Getting Started with Simulink Design Verifier

Simulink Design Verifier Product Description

Simulink Design Verifier Product Description

Identify design errors, prove requirements compliance, and generate tests

Simulink® Design Verifier™ uses formal methods to identify hidden design errors in models. It detects blocks in the model that result in integer overflow, dead logic, array access violations, and division by zero. It can formally verify that the design meets functional requirements. For each design error or requirements violation, it generates a simulation test case for debugging.

Simulink Design Verifier generates test cases for model coverage and custom objectives to extend existing requirements-based test cases. These test cases drive your model to satisfy condition, decision, modified condition/decision (MCDC), and custom coverage objectives. In addition to coverage objectives, you can specify custom test objectives to automatically generate requirements-based test cases.

Support for industry standards is available through IEC Certification Kit (for IEC 61508 and ISO 26262) and DO Qualification Kit (for DO-178).

Getting Started with Simulink Design Verifier

About Systematic Model Verification Using Simulink Design Verifier

Simulink Design Verifier helps you perform systematic model verification to identify hidden design errors, prove properties, and generate test cases for functional testing. Simulink Design Verifier uses formal methods to test design correctness that increases confidence in your design model that the production code generation uses.

You can perform systematic model verification for scenarios such as:

- Applications that are developed by using Model-based design, where you perform design verification to demonstrate that the model satisfies the functional requirements and does not contain unintended functionality.
- Analyzing a subset of a design model that is intended for control software. For open-loop control analysis, formal verification is widely used for rigorous testing of design models.
- Iteratively verifying your model against requirements, checking for design errors, and performing functional testing early in the design cycle and throughout the design process.
- Systematic verification and unit-level testing of small components in isolation or for system-level testing of an integrated design model.

When to Use Simulink Design Verifier

Consider a control engineer who is involved in designing a control system. During the design cycle, the control engineer creates a design model from system requirements. Throughout the development process, the engineer:

- Identifies and eliminates hidden design errors
- Test model against requirements
- Performs model and code coverage analysis to confirm test completeness
- Resolves missing coverage by using test generation and dead logic detection
- Performs baseline and equivalence testing

Simulink Design Verifier supports these model and code verification processes. It integrates with Simulink Requirements™, Simulink Coverage™, Simulink Check™, and Simulink Test™ to achieve model and code verification.

Using Simulink Design Verifier in a Model-Based Design Workflow

Model verification includes checking against standards, checking for design errors, proving properties, and generating test cases for coverage analysis.

With Simulink Design Verifier, you can:

- Identify hidden design errors, such as integer overflows or division by zero and generate couterexamples to debug unintended functionalities. You can also justify or exclude model objects from analysis.
- Verify model against requirements by using Simulink Requirements.
- Achieve model coverage (Simulink Coverage) by generating test cases that satisfies model coverage objectives.
- Perform code coverage (Embedded Coder) analysis by generating test cases for code generated by Embedded Coder®.
- Extend existing test cases and achieve missing coverage.
- Integrate test cases with Simulink Test to perform baseline and equivalence testing.
- Support industry standards through the IEC Certification Kit (for IEC 61508 and ISO 26262) and DO Qualification Kit (for DO-178).

This workflow diagram demonstrates the capabilities of Simulink Design Verifier at various stages of the verification and validation workflow. For more information, see "Verification and Validation".
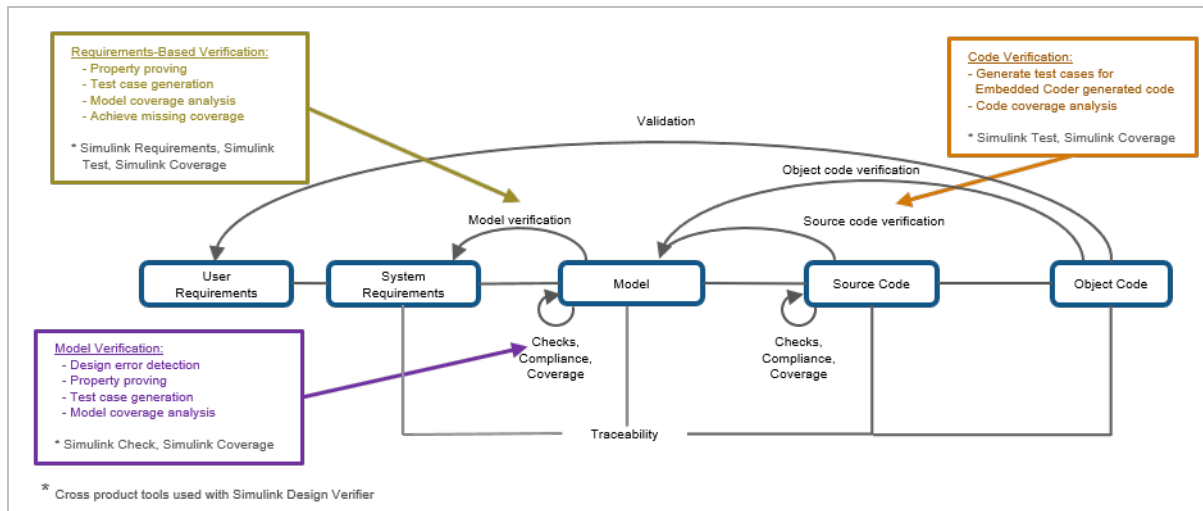

For an quick introduction to design error detection and test generation, see "Detect Design Errors in Controller Model" on page 2-6 and "Generate Test Cases for a Simplified Cruise Control Model" on page 2-14.

To learn more about Simulink Design Verifier analysis, see "Design Error Detection", "Test Case Generation", "Prove Properties in a Model", and "Results Interpretation and Use".

Creating Analysis Result Reports

You can also generate reports and review the analysis results. There are several ways to review the analysis results:

- Review the analysis results at a glance by highlighting the results on the model.
- Create a test harness model to simulate the test cases or debug counterexamples.
- Generate a model coverage report.
- View generated tests in the Simulation Data Inspector.
- Generate an HTML or PDF report that contains detailed information about the analysis results.

Detect Design Errors in Controller Model

To detect hidden design errors in your model early in the verification process, use design error detection analysis. This tutorial shows how to perform design error detection analysis, review the analysis results, and then fix the identified design errors.

Consider a controller that has three sensor inputs: `SensorA`, `SensorB`, and `SensorC`. The controller algorithm operates according to the equation:

$$If \ \left| \frac{(SensorA - SensorB)}{(SensorA + SensorB)} \right| > 0.1, then \ output = SensorC$$

$$else \ output = \frac{(SensorA + SensorB)}{2}$$

The algorithm is modeled as:

Simulink Design Verifier
Detect Integer Overflow Errors
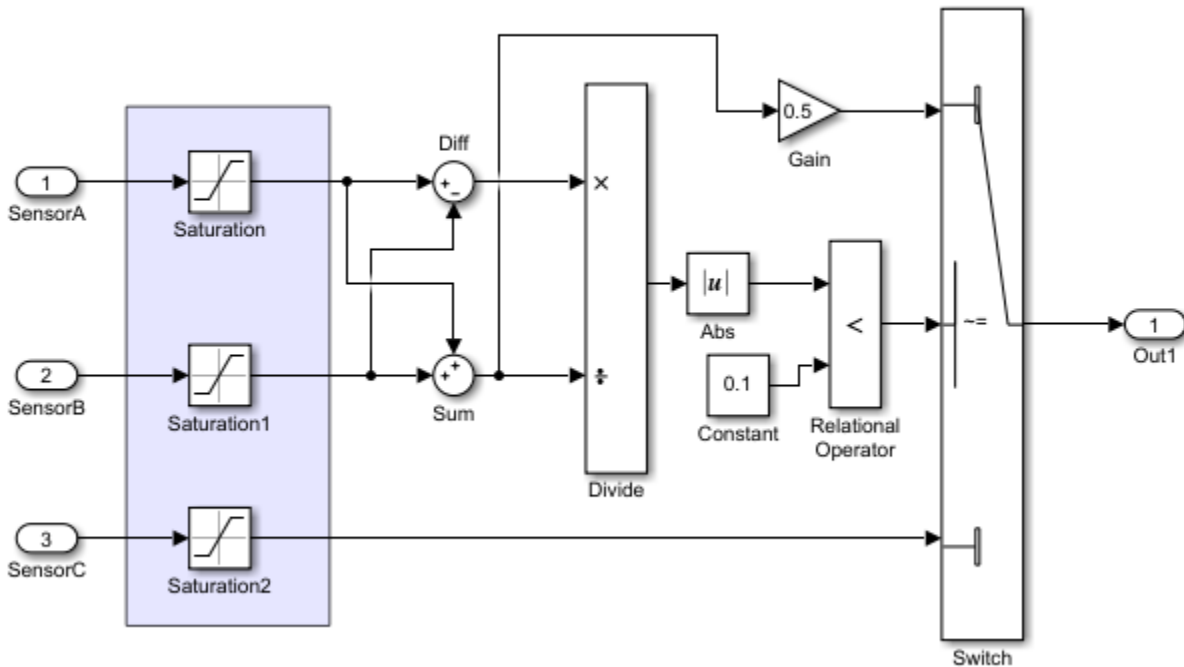

Copyright 2019 The MathWorks, Inc.

To perform design error detection analysis:

Step 1: Prepare Model for Design Error Detection

1   Open the model sldvexControllerIntegerOverflow.

2   On the **Design Verifier** tab, in the **Mode** section, select **Design Error Detection**.

3   Click **Error Detection Settings**. In the Configuration Parameters dialog box, on the **Design Verifier** > **Design Error Detection** pane, select the checks that you want to perform.

Design Error Detection

- ☐ Dead logic
  - ☐ Identify active logic
- ☐ Out of bound array access
- ☑ Division by zero
- ☑ Integer overflow
- ☐ Non-finite and NaN floating-point values
- ☐ Subnormal floating-point values
- ☐ Specified minimum and maximum value violations

Step 2: Perform Design Error Detection Analysis

To perform design error detection analysis, on the **Design Verifier** tab, click **Detect Design Errors**. The software analyzes the model for design errors and displays the results in the Results Summary window. The results indicate that three out of six objectives were falsified.

Progress

Objectives processed   6/6
Valid   3
Falsified   3
Elapsed time   0:35

Design error detection completed normally.

3/6 objectives valid
3/6 objectives falsified - need simulation

Results:

- Open filter viewer
- Highlight analysis results on model
- View tests in Simulation Data Inspector
- Detailed analysis report: (HTML) (PDF)
- Create harness model
- Export test cases to Simulink Test

Data saved in: sldvexControllerIntegerOverflow_sldvdata.mat
in folder: H:\Documents\MATLAB\sldv_output
\sldvexControllerIntegerOverflow

Step 3: Review the Analysis Results

You can review the analysis results by highlighting the results on the model and reviewing the analysis report.

Highlight Analysis Results on the Model

On the **Design Verifier** tab, in the **Review Results** section, click **Highlight in Model**.

The model items highlighted in red are the objectives that resulted in errors. You can replicate the error by simulating the test case.

1   Select the Sum block. The Results Inspector window displays the integer overflow objectives of the Sum block.
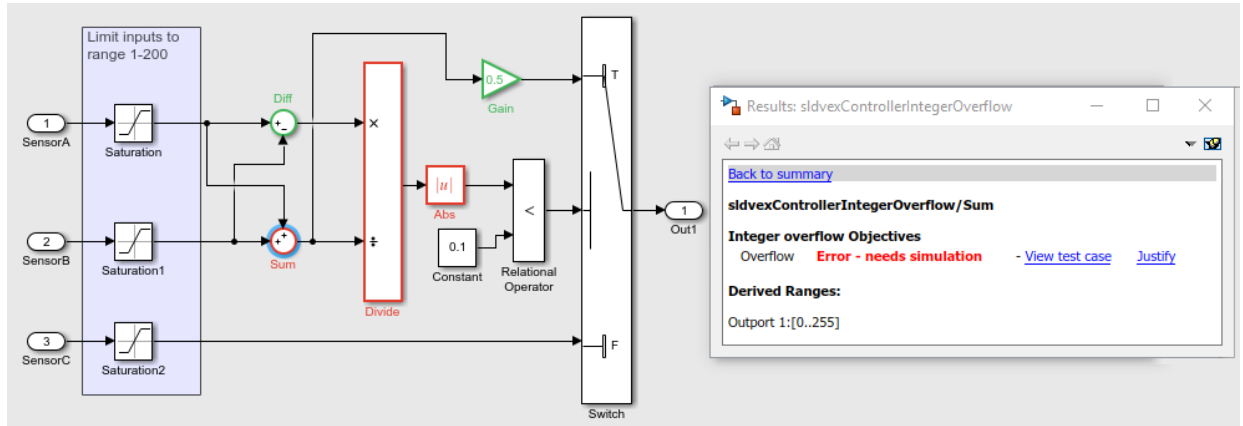

2   To debug the integer overflow error, click **View test case**. The harness model and the Signal Builder block open.

When the input value of `SensorA` is `96` and `SensorB` is `160`, the Sum block output overflows. The accumulator data type of the Sum block is set to an incorrect integer value of `uint8`, it results in overflow errors and division by zero errors on the downstream Divide block.

Review Analysis Report

To view the HTML report, in **Review Results**, click **HTML Report**. The Design Error Detection Objectives section lists the objectives of each model items and their description.

Objectives Valid

#	Type	Model Item	Description	Analysis Time (sec)	Test Case
6	Integer overflow	Diff	Overflow	17	n/a
9	Integer overflow	Divide	Overflow	45	n/a
14	Integer overflow	Gain	Overflow	17	n/a

Objectives Falsified - Needs Simulation

#	Type	Model Item	Description	Analysis Time (sec)	Test Case
4	Integer overflow	Sum	Overflow	29	2
8	Division by zero	Divide	Division by zero	29	2
11	Integer overflow	Abs	Overflow	29	1

Step 4: Fix Design Errors

In the tutorial model, the design error detection analysis found integer overflow and division by zero errors in the model. The errors were caused due to a mismatch in the integer data type.

To fix the errors, change the Accumulator data type to `uint16` to handle the range of possible signal values. Select the Sum block, and set **Accumulator data type** to uint16. When you rerun the design error detection analysis, the Results Summary window reports that `6/6` objectives are valid. When you simulate the test case for the Sum, observe that the test case resolves the error.

Generate Test Cases for a Simplified Cruise Control Model

With Simulink Design Verifier, you can generate test cases for model coverage and custom objectives. You can also measure coverage of existing requirements-based test cases and extend these test cases to increase coverage or achieve full coverage.

This tutorial explains a simplified cruise control model that controls the throttle speed. You generate test cases that satisfy condition and decision model coverage objectives and then, simulate these test cases to generate model coverage report.

Analyze a Simple Cruise Control Model

Consider a simplified cruise control model that adjusts the throttle to maintain a steady speed as set by the set speed.
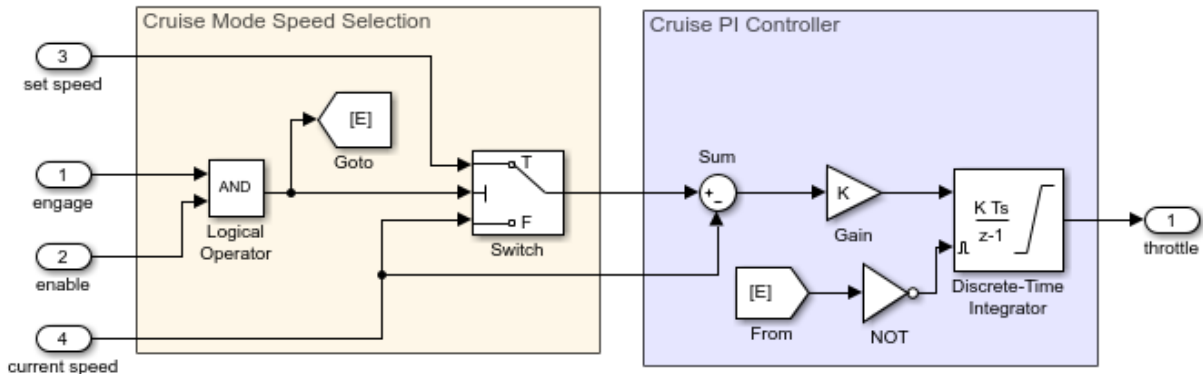

This cruise control model meets these requirements:

- The control system is activated when the `engage` and the `enable` signals are `true`. This condition is defined by the AND block.
- When the system is activated, the Switch block passes `set speed` to the PI controller. The PI controller calculates the `throttle` by integrating the error term defined by the difference `set speed - current speed`.
- `Throttle` continues to increase or decrease until `set speed` is higher or lower than `current speed`.

- When the system is not activated, the Discrete-Time Integrator block resets. The error term is `zero`, which means the `throttle` is in reset position.

When you perform test generation analysis, Simulink Design Verifier generates test cases for the model coverage objectives associated with each model item in the model. Table lists the condition and decision coverage objectives for the associated model blocks. For more information on model coverage objectives, see "Model Coverage Objectives for Test Generation" and "Model Objects That Receive Coverage" (Simulink Coverage).

Block	Model Coverage Objective	Generated Test Case Description
AND	Condition	Each input value is set to true or false independently.
NOT	Condition	Input is set to true or false independently.
Switch	Decision	Test case demonstrates that the Switch passes both the input signals to output.
Discrete-Time Integrator	Decision	• Test case demonstrates the saturation behavior of the integrator. • Satisfies external reset conditions.

Generate Test Cases for Coverage Analysis

The analysis results give detailed descriptions of the coverage objectives for each model item and generated test cases for all satisfied objectives. You simulate the generated test cases to measure model coverage.

Step 1: Generate Test Cases

1   Open the model sldvexSimpleCruiseControl.

2   On the **Design Verifier** tab, in the **Mode** section, select **Test Generation**.

3   To generate test cases, click **Generate Tests**.

   The Results Summary window displays the results. The result indicates that all 14 objectives are `satisfied`.

2-15

Progress ▮▮▮▮▮▮▮▮▮▮▮▮▮▮▮▮▮▮▮▮

Objectives processed   14/14
Satisfied   14
Unsatisfiable   0
Elapsed time   0:12

Test generation completed normally.

14/14 objectives satisfied.

Results:

- Open filter viewer
- Highlight analysis results on model
- View tests in Simulation Data Inspector
- Detailed analysis report: (HTML) (PDF)
- Create harness model
- Export test cases to Simulink Test
- Simulate tests and produce a model coverage report

Data saved in: sldvexSimpleCruiseControl_sldvdata.mat
in folder: H:\Documents\MATLAB\sldv_output
\sldvexSimpleCruiseControl

Step 2: Review the Analysis Results

1   On the **Design Verifier** tab, in the **Review Results** gallery, click **Highlight in Model**. The model objectives that the software found to be satisfied are highlighted in green.

Click the Switch block. The Result Inspector window displays the summary of the satisfied decision objectives.
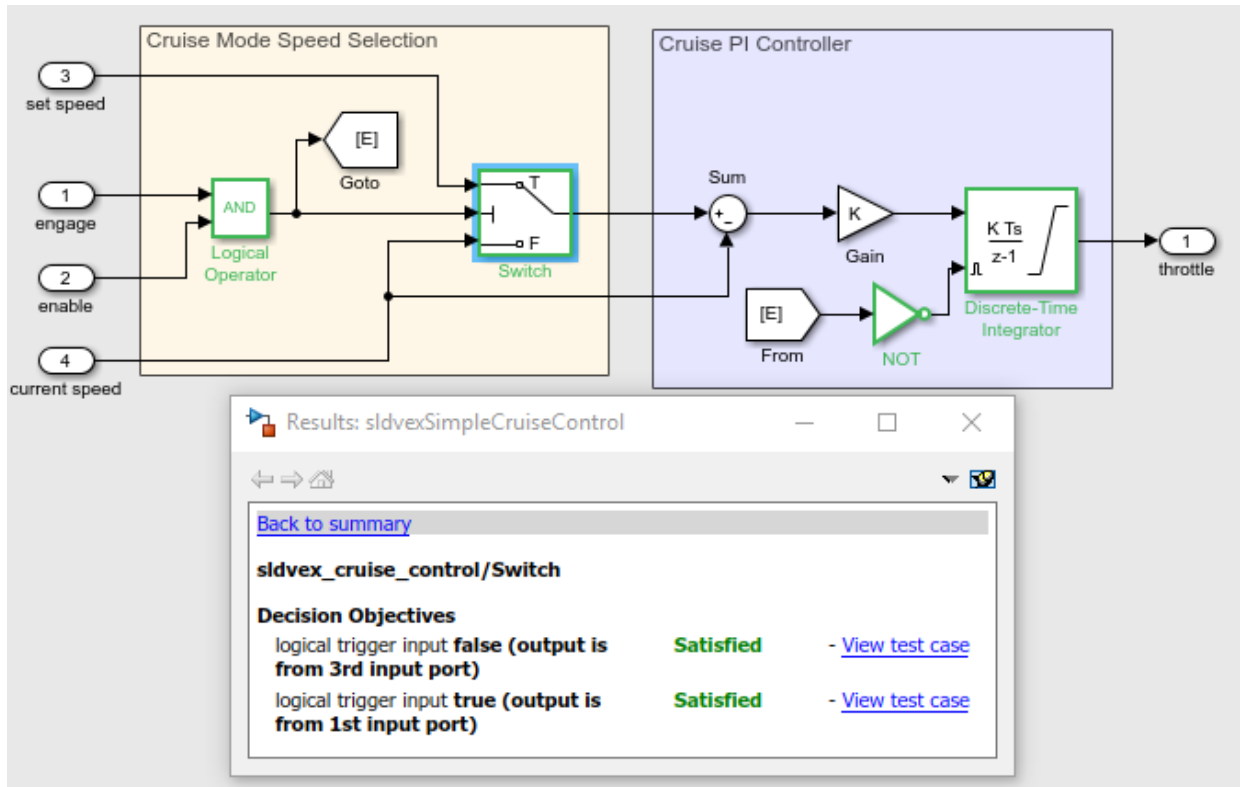

The summary shows that all the objectives of the Switch block are satisfied.

2   To view the HTML report, in the **Review Results** gallery, click **HTML Report**.

The test objective status section includes detailed descriptions of satisfied objectives for each model item and generated test case.

#	Type	Model Item	Description	Analysis Time (sec)	Test Case
1	Condition	Logical Operator	Logic: input port 1 **true**	10	1
2	Condition	Logical Operator	Logic: input port 1 **false**	10	1
3	Condition	Logical Operator	Logic: input port 2 **true**	10	1
4	Condition	Logical Operator	Logic: input port 2 **false**	10	1
5	Condition	NOT	Logic: input port 1 **true**	10	1
6	Condition	NOT	Logic: input port 1 **false**	10	1
7	Decision	Discrete-Time Integrator	Reset **true**	10	1
8	Decision	Discrete-Time Integrator	Reset **false**	10	1
9	Decision	Discrete-Time Integrator	integration result <= lower limit **true**	10	2
10	Decision	Discrete-Time Integrator	integration result <= lower limit **false**	10	1
11	Decision	Discrete-Time Integrator	integration result >= upper limit **true**	11	3
12	Decision	Discrete-Time Integrator	integration result >= upper limit **false**	10	1
13	Decision	Switch	logical trigger input **false (output is from 3rd input port)**	10	1
14	Decision	Switch	logical trigger input **true (output is from 1st input port)**	10	1

Step 3: Simulate Test Cases for Model Coverage Analysis

To view the test case for a model coverage objective, in the Result Inspector window, click **View test case**. The harness model and the Signal Builder block opens.

To simulate the test case, in the Signal Builder block, click the ▶ button.

The software simulates the test case and highlights the harness model. To view the coverage of the model items, point the cursor to each model object in the harness model.
