model` property of `H` to `'Nonfluctuating'`. In this case, the value of the `MeanRCS` property is used as the Radar cross-section (RCS) value. This syntax applies only when the `EnablePolarization` property is set to `false`. If you specify *M* incident signals, you can specify the radar cross-section as a scalar or as a 1-by-*M* vector. For a scalar, the same value will be applied to all signals.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,MEANRCS)` uses `MEANRCS` as the mean RCS value. This syntax is available when you set the `MeanRCSSource` property to `'Input port'` and set `Model` to `'Nonfluctuating'`. The value of `MEANRCS` must be a nonnegative scalar or 1-by-*M* row vector for multiple targets. This syntax applies only when the `EnablePolarization` property is set to `false`.

`Y = step(H,X,UPDATERCS)` uses `UPDATERCS` as the indicator of whether to update the RCS value. This syntax is available when you set the `Model` property to `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `UPDATERCS` is `true`, a new RCS value is generated. If `UPDATERCS` is `false`, the previous RCS value is used. This syntax applies only when the `EnablePolarization` property is set to `false`. In this case, the value of the `MeanRCS` property is used as the radar cross-section (RCS) value.

`Y = step(H,X,MEANRCS,UPDATERCS)` lets you can combine optional input arguments when their enabling properties are set. In this syntax, `MeanRCSSource` is set to `'Input port'` and `Model` is set to one of the `Swerling` models. This syntax applies only when the `EnablePolarization` property is set to `false`. For this syntax, changes in `MEANRCS` will be ignored after the first call to the `step` method.

`Y = step(H,X,ANGLE_IN,LAXES)` returns the reflected signal `Y` from an incident signal `X`. This syntax applies only when the `EnablePolarization` property is set to `true`. The input argument, `ANGLE_IN`, specifies the direction of the incident signal with respect to the target's local coordinate system. The input argument, `LAXES`, specifies the direction of the local coordinate axes with respect to the global coordinate system. This syntax requires that you set the `Model` property to `'Nonfluctuating'` and the `Mode` property to `'Monostatic'`. In this case, the value of the `ScatteringMatrix` property is used as the scattering matrix value.

`X` is a 1-by-*M* row array of MATLAB `struct` type, each member of the array representing a different signal. The `struct` contains three fields, `X.X`, `X.Y`, and `X.Z`. Each field corresponds to the *x*, *y*, and *z* components of the polarized input signal. Polarization components are measured with respect to the global coordinate system. Each field is a column vector representing a sequence of values for each incoming signal. The `X.X`, `X.Y`, and `Y.Z` fields must all have the same dimension. The argument, `ANGLE_IN`, is a 2-by-*M* matrix representing the signals' incoming directions with respect to the target's local coordinate system. Each column of ANGLE_IN specifies the incident direction of the corresponding signal in the form [AzimuthAngle; ElevationAngle]. Angle units are in degrees. The number of columns in ANGLE_IN must equal the number of signals in the X array. The argument, LAXES, is a 3-by-3 matrix. The columns are unit vectors specifying the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively, with respect to the global coordinate system. Each column is written in [x;y;z] form.

Y is a row array of struct type having the same size as X. Each struct contains the three reflected polarized fields, Y.X, Y.Y, and Y.Z. Each field corresponds to the *x*, *y*, and *z* component of the signal. Polarization components are measured with respect to the global coordinate system. Each field is a column vector representing one reflected signal.

The size of the first dimension of the matrix fields within the struct can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES), in addition, specifies the reflection angle, ANGLE_OUT, of the reflected signal when you set the Mode property to 'Bistatic'. This syntax applies only when the EnablePolarization property is set to true. ANGLE_OUT is a 2-row matrix representing the reflected direction of each signal. Each column of ANGLE_OUT specifies the reflected direction of the signal in the form [AzimuthAngle; ElevationAngle]. Angle units are in degrees. The number of columns in ANGLE_OUT must equal the number of members in the X array. The number of columns in ANGLE_OUT must equal the number of elements in the X array.

Y = step(H,X,ANGLE_IN,LAXES,SMAT) specifies SMAT as the scattering matrix. This syntax applies only when the EnablePolarization property is set to true. The input argument SMAT is a 2-by-2 matrix. You must set the ScatteringMatrixSource property 'Input port' to use SMAT.

Y = step(H,X,ANGLE_IN,LAXES,UPDATESMAT) specifies UPDATESMAT to indicate whether to update the scattering matrix when you set the Model property to 'Swerling1', 'Swerling2'', 'Swerling3', or 'Swerling4'. This syntax applies only when the EnablePolarization property is set to true. If UPDATESMAT is set to true, a scattering matrix value is generated. If UPDATESMAT is false, the previous scattering matrix value is used.

Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES,SMAT,UPDATESMAT). You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of their enabling properties.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# Examples

### Compute Reflected Signals from Two Non-fluctuating Radar Targets

Create two sinusoidal signals and compute the value of the reflected signals from targets having radar cross section of $5m^2$ and $10m^2$, respectively. Set the radar cross sections in the `step` method by choosing `Input port` for the value of the `MeanRCSSource` property. Set the radar operating frequency to 600 MHz.

```
sRadarTarget = phased.RadarTarget('Model','Nonfluctuating',...
        'MeanRCSSource','Input port',...
        'OperatingFrequency',600e6);
t = linspace(0,1,1000);
x = [cos(2*pi*250*t)',10*sin(2*pi*250*t)'];
y = step(sRadarTarget,x,[5,10]);
disp(y(1:3,1:2))
```

```
   15.8643         0
   -0.0249  224.3546
  -15.8642   -0.7055
```

# Algorithms

For a narrowband nonpolarized signal, the reflected signal, *Y*, is

$$Y = \sqrt{G} \cdot X,$$

where:

- *X* is the incoming signal.

- $G$ is the target gain factor, a dimensionless quantity given by

  $$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, *X*, is replaced by a vector signal, $(E_H, E_V)$, with horizontal and vertical components. The scattering matrix, *S*, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see Mott [1] or Richards[2].

# phased.Radiator

**Package:** phased

Narrowband signal radiator

## Description

The phased.Radiator System object implements a narrowband signal radiator. A radiator converts signals into radiated wavefields transmitted from arrays and individual sensor elements such as antennas, microphone elements, and sonar transducers. The radiator output represents the fields at a reference distance of one meter from the phase center of the element or array. You can then propagate the signals to the far field using, for example, the phased.FreeSpace, phased.LOSChannel, or phased.TwoRayChannel System objects.

The object radiates fields in one of two ways controlled by the CombineRadiatedSignals property.

- If the CombineRadiatedSignals is set to true, the radiated field in a specified directions is the coherent sum of the delayed radiated fields from all elements (or subarrays when subarrays are supported). The object uses the phase-shift approximation of time delays for narrowband signals.
- If the CombineRadiatedSignals is set to false, each element can radiate in an independent direction.

You can use this object to

- model electromagnetic radiated signals as polarized or non-polarized fields depending upon whether the element or array supports polarization and the value of the "Polarization" on page 1-0 property. Using polarization, you can transmit a signal as a polarized electromagnetic field, or transmit two independent signals using dual polarizations.
- model acoustic radiated fields by using nonpolarized microphone and sonar transducer array elements and by setting the "Polarization" on page 1-0 to 'None'. You must also set the PropagationSpeed to a value appropriate for the medium.
- radiate fields from subarrays created by the phased.ReplicatedSubarray and phased.PartitionedArray objects. You can steer all subarrays in the same

direction using the steering angle argument, `STEERANG`, or steer each subarray in a different direction using the Subarray element weights argument, `WS`. The radiator distributes the signal powers equally among the elements of each subarray. You cannot set the CombineRadiatedSignals property to `false` for subarrays.

To radiate signals:

1. Create the `phased.Radiator` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

# Syntax

```
radiator = phased.Radiator
radiator = phased.Radiator(Name,Value)
```

## Description

`radiator = phased.Radiator` creates a narrowband signal radiator object, `radiator`, with default property values.

`radiator = phased.Radiator(Name,Value)` creates a narrowband signal radiator with each property `Name` set to a specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose each property name in single quotes.

Example: `radiator = phased.Radiator('Sensor',phased.URA,'OperatingFrequency',300e6)` sets the sensor array to a uniform rectangular array (URA) with default URA property values. The beamformer has an operating frequency of 300 MHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### `Sensor` — Sensor element or sensor array

`phased.ULA` array with default property values (default) | Phased Array System Toolbox sensor or array

Sensor element or sensor array, specified as a System object belonging to Phased Array System Toolbox. A sensor array can contain subarrays.

Example: `phased.URA`

### `PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by `physconst('LightSpeed')`. See `physconst` for more information.

Example: `3e8`

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

### `CombineRadiatedSignals` — Combine radiated signals

`true` (default) | `false`

Combine radiated signals, specified as `true` or `false`. This property enables the coherent summation of the radiated signals from all elements of an array to produce plane waves. Set this property to `false` to obtain individual radiated signal for each radiating element.

- If the CombineRadiatedSignals is set to `true`, the radiated field in a specified directions is the coherent sum of the delayed radiated fields from all elements (or subarrays when subarrays are supported). The object uses the phase-shift approximation of time delays for narrowband signals.
- If the CombineRadiatedSignals is set to `false`, each element can radiate in an independent direction. If the Sensor property is an array that contains subarrays, you cannot set the CombineRadiatedSignals property to `'false`.

Data Types: `logical`

### `SensorGainMeasure` — Specify sensor gain

`'dB'` (default) | `'dBi'`

Sensor gain measure, specified as `'dB'` or `'dBi'`.

- When you set this property to `'dB'`, the input signal power is scaled by the sensor power pattern (in dB) at the corresponding direction and then combined.
- When you set this property to `'dBi'`, the input signal power is scaled by the directivity pattern (in dBi) at the corresponding direction and then combined. This option is useful when you want to compare results with the values computed by the radar equation that uses dBi to specify the antenna gain. The computation using the `'dBi'` option is expensive as it requires an integration over all directions to compute the total radiated power of the sensor.

#### Dependencies

To enable this property, set the `CombineRadiatedSignals` property to `true`.

Data Types: `char`

### `Polarization` — Polarization configuration

`'None'` (default) | `'Combined'` | `'Dual'`

Polarization configuration, specified as `'None'`, `'Combined'`, or `'Dual'`. When you set this property to `'None'`, the output field is considered a scalar field. When you set this property to `'Combined'`, the radiated fields are polarized and are interpreted as a single signal in the sensor's inherent polarization. When you set this property to `'Dual'`, the *H* and *V* polarization components of the radiated field are independent signals.

Example: `'Dual'`

Data Types: `char`

**`WeightsInputPort` — Enable weights input**
`false` (default) | `true`

Enable weights input, specified as `false` or `true`. When `true`, use the object input argument `W` to specify weights. Weights are applied to individual array elements (or at the subarray level when subarrays are supported).

Data Types: `logical`

# Usage

# Syntax

```
Y = radiator(X,ANG)
Y = radiator(X,ANG,LAXES)
Y = radiator(XH,XV,ANG,LAXES)
Y = radiator( ___ ,W)
Y = radiator( ___ ,STEERANG)
Y = radiator( ___ ,WS)
Y = radiator(X,ANG,LAXES,W,STEERANG)
```

## Description

`Y = radiator(X,ANG)` radiates the fields, `Y`, derived from signals, `X` in the directions specified by `ANG`.

`Y = radiator(X,ANG,LAXES)` also specifies `LAXES` as the local coordinate system axes directions. To use this syntax, set the “Polarization” on page 1-0 property to `'Combined'`.

`Y = radiator(XH,XV,ANG,LAXES)` specifies a horizontal-polarization port signal, `XH`, and a vertical-polarization port signal, `XV`. To use this syntax, set the “Polarization” on page 1-0 property to `'Dual'`.

`Y = radiator( ___ ,W)` also specifies `W` as element or subarray weights. To use this syntax, set the WeightsInputPort property to `true`.

`Y = radiator(___,STEERANG)` also specifies `STEERANG` as the subarray steering angle. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`.

`Y = radiator(___,WS)` also specifies `WS` as weights applied to each element within each subarray. To use this syntax, set the Sensor property to an array that supports subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

You can combine optional input arguments when their enabling properties are set, for example, `Y = radiator(X,ANG,LAXES,W,STEERANG)` combines several input arguments. Optional inputs must be listed in the same order as the order of the enabling properties.

## Input Arguments

### X — Signal to radiate

complex-valued *M*-by-1 vector | complex-valued *M*-by-*N* matrix

Signal to radiate, specified as a complex-valued *M*-by-1 vector or complex-valued *M*-by-*N* matrix. *M* is the length of the signal, and *N* is the number of array elements (or subarrays when subarrays are supported).

**Dimensions of X**

| Dimension | Signal |
|---|---|
| *M*-by-1 vector | The same signal is radiated from all array elements (or all subarrays when subarrays are supported). |
| `M-by-N matrix` | Each column corresponds to the signal radiated by the corresponding array element (or corresponding subarrays when subarrays are supported). |

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**Dependencies**

To enable this argument, set the Polarization property to `'None'` or `'Combined'`.

Data Types: `double`
Complex Number Support: Yes

### `ANG` — Radiating directions of signals

real-valued 2-by-*L* matrix

Radiating directions of signals, specified as a real-valued 2-by-*L* matrix. Each column specifies a radiating direction in the form `[AzimuthAngle;ElevationAngle]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive. When the CombineRadiatedSignals property is `false`, the number of angles must equal the number of array elements, *N*. Units are in degrees.

Example: `[30,20;45,0]`

Data Types: `double`

### `LAXES` — Local coordinate system

real-valued 3-by-3 orthogonal matrix

Local coordinate system, specified as a real-valued 3-by-3 orthogonal matrix. The matrix columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes with respect to the global coordinate system.

Example: `rotx(30)`

#### Dependencies

To enable this argument, set the `Polarization` property to `'Combined'` or `'Dual'`.

Data Types: `double`

### `XH` — H-polarization port signal to radiate

complex-valued *M*-by-1 vector | complex-valued *M*-by-*N* matrix

H-polarization port signal to radiate, specified as a complex-valued *M*-by-1 vector or complex-valued *M*-by-*N* matrix. *M* is the length of the signal, and *N* is the number of array elements (or subarrays when subarrays are supported).

**Dimensions of XH**

| Dimension | Signal |
|---|---|
| *M*-by-1 vector | The same signal is radiated from all array elements (or all subarrays when subarrays are supported). |
| `M-by-N matrix` | Each column corresponds to the signal radiated by the corresponding array element (or corresponding subarrays when subarrays are supported). |

The dimensions and sizes of `XH` and `XV` must be the same.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this argument, set the Polarization property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### XV — V-polarization port signal to radiate

complex-valued *M*-by-1 vector | complex-valued *M*-by-*N* matrix

V-polarization port signal to radiate, specified as a complex-valued *M*-by-1 vector or complex-valued *M*-by-*N* matrix. *M* is the length of the signal, and *N* is the number of array elements (or subarrays when subarrays are supported).

**Dimensions of XV**

| Dimension | Signal |
|---|---|
| *M*-by-1 vector | The same signal is radiated from all array elements (or all subarrays when subarrays are supported). |
| `M-by-N matrix` | Each column corresponds to the signal radiated by the corresponding array element (or corresponding subarrays when subarrays are supported). |

The dimensions and sizes of `XH` and `XV` must be the same.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

#### Dependencies

To enable this argument, set the Polarization property to `'Dual'`.

Data Types: `double`
Complex Number Support: Yes

### `W` — Element or subarray weights

*N*-by-1 column vector

Element or subarray weights, specified as a complex-valued *N*-by-1 column vector where *N* is the number of array elements (or subarrays when the array supports subarrays).

#### Dependencies

To enable this argument, set the WeightsInputPort property to `true`.

Data Types: `double`
Complex Number Support: Yes

### `WS` — Subarray element weights

complex-valued $N_{SE}$-by-*N* matrix | 1-by-*N* cell array

Subarray element weights, specified as complex-valued $N_{SE}$-by-*N* matrix or 1-by-*N* cell array where *N* is the number of subarrays. These weights are applied to the individual elements within a subarray.

**Subarray element weights**

| Sensor Array | Subarray weights |
|---|---|
| `phased.ReplicatedSubarray` | All subarrays have the same dimensions and sizes. Then, the subarray weights form an $N_{SE}$-by-$N$ matrix. $N_{SE}$ is the number of elements in each subarray and $N$ is the number of subarrays. Each column of `WS` specifies the weights for the corresponding subarray. |
| `phased.PartitionedArray` | Subarrays may not have the same dimensions and sizes. In this case, you can specify subarray weights as<br>• an $N_{SE}$-by-$N$ matrix, where $N_{SE}$ is now the number of elements in the largest subarray. The first $Q$ entries in each column are the element weights for the subarray where $Q$ is the number of elements in the subarray.<br>• a 1-by-$N$ cell array. Each cell contains a column vector of weights for the corresponding subarray. The column vectors have lengths equal to the number of elements in the corresponding subarray. |

**Dependencies**

To enable this argument, set the `Sensor` property to an array that contains subarrays and set the `SubarraySteering` property of the array to `'Custom'`.

Data Types: `double`
Complex Number Support: Yes

**`STEERANG` — Subarray steering angle**
real-valued 2-by-1 vector

Subarray steering angle, specified as a length-2 column vector. The vector has the form `[azimuthAngle;elevationAngle]`. The azimuth angle must be between –180° and

180°, inclusive. The elevation angle must be between –90° and 90°, inclusive. Units are in degrees.

Example: `[20;15]`

#### Dependencies

To enable this argument, set the `Sensor` property to an array that supports subarrays and set the `SubarraySteering` property of that array to either `'Phase'` or `'Time'`

Data Types: `double`

## Output Arguments

### Y — Radiated signals

complex-valued *M*-by-*L* matrix | complex-valued 1-by-*L* cell array of structures

Radiated signals, specified as a complex-valued *M*-by-*L* matrix or a 1-by-*L* cell array, where *L* is the number of radiating angles, `ANG`. *M* is the length of the input signal, `X`.

- If the Polarization property value is set to `'None'`, the output argument `Y` is an *M*-by-*L* matrix.
- If the Polarization property value is set to `'Combined'` or `'Dual'`, `Y` is a 1-by-*L* cell array of structures. Each cell corresponds to a separate radiating signal. Each `struct` contains three column vectors containing the *X*, *Y*, and *Z* components of the polarized fields defined with respect to the global coordinate system.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |

reset    Reset internal states of System object

## Examples

### Radiation from 5-Element ULA

Propagate and combine radiation from five isotropic antenna elements. Set up a uniform line array of five isotropic antennas.

First construct a ULA array.

```
array = phased.ULA('NumElements',5);
```

Construct a radiator object.

```
radiator = phased.Radiator('Sensor',array,...
    'OperatingFrequency',300e6,'CombineRadiatedSignals',true);
```

Create a simple signal to radiate.

```
x = [1;-1;1;-1;1;-1];
```

Specify the azimuth and elevation of the radiating direction.

```
radiatingAngle = [30;10];
```

Radiate the signal.

```
y = radiator(x,radiatingAngle)
```

```
y = 6×1 complex

  -0.9523 - 0.0000i
   0.9523 + 0.0000i
  -0.9523 - 0.0000i
   0.9523 + 0.0000i
  -0.9523 - 0.0000i
   0.9523 + 0.0000i
```

### Radiation from 5-Element ULA of Polarized Antennas

Propagate and combine the radiation from five short-dipole antenna elements.

Set up a uniform line array of five short-dipole antennas with polarization enabled. Then, construct the radiator object.

```
antenna = phased.ShortDipoleAntennaElement;
array = phased.ULA('Element',antenna,'NumElements',5);
radiator = phased.Radiator('Sensor',array,'OperatingFrequency',300e6,...
    'CombineRadiatedSignals',true,'Polarization','Combined');
```

Rotate the local coordinate system from the global coordinates by 10° around the x-axis. Demonstrate that the output represents a polarized field.

Specify a simple signal to radiate and specify the radiating direction in azimuth and elevation. Radiate the fields in two directions.

```
x = [1;-1;1;-1;1;-1];
radiatingAngles = [30 30; 0 20];
y = radiator(x,radiatingAngles,rotx(10))
```

```
y=2×3 struct
    X
    Y
    Z
```

Show the y-component of the polarized field radiating in the first direction.

```
disp(y(1).Y)
```

```
  -0.2131 + 0.0000i
   0.2131 - 0.0000i
  -0.2131 + 0.0000i
   0.2131 - 0.0000i
  -0.2131 + 0.0000i
   0.2131 - 0.0000i
```

### Radiate Signal From Isotropic Antenna

Radiate a signal from a single isotropic antenna.

```
antenna = phased.IsotropicAntennaElement;
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',300e6);
sig = [1;1];
radiatingAngles = [30 10]';
y = radiator(sig,radiatingAngles);
```

Radiate a far-field signal in two directions from a 5-element array.

```
array = phased.ULA('NumElements',5);
radiator = phased.Radiator('Sensor',array,'OperatingFrequency',300e6);
sig = [1;1];
radiatingAngles = [30 10; 20 0]';
y = radiator(sig,radiatingAngles);
```

Radiate signals from a 3-element antenna array. Each antenna radiates a separate signal in a separate direction.

```
array = phased.ULA('NumElements',3);
radiator = phased.Radiator('Sensor',array,'OperatingFrequency',1e9,...
    'CombineRadiatedSignals',false);
sig = [1 2 3; 2 8 -1];
radiatingAngles = [10 0; 20 5; 45 2]';
y = radiator(sig,radiatingAngles)
```

```
y = 2×3

     1     2     3
     2     8    -1
```

### Measure Target Scattering Matrix Using Dual Polarization

Use a dual-polarization system to obtain target scattering information. Simulate a transmitter and receiver where the vertical and horizontal components are transmitted successively using the input ports of the transmitter. The signals from the two polarization output ports of the receiver is then used to determine the target scattering matrix.

```
scmat = [0 1i; 1i 2];
radiator = phased.Radiator('Sensor', ...
    phased.CustomAntennaElement('SpecifyPolarizationPattern',true), ...
    'Polarization','Dual');
```

```
target = phased.RadarTarget('EnablePolarization',true,'ScatteringMatrix', ...
    scmat);
collector = phased.Collector('Sensor', ...
    phased.CustomAntennaElement('SpecifyPolarizationPattern',true), ...
    'Polarization','Dual');
xh = 1;
xv = 1;
```

Transmit a horizontal component and display the reflected Shh and Svh polarization components.

```
x = radiator(xh,0,[0;0],eye(3));
xrefl = target(x,[0;0],eye(3));
[Shh,Svh] = collector(xrefl,[0;0],eye(3))
```

```
Shh = 0

Svh = 0.0000 + 3.5474i
```

Transmit a vertical component and display the reflected Shv and Svv polarization components.

```
x = radiator(0,xv,[0;0],eye(3));
xrefl = target(x,[0;0],eye(3));
[Shv,Svv] = collector(xrefl,[0;0],eye(3))
```

```
Shv = 0.0000 + 3.5474i

Svv = 7.0947
```

Radiate signals

## Syntax

```
Y = step(H,X,ANG)
Y = step(H,X,ANG,LAXES)
Y = step(H,X,ANG,WEIGHTS)
Y = step(H,X,ANG,STEERANGLE)
Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,ANG)` radiates signal `X` in the direction `ANG`. `Y` is the radiated signal. The radiating process depends on the `CombineRadiatedSignals` property of `H`, as follows:

- If `CombineRadiatedSignals` has the value `true`, each radiating element or subarray radiates `X` in all the directions in `ANG`. `Y` combines the outputs of all radiating elements or subarrays. If the `Sensor` property of `H` contains subarrays, the radiating process distributes the power equally among the elements of each subarray.
- If `CombineRadiatedSignals` has the value `false`, each radiating element radiates `X` in only one direction in `ANG`. Each column of `Y` contains the output of the corresponding element. The `false` option is available when the `Sensor` property of `H` does not contain subarrays.

Y = step(H,X,ANG,LAXES) uses LAXES as the local coordinate system axes directions. This syntax is available when you set the EnablePolarization property to true.

Y = step(H,X,ANG,WEIGHTS) uses WEIGHTS as the weight vector. This syntax is available when you set the WeightsInputPort property to true.

Y = step(H,X,ANG,STEERANGLE) uses STEERANGLE as the subarray steering angle. This syntax is available when you configure H so that H.Sensor is an array that contains subarrays and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE) combines all input arguments. This syntax is available when you configure H so that H.EnablePolarization is true, H.WeightsInputPort is true, H.Sensor is an array that contains subarrays, and H.Sensor.SubarraySteering is either 'Phase' or 'Time'.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Input Arguments

### H

Radiator object.

### X

Signals to radiate. X can be either a vector or a matrix.

If X is a vector, that vector is radiated through all radiating elements or subarrays. The computation does not divide the signal’s power among elements or subarrays, but rather treats the X vector the same as a matrix in which each column equals this vector.

If X is a matrix, the number of columns of X must equal the number of subarrays if H.Sensor is an array that contains subarrays, or the number of radiating elements otherwise. Each column of X is radiated by the corresponding element or subarray.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

**ANG**

Radiating directions of signals. `ANG` is a two-row matrix. Each column specifies a radiating direction in the form `[AzimuthAngle;ElevationAngle]`, in degrees.

**LAXES**

Local coordinate system. `LAXES` is a 3-by-3 matrix whose columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively. Each axis is specified in terms of `[x;y;z]` with respect to the global coordinate system. This argument is only used when the `EnablePolarization` property is set to `true`.

**WEIGHTS**

Vector of weights. `WEIGHTS` is a column vector whose length equals the number of radiating elements or subarrays.

**STEERANGLE**

Subarray steering angle, specified as a length-2 column vector. The vector has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90° and 90°, inclusive.

## Output Arguments

**Y**

Radiated signals

- If the `EnablePolarization` property value is set to `false`, the output argument `Y` is a matrix. The number of columns of the matrix equals the number of radiating signals. Each column of `Y` contains a separate radiating signal. The number of radiating signals depends upon the `CombineRadiatedSignals` property of `H`.
- If the `EnablePolarization` property value is set to `true`, `Y` is a row vector of elements of MATLAB `struct` type. The length of the `struct` vector equals the number of radiating signals. Each `struct` contains a separate radiating signal. The

number of radiating signals depends upon the CombineRadiatedSignals property of H. Each struct contains three column-vector fields, X, Y, and Z. These fields represent the *x*, *y*, and *z* components of the polarized wave vector signal in the global coordinate system.

# Examples

### Radiation from 5-Element ULA

Propagate and combine radiation from five isotropic antenna elements. Set up a uniform line array of five isotropic antennas.

First construct a ULA array.

```
array = phased.ULA('NumElements',5);
```

Construct a radiator object.

```
radiator = phased.Radiator('Sensor',array,...
    'OperatingFrequency',300e6,'CombineRadiatedSignals',true);
```

Create a simple signal to radiate.

```
x = [1;-1;1;-1;1;-1];
```

Specify the azimuth and elevation of the radiating direction.

```
radiatingAngle = [30;10];
```

Radiate the signal.

```
y = radiator(x,radiatingAngle)
```

```
y = 6×1 complex

  -0.9523 - 0.0000i
   0.9523 + 0.0000i
  -0.9523 - 0.0000i
   0.9523 + 0.0000i
  -0.9523 - 0.0000i
   0.9523 + 0.0000i
```

### Radiation from 5-Element ULA of Polarized Antennas

Propagate and combine the radiation from five short-dipole antenna elements.

Set up a uniform line array of five short-dipole antennas with polarization enabled. Then, construct the radiator object.

```
antenna = phased.ShortDipoleAntennaElement;
array = phased.ULA('Element',antenna,'NumElements',5);
radiator = phased.Radiator('Sensor',array,'OperatingFrequency',300e6,...
    'CombineRadiatedSignals',true,'Polarization','Combined');
```

Rotate the local coordinate system from the global coordinates by 10° around the x-axis. Demonstrate that the output represents a polarized field.

Specify a simple signal to radiate and specify the radiating direction in azimuth and elevation. Radiate the fields in two directions.

```
x = [1;-1;1;-1;1;-1];
radiatingAngles = [30 30; 0 20];
y = radiator(x,radiatingAngles,rotx(10))
```

```
y=2×3 struct
    X
    Y
    Z
```

Show the y-component of the polarized field radiating in the first direction.

```
disp(y(1).Y)
```

```
  -0.2131 + 0.0000i
   0.2131 - 0.0000i
  -0.2131 + 0.0000i
   0.2131 - 0.0000i
  -0.2131 + 0.0000i
   0.2131 - 0.0000i
```

# RangeAngleResponse

**Package:** `phased`

Range-angle response

## Description

The `RangeAngleResponse` System object creates an range-angle response object. This object calculate the range-angle response of a signal using either a matched filter or an FFT.

The input to the range-angle response object is a data cube. The organization of the data cube follows the Phased Array System Toolbox convention. The first dimension of the cube represents the fast-time samples or ranges of the received signals. The second dimension represents multiple channels such as sensors or beams. The third dimension, slow time, represents pulses or sweeps. If the data contains only one channel, for example, the data cube can contain fewer than three dimensions. Range processing operates along the first dimension of the cube. Angle processing operates along the second dimension.

The output of the object is also a data cube with the same number of dimensions as the input. The first dimension contains range-processed data but its length can differ from the first dimension of the input. The second dimension contains angle-processed data. Its length can differ from the last dimension of the input.

To obtain the range-angle response:

1. Create the `RangeAngleResponse` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

## Syntax

```
response = phased.RangeAngleResponse
response = phased.RangeAngleResponse(Name,Value)
```

### Description

`response = phased.RangeAngleResponse` creates a `phased.RangeAngleResponse` System object, `response`, with default property values.

`response = phased.RangeAngleResponse(Name,Value)` sets properties for the `phased.RangeAngleResponse` object using one or more name-value pairs. For example, `response = phased.RangeAngleResponse('RangeMethod','FFT','SampleRate',1e6)` creates an object that uses an FFT range processing method at a sample rate of 1 MHz. Enclose property names in quotes.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**SensorArray — Sensor array**
phased.ULA array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object.

Example: `phased.URA`

### RangeMethod — Range processing method

'Matched filter' (default) | 'FFT'

Range processing method, specified as 'Matched filter' or 'FFT'.

- 'Matched filter' — The object match-filters the incoming signal. This approach is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal.
- 'FFT' — The object applies an FFT to the input signal. This approach is commonly used for chirped signals such as FMCW and linear FM pulsed signals.

Example: 'Matched filter'

Data Types: char

### PropagationSpeed — Signal propagation speed

physconst('LightSpeed') (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second. The default propagation speed is the value returned by physconst('LightSpeed'). See physconst for more information.

Example: 3e8

Data Types: double

### OperatingFrequency — Operating frequency

300e6 (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

Example: 1e9

Data Types: double

### SampleRate — Signal sample rate

1e6 (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: 1e6

Data Types: double

### SweepSlope — Linear FM sweep slope

1.0e9 (default) | scalar

Linear FM sweep slope, specified as a scalar. The fast-time dimension of the `signal` input argument to `step` must correspond to sweeps having this slope.

Example: `1.5e9`

**Dependencies**

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `double`

**`DechirpInput` — Enable dechirping of input signals**
`false` (default) | `true`

Option to enable dechirping of input signals, specified as `false` or `true`. Set this property to `false` to indicate that the input signal is already dechirped and no dechirp operation is necessary. Set this property to `true` when the input signal requires dechirping.

**Dependencies**

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

**`DecimationFactor` — Decimation factor for dechirped signals**
`1` (default) | positive integer

Decimation factor for dechirped signals, specified as a positive integer. The decimation algorithm uses a 30th-order FIR filter generated by `fir1(30,1/D)`, where `D` is the decimation factor. The default value of `1` implies no decimation.

When processing FMCW signals, decimating the dechirped signal is useful for reducing the load on A/D converters.

**Dependencies**

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`.

Data Types: `double`

**`RangeFFTLengthSource` — Source of FFT length for range processing of dechirped signals**
`'Auto` (default) | `'Property'`

Source of the FFT length used for the range processing of dechirped signals, specified as 'Auto' or 'Property'.

- 'Auto' — The FFT length equals the length of the fast-time dimension of the input data cube.
- 'Property' — Specify the FFT length by using the RangeFFTLength property.

**Dependencies**

To enable this property, set the RangeMethod property to 'FFT'.

Data Types: char

### RangeFFTLength — FFT length used for range processing

1024 (default) | positive integer

FFT length used for range processing, specified as a positive integer.

**Dependencies**

To enable this property, set the RangeMethod property to 'FFT' and the RangeFFTLengthSource property to 'Property'

Data Types: double

### RangeWindow — FFT weighting window for range processing

'None' (default) | 'Hamming' | 'Chebyshev' | 'Hann' | 'Kaiser' | 'Taylor' | 'Custom'

FFT weighting window for range processing, specified as 'None', 'Hamming', 'Chebyshev', 'Hann', 'Kaiser', 'Taylor', or 'Custom'.

If you set this property to 'Taylor', the generated Taylor window has four nearly constant sidelobes next to the mainlobe.

**Dependencies**

To enable this property, set the RangeMethod property to 'FFT'.

Data Types: char

### RangeSidelobeAttenuation — Sidelobe attenuation for range processing

30 (default) | positive scalar

Sidelobe attenuation for range processing, specified as a positive scalar. Attenuation applies to Kaiser, Chebyshev, or Taylor windows. Units are in dB.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Kaiser'`, `'Chebyshev'`, or `'Taylor'`.

### `CustomRangeWindow` — Custom window for range processing

`@hamming` (default) | function handle | cell array

Custom window for range processing, specified as a function handle or a cell array containing a function handle as its first entry. If you do not specify a window length, the object computes the window length and passes that into the function. If you specify a cell array, the remaining cells of the array can contain arguments to the function. If you use only the function handle without passing in arguments, all arguments take their default values.

If you write your own window function, the first argument must be the length of the window.

**Note** Instead of using a cell array, you can pass in all arguments by constructing a handle to an anonymous function. For example, you can set the value of `CustomRangeWindow` to `@(n)taylorwin(n,nbar,sll)`, where you have previously set the values of `nbar` and `sll`.

Example: `{@taylor,5,-35}`

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Custom'`.

Data Types: `function_handle` | `cell`

### `ReferenceRangeCentered` — Set reference range at center of range grid

`true` (default) | `false`

Set reference range at center of range grid, specified as `true` or `false`. Setting this property to `true` enables you to set the reference range at the center of the range grid. Setting this property to `false` sets the reference range to the beginning of the range grid.

#### Dependencies

To enable this property, set the `RangeMethod` to `'FFT'`.

Data Types: `logical`

### `ReferenceRange` — Reference range of range grid

`0.0` (default) | nonnegative scalar

Reference range of the range grid, specified as a nonnegative scalar.

- If you set the `RangeMethod` property to `'Matched filter'`, the reference range is set to the start of the range grid.
- If you set the `RangeMethod` property to `'FFT'`, the reference range is determined by the `ReferenceRangeCentered` property.

  - When you set the `ReferenceRangeCentered` property to `true`, the reference range is set to the center of the range grid.
  - When you set the `ReferenceRangeCentered` property to `false`, the reference range is set to the start of the range grid.

  Units are in meters.

This property is tunable.

Example: `1000.0`

Data Types: `double`

### `MaximumNumInputSamplesSource` — Source of maximum number of input signal samplesl

`'Auto'` (default) | `'Property'`

Source of the maximum number of input signal samples, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the object automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

To use this object with a variable-size signal in a MATLAB Function Block in Simulink, set this property to `'Property'` and set a value for the `MaximumNumInputSamples` property.

**Dependencies**

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

### `MaximumNumInputSamples` — Maximum number of input signal samples

`100` (default) | positive integer

Maximum number of samples in the input signal, specified as a positive integer. This property limits the size of the input signal. The input signal is the first argument to the object. The number of samples is the number of rows in the input. An input signal longer than this value is truncated.

Example: `1024`

**Dependencies**

To enable this property, set the `RangeMethod` property to `'Matched filter'` and set the `MaximumNumInputSamplesSource` property to `'Property'`.

Data Types: `double`

### `ElevationAngleSource` — Source of elevation angle

`'Property'` (default) | `'Input port'`

Source of elevation angle, specified as `'Property'` or `'Input port'`.

| | |
|---|---|
| `'Property'` | The elevation angle comes from the `ElevationAngle` property. |
| `'Input port'` | The elevation angle comes from an input argument. |

### `ElevationAngle` — Elevation angle

`0` (default) | scalar

Specify the elevation angle in degrees used to calculate the range-angle response as a scalar. The angle must lie in the range from –90° to 90°. Units are in degrees.

Example: `45.0`

**Dependencies**

To enable this property, set the `ElevationAngleSource` property to `'Property'`.

Data Types: `double`

### AngleSpan — Angle response span

[-90 90] (default) | real-valued 1-by-2 vector

Angle response span, specified as a real-valued 2-by-1 vector. The object calculates the range-angle response within the angle range, [min_angle max_angle].

Example: [-45 45]

Data Types: double

### NumAngleSamples — Number of samples in angle span

positive integer greater than two

Number of samples in angle span used to calculate range-angle response, specified as a positive integer greater than two.

Example: [256]

Data Types: double

You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of the enabling properties. For example,

```
[RESP,RANGE,ANG] = response(X,XREF,EL)
```

or

```
[RESP,RANGE,ANG] = response(X,COEFF,EL)
```

# Usage

# Syntax

```
[RESP,RANGE,ANG] = response(X)
[RESP,RANGE,ANG] = response(X,XREF)
[RESP,RANGE,ANG] = response(X,COEFF)
[RESP,RANGE,ANG] = response( ___ ,EL)
```

## Description

`[RESP,RANGE,ANG] = response(X)` returns the range-angle response, `RESP`, the ranges, `RANGE`, and the angles, `ANG`. `X` is a dechirped signal. This syntax applies when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`. This syntax is often applied to FMCW signals.

`[RESP,RANGE,ANG] = response(X,XREF)` also specifies the reference signal, `XREF` to dechirped the signal. This syntax applies when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`. This syntax is often applied to FMCW signals. Then, the reference signal can be the transmitted signal.

`[RESP,RANGE,ANG] = response(X,COEFF)` also specifies `COEFF` as matched filter coefficients. This syntax applies when you set the `RangeMethod` property to `'MatchedFilter'`. This syntax is often applied to pulsed signals.

`[RESP,RANGE,ANG] = response(___,EL)` also specifies `EL` as the elevation angle. This syntax applies when you set the `ElevationAngleSource` property to `'Input port'`.

## Input Arguments

### X — Input signal data cube

complex-valued *K*-by-*N* matrix | complex-valued *K*-by-*N*-by-*L* array

Input signal cube, specified as a complex-valued *K*-by-*N* matrix or complex-valued *K*-by-*N*-by-*L* array. The contents of the data cube depend on the type of range-angle processing specified by the different syntaxes.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or beams.
- *L* is the slow-time dimension that corresponds to the number of pulses or sweeps in the input signal.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

### XREF — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the fast-time dimension of `X`.

**Dependencies**

To enable this input argument, set the value of `RangeMethod` to `'FFT'` and `DechirpInput` to `true`.

Data Types: `double`

### `COEFF` — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*. *K* is the number of fast-time or range sample.

**Dependencies**

To enable this input argument, set the value of `RangeMethod` to `'Matched filter'`.

Data Types: `double`

### `EL` — Elevation angle

scalar

Elevation angle of response, specified as a scalar between –90° and +90°. The range-angle response is computed for this elevation. Units are in degrees.

**Dependencies**

To enable this argument, set the `ElevationAngleSource` property to `'Input port'`.

Data Types: `double`

## Output Arguments

### `RESP` — Range response data cube

complex-valued *M*-element column vector | complex-valued *M*-by-*L* matrix | complex-valued *M*-by-*N* by-*L* array

Range response data cube, returned as one of the following:

- Complex-valued *M*-element column vector
- Complex-valued *M*-by-*L* matrix

- Complex-valued *M*-by-*N* by-*L* array

The value of *M* depends on the type of processing

| RangeMethod Property | DechirpInput Property | Value of *M* |
|---|---|---|
| `'FFT'` | `false` | If you set the `RangeFFTLength` property to `'Auto'`, *M* = *K*, the length of the fast-time dimension of `x`. Otherwise, *M* equals the value of the `RangeFFTLength` property. |
| | `true` | *M* equals the quotient of the number of rows, *K*, of the input signal by the value of the decimation factor, *D*, specified in `DecimationFactor`. |
| `'Matched filter'` | n/a | *M* = *K*, the length of the fast-time dimension of `x`. |

Data Types: `double`

**RANGE — Range values along range dimension**
real-valued *M*-by-1 column vector

Range values along range dimension, returned as a real-valued *M*-by-1 column vector. `rnggrid` defines the ranges corresponding to the fast-time dimension of the `RESP` output data cube. *M* is the length of the fast-time dimension of `RESP`. Range values are monotonically increasing and equally spaced. Units are in meters.

Data Types: `double`

**ANG — Angle values along angle direction**
*P*-by-1 real-valued vector

Angle values along angle direction, returned as a *P*-by-1 real-valued vector. Units are in degrees.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to RangeAngleResponse

| | |
|---|---|
| plotResponse | Plot range-angle response |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### Range Angle Response of Antenna Array

Calculate the range-angle response from a pulsed radar transmitting a rectangular waveform using the matched filter approach. The signal includes three target returns. Two are approximately 2000 m away and the third is approximately 3500 m away. In addition, two targets are stationary relative to the radar while the third is moving away from the radar at approximately 100 m/s. The signals arrive at an 8-element uniform linear array.

First, load the example data.

```
load('RangeAngleResponseExampleData','rectdata');
fs = rectdata.fs;
propspeed = rectdata.propspeed;
fc = rectdata.fc;
rxdata = rectdata.rxdata;
mfcoeffs = rectdata.mfcoeffs;
%noisepower = rectdata.noisepower;
antennaarray = rectdata.antennaarray;
```

Second, create the range-angle response object for matched filter processing.

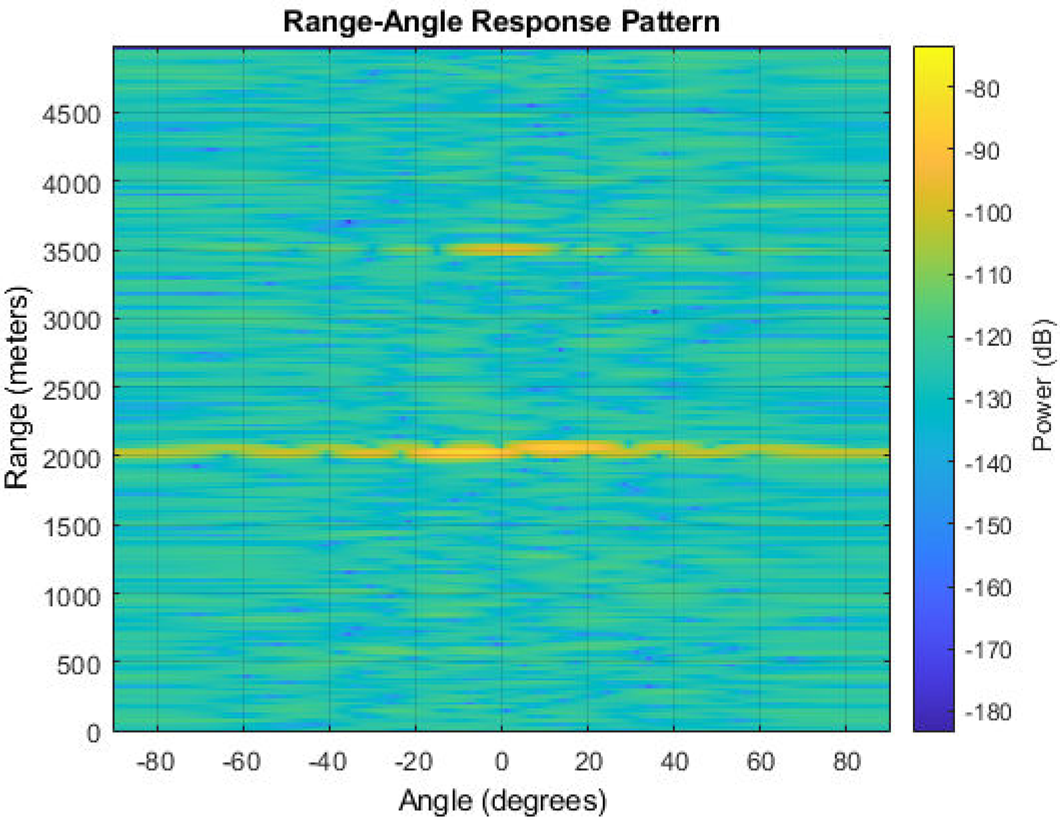
```
rngangresp = phased.RangeAngleResponse(...
    'SensorArray',antennaarray,'OperatingFrequency',fc,...
    'SampleRate',fs,'PropagationSpeed',propspeed);
```

Obtain the range-angle map.

```
[resp,rng_grid,ang_grid] = rngangresp(rxdata,mfcoeffs);
```

Plot the response.

```
plotResponse(rngangresp,rxdata,mfcoeffs,'Unit','db');
```



# Algorithms

### Range-Angle Response

The object generates the response by first processing the input signal in the range domain using either a matched filter or a dechirp operation and then by processing along azimuth angles.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `CustomRangeWindow` property is not supported.
- The `plotResponse` object function is not supported.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# plotResponse

**Package:** phased

Plot range-angle response

## Syntax

```
plotResponse(response,X)
plotResponse(response,X,XREF)
plotResponse(response,X,COEFF)
plotResponse(___,'Unit',unit)
```

## Description

plotResponse(response,X) plots the range response of a dechirped input signal, X, from the phased.RangeAngleResponse object, response. This syntax applies when you set the RangeMethod property to 'FFT' and the DechirpInput property to false.

plotResponse(response,X,XREF) plots the range response X, after performing a dechirp operation using the reference signal, XREF. This syntax applies when you set the RangeMethod property to 'FFT' and the DechirpInput property to true.

plotResponse(response,X,COEFF) plots the range response of X after match filtering using the match filter coefficients, coeff. This syntax applies when you set the RangeMethod property to 'Matched filter'.

plotResponse(___,'Unit',unit) plots the response in the units specified by units.

## Examples

### Range Angle Response of Antenna Array

Calculate the range-angle response from a pulsed radar transmitting a rectangular waveform using the matched filter approach. The signal includes three target returns.

Two are approximately 2000 m away and the third is approximately 3500 m away. In addition, two targets are stationary relative to the radar while the third is moving away from the radar at approximately 100 m/s. The signals arrive at an 8-element uniform linear array.

First, load the example data.

```
load('RangeAngleResponseExampleData','rectdata');
fs = rectdata.fs;
propspeed = rectdata.propspeed;
fc = rectdata.fc;
rxdata = rectdata.rxdata;
mfcoeffs = rectdata.mfcoeffs;
%noisepower = rectdata.noisepower;
antennaarray = rectdata.antennaarray;
```

Second, create the range-angle response object for matched filter processing.

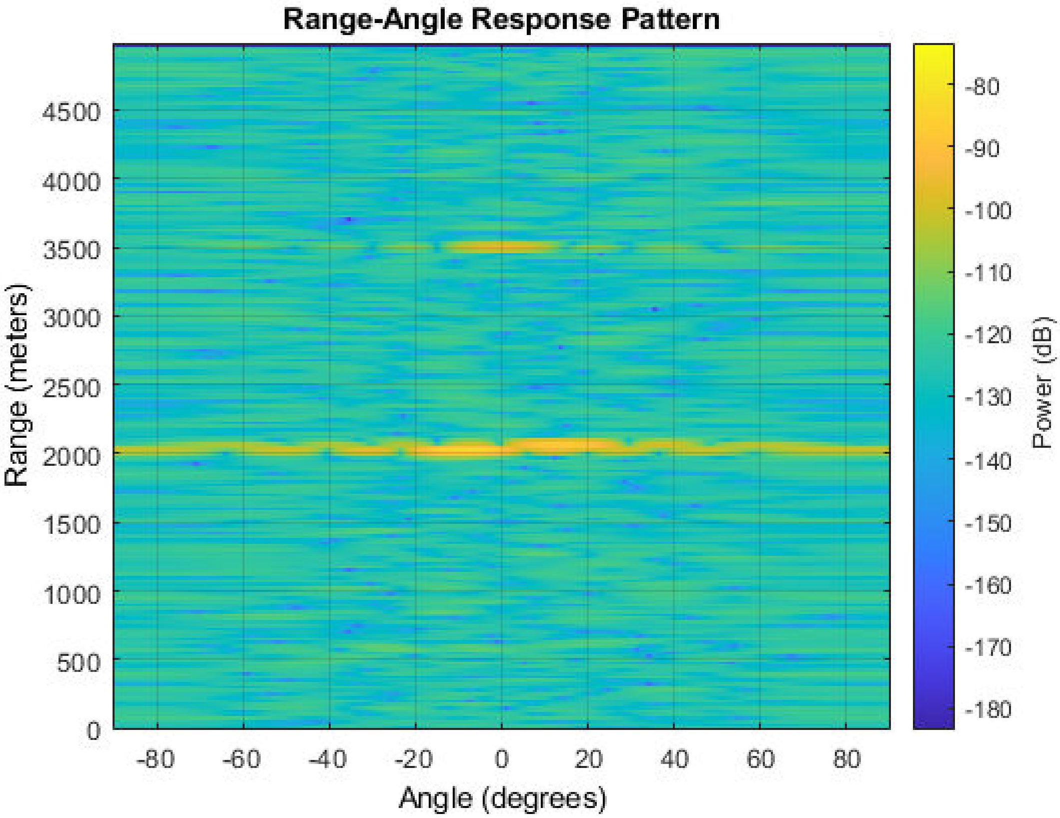
```
rngangresp = phased.RangeAngleResponse(...
    'SensorArray',antennaarray,'OperatingFrequency',fc,...
    'SampleRate',fs,'PropagationSpeed',propspeed);
```

Obtain the range-angle map.

```
[resp,rng_grid,ang_grid] = rngangresp(rxdata,mfcoeffs);
```

Plot the response.

```
plotResponse(rngangresp,rxdata,mfcoeffs,'Unit','db');
```



## Input Arguments

**response — Range-angle response object**
phased.RangeAngleResponse System object

Range-angle response object, specified as a `phased.RangeAngleResponse` System object.

**X — Input data**
complex-valued *K*-by-*N* matrix

Input data, specified as a complex-valued *K*-by-*N* matrix. The contents of the data cube depend on the type of range-angle processing specified by the different syntaxes. *K* always specifies the number of fast-time samples and *N* is always the number of channels, either array elements or beams.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or directions.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

### XREF — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the fast-time dimension of `X`.

#### Dependencies

To enable this input argument, set the value of `RangeMethod` to `'FFT'` and `DechirpInput` to `true`.

Data Types: `double`

### COEFF — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*. *K* is the number of fast-time or range sample.

#### Dependencies

To enable this input argument, set the value of `RangeMethod` to `'Matched filter'`.

Data Types: `double`

### unit — Plot units

`'db'` (default) | `'mag'` | `'pow'`

Plot units, specified as `'db'`, `'mag'`, or `'pow'`. who

- `'db'` – plot the response power in dB.

- `'mag'` – plot the magnitude of the response.
- `'pow'` – plot the response power.

Example: `'mag'`

Data Types: `char` | `string`

**Introduced in R2018b**

# phased.RangeDopplerScope

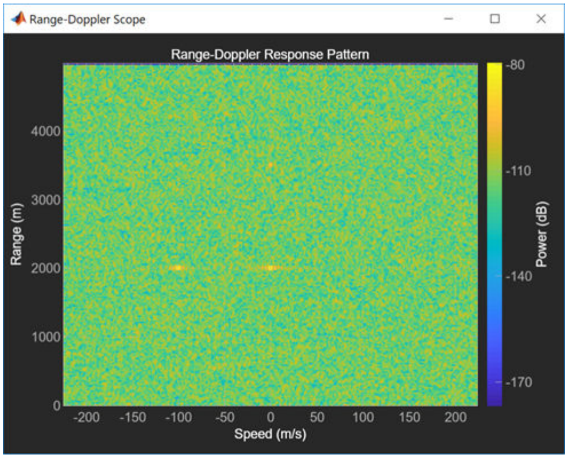
**Package:** `phased`

Range-Doppler scope

## Description

The `phased.RangeDopplerScope` System object creates a scope for viewing a range-response map. The map is a 2-D image of response intensity as a function of range and (or speed). You can input two types of data - in-phase and quadrature (I/Q) data and response data.

- I/Q data – The data consists of fast-time and slow-time I/Q samples of pulses or sweeps. The scope computes and displays the response map. To use I/Q data, set the `IQDataInput` property to `true`. In this mode, you can set the properties shown in “Properties Applicable to I/Q Data” on page 1-1773.
- Response data – The data consists of the range- response itself. The scope displays the range- response map. For example, you can obtain range- response from `phased.RangeDopplerResponse` object. To use response data, set the `IQDataInput` property to `false`. In this mode, you can set the properties shown in “Properties Applicable to Response Data” on page 1-1774.



To display a range-Doppler response map using the scope,

1. Create the `phased.RangeDopplerScope` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

# Syntax

```
scope = phased.RangeDopplerScope
scope = phased.phased.RangeDopplerScope(Name,Value)
```

## Description

`scope = phased.RangeDopplerScope` creates a range-Doppler scope System object, `scope`. This object displays the range-Doppler response of the input data.

`scope = phased.phased.RangeDopplerScope(Name,Value)` creates a range-Doppler scope object, `scope`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose property names in quotes. For example,

```
scope = phased.RangeDopplerScope('IQInputData',true,'RangeMethod', ...
        'FFT','SampleRate',1e6,'DopplerOutput','Speed', ...
        'OperatingFrequency',10e6,'SpeedUnits','km/h');
```

creates a scope object that uses FFT-based range processing for I/Q data having a sample rate of 1 MHz. The Doppler output units are speed in kilometers per hour.

# Properties

Unless otherwise indicated, properties are *nontunable,* which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

**Name — Display caption**
'Range-Doppler Scope' (default) | character vector

Display caption, specified as a character vector. The caption appears in the title bar of the window.

Example: 'Aircraft Range-Doppler Response'

**Tunable:** Yes

Data Types: char

**Position — Location and size of intensity scope window**
depends on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form [left bottom width height].

- left and bottom specify the location of the bottom-left corner of the window.
- width and height specify the width and height of the window.

Units are in pixels.

The default value of this property depends on the resolution of your display. By default, the window is positioned in the center of the screen, with a width and height of 800 and 450 pixels, respectively.

Example: [100 100 500 400]

**Tunable:** Yes

Data Types: double

**IQDataInput — Type of input data**
true (default) | false

Type of input data, specified as true or false. When true, the object assumes that the input consists of I/Q sample data and further processing is required in the range and Doppler domains. When false, the object assumes that the data is response data that has already been processed.

Data Types: `logical`

### `ResponseUnits` — Response units label

`'db'` (default) | `'magnitude'` | `'power'`

Response units, specified as `'db'`, `'magnitude'`, or `'power'`.

Data Types: `char`

### `RangeLabel` — Range-axis label

`'Range (m)'` (default) | character vector

Range-axis label, specified as a character vector.

Example: `'Range (km)'`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `IQDataInput` to `false`.

Data Types: `char`

### `DopplerLabel` — Doppler-axis label

`'Doppler Frequency (Hz)'` (default) | character vector

Doppler-axis label, specified as a character vector.

Example: `'Doppler Frequency (kHz)'`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `IQDataInput` to `false`.

Data Types: `char`

### `RangeMethod` — Range processing method

`'Matched filter'` (default) | `'FFT'`

Range-processing method, specified as `'Matched filter'` or `'FFT'`.

| | |
|---|---|
| `'Matched filter'` | The object applies a matched filter to the incoming signal. This approach is commonly used with pulsed signals, where the matched filter is a time-reversed replica of the transmitted signal. |
| `'FFT'` | Algorithm performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW continuous signals and linear FM pulsed signals. |

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

### RangeUnits — Range units

`'m'` (default) | `'km'` | `'mi'` | `'nmi'`

Range units, specified as:

- `'m'` – meters
- `'km'` – kilometers
- `'mi'` – miles
- `'nmi'` – nautical miles

Example: `'mi'`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `char`

### PropagationSpeed — Signal propagation speed

`physconst('Lightspeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value of this property is the speed of light. See `physconst`. Units are in meters/second.

Example: `3e8`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### SampleRate — Sample rate

1e6 (default) | positive scalar

Sample rate, specified as a positive scalar. Units are in Hz.

Example: 10e3

#### Dependencies

To enable this property, set the IQDataInput property to true.

Data Types: double

### SweepSlope — FM sweep slope

1e9 (default) | scalar

Slope of the linear FM sweep, specified as a scalar. Units are in Hz/sec.

#### Dependencies

To enable this property, set the IQDataInput property to true and the RangeMethod property to 'FFT'.

Data Types: double

### DechirpInput — Dechirp input signal

false (default) | true

Set this property to true to dechirp the input signal before performing range processing. false indicates that the input signal is already dechirped and no dechirp operation is necessary.

#### Dependencies

To enable this property, set the the IQDataInput property to true and the RangeMethod property to 'FFT'.

Data Types: logical

### RangeFFTLength — FFT length used in range processing

1024 (default) | positive integer

FFT length used for range processing, specified as a positive integer.

Example: 128

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `double`

### `ReferenceRangeCentered` — Set reference range at center of range span

`true` (default) | `false`

Set this property to `true` to set the reference range to the center of the range span. Set this property to `false` to set the reference range to the beginning of the range span.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

### `ReferenceRange` — Reference range

`0.0` (default) | nonnegative scalar

Reference range of the range span, specified as a nonnegative scalar.

- If you set the `RangeMethod` property to `'Matched filter'`, the reference range marks the start of the range span.
- If you set the `RangeMethod` property to `'FFT'`, the position of the reference range depends on the `ReferenceRangeCentered` property.

  - If you set the `ReferenceRangeCentered` property to `true`, the reference range marks the center of the range span.
  - If you set the `ReferenceRangeCentered` property to `false`, the reference range marks the start of the range span.

  Units are in meters.

Example: `1000.0`

**Tunable:** Yes

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `PRFSource` — Source of pulse repetition frequency

`'Auto'` (default) | `'Property'`

Source of the pulse repetition frequency (PRF) of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the PRF is a function of the number of rows in the input signal and the value of the `SampleRate` property. When you set this property to `'Property'`, you can specify the PRF using the `PRF` property.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `char`

### `PRF` — Pulse repetition frequency of input signal

`10e3` (default) | positive scalar

Pulse repetition frequency of input signal, specified as a positive scalar. Units are in Hz.

Example: `1.4e3`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and set the `PRFSource` property to `'Property'`.

Data Types: `double`

### `DopplerFFTLength` — FFT length used in Doppler processing

`1024` (default) | positive integer

FFT length used in Doppler processing, specified as a positive integer.

Example: `67`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `DopplerOutput` — Doppler output

`'Frequency'` (default) | `'Speed'`

Doppler output, specified as `'Frequency'` or `'Speed'`. If you set this property to `'Frequency'`, the Doppler output, `Dop`, at object execution time is the Doppler shift. If you set this property to `'Speed'`, the Doppler output is the equivalent radial speed.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `char`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `DopplerOutput` to `'Speed'`.

Data Types: `double`

### `NormalizeDoppler` — Normalize Doppler

`false` (default) | `true`

Set this property to `true` to plot the range-Doppler response with normalized Doppler frequency. Set this property to `false` to plot the range-Doppler response without normalizing the Doppler frequency.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `DopplerOutput` to `'Frequency'`.

Data Types: `logical`

### `SpeedUnits` — Doppler speed units

`'m/s'` (default) | `'km/h'` | `'mph'` | `'kt'`

Doppler speed units:

- `'m/s'` – meters per second
- `'km/h'` – kilometers per hour
- `'mph'` – miles per hour

- 'kt' – knots or nautical miles per hour

Example: 'mph'

**Dependencies**

To enable this property, set the IQDataInput property to true and the DopplerOutput property to 'Speed'.

Data Types: char

### FrequencyUnits — Doppler frequency units

'Hz' (default) | 'kHz' | 'MHz'

Doppler frequency units, specified as 'Hz', 'kHz', or 'MHz'.

Example: 'MHz'

**Dependencies**

To enable this property, set the IQDataInput property to true, the DopplerOutput to 'Frequency', and the NormalizedDoppler property to false.

Data Types: char

# Usage

# Syntax

```
scope(X,Range,Dop)
```

```
scope(X)
scope(X,XREF)
scope(X,COEFF)
```

## Description

scope(X,Range,Dop) displays a range-Doppler response map, X, at the ranges, Range, and Doppler shifts, Dop. This syntax applies when you set the IQDataInput to false.

scope(X) computes and displays the range-Doppler response map. This syntax applies when you set the IQDataInput property to true, the RangeMethod property to 'FFT', and the `DechirpInput` property to `false`. This syntax is most commonly used with FMCW signals. All sweeps in `X` are assumed to be contiguous. If the sweeps are not contiguous, set the PRF by setting the `PRFSource` property to `'Property'` and the `PRF` of the input data to the PRF.

`scope(X,XREF)` also specifies a reference signal to use for dechirping the input signal, `X`. This syntax applies when you set the `IQDataInput` property to `true`, the `RangeMethod` property to `'FFT'`, and the `DechirpInput` property to `true`. This syntax is most commonly used with FMCW signals. `XREF` is generally the transmitted signal.

`scope(X,COEFF)` also specifies matched filter coefficients, `COEFF`. This syntax applies when you set the `IQDataInput` property to `true` and the `RangeMethod` property to `'Matched Filter'`. This syntax is most commonly used with pulsed signals.

## Input Arguments

### X — Input data

complex-valued *K*-by-*L* matrix

Input data, specified as a complex-valued *K*-by-*L* matrix. The interpretation of the data depends on the value of the `IQDataInput` property.

- When `IQDataInput` is `true`, the input consists of received fast-time (range) samples for each PRI pulse or FMCW sweep. *K* denotes the number of fast-time samples. *L* is the number of Doppler samples. The number of Doppler samples is the number of pulses in the case of pulsed signals or the number of dechirped frequency sweeps for FMCW signals. The scope computes and displays the range-Doppler response.

  - When `RangeMethod` is set to `'FFT'` and `DechirpInput` is `false`, `X` has previously been dechirped.
  - When `RangeMethod` is set to `'FFT'` and `DechirpInput` is `true`, `X` has not been previously dechirped. Use the syntax that includes `XREF` as input data.
  - When `RangeMethod` is set to `'MatchedFilter'`, `X` has not been match filtered. Use the syntax that includes `COEFF` as input data.
- When `IQDataInput` is `false`, the input already consists of response data in the range-Doppler domain such as that produced by `phased.RangeDopplerResponse`. Each row of the response map corresponds to an element of the `Range` vector. Each column corresponds to an element of the `Dop` vector. The scope serves only as a display of the range-Doppler response.

### Range — Range grid values of range-Doppler response map

real-valued *K*-by-1 column vector

Range grid values of response map, specified as a real-valued *K*-by-1 column vector. `Range` denotes the range values at which the response has been computed. Elements of `Range` correspond to the rows of `X`.

#### Dependencies

To enable this argument, set the `IQInputData` property to `false`.

Data Types: `double`

### Dop — Doppler grid values of range-Doppler response map

real-valued *L*-by-1 column vector

Doppler grid values of response map, specified as a real-valued *L*-by-1 column vector. `Dop` denotes the Doppler values at which the response has been computed. Elements of `Dop` correspond to the columns of `X`. `Dop` can contain either Doppler or speed values at which the range-Doppler response is evaluated.

#### Dependencies

To enable this argument, set the `IQInputData` property to `false`.

Data Types: `double`

### XREF — Reference signal

complex-valued *K*-by-1 column vector

Reference signal used to dechirp `X`. `XREF` must be a column vector with the same number of rows as `X`.

#### Dependencies

To enable this argument, set the `IQDataInput` property to `true`, the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`

Data Types: `double`
Complex Number Support: Yes

### `COEFF` — Matched filter coefficients

complex-valued column vector

Matched filter coefficients, specified as a complex-valued column vector.

#### Dependencies

To enable this argument, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'Matched Filter'`.

Data Types: `double`
Complex Number Support: Yes

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Scope Objects

| | |
|---|---|
| show | Turn on visibility of scopes |
| hide | Turn off visibility of scope |
| isVisible | Visibility of scopes |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### View Target Response Using Range-Doppler Scope

Calculate and visualize the range-Doppler response from a pulsed radar transmitting a rectangular waveform. Compute the response using matched filtering. The signal contains returns from three targets. One target is approximately 2000 m away and is stationary relative to the radar. The second target is approximately 3500 m away and is also stationary relative to the radar. The third is approximately 2000 m away and is moving away from the radar at approximately 100 m/s.

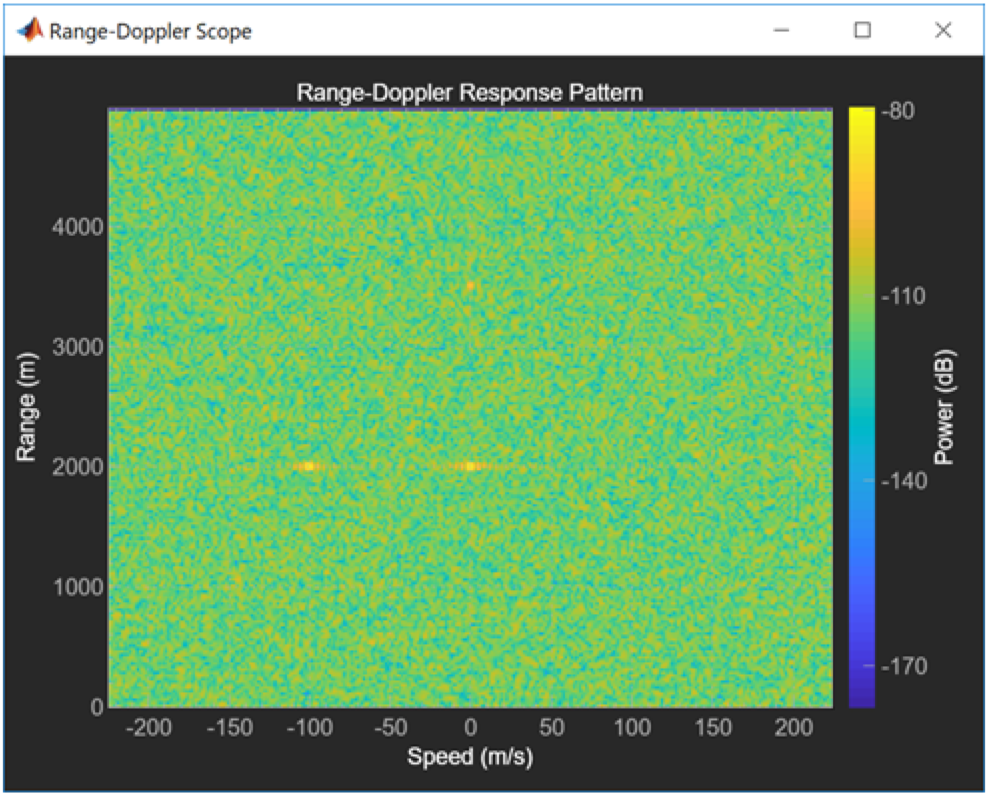
Load the IQ data and obtain the signals and parameters.

```
load('RangeDopplerResponseExampleData','rectdata');
fs = rectdata.fs;
c = rectdata.propspeed;
fc = rectdata.fc;
rxdata = rectdata.rxdata;
mfcoeffs = rectdata.mfcoeffs;
```

Create the range-Doppler scope for matched filter processing and visualization. Set the Doppler FFT size to 1024.

```
scope = phased.RangeDopplerScope( ...
    'IQDataInput',true,'RangeMethod','Matched filter', ...
    'Name','Range-Doppler Scope', ...
    'Position',[560 375 560 420],'ResponseUnits','db', ...
    'RangeUnits','m','DopplerFFTLength',1024, ...
    'DopplerOutput','Speed','OperatingFrequency',fc, ...
    'SampleRate',fs,'PropagationSpeed',c);
scope(rxdata,mfcoeffs);
```

The display shows the three targets.



# More About

## Properties Applicable to I/Q Data

These properties are applicable when `IQDataInput` is `true`.

| Properties | |
|---|---|
| `Name` | `Position` |
| `ResponseUnits` | `RangeMethod` |
| `RangeUnits` | `PropagationSpeed` |

| Properties | |
|---|---|
| SampleRate | SweepSlope |
| DechirpInput | RangeFFTLength |
| ReferenceRangeCentered | ReferenceRange |
| PRFSource | PRF |
| DopplerFFTLength | DopplerOutput |
| OperatingFrequency | NormalizeDoppler |
| SpeedUnits | FrequencyUnits |

### Properties Applicable to Response Data

These properties are applicable when `IQDataInput` is `false`.

| Properties | |
|---|---|
| Name | Position |
| ResponseUnits | RangeLabel |
| DopplerLabel | |

**Introduced in R2019a**

# phased.RangeAngleScope

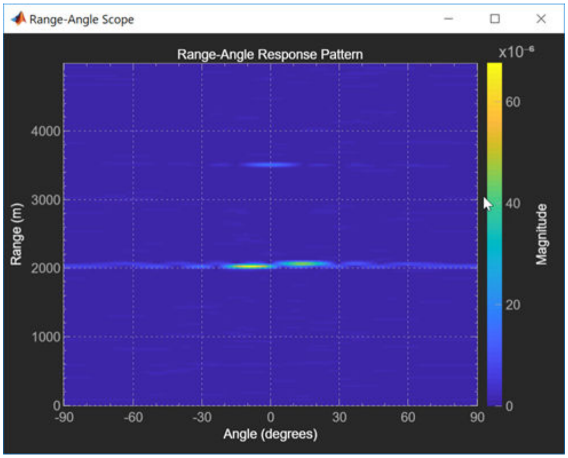
**Package:** `phased`

View range-angle response

## Description

The `phased.RangeAngleScope` System object creates a scope for displaying a range-angle response map. The map is a 2-D representation of response intensity as a function of range and angle of arrival. You can input two types of data – in-phase and quadrature (I/Q) data and response data.

- I/Q data – The data consists of fast-time I/Q samples of pulses or sweeps from multiple sensors. The scope computes and displays the response map. To use I/Q data, set the `IQDataInput` property to `true`. In this mode, you can set the properties shown in “Properties Applicable to I/Q Data” on page 1-1788.
- Response data – The data consists of the range-angle response itself. The scope displays the range-angle response map. You can obtain range-angle response data from the `RangeAngleResponse` object. To use response data, set the `IQDataInput` property to `false`. In this mode, you can set the properties shown in “Properties Applicable to Response Data” on page 1-1789.



To display a range-angle response map using a scope,

1. Create the `phased.RangeAngleScope` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

# Syntax

```
scope = phased.RangeAngleScope
scope = phased.phased.RangeAngleScope(Name,Value)
```

## Description

`scope = phased.RangeAngleScope` creates a range-angle scope System object for displaying the range-angle response.

`scope = phased.phased.RangeAngleScope(Name,Value)` creates a range-angle `scope` with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose property names in quotes. For example,

```
scope = phased.RangeAngleScope('IQInputData',true,'RangeMethod', ...
        'FFT','SampleRate',1e6)
```

creates a scope object that uses FFT-based range processing to process I/Q data with a sample rate of 1 MHz.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### Name — Display caption

'Range-Angle Scope' (default) | character vector

Display caption, specified as a character vector. The caption appears in the title bar of the window.

Example: 'Aircraft Range-Angle Response'

**Tunable:** Yes

Data Types: char

### Position — Location and size of intensity scope window

depends on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form [left bottom width height].

- left and bottom specify the location of the bottom-left corner of the window.
- width and height specify the width and height of the window.

Units are in pixels.

The default value of this property depends on the resolution of your display. By default, the window is positioned in the center of the screen, with a width and height of 800 and 450 pixels, respectively.

Example: [100 100 500 400]

**Tunable:** Yes

Data Types: double

### IQDataInput — Type of input data

true (default) | false

Type of input data, specified as true or false. When true, the object assumes that the input consists of I/Q sample data and further processing is required in the range and angle domains. When false, the object assumes that the data is response data that has already been processed.

Data Types: logical

### `ResponseUnits` — Response units label

`'db'` (default) | `'magnitude'` | `'power'`

Response units, specified as `'db'`, `'magnitude'`, or `'power'`.

Data Types: `char`

### `RangeLabel` — Range-axis label

`'Range (m)'` (default) | character vector

Range-axis label, specified as a character vector.

Example: `'Range (km)'`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `IQDataInput` to `false`.

Data Types: `char`

### `AngleLabel` — Angle-axis label

`'Angle (degrees)'` (default) | character vector

Angle-axis label, specified as a character vector.

Example: `'Angle Span (degrees)'`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `IQDataInput` to `false`.

Data Types: `char`

### `SensorArray` — Sensor array

`phased.ULA` array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object. See `phased.ULA` for the default values of a uniform linear array.

Example: `phased.URA`

#### Dependencies

To enable this property, set the `IQDataInput` to `true`.

### RangeMethod — Range processing method

`'Matched filter'` (default) | `'FFT'`

Range-processing method, specified as `'Matched filter'` or `'FFT'`.

| | |
|---|---|
| `'Matched filter'` | The object applies a matched filter to the incoming signal. This approach is commonly used with pulsed signals, where the matched filter is a time-reversed replica of the transmitted signal. |
| `'FFT'` | Algorithm performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW continuous signals and linear FM pulsed signals. |

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

### RangeUnits — Range units

`'m'` (default) | `'km'` | `'mi'` | `'nmi'`

Range units, specified as:

- `'m'` – meters
- `'km'` – kilometers
- `'mi'` – miles
- `'nmi'` – nautical miles

Example: `'mi'`

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `char`

### PropagationSpeed — Signal propagation speed

`physconst('Lightspeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value of this property is the speed of light. See `physconst`. Units are in meters/second.

Example: `3e8`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `SampleRate` — Sample rate

`1e6` (default) | positive scalar

Sample rate, specified as a positive scalar. Units are in Hz.

Example: `10e3`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `SweepSlope` — FM sweep slope

`1e9` (default) | scalar

Slope of the linear FM sweep, specified as a scalar. Units are in Hz/sec.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `double`

### `DechirpInput` — Dechirp input signal

`false` (default) | `true`

Set this property to `true` to dechirp the input signal before performing range processing. `false` indicates that the input signal is already dechirped and no dechirp operation is necessary.

**Dependencies**

To enable this property, set the the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

### `RangeFFTLength` — FFT length used in range processing

`1024` (default) | positive integer

FFT length used for range processing, specified as a positive integer.

Example: `128`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `double`

### `ReferenceRangeCentered` — Set reference range at center of range span

`true` (default) | `false`

Set this property to `true` to set the reference range to the center of the range span. Set this property to `false` to set the reference range to the beginning of the range span.

**Dependencies**

To enable this property, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

### `ReferenceRange` — Reference range

`0.0` (default) | nonnegative scalar

Reference range of the range span, specified as a nonnegative scalar.

- If you set the RangeMethod property to 'Matched filter', the reference range marks the start of the range span.
- If you set the RangeMethod property to 'FFT', the position of the reference range depends on the ReferenceRangeCentered property.
  - If you set the ReferenceRangeCentered property to true, the reference range marks the center of the range span.
  - If you set the ReferenceRangeCentered property to false, the reference range marks the start of the range span.

  Units are in meters.

Example: 1000.0

**Tunable:** Yes

**Dependencies**

To enable this property, set the IQDataInput property to true.

Data Types: double

### ElevationAngle — Elevation angle of response

0 (default) | scalar

Elevation angle at which to calculate the response, specified as a scalar. The elevation angle must lie in the interval from –90° to 90°, inclusive. Units are in degrees.

Example: 45.0

**Dependencies**

To enable this property, set the IQDataInput property to true.

Data Types: double

### AngleSpan — Azimuth angle span of response

[-90 90] (default) | real-valued 1-by-2 vector

Azimuth angle span at which to calculate response, specified as a real-valued 1-by-2 row vector. The object calculates the range-angle response within the angle range, [min_angle max_angle]. Angles must lie in the interval from –90° to 90°, inclusive. Units are in degrees.

Example: [-45 45]

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

**`NumAngleSamples` — Number of samples in azimuth angle span**
`256` (default) | positive integer greater than two

Number of samples in the azimuth angle span at which to calculate the range-angle response, specified as a positive integer greater than two.

Example: `256`

**Dependencies**

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

# Usage

# Syntax

```
scope(X,Range,Ang)
```

```
scope(X)
scope(X,XREF)
scope(X,COEFF)
```

## Description

`scope(X,Range,Ang)` displays a range-angle response map, `X`, at the ranges, `Range`, and angles, `Ang`. This syntax applies when you set the `IQDataInput` to `false`.

`scope(X)` computes and displays the range-angle response map for the dechirped signal `X`. This syntax applies when you set the `IQDataInput` property to `true`, the `RangeMethod` property to `'FFT'`, and the `DechirpInput` property to `false`. This syntax is most commonly used with FMCW signals.

scope(X,XREF) also specifies a reference signal to use for dechirping the input signal, X. This syntax applies when you set the IQDataInput property to true, the RangeMethod property to 'FFT', and the DechirpInput property to true. This syntax is most commonly used with FMCW signals. XREF is generally the transmitted signal.

scope(X,COEFF) also specifies matched filter coefficients, COEFF. This syntax applies when you set the IQDataInput property to true and the RangeMethod property to 'Matched Filter'. This syntax is most commonly used with pulsed signals.

## Input Arguments

### X — Input data

complex-valued *K*-by-*L* matrix

Input data, specified as a complex-valued *K*-by-*L* matrix. The interpretation of the data depends on the value of the IQDataInput property.

- When IQDataInput is true, the input consists of received fast-time data samples for each PRI pulse or FMCW sweep and for each array or subarray element. *K* denotes the number of fast-time (range) samples. *L* is the number of elements. If SensorArray contains subarrays, *L* is the number of subarrays. The scope computes and displays the range-angle response.

  - When RangeMethod is set to 'FFT' and DechirpInput is false, X has previously been dechirped.
  - When RangeMethod is set to 'FFT' and DechirpInput is true, X has not been previously dechirped. Use the syntax that includes XREF as input data.
  - When RangeMethod is set to 'MatchedFilter', X has not been match filtered. Use the syntax that includes COEFF as input data.
- When IQDataInput is false, the input already consists of response data in the range-angle domain, such as the data produced, for example, by RangeAngleResponse. Each row of the response map corresponds to an element of the Range vector. *K* is the number of range samples. Each column of the response map corresponds to an element of the Ang vector. *L* is the number of angles. The scope serves only as a display of the range-angle response.

### Range — Range grid values of range-angle response map

real-valued *K*-by-1 column vector

Range grid values of range-angle response map, specified as a real-valued *K*-by-1 column vector. `Range` denotes the range values at which the response has been computed. Elements of `Range` correspond to the rows of `X`.

**Dependencies**

To enable this argument, set the `IQInputData` property to `false`.

Data Types: `double`

### `Ang` — Angle grid values of range-angle response map

real-valued *L*-by-1 column vector

Angle grid values of response map, specified as a real-valued *K*-by-1 column vector. `Ang` denotes the angle values at which the response has been computed. Elements of `Ang` correspond to the columns of `X`.

**Dependencies**

To enable this argument, set the `IQInputData` property to `false`.

Data Types: `double`

### `XREF` — Reference signal

complex-valued K-by-1 column vector

Reference signal used to dechirp `X`. `XREF` must be a column vector with the same number of rows as `X`.

**Dependencies**

To enable this argument, set the `IQDataInput` property to `true`, the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`

Data Types: `double`
Complex Number Support: Yes

### `COEFF` — Matched filter coefficients

complex-valued column vector

Matched filter coefficients, specified as a complex-valued column vector.

**Dependencies**

To enable this argument, set the `IQDataInput` property to `true` and the `RangeMethod` property to `'Matched Filter'`.

Data Types: `double`
Complex Number Support: Yes

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Scope Objects

| | |
|---|---|
| show | Turn on visibility of scopes |
| hide | Turn off visibility of scope |
| isVisible | Visibility of scopes |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### View Target Response Using Range-Angle Scope

Calculate and visualize the range-angle response from a pulsed radar transmitting a rectangular waveform using a matched filter. One target is approximately 2000 m away and is stationary relative to the radar. The second target is approximately 3500 m away and is also stationary relative to the radar. The third is approximately 2000 m away and is moving away from the radar at approximately 100 m/s. The signals arrive at an 8-element uniform linear array.

Load the data to obtain signals and parameters.

```
load('RangeAngleResponseExampleData','rectdata');
fs = rectdata.fs;
c = rectdata.propspeed;
```

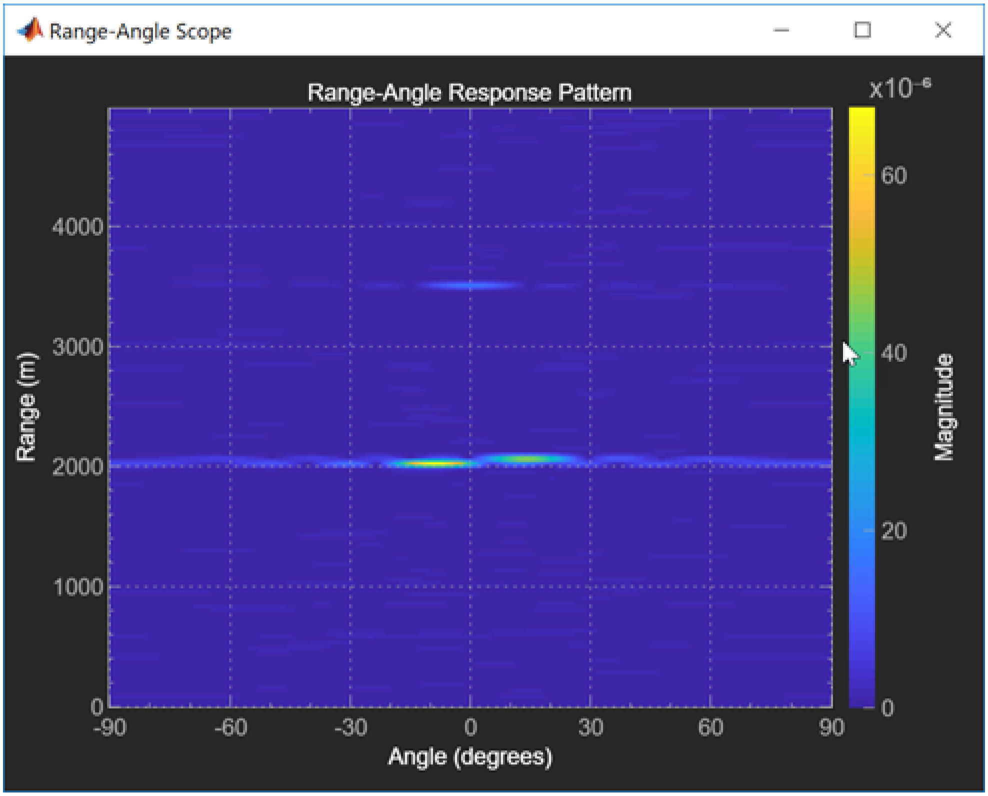
```
fc = rectdata.fc;
rxdata = rectdata.rxdata;
mfcoeffs = rectdata.mfcoeffs;
noisepower = rectdata.noisepower;
array = rectdata.antennaarray;
```

Create a range-angle scope for processing.

```
scope = phased.RangeAngleScope( ...
    'IQDataInput',true,'RangeMethod','Matched filter', ...
    'Name','Range-Angle Scope','ResponseUnits','magnitude', ...
    'Position',[560 375 560 420],'RangeUnits','m', ...
    'SensorArray',array,'OperatingFrequency',fc, ...
    'SampleRate',fs,'PropagationSpeed',c);
```

Call the scope to display the response map.

```
scope(rxdata,mfcoeffs);
```



# More About

## Properties Applicable to I/Q Data

These properties are applicable when `IQDataInput` is `true`.

| Properties | |
|---|---|
| `Name` | `Position` |
| `ResponseUnits` | `SensorArray` |
| `RangeMethod` | `PropagationSpeed` |

| Properties | |
|---|---|
| OperatingFrequency | RangeUnits |
| SampleRate | SweepSlope |
| DechirpInput | RangeFFTLength |
| ReferenceRangeCentered | ReferenceRange |
| ElevationAngle | AngleSpan |
| NumAngleSamples | |

## Properties Applicable to Response Data

These properties are applicable when `IQDataInput` is `false`.

| Properties | |
|---|---|
| Name | Position |
| ResponseUnits | RangeLabel |
| AngleLabel | |

**Introduced in R2019a**

# phased.AngleDopplerScope

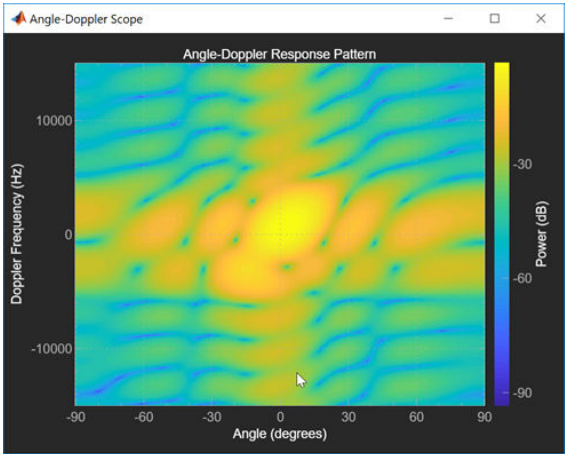
**Package:** `phased`

Angle-Doppler scope

## Description

The `phased.AngleDopplerScope` System object creates a scope for displaying an angle-Doppler response map. The map is a 2-D representation of response intensity as a function of angle and Doppler shift. You can input two types of data - in-phase and quadrature (I/Q) data and response data.

- I/Q data – The data consists of I/Q samples at the same range from multiple sensors over all pulses or sweeps. The scope computes and displays the response map. To use I/Q data, set the `IQDataInput` property to `true`. In this mode, you can set the properties listed in “Properties Applicable to I/Q Data” on page 1-1800.
- Response data – The data consists of the angle-Doppler response itself. The scope only displays the angle-Doppler response map. You can obtain angle-Doppler response data from the `phased.AngleDopplerResponse` object. To display response data, set the `IQDataInput` property to `false`. In this mode, you can set the properties listed in “Properties Applicable to Response Data” on page 1-1800.



To display an angle-Doppler response map using a scope,

1. Create the `phased.AngleDopplerScope` object and set its properties.
2. Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects? (MATLAB).

# Creation

## Syntax

```
scope = phased.AngleDopplerScope
scope = phased.phased.AngleDopplerScope(Name,Value)
```

### Description

`scope = phased.AngleDopplerScope` creates an angle-Doppler `scope` System object for displaying the angle-Doppler response map.

`scope = phased.phased.AngleDopplerScope(Name,Value)`creates an angle-Doppler `scope` with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). Enclose property names in quotes. For example,

```
scope = phased.AngleDopplerScope('IQInputData',true, ...
      'NumAngleSamples',128,'NumDopplerSamples',64)
```

creates a scope object that computes and displays the angle-Doppler response at 128 angle values and 64 Doppler values from I/Q data input.

# Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

### Name — Display caption

'Angle-Doppler Scope' (default) | character vector

Display caption, specified as a character vector. The caption appears in the title bar of the window.

Example: 'Aircraft Angle-Doppler Response'

**Tunable:** Yes

Data Types: char

### Position — Location and size of intensity scope window

depends on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form [left bottom width height].

- left and bottom specify the location of the bottom-left corner of the window.
- width and height specify the width and height of the window.

Units are in pixels.

The default value of this property depends on the resolution of your display. By default, the window is positioned in the center of the screen, with a width and height of 800 and 450 pixels, respectively.

Example: [100 100 500 400]

**Tunable:** Yes

Data Types: double

### IQDataInput — Type of input data

true (default) | false

Type of input data, specified as true or false. When true, the object assumes that the input consists of I/Q sample data and further processing is required in the range, angle, or Doppler domains. When false, the object assumes that the data is response data that has already been processed.

Data Types: logical

### `ResponseUnits` — Response units label

`'db'` (default) | `'magnitude'` | `'power'`

Response units, specified as `'db'`, `'magnitude'`, or `'power'`.

Data Types: `char`

### `AngleLabel` — Angle-axis label

`'Angle (degrees)'` (default) | character vector

Angle-axis label, specified as a character vector.

Example: `'Angle Span (degrees)'`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `IQDataInput` to `false`.

Data Types: `char`

### `DopplerLabel` — Doppler-axis label

`'Doppler Frequency (Hz)'` (default) | character vector

Doppler-axis label, specified as a character vector.

Example: `'Doppler Frequency (kHz)'`

**Tunable:** Yes

#### Dependencies

To enable this property, set the `IQDataInput` to `false`.

Data Types: `char`

### `SensorArray` — Sensor array

`phased.ULA` array with default array properties (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object. See `phased.ULA` for the default values of a uniform linear array.

Example: `phased.URA`

#### Dependencies

To enable this property, set the `IQDataInput` to `true`.

### `PropagationSpeed` — Signal propagation speed

`physconst('Lightspeed')` (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value of this property is the speed of light. See `physconst`. Units are in meters/second.

Example: `3e8`

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `OperatingFrequency` — Operating frequency

`300e6` (default) | positive scalar

Operating frequency, specified as a positive scalar. Units are in Hz.

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### PRF — Pulse repetition frequency of input signal

`1` (default) | positive scalar

Pulse repetition frequency of input signal, specified as a positive scalar. Units are in Hz.

Example: `1.4e3`

#### Dependencies

To enable this property, set the `IQDataInput` property to `true`.

Data Types: `double`

### `ElevationAngle` — Elevation angle of response

`0` (default) | scalar

Elevation angle at which to calculate the response, specified as a scalar. The elevation angle must lie in the interval from –90° to 90°, inclusive. Units are in degrees.

Example: 45.0

#### Dependencies

To enable this property, set the IQDataInput property to true.

Data Types: double

### NumAngleSamples — Number of bins in angle span

256 (default) | positive integer greater than two

Number of bins in the angle span at which to calculate the response, specified as a positive integer greater than two.

Example: 256

#### Dependencies

To enable this property, set the IQDataInput property to true.

Data Types: double

### NumDopplerSamples — Number of Doppler bins

256 (default) | positive integer greater than two

Number of bins in the Doppler domain used to calculate angle-Doppler response, specified as a positive integer greater than two.

Example: 512

#### Dependencies

To enable this property, set the IQDataInput property to true.

Data Types: double

### NormalizeDoppler — Normalize Doppler

false (default) | true

Set this property to true to plot the angle-Doppler response at the normalized Doppler frequency. Set this property to false to plot the angle-Doppler response without normalizing the Doppler frequency.

#### Dependencies

To enable this property, set the IQDataInput property to true.

Data Types: logical

### FrequencyUnits — Doppler frequency units

'Hz' (default) | 'kHz' | 'MHz'

Doppler frequency units, specified as 'Hz', 'kHz', or 'MHz'.

Example: 'MHz'

#### Dependencies

To enable this property, set the IQDataInput property to true and the NormalizedDoppler property to false.

Data Types: char

# Usage

# Syntax

```
scope(X,Ang,Dop)
```

```
scope(X)
```

## Description

scope(X,Ang,Dop) displays an angle-Doppler response map for the response data, scope, for direction azimuth angles, Ang, and Doppler shifts, Dop. This syntax applies when you set the IQDataInput to false.

scope(X) computes and displays the angle-Doppler response map of the I/Q data X. This syntax applies when you set the IQDataInput property to true.

## Input Arguments

### X — Input data

real-valued *P*-by-*Q* matrix | complex-valued *P*-by-*Q* matrix | complex-valued *L*-by-1 column vector

Input data, specified as a real-valued *P*-by-*Q* or complex-valued *P*-by-*Q* matrix. The processing of the data depends on the value of the `IQDataInput` property.

- When `IQDataInput` is `true`, `x` consists of I/Q samples at fixed range of pulses or sweeps from multiple elements or subarrays. *P* is the number of array elements. If `SensorArray` contains subarrays, *P* is the number of subarrays. *Q* is the number of pulses. The scope computes and displays the angle-Doppler response.

  When `x` is a column vector, *L* must be equal to an integer multiple of *P*.
- When `IQDataInput` is `false`, `x` consists of real-valued angle-Doppler response data such as the data produced by `phased.AngleDopplerResponse`. *P* is the number of Doppler samples and *Q* is the number of angle samples. Each row represents a Doppler value corresponding to an element of `Dop`. Each column represents an angle value corresponding to an element of the `Ang` vector. The scope serves only as a display of the angle-Doppler response.

### Ang — Azimuth angle grid values of response map

real-valued *Q*-by-1 column vector

Azimuth angle grid values of response map, specified as a real-valued *Q*-by-1 column vector. `Ang` contains the angle values corresponding to the columns of `X`.

#### Dependencies

To enable this argument, set the `IQInputData` property to `false`.

Data Types: `double`

### Dop — Doppler grid values of response map

real-valued *P*-by-1 column vector

Doppler grid values of response map, specified as a real-valued *P*-by-1 column vector. `Dop` contains the Doppler values corresponding to the rows of `X`.

#### Dependencies

To enable this argument, set the `IQInputData` property to `false`.

Data Types: `double`

# Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Scope Objects

| | |
|---|---|
| show | Turn on visibility of scopes |
| hide | Turn off visibility of scope |
| isVisible | Visibility of scopes |

## Common to All System Objects

| | |
|---|---|
| step | Run System object algorithm |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset | Reset internal states of System object |

# Examples

### View Target Response Using Angle-Doppler Scope

Calculate and visualize the angle-Doppler response at a single range cell of a collected data cube.

Load the I/Q data and analyze the 43th range cell.

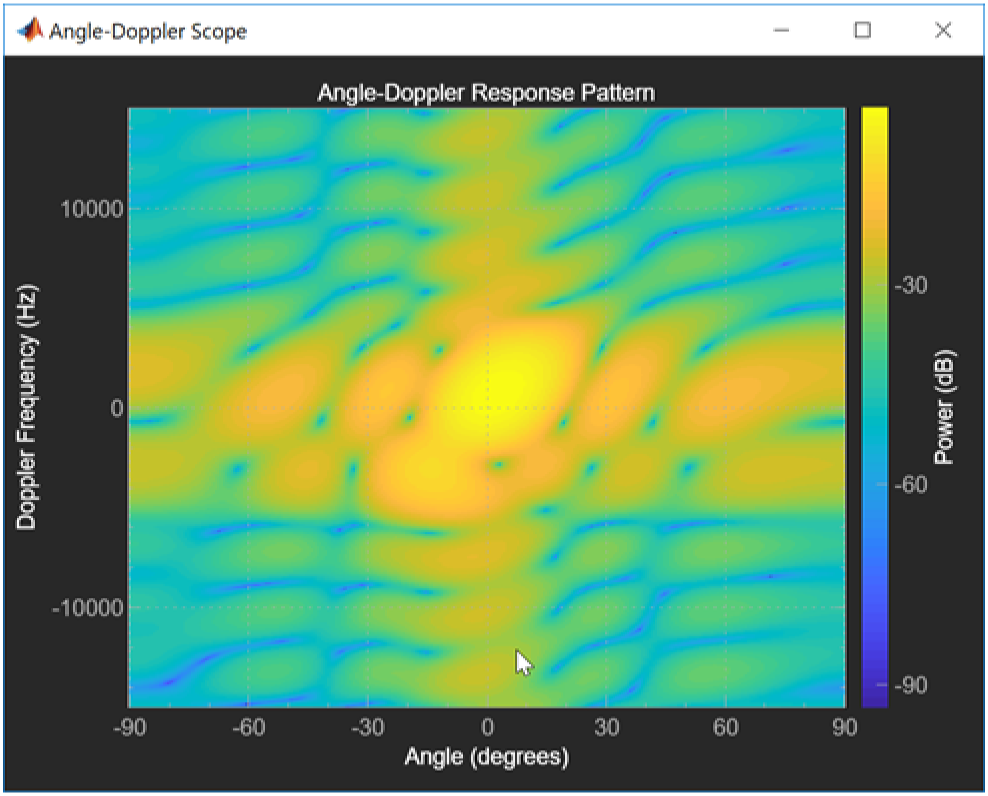
```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(43,:,:));
```

Create a scope object that processes I/Q data.

```
scope = phased.AngleDopplerScope( ...
    'IQDataInput', true, ...
    'Name','Angle-Doppler Scope', ...
    'Position',[560 375 560 420], ...
    'NormalizeDoppler',false, ...
    'ResponseUnits','db', ...
    'SensorArray',STAPEx_HArray, ...
    'OperatingFrequency',STAPEx_OperatingFrequency, ...
    'PropagationSpeed',STAPEx_PropagationSpeed, ...
    'PRF',STAPEx_PRF,'NumDopplerSamples',512);
```

Compute and visualize the angle-Doppler response.

```
scope(x)
```



# More About

## Properties Applicable to I/Q Data

These properties are applicable when `IQDataInput` is `true`.

| Properties | |
|---|---|

**Package:** phased

Visibility of scopes

## Syntax

```
vis = isVisible(scope)
```

## Description

`vis = isVisible(scope)` returns the visibility of the `scope` System object.

## Input Arguments

### scope — Scope system object

scope System object

Scope, specified as a scope System object such as `RangeDopplerScope`.

## Output Arguments

### vis — Visibility of scope

`true` | `false`

Visibility of scope, returned as `true` or `false`. When `true`, `scope` is visible. When `false`, `scope` is hidden.

Data Types: `logical`

# phased.RangeDopplerResponse

**Package:** `phased`

Range-Doppler response

## Description

The `phased.RangeDopplerResponse` System object calculates the filtered response to fast-time and slow-time data. or equivalently, range data, using either a matched filter or an FFT.

The input to the Doppler response object is a data cube. The organization of the data cube follows the Phased Array System Toolbox convention. The first dimension of the cube represents the fast-time samples or ranges of the received signals. The second dimension represents multiple channels such as sensors or beams. The third dimension, slow time, represent pulses. If the data contains only one channel or pulse, the data cube can contain fewer than three dimensions. Range processing operates along the first dimension of the cube. Doppler processing operates along the last dimension.

The output of the object is also a data cube with the same number of dimensions as the input. The first dimension contains range-processed data but its length can differ from the first dimension of the input. The last dimension contains Doppler processed data. Its length can differ from the last dimension of the input.

To compute the range-Doppler response:

1. Define and set up your `phased.RangeDopplerResponse` System object. See “Construction” on page 1-1806.
2. Call `step` to compute the range-Doppler response of the input signal according to the properties of `phased.RangeDopplerResponse`. The behavior of `step` is specific to each object in the toolbox.

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

## Construction

`H = phased.RangeDopplerResponse` creates a range-Doppler response System object, `H`. The object calculates the range-Doppler response of the input data.

`H = phased.RangeDopplerResponse(Name,Value)` creates a range-Doppler response object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name on page 1-1806, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

## Properties

### `RangeMethod`

Range processing method

Specify the method of range processing as `'Matched filter'` or `'FFT'`.

| | |
|---|---|
| `'Matched filter'` | Algorithm applies a matched filter to the incoming signal. This approach is common with pulsed signals, where the matched filter is the time reverse of the transmitted signal. |
| `'FFT'` | Algorithm performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW and linear FM pulsed signals. |

**Default:** `'Matched filter'`

### `PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can specify this property as single or double precision.

**Default:** Speed of light

### `SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. This property can be specified as single or double precision. The default value corresponds to 1 MHz.

**Default:** `1e6`

### `SweepSlope`

FM sweep slope

Specify the slope of the linear FM sweeping, in hertz per second, as a scalar. The `x` data you provide to `step` or `plotResponse` must correspond to sweeps having this slope. This property can be specified as single or double precision.

To enable this property, set the `RangeMethod` property to `'FFT'`.

**Default:** `1e9`

### `DechirpInput`

Option to dechirp input signal

Set this property to `true` to have the range-Doppler response object dechirp the input signal. Set this property to `false` to indicate that the input signal is already dechirped and no dechirp operation is necessary.

To enable this property, set the `RangeMethod` property to `'FFT'`.

**Default:** `false`

### `DecimationFactor`

Decimation factor for dechirped signal

Specify the decimation factor for the dechirped signal as a positive integer. When processing FMCW signals, you can often decimate the dechirped signal to reduce the requirements on the analog-to-digital converter.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`. This property can be specified as single or double precision. The default value indicates no decimation.

**Default:** `1`

### RangeFFTLengthSource

Source of FFT length used in range processing

Specify how the object determines the FFT length used in range processing. Values of this property are:

| | |
|---|---|
| 'Auto' | The FFT length equals the number of rows of the input signal. |
| 'Property' | The RangeFFTLength property of this object specifies the FFT length. |

To enable this property, set the RangeMethod property to 'FFT'.

**Default:** 'Auto'

### RangeFFTLength

FFT length in range processing

Specify the FFT length in the range domain as a positive integer. This property can be specified as single or double precision.

To enable this property, set the RangeMethod property to 'FFT' and the RangeFFTLengthSource property to 'Property'.

**Default:** 1024

### RangeWindow

Window for range weighting

Specify the window used for range processing using one of 'None', 'Hamming', 'Chebyshev', 'Hann', 'Kaiser', 'Taylor', or 'Custom'. If you set this property to 'Taylor', the generated Taylor window has four nearly constant sidelobes adjacent to the mainlobe.

To enable this property, set the RangeMethod property to 'FFT'.

**Default:** 'None'

### RangeSidelobeAttenuation

Sidelobe attenuation level for range processing

Specify the sidelobe attenuation level of a Kaiser, Chebyshev, or Taylor window in range processing as a positive scalar, in decibels. This property can be specified as single or double precision.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Kaiser'`, `'Chebyshev'`, or `'Taylor'`.

**Default:** `30`

### CustomRangeWindow

User-defined window for range processing

Specify the user-defined window for range processing using a function handle or a cell array.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Custom'`.

If `CustomRangeWindow` is a function handle, the specified function takes the window length as the input and generates appropriate window coefficients.

If `CustomRangeWindow` is a cell array, then the first cell must be a function handle. The specified function takes the window length as the first input argument, with other additional input arguments, if necessary. The function then generates appropriate window coefficients. The remaining entries in the cell array are the additional input arguments to the function, if any.

**Default:** `@hamming`

### ReferenceRangeCentered

Set reference range at center of range grid, specified as `true` or `false`. Setting this property to `true` enables you to set the reference range at the center of the range grid. Setting this property to `false` sets the reference range to the beginning of the range grid.

#### Dependencies

To enable this property, set the `RangeMethod` to `'FFT'`.

**Default:** `true`

### ReferenceRange

Reference range of the range grid, specified as a nonnegative scalar.

- If you set the `RangeMethod` property to `'Matched filter'`, the reference range is set to the start of the range grid.
- If you set the `RangeMethod` property to `'FFT'`, the reference range is determined by the `ReferenceRangeCentered` property.

  - When you set the `ReferenceRangeCentered` property to `true`, the reference range is set to the center of the range grid.
  - When you set the `ReferenceRangeCentered` property to `false`, the reference range is set to the start of the range grid.

  This property can be specified as single or double precision. Units are in meters.

This property is tunable.

Example: `1000.0`

**Default:** `0.0`

### PRFSource

Source of pulse repetition frequency

Source of pulse repetition frequency, specified as

- `'Auto'` — You assume that the pulse repetition frequency (prf) is the inverse of the duration of the input signal to the `step` method. Then the prf equals the sample rate of the signal divided by the number of rows in the input signal.
- `'Property'`— specify the pulse repetition frequency using the `PRF` property.
- `'Input port'`— specify the PRF using an input argument of the `step` method.

Use the `'Property'` or `'Input port'` option when the pulse repetition frequency cannot be determined by the signal duration, as is the case with range-gated data.

**Default:** `'Auto'`

### PRF

Pulse repetition frequency of input signal

Pulse repetition frequency of the input signal, specified as a positive scalar. PRF must be less than or equal to the sample rate divided by the number of rows of the input signal to the `step` method. When the signal length is variable, use the maximum possible number of rows of the input signal instead. This property can be specified as single or double precision.

To enable this property, set the `PRFSource` property to `'Property'`.

**Default:** `10e3`

### DopplerFFTLengthSource

Source of FFT length in Doppler processing

Specify how the object determines the FFT length in Doppler processing. Values of this property are:

| | |
|---|---|
| `'Auto'` | The FFT length is equal to the number of rows of the input signal. |
| `'Property'` | The `DopplerFFTLength` property of this object specifies the FFT length. |

To enable this property, set the `RangeMethod` property to `'FFT'`.

**Default:** `'Auto'`

### DopplerFFTLength

FFT length for Doppler processing

FFT length for Doppler processing, specified as a positive integer. This property can be specified as single or double precision.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DopplerFFTLengthSource` property to `'Property'`.

**Default:** `1024`

### DopplerWindow

Window for Doppler weighting

Specify the window used for Doppler processing using one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`. If you set this property to `'Taylor'`, the generated Taylor window has four nearly constant sidelobes adjacent to the mainlobe.

To enable this property, set the `RangeMethod` property to `'FFT'`.

**Default:** `'None'`

### DopplerSidelobeAttenuation

Sidelobe attenuation level for Doppler processing

Specify the sidelobe attenuation level of a Kaiser, Chebyshev, or Taylor window in Doppler processing as a positive scalar, in decibels. This property can be specified as single or double precision.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DopplerWindow` property to `'Kaiser'`, `'Chebyshev'`, or `'Taylor'`.

**Default:** `30`

### CustomDopplerWindow

User-defined window for Doppler processing

Specify the user-defined window for Doppler processing using a function handle or a cell array..

If `CustomDopplerWindow` is a function handle, the specified function takes the window length as the input and generates appropriate window coefficients.

If `CustomDopplerWindow` is a cell array, then the first cell must be a function handle. The specified function takes the window length as the first input argument, with other additional input arguments, if necessary. The function then generates appropriate window coefficients. The remaining entries in the cell array are the additional input arguments to the function, if any.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DopplerWindow` property to `'Custom'`

**Default:** `@hamming`

### `DopplerOutput`

Doppler domain output

Specify the Doppler domain output as `'Frequency'` or `'Speed'`. The Doppler domain output is the `DOP_GRID` argument of `step`.

| | |
|---|---|
| `'Frequency'` | `DOP_GRID` is the Doppler shift, in hertz. |
| `'Speed'` | `DOP_GRID` is the radial speed corresponding to the Doppler shift, in meters per second. |

**Default:** `'Frequency'`

### `OperatingFrequency`

Signal carrier frequency

Specify the carrier frequency, in hertz, as a scalar. The default value of this property corresponds to 300 MHz. This property can be specified as single or double precision.

To enable this property, set the `DopplerOutput` property to `'Speed'`

**Default:** `3e8`

### `MaximumNumInputSamplesSource`

Source of maximum number of samples

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the object automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

**Default:** `'Auto'`

#### `MaximumNumInputSamples`

Maximum number of input signal samples

Maximum number of samples in the input signal, specified as a positive integer. This property limits the size of the input signal. Any input signal longer than this value is truncated. The input signal is the first argument to the `step` method. The number of samples is the number of rows in the input. This property can be specified as single or double precision.

To enable this property, set the `RangeMethod` property to `'Matched filter'` and set the `MaximumNumInputSamplesSource` property to `'Property'`.

**Default:** `100`

## Methods

| | |
|---|---|
| plotResponse | Plot range-Doppler response |
| step | Calculate range-Doppler response |

| Common to All System Objects | |
|---|---|
| `release` | Allow System object property value changes |

## Examples

### Range-Doppler Response Using Matched Filter

Compute the range-doppler response of a pulsed radar signal using a matched filter.

Load data for a pulsed radar signal. The signal includes three target returns. Two targets are approximately 2000 m away, while the third is approximately 3500 m away. In addition, two of the targets are stationary relative to the radar. The third is moving away from the radar at about 100 m/s.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

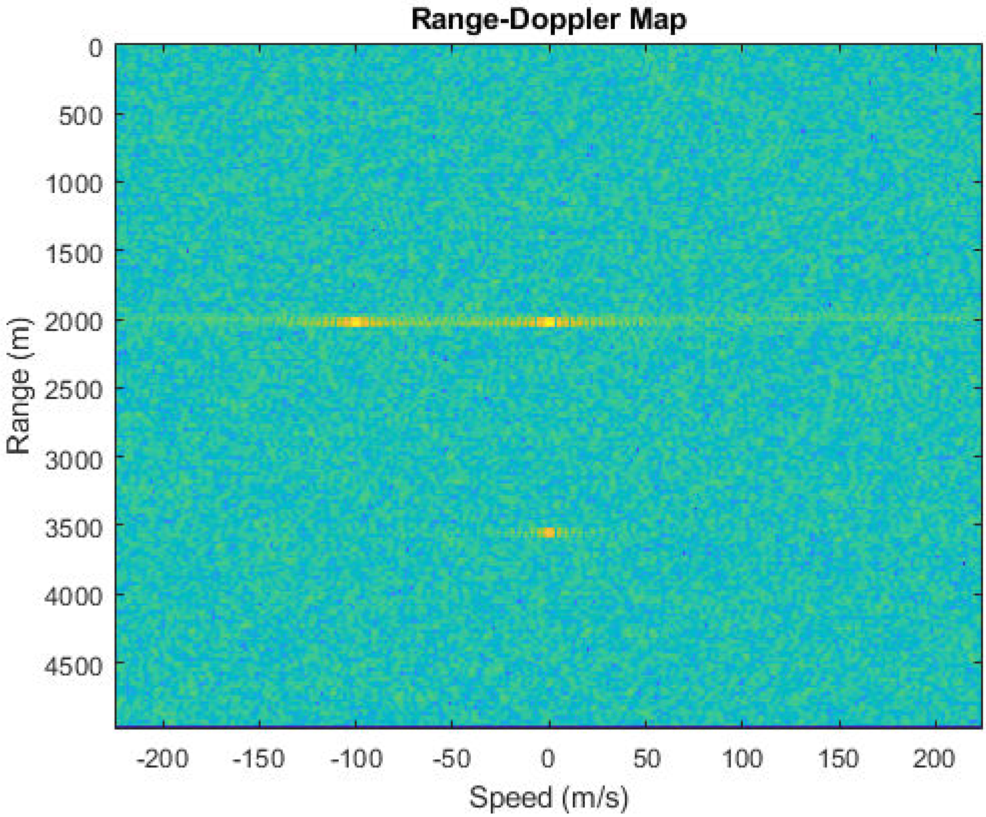
```
response = phased.RangeDopplerResponse('DopplerFFTLengthSource','Property', ...
   'DopplerFFTLength',RangeDopplerEx_MF_NFFTDOP, ...
   'SampleRate',RangeDopplerEx_MF_Fs,'DopplerOutput','Speed', ...
   'OperatingFrequency',RangeDopplerEx_MF_Fc);
```

Calculate the range-Doppler response.

```
[resp,rng_grid,dop_grid] = response(RangeDopplerEx_MF_X, ...
    RangeDopplerEx_MF_Coeff);
```

Plot the range-Doppler response.

```
imagesc(dop_grid,rng_grid,mag2db(abs(resp)));
xlabel('Speed (m/s)');
ylabel('Range (m)');
title('Range-Doppler Map');
```



### Range-Doppler Response of FMCW Signal

Compute the range-Doppler response of an FMCW signal using an FFT.

Load data for an FMCW signal that has not been dechirped. The signal contains the return from a target about 2200 m away. The signal has a normalized Doppler frequency of approximately -0.36 relative to the radar.

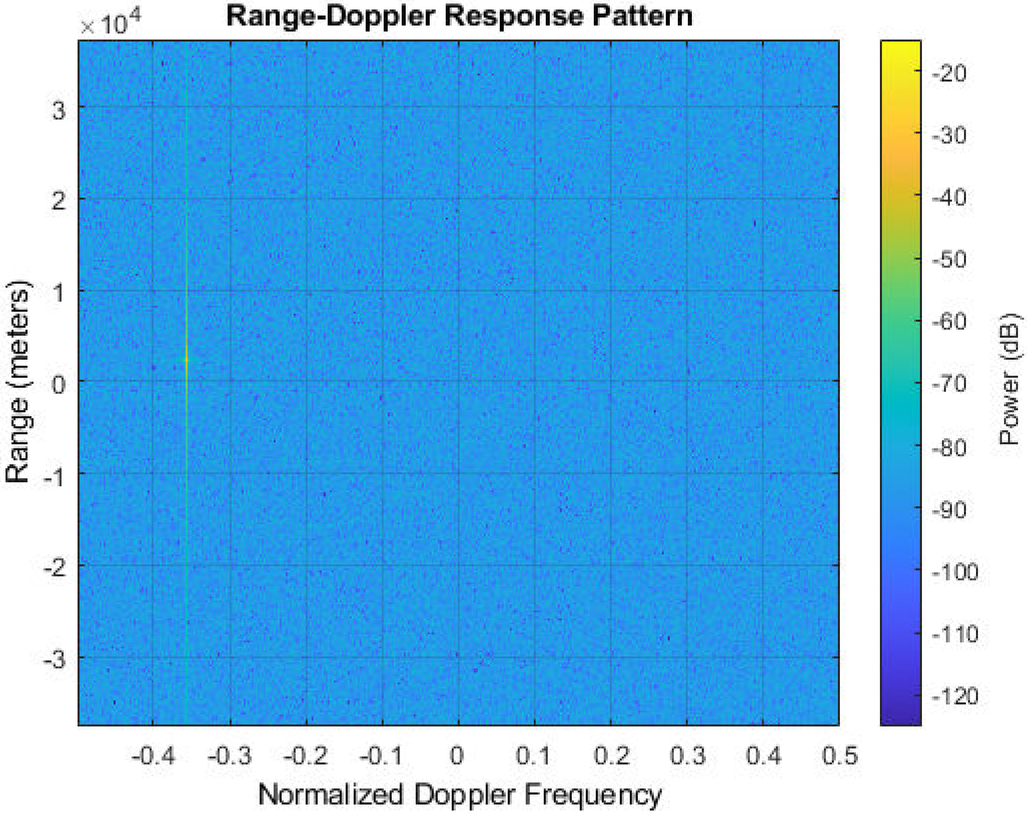
```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

```
hrdresp = phased.RangeDopplerResponse(...
   'RangeMethod','FFT',...
   'PropagationSpeed',RangeDopplerEx_Dechirp_PropSpeed,...
   'SampleRate',RangeDopplerEx_Dechirp_Fs,...
   'DechirpInput',true,...
   'SweepSlope',RangeDopplerEx_Dechirp_SweepSlope);
```

Plot the range-Doppler response.

```
plotResponse(hrdresp,...
   RangeDopplerEx_Dechirp_X,RangeDopplerEx_Dechirp_Xref,...
   'Unit','db','NormalizeDoppler',true)
```



### Estimate Doppler and Range with Specified PRF

Estimate the Doppler and range responses for three targets. Two targets are approximately 2000 m away, while the third is approximately 3500 m away. In addition, two of the targets are stationary relative to the radar. The third is moving away from the radar at about 100 m/s. Specify the pulse repetition frequency.

Load data for a pulsed radar signal.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object. Set the PRF to 25 kHz.

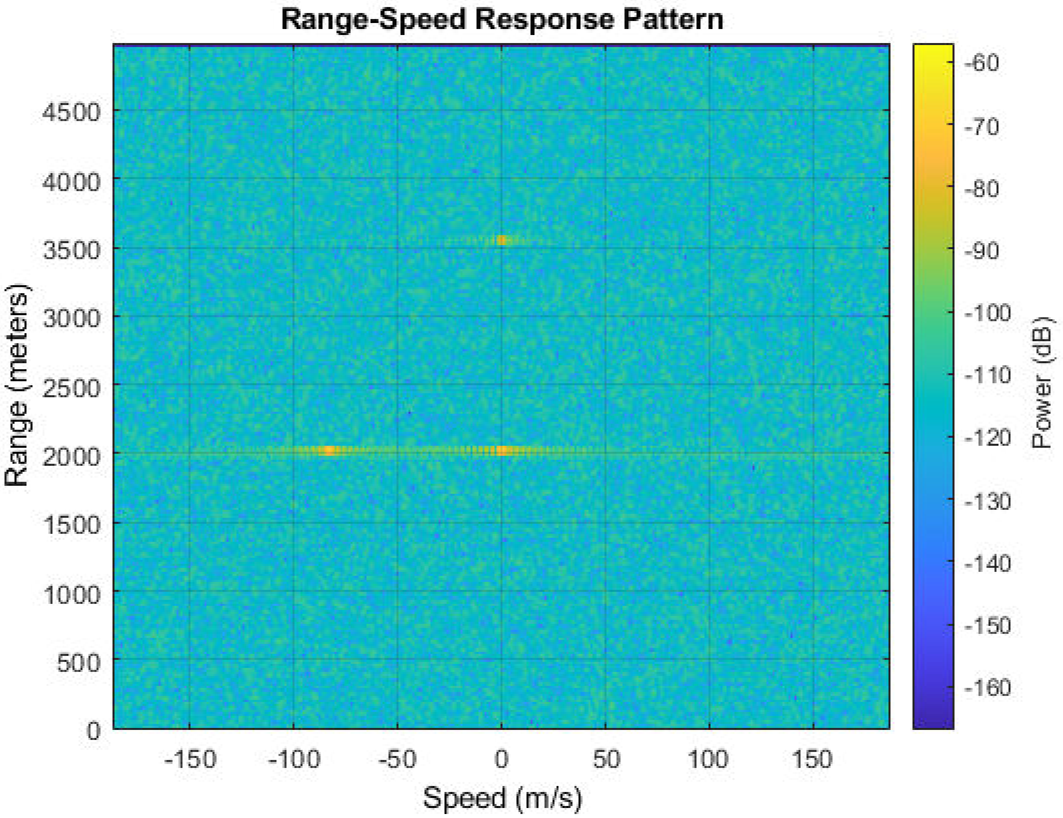
```
response = phased.RangeDopplerResponse('DopplerFFTLengthSource','Property', ...
   'DopplerFFTLength',RangeDopplerEx_MF_NFFTDOP,'SampleRate', ...
   RangeDopplerEx_MF_Fs,'DopplerOutput','Speed','OperatingFrequency', ...
   RangeDopplerEx_MF_Fc,'PRFSource','Property','PRF',25.0e3);
```

Calculate the range-Doppler response.

```
[resp,rng_grid,dop_grid] = response(RangeDopplerEx_MF_X, ...
    RangeDopplerEx_MF_Coeff);
```

Plot the range-Doppler response.

```
plotResponse(response,RangeDopplerEx_MF_X,RangeDopplerEx_MF_Coeff,'Unit','db')
```



# Algorithms

## Response Algorithm

The `phased.RangeDopplerResponse` object generates a response as follows:

1. Processes the input signal in the fast-time dimension using either a matched filter or dechirp/FFT operation.
2. Processes the input signal in the pulse dimension using an FFT.

The decimation algorithm uses a 30th order FIR filter generated by `fir1(30,1/R)`, where `R` is the value of the `DecimationFactor` property.

### Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `CustomRangeWindow` and `CustomDopplerWindow` properties are not supported.
- The `plotResponse` method is not supported.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This System object supports single and double precision for input data, properties, and arguments. If the input data `X` is single precision, the output data is single precision. If the input data `X` is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# plotResponse

**System object:** `phased.RangeDopplerResponse`
**Package:** `phased`

Plot range-Doppler response

## Syntax

```
plotResponse(H,x)
plotResponse(H,x,xref)
plotResponse(H,x,coeff)
plotResponse( ___ ,Name,Value)
hPlot = plotResponse( ___ )
```

## Description

`plotResponse(H,x)` plots the range-Doppler response of the input signal, `x`, in decibels. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`.

`plotResponse(H,x,xref)` plots the range-Doppler response after performing a dechirp operation on `x` using the reference signal, `xref`. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`.

`plotResponse(H,x,coeff)` plots the range-Doppler response after performing a matched filter operation on `x` using the matched filter coefficients in `coeff`. This syntax is available when you set the `RangeMethod` property to `'Matched filter'`.

`plotResponse( ___ ,Name,Value)` plots the angle-Doppler response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns the handle of the image in the figure window, using any of the input arguments in the previous syntaxes.

## Input Arguments

### `H`

Range-Doppler response object.

### `x`

Input data. Specific requirements depend on the syntax:

- In the syntax `plotResponse(H,x)`, each column of the matrix `x` represents a dechirped signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive.
- In the syntax `plotResponse(H,x,xref)`, each column of the matrix `x` represents a signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive and have not been dechirped yet.
- In the syntax `plotResponse(H,x,coeff)`, each column of the matrix `x` represents a signal from one pulse. The function assumes all pulses in `x` are consecutive.

In the case of an FMCW waveform with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeDopplerResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeDopplerResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. In the plot, change the tick mark labels on the horizontal axis to reflect that the Doppler or speed values are half of what the plot shows by default.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. In the plot, change the tick mark labels on the horizontal axis to reflect that the Doppler or speed values are half of what the plot shows by default.

You can specify this argument as single or double precision.

### `xref`

Reference signal, specified as a column vector having the same number of rows as `x`. You can specify this argument as single or double precision.

**coeff**

Matched filter coefficients, specified as a column vector. You can specify this argument as single or double precision.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**NormalizeDoppler**

Set this value to `true` to normalize the Doppler frequency. Set this value to `false` to plot the range-Doppler response without normalizing the Doppler frequency. This parameter applies when you set the `DopplerOutput` property of `H` to `'Frequency'`.

**Default:** `false`

**Unit**

The unit of the plot. Valid values are `'db'`, `'mag'`, and `'pow'`.

**Default:** `'db'`

# Examples

### Range-Doppler Response of FMCW Signal

Compute the range-Doppler response of an FMCW signal using an FFT.

Load data for an FMCW signal that has not been dechirped. The signal contains the return from a target about 2200 m away. The signal has a normalized Doppler frequency of approximately -0.36 relative to the radar.

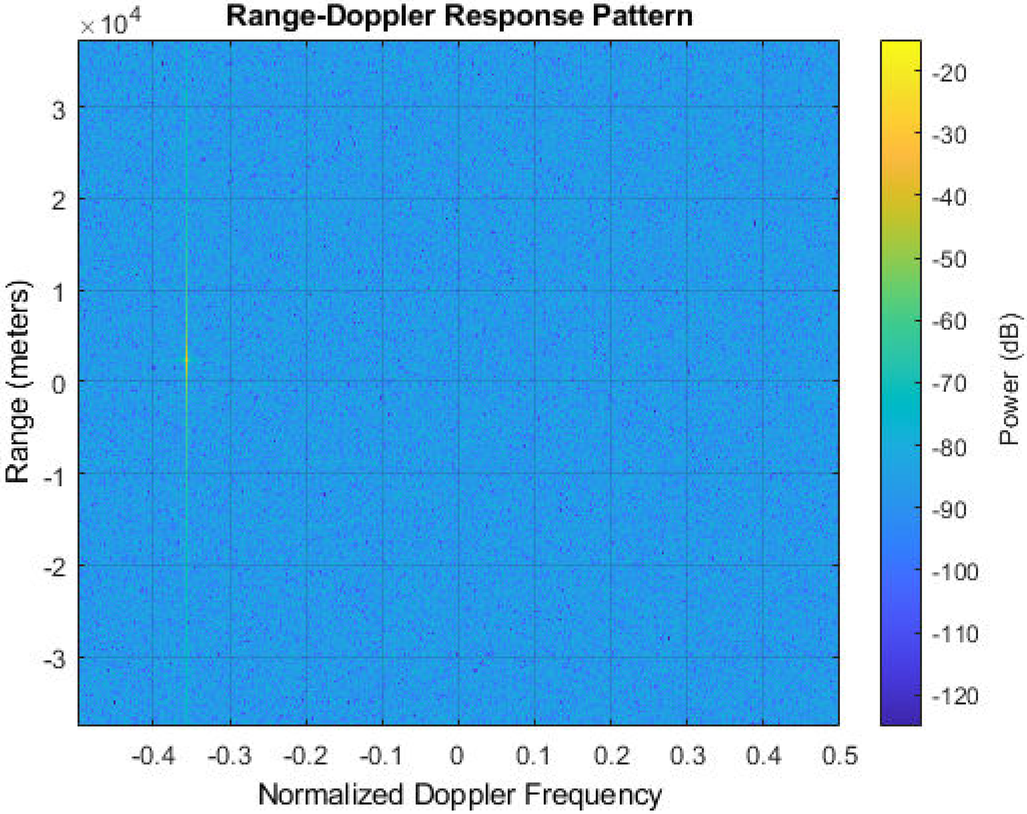
```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

```
hrdresp = phased.RangeDopplerResponse(...
   'RangeMethod','FFT',...
   'PropagationSpeed',RangeDopplerEx_Dechirp_PropSpeed,...
   'SampleRate',RangeDopplerEx_Dechirp_Fs,...
   'DechirpInput',true,...
   'SweepSlope',RangeDopplerEx_Dechirp_SweepSlope);
```

Plot the range-Doppler response.

```
plotResponse(hrdresp,...
   RangeDopplerEx_Dechirp_X,RangeDopplerEx_Dechirp_Xref,...
   'Unit','db','NormalizeDoppler',true)
```



## See Also

# step

**System object:** `phased.RangeDopplerResponse`
**Package:** `phased`

Calculate range-Doppler response

## Syntax

```
[resp,rnggrid,dopgrid] = step(H,x)
[resp,rnggrid,dopgrid] = step(H,x,xref)
[resp,rnggrid,dopgrid] = step(H,x,coeff)
[resp,rnggrid,dopgrid] = step(H,___,prf)
```

## Description

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[resp,rnggrid,dopgrid] = step(H,x)` calculates the range-Doppler response of the input signal, `x`. `resp` is the complex range-Doppler response. `rnggrid` and `dopgrid` provide the range samples and Doppler samples, respectively, at which the range-Doppler response is evaluated. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`. This syntax is most commonly used with FMCW signals.

`[resp,rnggrid,dopgrid] = step(H,x,xref)` uses `xref` as the reference signal to dechirp `x`. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`. This syntax is most commonly used with FMCW signals, where the reference signal is typically the transmitted signal.

`[resp,rnggrid,dopgrid] = step(H,x,coeff)` uses `coeff` as the matched filter coefficients. This syntax is available when you set the `RangeMethod` property to

`'Matched filter'`. This syntax is most commonly used with pulsed signals, where the matched filter is the time reverse of the transmitted signal.

`[resp,rnggrid,dopgrid] = step(H,___,prf)` uses `prf` as the pulse repetition frequency. These syntaxes are available when you set the `PRFSource` property to `'Input port'`. This syntax is most commonly used with pulsed signals, where the matched filter is the time reverse of the transmitted signal.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `H`

Range-Doppler response System object

### `x`

Input data, specified as a complex-valued *K*-by-*L* matrix or *K*-by-*N*-by-*L* array where

- *K* denotes the number of fast-time samples.
- *N* denotes the number of channels such as beams or sensors. When *N* is one, only a single data channel is present.
- *L* denotes the number of pulses for matched-filter processing and the number of sweeps for FFT processing.

Specific requirements depend on the syntax:

- In the syntax `step(H,x)`, each column of `x` represents a dechirped signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive.
- In the syntax `step(H,x,xref)`, each column of `x` represents a signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive and are not dechirped.

- In the syntax `step(H,x,coeff)`, each column of the matrix `x` represents a signal from one pulse. The function assumes all pulses in `x` are consecutive.

  The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

In the case of an FMCW waveform with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeDopplerResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeDopplerResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

You can specify this argument as single or double precision.

### `xref`

Reference signal, specified as a column vector having the same number of rows as `x`. You can specify this argument as single or double precision.

### `coeff`

Matched filter coefficients, specified as a column vector. You can specify this argument as single or double precision.

### `prf`

Pulse repetition frequency, specified as a positive scalar. `prf` must be less than or equal to the sample rate specified in the `SampleRate` property divided by the length of the first dimension of the input signal, `x`. You can specify this argument as single or double precision.

To enable this argument, set the `PRFSource` property to `'Input port'`.

## Output Arguments

### resp

Range-Doppler response of x, returned as a complex-valued *M*-by-*P* matrix or a *M*-by-*N*-by-*P* array. The values of *P* and *M* depend on the syntax. *N* has the same value as for the input argument, x.

| Syntax | Values of *M* and *P* |
|---|---|
| `step(H,x)` | If you set the `RangeFFTLength` property to `'Auto'`, *M* = *K*, the length of the first dimension of x. Otherwise, *M* equals the value of the `RangeFFTLength` property.<br>If you set the `DopplerFFTLength` property to `'Auto'`, *P* = *L*, the length of the last dimension of x. Otherwise, *P* equals the value of the `DopplerFFTLength` property. |
| `step(H,x,xref)` | *M* is the quotient of the length of the first dimension of x divided by the value of the `DecimationFactor` property.<br>If you set the `DopplerFFTLength` property to `'Auto'`, *P* = *L*, the length of the last dimension of x. Otherwise, *P* equals the value of the `DopplerFFTLength` property. |
| `step(H,x,coeff)` | *M* is the number of rows of x.<br>If you set the `DopplerFFTLength` property to `'Auto'`, *P* = *L*, the length of the last dimension of x. Otherwise, *P* equals the value of the `DopplerFFTLength` property. |

### rnggrid

Range samples at which the range-Doppler response is evaluated. `rnggrid` is a column vector of length *M*.

**dopgrid**

Doppler samples or speed samples at which the range-Doppler response is evaluated. `dopgrid` is a column vector of length *P*. Whether `dopgrid` contains Doppler or speed samples depends on the `DopplerOutput` property of `H`.

# Examples

### Range-Doppler Response Using Matched Filter

Compute the range-doppler response of a pulsed radar signal using a matched filter.

Load data for a pulsed radar signal. The signal includes three target returns. Two targets are approximately 2000 m away, while the third is approximately 3500 m away. In addition, two of the targets are stationary relative to the radar. The third is moving away from the radar at about 100 m/s.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

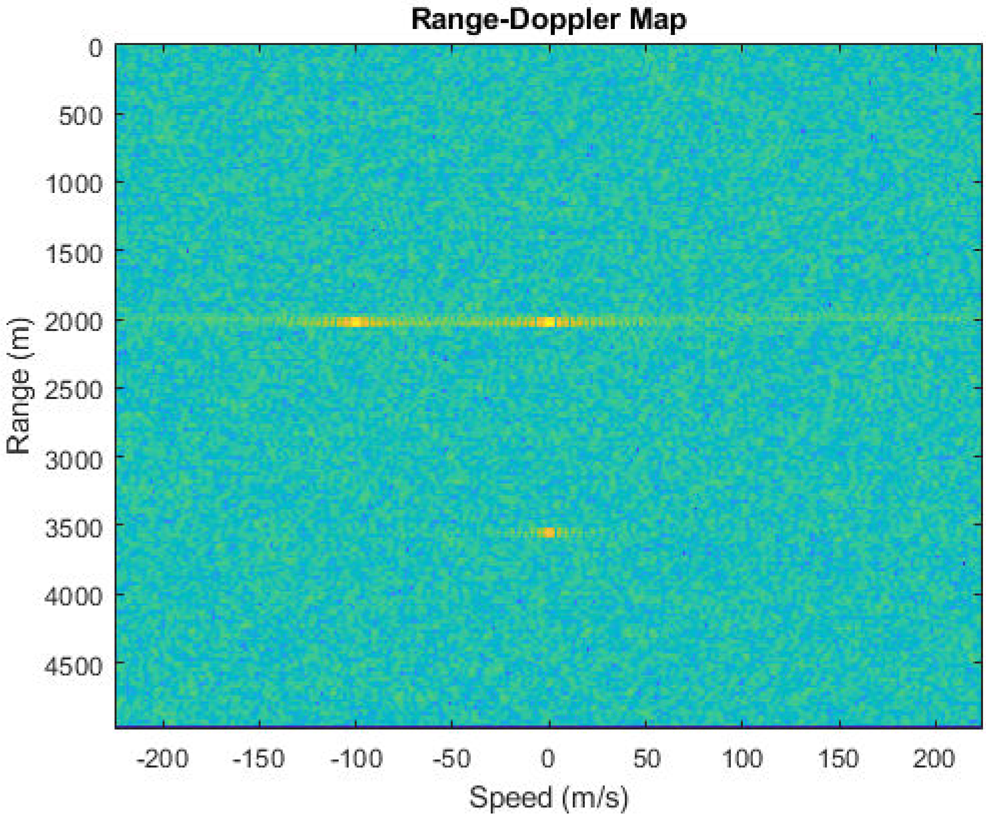
```
response = phased.RangeDopplerResponse('DopplerFFTLengthSource','Property', ...
   'DopplerFFTLength',RangeDopplerEx_MF_NFFTDOP, ...
   'SampleRate',RangeDopplerEx_MF_Fs,'DopplerOutput','Speed', ...
   'OperatingFrequency',RangeDopplerEx_MF_Fc);
```

Calculate the range-Doppler response.

```
[resp,rng_grid,dop_grid] = response(RangeDopplerEx_MF_X, ...
    RangeDopplerEx_MF_Coeff);
```

Plot the range-Doppler response.

```
imagesc(dop_grid,rng_grid,mag2db(abs(resp)));
xlabel('Speed (m/s)');
ylabel('Range (m)');
title('Range-Doppler Map');
```



### Estimate Doppler and Range from Range-Doppler Response

Estimate the Doppler and range values of a single target from the range-Doppler response.

Load data for an FMCW signal that has not yet been dechirped. The signal contains the return from one target.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

```
hrdresp = phased.RangeDopplerResponse(...
   'RangeMethod','FFT',...
   'PropagationSpeed',RangeDopplerEx_Dechirp_PropSpeed,...
   'SampleRate',RangeDopplerEx_Dechirp_Fs,...
   'DechirpInput',true,...
   'SweepSlope',RangeDopplerEx_Dechirp_SweepSlope);
```

Obtain the range-Doppler response data.

```
[resp,rng_grid,dop_grid] = step(hrdresp,...
   RangeDopplerEx_Dechirp_X,RangeDopplerEx_Dechirp_Xref);
```

Estimate the range and Doppler by finding the location of the maximum response.

```
[x_temp,idx_temp] = max(abs(resp));
[~,dop_idx] = max(x_temp);
rng_idx = idx_temp(dop_idx);
dop_est = dop_grid(dop_idx)
```

```
dop_est = -712.8906
```

```
rng_est = rng_grid(rng_idx)
```

```
rng_est = 2250
```

The target is approximately 2250 meters away, and is moving fast enough to cause a Doppler shift of approximately -713 Hz.

# phased.RangeEstimator

**Package:** phased

Range estimation

## Description

The phased.RangeEstimator System object estimates the ranges of targets. Input to the estimator consists of a range-response or range-Doppler response data cube, and detection locations from a detector. When information about clusters of detections is available, the ranges are computed using cluster information. Clustering associates multiple detections into one extended detection.

To compute the detections for a range-response or range-Doppler cube:

1. Define and set up a range estimator using the “Construction” on page 1-1834 procedure that follows.
2. Call the step method to compute the range, using the properties you specify for the phased.RangeEstimator System object.

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

estimator = phased.RangeEstimator creates a range estimator System object, estimator.

estimator = phased.RangeEstimator(Name,Value) creates a System object, estimator, with each specified property Name set to the specified Value. You can specify additional name and value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

**NumEstimatesSource — Source of number of range estimates to report**
'Auto' (default) | 'Property'

Source of the number of range estimates to report, specified as 'Auto' or 'Property'.

If you set this property to 'Auto', the number of reported estimates is determined from the number of columns in the detidx input to the step method. If cluster IDs are provided, the number of estimates is determined from the number of unique cluster IDs in the clusterids input to the step method.

If you set this property to 'Property', the number of reported estimates is obtained from the value of the NumEstimates property.

Data Types: char

**NumEstimates — Maximum number of estimates**
1 (default) | positive integer

The maximum number of range estimates to report, specified as a positive integer. The number of requested estimates can be greater than the number of columns in the detidx argument or the number of unique IDs in the clusterids argument of the step method. In that case, the remainder is filled with NaN.

**Dependencies**

To enable this property, set the NumEstimatesSource property to 'Property'.

Data Types: single | double

**ClusterInputPort — Accept cluster IDs as input**
false (default) | true

Option to accept cluster IDs as an input argument to the step method, specified as false or true. Setting this property to true enables the clusterids input argument.

Data Types: logical

**VarianceOutputPort — Output variance for range estimates**
false (default) | true

Option to enable output of range estimate variances, specified as false or true. Range variances are returned by the rngvar output argument of the step method.

Data Types: `logical`

### `RMSResolution` — Root-mean-square range resolution

`1.0` (default) | positive scalar

Root-mean-square range resolution of the detection, specified as a positive scalar. The value of the `RMSResolution` must have the same units as the `rangegrid` input argument of the `step` method.

**Dependencies**

To enable this property, set the value of the `VarianceOutputPort` property to `true`.

Data Types: `single` | `double`

### `NoisePowerSource` — Source of noise power values

`'Property'` (default) | `'Input port'`

Source of noise power values, specified as `'Property'` or `'Input port'`. Noise power is used to compute range estimation variance and SNR. If you set this property to `'Property'`, the value of the `NoisePower` property represents the noise power at the detection locations. If you set this property to `'Input port'`, you can specify noise power using the `noisepower` input argument, of the `step` method.

Data Types: `char`

### `NoisePower` — Noise power

`1.0` (default) | positive scalar

Constant noise power value over the range-response or range-Doppler response data cube, specified as a positive real scalar. Noise power units are linear. The same noise power value is applied to all detections.

**Dependencies**

To enable this property, set the value of the `VarianceOutputPort` property to `true` and set `NoisePowerSource` to `'Property'`.

Data Types: `single` | `double`

# Methods

| | |
|---|---|
| step | Estimate target range |

| Common to All System Objects | |
|---|---|
| release | Allow System object property value changes |

# Examples

### Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the `phased.RangeDopplerResponse` System object™. Then use the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis. The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
```

```
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

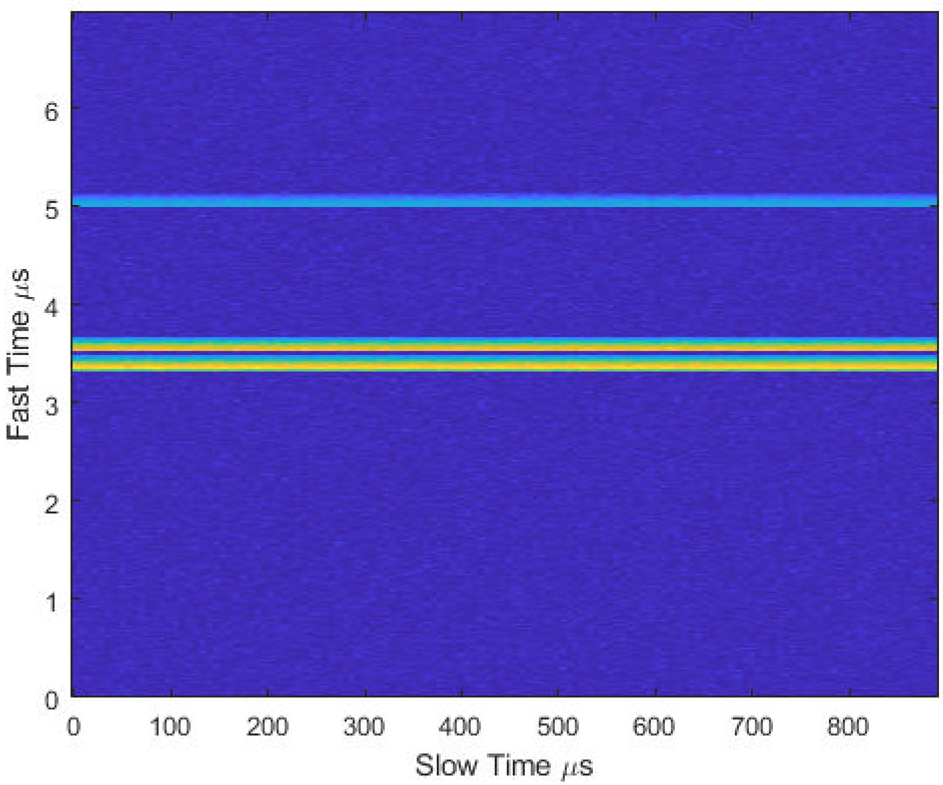
1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
```

```
        txsig = radiator(txsig,tgtang);
        txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
        tgtsig = target(txsig);
        rxcol = collector(tgtsig,tgtang);
        rxsig = receiver(rxcol);
        cube(:,n) = rxsig;
    end
```

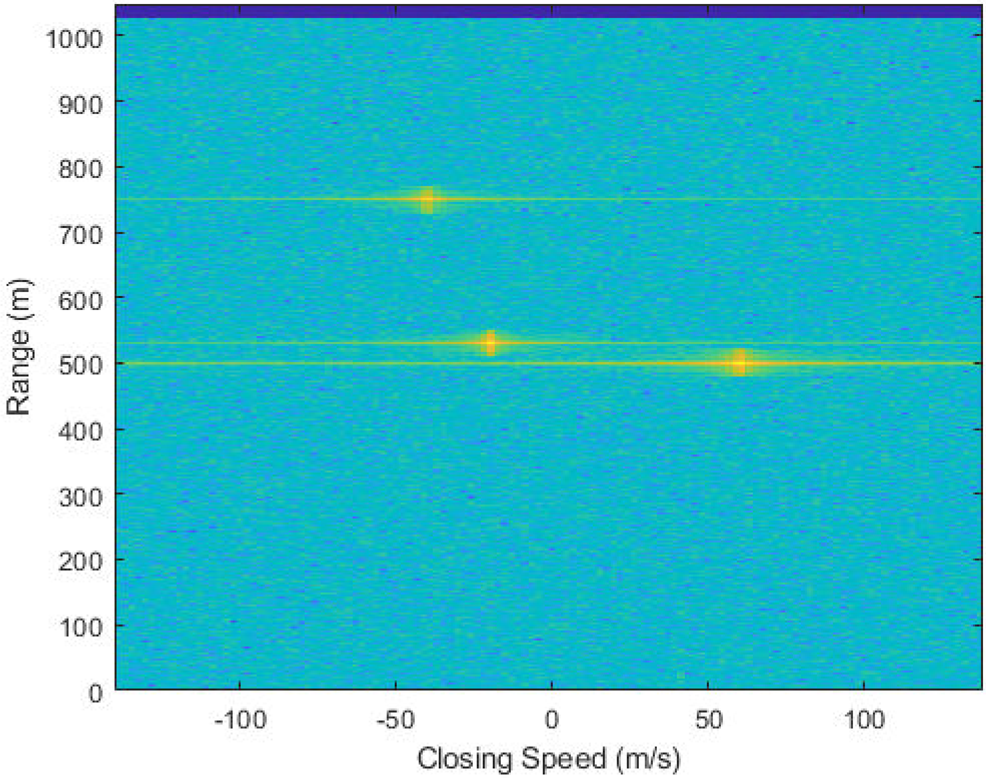
Display the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest = 3×1

  499.7911
  529.8380
  750.0983

rngvar = 3×1
10^-4 ×

    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest = 3×1

   60.5241
  -19.6167
  -39.5838

spdvar = 3×1

```

# More About

## Date Cube

One input to the range estimator is a response data cube. To create a response data cube, use the `phased.RangeDopplerResponse` or `phased.RangeResponse` System objects. The first dimension of the cube represents the range. Only the first dimension is used to estimate range. All other dimensions are ignored. To interpret the detection location, you must pass in the `rnggrid` vector corresponding to the range values along this dimension. See “Radar Data Cube Concept”.

# Algorithms

## Range Estimation

The `phased.RangeEstimator` System object estimates the range of a detection by following these steps:

1. Input a range-processed response data cube obtained from either the `phased.RangeResponse` or `phased.RangeDopplerResponse` System object. The first dimension of the cube represents the fast-time or equivalent range of the returned signal samples. Only this dimension is used to estimate detection range. All others are ignored.
2. Input a matrix of detection indices that specify the location of detections in the data cube. Each column denotes a separate detection. The row entries designate indices into the data cube. You can obtain detection indices as an output of the `phased.CFARDetector` or `phased.CFARDetector2D` detectors. To return these indices, set the `OutputFormat` property of either CFAR detector to `'Detection index'`.
3. Optionally input a row vector of cluster IDs. This vector is equal in length to the number of detections. Each element of this vector assigns an ID to a corresponding detection. To form clusters of detections, the same ID can be assigned to more than one detection. To enable this option, set the `ClusterInputPort` property to `true`.
4. When `ClusterInputPort` is `false`, the object computes the range for each detection. The algorithm finds the response values at the detection location and at two adjacent indices in the cube along the range dimension. Then, the algorithm fits a quadratic curve to the magnitudes of the range response at these three locations and finds the location of the peak. When detections occur at the first or last sample in the range dimension, the range response is estimated from a two-point centroid. The estimation is at the location of the detection index and at the sample adjacent to the detection index.

   When `ClusterInputPort` is `true`, the object computes range for each cluster. The algorithm finds the indices of the largest response value in the cluster and fits a quadratic formula to that detection in the same way as for individual detections.
5. Convert the fractional index values of the fitted peak locations to range. To convert the indices, choose appropriate units for the `rnggrid` input argument of the `step` method. You can use values for `rnggrid` obtained from either the `phased.RangeResponse` or `phased.RangeDopplerResponse` System objects.

The object computes the estimated range variance using the Ziv-Zakai bound.

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If

the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

## Topics

"Radar Data Cube Concept"

**Introduced in R2017a**

# step

**System object:** `phased.RangeEstimator`
**Package:** `phased`

Estimate target range

## Syntax

```
rngest = step(estimator,resp,rnggrid,detidx)
[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,noisepower)
[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,clusterids)
[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,noisepower,
clusterids)
```

## Description

**Note** Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`rngest = step(estimator,resp,rnggrid,detidx)` estimates ranges from detections derived from the range response data cube, `resp`. Range estimates are computed for each detection position reported in `detidx`. The `rnggrid` argument sets the units for the range dimension of the response data cube.

`[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,noisepower)` also specifies the noise power. This syntax applies when you set the `VarianceOutputPort` property to `true` and the `NoisePowerSource` property to `'Input port'`.

`[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,clusterids)` also specifies the cluster IDs for the detections. This syntax applies when you set the `ClusterInputPort` to `true`.

You can combine optional input and output arguments when their enabling properties are set. Optional inputs and outputs must be listed in the same order as the order of the enabling properties. For example, `[rngest,rngvar] = step(estimator,resp, rnggrid,detidx,noisepower,clusterids)`.

**Note** The object performs an initialization the first time the object is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

## Input Arguments

### `estimator` — Range estimator

`phased.RangeEstimator` System object

Range estimator, specified as a `phased.RangeEstimator` System object.

Example: `phased.RangeEstimator`

### `resp` — Range-processed response data cube

complex-valued *M*-by-1 column vector | complex-valued *M*-by-*N* matrix | complex-valued *M*-by-*N*-by-*P* matrix

Range-processed response data cube, specified as a complex-valued *M*-by-1 column vector, a complex-valued *M*-by-*N* matrix, or a complex-valued *M*-by-*N*-by-*P* array. *M* is the number of fast-time or range samples. *N* is the number of spatial elements, such as sensor elements or beams, *P* is the number of Doppler bins or pulses, depending on whether the data cube has been Doppler processed.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`

### `rnggrid` — Range values along range dimension

real-valued *M*-by-1 column vector

Range values along range dimension of the `resp` argument, specified as a real-valued *M*-by-1 column vector. `rnggrid` defines the range values corresponding to the fast-time or range dimension. Range values must be monotonically increasing and equally spaced. Units are in meters.

Example: `[0.1,0.2,0.3]`

Data Types: `single` | `double`

### `detidx` — Detection indices

real-valued $N_d$-by-$Q$ matrix

Detection indices, specified as a real-valued $N_d$-by-$Q$ matrix. $Q$ is the number of detections and $N_d$ is the number of dimensions of the response data cube, `resp`. Each column of `detidx` contains the $N_d$ indices of the detection in the response data cube.

To generate detection indices, you can use the `phased.CFARDetector` object or `phased.CFARDetector2D` object.

Data Types: `single` | `double`

### `noisepower` — Noise power at detection locations

positive scalar | real-valued 1-by-$Q$ row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-$Q$ row vector where $Q$ is the number of detections specified in `detidx`.

#### Dependencies

To enable this input argument, set the value of the `NoisePowerSource` property to `'Input port'`.

Data Types: `single` | `double`

### `clusterids` — Cluster IDs

real-valued 1-by-$Q$ row vector of positive values

Cluster IDs, specified as a real-valued 1-by-$Q$ row vector, where $Q$ is the number of detections specified in `detidx`. Each element of `clusterids` corresponds to a column in `detidx`. Detections with the same cluster ID are in the same cluster.

#### Dependencies

To enable this input argument, set the value of the `ClusterInputPort` property to `true`.

Data Types: `single` | `double`

## Output Arguments

**`rngest` — Range estimates**
real-valued *K*-by-1 column vector

Range estimates, returned as a real-valued *K*-by-1 column vector.

- When `ClusterInputPort` is `false`, Doppler estimates are computed for each detection location in the `detidx` argument. Then *K* equals the column dimension, *Q*, of `detidx`.
- When `ClusterInputPort` is `true`, Doppler estimates are computed for each cluster ID in the `clusterids` argument. Then *K* equals the number of unique cluster IDs, *Q*.

Data Types: `single` | `double`

**`rngvar` — Range estimation variance**
positive, real-valued *K*-by-1 column vector

Range estimation variance, returned as a positive, real-valued *K*-by-1 column vector, where *K* is the dimension of `rngest`. Each element of `rngvar` corresponds to an element of `rngest`. The estimator variance is computed using the Ziv-Zakai bound.

Data Types: `single` | `double`

## Examples

### Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the `phased.RangeDopplerResponse` System object™. Then use the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
```

```
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis. The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.

3 Propagate the waveform signal to the target.

4 Reflect the signal from the target.

5 Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.

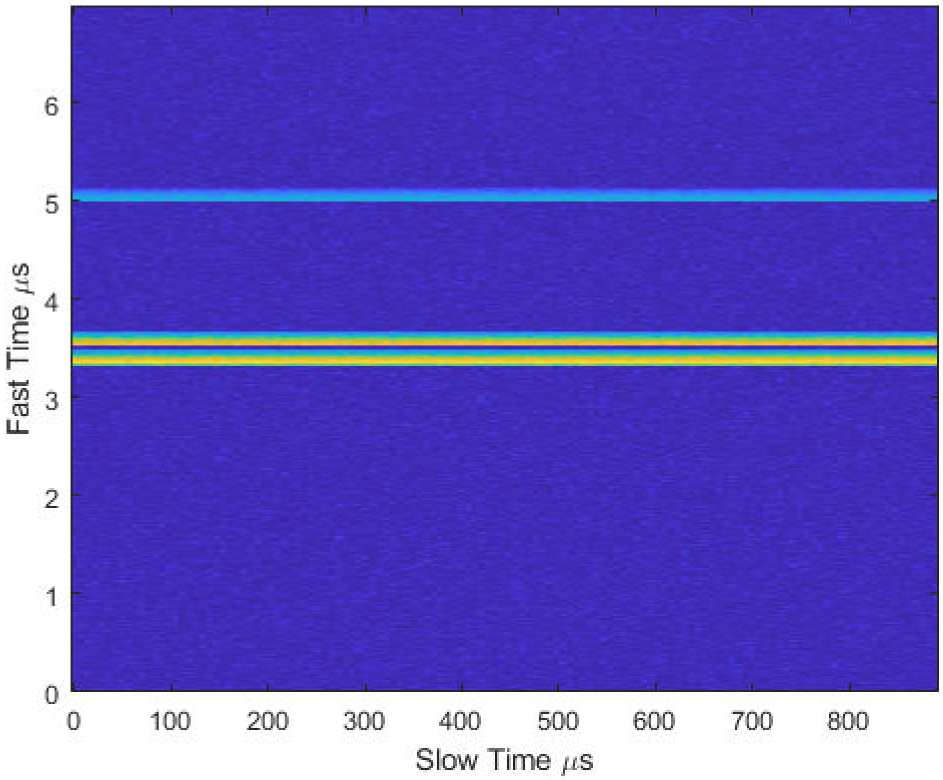
6 Receive the signal at the radar.

7 Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Display the data cube containing signals per pulse.

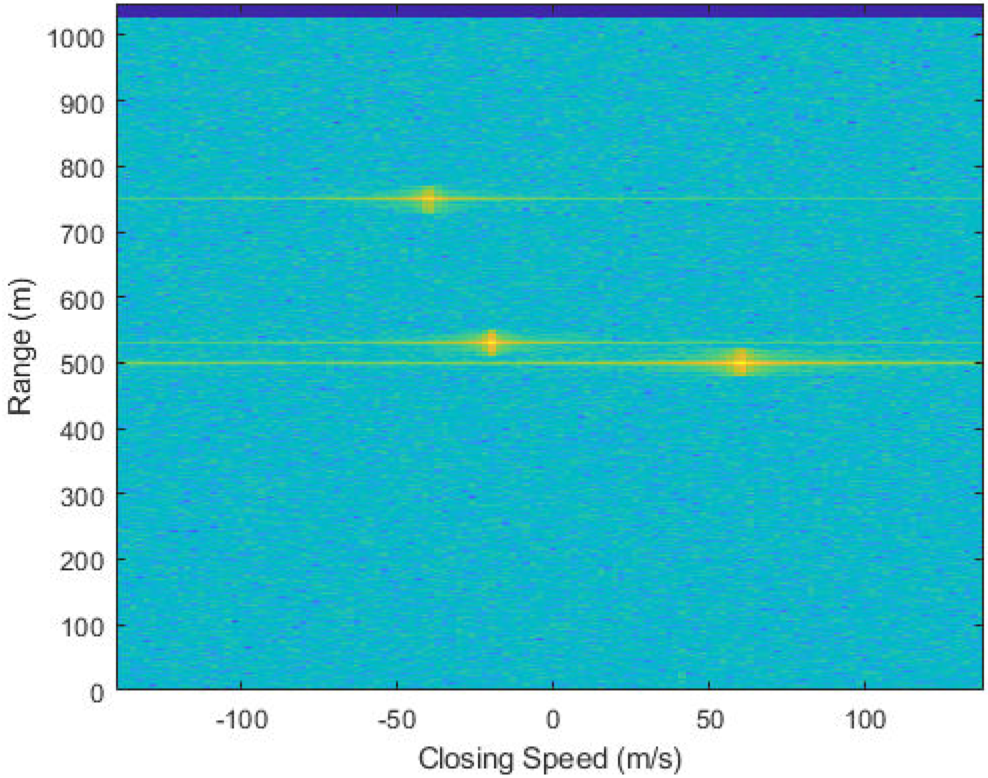
```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
```

```
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
```

```
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest = 3×1

  499.7911
  529.8380
  750.0983

rngvar = 3×1
10^-4 ×
```

```
    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest = 3×1

   60.5241

# phased.RangeResponse

**Package:** `phased`

Range response

## Description

The `phased.RangeResponse` System object performs range filtering on fast-time (range) data, using either a matched filter or an FFT-based algorithm. The output is typically used as input to a detector. Matched filtering improves the SNR of pulsed waveforms. For continuous FM signals, FFT processing extracts the beat frequency of FMCW waveforms. Beat frequency is directly related to range.

The input to the range response object is a radar data cube. The organization of the data cube follows the Phased Array System Toolbox convention.

- The first dimension of the cube represents the fast-time samples or ranges of the received signals.
- The second dimension represents multiple spatial channels, such as different sensors or beams.
- The third dimension, slow-time, represent pulses.

Range filtering operates along the fast-time dimension of the cube. Processing along the other dimensions is not performed. If the data contains only one channel or pulse, the data cube can contain fewer than three dimensions. Because this object performs no Doppler processing, you can use the object to process noncoherent radar pulses.

The output of the range response object is also a data cube with the same number of dimensions as the input. Its first dimension contains range-processed data but its length can differ from the first dimension of the input data cube.

To compute the range response:

1. Define and set up your `phased.RangeResponse` System object. See “Construction” on page 1-1860.
2. Call the `step` method to compute the range response using the properties you specify for the `phased.RangeResponse` System object.

**Note** Instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

## Construction

response = phased.RangeResponse creates a range response System object, response.

response = phased.RangeResponse(Name,Value) creates a System object, response, with each specified property Name set to the specified Value. You can specify additional name and value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

### RangeMethod — Range processing method

'Matched filter' (default) | 'FFT'

Range processing method, specified as 'Matched filter' or 'FFT'.

- 'Matched filter' — The object match-filters the incoming signal. This approach is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal.
- 'FFT' — The object applies an FFT to the input signal. This approach is commonly used for chirped signals such as FMCW and linear FM pulsed signals.

Example: 'Matched filter'

Data Types: char

### PropagationSpeed — Signal propagation speed

physconst('LightSpeed') (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in meters per second. The default propagation speed is the value returned by physconst('LightSpeed').

Example: 3e8

Data Types: `single` | `double`

### `SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `single` | `double`

### `SweepSlope` — Linear FM sweep slope

`1.0e9` (default) | scalar

Linear FM sweep slope, specified as a scalar. The fast-time dimension of the `signal` input argument to `step` must correspond to sweeps having this slope.

Example: `1.5e9`

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `single` | `double`

### `DechirpInput` — Enable dechirping of input signals

`false` (default) | `true`

Option to enable dechirping of input signals, specified as `false` or `true`. Set this property to `false` to indicate that the input signal is already dechirped and no dechirp operation is necessary. Set this property to `true` when the input signal requires dechirping.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

### `DecimationFactor` — Decimation factor for dechirped signals

`1` (default) | positive integer

Decimation factor for dechirped signals, specified as a positive integer. The decimation algorithm uses a 30th-order FIR filter generated by `fir1(30,1/D)`, where `D` is the decimation factor. The default value of `1` implies no decimation.

When processing FMCW signals, decimating the dechirped signal is useful for reducing the load on A/D converters.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`.

Data Types: `single` | `double`

### `RangeFFTLengthSource` — Source of FFT length for range processing of dechirped signals

`'Auto` (default) | `'Property'`

Source of the FFT length used for the range processing of dechirped signals, specified as `'Auto'` or `'Property'`.

- `'Auto'` — The FFT length equals the length of the fast-time dimension of the input data cube.
- `'Property'` — Specify the FFT length by using the `RangeFFTLength` property.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `char`

### `RangeFFTLength` — FFT length used for range processing

`1024` (default) | positive integer

FFT length used for range processing, specified as a positive integer.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeFFTLengthSource` property to `'Property'`

Data Types: `single` | `double`

### `RangeWindow` — FFT weighting window for range processing

`'None'` (default) | `'Hamming'` | `'Chebyshev'` | `'Hann'` | `'Kaiser'` | `'Taylor'` | `'Custom'`

FFT weighting window for range processing, specified as `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`.

If you set this property to `'Taylor'`, the generated Taylor window has four nearly constant sidelobes next to the mainlobe.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `char`

### `RangeSidelobeAttenuation` — Sidelobe attenuation for range processing

`30` (default) | positive scalar

Sidelobe attenuation for range processing, specified as a positive scalar. Attenuation applies to Kaiser, Chebyshev, or Taylor windows. Units are in dB.

#### Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Kaiser'`, `'Chebyshev'`, or `'Taylor'`.

Data Types: `single` | `double`

### `CustomRangeWindow` — Custom window for range processing

`@hamming` (default) | function handle | cell array

Custom window for range processing, specified as a function handle or a cell array containing a function handle as its first entry. If you do not specify a window length, the object computes the window length and passes that into the function. If you specify a cell array, the remaining cells of the array can contain arguments to the function. If you use only the function handle without passing in arguments, all arguments take their default values.

If you write your own window function, the first argument must be the length of the window.

**Note** Instead of using a cell array, you can pass in all arguments by constructing a handle to an anonymous function. For example, you can set the value of `CustomRangeWindow` to `@(n)taylorwin(n,nbar,sll)`, where you have previously set the values of `nbar` and `sll`.

Example: `{@taylor,5,-35}`

#### Dependencies

To enable this property, set the RangeMethod property to 'FFT' and the RangeWindow property to 'Custom'.

Data Types: function_handle | cell

### ReferenceRangeCentered — Set reference range at center of range grid

true (default) | false

Set reference range at center of range grid, specified as true or false. Setting this property to true enables you to set the reference range at the center of the range grid. Setting this property to false sets the reference range to the beginning of the range grid.

#### Dependencies

To enable this property, set the RangeMethod to 'FFT'.

Data Types: logical

### ReferenceRange — Reference range of range grid

0.0 (default) | nonnegative scalar

Reference range of the range grid, specified as a nonnegative scalar.

- If you set the RangeMethod property to 'Matched filter', the reference range is set to the start of the range grid.
- If you set the RangeMethod property to 'FFT', the reference range is determined by the ReferenceRangeCentered property.

  - When you set the ReferenceRangeCentered property to true, the reference range is set to the center of the range grid.
  - When you set the ReferenceRangeCentered property to false, the reference range is set to the start of the range grid.

  Units are in meters.

This property is tunable.

Example: 1000.0

Data Types: single | double

### MaximumNumInputSamplesSource — Source of maximum number of samples

'Auto' (default) | 'Property'

The source of the maximum number of samples the input signal, specified as 'Auto' or 'Property'. When you set this property to 'Auto', the object automatically allocates enough memory to buffer the input signal. When you set this property to 'Property', you specify the maximum number of samples in the input signal using the MaximumNumInputSamples property. Any input signal longer than that value is truncated.

To use this object with variable-size input signals in a MATLAB Function Block in Simulink, set the MaximumNumInputSamplesSource property to 'Property' and set a value for the MaximumNumInputSamples property.

Example: 'Property'

### MaximumNumInputSamples — Maximum number of input signal samples

100 (default) | positive integer

Maximum number of samples in the input signal, specified as a positive integer. Any input signal longer than this value is truncated. The input signal is the first argument to the step method. The number of samples is the number of rows in the input.

Example: 2048

**Dependencies**

To enable this property, set the RangeMethod property to 'Matched filter' and set the MaximumNumInputSamplesSource property to 'Property'.

Data Types: single | double

## Methods

# Examples

### Range Response of Three Targets

Compute the radar range response of three targets by using the `phased.RangeResponse` System object™. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system. The transmitted signal is a linear FM waveform with a pulse repetition interval of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The radar transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radars on the *x*-axis. The targets move along the *x*-axis at speeds of −60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB.

Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of half the sample rate. Find the length of the pri in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
```

Create a free-space propagation channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. The receiver gain is 42 dB and noise figure is 10.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 10;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over 128 pulses to build a data cube. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions, where last dimension corresponds to antennas or beams. Because only one sensor is used in this example, the cube has only two dimensions.

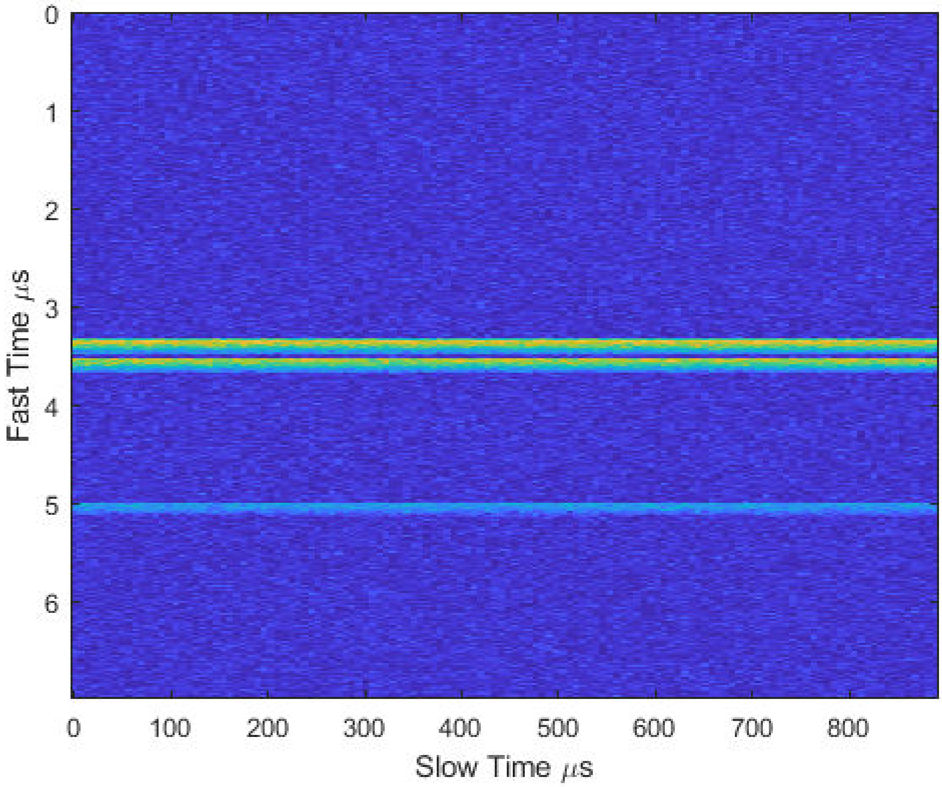
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation mode enables you to combine the returned propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(pri);
    [tgtpos,tgtvel] = tgtmotion(pri);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

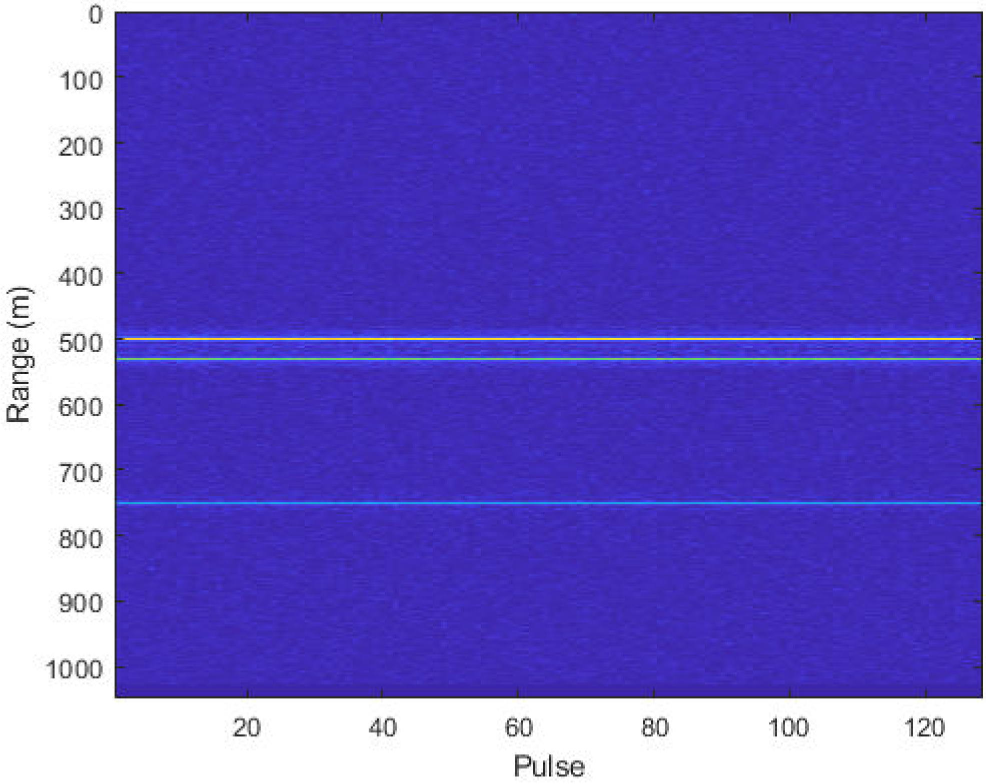
Display the image of the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
```



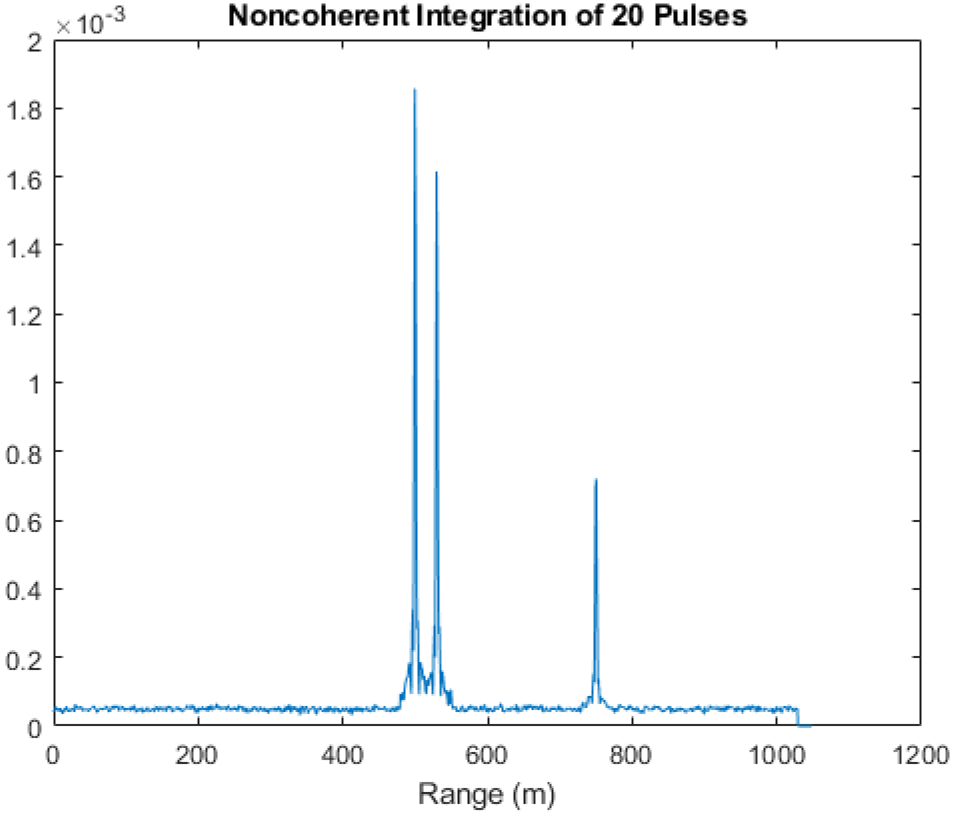
Create a `phased.RangeResponse` System object in matched filter mode. Then, display the range response image for the 128 pulses. The image shows range vertically and pulse number horizontally.

```
matchingcoeff = getMatchedFilter(waveform);
ndop = 128;
rangeresp = phased.RangeResponse('SampleRate',fs,'PropagationSpeed',c);
[resp,rnggrid] = rangeresp(cube,matchingcoeff);
imagesc([1:Np],rnggrid,abs(resp))
xlabel('Pulse')
ylabel('Range (m)')
```



Integrate 20 pulses noncoherently.

```
intpulse = pulsint(resp(:,1:20),'noncoherent');
plot(rnggrid,abs(intpulse))
xlabel('Range (m)')
title('Noncoherent Integration of 20 Pulses')
```



# Algorithms

## Data Precision

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

# Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `CustomRangeWindow` property is not supported.
- The `plotResponse` method is not supported.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This System object supports single and double precision for input data, properties, and arguments. If the input data X is single precision, the output data is single precision. If the input data X is double precision, the output data is double precision. The precision of the output is independent of the precision of the properties and other arguments.

Plot range response

## Syntax

```
plotResponse(response,x)
plotResponse(response,x,xref)
plotResponse(response,x,coeff)
plotResponse(response,___,Name,Value)
```

## Description

plotResponse(response,x) plots the range response of a dechirped input signal, x. This syntax applies when you set the RangeMethod property to 'FFT' and the DechirpInput property to false.

plotResponse(response,x,xref) plots the range response x, after performing a dechirp operation using the reference signal, xref. This syntax applies when you set the RangeMethod property to 'FFT' and the DechirpInput property to true.

plotResponse(response,x,coeff) plots the range response of x after match filtering using the match filter coefficients, coeff. This syntax applies when you set the RangeMethod property to 'Matched filter'.

plotResponse(response,___,Name,Value) plots the range response with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

**response — Range response**
phased.RangeResponse System object

Range response, specified as a `phased.RangeResponse` System object.

Example: `phased.RangeResponse`

### `x` — Input radar data cube

complex-valued *K*-element column vector | complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N*-by-*L* array

Input radar data cube, specified as a complex-valued *K*-by-1 column vector, a *K*-by-*L* matrix, or *K*-by-*N*-by-*L* array.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or directions.
- *L* is the slow-time dimension that corresponds to the number of pulses or sweeps in the input signal.

See “Radar Data Cube”.

Each *K*-element fast-time dimension is processed independently.

For FMCW waveforms with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

The size of the first dimension of the input matrix can vary to simulate a changing signal length. A size change can occur, for example, in the case of a pulse waveform with variable pulse repetition frequency.

Data Types: `single` | `double`

### `xref` — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The value of *K* must equal the length of the first dimension of `x`.

#### Dependencies

To enable this input argument, set the value of `RangeMethod` to `'FFT'` and `DechirpInput` to `true`.

Data Types: `single` | `double`

### `coeff` — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*, the length of the fast-time dimension.

#### Dependencies

To enable this input argument, set `RangeMethod` property to `'Matched filter'`.

Data Types: `single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### `Unit` — Vertical axes units

`'db'` (default) | `'mag'` | `'pow'`

Units for vertical axis of plot, specified as `'db'`, `'mag'`, or `'pow'`.

Example: `'pow'`

Data Types: `char`

# Examples

### Plot Range Response of Three Targets

Plot the radar range response of three targets usin the `plotResponse` method of the `phased.RangeResponse` System object™. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system. The transmitted signal is a linear FM waveform with a pulse repetition interval of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;fs = 150e6;
c = physconst('LightSpeed');
fc = 77e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The radar transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radars on the *x*-axis. The targets move along the *x*-axis at speeds of −60, 20, and 40 m/s. All three targets have a nonfluctuating RCS of 10 dB.

Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Construct an upsweep linear FM signal with a bandwidth of half the sample rate. Find the rms bandwidth and rms range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs,...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2,...
    'DurationSpecification','Duty cycle','DutyCycle',.02);
sig = waveform();
Nr = length(sig);
```

```
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
transmitter = phased.Transmitter(...
    'PeakPower',peakpower,...
    'Gain',txgain,...
    'InUseOutputPort',true);
radiator = phased.Radiator(...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Create a free-space propagation channel in two-way propagation mode.

```
channel = phased.FreeSpace(...
    'SampleRate',fs,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. The receiver gain is 42 dB and noise figure is 10.

```
collector = phased.Collector(...
    'Sensor',rxantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 10;
receiver = phased.ReceiverPreamp(...
    'SampleRate',fs,...
    'Gain',rxgain,...
    'NoiseFigure',noisefig);
```

Loop over 128 pulses to build a data cube. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions. The last dimension corresponds to antennas or beams. Because only one sensor is used in this example, the cube has only two dimensions.

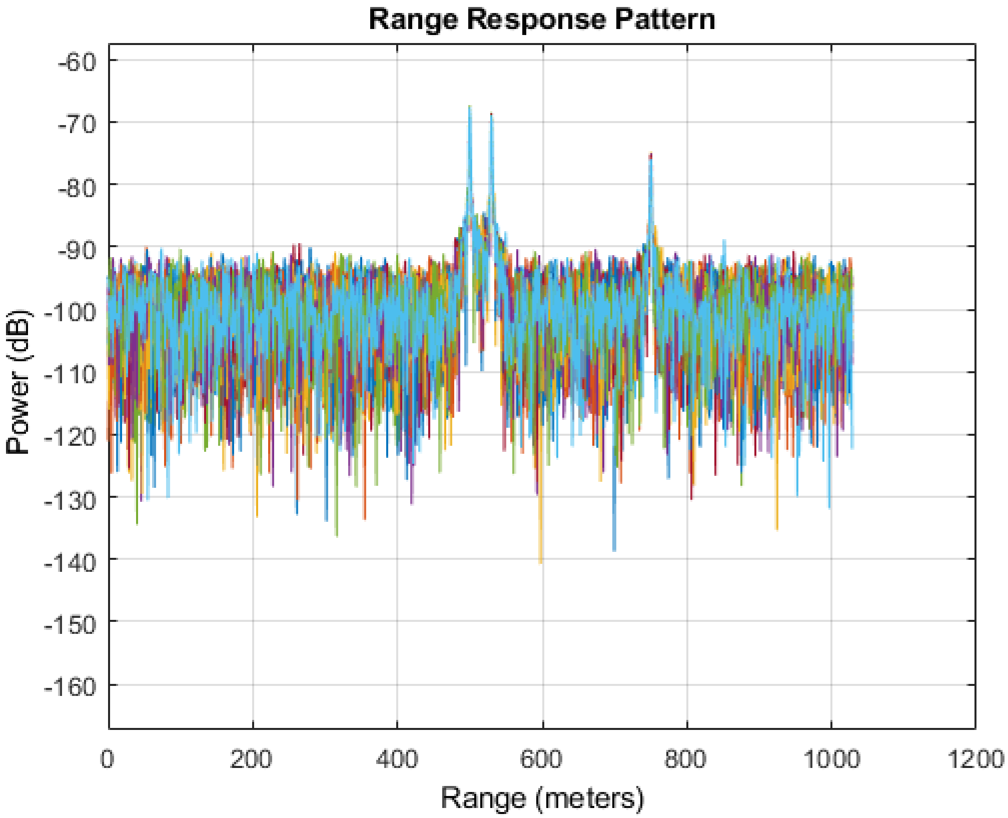
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation mode allows the return propagation to be combined with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(pri);
    [tgtpos,tgtvel] = tgtmotion(pri);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Create a `phased.RangeResponse` System object in matched filter mode. Then, call the `plotResponse` method to show the first 20 pulses.

```
matchcoeff = getMatchedFilter(waveform);
rangeresp = phased.RangeResponse('SampleRate',fs,'PropagationSpeed',c);
plotResponse(rangeresp,cube(:,1:20),matchcoeff);
```



**Introduced in R2017a**
