The forgetting factor used by the adaptive algorithm is specified as a scalar in the range $(0,1]$. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. $H$ denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$
P_{\text {new }}=\frac{P_{\text {current }}\left(1-K u^{H}\right)}{\text { ForgettingFactor }} .
$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+K^{*} e .
$$

The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=y\left(R-|y|^{2}\right)$, where $R$ is a constant related to the signal constellation.

## comm.DecisionFeedbackEqualizer

Package: comm
Equalize modulated signals using decision feedback filtering

## Description

The comm. DecisionFeedbackEqualizer System object uses a decision feedback filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see "Algorithms" on page 3-513.

To equalize modulated signals using a decision feedback filter:
1 Create the comm. DecisionFeedbackEqualizer object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

dfe = comm. DecisionFeedbackEqualizer
dfe = comm. DecisionFeedbackEqualizer(Name,Value)

## Description

dfe $=$ comm. DecisionFeedbackEqualizer creates a decision feedback equalizer System object to adaptively equalize a signal.
dfe = comm.DecisionFeedbackEqualizer(Name, Value) sets properties using one or more name-value pairs. For example, comm. DecisionFeedbackEqualizer('Algorithm','RLS') configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Algorithm - Adaptive algorithm

'LMS' (default) |'RLS' | 'CMA'

Adaptive algorithm used for equalization, specified as one of these values:

- 'LMS ' — Update the equalizer tap weights using the "Least Mean Square (LMS) Algorithm" on page 3-515.
- 'RLS' - Update the equalizer tap weights using the "Recursive Least Square (RLS) Algorithm" on page 3-515.
- 'CMA' - Update the equalizer tap weights using the "Constant Modulus Algorithm (CMA)" on page 3-515.

## Data Types: char|string

## NumForwardTaps - Number of forward equalizer taps

5 (default) | positive integer
Number of forward equalizer taps, specified as a positive integer.
Data Types: double
NumFeedbackTaps - Number of feedback equalizer taps
3 (default) | positive integer
Number of feedback equalizer taps, specified as a positive integer.
Data Types: double

## StepSize - Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tip To determine the maximum step size allowed, use the maxstep object function.

## Tunable: Yes

## Dependencies

To enable this property, set Algorithm to 'LMS ' or 'CMA '.
Data Types: double

## ForgettingFactor - Forgetting factor

0.99 (default) | scalar in the range (0,1]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range ( 0,1 ]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes
Dependencies
To enable this property, set Algorithm to 'RLS '.
Data Types: double

## InitialInverseCorrelationMatrix - Initial inverse correlation matrix <br> 0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an $N_{\text {Taps }}$-by- $N_{\text {Taps }}$ matrix. $N_{\text {Taps }}$ is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. If you specify InitialInverseCorrelationMatrix as a scalar, $a$, the equalizer sets the initial inverse correlation matrix to $a$ times the identity matrix: $a\left(\operatorname{eye}\left(N_{\text {Taps }}\right)\right.$ ).

Tunable: Yes

## Dependencies

To enable this property, set Algorithm to 'RLS ' .
Data Types: double

## Constellation - Signal constellation

pskmod(0:3,4,pi/4) (default)| vector
Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: pskmod (0:3,4, pi/4).

Tunable: Yes
Data Types: double

## ReferenceTap - Reference tap

3 (default) | positive integer
Reference tap, specified as a positive integer less than or equal to the NumForwardTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.
Data Types: double

## InputDelay - Input signal delay

0 (default) | nonnegative integer
Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1 , then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the release or reset object function.

## Data Types: double

## InputSamplesPerSymbol - Number of input samples per symbol <br> 1 (default) | positive integer

Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer.
Data Types: double

## TrainingFlagInputPort - Enable training control input

false (default) |true
Enable training control input, specified as false or true. Setting this property to true enables the equalizer training flag input $t f$.

Tunable: Yes
Data Types: logical

## AdaptAfterTraining - Update tap weights when not training true (default) | false

Update tap weights when not training, specified as true or false. If this property is set to true, the System object uses decision directed mode to update equalizer tap weights. If this property is set to false, the System object keeps the equalizer tap weights unchanged after training.

Tunable: Yes
Data Types: logical

## AdaptWeightsSource - Source of adapt tap weights request

'Property' (default)|'Input port'
Source of adapt tap weights request, specified as one of these values:

- 'Property ' - Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- 'Input port' - Specify this value to use the aw input to control when the System object adapts tap weights.

## Dependencies

To enable this property, set Algorithm to 'CMA ' .
Data Types: char | string

## AdaptWeights - Adapt tap weights

true (default) | false
Adapt tap weights, specified as true or false. If this property is set to true, the System object updates the equalizer tap weights. If this property is set to false, the System object keeps the equalizer tap weights unchanged.

Tunable: Yes
Dependencies
To enable this property, set AdaptWeightsSource to 'Property' and set AdaptAfterTraining to true.
Data Types: logical

## InitialWeightsSource - Source for initial tap weights

'Auto' (default)|'Property'
Source for initial tap weights, specified as one of these values:

- 'Auto' - Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- 'Property ' - Initialize the tap weights using the InitialWeights property value.

Data Types: char|string

## InitialWeights - Initial weights

0 or $[0 ; 0 ; 1 ; 0 ; 0]$ (default) | scalar | vector
Initial weights used by the adaptive algorithm, specified as a scalar or vector. The default is 0 when the Algorithm property is set to 'LMS' or 'RLS'. The default is $[0 ; 0 ; 1 ; 0 ; 0$ ] when the Algorithm property is set to 'CMA'.

If you specify InitialWeights as a scalar, the equalizer uses scalar expansion to create a vector of length $N_{\text {Taps }}$ with all values set to InitialWeights. $N_{\text {Taps }}$ is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. If you specify InitialWeights as a vector, the vector length must be $N_{\text {Taps }}$.

Tunable: Yes

## Data Types: double

## WeightUpdatePeriod - Tap weight update period

## 1 (default) | positive integer

Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.
Data Types: double

## Usage

## Syntax

```
y = dfe(x,tsym)
\(y=d f e(x, t s y m, t f)\)
\(y=d f e(x)\)
y = dfe(x,aw)
[y,err] = dfe( __ )
[y,err,weights] = dfe( __ )
```

## Description

$y=d f e(x, t s y m)$ equalizes input signal $x$ by using training symbols tsym. The output is the equalized symbols. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS'.
$y=d f e(x, t s y m, t f)$ also specifies training flag $t f$. The System object starts training when $t f$ changes from false to true (at the rising edge). The System object trains until all symbols in tsym are processed. The input tsym is ignored when $t f$ is false. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to true.
$y=d f e(x)$ equalizes input signal $x$. To enable this syntax, set the Algorithm property to 'CMA'.
$y=d f e(x, a w)$ also specifies adapts weights flag aw. The System object adapts the equalizer tap weights when aw is true. If aw is false, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.
[y,err] = dfe( $\qquad$ ) also returns error signal err using input arguments from any of the previous syntaxes.
[y,err,weights] = dfe(__) also returns weights, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

## Input Arguments

x - Input signal
column vector
Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property value. For more information, see "Symbol Tap Spacing" on page 3-513.

Data Types: double
Complex Number Support: Yes

## tsym - Training symbols

column vector
Training symbols, specified as a column vector of length less than or equal to the length of input $x$. The input tsym is ignored when tf is false.

## Dependencies

To enable this argument, set the Algorithm property to 'LMS ' or 'RLS '.

## Data Types: double

## tf - Training flag

true | false
Training flag, specified as true or false. The System object starts training when tf changes from false to true (at the rising edge). The System object trains until all symbols in tsym are processed. The input tsym is ignored when tf is false.

## Dependencies

To enable this argument, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to true.
Data Types: logical
aw - Adapt weights flag
true | false
Adapt weights flag, specified as true or false. If aw is true, the System object adapts weights. If aw is false, the System object keeps the weights unchanged.

## Dependencies

To enable this argument, set the Algorithm property to ' CMA ' and AdaptWeightsSource property to 'Input port'.
Data Types: logical
Output Arguments
y - Equalized symbols
column vector

Equalized symbols, returned as a column vector that has the same length as input signal x .
err - Error signal
column vector
Error signal, returned as a column vector that has the same length as input signal x .

## weights - Tap weights

column vector
Tap weights, returned as a column vector that has $N_{\text {Taps }}$ elements. $N_{\text {Taps }}$ is equal to the sum of the NumForwardTaps and NumFeedbackTaps property values. weights contains the tap weights from the last tap weight update.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Specific to comm.DecisionFeedbackEqualizer

| isLocked | Determine if System object is in use |
| :--- | :--- |
| clone | Create duplicate System object |
| info | Characteristic information about the equalizer object |
| maxstep | Maximum step size for LMS equalizer convergence |
| mmseweights | Linear equalizer MMSE tap weights |

## Common to All System Objects

| step | Run System object algorithm <br> release |
| :--- | :--- |
| Release resources and allow changes to System object property values and input <br> characteristics |  |
| reset | Reset internal states of System object |

## Examples

## Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object ${ }^{\text {TM }}$, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03 .

```
bpsk = comm.BPSKModulator;
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.
eqdfe_lms.ReferenceTap $=4$;
Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use maxstep to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

## Decision Feedback Equalize QPSK-Modulated Signal

Apply decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a delayed multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a decision feedback equalizer System object and display the default configuration. Adjust the reference tap to 1 . Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.DecisionFeedbackEqualizer
eq =
    comm.DecisionFeedbackEqualizer with properties:
                            Algorithm: 'LMS'
            NumForwardTaps: 5
            NumFeedbackTaps: 3
                    StepSize: 0.0100
            Constellation: [1x4 double]
                        ReferenceTap: 3
                    InputDelay: 0
        InputSamplesPerSymbol: 1
        TrainingFlagInputPort: false
            AdaptAfterTraining: true
            InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
```

eq.ReferenceTap = 1;
$m x S t e p=\operatorname{maxstep}(e q, r x)$
mxStep = 0.2141
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
Plot the constellation of the impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
```

constell(rx,y)

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')

errevm = comm.EVM;
evm $=$ errevm(tx,y)
evm $=10.1621$
Plot the equalizer tap weights.
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8 line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1) title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8 line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1) subplot (3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 - 0 line([eq.NumForwardTaps+0.5 eq.NumForwardTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)

## Decision Feedback Equalize System Using Different Training Schemes

Demonstrate decision feedback equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

## System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a decision feedback LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',5,'NumFeedbackTaps',4,'ReferenceTap',3,'StepSize',0.01);
```

## Train the Equalizer at the Beginning of Each Packet With Reset

Process each packet using prepended training symbols. Reset the equalizer after processing each packet. Resetting the equalizer after each packet forces the equalizer to train taps with no a priori
knowledge. Equalizer error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.
jj = 1;
figure
for ii = 1:numpkts
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M, pi/4);
packet = [trainingSymbols;dataSym];
rx = awgn(packet,SNR);
[ $\sim$,err] = dfeq(rx,trainingSymbols);
reset(dfeq)
if (ii ==1 || ii == 2 ||ii == numPkts) subplot $(3,1, j j)$
plot(abs(err))
ylim([0 1])
title(['Packet \# ',num2str(ii)])
xlabel('Symbols');
ylabel('Error Magnitude');
grid on;
jj = jj+1;
end
end

## Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have less symbol errors at the start of each packet.

```
release(dfeq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    channel = 1;
    rx = awgn(packet*channel,SNR);
    [~,err] = dfeq(rx,trainingSymbols);
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        ylim([0 1])
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols');
        ylabel('Error Magnitude');
        grid on;
        jj = jj+1;
    end
end
```

## Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
tx = (0:length(stream)-1)'/Rs;
channel = exp(li*2*pi*fd*tx);
rx = awgn(stream.*channel,SNR);
```

Set the AdaptAfterTraining property to false to stop the equalizer tap weight updates after the training phase.

```
release(dfeq)
dfeq.AdaptAfterTraining = false
dfeq =
    comm.DecisionFeedbackEqualizer with properties:
```

```
            Algorithm: 'LMS'
    NumForwardTaps: 5
        NumFeedbackTaps: 4
            StepSize: 0.0100
        Constellation: [1x4 double]
            ReferenceTap: 3
            InputDelay: 0
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
    AdaptAfterTraining: false
InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. Also, the output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = dfeq(rx,trainingSymbols);
figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('Time (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(err))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel Without Retraining')
```

scatterplot(y)

Set the TrainingInputPort property to true to configure the equalizer to retrain the taps when signaled by the trainFlag input. The equalizer trains only when trainFlag is true. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. Also, the output constellation does not rotate out of sync, and bit errors are reduced.

```
release(dfeq)
dfeq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        dfeq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
```

```
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```

Time-Varying Channel With Retraining

scatterplot (yVec)

## Decision Feedback Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Decision feedback equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
systemDelay = dsp.Delay(20);
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4); % OQPSK
delayedSym = systemDelay(filter(mpChan,1,tx));
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the LMS algorithm.

```
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',9,'NumFeedbackTaps',6,'ReferenceTap',5);
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
```

## Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the finddelay function.

```
rxDelay = finddelay(tx,rx)
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of rxDelay and the equalizer latency.

```
eqInfo = info(dfeq)
eqInfo = struct with fields:
    Latency: 4
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, err1, to determine when the equalized output converges.

```
plot(abs(err1))
xlabel('Symbols')
ylabel('Error Magnitude')
title('Equalizer Error Signal')
```

Equalizer Error Signal

The plot shows excessive errors for the first 2000 symbols. When demodulating symbols and computing symbol errors, account for the unconverged output and the system delay between the equalizer output and transmitted symbols.

```
dataRecl = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
symErrWithDelay = 6001
evmWithDelay = evm(y1)
evmWithDelay = 25.6868
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

## Adjust Input Delay in Decision Feedback Equalizer

Equalize the received data by using the delay value to set the InputDelay property. Since InputDelay is a nontunable property, you must release the dfeq System object to reconfigure the InputDelay property. Equalize the received symbols.

```
release(dfeq)
dfeq.InputDelay = rxDelay
dfeq =
    comm.DecisionFeedbackEqualizer with properties:
```

```
            Algorithm: 'LMS'
            NumForwardTaps: 9
            NumFeedbackTaps: 6
            StepSize: 0.0100
            Constellation: [1x4 double]
            ReferenceTap: 5
            InputDelay: 20
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
[y2,err2,wts2] = dfeq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal, as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1),real(wts2)])
xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed','rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed','rxDelayRemoved')
grid on
```

figure
plot([abs(err1), abs(err2)])
xlabel('Symbols')
ylabel('Error Magnitude')
legend('rxDelayed','rxDelayRemoved')
grid on

Plot error output of the equalized signals, rxDelayed and rxDelayRemoved. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols.
Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(dfeq)
eqInfo = struct with fields:
    Latency: 4
totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)
symErrDelayRemoved = 0
evmDelayRemoved = evm(y2(500+totalDelay:end))
evmDelayRemoved = 7.5147
```

## Decision Feedback Equalize Symbols Using EVM-Based Training

Recover QPSK symbols with a decision equalizer, using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, you can train the
equalizer taps using the AdaptWeights property to start and stop training. Use helper functions to generate plots and apply phase correction.

Initialize system variables.

```
rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
refTap = 3;
nFwdTaps = 5;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -12],'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;
```

Create the equalizer and EVM System objects. The equalizer System object specifies a decision feedback equalizer using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```
dfeq = comm.DecisionFeedbackEqualizer('Algorithm','CMA', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',0.03,'AdaptWeightsSource','Input port')
dfeq =
    comm.DecisionFeedbackEqualizer with properties:
                    Algorithm: 'CMA'
            NumForwardTaps: 5
            NumFeedbackTaps: 4
                    StepSize: 0.0300
                Constellation: [1x4 double]
                    ReferenceTap: 3
        InputSamplesPerSymbol: 1
                AdaptWeightsSource: 'Input port'
            InitialWeightsSource: 'Auto'
                WeightUpdatePeriod: 1
info(dfeq)
ans = struct with fields:
    Latency: 2
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
[errPlot,evmPlot,scatSym,adaptState] = initFigures(numPackets,ttlTaps);
```

## Equalization Loop

Follow these steps to implement the equalization loop.
1 Generate OQPSK data packets.
2 Apply Rayleigh fading and AWGN to the transmission data.

3 Apply equalization to the received data and phase correction to the equalizer output.
4 Estimate the EVM and toggle the adaptWeights flag to true or false based on the EVM level.
5 Update the figure plots.

```
for p=1:numPackets
    data = randi([0 M-1],numSymbols,1);
    tx = pskmod(data,M,pi/4);
    rx = awgn(raylChan(tx),SNR);
    rxDelay = finddelay(rx,tx);
    [y,err,wts] = dfeq(rx,adaptWeights);
    y = phaseCorrection(y);
    evmEst = evm(y);
    adaptWeights = (evmEst > 20);
    updateFigures(errPlot,evmPlot,scatSym,adaptState, ...
        wts,y(end),evmEst,adaptWeights,p,numPackets)
end
```

rxDelay
rxDelay $=0$
The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

## Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot,evmPlot,scatter,adaptState] = initFigures(numPkts,ttlTaps)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(ttlTaps,1);
adaptVec = nan(numPkts,1);
figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 ttlTaps 0 1.8])
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2)
scatter = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on
xlabel('In-phase'); ylabel('Quadrature'); title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on; axis([0 numPkts -0.2 1.2])
ylabel('Training'); xlabel('Symbols'); title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on; axis([1 numPkts 0 100])
xlabel('Symbols'); ylabel('EVM (%)'); title('EVM')
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,evmPlot,scatSym, ...
    adaptState,w,y,evmEst,adaptWts,p,numFrames)
persistent yVec evmVec adaptVec
if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end
yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;
errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end
```

This helper function applies phase correction.

```
function y = phaseCorrection(y)
```

$a=\operatorname{angle}(y((\operatorname{real}(y)>0) \&(i m a g(y)>0)))$;

```
a(a<0.1) = a(a< 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end
```

## Decision Feedback Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a decision feedback equalizer, using the least mean squares (LMS) algorithm. Use the reset object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and framebased processing.

## Setup

Initialize system variables, create the equalizer System object, and initialize the plot figures.

```
M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
refTap = 5;
nFwdTaps = 9;
nFdbkTaps = 4;
ttlTaps = nFwdTaps + nFdbkTaps;
stepsz = 0.01;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGains0utputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);
dfeq1 = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',nFwdTaps,'NumFeedbackTaps',nFdbkTaps,'ReferenceTap',refTap, ...
    'StepSize',stepsz,'TrainingFlagInputPort',true);
[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,ttlTaps, ...
    raylChan.AveragePathGains);
```

## Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

```
for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = dfeq1(rx,tx,trainingFlag);
```

Disable training after processing numTrainingSym training symbols.

```
    if q == numTrainingSym
    trainingFlag = false;
end
updateFigures(errPlot,wStem,hStem,scatPlot,err,wts,y,pg,q,ttlNumSym);
txVec(q,p) = tx;
rxVec(q,p) = rx;
end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
reset(raylChan)
reset(dfeq1)
```

end

## Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains ttlNumSym symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.
yVecPkt = zeros(ttlNumSym, numPackets);
errVecPkt $=$ zeros(ttlNumSym,numPackets);
wgtVecPkt = zeros(ttlTaps,numPackets);
dfeq2 = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
'NumForwardTaps', nFwdTaps, 'NumFeedbackTaps ' , nFdbkTaps, 'ReferenceTap', refTap, ...

```
    'StepSize',stepsz);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        dfeq2(rxVec(:,p),txVec(1:numTrainingSym,p));
    for q=1:ttlNumSym
        updateFigures(errPlot,wStem,hStem,scatPlot, ...
        errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p),pg,q,ttlNumSym);
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default taps weights.

```
reset(raylChan)
reset(dfeq2)
```

end

## Helper Functions

This helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,ttlTap,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(ttlTap,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 ttlTap 0 1.8]); grid on
```

```
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps'); ylabel('|Path Gain|'); title('Channel Path Gain Magnitude')
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]); grid on
xlabel('Symbols'); ylabel('|Error Magnitude|'); title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec,'.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on;
xlabel('In-phase'); ylabel('Quadrature'); title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1
    yVec = nan(ttlNumSym,1);
    eVec = nan(ttlNumSym,1);
end
yVec(p) = y;
eVec(p) = abs(err);
errPlot.YData = abs(eVec);
wStem.YData = abs(wts);
hStem.YData = [0 abs(pg) 0];
scatPlot.XData = real(yVec);
scatPlot.YData = imag(yVec);
drawnow limitrate
end
```

## More About

## Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbolspaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1 . Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

## Decision Feedback Equalizers

A decision feedback equalizer (DFE) is a nonlinear equalizer that reduces intersymbol interference (ISI) in frequency-selective channels. If a null exists in the frequency response of a channel, DFEs do
not enhance the noise. A DFE consists of a tapped delay line that stores samples from the input signal and contains a forward filter and a feedback filter. The forward filter is similar to a linear equalizer. The feedback filter contains a tapped delay line whose inputs are the decisions made on the equalized signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

DFEs can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, $K$, is 1 . The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, $K$, is an integer greater than 1 . Typically, $K$ is 4 for fractional symbol-spaced equalizers. The output sample rate is $1 / T$ and the input sample rate is $K / T$. Tap weight updating occurs at the output rate.

This schematic shows a fractional symbol-spaced DFE with a total of $N$ weights, a symbol period of $T$, and $K$ samples per symbol. The filter has $L$ forward weights and $N-L$ feedback weights. The forward filter is at the top, and the feedback filter is at the bottom. If $K$ is 1 , the result is a symbol-spaced DFE instead of a fractional symbol-spaced DFE.

In each symbol period, the equalizer receives $K$ input samples at the forward filter and one decision or training sample at the feedback filter. The equalizer then outputs a weighted sum of the values in the forward and feedback delay lines and updates the weights to prepare for the next symbol period.

Note The algorithm for the Adaptive Algorithm block in the schematic jointly optimizes the forward and feedback weights. Joint optimization is especially important for convergence in the recursive least square (RLS) algorithm.

For more information, see "Equalization".

## Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, $w$ is a vector of all weights $w_{i}$, and $u$ is a vector of all inputs $u_{i}$. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e .
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of inputs, $u$, and the inverse correlation matrix, $P$, the RLS algorithm first computes the Kalman gain vector, $K$, as

$$
K=\frac{P u}{(\text { ForgettingFactor })+u^{H} P u} .
$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range $(0,1]$. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. $H$ denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$
P_{\text {new }}=\frac{P_{\text {current }}\left(1-K u^{H}\right)}{\text { ForgettingFactor }} .
$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+K^{*} e .
$$

The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e .
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=y\left(R-|y|^{2}\right)$, where $R$ is a constant related to the signal constellation.

## comm.EVM

Package: comm
Measure error vector magnitude

## Description

The comm. EVM (error vector magnitude) System object measures the modulator or demodulator performance of an impaired signal.

To measure error vector magnitude:
1 Define and set up your EVM object. See "Construction" on page 3-517.
2 Call step to measure the modulator or demodulator performance according to the properties of comm. EVM. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj,x) and $y=o b j(x)$ perform equivalent operations.

## Construction

$E V M=$ comm. EVM creates an error vector magnitude object, EVM. This object measures the amount of impairment in a modulated signal.

EVM $=$ comm. EVM (Name, Value) creates an EVM object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Example: EVM = comm.EVM('ReferenceSignalSource','Estimated from reference constellation') creates an object, EVM, that measures the RMS EVM of a received signal by using a reference constellation.

## Properties

## Normalization

Normalization method
Normalization method used in EVM calculation, specified as one of the following: 'Average reference signal power' (default), 'Average constellation power', or 'Peak constellation power'.

## AverageConstellationPower

Average constellation power
Average constellation power, specified in watts as a positive real scalar. This property is available when Normalization is 'Average constellation power'. The default is 1.

## PeakConstellationPower

Peak constellation power
Peak constellation power, specified in watts as a positive real scalar. This property is available when Normalization is 'Peak constellation power'. The default is 1.

## ReferenceSignalSource

Reference signal source
Reference signal source, specified as either 'Input port' (default) or 'Estimated from reference constellation'. To provide an explicit reference signal against which the input signal is measured, set this property to 'Input port '. To measure the EVM of the input signal against a reference constellation, set this property to 'Estimated from reference constellation'.

## ReferenceConstellation

Reference constellation
Reference constellation, specified as a vector. This property is available when the ReferenceSignalSource property is 'Estimated from reference constellation'.

The default is [0.7071-0.7071i; -0.7071-0.7071i; -0.7071 + 0.7071i; $0.7071+$ 0.7071 i ], which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16QAM signal, you can use qammod $(0: 15,16)$.

## MeasurementIntervalSource

Measurement interval source
Measurement interval source, specified as one of the following: ' Input length' (default), 'Entire history','Custom', or 'Custom with periodic reset'. This property affects the RMS and maximum EVM outputs only.

- To calculate EVM using only the current samples, set this property to 'Input length '.
- To calculate EVM for all samples, set this property to 'Entire history'.
- To calculate EVM over an interval you specify and to use a sliding window, set this property to 'Custom'.
- To calculate EVM over an interval you specify and to reset the object each time the measurement interval is filled, set this property to 'Custom with periodic reset'.

## MeasurementInterval

Measurement interval
Measurement interval over which the EVM is calculated, specified in samples as a real positive integer. This property is available when MeasurementIntervalSource is 'Custom' or 'Custom with periodic reset'. The default is 100 .

## AveragingDimensions

Averaging dimensions

Averaging dimensions, specified as a positive integer or row vector of positive integers. This property determines the dimensions over which the averaging is performed. For example, to average across the rows, set this property to 2 . The default is 1 .

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between step calls. For example, if the input has size [ 4 3 2] and Averaging dimensions is [13], the output size is [lll $\left.\begin{array}{lll}1 & 3 & 1\end{array}\right]$, and the second dimension must remain fixed at 3 .

## MaximumEVMOutputPort

Maximum EVM measurement output port
Maximum EVM measurement output port, specified as a logical scalar. To create an output port for maximum EVM measurements, set this property to true. The default is false.

## XPercentileEVMOutputPort

$X$-percentile EVM measurement output port
$X$-percentile EVM measurement output port, specified as a logical scalar. To create an output port for $X$-percentile EVM measurements, set this property to true. The $X$-percentile EVM measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is false.

## XPercentileValue

$X$-percentile value
$X$-percentile value below which $X \%$ of the EVM measurements fall, specified as a real scalar from 0 to 100. This property is available when XPercentileEVMOutputPort is true. The default is 95.

## SymbolCountOutputPort

Symbol count output port
Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the $X$-percentile EVM measurements, set this property to true. This property is available when XPercentileEVMOutputPort is true. The default is false.

## Methods

| reset | Reset states of EVM measurement object |
| :--- | :--- |
| step | Measure error vector magnitude |

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Measure EVM of Noisy 16-QAM Modulated Signal

Create an EVM object. Configure it using name-value pairs to output maximum EVM, 90th percentile EVM, and the symbol count.

```
evm = comm.EVM('MaximumEVMOutputPort',true,...
    'XPercentileEVMOutputPort',true, 'XPercentileValue',90,...
    'SymbolCountOutputPort',true);
```

Generate random data symbols. Apply 16-QAM modulation. The modulated signal serves as the reference for the subsequent EVM measurements.

```
data = randi([0 15],1000,1);
refSym = qammod(data,16,'UnitAveragePower',true);
```

Pass the modulated signal through an AWGN channel.

```
rxSym = awgn(refSym,20);
```

Measure the EVM of the noisy signal.

```
[rmsEVM,maxEVM,pctEVM,numSym] = evm(refSym,rxSym)
rmsEVM = 9.8775
maxEVM = 26.8385
pctEVM = 14.9750
numSym = 1000
```

## Estimate Received EVM

Generate filtered QAM data and pass it through an AWGN channel. Compute the symbol error rate, and estimate the EVM of the received signal.

Create channel and filter System objects ${ }^{\mathrm{TM}}$.

```
M = 16;
refConst = qammod(0:M-1,M);
channel = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)',...
    'SNR',15,'SignalPower',10);
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',4);
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',4, ...
    'DecimationFactor',4);
```

Create an EVM object to output RMS and maximum EVM measurements.

```
evm = comm.EVM('MaximumEVMOutputPort',true, ...
    'ReferenceSignalSource','Estimated from reference constellation', ...
    'ReferenceConstellation',refConst);
```

Create an error rate object and account for the signal delay through the transmit and receive filters. For a filter, the group delay is equal to $1 / 2$ of the FilterSpanInSymbols property.

```
rxd = (txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols)/2;
errorRate = comm.ErrorRate('ReceiveDelay',rxd);
```

Perform the following channel operations:

- Generate random data symbols.
- Apply 16-QAM modulation.
- Filter the modulated data through a raised cosine Tx filter.
- Pass the transmitted signal through an AWGN channel.
- Filter the received data through a raised cosine Rx filter.
- Demodulate the filtered data.

```
txData = randi([0 15],1000,1);
modData = qammod(txData,M);
txSig = txfilter(modData);
rxSig = channel(txSig);
filtSig = rxfilter(rxSig);
rxData = qamdemod(filtSig,M);
```

Calculate the error statistics and display the symbol error rate.

```
errStats = errorRate(txData,rxData);
symErrRate = errStats(1)
symErrRate = 0.0222
```

Measure and display the received RMS EVM and maximum EVM values. Take the filter delay into account by deleting the first rxd +1 symbols. Because there are symbol errors, the EVM may not be totally accurate.

```
[rmsEVM,maxEVM] = evm(filtSig(rxd+1:end))
rmsEVM = 17.2966
maxEVM = 40.1595
```

## Measure EVM Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an EVM object. Measure the RMS EVM using the transmitted signal as the reference.

```
evm = comm.EVM;
rmsEVM1 = evm(txSig,rxSig);
```

Release the EVM object. Configure the object to estimate the EVM of the received signal against a reference constellation.

```
release(evm)
evm.ReferenceSignalSource = 'Estimated from reference constellation';
evm.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the RMS EVM using only the received signal as an input. Verify that it matches the result obtained when using a reference signal.

```
rmsEVM2 = evm(rxSig);
[rmsEVM1 rmsEVM2]
ans = 1\times2
    3.1524 3.1524
```

## Measure EVM Using Custom Measurement Interval

Measure the EVM of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames, $M$, and the number of subframes per frame, $K$.
$M=2 ;$
$K=5$;
Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen
frmLen = 500
```

Create an EVM object. Configure the object to use a custom measurement interval equal to the frame length.

```
evm1 = comm.EVM('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);
```

Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm1.ReferenceSignalSource = 'Estimated from reference constellation';
evml.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an EVM object, and configure it use a 500 -symbol measurement interval with a periodic reset. Configure the object to measure EVM using an 8-PSK reference constellation.

```
evm2 = comm.EVM('MeasurementIntervalSource','Custom with periodic reset', ...
    'MeasurementInterval',frmLen);
evm2.ReferenceSignalSource = 'Estimated from reference constellation';
evm2.ReferenceConstellation = pskmod(0:7,8,pi/8);
Initialize the EVM and signal-to-noise arrays.
```

```
rmsEVM1 = zeros(K,M);
rmsEVM2 = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the EVM for a noisy 8-PSK signal using both objects. The SNR increases by 1 dB from subframe to subframe. For evm1, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire frame of data is always processed. For evm2, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*K+7;
        rxSig = awgn(txSig,snrdB(k,m));
        rmsEVM1(k,m) = evm1(rxSig);
        rmsEVM2(k,m) = evm2(rxSig);
    end
end
```

Display the EVM measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the EVM object resets after the first frame so that the calculated EVM values more accurately reflect the current SNR.

```
stairs(snrdB(:),[rmsEVM1(:) rmsEVM2(:)])
xlabel('SNR (dB)')
ylabel('EVM (%)')
legend('No Reset','Periodic Reset')
```

## Measure EVM Across Different Dimensions

Create OFDM modulator and demodulator objects.
ofdmmod = comm. OFDMModulator('FFTLength', 32,'NumSymbols',4);
ofdmdemod = comm.OFDMDemodulator('FFTLength', 32,'NumSymbols',4);
Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1)
numSC = 21
numSym = ofdmDims.DataInputSize(2)
numSym = 4
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
modSig = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(modSig);
rxSig = awgn(txSig,10,'measured');
demodSig = ofdmdemod(rxSig);
```

Create an EVM object, where the result is averaged over the subcarriers. Measure the EVM. There are four entries corresponding to each of the 4 OFDM symbols.

```
evm = comm.EVM('AveragingDimensions',1);
rmsEVM = evm(demodSig,modSig)
rmsEVM = 1\times4
    27.4354 23.6279 22.6772 23.1699
```

Overwrite the EVM object, where the result is averaged over the OFDM symbols. Measure the EVM. There are 21 entries corresponding to each of the 21 subcarriers.

```
evm = comm.EVM('AveragingDimensions',2);
rmsEVM = evm(demodSig,modSig)
rmsEVM = 21\times1
    28.8225
    17.8536
    18.6809
    20.8872
    22.3532
    24.7197
    30.1954
    33.4899
    36.2847
    21.4230
```

Measure the EVM and average over both the subcarriers and the OFDM symbols.

```
evm = comm.EVM('AveragingDimensions',[1 2]);
rmsEVM = evm(demodSig,modSig)
rmsEVM = 24.2986
```

## Plot Time-Varying EVM for OFDM Signal

Calculate and plot the EVM of an OFDM signal. The signal consists of two packets separated by an interval.

Create System objects to:

- OFDM modulate a signal
- Introduce phase noise
- Plot time-varying signals
ofdmmod $=$ comm. OFDMModulator('FFTLength',256,'NumSymbols',2);
pnoise $=$ comm. PhaseNoise('Level',-60,'FrequencyOffset', 20,'SampleRate', 1000);
tscope = dsp.TimeScope('YLabel','EVM (\%)','YLimits',[0 40], ...
'SampleRate',1000,'TimeSpan',1.2, ...
'ShowGrid',true);
Create an EVM object. To generate a time-varying estimate of the EVM, set the AveragingDimensions property to 2.

```
evm = comm.EVM('MaximumEVMOutputPort',false, ...
    'ReferenceSignalSource','Input port', ...
    'AveragingDimensions',2);
```

Determine the input data dimensions of the OFDM modulator.

```
modDims = info(ofdmmod)
modDims =
    struct with fields:
        DataInputSize: [245 2]
            OutputSize: [544 1]
```

Create QPSK-modulated random data for the first packet. Apply OFDM modulation.

```
data = randi([0 3],modDims.DataInputSize);
qpskSig = pskmod(data,4,pi/4);
txSig1 = ofdmmod(qpskSig);
```

Create a second data packet.

```
data = randi([0 3],modDims.DataInputSize);
qpskSig = pskmod(data,4,pi/4);
txSig2 = ofdmmod(qpskSig);
```

Concatenate the two packets and include an interval in which nothing is transmitted.

```
txSig = [txSig1; zeros(112,1); txSig2];
```

Apply I/Q amplitude and phase imbalance to the transmitted signal.

```
rxSigIQimb = iqimbal(txSig,2,5);
```

Apply phase noise.

```
rxSig = pnoise(rxSigIQimb);
```

Measure the EVM of the received signal, and plot its time-varying EVM.

```
e = evm(txSig,rxSig);
tscope(e)
```

## Algorithms

Both the EVM block and the EVM object provide three normalization methods. You can normalize measurements according to the average power of the reference signal, average constellation power, or peak constellation power. Different industry standards follow one of these normalization methods.

The block or object calculates the RMS EVM value differently for each normalization method.

| EVM Normalization Method | Algorithm |
| :--- | :--- |
| Reference signal | $E V M_{R M S}=\sqrt{\frac{\sum_{\frac{1}{N}}^{\sum_{k} \sum_{k=1}^{N}\left(e_{k}\right)}\left(I_{k}^{2}+Q_{k}^{2}\right)}{N}} * 100$ |

| EVM Normalization Method | Algorithm |
| :---: | :---: |
| Average power | $\operatorname{EVM}_{\mathrm{RMS}}(\%)=100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{P_{\mathrm{avg}}}}$ |
| Peak power | $\operatorname{EVM}_{\mathrm{RMS}}(\%)=100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{P_{\max }}}$ |

Where:

- $e_{k}=e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}$
- $I_{k}=$ In-phase measurement of the $k$ th symbol in the burst
- $Q_{k}=$ Quadrature phase measurement of the $k$ th symbol in the burst
- $N=$ Input vector length
- $P_{\text {avg }}=$ The value for Average constellation power
- $P_{\max }=$ The value for Peak constellation power
- $I_{k}$ and $Q_{k}$ represent ideal (reference) values. $\tilde{I}_{k}$ and $\widetilde{Q}_{k}$ represent measured (received) symbols.

The max EVM is the maximum EVM value in a frame or $\mathrm{EVM}_{\max }=\max _{k \in[1, \ldots, N]}\left\{\mathrm{EVM}_{k}\right\}$, where $k$ is the $k$ th symbol in a burst of length $N$.

The definition for $\mathrm{EVM}_{\mathrm{k}}$ varies depending upon which normalization method you select for computing measurements. The block or object supports these algorithms.

| EVM Normalization | Algorithm |
| :--- | :--- |
| Reference signal | $E V M_{k}=\sqrt{\frac{e_{k}}{\frac{1}{N} \sum_{k=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}} * 1001$ |

The block or object computes the $X$-percentile EVM by creating a histogram of all the incoming $E V M_{k}$ values. The output provides the EVM value below which X\% of the EVM values fall.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

comm. ACPR | comm. CCDF | comm.MER

## Introduced in R2012a

## reset

System object: comm.EVM
Package: comm
Reset states of EVM measurement object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the EVM object, H .

## step

System object: comm. EVM
Package: comm
Measure error vector magnitude

## Syntax

RMSEVM = step(EVM,REFSYM,RXSYM)
RMSEVM = step(EVM,RXSYM)
[ ___ , MAXEVM] = step (___)
[__, ,XEVM] = step( $\qquad$
[___, NUMSYM] = step(___)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

RMSEVM = step(EVM, REFSYM, RXSYM) returns the measured root-mean-square EVM, RMSEVM, of the received signal RXSYM, based on reference signal REFSYM. EVM values are measured as a percentage.

REFSYM and RXSYM inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type double. To set the interval over which the EVM is measured, use the MeasurementIntervalSource and MeasurementInterval properties.

RMSEVM = step(EVM, RXSYM) returns the measured EVM of received signal RXSYM based on a reference signal specified in the ReceivedConstellation property.
[ __ , MAXEVM] = step ( ___ ) returns the maximum EVM, MAXEVM, given either of the two previous syntaxes.

To return the maximum EVM value, set the MaximumEVMOutputPort property to true. To set the interval over which the maximum EVM is measured, use the MeasurementIntervalSource and MeasurementInterval properties.
$\qquad$ ,XEVM] = step ( ___ ) returns the $X$-percentile EVM, XEVM.

To return the X-percentile EVM, set the XPercentileEVMOutputPort property to true. XEVM is the EVM below which $X \%$ of the measurements fall, where $X$ is set by the XPercentileValue property. XEVM is measured using all the input frames since the last reset.
[ ___ , NUMSYM] = step ( ___ ) returns the number of symbols, NUMSYM, used to calculate the $X$ percentile EVM.

To return NUMSYM, set the SymbolCountOutputPort property to true. NUMSYM is measured using all the input frames since the last reset.

Note EVM specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.EyeDiagram

Package: comm
Display eye diagram of time-domain signals

## Description

The comm. EyeDiagram System object displays multiple traces of a modulated signal to produce an eye diagram. You can use the object to reveal the modulation characteristics of the signal, such as the effects of pulse shaping or channel distortions. The eye diagram can measure signal characteristics and plot horizontal and vertical bathtub curves when the jitter and noise comply with the dual-Dirac model [1].

To display the eye diagram of an input signal:
1 Create the comm. EyeDiagram object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

ed = comm.EyeDiagram
ed = comm.EyeDiagram(Name,Value)

## Description

ed = comm.EyeDiagram creates an eye diagram System object with default property values.
ed = comm.EyeDiagram(Name, Value) sets properties using one or more name-value pair argument. Enclose each property name in single quotes. Unspecified properties have default values.

Example: comm.EyeDiagram('SampleRate',2,'DisplayMode','2D color histogram')

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Name - Title of eye diagram window

'Eye Diagram' (default) | character vector

Title of eye diagram window, specified as a character vector.
Tunable: Yes
Data Types: char

## SampleRate - Sample rate of input signal

1 (default) | positive real-valued scalar
Sample rate of the input signal in hertz, specified as a positive real-valued scalar.
Data Types: double

## SamplesPerSymbol - Number of samples per symbol

8 (default) | positive integer
Number of samples per symbol, specified as a positive integer.
Tunable: Yes
Data Types: double

## SampleOffset - Number of samples to skip before plotting the first point

0 (default) | nonnegative integer
Number of samples to skip before plotting the first point, specified as a nonnegative integer. To avoid irregular behavior, specify the offset to be less than the product of the SamplesPerSymbol and SymbolsPerTrace properties.

Tunable: Yes
Data Types: double

## SymbolsPerTrace - Number of symbols per trace <br> 2 (default) | positive integer

Number of symbols per trace, specified as a positive integer. To obtain eye measurements and visualize bathtub curves, use the default value of 2 .

Tunable: Yes
Data Types: double

## TracesToDisplay - Number of traces to display

40 (default) | positive integer
Number of traces to display, specified as a positive integer.
Tunable: Yes

## Dependencies

To enable this property, set DisplayMode property to 'Line plot'.

## Data Types: double

DisplayMode - Eye diagram display mode
'Line plot' (default)|'2D color histogram'

Eye diagram display mode, specified as one of these values.

- 'Line plot' - Overlay traces by plotting one line for each of the last TracesToDisplay traces.
- '2D color histogram' - Display a color gradient that shows how often the input matches different time and amplitude values.

Tunable: Yes
Data Types: char

## EnableMeasurements - Option to enable eye diagram measurements <br> false (default) | true

Option to enable eye diagram measurements, specified as true or false. Set this property to true to display the measurement pane and calculations in the eye diagram.

Tunable: Yes

## Data Types: logical

## ShowBathtub - Option to enable visualization of bathtub curves

'None' (default) | 'Horizontal' | 'Vertical' |'Both'
Option to enable visualization of bathtub curves, specified as 'None', 'Horizontal', 'Vertical', or 'Both'.

Tunable: Yes
Dependencies
To enable this property, set the EnableMeasurements property to true.

## Data Types: char

## OverlayHistogram - Histogram overlay

## 'None' (default)|'Jitter'|'Noise'

Histogram overlay, specified as 'None', 'Jitter', or 'Noise'.

- To overlay a horizontal histogram on the eye diagram, set this property to 'Jitter'.
- To overlay a vertical histogram on the eye diagram, set this property to 'Noise'.
- To display no histogram overlay, set this property to 'None'.

Tunable: Yes

## Dependencies

To enable this property, set the DisplayMode property to ' 2 D color histogram' and EnableMeasurements property to true.

## Data Types: char

## DecisionBoundary - Amplitude level threshold

0 (default) | real-valued scalar
Amplitude level threshold in volts, specified as a real-valued scalar. This property separates the different signaling regions for horizontal (jitter) histograms. Jitter histograms reset when this property changes.

For non-return-to-zero (NRZ) signals, set DecisionBoundary to 0. For return-to-zero (RZ) signals, set DecisionBoundary to half the maximum amplitude.

Tunable: Yes
Dependencies
To enable this property, set the EnableMeasurements property to true.
Data Types: double
EyeLevelBoundaries - Time range for calculating eye levels
[40 60] (default)| two-element row vector
Time range for calculating eye levels, specified as a two-element row vector. Specify the vector values as percentages of the symbol duration.

Tunable: Yes
Dependencies
To enable this property, set the EnableMeasurements property to true.

## Data Types: double

## RiseFallthresholds - Amplitude levels of the rise and fall transitions

[10 90] (default)| two-element row vector
Amplitude levels of the rise and fall transitions, specified as a two-element row vector. Specify the vector values as percentages of the eye amplitude. The crossing histograms of the rise and fall thresholds reset when this property changes.

Tunable: Yes
Dependencies
To enable this property, set the EnableMeasurements property to true.

## Data Types: double

## Hysteresis - Amplitude tolerance of the horizontal crossings

0 (default) | real-valued scalar
Amplitude tolerance of the horizontal crossings in volts, specified as a real-valued scalar. Increase this value to provide more tolerance to spurious crossings due to noise. Jitter and the rise and fall histograms reset when this property changes.

Tunable: Yes
Dependencies
To enable this property, set the EnableMeasurements property to true.

## Data Types: double

## BERThreshold - BER used for eye measurements

$1 \mathrm{e}-12$ (default) | scalar in the range [0, 0.5]

Bit error rate (BER) used for eye measurements, specified as a scalar in the range [0, 0.5]. The System object uses this value to measure the random jitter, the total jitter, horizontal eye openings, and vertical eye openings.

Tunable: Yes

## Dependencies

To enable this property, set the EnableMeasurements property to true.
Data Types: double

## BathtubBER - BER values used to calculate openings of bathtub curves

[0.5 10.^-(1:12)] (default)| vector
BER values used to calculate the openings of bathtub curves, specified as a vector of elements in the range [0, 0.5]. Horizontal and vertical eye openings are calculated for each of the values specified by this property.

Tunable: Yes
Dependencies
To enable this property, set the EnableMeasurements property to true and ShowBathtub property to 'Both', 'Horizontal', or 'Vertical'.
Data Types: double
MeasurementDelay - Duration of initial data discarded from measurements
0 (default) | nonnegative scalar
Duration of initial data discarded from measurements in seconds, specified as a nonnegative scalar.

## Dependencies

To enable this property, set the EnableMeasurements property to true.
Data Types: double

## OversamplingMethod - Oversampling method

'None' (default)|'Input interpolation'|'Histogram interpolation'
Oversampling method, specified as 'None', 'Input interpolation', or 'Histogram interpolation'.

To plot eye diagrams as quickly as possible, set OversamplingMethod to 'None'. The drawback to not oversampling is that the plots look pixelated when the number of sybomls per trace is small.

To create smoother, less-pixelated plots using a small number of symbols per trace, set OversamplingMethod to'Input interpolation' or 'Histogram interpolation'. In this case, ' Input interpolation' is the faster interpolation method and produces good results when the signal-to-noise ratio (SNR) is high. With a low SNR, this oversampling method is not recommended because it introduces a bias to the centers of the histogram ranges. 'Histogram interpolation' is not as fast as the other techniques, but it provides good results even when the SNR is low.

Tunable: Yes

## Dependencies

To enable this property, set the DisplayMode property to '2D color histogram'.
Data Types: char

## ColorScale - Color scale of the histogram

'Linear' (default)|'Logarithmic'
Color scale of the histogram, specified as 'Linear' or 'Logarithmic'. Change this property if certain areas of the histogram include a disproportionate number of points. Use the 'Logarithmic' option for eye diagrams with sharp peaks, where the signal repetitively matches specific time and amplitude values.

Tunable: Yes

## Dependencies

To enable this property, set the DisplayMode property to '2D color histogram'.

## Data Types: char

## ColorFading - Color fading

false (default) | true
Color fading, specified as true or false. To fade the points in the display as the interval of time after they are first plotted increases, set this property to true. This animation resembles an oscilloscope.

Tunable: Yes

## Dependencies

To enable this property, set the DisplayMode property to 'Line plot'.

## Data Types: logical

## ShowImaginaryEye - Show imaginary signal component

false (default) | true
Show imaginary signal component, specified as true or false. To view the imaginary or quadrature component of the input signal, set this property to true.

Tunable: Yes

## Dependencies

To enable this property, set the EnableMeasurements property to false.

## Data Types: logical

## YLimits $\boldsymbol{-} \boldsymbol{Y}$-axis limits

[-1.1 1.1] (default)| two-element row vector
$Y$-axis limits of the eye diagram in volts, specified as a two-element vector. The first element corresponds to ymin and the second to ymax. The second element must be greater than the first.

Tunable: Yes

## Data Types: double

## ShowGrid - Option to enable grid display

false (default) | true
Option to enable grid display on the eye diagram, specified as true or false. To display a grid on the eye diagram, set this property to true.

Tunable: Yes
Data Types: logical

## Position - Scope window position

four-element row vector
Scope window position in pixels, specified as a four-element row vector of the form [left bottom width height].

Tunable: Yes
Data Types: double

## Usage

## Syntax

```
ed(x)
```

## Description

$e d(x)$ displays and analyzes input signal $x$ in an eye diagram.

## Input Arguments

x-Input signal
vector | matrix
Input signal to be analyzed and displayed in the eye diagram, specified as a vector or matrix. x can be either a real or complex vector, or a real two-column matrix.
Data Types: double
Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Specific to comm.EyeDiagram

show
hide

Show scope window
Hide scope window

| horizontalBathtub | Horizontal bathtub curve |
| :--- | :--- |
| verticalBathtub | Vertical bathtub curve |
| jitterHistogram | Jitter histogram |
| noiseHistogram | Noise histogram |
| measurements | Measure eye diagram parameters |

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;
sps = 4;
```

Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
ed = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);
txSig = txfilter(modSig);
ed(txSig)
```

## Effect of Interpolation on 2D Histogram Eye Diagrams

Show the effects of different interpolation methods on 2-D histograms for different signal-to-noise ratio (SNR) conditions.

Create GMSK modulator and eye diagram System objects. Specify that the eye diagram displays using a 2-D color histogram and plots the real and imaginary signals.

```
gmsk = comm.GMSKModulator('PulseLength',3);
ed = comm.EyeDiagram('DisplayMode','2D color histogram', ...
    'ShowImaginaryEye',true,'YLimits',[-2 2]);
```

Generate bipolar data and apply GMSK modulation.

```
d = 2*randi([0 1],1e4,1)-1;
x = gmsk(d);
```

\%Pass the signal through an AWGN channel having a 25 dB SNR and with a fixed seed for repeatable randStream = RandStream('mt19937ar','Seed',5489); $y=\operatorname{awgn}\left(x, 25\right.$, 'measured' $^{\prime}$, randStream);

Display the eye diagram.
ed (y)

For a small number of samples per trace (16), the lack of interpolation causes piecewise-continuous behavior.

To compensate for the piecewise-continuous behavior, set the OversamplingMethod property to
'Input interpolation'. Reset the object and display the eye diagram.
ed.OversamplingMethod = 'Input interpolation';
reset(ed)
ed (y)

The interpolation smooths the eye diagram.
Now pass the GMSK-modulated signal through an AWGN channel having a 10 dB SNR. Display the eye diagram.
$y=\operatorname{awgn}(x, 10, ' m e a s u r e d ', r a n d S t r e a m) ;$
reset(ed)
ed(y)

The vertical striping is the result of input interpolation, which has limited accuracy in low-SNR conditions.

Set the OversamplingMethod property to 'Histogram interpolation'. Plot the eye diagram.
ed.OversamplingMethod = 'Histogram interpolation';
reset(ed)
ed (y)

The eye diagram plot now renders accurately because the histogram interpolation method works for all SNR values. This method results in increased execution time.

## Eye Diagram Jitter Measurements and Bathtub Curve Plots

Visualize the eye diagram of a dual-dirac input signal. Compute eye measurements, and visualize horizontal and vertical bathtub curves. Overlay the horizontal (jitter) histogram.

Specify the sample rate, the samples per symbol, and the number of traces.
fs = 10000;
sps = 200;
numTraces = 2000;
Create an eye diagram object having these properties:

- 2-D color histogram display
- Logarithmic color scale
- Jitter histogram overlay
- Horizontal and vertical bathtub curves
- Y-axis limits of [-1.3 1.3]
- Increased window height

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...
```

    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true, 'OverlayHistogram','Jitter', ...
    'ShowBathtub','Both','YLimits', [-1.3 1.3]);
    ed.Position = ed.Position + [0 0 0 120];

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
    'DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.
symbols = src.generate(numTraces*2);
Process the data in packets of 40 e 3 symbols, add noise, and display the eye diagram.

```
for idx = 1:(numTraces-1)/100
    x = symbols(1+(idx-1)*100*2*sps:idx*100*2*sps); % Read 40,000 symbols
    y = awgn(x,30); % Add noise
    ed(y); % Display eye diagram
end
```

## Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.
fs = 1000;
sps = 200;
numTraces = 1000;
Create an eye diagram object.
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'Sample0ffset',sps/2, ... 'DisplayMode','2D color histogram','ColorScale','Logarithmic', ... 'EnableMeasurements',true,'YLimits',[-1.2 1.2]);

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3); src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
'DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
Generate two symbols for each trace.
$x=$ src.generate(numTraces*2);
Pass the signal through an AWGN channel with a fixed seed for repeatable results.
randStream = RandStream('mt19937ar','Seed',5489);
$y=\operatorname{awgn}(x, 30$, 'measured', randStream); ed (y)

Calculate the jitter histogram count for each bin by using the jitterHistogram method. Plot the histogram.

```
jbins = jitterHistogram(ed);
```

plot(jbins)

Calculate the noise histogram count for each bin by using the noiseHistogram method. Plot the histogram.
nbins = noiseHistogram(ed);
plot(nbins)

## Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'Sample0ffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
    'DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.
$x=$ src.generate(numTraces*2);

Pass the signal through an AWGN channel with a fixed seed for repeatable results.
randStream $=$ RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured', randStream);
Display the eye diagram.
ed ( y )

Generate the horizontal bathtub data for the eye diagram. Plot the curve.
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER],'b',[hb.RightThreshold],[hb.BER], 'b')
grid
hb =
$1 \times 13$ struct array with fields:
BER
LeftThreshold
RightThreshold

Generate the vertical bathtub data for the eye diagram. Plot the curve.
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b',[vb.BER],[vb.UpperThreshold],'b') grid
$\mathrm{vb}=$
$1 \times 13$ struct array with fields:
BER
UpperThreshold
LowerThreshold

## Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a $2 \mathrm{e}-4$ standard deviation.
jtr $=$ commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency,'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation','ColorScale','Logarithmic','YLimits',[-1.2 1.2]);
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.
ed (y)

Pass the signal through the eye diagram object again to measure the rise and fall times.
ed (y)
hide(ed)
Display the data by using the measurements method.
eyestats $=$ measurements(ed);
riseTime = eyestats.RiseTime
fallTime $=$ eyestats.FallTime
riseTime =
0.0030
fallTime =
0.0030

The measured values match the 3 ms specification.

## More About

## Measurements

Measurements assume that the eye diagram object has valid data. A valid eye diagram has two distinct eye crossing points and two distinct eye levels.

To open the measurements pane, click on the Eye Measurements button or select Tools > Measurements > Eye Measurements from the toolbar menu.

## Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.
- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.
- When an eye crossing time measurement falls within the $[-0.5 / \mathrm{Fs}, 0$ ) seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by $2 \times T_{s}$ seconds (where $T_{\mathrm{s}}$ is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid time-wrapping or a warning, add a half-symbol duration delay to the current value in the MeasurementDelay property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

Eye Levels - Amplitude level used to represent data bits
Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are -1 V and +1 V . The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries. For example, when the EyeLevelBoundaries property is set to [40 60], that is, $40 \%$ and $60 \%$ of the symbol duration, the eye levels are calculated by estimating the mean value of the vertical histogram in this window marked by the eye level boundaries.

Eye Amplitude - Distance between eye levels
Eye amplitude is the distance in V between the mean value of two eye levels.

Eye Height - Statistical minimum distance between eye levels
Eye height is the distance between $\mu-3 \sigma$ of the upper eye level and $\mu+3 \sigma$ of the lower eye level. $\mu$ is the mean of the eye level, and $\sigma$ is the standard deviation.

Vertical Opening - Distance between BER threshold points
The vertical opening is the distance between the two points that correspond to the BERThreshold property. For example, for a BER threshold of $10^{-12}$, these points correspond to the $7 \sigma$ distance from each eye level.

Eye SNR - Signal-to-noise ratio
The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:
$\mathrm{SNR}=\frac{L_{1}-L_{0}}{\sigma_{1}-\sigma_{0}}$,
where $L_{1}$ and $L_{0}$ represent the means of the upper and lower eye levels and $\sigma_{1}$ and $\sigma_{0}$ represent their standard deviations.
Q Factor - Quality factor
The Q factor is the quality factor and is calculated using the same formula as the eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.
Crossing Levels - Amplitude levels for eye crossings
The crossing levels are the amplitude levels at which the eye crossings occur.
The level at which the input signal crosses the amplitude value is specified by the DecisionBoundary property.

Crossing Times - Times for which crossings occur
The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.

Eye Delay - Mean time between eye crossings
Eye delay is the midpoint between the two crossing times.

Eye Width - Statistical minimum time between eye crossings
Eye width is the horizontal distance between $\mu+3 \sigma$ of the left crossing time and $\mu-3 \sigma$ of the right crossing time. $\mu$ is the mean of the jitter histogram, and $\sigma$ is the standard deviation.

Horizontal Opening - Time between BER threshold points
The horizontal opening is the distance between the two points that correspond to the BERThreshold property. For example, for a $10^{-12} \mathrm{BER}$, these two points correspond to the $7 \sigma$ distance from each crossing time.

Rise Time - Time to transition from low to high
Rise time is the mean time between the low and high rise/fall thresholds defined in the eye diagram. The default thresholds are $10 \%$ and $90 \%$ of the eye amplitude.

Fall Time - Time to transition from high to low
Fall time is the mean time between the high and low rise/fall thresholds defined in the eye diagram. The default thresholds are $10 \%$ and $90 \%$ of the eye amplitude.

Deterministic Jitter - Deterministic deviation from ideal signal timing
Jitter is the deviation of a signal's timing event from its intended (ideal) occurrence in time [2]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ).

DJ is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.

Random Jitter - Random deviation from ideal signal timing
RJ is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation of $\sigma$. The RJ is computed as:
$\mathrm{RJ}=\left(Q_{L}+Q_{R}\right) \sigma$,
where
$Q=\sqrt{2} \operatorname{erfc}^{-1}\left(2 \frac{B E R}{\rho}\right)$.
BER is the specified BER threshold. $\rho$ is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

Total Jitter - Deviation from ideal signal timing
Total jitter (TJ) is the sum of the deterministic and random jitter, such that $\mathrm{TJ}=\mathrm{DJ}+\mathrm{RJ}$.

The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.

RMS Jitter - Standard deviation of jitter
RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.

Peak-to-Peak Jitter - Distance between extreme data points of histogram
Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

- EnableMeasurements is true
- ShowBathtub is 'Horizontal' or 'Both'

## Examples

## Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.
fs = 1000;
sps = 200;
numTraces $=1000$;
Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
    'DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.
x = src.generate(numTraces*2);
Pass the signal through an AWGN channel with a fixed seed for repeatable results.
randStream = RandStream('mt19937ar','Seed',5489); y = awgn(x,30,'measured',randStream);

Display the eye diagram.
ed(y)

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

## Input Arguments

## ed - Eye Diagram System object

System object
Eye Diagram System object, where you get the bathtub curve information from.

## Output Arguments

## s-Structure containing information

struct
Structure containing information about the horizontal bathtub curve.

## BER - Bit error rate values

numeric scalar
Bit error rate values, mapped on the Y -axis of the horizontalBathtub plot against the corresponding LeftThreshold and RightThreshold values on the $x$-axis, specified as a numeric scalar.
Data Types: double

## LeftThreshold - Left threshold values <br> numeric scalar

Left threshold values, mapped on the x -axis in the plot against corresponding BER values on the x axis.
Data Types: double

## RightThreshold - Right threshold values

numeric scalar
Right threshold values, mapped on the $x$-axis in the plot against corresponding $B E R$ values on the $x$ axis.
Data Types: double

Package: comm
Jitter histogram

## Syntax

jh = jitterHistogram(ed)

## Description

$j h=j i t t e r H i s t o g r a m(e d)$ returns the bin counts for decision boundary crossings set in eye diagram System object.

Note This method is available when EnableMeasurements is true.

## Examples

## Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
    'DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.
$x=$ src.generate(numTraces*2);
Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```

Calculate the jitter histogram count for each bin by using the jitterHistogram method. Plot the histogram.
jbins = jitterHistogram(ed);
plot(jbins)

Calculate the noise histogram count for each bin by using the noiseHistogram method. Plot the histogram.
nbins = noiseHistogram(ed);
plot(nbins)

## Input Arguments

## ed - Eye Diagram System object

System object
Eye Diagram System object, where the count for decision boundary crossings is set.

## Output Arguments

jh - Jitter histogram
nonnegative integer
Jitter histogram, which represent the counts for decision boundary crossings, specified as a nonnegative integer.

Measure eye diagram parameters

## Syntax

$\mathrm{m}=$ measurements(ed)

## Description

$m=$ measurements(ed) returns the parameter measurements calculated by eye diagram System object.

Note This method is available when EnableMeasurements is true.

## Examples

## Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a $2 \mathrm{e}-4$ standard deviation.
jtr = commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency,'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation','ColorScale','Logarithmic','YLimits',[-1.2 1.2]);
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.
ed (y)

Pass the signal through the eye diagram object again to measure the rise and fall times.
ed (y)
hide(ed)
Display the data by using the measurements method.

```
eyestats = measurements(ed);
riseTime = eyestats.RiseTime
fallTime = eyestats.FallTime
riseTime =
    0.0030
fallTime =
    0.0030
```

The measured values match the 3 ms specification.

## Input Arguments

ed - Eye Diagram System object
System object

Eye Diagram System object, where the parameter measurements are calculated.

## Output Arguments

m - Eye Diagram parameters measurement
struct
Eye Diagram parameters measurement, returned as a structure containing all 18 parameters mentioned in "Measurements" on page 3-555, along with their values.
Data Types: double

Noise histogram

## Syntax

nh = noiseHistogram(ed)

## Description

nh = noiseHistogram(ed) returns the bin counts for the signal values at the vertical opening (eye delay) as set in eye diagram System object.

Note This method is available when both of these conditions apply:

- EnableMeasurements is true
- DisplayMode is '2D color histogram'

## Examples

## Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.
fs = 1000;
sps = 200;
numTraces $=1000$;
Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'Sample0ffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
    'DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.
$x=$ src.generate(numTraces*2);
Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```

Calculate the jitter histogram count for each bin by using the jitterHistogram method. Plot the histogram.
jbins = jitterHistogram(ed);
plot(jbins)

Calculate the noise histogram count for each bin by using the noiseHistogram method. Plot the histogram.
nbins = noiseHistogram(ed);
plot(nbins)

## Input Arguments

## ed - Eye Diagram System object

System object
Eye Diagram System object, where the counts for signal values at the eye delay is set.

## Output Arguments

nh - Noise histogram
nonnegative integer
Noise histogram, which represent the counts for the signal values at the vertical opening (eye delay), specified as a nonnegative integer.

## step

System object: comm. EyeDiagram<br>Package: comm

Plot eye diagram of input signal

## Syntax

```
step(ed,x)
ed(x)
```

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
step (ed, x ) plots the eye diagram of input signal x using comm. EyeDiagram object ed.
$\mathrm{ed}(x)$ is equivalent to the first syntax.

Note ed specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## Examples

## Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;
sps = 4;
```

Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
ed = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);
```

txSig = txfilter(modSig);
ed(txSig)

Introduced in R2016b

## verticalBathtub

Package: comm
Vertical bathtub curve

## Syntax

s = verticalBathtub(ed)

## Description

$\mathrm{s}=$ verticalBathtub(ed) returns a structure containing information of verticalBathtub curve for the System object.

Note This method is available when both of these conditions apply:

- EnableMeasurements is true
- ShowBathtub is 'Vertical' or 'Both'

## Examples

## Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.
fs = 1000;
sps = 200;
numTraces $=1000$;
Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps,'Sample0ffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps,'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on','DiracJitter','on', ...
    'DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.
x = src.generate(numTraces*2);
Pass the signal through an AWGN channel with a fixed seed for repeatable results.
randStream $=$ RandStream('mt19937ar','Seed',5489); $y=\operatorname{awgn}(x, 30, ' m e a s u r e d ', r a n d S t r e a m) ;$

Display the eye diagram.
ed (y)

Generate the horizontal bathtub data for the eye diagram. Plot the curve.
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold],[hb.BER],'b',[hb.RightThreshold],[hb.BER],'b') grid
$\mathrm{hb}=$
$1 \times 13$ struct array with fields:
BER
LeftThreshold
RightThreshold

Generate the vertical bathtub data for the eye diagram. Plot the curve.
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b',[vb.BER],[vb.UpperThreshold],'b') grid
$\mathrm{vb}=$
$1 \times 13$ struct array with fields:
BER
UpperThreshold
LowerThreshold

## Input Arguments

## ed - Eye Diagram System object

System object
Eye Diagram System object, where you get the bathtub curve information from.

## Output Arguments

## s-Structure containing information

struct
Structure containing information about the vertical bathtub curve.

## BER - Bit error rate values

numeric scalar
Bit error rate values, mapped on the Y -axis of the verticalBathtub plot against the corresponding UpperThreshold and LowerThreshold values on the x-axis, specified as a numeric scalar.

Data Types: double

## UpperThreshold - Upper threshold value

numeric scalar

Upper threshold value, mapped on the x -axis in the plot against its corresponding BER value on the x axis.
Data Types: double
LowerThreshold - Lower threshold value
numeric scalar
Lower threshold value, mapped on the $x$-axis in the plot against its corresponding $B E R$ value on the $x$ axis.
Data Types: double

## comm.FMBroadcastDemodulator

Package: comm
Demodulate broadcast FM signal

## Description

The comm. FMBroadcastDemodulator System object demodulates a complex baseband FM signal and filters the signal with a de-emphasis filter to produce an audio signal. If the Stereo property is set to true, the object performs stereo decoding. If the RBDS property is set to true, the object also demodulates the RDS/RBDS waveform. For more details, see "Algorithms" on page 3-597.

To demodulate a complex baseband FM signal:
1 Define and set up the comm. FMBroadcastDemodulator object. See "Construction" on page 3593.

2 Call step to demodulate the complex baseband FM signal according to the properties of comm. FMBroadcastDemodulator.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

fmbDemod = comm.FMBroadcastDemodulator creates a demodulator System object, fmbDemod, that frequency demodulates an input signal.
fmbDemod = comm.FMBroadcastDemodulator(Name, Value) creates an FM demodulator object, fmbDemod, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).
fmbDemod = comm.FMBroadcastDemodulator(MOD) creates an FM demodulator object, fmbDemod, whose properties are determined by the corresponding FM modulator object, MOD.

## Properties

## SampleRate

Input signal sample rate (Hz)
Specify the sample rate of the input signal in Hz as a positive real scalar. The default value is 240 e 3 . This property is nontunable.

## FrequencyDeviation

Peak deviation of the output signal frequency (Hz)
Specify the frequency deviation of the FM demodulator in Hz as a positive real scalar. The default value is 75 e 3 . System bandwidth is equal to twice the sum of the frequency deviation and the
message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe. This property is nontunable.

## FilterTimeConstant

Time constant of the de-emphasis filter (s)
Specify the de-emphasis lowpass filter time constant as a positive real scalar. The default value is $7.5 \mathrm{e}-05$. FM broadcast standards specify a value of $75 \mu \mathrm{~s}$ in the United States and $50 \mu \mathrm{~s}$ in Europe. This property is nontunable.

## AudioSampleRate

Audio sample rate of the output signal (Hz)
Specify the output audio sample rate as a positive real scalar. The default value is 48000 . This property is nontunable.

## PlaySound

Flag to enable or disable audio playback
To playback the output signal on the default audio device, set this property to true. The default is false. This property is nontunable.

## BufferSize

Buffer size of the audio device
Specify the size of the buffer (in samples) that the object uses to communicate with an audio device as a positive scalar integer. The default is 4096 . This property is available only when PlaySound is true. This property is nontunable.

## Stereo

Flag to enable or disable stereo audio
Set this property to true to demodulate a stereophonic audio signal. Set to fal se if the input signal is monophonic. The default is false. This property is nontunable.

## RBDS

Flag to demodulate RDS/RBDS waveform
If RBDS is set to true, the second output of the step method is the baseband RDS/RBDS waveform. The default value is false. This property is nontunable.

## RBDSSamplesPerSymbol

Oversampling factor of RDS/RBDS output
Specify the number of samples of the RDS/RBDS output as a positive integer. The RDS/RBDS sample rate is given by RBDSSamplesPerSymbol $\times 1187.5 \mathrm{~Hz}$. According to the RDS/RBDS standard, the sample rate of each bit is 1187.5 Hz .

This property applies only when you set RBDS to true.

The default is 10 .

## RBDSCostasLoop

Option to recover phase of RDS/RBDS signal
Specify whether a Costas loop is used to recover the phase of the RDS/RBDS signal. Set this option to true for radio stations that do not lock the 57 kHz RDS/RBDS signal in phase with the third harmonic of the 19 kHz pilot tone.

This property applies only when you set RBDS to true.
The default value is false.

## Examples

## FM Broadcast a Streaming Audio Signal

Modulate and demodulate a streaming audio signal with the FM broadcast modulator and demodulator objects. Play the audio signal using a default audio device.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

Create an audio file reader System object ${ }^{\mathrm{TM}}$ and read the file guitartune.wav.

```
audio = dsp.AudioFileReader('guitartune.wav','SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the AudioSampleRate property to match the sample rate of the input signal. Set the SampleRate property of the demodulator to match the specified sample rate of the modulator. Set the PlaySound property of the demodulator to true to enable audio playback.

```
fmbMod = comm.FMBroadcastModulator('AudioSampleRate',audio.SampleRate, ...
    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audio.SampleRate, ...
    'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal and playback the audio input.

```
while ~isDone(audio)
    audioData = audio();
```

```
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData);
end
```

## FM Modulate and Demodulate an RBDS Waveform

Generate a basic RBDS waveform, FM modulate it with an audio signal, and then demodulate it.
Note: This example runs only in R2017a or later.
Create a RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by $1187.5 \times 10$. Set the audio sample rate to $1187.5 \times 40$.

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;
afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRa
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);
fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'RBDSSamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'PlaySound',true);
scope = dsp.TimeScope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
```

Get the current audio input. Generate RBDS information at the same configured rate as audio. FM modulate the stereo audio with RBDS information. Add additive white Gaussian noise. FM demodulate the audio and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input], rbdsWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end

## Algorithms

The FM Broadcast demodulator includes the functionality of the baseband FM demodulator, deemphasis filtering, and the ability to receive stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in comm. FMDemodulator.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$
H_{p}(f)=1+j 2 \pi f \tau_{s},
$$

where $\tau_{s}$ is the filter time constant. The time constant is $50 \mu \mathrm{~s}$ in Europe and $75 \mu$ s in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$
H_{d}(f)=\frac{1}{1+j 2 \pi f \tau_{s}} .
$$

For an audio sample rate of 44.1 kHz , the de-emphasis filter has the following response.

```
Figure 1: Magnitude Response(dB) }\times\mathrm{ Figure 2: Magnitude Response (dB) }
```

## Stereo and RDS/RBDS FM - Multiplex Signal

The FM broadcast demodulator supports stereophonic and monophonic operations. To support stereo transmission, the left ( L ) and right ( R ) channel information ( $\mathrm{L}+\mathrm{R}$ ) is assigned to the mono portion of the spectrum ( 0 to 15 kHz ). The ( $\mathrm{L}-\mathrm{R}$ ) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals.

Here is the spectrum of the multiplex baseband signal, $m(t)$.

$m(t)$ is given by
$m(t)=C_{0}[L(t)+R(t)]+C_{1} \cos (2 \Pi \times 19 k H z \times t)+C_{0}[L(t)-R(t)] \cos (2 \Pi \times 38 k H z \times t)+C_{2} R B D S(t$ $) \cos (2 \pi \times 57 k H z \times t)$,
where $C_{0}, C_{1}$, and $C_{2}$ are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the $(L(t) \pm R(t))$ signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

The demodulator applies $m(t)$ to three bandpass filters with center frequencies at 19,38 , and 57 kHz , and to a lowpass filter with a $3-\mathrm{dB}$ cutoff frequency of 15 kHz . The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the ( $L-R$ ) and RDS/RBDS signals, respectively. To generate a scaled version of the left and right channels that produce the stereo sound, the $(L+R)$ and $(L-R)$ signals are added and subtracted. The RDS/RBDS signal is recovered by mixing with the 57 kHz signal.

Here is the block diagram of the FM broadcast demodulator.

## Limitations

The input length must be an integer multiple of the AudioDecimationFactor property. If RBDS is set to true, the input length in addition must be an integer multiple of RBDSDecimationFactor. For more information on these two properties, see the info method.

Filter information about FM broadcast demodulator

## Syntax

S = info(fmbDemod)

## Description

$\mathrm{S}=$ info(fmbDemod) returns a structure, S , containing this information for the comm. FMBroadcastDemodulator System object, fmbDemod:

| Field | Description |
| :--- | :--- |
| AudioDecimationFactor | Decimation factor of the audio demodulator filter. |
| AudioInterpolationFactor | Interpolation factor of the audio demodulator <br> filter. |
| RBDSDecimationFactor | Decimation factor of the RDS/RBDS demodulator <br> filter. |
| RBDSInterpolationFactor | Interpolation factor of the RDS/RBDS <br> demodulator filter. |

Note When RBDS is true, the demodulator input sequence length must be a multiple of AudioDecimationFactor and RBDSDecimationFactor.

When RBDS is false, the demodulator input sequence length must be a multiple of AudioDecimationFactor.

## Introduced in R2015a

## reset

System object: comm. FMBroadcastDemodulator
Package: comm
Reset states of the FM broadcast demodulator object

## Syntax

reset(fmbDemod)

## Description

reset (fmbDemod) resets the states of the comm. FMBroadcastDemodulator object, fmbDemod.
This method resets the windowed suffix from the last symbol in the previously processed frame.

Introduced in R2015a

## step

System object: comm. FMBroadcastDemodulator Package: comm

Apply FM broadcast demodulation

## Syntax

audioSig = step(fmbDemod,X)
[audioSig,rbdsSig] = step(fmbDemod,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
audioSig = step(fmbDemod,X) demodulates the complex baseband FM signal, X , and filters this signal with a de-emphasis filter to produce an audio signal, audioSig. If the Stereo property is set to true, stereo decoding is also performed. The output, audioSig, is a real vector with length equal to (AudioSampleRate/SampleRate) $\times$ length (X).
[audioSig,rbdsSig] = step(fmbDemod,X) also demodulates the baseband RBDS signal, rbdsSig. The step method outputs the RBDS signal only if the RBDS property is set to true. The output, rbdsSig, is a real vector with length equal to (RBDSSamplesPerSymbol $\times 1187.5 /$ SampleRate) $\times$ length (X).

Note fmbDemod specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Introduced in R2015a

## comm.FMBroadcastModulator

Package: comm
Modulate broadcast FM signal

## Description

The comm. FMBroadcastModulator System object pre-emphasizes an audio signal and modulates it onto a baseband FM signal. If the Stereo property is set to true, the object modulates the audio input ( $L-R$ ) in the 38 kHz band, in addition to modulating it in the baseband $(L+R)$. If the RBDS property is set to true, the object modulates a baseband RDS/RBDS signal at 57 kHz . For more details, see "Algorithms" on page 3-609.

To FM modulate an audio signal:
1 Define and set up the comm. FMBroadcastModulator object. See "Construction" on page 3605.

2 Call step to apply broadcast FM modulation to an audio signal according to the properties of comm. FMBroadcastModulator.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

fmbMod $=$ comm.FMBroadcastModulator creates a modulator System object, fmbMod, that frequency modulates an input signal.
fmbMod = comm. FMBroadcastModulator(demod) creates a broadcast FM modulator object whose properties are determined by the corresponding broadcast FM demodulator object, demod.
fmbMod = comm.FMBroadcastModulator(Name, Value) creates a broadcast FM modulator object with each specified property Name set to the specified Value. You can specify additional namevalue pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## SampleRate

Output signal sample rate (Hz)
Specify the sample rate of the output signal in Hz as a positive real scalar. The default value is 240 e 3 . This property is nontunable.

## FrequencyDeviation

Peak deviation of the output signal frequency ( Hz )

Specify the frequency deviation of the FM modulator in Hz as a positive real scalar. The default value is 75 e 3 . The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe. This property is nontunable.

## FilterTimeConstant

Filter time constant (s)
Specify the pre-emphasis highpass filter time constant as a positive real scalar. FM broadcast standards specify a value of $75 \mu$ s in the United States and $50 \mu \mathrm{~s}$ in Europe. The default value is $7.5 \mathrm{e}-05$. The property is nontunable.

## AudioSampleRate

Sample rate of the input audio signal ( Hz )
Specify the audio sample rate as a positive real scalar. The default value is 48000. This property is nontunable.

## Stereo

Flag to set stereo operations
Set this property to true if the input is a stereophonic audio signal. Set to false if the input signal is monophonic. The default is false. This property is nontunable.

## RBDS

Flag to modulate RDS/RBDS waveform
If RBDS is set to true, the step method accepts the baseband RDS/RBDS waveform as its second input and the object modulates the signal at 57 kHz . The default value is false. This property is nontunable.

## RBDSSamplesPerSymbol

Oversampling factor of RDS/RBDS input
Specify the number of samples per RDS/RBDS symbol as a positive integer. The RDS/RBDS sample rate is given by RBDSSamplesPerSymbol $\times 1187.5 \mathrm{~Hz}$. According to the RDS/RBDS standard, the sample rate of each bit is 1187.5 Hz .

This property applies only when you set RBDS to true.
The default is 10 .

## Algorithms

The FM Broadcast modulator includes the functionality of the baseband FM modulator, pre-emphasis filtering, and the ability to transmit stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in comm. FMModulator.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$
H_{p}(f)=1+j 2 \pi f \tau_{s},
$$

where $\tau_{s}$ is the filter time constant. The time constant is $50 \mu$ s in Europe and $75 \mu$ s in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$
H_{d}(f)=\frac{1}{1+j 2 \pi f \tau_{s}}
$$

Irrespective of the audio sampling rate, the signal is converted to a 152 kHz output sampling rate. For an audio sample rate of 44.1 kHz , the pre-emphasis filter has the following response.

## Stereo and RDS/RBDS FM - Multiplex Signal

The FM broadcast modulator supports stereophonic and monophonic operations. To support stereo transmission, the left ( L ) and right ( R ) channel information ( $\mathrm{L}+\mathrm{R}$ ) is assigned to the mono portion of the spectrum ( 0 to 15 kHz ). The ( $\mathrm{L}-\mathrm{R}$ ) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals. Here is the spectrum of the multiplex baseband signal.

Here is the block diagram of the FM broadcast modulator, which is used to generate the multiplex baseband signal. $L(t)$ and $R(t)$ denote the time-domain waveforms from the left and right channels. RBDS $(t)$ denotes the time-domain waveform of the RDS/RBDS signal.

## MPX Encoder

The multiplex message signal, $m(t)$ is given by

$$
m(t)=C_{0}[L(t)+R(t)]+C_{1} \cos (2 \pi \times 19 k H z \times t)+C_{0}[L(t)-R(t)] \cos (2 \pi \times 38 k H z \times t)+C_{2} R B D S(t
$$ $) \cos (2 \Pi \times 57 \mathrm{kHz} \times t)$,

where $C_{0}, C_{1}$, and $C_{2}$ are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the $(L(t) \pm R(t)$ ) signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

## Limitations

- If RBDS is true, both the audio and RDS/RBDS inputs must satisfy the following equation:

$$
\frac{\text { audioLength }}{\text { audioSampleRate }}=\frac{\text { RBDSLength }}{\text { RBDSSampleRate }}
$$

- The input length of the audio signal must be an integer multiple of the AudioDecimationFactor property. The input length of the RDS/RBDS signal must be an integer multiple of the RBDSDecimationFactor property. For more information on these two properties, see the info method.

The modulator input sequence length for the RDS/RBDS input must be a multiple of RBDSDecimationFactor.

## Introduced in R2015a

## reset

System object: comm. FMBroadcastModulator
Package: comm
Reset states of the FM broadcast modulator object

## Syntax

reset(fmbMod)

## Description

reset (fmbMod) resets the states of the comm. FMBroadcastModulator object, fmbMod.
This method resets the windowed suffix from the last symbol in the previously processed frame.
Introduced in R2015a

## step

System object: comm. FMBroadcastModulator Package: comm

Apply FM broadcast modulation

## Syntax

modSig = step(fmbMod,audioSig)
modSig = step(fmbMod,audioSig,rbdsSig)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
modSig = step(fmbMod,audioSig) pre-emphasizes the audio signal, audioSig, and modulates it onto a baseband FM signal. The audio signal can be real or complex with a single-precision or a double-precision data type. If the Stereo property of fmbMod is set to true, stereo encoding is performed after pre-emphasis and the audio signal must have at least two channels. If Stereo is false, the audio signal must be a column vector. The length of the modulated signal, modSig, is (SampleRate/AudioSampleRate) $\times$ length(audioSig).
modSig $=$ step(fmbMod,audioSig,rbdsSig) also modulates a baseband RBDS signal at 57 kHz . You can pass rbdsSig as an input only if you set the RBDS property to true. The length of output vector modSig is (SampleRate/AudioSampleRate) $\times$ length(audioSig).

Note fmbMod specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Introduced in R2015a

## comm.FMDemodulator

Package: comm
Demodulate using FM method

## Description

The FMDemodulator System object demodulates an FM modulated signal.
To FM demodulate a signal:
1 Define and set up the FMDemodulator object. See "Construction" on page 3-616.
2 Call step to FM demodulate a signal according to the properties of comm. FMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

$\mathrm{H}=$ comm. FMDemodulator creates a demodulator System object, H , that frequency demodulates an input signal.

H = comm. FMDemodulator(mod) creates an FM demodulator object whose properties are determined by the corresponding FM modulator object, mod.

H = comm. FMDemodulator(Name, Value) creates an FM demodulator object with each specified property Name set to the specified Value. Name must appear inside single quotes. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## FrequencyDeviation

Peak deviation of the output signal frequency (Hz)
Specify the frequency deviation of the FM demodulator in Hz as a positive real scalar. The default value is 75 e 3 . The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. This property is nontunable.

## SampleRate

Sample rate of input signal (Hz)
Specify the sample rate in Hz as a positive real scalar. The default value is 240 e 3 . The output sample rate is equal to the input sample rate. This property is nontunable.

## Methods

reset Reset states of the FM demodulator object
step Applies FM baseband demodulation

## Examples

## FM Modulate and Demodulate a Sinusoidal Signal

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Set the example parameters.

```
fs = 100; % Sample rate (Hz)
ts = l/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5 s and frequency 4 Hz .
$\mathrm{t}=(0: \mathrm{ts}: 0.5-\mathrm{ts})^{\prime}$;
$x=\sin \left(2 *{ }^{*} i^{*} 4 *\right)$;
Create an FM modulator System object ${ }^{\text {TM }}$.
MOD $=$ comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.
$y=\operatorname{step}(M O D, x) ;$
plot(t,[x real(y)])

Demodulate the FM modulated signal.

```
DEMOD = comm.FMDemodulator('SampleRate',fs,'FrequencyDeviation',fd);
```

z = step(DEMOD,y);

Plot the input and demodulated signals. The demodulator output signal exactly aligns with the input signal.

```
plot(t,x,'r',t,z,'ks')
legend('Input Signal','Demod Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```

## Create an FM Demodulator from an FM Modulator

Create an FM demodulator System object? from an FM modulator object. Modulate and demodulate audio data loaded from a file and compare its spectrum with that of the input data.

Set the example parameters.

```
fd = 50e3; % Frequency deviation (Hz)
fs = 300e3;
% Sample rate (Hz)
```

Create an FM modulator System object.
MOD = comm.FMModulator('FrequencyDeviation',fd,'SampleRate',fs);
Create a companion demodulator object based on the modulator.
DEMOD = comm.FMDemodulator(MOD);
Verify that the properties are identical in the two System objects.
MOD
DEMOD

MOD =

```
    comm.FMModulator with properties:
    SampleRate: 300000
    FrequencyDeviation: 50000
DEMOD =
    comm.FMDemodulator with properties:
        SampleRate: 300000
        FrequencyDeviation: 50000
```

Load audio data into structure variable, S.
S = load('handel.mat');
data = S.y;
fsamp = S.Fs;
Create a spectrum analyzer System object.
SA = dsp.SpectrumAnalyzer('SampleRate',fsamp,'ShowLegend',true);
FM modulate and demodulate the audio data.
modData = step(MOD,data);
demodData $=$ step(DEMOD,modData);
Verify that the spectrum plot of the input data (Channel 1) is aligned with that of the demodulated data (Channel 2).
step(SA,[data demodData])

## FM Modulate and Demodulate an Audio File

Playback an audio file after applying FM modulation and demodulation. The example takes advantage of the characteristics of System objects ${ }^{\mathrm{TM}}$ to process the data in streaming mode.

Load the audio file, guitartune.wav, using an audio file reader object.
AUDIO = dsp.AudioFileReader...
('guitartune.wav','SamplesPerFrame',4410);
Create an audio device writer object for audio playback.
AUDIOPLAYER = audioDeviceWriter;
Create modulator and demodulator objects having default properties.
MOD = comm.FMModulator;
DEMOD = comm.FMDemodulator;
Read audio data, FM modulate, FM demodulate, and playback the demodulated signal, z.
while ~isDone(AUDIO)
$x=\operatorname{step}(A U D I O) ; \quad$ R Read audio data

```
    y = step(MOD,x); % FM modulate
    z = step(DEMOD,y); % FM demodulate
    step(AUDIOPLAYER,z); % Playback the demodulated signal
end
```

McGraw-Hill, 1971, pp. 142-155.

## Algorithms

Represent a frequency modulated passband signal, $Y(t)$, as

$$
Y(t)=A \cos \left(2 \pi f_{C} t+2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau\right),
$$

where $A$ is the carrier amplitude, $f_{c}$ is the carrier frequency, $x(\tau)$ is the baseband input signal, and $f_{\Delta}$ is the frequency deviation in Hz . The frequency deviation is the maximum shift from $f_{c}$ in one direction, assuming $|x(t)| \leq 1$.

A baseband FM signal can be derived from the passband representation by downconverting it by $f_{c}$ such that

$$
\begin{gathered}
y_{S}(t)=Y(t) e^{-j 2 \pi f_{c} t}=\frac{A}{2}\left[e^{\left.j\left(2 \pi f_{C} t+2 \pi f_{\Delta} S_{b}^{t} x(\tau) d \tau\right)+e^{-j\left(2 \pi f_{C} t+2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau\right)}\right] e^{-j 2 \pi f_{C} t}}\right. \\
=\frac{A}{2}\left[e^{j 2 \pi f_{\Delta} \int_{b}^{t} x(\tau) d \tau}+e^{-j 4 \pi f_{C} t-j 2 \pi f_{\Delta}} \int_{b}^{t} x(\tau) d \tau\right.
\end{gathered} .
$$

Removing the component at $-2 f_{c}$ from $y_{s}(t)$ leaves the baseband signal representation, $y(t)$, which is expressed as

$$
y(t)=\frac{A}{2} e^{j 2 \pi f_{\Delta}} \int_{0}^{t} x(\tau) d \tau .
$$

The expression for $y(t)$ is rewritten as

$$
y(t)=\frac{A}{2} e^{j \phi(t)},
$$

where $\phi(t)=2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau$, which implies that the input signal is a scaled version of the derivative of the phase, $\phi(t)$.

A baseband delay demodulator is used to recover the input signal from $y(t)$.

A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$
w(t)=\frac{A^{2}}{4} e^{j \phi(t)} e^{-j \phi(t-T)}=\frac{A^{2}}{4} e^{j[\phi(t)-\phi(t-T)]}
$$

where $T$ is the sample period. In discrete terms, $w_{n}=w(n T)$, and

$$
\begin{aligned}
& w_{n}=\frac{A^{2}}{4} e^{j\left[\phi_{n}-\phi_{n}-1\right]}, \\
& v_{n}=\phi_{n}-\phi_{n-1} .
\end{aligned}
$$

The signal $v_{n}$ is the approximate derivative of $\phi_{n}$, such that $v_{n} \approx x_{n}$.

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the FMDemodulator object, H .
This method resets the windowed suffix from the last symbol in the previously processed frame.

## step

System object: comm. FMDemodulator
Package: comm
Applies FM baseband demodulation

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ frequency demodulates an input signal, X , and returns an output signal, Y . The input $X$ is real or complex and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output Y is real and has the same data type and dimensions as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.FMModulator

Package: comm
Modulate using FM method

## Description

The FMModulator System object applies FM modulation to an input signal.
To FM modulate a signal:
1 Define and set up the FMModulator object. See "Construction" on page 3-626.
2 Call step to apply FM modulation to a signal according to the properties of comm. FMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. FMModulator creates a modulator System object, H, that frequency modulates an input signal.

H = comm. FMModulator(demod) creates an FM modulator object whose properties are determined by the corresponding FM demodulator object, demod.

H = comm. FMModulator(Name, Value) creates an FM modulator object with each specified property Name set to the specified Value. Name must appear inside single quotes. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## FrequencyDeviation

Peak deviation of the output signal frequency (Hz)
Specify the frequency deviation of the FM modulator in Hz as a positive real scalar. The default value is 75 e 3 . The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. This property is nontunable.

## SampleRate

Sample rate of the input signal (Hz)

## Examples

## FM Modulate a Sinusoidal Signal

Apply baseband modulation to a sine wave input signal and plot its response.
Set the example parameters.

```
fs = 1e3; % Sample rate (Hz)
ts = l/fs; % Sample period (s)
fd = 50; % Frequency deviation (Hz)
```

Create a sinusoidal input signal with duration 0.5 s and frequency 4 Hz .
t = (0:ts:0.5-ts)';
$x=\sin (2 * p i * 4 * t) ;$
Create an FM modulator System object ${ }^{\mathrm{TM}}$.
MOD = comm. FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
FM modulate the input signal and plot its real part. You can see that the frequency of the modulated signal changes with the amplitude of the input signal.
$y=\operatorname{step}(M O D, x) ;$
plot(t,[x real(y)])

Plot Spectrum of FM Modulated Baseband Signal
Apply FM baseband modulation to a white Gaussian noise source and plot its spectrum.
Set the example parameters.

```
fs = 1e3; % Sample rate (Hz)
ts = 1/fs; %Sample period (s)
fd = 10; % Frequency deviation (Hz)
```

Create a white Gaussian noise source having a duration of 5 s .
t = (0:ts:5-ts)';
$x=$ wgn(length(t), 1, 0);
Create an FM modulator System object? and modulate the input signal.
MOD1 = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',fd);
y = step(MOD1,x);
Create another modulator object, MOD2, whose frequency deviation is five times larger and apply FM modulation.

```
MOD2 = comm.FMModulator('SampleRate',fs,'FrequencyDeviation',5*fd);
z = step(MOD2,x);
```

Plot the spectra of the two modulated signals. The larger frequency deviation associated with channel 2 results in a noise level that is 10 dB higher.

SA = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true); step(SA,[y z])

## Algorithms

Represent a frequency modulated passband signal, $Y(t)$, as

$$
Y(t)=A \cos \left(2 \pi f_{C} t+2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau\right),
$$

where $A$ is the carrier amplitude, $f_{c}$ is the carrier frequency, $x(\tau)$ is the baseband input signal, and $f_{\Delta}$ is the frequency deviation in Hz . The frequency deviation is the maximum shift from $f_{c}$ in one direction, assuming $|x(t)| \leq 1$.

A baseband FM signal can be derived from the passband representation by downconverting it by $f_{c}$ such that

$$
\begin{aligned}
& \left.y_{S}(t)=Y(t) e^{-j 2 \pi f_{C} t}=\frac{A}{2}\left[e^{j}\left(2 \pi f_{C} t+2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau\right)+e^{-j\left(2 \pi f_{C} t+2 \pi f_{\Delta}\right.} \int_{0}^{t} x(\tau) d \tau\right)\right] e^{-j 2 \pi f_{C} t} \\
& =\frac{A}{2}\left[e^{j 2 \pi f_{\Delta}} \int_{0}^{t} x(\tau) d \tau+e^{-j 4 \pi f_{C} t-j 2 \pi f_{\Delta}} \int_{0}^{t} x(\tau) d \tau\right] .
\end{aligned}
$$

Removing the component at $-2 f_{c}$ from $y_{s}(t)$ leaves the baseband signal representation, $y(t)$, which is expressed as

$$
y(t)=\frac{A}{2} e^{j 2 \Pi f f_{\Delta}} \int_{0}^{t} x(\tau) d \tau .
$$

The expression for $y(t)$ is rewritten as

$$
y(t)=\frac{A}{2} e^{j \phi(t)},
$$

where $\phi(t)=2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau$, which implies that the input signal is a scaled version of the derivative of the phase, $\phi(t)$.

A baseband delay demodulator is used to recover the input signal from $y(t)$.

A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$
w(t)=\frac{A^{2}}{4} e^{j \phi(t)} e^{-j \phi(t-T)}=\frac{A^{2}}{4} e^{j[\phi(t)-\phi(t-T)]},
$$

where $T$ is the sample period. In discrete terms, $w_{n}=w(n T)$, and

$$
\begin{aligned}
& w_{n}=\frac{A^{2}}{4} e^{j\left[\phi_{n}-\phi_{n}-1\right]} \\
& v_{n}=\phi_{n}-\phi_{n-1} .
\end{aligned}
$$

The signal $v_{n}$ is the approximate derivative of $\phi_{n}$, such that $v_{n} \approx x_{n}$.

## comm.FSKDemodulator

Package: comm
Demodulate using M-ary FSK method

## Description

The FSKDemodulator object demodulates a signal that was modulated using the M-ary frequency shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals.

To demodulate a signal that was modulated using frequency shift keying:
1 Define and set up your FSK demodulator object. See "Construction" on page 3-634.
2 Call step to demodulate a signal according to the properties of FSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = $\underline{\text { step }(o b j, x) \text { and } y=o b j(x) \text { perform equivalent operations. }}$

## Construction

H = comm.FSKDemodulator creates a demodulator System object, H. This object demodulates an M -ary frequency shift keying (M-FSK) signal using a noncoherent energy detector.

H = comm. FSKDemodulator(Name,Value) creates an M-FSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.FSKDemodulator(M,FREQSEP,RS,Name, Value) creates an M-FSK demodulator object, H. This object has the ModulationOrder property set to M, the FrequencySeparation property set to FREQSEP, the Symbol Rate property set to RS, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of frequencies in modulated signal
Specify the number of frequencies in the modulated signal as a numeric, positive, integer scalar value that is a power of two. The default is 8 .

## BitOutput

Output data as bits
Specify whether the output is groups of bits or integer values. The default is false.

When you set this property to false, the step method outputs a column vector of length equal to N/ SamplesPerSymbol on page 3-0.$N$ is the length of the input data vector to the step method. The elements of the output vector are integers between 0 and Modulation0rder on page 3-0 -1.
When you set this property to true, the step method outputs a column vector of length equal to $\log 2(M o d u l a t i o n O r d e r) \times(N / S a m p l e s P e r S y m b o l)$. The property's elements are bit representations of integers between 0 and Modulation0rder-1.

## SymbolMapping

Symbol encoding
Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses Gray-coded ordering.
When you set this property to Binary, the object uses natural binary-coded ordering.
For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer $M-1$. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

## FrequencySeparation

Frequency separation between successive tones
Specify the frequency separation between successive symbols in the modulated signal in Hertz as a positive, real scalar value. The default is 6 Hz .

## SamplesPerSymbol

Number of samples per input symbol
Specify the number of samples per input symbol as a positive, integer scalar value. The default is 17.

## SymbolRate

Symbol duration
Specify the symbol rate in symbols per second as a positive, double-precision, real scalar value. The default is 100. To avoid output signal aliasing, specify an output sampling rate, $F s=$ SamplesPerSymbol on page 3-0 $\times$ SymbolRate, which is greater than Modulation0rder on page 3-0 $\times$ FrequencySeparation on page 3-0 . The symbol duration remain the same, regardless of whether the input is bits or integers.

## OutputDataType

Data type of output
Specify the output data type as one of logical | int8| uint8| int16|uint16|int32|uint32| double. The default is double. The logical type is valid only when you set the BitOutput on page 3-0 property to false and the Modulation0rder on page 3-0 property to two. When you set the BitOutput property to true, the output data requires a type of logical|double.

## Methods

## Examples

FSK Modulation and Demodulation in AWGN
Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz .
Set the modulation order and frequency separation parameters.

```
M = 8;
freqSep = 100;
```

Create FSK modulator and demodulator System objects ${ }^{\mathrm{TM}}$ with modulation order 8 and 100 Hz frequency separation.
fskMod = comm.FSKModulator(M,freqSep);
fskDemod = comm.FSKDemodulator(M,freqSep);
Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',-2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50 -symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end
```

Display the error statistics.

```
es = 'Error rate = %4.2e\nNumber of errors = %d\nNumber of symbols = %d\n';
fprintf(es,errorStats)
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Demodulator
Baseband block reference page. The object properties correspond to the block parameters, except:

- The Symbol set ordering parameter corresponds to the SymbolMapping on page 3-0 property.
- The SymbolRate on page 3-0 property replaces the block sample rate capability.

## Extended Capabilities

## step

System object: comm. FSKDemodulator
Package: comm
Demodulate using M-ary FSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the FSK demodulator System object, H , and returns Y. X must be a double or single precision data type column vector of length equal to an integer multiple of the number of samples per symbol that you specify in the SamplesPerSymbol property. Depending on the BitOutput property value, output $Y$ can be integer or bit valued.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.FSKModulator

Package: comm
Modulate using M-ary FSK method

## Description

The FSKModulator object modulates using the M-ary frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using frequency shift keying:
1 Define and set up your FSK modulator object. See "Construction" on page 3-640.
2 Call step to modulate a signal according to the properties of comm. FSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. FSKModulator creates a modulator System object, H. This object modulates the input signal using the M-ary frequency shift keying (M-FSK) method.

H = comm. FSKModulator(Name,Value) creates an M-FSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.FSKModulator(M,FREQSEP,RS,Name,Value) creates an M-FSK modulator object, H. This object has the ModulationOrder property set to M, the FrequencySeparation property set to FREQSEP, the SymbolRate property set to RS, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of frequencies in modulated signal
Specify the number of frequencies in the modulated signal as a numeric positive integer scalar value that is a power of two. The default is 8 .

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false.

When you set this property to false, the step method input requires a numeric (except single precision data type) column vector of integer values between 0 and Modulation0rder on page 3-
$0-1$. In this case, the input vector can also be of data type logical if Modulation0rder equals 2.
When you set this property to true, the step method input requires a double-precision or logical data type column vector of bit values. The length of this vector is an integer multiple of $\boldsymbol{\operatorname { l o g }} 2($ Modulation0rder). This vector contains bit representations of integers between 0 and ModulationOrder-1.

## SymbolMapping

Symbol encoding
Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses Gray-coded ordering.
When you set this property to Binary, the object uses natural binary-coded ordering. For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer $M-1$. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

## FrequencySeparation

Frequency separation between successive tones
Specify the frequency separation between successive tones in the modulated signal in Hertz as a positive, real scalar value. The default is 6 Hz . To avoid output signal aliasing, specify an output sampling rate, Fs = SamplesPerSymbol on page 3-0 $\times$ SymbolRate on page 3-0 , which is greater than Modulation0rder on page 3-0 multiplied by FrequencySeparation on page 30

ContinuousPhase
Phase continuity
Specify if the phase of the output modulated signal is continuous or discontinuous. The default is true.

When you set this property to true, the modulated signal maintains continuous phase even when its frequency changes.

When you set this property to false, the modulated signal comprises portions of Modulation0rder on page 3-0 sinusoids of different frequencies. In this case, a change in the input value can cause a discontinuous change in the phase of the modulated signal.

## SamplesPerSymbol

Number of samples per output symbol
Specify the number of output samples that the object produces for each integer or binary word in the input as a positive, integer scalar value. The default is 17.

## SymbolRate

Symbol duration
Specify the symbol rate in symbols per second as a positive, double-precision, real scalar. The default is 100 . To avoid output signal aliasing, specify an output sampling rate, Fs $=$ SamplesPerSymbol on page 3-0 $\times$ SymbolRate, which is greater than ModulationOrder on page 3-0 $\times$ FrequencySeparation on page 3-0 . The symbol duration remain the same, regardless of whether the input is bits or integers.

## OutputDataType

Data type of output
Specify the output data type as one of double | single. The default is double.

## Methods

reset Reset states of M-FSK modulator object
step Modulate using M-ary FSK method

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- |

## Examples

## FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz .
Set the modulation order and frequency separation parameters.
M = 8;
freqSep = 100;
Create FSK modulator and demodulator System objects ${ }^{\mathrm{TM}}$ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M,freqSep);
fskDemod = comm.FSKDemodulator(M,freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',-2);
```

Create an error rate calculator object.
err = comm.ErrorRate;
Transmit one hundred 50 -symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end
```

Display the error statistics.

```
es = 'Error rate = %4.2e\nNumber of errors = %d\nNumber of symbols = %d\n';
fprintf(es,errorStats)
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

## Visualize FSK Modulated Symbol Mapping

Visualize symbol mapping of an FSK modulated signal with a spectrogram.
Specify 20 samples for each symbol. 0 maps to -50 kHz (negative phase slope) and 1 maps to +50 kHz (positive phase slope).

```
mod = comm.FSKModulator:
mod.ModulationOrder = 2;
mod.FrequencySeparation = 100000;
mod.SamplesPerSymbol = 20;
mod.SymbolMapping = 'Gray';
mod.SymbolRate = 1e4
mod =
    comm.FSKModulator with properties:
            ModulationOrder: 2
                BitInput: false
                SymbolMapping: 'Gray'
        FrequencySeparation: 100000
            ContinuousPhase: true
            SamplesPerSymbol: 20
                    SymbolRate: 10000
                OutputDataType: 'double'
```

x = mod([0 1 0 1 0 1]');
figure; subplot(1,2,1); plot(unwrap(angle(x)), 0:length(x)-1);
grid on; xlabel('Phase'); ylabel('Samples')
subplot(1,2,2);
spectrogram(x,20,0,[],mod.SymbolRate*mod.SamplesPerSymbol,'centered')

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Modulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The Symbol set ordering parameter corresponds to the SymbolMapping on page 3-0 property.
- The SymbolRate on page 3-0 property takes the place of the block sample rate capability.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

comm. CPFSKModulator | comm. FSKDemodulator

## Introduced in R2012a

## reset

System object: comm. FSKModulator
Package: comm
Reset states of M-FSK modulator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the FSKModulator object, H .

## step

System object: comm. FSKModulator
Package: comm
Modulate using M-ary FSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

Y = step ( $\mathrm{H}, \mathrm{X}$ ) modulates input data, X , with the FSK modulator System object, H . It returns the baseband modulated output, $Y$. Depending on the value of the BitInput property, input $X$ can be an integer or bit- valued column vector with numeric or logical data types. The length of output vector, $Y$, is equal to the number of input samples times the number of samples per symbol you specify in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.GeneraIQAMDemodulator

Package: comm
Demodulate using arbitrary QAM constellation

## Description

The GeneralQAMDemodulator object demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature amplitude modulation:
1 Define and set up your QAM demodulator object. See "Construction" on page 3-647.
2 Call step to demodulate a signal according to the properties of comm. GeneralQAMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.GeneralQAMDemodulator creates a demodulator System object, H. This object demodulates the input signal using a general quadrature amplitude modulation (QAM) method.

H = comm.GeneralQAMDemodulator(Name, Value) creates a general QAM demodulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. GeneralQAMDemodulator(CONST,Name, Value) creates a general QAM demodulator object, H . This object has the Constellation property set to CONST, and the other specified properties set to the specified values.

## Properties

## Constellation

Signal constellation
Specify the constellation points as a real or complex, double-precision data type vector. The default is $\boldsymbol{\operatorname { e x p }}(2 \times \pi \times 1 i \times(0: 7) / 8)$. The length of the vector determines the modulation order.

When you set the BitOutput on page 3-0 property to false, the step method outputs a vector with integer values. These integers are between 0 and $M-1$, where $M$ is the length of this property vector. The length of the output vector equals the length of the input signal.

When you set the BitOutput property to true, the output signal contains bits. For bit outputs, the size of the signal constellation requires an integer power of two and the output length is an integer multiple of the number of bits per symbol.

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values. The default is false.
When you set this property to true the step method outputs a column vector of bit values with length equal to $\log 2(M)$ times the number of demodulated symbols, where $M$ is the length of the signal constellation specified in the Constellation on page 3-0 property. The length M determines the modulation order.

When you set this property to false, the step method outputs a column vector, of length equal to the input data vector. The vector contains integer symbol values between 0 and $M-1$.

## DecisionMethod

## Demodulation decision method

Specify the decision method the object uses as one of Hard decision | Log-likelihood ratio| Approximate log-likelihood ratio. The default is Hard decision. When you set the BitOutput on page 3-0 property to false the object always performs hard decision demodulation. This property applies when you set the BitOutput property to true.

## VarianceSource

Source of noise variance
Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio.

## Variance

## Noise variance

Specify the variance of the noise as a nonzero, real scalar value. The default is 1 . If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm would compute the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the VarianceSource on page 3-0 property to Property. This property is tunable.

## OutputDataType

Data type of output
Specify the output data type as one of Full precision | Smallest unsigned integer|double | single | int8|uint8|int16|uint16| int32|uint32. The default is Full precision .

This property applies only when you set the Bit0utput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard
decision or Approximate log-likelihood ratio. In this case, when you set the OutputDataType on page 3-0 property to Full precision, the output data type is the same as that of the input when the input data has a single or double-precision data type.

When the input data is of a fixed-point type, the output data type works as if you had set the OutputDataType property to Smallest unsigned integer.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

When you set the BitOutput property to true, and the DecisionMethod property to Hard Decision the data type logical becomes a valid option.

When you set the BitOutput property to true and the DecisionMethod property to Approximate log-likelihood ratio you may only set this property to Full precision|Custom.

If you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio, the output data has the same type as that of the input. In this case, that value can be only single or double precision.

## Fixed-Point Properties

## FullPrecisionOverride

Full precision override for fixed-point arithmetic
Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for FixedPoint System Objects" on page 3-653.

## RoundingMethod

Rounding of fixed-point numeric values
Specify the rounding method as one of Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero. The default is Floor. This property applies when the object is not in a full precision configuration. This property does not apply when you set BitOutput on page 3-0 to true and DecisionMethod on page 3-0 to Log-likelihood ratio.

## OverflowAction

Action when fixed-point numeric values overflow
Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property applies when the object is not in a full precision configuration. This property does not apply when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

## ConstellationDataType

Data type of signal constellation

Specify the constellation fixed-point data type as one of Same word length as input | Custom. The default is Same word length as input. This property does not apply when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

## CustomConstellationDataType

Fixed-point data type of signal constellation
Specify the constellation fixed-point type as an unscaled numerictype object with a Signedness of Auto. The default is numerictype([],16). This property applies when you set the ConstellationDataType on page 3-0 property to Custom.

## Accumulator1DataType

Data type of accumulator 1
Specify the accumulator 1 fixed-point data type as one of Full precision | Custom. The default is Full precision. This property applies when you set the FullPrecisionOverride on page 30 property to false. This property does not apply when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

## CustomAccumulator1DataType

Fixed-point data type of accumulator 1
Specify the accumulator 1 fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype( []$, 32,30$ ). This property applies when you set the
Accumulator1DataType on page 3-0 property to Custom.

## ProductInputDataType

Data type of product
Specify the product input fixed-point data type as one of Same as accumulator 1|Custom. The default is Same as accumulator 1. This property applies when you set the FullPrecisionOverride on page 3-0 property to false, the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

## CustomProductInputDataType

Fixed-point data type of product
Specify the product input fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype( [ ] , 32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the ProductInputDataType on page 3-0 property to Custom.

## ProductOutputDataType

Data type of product output
Specify the product output fixed-point data type as one of Full precision |Custom. The default is Full precision. This property applies when you set the FullPrecision0verride on page 30 property to false, the Bit0utput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

## CustomProductOutputDataType

Fixed-point data type of product output
Specify the product output fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype( [],32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the ProductOutputDataType on page 3-0 property to Custom.

## Accumulator2DataType

Data type of accumulator 2
Specify the accumulator 2 fixed-point data type as one of Full precision |Custom. The default is Full precision. This property applies when you set the FullPrecisionOverride on page 30 property to false, the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio.

## CustomAccumulator2DataType

Fixed-point data type accumulator 2
Specify the accumulator 2 fixed-point data type as a scaled numerictype object with a Signedness of Auto. The default is numerictype( []$, 32,30$ ). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the Accumulator2DataType on page 3-0 property to Custom.

## Accumulator3DataType

Data type of accumulator 3
Specify the accumulator 3 fixed-point data type as one of Full precision | Custom. The default is Full precision. This property applies when you set the FullPrecisionOverride on page 30 property to false, the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Approximate log-likelihood ratio.

## CustomAccumulator3DataType

Fixed-point data type of accumulator 3
Specify the accumulator 3 fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype ([],32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the Accumulator3DataType on page 3-0 property to Custom.

## NoiseScalingInputDataType

Data type of noise-scaling input
Specify the noise-scaling input fixed-point data type as one of Same as accumulator 3|Custom. The default is Same as accumulator 3. This property applies when you set the FullPrecisionOverride on page 3-0 property to false, the Bit0utput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Approximate loglikelihood ratio.

## CustomNoiseScalingInputDataType

Fixed-point data type of noise-scaling input
Specify the noise-scaling input fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([],32,30). This property applies when you set the
FullPrecisionOverride on page 3-0 property to false and the
NoiseScalingInputDataType on page 3-0 property to Custom.

## InverseVarianceDataType

Data type of inverse noise variance
Specify the inverse noise variance fixed-point data type as one of Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Approximate log-likelihood ratio, and the VarianceSource on page 3-0 property to Property.

## CustomInverseVarianceDataType

Fixed-point data type of inverse noise variance
Specify the inverse noise variance fixed-point type as a numerictype object with a Signedness of Auto. The default is numerictype ( []$, 16,8$ ). This property applies when you set the InverseVarianceDataType on page 3-0 property to Custom.

## CustomOutputDataType

Data type of output
Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([],32,30). This property applies when you set the
FullPrecisionOverride on page 3-0 property to false and the OutputDataType on page 30 property to Custom.

## Methods

step Demodulate using arbitrary QAM constellation

## Common to All System Objects

release Allow System object property value changes

## Examples

Modulate and demodulate data using an arbitrary three-point constellation.

% Setup a three point constellation
    c = [1 1i -1];
    hQAMMod = comm.GeneralQAMModulator(c);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                            'Signal to noise ratio (SNR)','SNR',15, 'SignalPower', 0.89);
    hQAMDemod = comm.GeneralQAMDemodulator(c);
```

```
%Create an error rate calculator
    hError = comm.ErrorRate;
    for counter = 1:100
        % Transmit a 50-symbol frame
        data = randi([0 2],50,1);
        modSignal = step(hQAMMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hQAMDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

## More About

## Full Precision for Fixed-Point System Objects

FullPrecision0verride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to true, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to false.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® $\mathrm{Coder}^{\mathrm{TM}}$.
Usage notes and limitations:

## Objects

comm. GeneralQAMModulator | comm. RectangularQAMDemodulator

Introduced in R2012a

## step

System object: comm.GeneralQAMDemodulator
Package: comm
Demodulate using arbitrary QAM constellation

## Syntax

$Y=\operatorname{step}(H, X)$
Y = step(H,X,VAR)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates the input data, X , with the general QAM demodulator System object, H , and returns Y . Input X must be a scalar or a column vector with double or single precision data type. When you set the BitOutput property to true and the DecisionMethod property to 'Log-likelihood ratio' the input data type must be single or double precision. Depending on the BitOutput property value, output $Y$ can be integer or bit valued.
$Y=$ step ( $H, X$, VAR) uses soft decision demodulation and noise variance VAR. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to Approximate log-likelihood ratio or Log-likelihood ratio, and the VarianceSource property to 'Input port'.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

# comm.GeneralQAMModulator 

Package: comm
Modulate using arbitrary QAM constellation

## Description

The GeneralQAMModulator object modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using quadrature amplitude modulation:
1 Define and set up your QAM modulator object. See "Construction" on page 3-656.
2 Call step to modulate a signal according to the properties of comm. GeneralQAMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.GeneralQAMModulator creates a modulator System object, H. This object modulates the input signal using a general quadrature amplitude modulation (QAM) method.

H = comm. GeneralQAMModulator(Name, Value) creates a QAM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. GeneralQAMModulator(CONST, Name, Value) creates a General QAM modulator object, H. This object has the Constellation property set to CONST, and the other specified properties set to the specified values.

## Properties

## Constellation

Signal constellation
Specify the constellation points as a vector of real or complex double-precision data type. The default is $\exp (2 \times \pi \times 1 i \times(0: 7) / 8)$. The length of the vector determines the modulation order. The step method inputs requires integers between 0 and $M-1$, where $M$ indicates the length of this property vector. The object maps an input integer $m$ to the $(m+1)^{\text {st }}$ value in the Constellation vector.

## OutputDataType

Data type of output
Specify the output data type as one of double | single | Custom. The default is double.

## Fixed-Point Properties

## CustomOutputDataType

Fixed-point data type of output
Specify the output fixed-point type as a numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the OutputDataType on page 3-0 property to Custom.

## Methods

# comm.GeneralQAMTCMDemodulator 

Package: comm
Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

## Description

The GeneralQAMTCMDemodulator object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

To demodulate a signal that was modulated using a trellis-coded, general quadrature amplitude modulator:

1 Define and set up your general QAM TCM modulator object. See "Construction" on page 3-660.
2 Call step to demodulate a signal according to the properties of
comm. GeneralQAMTCMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.GeneralQAMTCMDemodulator creates a trellis-coded, general quadrature amplitude (QAM TCM) demodulator System object, H. This object demodulates convolutionally encoded data that has been mapped to an arbitrary QAM constellation.

H = comm. GeneralQAMTCMDemodulator(Name, Value) creates a general QAM TCM demodulator object, H, with each specified property set to the specified value. You can specify additional namevalue pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. GeneralQAMTCMDemodulator(TRELLIS, Name, Value) creates a general QAM TCM demodulator object, H. This object has the TrellisStructure property set to TRELLIS, and the other specified properties set to the specified values.

## Properties

## TrellisStructure

Trellis structure of convolutional code
Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the value that results from poly2trellis([1 3], [1 0 0; 0 5 2]).

## TerminationMethod

Termination method of encoded frame

Specify the termination method as one of Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use Continuous mode.

When you set this property to Truncated, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to Terminated, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

## TracebackDepth

Traceback depth for Viterbi decoder
Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay indicates the number of zero symbols that precede the first decoded symbol in the output.

When you set the TerminationMethod on page 3-0 property to Continuous, the decoding delay consists of TracebackDepth zero symbols or TracebackDepth $\times$ K zero bits for a rate $K / N$ convolutional code.

When you set the TerminationMethod property to Truncated or Terminated, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

## ResetInputPort

Enable demodulator reset input
Set this property to true to enable an additional input to the step method. The default is false. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

## Constellation

Signal constellation
Specify a double- or single-precision complex vector. This vector lists the points in the signal constellation that were used to map the convolutionally encoded data. The constellation must be specified in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to $2^{N}$ for a rate $K / N$ convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed as
$\boldsymbol{\operatorname { e x p }}\left(2 \times \pi \times j \times\left[\begin{array}{lllllll}0 & 4 & 2 & 6 & 1 & 5 & 3\end{array}\right] / 8\right)$.

## OutputDataType

Data type of output

Specify output data type as one of logical | double. The default is double.

## Methods

reset Reset states of the general QAM TCM demodulator object
step Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

## Modulate and Demodulate Data Using QAM TCM

Modulate and demodulate noisy data using QAM TCM modulation with an arbitrary 4-point constellation. Estimate the resultant BER.

Define a trellis structure with two input symbols and four output symbols using a [171 133] generator polynomial. Define an arbitrary four-point constellation.

```
qamTrellis = poly2trellis(7,[171 133]);
refConst = exp(pi*li*[1 2 3 6]/4);
```

Create a QAM TCM modulator and demodulator System object ${ }^{\text {TM }}$ pair using qamTrellis and refConst.

```
hMod = comm.GeneralQAMTCMModulator(qamTrellis,'Constellation', refConst);
hDemod = comm.GeneralQAMTCMDemodulator(qamTrellis,'Constellation',refConst);
```

Create an AWGN channel object in which the noise is set by using a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',4);
```

Create an error rate calculator with delay (in bits) equal to the product of TracebackDepth and the number of bits per symbol

```
hError = comm.ErrorRate(...
    'ReceiveDelay', hDemod.TracebackDepth*log2(qamTrellis.numInputSymbols));
```

Generate random binary data and apply QAM TCM modulation. Pass the signal through an AWGN channel and demodulate. Collect the error statistics.

```
for counter = 1:10
    % Generate binary data
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through an AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate the error statistics
```

errorStats = step(hError,data, receivedData);
end
Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
Error rate = 1.16e-02
Number of errors = 58
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:

## Introduced in R2012a

## reset

System object: comm.GeneralQAMTCMDemodulator
Package: comm
Reset states of the general QAM TCM demodulator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the GeneralQAMTCMDemodulator object, H .

## step

## System object: comm.GeneralQAMTCMDemodulator

Package: comm
Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

## Syntax

$Y=\operatorname{step}(H, X)$
Y = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates the general QAM modulated input data, X , and uses the Viterbi algorithm to decode the resulting demodulated convolutionally encoded bits. X must be a complex double or single precision column vector. The step method outputs a demodulated binary column data vector, Y . When the convolutional encoder represents a rate $K / N$ code, the length of the output vector equals $K \times L$, where $L$ is the length of the input vector, $X$.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})$ resets the decoder states of the general QAM TCM demodulator System object to the all-zeros state when you input a non-zero reset signal, R. R must be a double precision or logical scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.GeneraIQAMTCMModulator

Package: comm
Convolutionally encode binary data and map using arbitrary QAM constellation

## Description

The GeneralQAMTCMModulator object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal. The object then maps the result to an arbitrary signal constellation. The Signal constellation property lists the signal constellation points in setpartitioned order.

To modulate a signal using a trellis-coded, general quadrature amplitude modulator:
1 Define and set up your general QAM TCM modulator object. See "Construction" on page 3-666.
2 Call step to modulate a signal according to the properties of
comm.GeneralQAMTCMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. GeneralQAMTCMModulator creates a trellis-coded, general quadrature amplitude (QAM TCM) modulator System object, H. This object convolutionally encodes a binary input signal and maps the result using QAM modulation with a signal constellation specified in the Constellation property.

H = comm. GeneralQAMTCMModulator(Name,Value) creates a general QAM TCM modulator System object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.GeneralQAMTCMModulator(TRELLIS,Name,Value) creates a general QAM TCM modulator System object, H. This object has the TrellisSt ructure property set to TRELLIS, and the other specified properties set to the specified values.

## Properties

## TrellisStructure

Trellis structure of convolutional code
Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the result of poly2trellis([1 3], [1 0 0; 052$]$ ).

## TerminationMethod

Termination method of encoded frame
Specify the termination method as one of Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to Truncated, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to Terminated, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate $K / N$ code, the step method outputs the vector with length $y=N \times(L+S) / K$, where $S=$ constraintLength -1 . In the case of multiple constraint lengths, $S=\mathbf{s u m}($ constraintLength(i)-1)). L represents the length of the input to the step method.

## ResetInputPort

Enable modulator reset input
Set this property to true to enable an additional input to the step method. The default is false. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

## Constellation

Signal constellation
Specify a double- or single-precision complex vector that lists the points in the signal constellation that were used to map the convolutionally encoded data. You must specify the constellation in setpartitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to $2^{N}$ for a rate $K / N$ convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed $\exp \left(2 \times \pi \times j \times\left[\begin{array}{llllll}0 & 4 & 2 & 6 & 1 & 5 \\ 3 & 7\end{array}\right] / 8\right)$.

## OutputDataType

Data type of output
Specify the output data type as one of double | single. The default is double.

## Methods

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )
Y = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ convolutionally encodes and modulates the input data, X , and returns the encoded and modulated data, Y . X must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate $K / N$ code, the length of the input vector, X , must be $K \times L$, for some positive integer $L$. The step method outputs a complex column vector, Y , of length $L$.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})$ resets the encoder of the general QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, R. R must be a double precision or logical scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.GMSKDemodulator

Package: comm
Demodulate using GMSK method and the Viterbi algorithm

## Description

The GMSKDemodulator object uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using Gaussian minimum shift keying:
1 Define and set up your GMSK demodulator object. See "Construction" on page 3-634.
2 Call step to demodulate a signal according to the properties of GMSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. GMSKDemodulator creates a demodulator System object, H. This object demodulates the input Gaussian minimum shift keying (GMSK) modulated data using the Viterbi algorithm.

H = comm.GMSKDemodulator(Name, Value) creates a GMSK demodulator object, H. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## BitOutput

Output data as bits
Specify whether the output is groups of bits or integer values. The default is false.
When you set the BitOutput on page 3-0 property to false, the step method outputs a column vector of length equal to $N /$ SamplesPerSymbol on page 3-0.$N$ is the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are -1 or 1.

When you set the BitOutput property to true, the step method outputs a binary column vector of length equal to $N / S a m p l e s P e r S y m b o l$ with bit values of 0 or 1 .

## BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse

Specify the product of bandwidth and symbol time for the Gaussian pulse shape as a real, positive scalar. The default 0.3.

## PulseLength

Pulse length
Specify the length of the Gaussian pulse shape in symbol intervals as a real positive integer. The default 4.

## SymbolPrehistory

Symbol prehistory
Specify the data symbols used by the modulator prior to the first call to the step method. The default is 1 . This property requires a scalar or vector with elements equal to -1 or 1 . If the value is a vector, its length must be one less than the value you set in the PulseLength on page 3-0 property.

## InitialPhase0ffset

Initial phase offset
Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is 0 .

## SamplesPerSymbol

Number of samples per input symbol
Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is 8.

## TracebackDepth

Traceback depth for Viterbi algorithm
Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The value of this property is also the output delay, and the number of zero symbols that precede the first meaningful demodulated symbol in the output. The default is 16.

## OutputDataType

Data type of output
Specify the output data type as one of int8|int16|int32| double, when you set the Bit0utput on page 3-0 property to false.

When you set the BitOutput property to true, specify the output data type as one of logical | double. The default is double.

## Methods

reset Reset states of the GMSK demodulator object
step Demodulate using GMSK method and the Viterbi algorithm
Common to All System Objects
release Allow System object property value changes

## Examples

## Demodulate a GMSK signal with bit inputs and phase offset

```
% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator. Use a phase offset of pi/4.
    hMod = comm.GMSKModulator('BitInput', true, 'InitialPhaseOffset', pi/4);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                            Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.GMSKDemodulator('BitOutput', true, ...
            'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
    hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
Error rate = 0.000133
Number of errors = 4
```

## Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1 .

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
y = 5x1 complex
```

```
1.0000 + 0.0000i
-0.0000 - 1.0000i
-1.0000 + 0.0000i
0.0000 + 1.0000i
1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5x1
```

    0
    -1.5708
$-3.1416$
-4.7124
$-6.2832$

A sequence of zeros causes the phase to shift by $-\Pi / 2$ between samples.
Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 + 1.0000i
    -1.0000 - 0.0000i
    0.0000 - 1.0000i
    1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5×1
```

    1.5708
    3.1416
    4.7124
    6.2832
    A sequence of ones causes the phase to shift by $+\Pi / 2$ between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the GMSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For GMSK the phase shift per symbol is $\pi / 2$, which is a modulation index of 0.5 .

## step

System object: comm.GMSKDemodulator
Package: comm
Demodulate using GMSK method and the Viterbi algorithm

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the GMSK demodulator object, H , and returns $\mathrm{Y} . \mathrm{X}$ must be a double or single precision column vector with a length equal to an integer multiple of the number of samples per symbol you specify in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.GMSKModulator

Package: comm
Modulate using GMSK method

## Description

The GMSKModulator object modulates using the Gaussian minimum shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using Gaussian minimum shift keying:
1 Define and set up your GMSK modulator object. See "Construction" on page 3-679.
2 Call step to modulate a signal according to the properties of comm. GMSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y=$ step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.GMSKModulator creates a modulator System object, H. This object modulates the input signal using the Gaussian minimum shift keying (GMSK) modulation method.

H = comm.GMSKModulator(Name, Value) creates a GMSK modulator object, H. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Namel,Valuel,...,NameN,ValueN).

## Properties

## BitInput

Assume input is bits
Specify whether the input is bits or integers. The default is false.
When you set the BitInput on page 3-0 property to false, the step method input requires a double-precision or signed integer data type column vector with values of -1 or 1 .

When you set the BitInput property to true, step method input requires a double-precision or logical data type column vector of 0 s and 1 s .

## BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse
Specify the product of the bandwidth and symbol time for the Gaussian pulse shape as a real, positive scalar value. The default is 0.3 .

## PulseLength

Pulse length
Specify the length of the Gaussian pulse shape in symbol intervals as a real, positive integer. The default is 4 .

## SymbolPrehistory

Symbol prehistory
Specify the data symbols the modulator uses prior to the first call to the step method in reverse chronological order. The default is 1 . This property requires a scalar or vector with elements equal to -1 or 1 . If the value is a vector, then its length must be one less than the value in the PulseLength on page 3-0 property.

## InitialPhaseOffset

Initial phase offset
Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is 0 .

## SamplesPerSymbol

Number of samples per output symbol
Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is 8 . The upsampling factor is the number of output samples that the step method produces for each input sample.

## OutputDataType

Data type of output
Specify output data type as one of double | single. The default is double.

## Methods

reset Reset states of the GMSK modulator object
step Modulate using GMSK method

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Modulate a GMSK signal with bit inputs and phase offset

[^1]```
                            Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.GMSKDemodulator('BitOutput', true, ...
                            InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
    hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
Error rate = 0.000133
Number of errors = 4
```

## Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 - 1.0000i
    -1.0000 + 0.0000i
    0.0000 + 1.0000i
    1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5×1
```

$-3.1416$
-4.7124
$-6.2832$

A sequence of zeros causes the phase to shift by $-\Pi / 2$ between samples.
Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 + 1.0000i
    -1.0000 - 0.0000i
    0.0000 - 1.0000i
    1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5×1
    0
    1.5708
    3.1416
    4.7124
    6.2832
```

A sequence of ones causes the phase to shift by $+\Pi / 2$ between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the GMSK Modulator Baseband block reference page. The object properties correspond to the block parameters. For GMSK the phase shift per symbol is $\pi / 2$, which is a modulation index of 0.5 .

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

comm. CPMDemodulator | comm.CPMModulator | comm.GMSKDemodulator

## Introduced in R2012a

## reset

System object: comm.GMSKModulator
Package: comm
Reset states of the GMSK modulator object

## Syntax

reset(H)

## Description

reset $(H)$ resets the states of the GMSKModulator object, $H$.

## step

System object: comm.GMSKModulator
Package: comm
Modulate using GMSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the GMSK modulator object, H . It returns the baseband modulated output in Y. Depending on the BitInput property value, input X can be a double precision, signed integer, or logical column vector. The length of vector $Y$ is equal to the number of input samples times the number of samples per symbol that you specify in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.GMSKTimingSynchronizer

## Package: comm

Recover symbol timing phase using fourth-order nonlinearity method

## Description

The GMSKTimingSynchronizer object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method. This timing synchronization is a non-data-aided feedback method that is independent of carrier phase recovery, but requires prior compensation for the carrier frequency offset. You can use this block for systems that use Gaussian minimum shift keying (GMSK) modulation.

To recover the symbol timing phase of the input signal:
1 Define and set up your GMSK timing synchronizer object. See "Construction" on page 3-685.
2 Call step to recover the symbol timing phase of the input signal according to the properties of comm.GMSKTimingSynchronizer. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. GMSKTimingSynchronizer creates a timing phase synchronizer System object, H. This object recovers the symbol timing phase of the GMSK input signal using a fourth-order nonlinearity method.

H = comm.GMSKTimingSynchronizer(Name,Value) creates a GMSK timing synchronizer object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## SamplesPerSymbol

Number of samples representing each symbol
Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar value greater than 1 . The default is 4 .

## ErrorUpdateGain

Error update step size

Specify the step size for updating successive timing phase estimates as a positive real scalar value. Typically, this number is less than $1 /$ SamplesPerSymbol on page 3-0 , which corresponds to a slowly varying timing phase. The default is 0.05 . This property is tunable.

## ResetInputPort

Enable synchronization reset input
Set this property to true to enable resetting the timing phase recovery process based on an input argument value. The default is false.

When you set this property to true, you must specify a reset input value to the step method.
When you specify a nonzero value as the reset input, the object restarts the timing phase recovery process. When you set this property to false, the object does not restart.

## ResetCondition

Condition for timing phase recovery reset
Specify the conditions to reset the timing phase recovery process as one of Never | Every frame. The default is Never.

When you set this property to Never, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to Every frame, the timing phase recovery restarts at the start of each frame of data. In this case, the restart occurs at each step method call. This property applies when you set the ResetInputPort on page 3-0 property to false.

## Methods

reset Reset states of GMSK timing phase synchronizer object
step Recover symbol timing phase using fourth-order nonlinearity method

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Recover Timing Phase of GMSK Signal

Create GMSK modulator, variable fractional delay, and GMSK timing synchronizer System objects.

```
gmskMod = comm.GMSKModulator('BitInput', true, ...
    'SamplesPerSymbol', 14);
timing0ffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
gmskTimingSync = comm.GMSKTimingSynchronizer('SamplesPerSymbol', 14, ...
    'ErrorUpdateGain', 0.05);
Main processing loop:
```

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = gmskMod(data); % Modulate data
    % Apply timing offset error
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery
    [~,phase] = gmskTimingSync(impairedData);
    phEst(i) = phase(1)/14;
end
```

Plot the results.
plot(1:50,[0.2*ones(50,1) phEst])
legend( 'Original','Estimated')
title('Original and Estimated timing phases')

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the Modulation type parameter set to GMSK.
- The Reset parameter corresponds to the ResetInputPort on page 3-0
and ResetCondition on page 3-0 properties.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states for the GMSKTimingSynchronizer object H .

## step

System object: comm.GMSKTimingSynchronizer
Package: comm
Recover symbol timing phase using fourth-order nonlinearity method

## Syntax

[Y,PHASE] = step(H,X)
[Y,PHASE] = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
[ $\mathrm{Y}, \mathrm{PHASE}]=\operatorname{step}(\mathrm{H}, \mathrm{X})$ performs timing phase recovery and returns the time-synchronized signal, Y , and the estimated timing phase, PHASE, for input signal X . X must be a double or single precision complex column vector.
[ $\mathrm{Y}, \mathrm{PHASE}$ ] $=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})$ restarts the timing phase recovery process when you input a reset signal, $R$, that is non-zero. R must be a logical or double scalar. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.GoldSequence

Package: comm
Generate Gold sequence

## Description

The GoldSequence object generates a Gold sequence. Gold sequences form a large class of sequences that have good periodic cross-correlation properties.

To generate a Gold sequence:
1 Define and set up your Gold sequence object. See "Construction" on page 3-691.
2 Call step to generate the Gold sequence according to the properties of comm. GoldSequence.
The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj) and $y=o b j()$ perform equivalent operations.

## Construction

H = comm.GoldSequence creates a Gold sequence generator System object, H. This object generates a pseudo-random Gold sequence.

H = comm.GoldSequence(Name, Value) creates a Gold sequence generator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## FirstPolynomial

Generator polynomial for first preferred PN sequence
Specify the polynomial that determines the feedback connections for the shift register of the first preferred PN sequence generator. The default is ' $z \wedge 6+z+1$ '. You can specify the polynomial as a character vector. You can also specify the generator polynomial as a numeric, binary vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1 , and the length of this vector requires a value of $n+1$, where $n$ is the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 . For example, $\left[\begin{array}{lllllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1\end{array}\right]$ and $\left[\begin{array}{llll}8 & 2 & 0\end{array}\right]$ represent the same polynomial, $g(z)=z^{8}+z^{2}+1$. The degree of the first generator polynomial must equal the degree of the second generator polynomial specified in the SecondPolynomial on page 3-0 property.

## FirstInitialConditions

Initial conditions for first PN sequence generator

Specify the initial conditions for the shift register of the first preferred PN sequence generator. The default is [0 0 0 0 0 0 1]. The initial conditions require a numeric, binary scalar, or a numeric, binary vector with length equal to the degree of the first generator polynomial specified in the FirstPolynomial on page 3-0 property. If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. If you set this property to a scalar, the initial conditions of all shift register cells are the specified scalar value.

## SecondPolynomial

Generator polynomial for second preferred PN sequence
Specify the polynomial that determines the feedback connections for the shift register of the second preferred PN sequence generator. The default is ' $z^{\wedge} 6+z^{\wedge} 5+z^{\wedge} 2+z+1$ '. You can specify the polynomial as a character vector. You can also specify the generator polynomial as a binary, numeric vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1 and the length of this vector requires a value of $n+1$, where $n$ is the degree of the generator polynomial. Lastly, you can specify the generator polynomial as a numeric vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 . For example, $\left[\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 1 & 0 & 1\end{array}\right]$ and $\left[\begin{array}{llll}8 & 2 & 0\end{array}\right]$ represent the same polynomial, $g(z)=z^{8}+z^{2}+1$. The degree of the second generator polynomial must equal the degree of the first generator polynomial specified in the FirstPolynomial on page 3-0 property.

## SecondInitialConditionsSource

Source of initial conditions for second PN sequence
Specify the source of the initial conditions that determines the start of the second PN sequence as one of Property | Input port. The default is Property. When you set this property to Property, you can specify the initial conditions as a scalar or binary vector using the SecondInitialConditions property. When you set this property to Input port, you specify the initial conditions as an input to the stepmethod. The object accepts a binary scalar or a binary vector input. The length of the input must equal the degree of the generator polynomial that the SecondPolynomial on page 3-0 property specifies.

## SecondInitialConditions

Initial conditions for second PN sequence generator
Specify the initial conditions for the shift register of the second preferred PN sequence generator as a numeric, binary scalar, or as a numeric, binary vector. The length must equal the degree of the second generator polynomial. You set the second generator polynomial in the SecondPolynomial on page 3-0 property.

When you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The default is $\left[\begin{array}{llllll}0 & 0 & 0 & 0 & 0 & 1\end{array}\right]$.

When you set this property to a scalar, the initial conditions of all shift register cells are the specified scalar value.

## Index

Index of output sequence of interest
Specify the index of the output sequence of interest from the set of available sequences as a scalar integer. The default is 0 . The scalar integer must be in the range $\left[-2,2^{\mathrm{n}}-2\right.$ ], where $n$ is the degree of
the generator polynomials you specify in the FirstPolynomial on page 3-0 and SecondPolynomial on page 3-0 properties.

The index values - 2 and -1 correspond to the first and second preferred PN sequences as generated by the FirstPolynomial and SecondPolynomial, respectively.

The set $G(u, v)$ of available Gold sequences is defined by $G(u, v)=\left\{u, v\right.$, (uxor $\left.T^{v}\right)$, (u xor $\left.T^{2 v}\right), \ldots,(u$ xor $\left.\left.T^{(N-1) v)}\right)\right\}$.In this case, $T$ represents the operator that shifts vectors cyclically to the left by one place, and $u, v$ represent the two preferred PN sequences. Also, $G(u, v)$ contains $N+2$ Gold sequences of period $N$. You select the desired sequence from this set using the Index on page 3-0 property.

## Shift

Sequence offset from initial time
Specify the offset of the Gold sequence from its starting point as a numeric, integer scalar value that can be positive or negative. The default is 0 . The Gold sequence has a period of $N=2^{n}-1$, where $n$ is the degree of the generator polynomials specified in the FirstPolynomial on page 3-0 and SecondPolynomial on page 3-0 properties. The shift value is wrapped with respect to the sequence period.

## VariableSizeOutput

Enable variable-size outputs
Set this property to true to enable an additional input to the step method. The default is false. When you set this property to true, the enabled input specifies the output size of the Gold sequence used for the step. The input value must be less than or equal to the value of the MaximumOutputSize property.

When you set this property to false, the SamplesPerFrame property specifies the number of output samples.

## MaximumOutputSize

Maximum output size
Specify the maximum output size of the Gold sequence as a positive integer 2-element row vector. The second element of the vector must be 1. The default is [10 1].

This property applies when you set the VariableSizeOutput property to true.

## SamplesPerFrame

Number of output samples per frame
Specify the number of Gold sequence samples that the step method outputs as a numeric, integer scalar value. The default is 1 . If you set this property to a value of $M$, then the step method outputs $M$ samples of a Gold sequence with a period of $N=2^{n}-1$. The value of $n$ represents the degree of the generator polynomials that you specify in the FirstPolynomial on page 3-0 and SecondPolynomial on page 3-0 properties.

## ResetInputPort

Enable generator reset input

Set this property to true to enable an additional reset input to the step method. The default is false. This input resets the states of the two shift registers of the Gold sequence generator to the initial conditions specified in the FirstInitialConditions on page 3-0 and SecondInitialConditions on page 3-0 properties.

## OutputDataType

Data type of output
Specify the output data type as one of double|logical|Smallest unsigned integer. The default is double.

You must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer mode.

## Methods

| reset | Reset states of Gold sequence generator object |
| :--- | :--- |

## reset

System object: comm.GoldSequence
Package: comm
Reset states of Gold sequence generator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the GoldSequence object, H .

## step

System object: comm. GoldSequence
Package: comm
Generate a Gold sequence

## Syntax

$Y=\operatorname{step}(H)$
Y = step(H,RESET)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H})$ outputs a frame of the Gold sequence in column vector Y . Specify the frame length with the SamplesPerFrame property. The object uses two PN sequence generators to generate a preferred pair of sequences with period $N=2^{\wedge} \mathrm{n}-1$. Then the object XORs these sequences to produce the output Gold sequence. The value in n is the degree of the generator polynomials that you specify in the FirstPolynomial and SecondPolynomial properties.
$Y=$ step ( $\mathrm{H}, \mathrm{RESET}$ ) uses RESET as the reset signal when you set the ResetInputPort property to true. The data type of the RESET input must be double precision or logical. RESET can be a scalar value or a column vector with length equal to the number of samples per frame specified in the SamplesPerFrame property. When the RESET input is a non-zero scalar, the object resets to the initial conditions that you specify in the FirstInitialConditions and
SecondInitialConditions properties. It then generates a new output frame. A column vector RESET input allows multiple resets within an output frame. A non-zero value at the ith element of the vector causes a reset at the ith output sample time.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.AWGNChannel

Package: comm
Add white Gaussian noise to input signal with GPU

## Description

The GPU AWGNChannel object adds white Gaussian noise to an input signal using a graphics processing unit (GPU).

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

To add white Gaussian noise to an input signal:
1 Define and set up your additive white Gaussian noise channel object. See "Construction" on page 3-698.
2 Call step to add white Gaussian noise to the input signal according to the properties of comm.gpu. AWGNChannel. The behavior of step is specific to each object in the toolbox.

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y=$ step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.AWGNChannel creates a GPU-based additive white Gaussian noise (AWGN) channel System object, H. This object adds white Gaussian noise to a real or complex input signal.

H = comm. gpu.AWGNChannel (Name, Value) creates a GPU-based AWGN channel object, H, with the specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuAr ray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

## Properties

## NoiseMethod

Method to specify noise level
Select the method to specify the noise level as one of Signal to noise ratio (Eb/No) | Signal to noise ratio (Es/No)|Signal to noise ratio (SNR)|Variance. The default is Signal to noise ratio (Eb/No).

## EbNo

Energy per bit to noise power spectral density ratio (Eb/No)
Specify the Eb/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (Eb/No). The default is 10. This property is tunable.

## EsNo

Energy per symbol to noise power spectral density ratio (Es/No)
Specify the Es/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (Es/No). The default is 10. This property is tunable.

## SNR

Signal to noise ratio (SNR)
Specify the SNR value in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (SNR). The default is 10. This property is tunable.

## BitsPerSymbol

Number of bits in one symbol
Specify the number of bits in each input symbol. You can set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (Eb/No). The default is 1 bit.

## SignalPower

Input signal power in Watts
Specify the mean square power of the input signal in Watts. Set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (Eb/No), Signal to noise ratio (Es/No) or Signal to noise ratio (SNR). The default is 1 Watt. The object assumes a nominal impedance of 1 Ohm . This property is tunable.

## SamplesPerSymbol

Number of samples per symbol
Specify the number of samples per symbol. Set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Signal to noise ratio (Eb/No) or Signal to noise ratio (Es/ No). The default is 1 sample.

## VarianceSource

Source of noise variance
Specify the source of the noise variance as one of Property | Input port. The default is Property. Set VarianceSource to Input port to specify the noise variance value via an input to the step method. Set VarianceSource to Property to specify the noise variance value using the Variance property. This property applies when you set the NoiseMethod property to Variance.

## Variance

Noise variance
Specify the variance of the white Gaussian noise. You can set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the NoiseMethod property to Variance and the VarianceSource property to Property. The default is 1 . This property is tunable.

## RandomStream

Source of random number stream
Specify the source of random number stream. The only valid setting for this property is Global stream. The object generates the normally distributed random numbers from the current global random number stream.

## Seed

Initial seed of mt19937ar random number stream
The GPU version of the AWGN Channel System object does not use this property.

## Methods

step Add white Gaussian noise to input signal

## Common to All System Objects

```
release Allow System object property value changes
```

## Algorithm

This object uses the same algorithm as the comm. AWGNChannel System object. See the Algorithms section of the comm. AWGNChannel help page for more details. The object properties correspond to the related block parameters, except that:

- This object uses parallel.gpu.RandStream to provide an interface for controlling the properties of one or more random number streams that the GPU uses. Usage is the same as RandStream with the following restrictions:
- Only the combRecursive (MRG32K3A) generator is supported.
- Only the Inversion normal transform is supported.
- Setting the substream property is not allowed.

Enter help parallel.gpu.RandStream at the MATLAB command line for more information.

## Examples

## GPU AWGN Channel

Specify the modulation order and generate PSK-modulated random data.

```
M = 8;
modData = pskmod(randi([0 M-1],1000,1),M,pi/M);
```

Create an AWGN channel object that uses a GPU. Pass the modulated data through the channel.

```
gpuChannel = comm.gpu.AWGNChannel('EbNo',15,'BitsPerSymbol', ...
    log2(M));
channelOutput = gpuChannel(modData);
```

Visualize the noiseless and noisy data in scatter plots.

```
scatterplot(modData)
scatterplot(channelOutput)
```

## Extended Capabilities

## GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.
This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

## See Also

comm. AWGNChannel
Introduced in R2012a

## step

System object: comm. gpu. AWGNChannel
Package: comm
Add white Gaussian noise to input signal

## Syntax

$Y=\operatorname{step}(H, X)$
Y = step(H,X,VAR)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X)$ adds white Gaussian noise to input $X$ and returns the result in $Y$. The input $X$ can be a double or single precision data type scalar, vector, or matrix with real or complex values. The dimensions of input $X$ determine single or multichannel processing. For an M-by-N matrix input, M represents the number of time samples per channel and $N$ represents the number of channels. $M$ and $N$ can be equal to 1 . The object adds frames of length $M$ of Gaussian noise to each of the $N$ channels independently.

Y = step( $\mathrm{H}, \mathrm{X}, \mathrm{VAR}$ ) uses input VAR as the variance of the white Gaussian noise. This applies when you set the NoiseMethod property to Variance and the VarianceSource property to Input port. Input VAR can be a positive scalar or row vector with a length equal to the number of channels. VAR must be of the same data type as input $X$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.BlockDeinterleaver

Package: comm
Restore original ordering of block interleaved sequence with GPU

## Description

The BlockDeinterleaver System object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To deinterleave the input vector:
1 Define and set up your block deinterleaver object. See "Construction" on page 3-705.
2 Call step to rearrange the elements of the input vector according to the properties of comm.gpu. BlockDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.BlockDeinterleaver creates a GPU-based block deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the BlockInterleaver System object

H = comm.gpu.BlockDeinterleaver(Name,Value) creates a GPU-based block deinterleaver object, H , with the specified property name set to the specified value.

H = comm.gpu.BlockDeinterleaver(PERMVEC) creates a GPU-based block deinterleaver object, $H$, with the PermutationVector property set to PERMVEC.

## Properties

## PermutationVector

Permutation vector
Specify the mapping used to permute the input symbols as a column vector of integers. The default is $[5 ; 4 ; 3 ; 2 ; 1]$. The mapping is a vector where the number of elements is equal to the length, N, of the input to the step method. Each element must be an integer between 1 and $N$, with no repeated values.

## Methods

step Deinterleave input sequence

## Common to All System Objects

release Allow System object property value changes

## Algorithm

This object uses the same algorithm as the comm.BlockDeinterleaver System object. See Algorithms on the comm. BlockDeinterleaver help page for details.

## Examples

## Block Interleaving and Deinterleaving with GPU

Create interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deIntData]
```

ans =

| 6 | 1 | 6 |
| :--- | :--- | :--- |
| 7 | 7 | 7 |
| 1 | 6 | 1 |
| 7 | 7 | 7 |

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
ans =
    1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify permVec as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

ans =
1

## Extended Capabilities

## GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.
This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

## step

System object: comm.gpu. BlockDeinterleaver
Package: comm
Deinterleave input sequence

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X)$ restores the original ordering of the sequence, $X$, that was interleaved using a block interleaver. The step method forms the output, Y , based on the mapping specified by the PermutationVector property as Output(PermutationVector $(\mathrm{k})$ )=Input( k ), for $\mathrm{k}=1: \mathrm{N}$, where N is the length of the permutation vector. The input X must be a column vector of the same length, N . The data type of $X$ can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.BlockInterleaver

Package: comm
Create block interleaved sequence with GPU

## Description

The GPU BlockInterleaver object permutes the symbols in the input signal using a graphics processing unit (GPU).

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To interleave the input signal:
1 Define and set up your block interleaver object. See "Construction" on page 3-709.
2 Call step to reorder the input symbols according to the properties of comm.gpu. BlockInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.BlockInterleaver creates a GPU-based block interleaver System object, H. This object permutes the symbols in the input signal based on a permutation vector.

H = comm.gpu.BlockInterleaver(Name, Value) creates a GPU-based block interleaver object, H, with the specified property Name set to the specified Value.
$\mathrm{H}=$ comm.gpu.BlockInterleaver(PERMVEC) creates a GPU-based block deinterleaver object, H , with the PermutationVector property set to PERMVEC.

## Properties

## PermutationVector

Permutation vector
Specify the mapping used to permute the input symbols as a column vector of integers. The default is [ $5 ; 4 ; 3 ; 2 ; 1$ ]. The mapping is a vector where the number of elements is equal to the length, N, of the input to the step method. Each element must be an integer between 1 and $N$, with no repeated values.

## Methods

step Permute input symbols using a permutation vector

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ permutes input sequence, X , and returns interleaved sequence, Y . The step method forms the output $Y$, based on the mapping defined by the PermutationVector property as Output( $k$ )=Input (PermutationVector( $k$ )), for $k=1: N$, where $N$ is the length of the PermutationVector property. The input $X$ must be a column vector of length $N$. The data type of $X$ can be numeric, logical, or fixed-point (fi objects). $Y$ has the same data type as $X$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.ConvolutionalEncoder

Package: comm.gpu
Convolutionally encode binary data with GPU

## Description

The GPU ConvolutionalEncoder object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To convolutionally encode a binary signal:
1 Define and set up your convolutional encoder object. See "Construction" on page 3-713.
2 Call step to encode a sequence of binary input vectors to produce a sequence of binary output vectors according to the properties of comm. gpu. ConvolutionalEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.ConvolutionalEncoder creates a System object, H, that convolutionally encodes binary data.

H = comm.gpu.ConvolutionalEncoder(Name, Value) creates a convolutional encoder object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.gpu.ConvolutionalEncoder(TRELLIS,Name, Value) creates a convolutional encoder object, H. This object has the TrellisStructure on page 3-0 property set to TRELLIS, and the other specified properties set to the specified values.

## Properties

## TrellisStructure

Trellis structure of convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of poly2trellis(7, [171 133]). Use the istrellis function to check if a structure is a valid trellis structure.

## TerminationMethod

Termination method of encoded frame
Specify how the encoded frame is terminated as one of Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to Truncated, the object treats each input vector independently and resets its states to the all-zeros state.

When you set this property to Terminated, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to the all-zeros state at the end of the vector. For a rate $K / N$ code, the step method outputs a vector with length $N \times(L+S) / K$, where $S=$ constraintLength-1. In the case of multiple constraint lengths, $S=\mathbf{s u m}($ constraintLength(i)-1)). $L$ is the length of the input to the step method.

## ResetInputPort

Enable encoder reset input
You cannot reset this encoder object using an input port. The only valid property setting is false.

## DelayedResetAction

Delay output reset
You cannot reset this encoder object using an input port. The only valid property setting is false.

## InitialStateInputPort

You cannot set the initial state of this encoder object. The only valid property setting is false.

## FinalStateOutputPort

You cannot output the final state of this encoder object. The only valid property setting is false.

## PuncturePatternSource

Source of puncture pattern
Specify the source of the puncture pattern as one of None | Property. The default is None. When you set this property to None the object does not apply puncturing. When you set this property to Property, the object punctures the code. This puncturing is based on the puncture pattern vector that you specify in the PuncturePattern on page 3-0 property. This property applies when you set the TerminationMethod on page 3-0 property to Continuous or Truncated.

## PuncturePattern

Puncture pattern vector
Specify the puncture pattern that the object uses to puncture the encoded data as a column vector.
The default is $[1 ; 1 ; 0 ; 1 ; 0 ; 1]$. The vector contains 1 s and 0 s , where 0 indicates a punctured, or excluded, bit. This property applies when you set the TerminationMethod on page 3-0 property to Continuous or Truncated and the PuncturePatternSource on page 3-0 property to Property.

## NumF rames

Number of independent frames present in the input and output data vectors.
Specify the number of independent frames contained in a single data input/output vector. The default value of this property is 1 . The objects segments the input vector into NumFrames segments and encodes them independently. The output contains NumFrames encoded segments. This property is applicable when you set the TerminationMethod on page 3-0 to Terminated or Truncated.

## Methods

## reset Reset states of the convolutional encoder object

## Examples

## 8-PSK-Modulation With Convolutional Encoding

Transmit a Convolutionally Encoded, 8-PSK-Modulated Bit Stream Through an AWGN Channel.
Create a GPU-based Convolutional Encoder System object.
hConEnc $=$ comm.gpu. ConvolutionalEncoder;
Create a GPU-based PSK Modulator System object that accepts a bit input signal.
hMod $=$ comm.gpu.PSKModulator('BitInput',true);
Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of seven.

```
hChan = comm.gpu.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)',...
    'SNR',7);
```

Create a GPU-based PSK Demodulator System object that outputs a column vector of bit values.
hDemod = comm.gpu.PSKDemodulator('Bit0utput',true);
Create a GPU-based Viterbi Decoder System object that accepts an input vector of hard decision values, which are zeros or ones.
hDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
Create an Error Rate System object that ignores 3 data samples before makings comparisons. The received data lags behind the transmitted data by 34 samples.

```
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
```

Run the simulation by using the step method to process data.

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = step(hConEnc, gpuArray(data));
    modSignal = step(hMod, encodedData);
    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, gather(receivedBits));
end
```

Display the errors.

```
disp(errors)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Encoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.
This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

## step

System object: comm.gpu. ConvolutionalEncoder
Package: comm.gpu
Convolutionally encode binary data

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X)$ encodes the binary data, $X$, using the convolutional encoding that you specify in the TrellisStructure property. It returns the encoded data, $Y$. Both $X$ and $Y$ are column vectors of data type single, double, or logical. When the convolutional encoder represents a rate $K / N$ code, the length of the input vector equals $K \times L$, for a positive integer, $L$. The step method sets the length of the output vector, Y , to $L \times N$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.ConvolutionalInterleaver

Package: comm
Permute input symbols using shift registers with GPU

## Description

The GPU Convolutional Interleaver object permutes the symbols in the input signal using a graphics processing unit (GPU). Internally, this class uses a set of shift registers.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To convolutionally interleave binary data:
1 Define and set up your convolutional interleaver object. See "Construction" on page 3-719.
2 Call step to convolutionally interleave according to the properties of comm.gpu. ConvolutionalInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.ConvolutionalInterleaver creates a GPU-based convolutional interleaver System object, H . This object permutes the symbols in the input signal using a set of shift registers.

H = comm.gpu.ConvolutionalInterleaver(Name, Value) creates a GPU-based convolutional interleaver System object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.gpu. ConvolutionalInterleaver(M,B,IC) creates a GPU-based convolutional interleaver System object H, with the NumRegisters property set to M, the RegisterLengthStep
property set to B, and the InitialConditions property set to IC. M, B, and IC are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments.

## Properties

## NumRegisters

Number of internal shift registers
Specify the number of internal shift registers as a scalar, positive integer. The default is 6 .

## RegisterLengthStep

Number of additional symbols that fit in each successive shift register
Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2 . The first register holds zero symbols.

## InitialConditions

Initial conditions of shift registers
Specify the values that are initially stored in each shift register as a numeric scalar or vector. You do not need to specify a value for the first shift register, which has zero delay. The default is 0 . The value of the first element of this property is unimportant because the first shift register has zero delay. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 30 property, then the $i$-th shift register stores the $i$-th element of the specified vector.

## Methods

step Permute input symbols using shift registers

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

## Convolutional Interleaving and Deinterleaving with GPU

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

ans =

| 0 | 0 | 0 |
| ---: | ---: | ---: |
| 1 | 0 | 0 |
| 2 | 2 | 0 |
| 3 | 0 | 0 |
| 4 | 4 | 0 |
| 5 | 0 | 0 |
| 6 | 6 | 0 |
| 7 | 1 | 1 |
| 8 | 8 | 2 |
| 9 | 3 | 3 |
| 10 | 10 | 4 |
| 11 | 5 | 5 |
| 12 | 12 | 6 |
| 13 | 7 | 7 |
| 14 | 14 | 8 |
| 15 | 9 | 9 |
| 16 | 16 | 10 |
| 17 | 11 | 11 |
| 18 | 18 | 12 |
| 19 | 13 | 13 |
| 20 | 20 | 14 |

The delay through the interleaver and deinterleaver pair is equal to the product of the NumRegisters and RegisterLengthStep properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
intrlvDelay =
    6
numSymErrors =
    0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Interleaver block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.
This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

## reset

System object: comm.gpu.ConvolutionalInterleaver
Package: comm
Reset states of the convolutional interleaver object

## Syntax

reset (H)

## Description

reset $(H)$ resets the states of the GPU ConvolutionalInterleaver object, H.

## step

System object: comm.gpu.ConvolutionalInterleaver
Package: comm
Permute input symbols using shift registers

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ permutes input sequence, X , and returns interleaved sequence, Y . The input X must be a column vector. The data type can be of type double, single, uint32, int32, or logical. Y has the same data type as $X$. The convolutional interleaver object uses a set of $N$ shift registers, where $N$ is the value specified by the NumRegisters property. The object sets the delay value of the $k^{\text {th }}$ shift register to the product of ( $k-1$ ) and the RegisterLengthStep property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the $N^{\text {th }}$ register and the next new input occurs, it returns to the first register.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.gpu.ConvolutionalDeinterleaver

Package: comm
Restore ordering of symbols using shift registers with GPU

## Description

The GPU ConvolutionalDeinterleaver object recovers a signal that was interleaved using the GPU-based convolutional interleaver object. The parameters in the two blocks should have the same values.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To recover convolutionally interleaved binary data:
1 Define and set up your convolutional deinterleaver object. See "Construction" on page 3-725.
2 Call step to convolutionally deinterleave according to the properties of comm.gpu. ConvolutionalDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.ConvolutionalDeinterleaver creates a GPU-based convolutional deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using a convolutional interleaver.

H = comm.gpu.ConvolutionalDeinterleaver(Name,Value) creates a GPU-based convolutional deinterleaver System object, $H$, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.gpu. ConvolutionalDeinterleaver( $\mathrm{M}, \mathrm{B}, \mathrm{IC}$ ) creates a convolutional deinterleaver System object H, with the NumRegisters property set to M, the RegisterLengthStep property set to B, and the InitialConditions property set to IC. M, B, and IC are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments.

## Properties

## NumRegisters

Number of internal shift registers
Specify the number of internal shift registers as a scalar, positive integer. The default is 6 .

## RegisterLengthStep

Number of additional symbols that fit in each successive shift register
Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2 . The first register holds zero symbols.

## InitialConditions

Initial conditions of shift registers
Specify the values that are initially stored in each shift register (except the first shift register, which has zero delay) as a numeric scalar or vector. The default is 0 . If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 3-0 property, then the $i$-th shift register stores the $i$-th element of the specified vector. The value of the first element of this property is unimportant, since the first shift register has zero delay.

## Methods

step Permute input symbols using shift registers
reset Reset states of the convolutional deinterleaver object

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Convolutional Interleaving and Deinterleaving with GPU

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

ans $=$

| 0 | 0 | 0 |
| ---: | ---: | ---: |
| 1 | 0 | 0 |
| 2 | 2 | 0 |
| 3 | 0 | 0 |
| 4 | 4 | 0 |
| 5 | 0 | 0 |
| 6 | 6 | 0 |
| 7 | 1 | 1 |
| 8 | 8 | 2 |
| 9 | 3 | 3 |
| 10 | 10 | 4 |
| 11 | 5 | 5 |
| 12 | 12 | 6 |
| 13 | 7 | 7 |
| 14 | 14 | 8 |
| 15 | 9 | 9 |

| 17 | 11 | 11 |
| 18 | 18 | 12 |
| 19 | 13 | 13 |
| 20 | 20 | 14 |

The delay through the interleaver and deinterleaver pair is equal to the product of the NumRegisters and RegisterLengthStep properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
intrlvDelay =
    6
numSymErrors =
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Deinterleaver block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.
This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

## See Also

comm. ConvolutionalDeinterleaver|comm.gpu.ConvolutionalInterleaver
Introduced in R2012a

## step

System object: comm.gpu.ConvolutionalDeinterleaver
Package: comm
Permute input symbols using shift registers

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ restores the original ordering of the sequence, $X$, that was interleaved using a convolutional interleaver and returns Y . The input X must be a column vector. The data type can be numeric, logical, or fixed-point (fi objects). Y has the same data type as $X$. The convolutional deinterleaver object uses a set of N shift registers, where N represents the value specified by the NumRegisters property. The object sets the delay value of the $k^{\text {th }}$ shift register to the product of ( $k-1$ ) and the RegisterLengthStep property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the $N$ th register and the next new input occurs, it returns to the first register.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## reset

System object: comm.gpu.ConvolutionalDeinterleaver
Package: comm
Reset states of the convolutional deinterleaver object

## Syntax

reset(H)

## Description

reset $(\mathrm{H})$ resets the states of the GPU ConvolutionalDeinterleaver object, H .

## comm.gpu.LDPCDecoder

Package: comm
Decode binary low-density parity-check (LDPC) code with GPU

Note To use this object, you must install Parallel Computing Toolbox ${ }^{\mathrm{TM}}$ and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

## Description

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

The comm.gpu.LDPCDecoder System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see "Belief Propagation Decoding" on page 3-737.

To decode an LDPC-encoded signal:
1 Create the comm.gpu. LDPCDecoder object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
gpu_ldpcdecoder = comm.gpu.LDPCDecoder
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(
```

$\qquad$

``` ,Name, Value)
```

## Description

gpu_ldpcdecoder = comm.gpu.LDPCDecoder creates a GPU-based binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity) sets the ParityCheckMatrix property to parity and creates a GPU-based LDPC decoder System object. The parity input must be specified as described by the ParityCheckMatrix property.
gpu_ldpcdecoder = comm.gpu.LDPCDecoder( $\qquad$ , Name, Value) sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, comm. LDPCDecoder('DecisionMethod', 'Soft decision') configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type double. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## ParityCheckMatrix - Parity-check matrix

dvbs2ldpc (1/2) (default) | sparse binary matrix | nonsparse index matrix
Parity-check matrix, specified as a sparse ( $N-K$ )-by- $N$ binary-valued matrix. $N$ is the length of the received signal and must be in the range ( $0,2^{31}$ ). $K$ is the length of the uncoded message and must be less than $N$. The last ( $N-K$ ) columns in the parity-check matrix must be an invertible matrix in the Galois field of order $2, \mathrm{gf}(2)$.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, $I$, that defines the row and column indices of the 1 s in the parity-check matrix such that
sparse(I(:,1),I(: 2),1).
This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the logical data type.

The default value uses the dvbs2ldpc function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S. 2 standard.
Example: dvbs2ldpc (R, 'indices') configures the index matrix for the DVB-S. 2 standard, where R is the code rate, and 'indices' specifies the output format of dvbs2ldpc as a two-column doubleprecision matrix that defines the row and column indices of the 1 s in the parity-check matrix.
Data Types: double | logical

## OutputValue - Output value format

'Information part' (default)|'Whole codeword'
Output value format, specified as one of these values:

- 'Information part' - The object outputs a K-by-1 column vector containing only the information-part of the received log-likelihood ratio vector. $K$ is the length of the uncoded message.
- 'Whole codeword ' - The object outputs an $N$-by-1 column vector containing the whole loglikelihood ratio vector. $N$ is the length of the received signal.
$N$ and $K$ must align with the dimension of the $(N-K)$-by- $K$ parity-check matrix.
Data Types: char
DecisionMethod - Decision method
'Hard decision' (default)|'Soft decision'
Decision method used for decoding, specified as one of these values:
- 'Hard decision' - The object outputs decoded data of data type logical.
- 'Soft decision' - The object outputs log-likelihood ratios of data type double.

Data Types: char

## IterationTerminationCondition - Condition for iteration termination

'Maximum iteration count' (default)|'Parity check satisfied'
Condition for iteration termination, specified as one of these values:

- 'Maximum iteration count ' - Decoding terminates after the number of iterations specified by the MaximumIterationCount property.
- 'Parity check satisfied ' - Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the MaximumIterationCount property.

## Data Types: char

MaximumIterationCount - Maximum number of decoding iterations
50 (default) | positive integer
Maximum number of decoding iterations, specified as a positive integer.
Data Types: double

## NumIterationsOutputPort - Output number of iterations performed

false (default) | true
Output number of iterations executed, specified as false or true. To output the number of iterations executed, set this property to true.
Data Types: logical

## FinalParityChecksOutputPort - Output final parity checks

false (default) | true
Output final parity checks, specified as false or true. To output the final calculated parity checks, set this property to true.
Data Types: logical

## Usage

## Syntax

```
y = gpu_ldpcdecoder(x)
```

```
[y,numiter] = gpu_ldpcdecoder(x)
[y,parity] = gpu_ldpcdecoder(x)
[y,numiter,parity] = gpu_ldpcdecoder(x)
```

## Description

$y=$ gpu_ldpcdecoder( $x$ ) decodes input data using an LDPC code based on the default paritycheck matrix.
[ $y$, numiter] = gpu_ldpcdecoder $(x)$ returns the decoded data, $y$, and number of iterations performed, numiter. To use this syntax, set the NumIterationsOutputPort property to true.
[y, parity] = gpu_ldpcdecoder $(x)$ returns the decoded data, $y$, and final parity checks, parity. To use this syntax, set the FinalParityChecksOutputPort property to true.
[y, numiter, parity] = gpu_ldpcdecoder (x) returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the NumIterationsOutputPort and FinalParityChecksOutputPort properties to true.

## Input Arguments

## x - Log-likelihood ratios

## column vector

Log-likelihood ratios, specified as an $N$-by-1 column vector containing the soft-decision output from demodulation. $N$ is the number of bits in the LDPC codeword before modulation. Each element is the $\log$-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first $K$ elements correspond to the information-part of the input message.

## Data Types: double

## Output Arguments

## y - Decoded data

column vector
Decoded data, returned as a column vector. The DecisionMethod property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the OutputValue property is set to 'Information part', the output includes only the information-part of the received log-likelihood ratio vector.
- If the OutputValue property is set to 'Whole codeword ' , the output includes the whole loglikelihood ratio vector.

## Data Types: double | logical

## numiter - Number of executed decoding iterations

positive integer
Number of executed decoding iterations, returned as a positive integer.

## Dependencies

To enable this output, set the NumIterationsOutputPort property to true.

## parity - Final parity checks

column vector
Final parity checks after decoding the input LDPC code, returned as an ( $N-K$ )-by- 1 column vector. $N$ is the number of bits in the LDPC codeword before modulation. $K$ is the length of the uncoded message.

## Dependencies

To enable this output, set the FinalParityChecksOutputPort property to true.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## LDPC Encode and Decode QPSK-Modulated Signal Using GPU

Using a comm.gpu.LDPCDecoder System Object ${ }^{\text {TM }}$ to decode the signal, transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. After adding AWGN, demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals. For more information, see "Simulation Acceleration Using GPUs".

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
gpuldpcDecoder = comm.gpu.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
```

```
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = gpuldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

## Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

## Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.

For transmitted LDPC-encoded codeword $c=c_{0}, c_{1}, \ldots, c_{n-1}$, the input to the LDPC decoder is the loglikelihood ratio (LLR) value $L\left(c_{i}\right)=\log \left(\frac{\operatorname{Pr}\left(c_{i}=0 \mid \text { channel output for } c_{i}\right)}{\operatorname{Pr}\left(c_{i}=1 \mid \text { channel output for } c_{i}\right)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:
$L\left(r_{j i}\right)=2 \operatorname{atanh}\left(\prod_{i^{\prime} \in V_{j}(i} \tanh \left(\frac{1}{2} L\left(q_{i^{\prime} j}\right)\right)\right)$,
$L\left(q_{i j}\right)=L\left(c_{i}\right)+\sum_{j^{\prime} \in C_{i} \backslash j} L\left(r_{j^{\prime} i}\right)$, initialized as $L\left(q_{i j}\right)=L\left(c_{i}\right)$ before the first iteration, and
$L\left(Q_{i}\right)=L\left(c_{i}\right)+\sum_{j^{\prime} \in C_{i}} L\left(r_{j^{\prime}}\right)$.
At the end of each iteration, $L\left(Q_{i}\right)$ contains the updated estimate of the LLR value for transmitted bit $c_{i}$. The value $L\left(Q_{i}\right)$ is the soft-decision output for $c_{i}$. If $L\left(Q_{i}\right)<0$, the hard-decision output for $c_{i}$ is 1 . Otherwise, the hard-decision output for $c_{i}$ is 0 .

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation $\left(H c^{\prime}=0\right)$ at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_{i} \backslash j$ and $V_{j} \backslash i$ are based on the parity-check matrix (PCM). Index sets $C_{i}$ and $V_{j}$ correspond to all nonzero elements in column $i$ and row $j$ of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for $i=5$ and $j=3$.

To avoid infinite numbers in the algorithm equations, $\operatorname{atanh}(1)$ and atanh( -1 ) are set to 19.07 and 19.07, respectively. Due to finite precision, MATLAB returns 1 for $\tanh (19.07)$ and -1 for $\tanh (-19.07)$.

## comm.gpu.PSKDemodulator

Package: comm
Demodulate using M-ary PSK method with GPU

## Description

The GPU PSKDemodulator object demodulates an input signal using the M-ary phase shift keying (M-PSK) method.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To demodulate a signal that was modulated using phase shift keying:
1 Define and set up your PSK demodulator object. See "Construction" on page 3-740.
2 Call step to demodulate the signal according to the properties of comm.gpu. PSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y=$ step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.PSKDemodulator returns a GPU-based demodulator System object, H. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

H = comm.gpu.PSKDemodulator(Name, Value) creates a GPU-based M-PSK demodulator object, $H$, with the specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN)

H = comm.gpu.PSKDemodulator(M,PHASE,Name,Value) creates a GPU-based M-PSK demodulator object, $H$, with the ModulationOrder property set to $M$, the PhaseOffset property set to PHASE and other specified property names set to the specified values. M and PHASE are value-only
arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8 .

## PhaseOffset

Phase of zeroth point of constellation
Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is $\pi / 8$.

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values. When you set this property to true, the step method outputs a column vector of bit values with length equal to $\log 2$ (ModulationOrder) times the number of demodulated symbols. When you set this property to false, the step method outputs a column vector, with a length equal to the input data vector that contains integer symbol values between 0 and ModulationOrder-1. The default is false.

## SymbolMapping

## Constellation encoding

Specify how the object maps an integer or group of $\log 2$ (ModulationOrder) bits to the corresponding symbol as Binary |Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the integer m ( $0 \leq \mathrm{m} \leq$ ModulationOrder-1) maps to the complex value. This value is represented as $\exp \left(j^{*}\right.$ PhaseOffset $+j^{*} 2^{*} \mathrm{pi}{ }^{*} \mathrm{~m} /$ ModulationOrder $)$. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping property.

## CustomSymbolMapping

Custom constellation encoding
Specify a custom constellation symbol mapping vector. The default is $0: 7$. This property must be a row or column vector of size ModulationOrder with unique integer values in the range [ 0 , ModulationOrder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of $0+$ PhaseOffset, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of -n/ ModulationOrder + PhaseOffset. This property applies when you set the SymbolMapping property to Custom.

## DecisionMethod

Demodulation decision method

Specify the decision method that the object uses as one of Hard decision | Log-likelihood ratio|Approximate log-likelihood ratio. The default is Hard decision. When you set DecisionMethod to false, the object always performs hard decision demodulation. This property applies when you set the BitOutput property to true.

## VarianceSource

Source of noise variance
Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio.

## Variance

Specify the variance of the noise as a positive, real scalar. The default is 1 . If this value is very small (i.e., SNR is very high), then log-likelihood ratio (LLR) computations may yield Inf or -Inf. This occurs because the LLR algorithm computes the exponential value of very large or very small numbers using finite precision arithmetic. In such cases, use approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the BitOutput property to true, the DecisionMethod property to Log-likelihood ratio or Approximate loglikelihood ratio, and the VarianceSource property to Property. This property is tunable.

## OutputDataType

Data type of output
When you set this property to Full precision, the output signal inherits its data type from the input signal.

## Algorithm

The GPU PSK Demodulator System object uses the same algorithm as the comm. PSKDemodulator System object. See Decoding Algorithm for details.

## Examples

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Then demodulate, decode, and count errors.

## 16-PSK Modulation and Demodulation

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel.

Create a GPU-based PSK Modulator System object.
hMod $=$ comm.gpu.PSKModulator(16, 'PhaseOffset',pi/16);
Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of 15.
hAWGN = comm.gpu.AWGNChannel('NoiseMethod', . .
'Signal to noise ratio (SNR)','SNR',15);
Create a GPU-based PSK Demodulator System object.

```
hDemod = comm.gpu.PSKDemodulator(16, 'PhaseOffset',pi/16);
```

Create an error rate calculator System object.
hError = comm.ErrorRate;
Transmit a frame of data containing 50 symbols.

```
for counter = 1:100
data = gpuArray.randi([0 hMod.ModulationOrder-1], 50, 1);
```

Run the simulation by using the step method to process data.

```
modSignal = step(hMod, data);
noisySignal = step(hAWGN, modSignal);
receivedData = step(hDemod, noisySignal);
errorStats = step(hError, gather(data), gather(receivedData));
end
```

Compute the error rate results.

```
fprintf('Error rate = %f\nNumber of errors = %d\n',...
    errorStats(1), errorStats(2))
```

## GPU PSK Demodulator

Create GPU PSK modulator and demodulator pair.

```
gpuMod = comm.gpu.PSKModulator;
gpuDemod = comm.gpu.PSKDemodulator;
```

Generate random data symbols. Modulate the data.

```
txData = randi([0 7],1000,1);
txSig = gpuMod(txData);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,20);
```

Demodulate the received signal.

```
rxData = gpuDemod(rxSig);
```

Determine the number of symbol errors.

```
numSymErrors = symerr(txData,rxData)
```

numSymErrors =

## step

Demodulate using M-ary PSK method

## Syntax

$Y=\operatorname{step}(H, X)$
$Y=\operatorname{step}(H, X, V A R)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

Y $=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates data, X , with the GPU PSK Demodulator System object, H , and returns Y . Input X must be a scalar or a column vector with double- or single- precision data type. Depending on the BitOutput property value, output $Y$ can be integer or bit valued.

Y = step( $H, X$, VAR) uses soft decision demodulation and noise variance VAR. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to Approximate loglikelihood ratio or Log-likelihood ratio, and the VarianceSource property to Input port. The data type of input VAR must be double or single precision.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.PSKModulator

Package: comm
Modulate using M-ary PSK method with GPU

## Description

The GPU PSKModulator object modulates a signal using the M-ary phase shift keying method implemented on a graphics processing unit (GPU). The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To modulate a signal using phase shift keying:
1 Define and set up your PSK modulator object. See "Construction" on page 3-747.
2 Call step to modulate the signal according to the properties of comm.gpu.PSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.PSKModulator returns a GPU-based demodulator System object, H. This object modulates the input signal using the M-ary phase shift keying (M-PSK) method with soft decision using the approximate log-likelihood ratio algorithm.

H = comm.gpu.PSKModulator(Name,Value) creates a GPU-based M-PSK modulator object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN)

H = comm.gpu.PSKModulator(M,PHASE, Name, Value) creates a GPU-based M-PSK modulator object, H, with the ModulationOrder property set to M, the PhaseOffset property set to PHASE and other specified property Names set to the specified Values. M and PHASE are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8 .
PhaseOffset
Phase of zeroth point of constellation
Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is $\Pi / 8$.

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input must be a column vector of bit values whose length is an integer multiple of $\log 2$ (ModulationOrder). This vector contains bit representations of integers between 0 and ModulationOrder-1. The input data type can be numeric or logical. When you set the BitInput property to false, the step method input must be a column vector of integer symbol values between 0 and ModulationOrder-1. The data type of the input must be numeric.

## SymbolMapping

## Constellation encoding

Specify how the object maps an integer or group of $\log 2$ (ModulationOrder) bits to the corresponding symbol as one of Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the integer m ( $0 \leq \mathrm{m} \leq$ ModulationOrder-1) maps to the complex value $\exp \left(\mathrm{j}^{*}\right.$ PhaseOffset $+\mathrm{j} * 2 * \mathrm{pi} * \mathrm{~m} /$ ModulationOrder). When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping property.

## CustomSymbolMapping

Custom constellation encoding
Specify a custom constellation symbol mapping vector. This property must be a row or column vector of size ModulationOrder with unique integer values in the range [0, ModulationOrder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of $0+$ PhaseOffset, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of -n/ModulationOrder + PhaseOffset. This property applies when you set the SymbolMapping property to Custom. The default is 0:7.

## OutputDataType

Data type of output
Specify the output data type as one of double | single. The default is double.

## Methods

| constellation | Calculate or plot ideal signal constellation |
| :--- | :--- |
| step | Modulate using M-ary PSK method with GPU |

## Common to All System Objects

release Allow System object property value changes

## Algorithm

The GPU PSK Modulator System object supports floating-point and integer input data types. This object uses the same algorithm as the comm. PSKModulator System object. See the Algorithms section of the comm. PSKModulator help page for details.

## Examples

## GPU PSK Modulator

Create binary data for 100, 4-bit symbols

```
data = randi([0 1],400,1);
```

Create a 16-PSK modulator System object with bits as inputs and Gray-coded signal constellation. Change the phase offset to $\pi / 16$.

```
gpuMod = comm.gpu.PSKModulator(16,'BitInput',true);
```

gpuMod.PhaseOffset = pi/16;

Modulate and plot the data
modData = gpuMod(data);
scatterplot(modData)

## Extended Capabilities

Plot the ideal signal constellation by calling the constellation method.

```
constellation(h)
```

## step

Modulate using M-ary PSK method with GPU

## Syntax

Y $=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ modulates the input data, X , using the GPU-based PSK modulator System object, H . The object returns the baseband modulated output $Y$. Depending upon the value of the BitInput property, input $X$ can be an integer or bit-valued column vector with numeric or logical data types.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.gpu.TurboDecoder

Package: comm.gpu
Decode input signal using parallel concatenation decoding with GPU

## Description

The GPU Turbo Decoder System object decodes the input signal using a parallel concatenated decoding scheme. This scheme uses the a-posteriori probability (APP) decoder as the constituent decoder. Both constituent decoders use the same trellis structure and algorithm.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To decode an input signal using a turbo decoding scheme:
1 Define and set up your turbo decoder object. See "Construction" on page 3-753.
2 Call step to decode a binary signal according to the properties of comm.gpu.TurboDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.TurboDecoder creates a GPU-based turbo decoder System object, H. This object uses the a-posteriori probability (APP) constituent decoder to iteratively decode the parallelconcatenated convolutionally encoded input data.

H = comm.gpu.TurboDecoder(Name, Value) creates a GPU-based turbo decoder object, H, with the specified property name set to the specified value. Name must appear inside single quotes (' ' ). You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

H = comm.gpu.TurboDecoder(TRELLIS, INTERLVRINDICES, NUMITER) creates a GPU-based turbo decoder object, $H$. In this object, the TrellisStructure property is set to TRELLIS, the InterleaverIndices property set to INTERLVRINDICES, and the NumIterations property set to NUMITER.

## Properties

## TrellisStructure

Trellis structure of constituent convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. The default is the result of poly2trellis (4, [13 15] , 13). Use the istrellis function to check if a structure is a valid trellis structure.

## InterleaverIndicesSource

Source of interleaver indices
Specify the source of the interleaver indices. The only valid setting for this property is Property.

## InterleaverIndices

Interleaver indices
Specify the mapping used to permute the input bits at the encoder as a column vector of integers. The default is (64:-1:1).'. This mapping is a vector with the number of elements equal to the length, $L$, of the output of the step method. Each element must be an integer between 1 and $L$, with no repeated values.

## Algorithm

Decoding algorithm
Specify the decoding algorithm. This object implements true a posteriori probability decoding. The only valid setting is True APP.

## NumScalingBits

Number of scaling bits
The GPU version of the Turbo Decoder does not use this property.

## NumIterations

Number of decoding iterations
Specify the number of decoding iterations used for each call to the step method. The default is 6 .
The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits.
The output of the step method is the hard-decision output of the final LLR update.

## NumF rames

Number of independent frames present in the input and output data vectors.

Specify the number of independent frames that a single data input/output vector contains. The default value of this property is 1 . This object segments the input vector into NumFrames segments and decodes the segments independently. The output contains NumFrames decoded segments.

## Methods

reset Reset states of the turbo decoder object
step Decode input signal using parallel concatenated decoding scheme
Common to All System Objects
release Allow System object property value changes

## Examples

## Transmit and decode using turbo coding

Transmit turbo-encoded blocks of data over a BPSK-modulated AWGN channel. Then, decode using an iterative turbo decoder and display errors.

Define a noise variable, establish a frame length of 256 , and use the random stream property so that the results are repeatable.

```
noiseVar = 4; frmLen = 256;
s = RandStream('mt19937ar', 'Seed', 11);
intrlvrIndices = randperm(s, frmLen);
```

Create a Turbo Encoder System object. The trellis structure for the constituent convolutional code is poly2trellis(4, [13 15 17], 13). The InterleaverIndices property specifies the mapping the object uses to permute the input bits at the encoder as a column vector of integers.

```
turboEnc = comm.TurboEncoder('TrellisStructure', poly2trellis(4, ...
```

    [13 15 17], 13), 'InterleaverIndices', intrlvrIndices);
    Create a BPSK Modulator System object.

```
bpsk = comm.BPSKModulator;
```

Create an AWGN Channel System object.

```
channel = comm.AWGNChannel('NoiseMethod', 'Variance', 'Variance', ...
    noiseVar);
```

Create a GPU-Based Turbo Decoder System object. The trellis structure for the constituent convolutional code is poly2trellis(4, [13 15 17], 13). The InterleaverIndicies property specifies the mapping the object uses to permute the input bits at the encoder as a column vector of integers.

```
turboDec = comm.gpu.TurboDecoder('TrellisStructure', poly2trellis(4, ...
    [13 15 17], 13), 'InterleaverIndices', intrlvrIndices, ...
    'NumIterations', 4);
```

Create an Error Rate System object.

```
errorRate = comm.ErrorRate;
```

Run the simulation.

```
for frmIdx = 1:8
    data = randi(s, [0 1], frmLen, 1);
    encodedData = turboEnc(data);
    modSignal = bpsk(encodedData);
    receivedSignal = channel(modSignal);
```

Convert the received signal to log-likelihood ratios for decoding.

```
receivedBits = turboDec(-2/(noiseVar/2))*real(receivedSignal));
```

Compare original the data to the received data and then calculate the error rate results.

```
errorStats = errorRate(data,receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\nTotal bits = %d\n', ...
errorStats(1), errorStats(2), errorStats(3))
```

## Algorithms

This object implements the inputs and outputs described on the Turbo Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox ${ }^{\mathrm{TM}}$.
This System object runs on a GPU, and also supports GPU array inputs. For more information, see "Simulation Acceleration Using GPUs".

## See Also

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the GPU TurboDecoder object, H .

## step

System object: comm.gpu.TurboDecoder
Package: comm.gpu
Decode input signal using parallel concatenated decoding scheme

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X)$ decodes the input data, $X$, using the parallel concatenated convolutional coding scheme. You specify this scheme using the TrellisStructure and InterleaverIndices properties. It returns the binary decoded data, Y . Both X and Y are column vectors of double-precision data type. When the constituent convolutional code represents a rate $1 / N$ code, the step method sets the length of the output vector, Y, to $\left(M-2^{*} N_{\text {Tails }}\right) /(2 * N-1)$. $M$ represents the input vector length and $N_{\text {Tails }}$ is given by $\log 2$ (TrellisStructure. numStates) ${ }^{*} N$. The output length, $L$, is the same as the length of the interleaver indices.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.gpu.ViterbiDecoder

## Package: comm

Decode convolutionally encoded data using Viterbi algorithm with GPU

## Description

The GPU ViterbiDecoder System object decodes input symbols to produce binary output symbols using a graphics processing unit (GPU). This object processes variable-size signals; however, variablesize signals cannot be applied for erasure inputs.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the gpuArray class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a gpuArray, the data remains on the GPU. The output signal is a gpuArray. When the object is given a gpuArray, calculations take place entirely on the GPU, and no data transfer occurs. Passing gpuArray arguments provides increased performance by reducing simulation time. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

To decode input symbols and produce binary output symbols:
1 Define and set up your Viterbi decoder object. See "Construction" on page 3-759.
2 Call step to decode input symbols according to the properties of comm.gpu.ViterbiDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.gpu.ViterbiDecoder creates a Viterbi decoder System object, H. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

H = comm.gpu.ViterbiDecoder(Name,Value) creates a Viterbi decoder object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN.

H = comm.gpu.ViterbiDecoder(TRELLIS, Name, Value) creates a Viterbi decoder object, H, with the TrellisStructure property set to TRELLIS, and other specified property Names set to the specified Values.

## Properties

## TrellisStructure

Trellis structure of convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. This object supports rate $1 / 2,1 / 3$ and $1 / 4$ trellises from simple feedforward encoders. The default value is the result of poly2trellis(7, [171 133]).

## InputFormat

Input format
Specify the format of the input to the decoder as one of Unquantized | Hard | Soft. The default is Unquantized.

When you set this property to Unquantized, the input must be a real vector of double or single precision unquantized soft values. The object considers negative numbers to be ones and positive numbers to be zeros. When you set this property to Hard, the input must be a vector of hard decision values, which are zeros or ones. The data type of the inputs can be double precision or single precision. When you set this property to Soft, the input must be a vector of quantized soft values represented as integers between 0 and $\mathbf{2}^{\wedge}$ SoftInputWordLength-1. The data type of the inputs can be double precision or single precision.

## SoftInputWordLength

Soft input word length
Specify the number of bits used to represent each quantized soft input value as a positive, integer scalar. This property applies when you set the InputFormat property to Soft. The default is 4 bits.

## InvalidQuantizedInputAction

Action when input values are out of range
The only valid setting is Ignore which ignores out of range inputs.

## TracebackDepth

## Traceback depth

Specify the number of trellis branches used to construct each traceback path as a positive, integer scalar less than or equal to 256 . The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay. When you set the TerminationMethod property to Continuous, the decoding delay consists of TracebackDepth zero symbols, or TracebackDepth zero bits for a rate $1 / \mathrm{N}$ convolutional code. When you set the TerminationMethod property to Truncated or Terminated, there is no output delay and TracebackDepth must be less than or equal to the number of symbols in each input. If the
code rate is $1 / 2$, a typical traceback depth value is about five times the constraint length of the code. The default is 34 .

## TerminationMethod

Termination method of encoded frame
Specify TerminationMethod as one of Continuous | Truncated| Terminated. The default is Continuous. In Continuous mode, the object saves its internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently. Select Continuous mode when the input signal contains only one symbol. In Truncated mode, the object treats each frame independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. In Terminated mode, the object treats each frame independently, and the traceback path always starts and ends in the all-zeros state.

## ResetInputPort

Enable decoder reset input
Set this property to true to enable an additional step method input. When the reset input is a nonzero value, the object resets the internal states of the decoder to initial conditions. This property applies when you set the TerminationMethod property to Continuous. The default is false.

## DelayedResetAction

Delay output reset
Delaying the output reset is not supported. The only valid setting is false.

## PuncturePatternSource

Source of puncture pattern
Specify the source of the puncture pattern as one of None | Property. The default is None. When you set this property to None the object assumes no puncturing. Set this property to Property to decode punctured codewords based on a puncture pattern vector specified via the
PuncturePattern property.

## PuncturePattern

Puncture pattern vector
Specify puncture pattern used to puncture the encoded data. The default is $[1 ; 1 ; 0 ; 1 ; 0 ; 1]$. The puncture pattern is a column vector of ones and zeros, where the zeros indicate where to insert dummy bits. The puncture pattern must match the puncture pattern used by the encoder. This property applies when you set the PuncturePatternSource property to Property.

## ErasuresInputPort

Enable erasures input
Erasures are not supported. The only valid setting is false.

## OutputDataType

Data type of output

The only valid setting is Full precision which makes the output data type match the input data type.

## NumFrames

Number of independent frames present in the input and output data vectors.
Specify the number of independent frames contained in a single data input/output vector. The input vector will be segmented into NumFrames segments and decoded independently. The output will contain NumFrames decoded segments. The default value of this property is 1 . This property is applies when you set the TerminationMethod is set to Terminated or Truncated.

## Methods

info Display information about GPU-based Viterbi Decoder object

release $\quad$ Allow System object property value changes

## Examples

Transmit a convolutionally encoded 8-DPSK-modulated bit stream through an AWGN channel. Then, demodulate, decode using a Viterbi decoder, and count errors.

```
hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.gpu.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR',10);
hDemod = comm.DPSKDemodulator('BitOutput',true);
hDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
% Delay in bits is TracebackDepth times the number of
% bits per symbol
        delay = hDec.TracebackDepth*...
                            log2(hDec.TrellisStructure.numInputSymbols);
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',delay);
    for counter = 1:20
        data = randi([0 1],30,1);
        encodedData = step(hConEnc, data);
        modSignal = step(hMod, encodedData);
        receivedSignal = step(hChan, modSignal);
        demodSignal = step(hDemod, receivedSignal);
        receivedBits = step(hDec, demodSignal);
        errorStats = step(hError, data, receivedBits);
        end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

Introduced in R2012a

## info

System object: comm.gpu.ViterbiDecoder
Package: comm
Display information about GPU-based Viterbi Decoder object

## Syntax

$\mathrm{S}=\mathrm{info}(0 \mathrm{BJ})$

## Description

$S=$ info(OBJ) returns a structure, $S$, containing characteristic information for the System object, OBJ. If OBJ has no characteristic information, S is empty. If $0 B J$ has characteristic information, the fields of $S$ vary depending on OBJ. For object specific details, refer to the help on the infoImpl method of that object.

## reset

System object: comm.gpu.ViterbiDecoder
Package: comm
Reset states of the GPU-based Viterbi Decoder modulator object

## Syntax

reset(H)

## Description

reset (H) resets the states of the GPU-based ViterbiDecoder object, H.

## step

System object: comm.gpu.ViterbiDecoder
Package: comm
Decode convolutionally encoded data using Viterbi algorithm

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )
Y = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step ( $H, X$ ) decodes encoded data, $X$, using the Viterbi algorithm and returns $\mathrm{Y} . \mathrm{X}$, must be a column vector with data type and values that depend on how you set the InputFormat property. If the convolutional code uses an alphabet of $2^{\wedge} \mathrm{N}$ possible symbols, the length of the input vector, X , must be $L^{*} \mathrm{~N}$ for some positive integer L. Similarly, if the decoded data uses an alphabet of $2^{\wedge} \mathrm{K}$ possible output symbols, the length of the output vector, Y , is $\mathrm{L}^{*} \mathrm{~K}$.
$Y=\operatorname{step}(H, X, R)$ resets the internal states of the decoder when you input a non-zero reset signal, R. R must be a double precision, single precision or logical scalar. This syntax applies when you set the TerminationMethod property to Continuous and the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## gsmDownlinkConfig

Create GSM downlink TDMA frame configuration object

## Description

The gsmDownlinkConfig object is a GSM downlink TDMA frame configuration object. Use gsmDownlinkConfig objects to create GSM downlink waveforms.

## Creation

## Syntax

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl = gsmDownlinkConfig(sps)
cfggsmdl = gsmDownlinkConfig(___,Name,Value)
```

## Description

cfggsmdl = gsmDownlinkConfig creates a GSM downlink TDMA frame configuration object.
cfggsmdl = gsmDownlinkConfig(sps) sets the SamplesPerSymbol property to sps.
cfggsmdl = gsmDownlinkConfig( $\qquad$ , Name, Value) sets one or more name-value pair arguments using any of the previous syntaxes. For example, 'RiseTime', 4 sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

## Properties

## SamplesPerSymbol - Samples per symbol

16 (default) | positive integer multiple of 4
Samples per symbol, specified as a positive integer multiple of 4.

## Data Types: double

## BurstType - Burst types

["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"] (default) | string row vector with 8 elements | "NB" | "FB" | "SB" | "Dummy" | "Off"

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is "NB", "FB", "SB", "Dummy", or "Off" - Each element specifies the burst type for the corresponding time slot.
- "NB" - Transmit data using a normal burst for every time slot.
- "FB" - Transmit data using a frequency correction burst for every time slot.
- "SB" - Transmit data using a time synchronization burst for every time slot.
- "Dummy" - Transmit data using a dummy burst for every time slot.
- "Off" - All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-780.

Note The BurstType property is an enumeration. To perform code generation, see "Code Generation" on page 3-801 and the "MEX Generation for GSM Downlink Waveform" on page 3-775 example.

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0,3 , and 5 , use access bursts in time slots 1,2 , and 6 , and transmit no data in time slots 4 and 7.

## TSC - Training sequence code

$\left[\begin{array}{llllllll}0 & 1 & 2 & 3 & 4 & 5 & 6 & 7\end{array}\right]$ (default) | eight-element row vector | integer in the range [0, 7]
Training sequence code (TSC) for normal bursts in time slots $0-7$ in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] - Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] - Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-782.
Example: [ $\begin{gathered}5 \\ 7\end{gathered} 0$ training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7 .

## Dependencies

To enable this property for a time slot, set the corresponding element of BurstType to "NB".
Data Types: double

## Attenuation - Power attenuation

[0 0 0 0 0 0 0 0 0 0 (default) | eight-element row vector | nonnegative integer
Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers - Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer - Specifies the power attenuation value for every time slot.

Example: $\left[\begin{array}{llllllll}0 & 0 & 0 & 0 & 0 & 0 & 0 & 3\end{array}\right]$ configures the frame to apply 0 dB attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7 .
Data Types: double

## RiseTime - Burst rise time

2 (default) | positive scalar
Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is $1 / S a m p l e s P e r S y m b o l$. The total ramp-up and ramp-down duration
(RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-780.
Data Types: double

## RiseDelay - Burst rise delay

0 (default) | positive scalar
Burst rise delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is $1 / \mathrm{SamplesPerSymbol}$. The total ramp-up and ramp-down duration (RiseTime RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-780.

When the burst rise delay is 0 , the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude RiseDelay symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude RiseDelay symbols before the start of the useful part.

## Data Types: double

## FallTime - Burst fall time

2 (default) | positive scalar
Burst fall time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is $1 /$ SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-780.
Data Types: double

## FallDelay - Burst fall delay

0 (default) | positive scalar
Burst fall delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is $1 /$ SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-780.

When the burst fall delay is 0 , the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude FallDelay symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude FallDelay symbols before the end of the useful part.
Data Types: double

## Examples

## Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl =
    gsmDownlinkConfig with properties:
```

```
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
            TSC: [0 1 1 2 3 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
                    RiseTime: 2
                RiseDelay: 0
                    FallTime: 2
            FallDelay: 0
```

Display information about the configured gsmDownlinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

GSM Downlink Waveform - Phase

## Create GSM Downlink Waveform with Specified Samples per Symbol

Create a GSM downlink TDMA frame configuration object that specifies 8 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$ separates each time slot. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object, specifying 8 samples per symbols.

```
sps = 8;
cfggsmdl = gsmDownlinkConfig(sps)
cfggsmdl =
    gsmDownlinkConfig with properties:
```

```
            BurstType: [NB NB NB NB NB NB NB NB
        SamplesPerSymbol: 8
                            TSC: [0 1 2 2 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
            RiseDelay: 0
            FallTime: 2
            FallDelay: 0
```

Display information about the configured gsmDownlinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 2.1667e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 1250
    FrameLengthInSamples: 10000
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
```

$\mathrm{t}=(0:$ length (waveform)-1)/Rs*1e3;
subplot $(2,1,1)$
plot(t,abs(waveform))
grid on
axis([0 50 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot $(2,1,2)$
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')

## Create GSM Downlink Waveform with Specified Attenuation

Create two GSM downlink TDMA frame configuration objects. Specify default settings for the first gsmDownlinkConfig object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl =
    gsmDownlinkConfig with properties:
```

```
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
            TSC: [0 1 1 2 3 3 4 5 6 7
                Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
            RiseDelay: 0
                    FallTime: 2
            FallDelay: 0
```

Create another GSM downlink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmdl2 = gsmDownlinkConfig('Attenuation',[1 0 3 4 5 6 4 2])
cfggsmdl2 =
    gsmDownlinkConfig with properties:
        BurstType: [NB 
```

Display information about the configured gsmDownlinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the gsmFrame function. GSM TDMA frames have are eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$ separates each time slot. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
waveform2 = gsmFrame(cfggsmdl2);
t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

## MEX Generation for GSM Downlink Waveform

Generate and run a GSM waveform MEX function from the helper function createDownlinkWaveform. The createDownlinkWaveform helper function creates a GSM downlink waveform.

## Write MATLAB Function

Open createDownlinkWaveform.m to see the code. The createDownlinkWaveform helper function generates a GSM downlink waveform by using the gsmDownlinkConfig object and the gsmInfo and gsmFrame functions.

## Generate GSM Waveform

Use the createDownlinkWaveform helper function to create a GSM waveform containing two TDMA frames, and then plot the waveform.

```
[x,t] = createDownlinkWaveform(2);
figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Downlink Waveform - Amplitude');
```

```
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

## Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, codegen names the generated MEX function createDownlinkWaveform_mex. Generate a MEX function from the createDownlinkWaveform helper function, and then run the MEX function to create two TDMA frames.
codegen createDownlinkWaveform -args 3

## Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the generateDownlinkFrame helper function or createDownlinkWaveform_mex function.
[x,t] = createDownlinkWaveform_mex(2);
figure

```
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Downlink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

## GSM Downlink Waveform Generation in Simulink

Model a GSM® waveform generator in Simulink ${ }^{\circledR}$ by using the MATLAB Function block and Communications Toolbox ${ }^{\mathrm{TM}}$ functions.

## GSM Downlink Waveform Generation

The MATLAB Function block contains the gsmDownlinkWaveform function code. The code in the MATLAB Function block creates a GSM waveform by using the gsmDownlinkConfig object and the gsmFrame function.

## GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The gsmDownlinkConfig object specifies 16 samples per symbol and the time slot configuration for the GSM downlink TDMA frame shown is this table.

| Timeslot | Burst Type | Attenuation |
| :---: | :--- | :---: |
| 0 | Normal burst | 0 dB |
| 1 | FrequencyCorrection burst | 0 dB |
| 2 | Normal burst | 3 dB |
| 3 | Synchronization burst | 0 dB |
| 4 | No data | 0 dB |
| 5 | Normal burst | 6 dB |
| 6 | Dummy burst | 0 dB |
| 7 | Normal burst | 3 dB |

The output waveform has 16 samples for each GMSK symbol. The gsmFrame function generates the samples of the waveform.

## Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the gsmDownlinkWaveform function code is set to the GSM symbol rate of $1625 e 3 / 6$ symbols per second. Display the current gsmDownlinkConfig object settings by using the gsmInfo function.

```
wfInfo =
    struct with fields:
                            SymbolRate: 2.7083e+05
                            SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
```

The model sample time of the MATLAB Function block is set to wfInfo.FrameLengthInSamples/ wfInfo. SampleRate. To view the Sample time parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting Block Parameters (Subsystem).

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The PreLoadFcn and InitFcn callback functions configure the MATLAB Function block by creating a gsmDownlinkConfig object and wfInfo structure. To view the callback functions, on the Modeling tab, in the Setup section, select Model Settings > Model Properties. Then, on the Callbacks tab, select the PreLoadFcn or InitFcn callback function in the Model callbacks pane.

## Results

Display the time domain signal and the spectrogram by running the simulation.

## More About

## GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25 -symbol duration when using the normal symbol period, which is a time interval of $15 / 26 \mathrm{~ms}$ or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

| Burst Type | Description | Link Direction | Useful Duration |
| :--- | :--- | :--- | :--- |
| NB | Normal burst | Uplink/Downlink | 147 |
| FB | Frequency correction <br> burst | Downlink | 147 |
| SB | Synchronization burst | Downlink | 147 |
| Dummy | Dummy burst | Downlink | 147 |
| AB | Access burst | Uplink | 87 |
| Off | No burst sent | Uplink/Downlink | 0 |

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing $1 / 2$ bit difference between the useful and active parts of the burst.

For more information, see "GSM TDMA Frame Parameterization for Waveform Generation".

## Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

| Training Sequence Code (TSC) | Training Sequence Bits (BN61, BN62, ..., <br> BN86) |
| :--- | :--- |
| 0 | $(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)$ |
| 1 | $(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)$ |
| 2 | $(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)$ |
| 3 | $(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)$ |
| 4 | $(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)$ |
| 5 | $(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)$ |
| 6 | $(1,0,1,0,0,1,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)$ |
| 7 | $(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,0)$ |

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\text {TM }}$.
Usage notes and limitations:

- The SamplesPerSymbol, RiseTime, RiseDelay, FallTime, and FallDelay properties must be set when creating the object, and their settings are static in the generated code.
- The BurstType [property must be set using the enumeration type instead of the string representation. Use these gsmDownlinkBurstType enumerations: gsmDownlinkBurstType.NB, gsmDownlinkBurstType.FB, gsmDownlinkBurstType.SB, gsmDownlinkBurstType.Dummy, and gsmUplinkBurstType.Off. For example, this code assigns a frequency correction burst in time slot 2 and 5.

```
cfg = gsmDownlinkConfig
cfg =
    gsmDownlinkConfig with properties:
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
                            TSC: [[0 1 1 2 3 3
            Attenuation: [0 0 0 0 0 0 0 0]
                        RiseTime: 2
                        RiseDelay: 0
                        FallTime: 2
            FallDelay: 0
cfg.BurstType([2 5] +1) = gsmDownlinkBurstType.FB
cfg =
    gsmDownlinkConfig with properties:
                            BurstType: [NB NB FB NB NB FB NB NB]

## gsmUplinkConfig

Create GSM uplink TDMA frame configuration object

## Description

The gsmUplinkConfig object is a GSM uplink TDMA frame configuration object. Use gsmUplinkConfig objects to create GSM uplink waveforms.

## Creation

## Syntax

```
cfggsmul = gsmUplinkConfig
cfggsmul = gsmUplinkConfig(sps)
cfggsmul = gsmUplinkConfig(___,Name,Value)
```

## Description

cfggsmul = gsmUplinkConfig creates a GSM uplink TDMA frame configuration object.
cfggsmul = gsmUplinkConfig(sps) sets the SamplesPerSymbol property to sps.
cfggsmul = gsmUplinkConfig( __ , Name, Value) sets one or more name-value pair arguments using any of the previous syntaxes. For example, 'RiseTime' , 4 sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

## Properties

## SamplesPerSymbol - Samples per symbol

16 (default) | positive integer multiple of 4
Samples per symbol, specified as a positive integer multiple of 4.

## Data Types: double

## BurstType - Burst types

["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"] (default) | string row vector with 8 elements |
"NB" | "AB" | "Off"
Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is "NB", "AB", or "Off" - Each element specifies the burst type for the corresponding time slot.
- "NB" - Transmit data using a normal burst for every time slot.
- "AB" - Transmit data using an access burst for every time slot.
- "Off" - All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-798

Note The BurstType property is an enumeration. To perform code generation, see "Code Generation" on page 3-801 and the "MEX Generation for GSM Uplink Waveform" on page 3-793 example.

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0,3 , and 5 , use access bursts in time slots 1,2 , and 6 , and transmit no data in time slots 4 and 7 .

## TSC - Training sequence code

[0 1 2434567$]$ (default) |eight-element row vector | integer in the range [0, 7]
Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] - Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] - Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-800.
Example: $\left.\begin{array}{llllllll}5 & 7 & 0 & 0 & 0 & 0 & 0 & 0\end{array}\right]$ configures the frame to use training sequence 5 in time slot 0 , training sequence 7 in time slot 1 , and training sequence 0 in time slots 2 through 7 .

## Dependencies

To enable this property for a time slot, set the corresponding element of BurstType to "NB".
Data Types: double

## Attenuation - Power attenuation

[000000000] (default) | eight-element row vector | nonnegative integer
Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers - Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer - Specifies the power attenuation value for every time slot.

Example: [ $\left.\begin{array}{lllllll}0 & 0 & 0 & 0 & 0 & 0 & 0\end{array}\right]$ configures the frame to apply 0 dB of attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7 .
Data Types: double

## RiseTime - Burst rise time

2 (default) | positive scalar
Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is $1 /$ SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-798.

## Data Types: double

## RiseDelay - Burst rise delay

0 (default) | positive scalar
Burst rise delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is $1 /$ SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-798.

When the burst rise delay is 0 , the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude RiseDelay symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude RiseDelay symbols before the start of the useful part.

## Data Types: double

## FallTime - Burst fall time

2 (default) | positive scalar
Burst fall time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is $1 /$ SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-798.

## Data Types: double

## FallDelay - Burst fall delay

0 (default) | positive scalar
Burst fall delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is 1 /SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-798.

When the burst fall delay is 0 , the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude FallDelay symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude FallDelay symbols before the end of the useful part.
Data Types: double

## Examples

## Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
cfggsmul =
    gsmUplinkConfig with properties:
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
            TSC: [0 1 1 2 3 3 4 5 6 7
            Attenuation: [0 0 0 0 0 0 0 0]
                    RiseTime: 2
                    RiseDelay: 0
                    FallTime: 2
            FallDelay: 0
```

Display information about the configured gsmUplinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);
t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

## Create GSM Uplink Waveform with Specified Samples per Symbol

Create a GSM uplink TDMA frame configuration object that specifies 4 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$ separates each time slot. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 4 samples per symbols.

```
sps = 4;
cfggsmul = gsmUplinkConfig(sps)
cfggsmul =
    gsmUplinkConfig with properties:
```

```
            BurstType: [NB NB NB NB NB NB NB NB
```

            BurstType: [NB NB NB NB NB NB NB NB
        SamplesPerSymbol: 4
        SamplesPerSymbol: 4
            TSC: [0 1 2 3 4 5 6 7]
            TSC: [0 1 2 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
            Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
            RiseTime: 2
            RiseDelay: 0
            RiseDelay: 0
            FallTime: 2
            FallTime: 2
            FallDelay: 0
    ```
            FallDelay: 0
```

Display information about the configured gsmUplinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 1.0833e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 625
    FrameLengthInSamples: 5000
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);
```

$\mathrm{t}=(0:$ length (waveform)-1)/Rs*1e3;
subplot $(2,1,1)$
plot(t,abs(waveform))
grid on
axis([0 50 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot $(2,1,2)$
plot(t, unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')

## Create GSM Uplink Waveform with Specified Attenuation

Create two GSM uplink TDMA frame configuration objects. Specify default settings for the first gsmUplinkConfig object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM uplink TDMA frame configuration object with default settings.
cfggsmul = gsmUplinkConfig
cfggsmul =
gsmUplinkConfig with properties:

```
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
TSC: [0 \(\left.012 \begin{array}{llllll} & 2 & 4 & 5 & 6 & 7\end{array}\right]\)
                Attenuation: [0 0 0 0 0 0 0 0]
                    RiseTime: 2
                    RiseDelay: 0
                    FallTime: 2
            FallDelay: 0
```

Create another GSM uplink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmul2 = gsmUplinkConfig('Attenuation',[llllllll
cfggsmul2 =
    gsmUplinkConfig with properties:
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline BurstType & [ NB & NB & NB & NB & NB & NB & NB & NB] \\
\hline \multicolumn{9}{|l|}{SamplesPerSymbol: 16} \\
\hline \multicolumn{9}{|c|}{TSC: [00 \(0122 c c c c c c]\)} \\
\hline \multicolumn{9}{|l|}{Attenuation: [1 2345432\(]\)} \\
\hline \multicolumn{9}{|l|}{RiseTime: 2} \\
\hline \multicolumn{9}{|l|}{RiseDelay: 0} \\
\hline \multicolumn{9}{|l|}{FallTime: 2} \\
\hline \multicolumn{9}{|l|}{Falldelay: 0} \\
\hline
\end{tabular}
```

Display information about the configured gsmUplinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the gsmFrame function. GSM TDMA frames are eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \mathrm{x} 10 \mathrm{e}-3 \mathrm{~ms}$. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmul);
waveform2 = gsmFrame(cfggsmul2);
t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

## MEX Generation for GSM Uplink Waveform

Generate and run a GSM waveform MEX function from the helper function createUplinkWaveform. The createUplinkWaveform helper function creates a GSM uplink waveform.

## Write MATLAB Function

Open createUplinkWaveform.m to see the code. The createUplinkWaveform helper function generates a GSM uplink waveform by using the gsmUplinkConfig object and the gsmInfo and gsmFrame functions.

## Generate GSM Waveform

Use the createUplinkWaveform helper function to create a GSM waveform containing three TDMA frames, and then plot the waveform.

```
[x,t] = createUplinkWaveform(3);
figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Uplink Waveform - Amplitude');
```

```
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

## Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, codegen names the generated MEX function createUplinkWaveform_mex. Generate a MEX function from the createUplinkWaveform helper function, and then run the MEX function to create three TDMA frames.

```
codegen createUplinkWaveform -args 3
```

## Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the generateUplinkFrame helper function or createUplinkWaveform_mex function.
[x,t] = createUplinkWaveform_mex(3);
figure

```
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Uplink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')
```

MEX - GSM Uplink Waveform - Phase

## GSM Uplink Waveform Generation in Simulink

Model a GSM® waveform generator in Simulink ${ }^{\circledR}$ by using the MATLAB Function block and Communications Toolbox ${ }^{\text {TM }}$ functions.

## GSM Uplink Waveform Generation

The MATLAB Function block contains the gsmUplinkWaveform function code. The code in the MATLAB Function block creates a GSM waveform by using the gsmUplinkConfig object and the gsmFrame function.

## GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The gsmUplinkConfig object specifies 16 samples per symbol and the time slot configuration for the GSM uplink TDMA frame shown is this table.

| Timeslot | Burst Type | Attenuation |
| :---: | :--- | :---: |
| 0 | Normal burst | 0 dB |
| 1 | Access burst | 0 dB |
| 2 | Normal burst | 3 dB |
| 3 | Normal burst | 0 dB |
| 4 | No data | 0 dB |
| 5 | Normal burst | 6 dB |
| 6 | Normal burst | 0 dB |
| 7 | Normal burst | 3 dB |

The output waveform has 16 samples for each GMSK symbol. The gsmFrame function generates the samples of the waveform.

## Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the gsmUplinkWaveform function code is set to the GSM symbol rate of $1625 \mathrm{e} 3 / 6$ symbols per second. Display the current gsmUplinkConfig object settings by using the gsmInfo function.

```
wfInfo =
    struct with fields:
        SymbolRate: 2.7083e+05
            SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
```

The model sample time of the MATLAB Function block is set to wfInfo.FrameLengthInSamples/ wfInfo. SampleRate. To view the Sample time parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting Block Parameters (Subsystem).

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The PreLoadFcn and InitFcn callback functions configure the MATLAB Function block by creating a gsmUplinkConfig object and wfInfo structure. To view the callback functions, on the Modeling tab, in the Setup section, select Model Settings > Model Properties. Then, on the Callbacks tab, select the PreLoadFcn or InitFcn callback function in the Model callbacks pane.

## Results

Displays the time domain signal and the spectrogram by running the simulation.

## More About

## GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25 -symbol duration when using the normal symbol period, which is a time interval of $15 / 26 \mathrm{~ms}$ or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BNO is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

| Burst Type | Description | Link Direction | Useful Duration |
| :--- | :--- | :--- | :--- |
| NB | Normal burst | Uplink/Downlink | 147 |
| FB | Frequency correction <br> burst | Downlink | 147 |
| SB | Synchronization burst | Downlink | 147 |
| Dummy | Dummy burst | Downlink | 147 |
| AB | Access burst | Uplink | 87 |
| Off | No burst sent | Uplink/Downlink | 0 |

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing $1 / 2$ bit difference between the useful and active parts of the burst.

For more information, see "GSM TDMA Frame Parameterization for Waveform Generation".

## Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

| Training Sequence Code (TSC) | Training Sequence Bits (BN61, BN62, ..., <br> BN86) |
| :--- | :--- |
| 0 | $(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)$ |
| 1 | $(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)$ |
| 2 | $(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)$ |
| 3 | $(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)$ |
| 4 | $(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)$ |
| 5 | $(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)$ |
| 6 | $(1,0,1,0,0,1,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)$ |
| 7 | $(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,0)$ |

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:

- The SamplesPerSymbol, RiseTime, RiseDelay, FallTime, and FallDelay properties must be set when creating the object, and their settings are static in the generated code.
- The BurstType property must be set using the enumeration type instead of the string representation. Use these gsmDownlinkBurstType enumerations: gsmDownlinkBurstType.NB, gsmDownlinkBurstType.AB, and gsmUplinkBurstType.Off. For example, this code assigns an access burst in time slot 2 and 5 .

```
cfg = gsmUplinkConfig
cfg =
    gsmUplinkConfig with properties:
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
                    TSC: [00 1 2 2 3 4 5 6 7}
            Attenuation: [0 0 0 0 0 0 0 0]
                        RiseTime: 2
                        RiseDelay: 0
                        FallTime: 2
                        FallDelay: 0
cfg.BurstType([2 5] +1) = gsmUplinkBurstType.AB
cfg =
    gsmUplinkConfig with properties:
                            BurstType: [NB NB AB NB NB AB NB NB]
        SamplesPerSymbol: 16
                            TSC: [00 1 2 2 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
                        RiseTime: 2
                        RiseDelay: 0
                        FallTime: 2
                        FallDelay: 0
```

## comm.HadamardCode

Package: comm
Generate Hadamard code

## Description

The HadamardCode object generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. You can use orthogonal codes for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, because the codes decorrelate completely.

To generate a Hadamard code:
1 Define and set up your Hadamard code object. See "Construction" on page 3-803.
2 Call step to generate a Hadamard according to the properties of comm.HadamardCode. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.

## Construction

H = comm.HadamardCode creates a Hadamard code generator System object, H. This object generates Hadamard codes from a set of orthogonal codes.

H = comm. HadamardCode(Name, Value) creates a Hadamard code generator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## Length

Length of generated code
Specify the length of the generated code as a numeric, integer scalar value with a power of two. The default is 64 .

## Index

Row index of Hadamard matrix
Specify the row index of the Hadamard matrix as a numeric, integer scalar value in the range [0, $1, \ldots, N-1] . N$ is the value of the Length on page 3-0 property. The default is 60 . An $N \times N$ Hadamard matrix, denoted as $P(N)$, is defined recursively as follows: $P(1)=[1] P(2 N)=[P(N) P(N)$; $P(N)-P(N)]$ The $N \mathrm{x} N$ Hadamard matrix has the property that $P(N) \times P(N)^{\prime}=N \times e y e(N)$. The step method outputs code samples from the row of the Hadamard matrix that you specify in this property.

When you set this property to an integer $k$, the output code has exactly $k$ zero crossings, for $k=0$, $1, \ldots, N-1$.

## SamplesPerFrame

Number of output samples per frame
Specify the number of Hadamard code samples that the step method outputs as a numeric, positive, integer scalar value. The default is 1 .

When you set this property to a value of $M$, the step method outputs $M$ samples of a Hadamard code of length $N . N$ equals the length of the code that you specify in the Length on page 3-0 property.

## OutputDataType

Data type of output
Specify the output data type as one of double \| int8. The default is double.

## Methods

reset Reset states of Hadamard code generator object
step Generate Hadamard code

Common to All System Objects
release $\quad$ Allow System object property value changes

## Examples

## Hadamard Code Sequence

Generate 10 samples of a Hadamard code sequence having a length of 128.

```
hadamard = comm.HadamardCode('Length',128,'SamplesPerFrame',10)
hadamard =
    comm.HadamardCode with properties:
            Length: 128
            Index: 60
        SamplesPerFrame: 10
            OutputDataType: 'double'
seq = hadamard()
seq = 10\times1
```

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Hadamard Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the Sample time parameter.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder ${ }^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## Introduced in R2012a

## reset

System object: comm. HadamardCode
Package: comm
Reset states of Hadamard code generator object

## Syntax

reset(H)

## Description

reset $(\mathrm{H})$ resets the states of the HadamardCode object, H .

## step

System object: comm. HadamardCode
Package: comm
Generate Hadamard code

## Syntax

Y = step(H)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H})$ outputs a frame of the Hadamard code in column vector Y . Specify the frame length with the SamplesPerFrame property. The Hadamard code corresponds to one of the rows of an NxN Hadamard matrix, where $N$ is a nonnegative power of 2 , which you specify in the Length property. Use the Index property to choose the row of the Hadamard matrix. The step method outputs the code in a bi-polar format with 0 and 1 mapped to 1 and -1 , respectively.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.HDLCRCDetector

Package: comm
Detect errors in input data using CRC

## Description

This HDL-optimized cyclic redundancy code (CRC) detector System object computes a checksum on the input data and compares the result against the input checksum. Instead of frame processing, the HDLCRCDetector System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To compute and compare checksums:
1 Create the comm. HDLCRCDetector object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

CRCDet = comm. HDLCRCDetector
CRCDet $=$ comm. HDLCRCDetector(Name, Value)
CRCDet $=$ comm. HDLCRCDetector (poly, Name, Value)

## Description

CRCDet $=$ comm.HDLCRCDetector creates an HDL-optimized CRC detector System object, CRCDet, that detects errors in the input data according to a specified generator polynomial.

CRCDet = comm.HDLCRCDetector(Name,Value) sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

CRCDet $=$ comm. HDLCRCDetector('Polynomial', $[100010000]$. 0. .
'FinalXORValue',[1 1000000$]) ;$
specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.
CRCDet $=$ comm.HDLCRCDetector(poly,Name, Value) creates an HDL-optimized CRC detector System object, CRCDet, with the Polynomial property set to poly, and the other specified property names set to the specified values.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Polynomial - Generator polynomial

## [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

## InitialState - Initial conditions of shift register <br> 0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the Polynomial property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## DirectMethod - Method of calculating checksum <br> false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is true, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see "Cyclic Redundancy Check Codes".

## ReflectInput - Input byte order false (default) | true

Input byte order, specified as a logical scalar. When this property is true, the object flips the input data on a bytewise basis before it enters the shift register.

## ReflectCRCChecksum - Checksum byte order false (default) | true

Checksum byte order, specified as a logical scalar. When this property is true, the object flips the output CRC checksum around its center.

## FinalXORValue - Checksum mask <br> 0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the Polynomial property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## Usage

## Syntax

[Y, start0ut,endOut, valid0ut,err] = CRCn(X, startIn,endIn, validIn)

## Description

[Y,startOut,endOut, validOut,err] = CRCn(X,startIn,endIn, validIn) computes CRC checksums for an input message X based on the control signals and compares the computed checksum with input checksum. If the two checksums are not equal, the output err is set to 1 true).

## Input Arguments

## X - Input message and appended checksum

binary column vector | scalar integer
Input message and appended checksum, specified as a binary vector or a scalar integer representing several bits. For example, vector input $[0,0,0,1,0,0,1,1]$ is equivalent to uint8 input 19.
If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (fi([],0,N,0)).
$X$ can be part or all of the message to be checked.
The length of $X$ must be less than or equal to the CRC length, and the CRC length must be divisible by the length of $X$.

The CRC length is the order of the polynomial that you specify in the Polynomial property.
Data Types: double |uint8|uint16|uint32|logical|unsigned fi

## startIn - Start of input message

logical scalar
Start of the input message, specified as a logical scalar.

## endIn - End of input message

logical scalar
End of the input message, specified as a logical scalar.

## validIn - Validity of input data

logical scalar
Validity of input data, specified as a logical scalar. When validIn is 1 (true), the object computes the CRC checksum for input $X$.

## Output Arguments

## Y - Message with checksum removed

binary column vector | scalar integer
Message with checksum removed, returned as a scalar integer or binary column vector with the same width and data type as input X .

## startOut - Start of input message

logical scalar
Start of the input message, returned as a logical scalar.

## endOut - End of input message

logical scalar

End of the input message, returned as a logical scalar.

## validOut - Validity of input data

logical scalar
Validity of input data, returned as a logical scalar. When valid0ut is 1 (true), the output data Y is valid.

## err - Checksum mismatch

logical scalar
Checksum mismatch, returned as a logical scalar. err is 1 (true) when the input checksum does not match the calculated checksum.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32 -bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object ${ }^{\mathrm{TM}}$ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10 .

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object ${ }^{\mathrm{TM}}$. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace myObject ( $x$ ) with step (my0bject,x).

```
function [data0ut,start0ut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent crcg16;
    if isempty(crcg16)
        crcg16 = comm.HDLCRCGenerator()
    end
    [dataOut,start0ut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,start0ut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent crcd16;
    if isempty(crcd16)
        crcd16 = comm.HDLCRCDetector()
    end
    [dataOut,start0ut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
for i = 1:numSteps
[dataOutGen(:,i),start0utGen(i),endOutGen(i),validOutGen(i)] = ....
    HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end
```

crcg16 =
comm.HDLCRCGenerator with properties:
Polynomial: [1 00001000000100001$]$
InitialState: 0
DirectMethod: false

```
    ReflectInput: false
ReflectCRCChecksum: false
    FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the err flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),start0ut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(data0utNoise(:,i)),start0utGen(i),end0utGen(i),valid0utGen(i));
end
crcd16 =
    comm.HDLCRCDetector with properties:
```

```
            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
```

            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
            InitialState: 0
            InitialState: 0
            DirectMethod: false
            DirectMethod: false
            ReflectInput: false
            ReflectInput: false
    ReflectCRCChecksum: false
    ReflectCRCChecksum: false
            FinalXORValue: 0
    ```
            FinalXORValue: 0
```

Use the Logic Analyzer to view the input and output signals.

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','start0utGen','end0utGen',...
    {'data0utGen','Radix','Hexadecimal'},...
    {'data0utNoise','Radix','Hexadecimal'},...
    'valid0ut','start0ut','end0ut','err',...
    {'data0ut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
                        BackgroundColor','Black','DisplayChannelHeight',8);
    for ii = 1:length(channels)
        if iscell(channels{ii})
            % Display data signals as hexadecimal integers
            c = channels{ii};
            modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
            % Convert binary column vector to integer
            dat2 = uint16(bi2de(eval(c{1})'));
            chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii})');
    end
    end
la(chanData{:})
```

## Algorithms

## Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous. The output frames include space between them because the detector block removes the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported.

## Initial Delay

The HDLCRCDetector System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

```
initialDelay = 3 * (CRCLength/inputDataWidth) + 2
```

## Extended Capabilities

## comm.HDLCRCGenerator

Package: comm
Generate CRC code bits and append to input data

## Description

This HDL-optimized cyclic redundancy code (CRC) generator System object generates cyclic redundancy code (CRC) bits. Instead of frame processing, the HDLCRCGenerator System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To generate cyclic redundancy code bits:
1 Create the comm. HDLCRCGenerator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

CRCGen = comm. HDLCRCGenerator
CRCGen = comm.HDLCRCGenerator(Name,Value)
CRCGen $=$ comm. HDLCRCGenerator (poly, Name, Value)

## Description

CRCGen $=$ comm.HDLCRCGenerator creates an HDL-optimized CRC generator System object, CRCGen. This object generates CRC bits according to a specified generator polynomial and appends them to the input data.

CRCGen = comm.HDLCRCGenerator(Name, Value) sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

'FinalXORValue',[1 1000000$]) ;$
specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.
CRCGen = comm.HDLCRCGenerator(poly,Name, Value) sets the Polynomial property to poly, and the other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Polynomial - Generator polynomial

## [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

## InitialState - Initial conditions of shift register <br> 0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the Polynomial property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## DirectMethod - Method of calculating checksum <br> false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is true, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see "Cyclic Redundancy Check Codes".

## ReflectInput - Input byte order false (default) | true

Input byte order, specified as a logical scalar. When this property is true, the object flips the input data on a bytewise basis before it enters the shift register.

## ReflectCRCChecksum - Checksum byte order false (default) | true

Checksum byte order, specified as a logical scalar. When this property is true, the object flips the output CRC checksum around its center.

## FinalXORValue - Checksum mask <br> 0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the Polynomial property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## Usage

## Syntax

[Y,startOut,endOut, validOut] = CRCn(X,startIn,endIn, validIn)

## Description

[Y,startOut,endOut, validOut] = CRCn(X,startIn,endIn, validIn) generates CRC checksums for input message X based on control signals and appends the checksums to X .

Input Arguments

## X - Input message

binary column vector | scalar integer
Input message, specified as a binary vector or a scalar integer representing several bits. For example, vector input $[0,0,0,1,0,0,1,1]$ is equivalent to uint8 input 19.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits ( $\mathrm{fi}([], 0, N, 0)$ ).

X can be part or all of the message to be encoded.
The length of $X$ must be less than or equal to the CRC length, and the CRC length must be divisible by the length of $X$.

The CRC length is the order of the polynomial that you specify in the Polynomial property.
Data Types: double |uint8|uint16|uint32|logical|unsigned fi

## startIn - Start of input message

logical scalar
Start of the input message, specified as a logical scalar.

## endIn - End of input message

logical scalar
End of the input message, specified as a logical scalar.

## validIn - Validity of input data

logical scalar
Validity of input data, specified as a logical scalar. When validIn is 1 (true), the object computes the CRC checksum for input $X$.

## Output Arguments

## Y - Output message with appended checksum

binary column vector | scalar integer
Output message, consisting of $X$ with appended checksum, returned as a scalar integer or binary column vector with the same width and data type as input $X$.

## startOut - Start of input message

logical scalar
Start of the input message, returned as a logical scalar.

## endOut - End of input message

logical scalar

End of the input message, returned as a logical scalar.

## validOut - Validity of input data

logical scalar
Validity of input data, returned as a logical scalar. When validOut is 1 (true), the output data $Y$ is valid.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32 -bit message to be encoded, in two 16 -bit columns.
msg = randi([0 1],16,2);
Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object ${ }^{\text {TM }}$ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10 .

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object ${ }^{\mathrm{TM}}$. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace myObject (x) with step(my0bject,x).

```
function [dataOut,start0ut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent crcg16;
    if isempty(crcg16)
        crcg16 = comm.HDLCRCGenerator()
    end
    [dataOut,start0ut,endOut,valid0ut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,start0ut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
```

function [dataOut,start0ut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
% You can generate HDL code from this function.
persistent crcd16;
persistent crcd16;
if isempty(crcd16)
if isempty(crcd16)
crcd16 = comm.HDLCRCDetector()
crcd16 = comm.HDLCRCDetector()
end
end
[dataOut,start0ut,endOut,valid0ut,err] = crcd16(dataIn,startIn,endIn,validIn);
[dataOut,start0ut,endOut,valid0ut,err] = crcd16(dataIn,startIn,endIn,validIn);
end

```
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
for i = 1:numSteps
[data0utGen(:,i),start0utGen(i),endOutGen(i),validOutGen(i)] = ...
    HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end
```

$\operatorname{crcg} 16=$
comm. HDLCRCGenerator with properties:
Polynomial: [1 00001000000100001$]$
InitialState: 0
DirectMethod: false
ReflectInput: false
ReflectCRCChecksum: false
FinalXORValue: 0

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the err flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),start0ut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(data0utNoise(:,i)),start0utGen(i),endOutGen(i),validOutGen(i));
end
crcd16 =
    comm.HDLCRCDetector with properties:
```

```
            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
```

            Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
            InitialState: 0
            InitialState: 0
            DirectMethod: false
            DirectMethod: false
            ReflectInput: false
            ReflectInput: false
    ReflectCRCChecksum: false
    ReflectCRCChecksum: false
            FinalXORValue: 0
    ```
            FinalXORValue: 0
```

Use the Logic Analyzer to view the input and output signals.

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','start0utGen','end0utGen',...
    {'data0utGen','Radix','Hexadecimal'},...
    {'data0utNoise','Radix','Hexadecimal'},...
    'validOut','start0ut','end0ut','err',...
    {'data0ut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
                        BackgroundColor','Black','DisplayChannelHeight',8);
    for ii = 1:length(channels)
        if iscell(channels{ii})
            % Display data signals as hexadecimal integers
            c = channels{ii};
            modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
            % Convert binary column vector to integer
            dat2 = uint16(bi2de(eval(c{1})'));
            chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii})');
    end
    end
la(chanData{:})
```

## Algorithms

## Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with an 8-bit binary vector input. To insert the checksum word, input frames must have enough space between the

This waveform diagram shows continuous input data. The block also supports noncontinuous data. The output valid signal matches the input valid pattern.

## Initial Delay

The HDLCRCGeneratorSystem object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

```
initialDelay = (CRCLength/inputDataWidth) + 2
```

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## Blocks

General CRC Generator HDL Optimized
Introduced in R2012a

## comm.HDLRSDecoder

Package: comm
Decode message using Reed-Solomon decoder

## Description

The HDL-optimized HDLRSDecoder System object recovers a message vector from a Reed-Solomon (RS) codeword vector. For proper decoding, the code and polynomial property values for this object must match those values in the corresponding encoder.

To recover a message vector from a Reed-Solomon codeword vector:
1 Create the comm. HDLRSDecoder object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Troubleshooting

- Each input frame must contain more than ( $\mathrm{N}-\mathrm{K}$ ) $* 2$ symbols and fewer than or exactly N symbols. The object infers a shortened code when the number of valid data samples between startIn and endIn is less than N . A shortened code still requires N cycles to perform the Chien search. If the input message is less than $N$ symbols, leave a guard interval of at least $N$ - size inactive cycles before starting the next frame, where sizeis the message length.
- The decoder can operate on up to four messages at a time. If the object receives the start of a fifth message before completely decoding the first message, the object drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.
- The generator polynomial is not specified explicitly. However, it is defined by the codeword length, the message length, and the $B$ value for the starting exponent of the roots. To get the value of $B$ from a generator polynomial, use the genpoly2b function.

## Creation

## Syntax

RSDec = comm.HDLRSDecoder
RSDec = comm.HDLRSDecoder(Name,Value)
RSDec $=$ comm.HDLRSDecoder(N,K,Name, Value)

## Description

RSDec = comm.HDLRSDecoder creates an HDL-optimized RS decoder System object, RSDec, that performs Reed-Solomon decoding.

RSDec $=$ comm.HDLRSDecoder(Name, Value) sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,
comm. HDLRSDecoder('BSource','Property', 'B',2)
sets a starting power of 2 for the roots of the primitive polynomial.
RSDec $=$ comm. HDLRSDecoder (N, K, Name, Value) sets the CodewordLength property to $N$, the MessageLength property to K, and other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## B - Starting power for roots of primitive polynomial

1 (default) | positive integer
Starting power for roots of the primitive polynomial, specified as a positive integer.

## Dependencies

The object uses this value when you set BSource to 'Property'.

## BSource - Source of starting power for roots of primitive polynomial

 'Auto' (default)|'Property'Source of the starting power for roots of the primitive polynomial, specified as either 'Property' or 'Auto'. When you select 'Auto', the object uses B = 1 .

## CodewordLength - Number of symbols, N, in RS codeword

7 (default) | positive integer
Number of symbols, $N$, in the RS codeword, specified as a positive integer. This value is rounded up to $2^{M}-1 . M$ is the degree of the primitive polynomial, as specified by the PrimitivePolynomialSource and PrimitivePolynomial properties. The difference of CodewordLength - MessageLength must be an even integer.

If the value of this property is less than $2^{M}-1$, the object assumes a shortened RS code.
If you set PrimitivePolynomialSource to 'Auto', then CodewordLength must be in the range 3 $<$ CodewordLength $\leq 2^{16}-1$.

If you set PrimitivePolynomialSource to 'Property', then CodewordLength must be in the range $3 \leq$ CodewordLength $\leq 2^{M_{-}} 1 . M$ must be in the range $3 \leq M \leq 16$.

## MessageLength - Message length, K

3 (default) | positive integer
Message length, $K$, specified as a positive integer. The difference of CodewordLength -
MessageLength must be an even integer.
NumErrorsOutputPort - Enable number of errors output argument false (default)|true

When you set this property to true, the object returns the number of corrected errors. The number of corrected errors is not valid when errOut is true, since there were more errors than could be corrected.

## PrimitivePolynomialSource - Source of primitive polynomial <br> 'Auto ' (default)|'Property'

Source of the primitive polynomial, specified as either 'Property ' or 'Auto'.

- When you set this property to 'Auto' , the object uses a primitive polynomial of degree $M=$ ceil(log2(CodewordLength+1)), which is the result of fliplr(de2bi(primpoly(M))).
- When you set this property to 'Property', you must specify a polynomial using the PrimitivePolynomial property.

PrimitivePolynomial - Primitive polynomial
[1 0 1 1] (default) | binary row vector
Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over $g f(2)$ of degree $M$, in descending order of powers. The polynomial defines the finite field $g f\left(2^{M}\right)$ corresponding to the integers that form messages and codewords.

## Dependencies

The object uses this value when you set PrimitivePolynomialSource to 'Property'.

## Usage

## Syntax

[Y,startOut,endOut, validOut,errOut] = RSDec(X,startIn,endIn, validIn)
[Y,start0ut,endOut, validOut,errOut, numErrors] = RSDec(X,startIn,endIn, validIn)

## Description

[Y,startOut,endOut, validOut,errOut] = RSDec(X,startIn,endIn, validIn) decodes one encoded message symbol, $X$, and returns the decoded symbol $Y$. The start and end signals indicate the message frame boundaries. If errOut is 1 (true), then the object detected uncorrectable errors in the input frame.
[Y,start0ut,endOut, validOut,err0ut,numErrors] = RSDec (X, startIn,endIn, validIn) decodes the input data, and also returns the number of errors detected and corrected. To use this syntax, set the NumErrorsOutputPort property to true. If errOut is 1 (true), then the object detected uncorrectable errors in the output frame, and numErrors is invalid.

## Input Arguments

## X - Input message data or parity symbols

integer
Input message data and parity symbols, one symbol at a time, specified as an unsigned integer or fi() with any binary point scaling.
double type is allowed for simulation but not supported for HDL code generation.

Data Types: double|uint8|uint16|uint32|fi
startIn - Start of input data frame
logical scalar
Start of input data frame, specified as a logical scalar.
Data Types: logical
endIn - End of input data frame
logical scalar
End of input data frame, specified as a logical scalar.
Data Types: logical
validIn - Validity of input data
logical scalar
Validity of input data, specified as a logical scalar.
Data Types: logical

## Output Arguments

Y - Message data symbols
integer
Message data symbols, returned one symbol at a time, as an integer with the same data type as the input message, X .
Data Types: double | uint8 | uint16 | uint32 | fi

## startOut - Start of output data frame

## logical scalar

Start of output data frame, returned as a logical scalar.
Data Types: logical
endOut - End of output data frame
logical scalar
End of output data frame, returned as a logical scalar.
Data Types: logical
validOut - Validity of output data
logical scalar
Validity of output data, returned as a logical scalar.
Data Types: logical
errOut - Uncorrectable error in output data frame
logical scalar

Uncorrectable error in output data frame, returned as a logical scalar. This signal is 1 (true) when the message frame contains uncorrectable errors. In this case, the output data symbols are corrupted. This value is valid when endOut is 1 (true).

## Data Types: logical

## numErrors - Number of errors detected and corrected <br> integer

Number of errors detected and corrected, returned as an integer. This value is valid when endOut is 1 (true) and errOut is 0 (false).
Data Types: uint8

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a HDLRSEncoder System object ${ }^{\mathrm{TMM}}$ with an RS $(255,239)$ code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. B is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace myObject (x) with step(myObject,x).

```
function [data0ut,start0ut,endOut,valid0ut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
```

```
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent rsEnc80216;
    if isempty(rsEnc80216)
        rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
    end
    [dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to encode the message.

```
for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),start0ut(ii),endOut(ii),valid0ut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end
rsEnc80216 =
    comm.HDLRSEncoder with properties:
                    CodewordLength: 255
                            MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
        PuncturePatternSource: 'None'
                            BSource: 'Property'
                            B: 0
```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to ( $N$ - K)/2 errors in each $N$ symbols. So, in this example, the error correction capability is (255-239)/2=8 symbols.

```
numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end
Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a HDLRSDecoder System object ${ }^{\mathrm{Tm}}$. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function [dataOut,start0ut,endOut,valid0ut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent rsDec80216;
    if isempty(rsDec80216)
        rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
    end
    [data0ut,start0ut,end0ut,valid0ut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
            HDLRSDec80216(enc0ut(ii),start0ut(ii), endOut(ii),validOut(ii));
end
rsDec80216 =
    comm.HDLRSDecoder with properties:
                CodewordLength: 255
                    MessageLength: 239
        PrimitivePolynomialSource: 'Auto'
                        BSource: 'Property'
                        B: 0
            NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOl
        end
    end
end
```

All 188 message symbols were correctly decoded.

## Extended Capabilities

## comm.HDLRSEncoder

Package: comm
Encode message using Reed-Solomon encoder

## Description

The HDL-optimized HDLRSEncoder System object creates a Reed-Solomon (RS) code with message and codeword lengths that you specify.

To encode a message using a Reed-Solomon code:
1 Create the comm. HDLRSEncoder object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

RSEnc = comm.HDLRSEncoder
RSEnc = comm.HDLRSEncoder(Name,Value)
RSEnc = comm.HDLRSEncoder(N,K,Name, Value)

## Description

RSEnc = comm.HDLRSEncoder creates an HDL-optimized block encoder System object, RSEnc, that performs Reed-Solomon encoding in a streaming fashion for HDL.

RSEnc $=$ comm.HDLRSEncoder(Name, Value) sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,
comm. HDLRSEncoder('BSource','Property', 'B',2)
sets a starting power of 2 for the roots of the primitive polynomial.
RSEnc = comm.HDLRSEncoder(N,K,Name,Value) sets the CodewordLength property to N, the MessageLength property to K , and other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## B - Starting power for roots of primitive polynomial

1 (default) | positive integer
Starting power for roots of the primitive polynomial, specified as a positive integer.

## Dependencies

The object uses this value when you set BSource to 'Property '.

## BSource - Source of starting power for roots of primitive polynomial

'Auto' (default) | 'Property'
Source of the starting power for roots of the primitive polynomial, specified as either 'Property ' or 'Auto'. When you select 'Auto', the object uses B = 1 .

## CodewordLength - Number of symbols, N, in RS codeword

7 (default) | positive integer
Number of symbols, $N$, in the RS codeword, specified as a positive integer. This value is rounded up to $2^{M}-1 . M$ is the degree of the primitive polynomial, as specified by the PrimitivePolynomialSource and PrimitivePolynomial properties. The difference of CodewordLength - MessageLength must be an even integer.

If the value of this property is less than $2^{M}-1$, the object assumes a shortened RS code.
If you set PrimitivePolynomialSource to 'Auto', then CodewordLength must be in the range 3 $<$ CodewordLength $\leq 2^{16}-1$.

If you set PrimitivePolynomialSource to 'Property', then CodewordLength must be in the range $3 \leq$ CodewordLength $\leq 2^{M}-1 . M$ must be in the range $3 \leq M \leq 16$.

## MessageLength - Message length, K

3 (default) | positive integer
Message length, $K$, specified as a positive integer. The difference of CodewordLength MessageLength must be an even integer.

## PrimitivePolynomialSource - Source of primitive polynomial

'Auto ' (default) |'Property'
Source of the primitive polynomial, specified as either 'Property ' or 'Auto'.

- When you set this property to 'Auto' , the object uses a primitive polynomial of degree $M=$ ceil( $\log 2(C o d e w o r d L e n g t h+1))$, which is the result of fliplr(de2bi(primpoly(M))).
- When you set this property to 'Property', you must specify a polynomial using the PrimitivePolynomial property.

## PrimitivePolynomial - Primitive polynomial

[1 0 1 1] (default) | binary row vector
Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over $g f(2)$ of degree $M$, in descending order of powers. The polynomial defines the finite field $g f\left(2^{M}\right)$ corresponding to the integers that form messages and codewords.

## Dependencies

The object uses this value when you set PrimitivePolynomialSource to 'Property '.

## PuncturePatternSource - Source of puncture pattern

'None' (default)|'Property'
Source of the puncture pattern, specified as 'None' or 'Property'. If you set this property to ' None ', then the object does not apply puncturing to the code. If you set this property to 'Property ' , then the object punctures the code based on a puncture pattern vector specified in the PuncturePattern property.

## PuncturePattern - Pattern used to puncture encoded data

[ones $(2,1)$; zeros $(2,1)$ ] (default) | binary column vector
Pattern used to puncture the encoded data, specified as a double-precision, binary column vector with a length of CodewordLength - MessageLength. The default is [ones ( 2,1 ); zeros(2,1)]. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

## Dependencies

This property applies when you set the PuncturePatternSource property to 'Property '.

## Usage

## Syntax

[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)

## Description

[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn) encodes one input message symbol, X , and returns one symbol of encoded data, Y . The start and end signals indicate the message frame boundaries. The object returns associated parity symbols at the end of each message frame.

## Input Arguments

## X - Input message symbol

integer
Input message data, one symbol at a time, specified as an unsigned integer or fi() with any binary point scaling. The word length of each symbol must be ceil( $\log _{2}$ (CodewordLength+1)).
double type is allowed for simulation but not supported for HDL code generation.
Data Types: double|uint8|uint16|uint32|fi

## startIn - Start of input data frame

logical scalar
Start of input data frame, specified as a logical scalar.
Data Types: logical

## endIn - End of input data frame

## logical scalar

End of input data frame, specified as a logical scalar.
Data Types: logical
validIn - Validity of input data
logical scalar
Validity of input data, specified as a logical scalar.
Data Types: logical
Output Arguments
Y - Output message data and parity symbols integer

Message data and parity symbols, returned one symbol at a time, as an integer with the same data type as the input message, X .

Data Types: double |uint8|uint16 | uint32 | fi

## start0ut - Start of output data frame

logical scalar
Start of output data frame, returned as a logical scalar.
Data Types: logical
endOut - End of output data frame
logical scalar
End of output data frame, returned as a logical scalar.
Data Types: logical
validOut - Validity of output data
logical scalar
Validity of output data, returned as a logical scalar.
Data Types: logical

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a HDLRSEncoder System object ${ }^{\text {TM }}$ with an RS $(255,239)$ code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. B is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace my0bject (x) with step (my0bject,x).

```
function [dataOut,start0ut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent rsEnc80216;
    if isempty(rsEnc80216)
        rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
    end
        [data0ut,start0ut,endOut,valid0ut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to encode the message.

```
for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),start0ut(ii),endOut(ii),valid0ut(ii)] = ...
            HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end
rsEnc80216 =
    comm.HDLRSEncoder with properties:
```

```
    CodewordLength: 255
    MessageLength: 239
PrimitivePolynomialSource: 'Auto'
    PuncturePatternSource: 'None'
    BSource: 'Property'
B: 0
```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to ( $N$ - K)/2 errors in each $N$ symbols. So, in this example, the error correction capability is ( $255-239$ )/2=8 symbols.

```
numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end
Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a HDLRSDecoder System object ${ }^{\text {TM }}$. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function [dataOut,start0ut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
    persistent rsDec80216;
    if isempty(rsDec80216)
        rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
    end
    [dataOut,start0ut,endOut,valid0ut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStart0ut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(enc0ut(ii),start0ut(ii), end0ut(ii),valid0ut(ii));
end
```

```
rsDec80216 =
    comm.HDLRSDecoder with properties:
        CodewordLength: 255
            MessageLength: 239
        PrimitivePolynomialSource: 'Auto'
            BSource: 'Property'
                            B: 0
        NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
        fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOl
            end
    end
end
All 188 message symbols were correctly decoded.
```

## comm.HelicalDeinterleaver

Package: comm
Restore ordering of symbols using helical array

## Description

The HelicalDeinterleaver object permutes the symbols in the input signal by placing them in a row-by-row array and then selecting groups helically to send to the output port.

To helically deinterleave input symbols:
1 Define and set up your helical deinterleaver object. See "Construction" on page 3-839.
2 Call step to deinterleave input symbols according to the properties of comm. HelicalDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.HelicalDeinterleaver creates a helical deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the helical interleaver System object.

H = comm. HelicalDeinterleaver(Name, Value) creates a helical deinterleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## NumColumns

Number of columns in helical array
Specify the number of columns in the helical array as a positive integer scalar value. The default is 6 .

## GroupSize

Size of each group of input symbols
Specify the size of each group of input symbols as a positive integer scalar value. The default is 4 .

## StepSize

Helical array step size

Specify number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires a positive integer scalar value. The default is 1 .

## InitialConditions

Initial conditions of helical array
Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0 .

## Methods

reset Reset states of the helical deinterleaver object
step Restore ordering of symbols using a helical array

```
Common to All System Objects
release Allow System object property value changes
```

## Examples

## Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);
for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);
    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)
intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay), dataOut(1+intlvDelay:end))
```

```
ans = logical
```

## Description

reset $(\mathrm{H})$ resets the states of the HelicalDeinterleaver object, H .

## step

System object: comm. HelicalDeinterleaver
Package: comm
Restore ordering of symbols using a helical array

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ restores the original ordering of the sequence, $X$, that was interleaved using a helical interleaver and returns Y . The input X must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects). Y has the same data type as X . The helical deinterleaver object uses an array for its computations. If you set the NumColumns property of the object to $C$, then the array has $C$ columns and unlimited rows. If you set the GroupSize property to $N$, then the object accepts an input of length $C \times N$ and inserts it into the next $N$ rows of the array. The object also places the value of the InitialConditions property into certain positions in the top few rows of the array. This accommodates the helical pattern and also preserves the vector indices of symbols that pass through the HelicalInterleaver and HelicalDeinterleaver objects. The output consists of consecutive groups of $N$ symbols. The object selects the $k$-th output group in the array from column $k \bmod C$. This selection is of type helical because of the reduction modulo $C$ and because the first symbol in the $k$-th group is in row $1+(k-1) \times s$, where $s$ is the value for the StepSize property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.HelicalInterleaver

Package: comm
Permute input symbols using helical array

## Description

The Helical Interleaver object permutes the symbols in the input signal by placing them in an array in a helical arrangement and then sending rows of the array to the output port.

To helically interleave input symbols:
1 Define and set up your helical interleaver object. See "Construction" on page 3-844.
2 Call step to interleave input symbols according to the properties of comm. HelicalInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $\mathrm{y}=$ step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. HelicalInterleaver creates a helical interleaver System object, H. This object permutes the input symbols in the input signal by placing them in an array in a helical arrangement.

H = comm. HelicalInterleaver(Name, Value) creates a helical interleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## NumColumns

Number of columns in helical array
Specify the number of columns in the helical array as a positive integer scalar value. The default is 6 .

## GroupSize

Size of each group of input symbols

## step

System object: comm. HelicalInterleaver
Package: comm
Permute input symbols using a helical array

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ permutes input sequence, $X$, and returns interleaved sequence, $Y$. The input $X$ must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects). $Y$ has the same data type as $X$. The helical interleaver object places the elements of $X$ in an array in a helical fashion. If you set the NumColumns property of the object to $C$, then the array has $C$ columns and unlimited rows. If you set the GroupSize property to $N$, then the object accepts an input of length $C \times N$ and partitions the input into consecutive groups of $N$ symbols. The object places the $k$-th group in the array along column $k \bmod C$. This placement is of type helical because of the reduction modulo $C$ and because the first symbol in the $k$-th group is in the row $1+(k-1) \times s$, where $s$ is the value for the StepSize property. Positions in the array that do not contain input symbols have default contents specified by the InitialConditions property. The object outputs $C \times N$ symbols from the array by reading the next $N$ rows sequentially.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.IntegerToBit

Package: comm
(To be removed) Convert vector of integers to vector of bits

Note will be removed in a future release. Use de2bi instead. For more information, see "Compatibility Considerations".

## Description

The IntegerToBit object maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

To map integers to bits:
1 Define and set up your integer to bit object. See "Construction" on page 3-849.
2 Call step to map integers in the input vector to groups of bits in the output vector according to the properties of comm. IntegerToBit. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. IntegerToBit creates an integer-to-bit converter System object, H. This object maps a vector of integer-valued or fixed-point inputs to a vector of bits.

H = comm. IntegerToBit (Name, Value) creates an integer-to-bit converter object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.IntegerToBit (NUMBITS,Name, Value) creates an integer-to-bit converter object, H . This object has the BitsPerInteger property set to NUMBITS and the other specified properties set to the specified values.

## Properties

## BitsPerInteger

Number of bits per integer
Specify the number of bits the System object uses to represent each input integer. You must set this property to a scalar integer between 1 and 32 . The default is 3 .

## MSBFirst

Output bit words with first bit as most significant bit
Set this property to true to indicate that the first bit of the output bit words is the most significant bit (MSB). The default is true. Set this property to false to indicate that the first bit of the output bit words is the least significant bit (LSB).

## SignedIntegerInput

Assume inputs are signed integers
Set this property to true if the integer inputs are signed. The default is false. Set this property to false if the integer inputs are unsigned. If the SignedIntegerInput on page 3-0 property is false, the input values must be between 0 and $\left(2^{\wedge} \mathrm{N}\right)-1$. In this case, $N$ is the value you specified in the BitsPerInteger on page 3-0 property. When you set this property to true, the input values must be between $-\left(2^{(N-1)}\right)$ and $\left(2^{(N-1)}\right)-1$.

## OutputDataType

Data type of output
Specify output data type as one of Full precision|Smallest unsigned integer|Same as input | double | single |int8|uint8|int16|uint16|int32|uint32|logical. The default is Full precision.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

When you set this property to Full precision, the object determines the output data type based on the input data type. If the input data type is double- or single-precision, the output data has the same data type as the input data. Otherwise, the output data type is determined in the same way as when you set this property to Smallest unsigned integer.

When you set this property to Same as input, and the input data type is numeric or fixed-point integer (fi object), the output data has the same data type as the input data.

## Methods

step (To be removed) Convert vector of integers to vector of bits

## Common to All System Objects

release Allow System object property value changes

## Examples

## Convert random integers to 4-bit words

```
hIntToBit = comm.IntegerToBit(4);
intData = randi([0 2^hIntToBit.BitsPerInteger-1],3,1);
bitData = step(hIntToBit,intData)
```

```
bitData = 12×1
    1
1
0
1
1
1
1
0
0
0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Integer to Bit Converter block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

comm. IntegerToBit will be removed in a future release. Use de2bi instead.
Not recommended starting in R2019b
Data types as supported by comm.IntegerToBit are not inherently supported by functions. This code shows decimal to binary conversion for various data types using this function.

## Examples Using de2bi for Various Data Types

```
function compde2bi
% Number of integers
n = randi([1 100]);
% Default
h1 = comm.IntegerToBit;
bpi = h1.BitsPerInteger;
x = randi([0,2^bpi-1],n,1);
y1 = h1(x);
y2 = reshape(de2bi(x,bpi,'left-msb')',[],1);
isequal(y1,y2)
% Right MSB, logical input
h2 = comm.IntegerToBit( ...
    'BitsPerInteger',5, ...
    'MSBFirst',false);
bpi = h2.BitsPerInteger;
x = randi([0,2^bpi-1],n,1);
y1 = h2(x);
y2 = reshape(de2bi(x,bpi,'right-msb')',[],1);
isequal(y1,y2)
% Right MSB, signed input, single input
h3 = comm.IntegerToBit(
    BitsPerInteger',8, ...
    'MSBFirst',false,
    'SignedIntegerInput',true);
bpi = h3.BitsPerInteger;
N = 2^bpi;
x = randi([-N/2,N/2-1],n,1);
y1 = h3(x);
y2 = reshape(de2bi (x+(x<0)*N,bpi,'right-msb')',[],1);
isequal(y1,y2)
end
```

## See Also

## step

System object: comm. IntegerToBit
Package: comm
(To be removed) Convert vector of integers to vector of bits

Note comm. IntegerToBit will be removed in a future release. Use de2bi instead.

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ converts integer input, X , to corresponding bits, Y . The input must be scalar or a column vector and the data type can be numeric or fixed-point (fi objects). The output is a column vector with length equal to length $(\mathrm{X}) \times N$, where $N$ is the value of the BitsPerInteger property. If any input value is outside the range of $N$, the object issues an error. If the SignedIntegerInput property is false, the input values must be between 0 and $\left(2^{N}\right)$-1. If you set the SignedIntegerInput property to true, the input values must be between $-\left(2^{(N-1)}\right)$ and $\left(2^{(N-1)}\right)-1$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.IntegrateAndDumpFilter

Package: comm
Integrate discrete-time signal with periodic resets

## Description

The IntegrateAndDumpFilter object creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the object discards the number of samples specified in the Offset property. After this initial period, the object sums the input signal along columns and resets the sum to zero every Ninput samples, set by the integration period property. The reset occurs after the object produces output at that time step.

To integrate discrete-time signals with periodic resets:
1 Define and set up your integrate and dump filter object. See "Construction" on page 3-854.
2 Call step to integrate discrete-time signals according to the properties of comm. IntegrateAndDumpFilter. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

$H=$ comm. IntegrateAndDumpFilter creates an integrate and dump filter System object, H. this object integrates over a number of samples in an integration period, and then resets at the end of that period.

H = comm. IntegrateAndDumpFilter(Name,Value) creates an integrate and dump filter object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. IntegrateAndDumpFilter(PERIOD,Name, Value) creates an integrate and dump filter object, H . This object has the IntegrationPeriod property set to PERIOD and the other specified properties set to the specified values.

## Properties

## IntegrationPeriod

Integration period
Specify the integration period, in samples, as a positive, integer scalar value greater than 1. The integration period defines the length of the sample blocks that the object integrates between resets. The default is 8 .

## Offset

Number of offset samples
Specify a nonnegative, integer vector or scalar specifying the number of input samples that the object discards from each column of input data at the beginning of data processing. Discarding begins when you call the step method for the first time. The default is 0 .

When you set the Offset on page 3-0 property to a nonzero value, the object outputs one or more zeros during the initial period while discarding input samples.

When you specify this property as a vector of length $L$, the $i$-th element of the vector corresponds to the offset for the $i$-th column of the input data matrix, which has $L$ columns.

When you specify this property as a scalar value, the object applies the same offset to each column of the input data matrix. The offset creates a transient effect, rather than a persistent delay.

## DecimateOutput

Decimate output
Specify whether the step method returns intermediate cumulative sum results or decimates intermediate results. The default is true.

When you set this property to true, the step method returns one output sample, consisting of the final integration value, for each block of IntegrationPeriod on page 3-0 input samples. If the inputs are ( $K \times$ IntegrationPeriod) $\times L$ matrices, then the outputs are $K \times L$ matrices.

When you set this property to false, the step method returns IntegrationPeriod output samples, comprising the intermediate cumulative sum values, for each block of IntegrationPeriod input samples. In this case, inputs and outputs have the same dimensions.

## Fixed-Point Properties

## FullPrecisionOverride

Full precision override for fixed-point arithmetic
Specify whether to use full precision rules. If you set FullPrecision0verride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for FixedPoint System Objects" on page 3-858.

## RoundingMethod

Rounding of fixed-point numeric values
Specify the rounding method as one of Ceiling | Convergent | Floor | Nearest | Round |
Simplest | Zero. The default is Floor. This property applies only if the object is not in full precision mode.

## OverflowAction

Action when fixed-point numeric values overflow
Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property applies only if the object is not in full precision mode.

## AccumulatorDataType

Data type of accumulator
Specify the accumulator data type as one full precision | Same as input | Custom. The default is Full precision. When you set this property to Full precision the object automatically calculates the accumulator output word and fraction lengths. Set this property to Custom to specify the accumulator data type using the CustomAccumulatorDataType on page 30 property. This property applies when you set the FullPrecisionOverride on page 3-0 property to false.

## CustomAccumulatorDataType

Fixed-point data type of accumulator
Specify the accumulator fixed-point type as a scaled numerictype object with a signedness of Auto.
The default is numerictype( [],32,30). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the AccumulatorDataType on page 3-0 property to Custom.

## OutputDataType

Data type of output
Specify the output fixed-point type as one of Same as accumulator | Same as input | Custom.
The default is Same as accumulator. This property applies when you set the
FullPrecisionOverride on page 3-0 property to false.

## CustomOutputDataType

Fixed-point data type of output
Specify the output fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype([],32,30). This property applies when you set the
FullPrecisionOverride on page 3-0 property to false and the OutputDataType on page 30 property to Custom.

## Examples

## Pass Noisy Pulses Through Integrate and Dump Filter

Create an integrate and dump filter having an integration period of 20 samples.
intdump = comm.IntegrateAndDumpFilter(20);
Generate binary data.
$\mathrm{d}=$ randi([0 1],50,1);
Upsample the data, and pass it through an AWGN channel.
x = upsample(d,20);
y = awgn(x,25,'measured');
Pass the noisy data through the filter.
z = intdump(y);
Plot the original and filtered data. The integrate and dump filter removes most of the noise effects.

```
stairs([d z])
legend('Original Data','Filtered Data')
xlabel('Samples')
ylabel('Amplitude')
grid
```

## More About

## Full Precision for Fixed-Point System Objects

FullPrecisionOverride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to true, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to false.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Integrate and Dump block reference page. The object properties correspond to the block parameters, except:
The Output intermediate values parameter corresponds to the DecimateOutput on page 3-0 property.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder ${ }^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).
Introduced in R2012a

## step

System object: comm. IntegrateAndDumpFilter
Package: comm
Integrate discrete-time signal with periodic resets

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ periodically integrates blocks of N samples from the input data, X , and returns the result in Y . N is the number of samples that you specify in the IntegrationPeriod property. X is a column vector or a matrix and the data type is double, single or fixed-point (fi objects). X must have K*N rows for some positive integer K, with one or more columns. The object treats each column as an independent channel with integration occurring along every column. The dimensions of output Y depend on the value you set for the DecimateOutput property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.KasamiSequence

Package: comm

Generate Kasami sequence

## Description

The KasamiSequence object generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have good cross-correlation properties.

To generate a Kasami sequence:
1 Define and set up your Kasami sequence object. See "Construction" on page 3-860.
2 Call step to generate a Kasami sequence according to the properties of comm. KasamiSequence. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.

## Construction

H = comm.KasamiSequence creates a KasamiSequence System object, H. This object generates a Kasami sequence.

H = comm. KasamiSequence(Name, Value) creates a Kasami sequence generator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## Polynomial

Generator polynomial
Specify the polynomial that determines the shift register's feedback connections. The default is ' $z^{\wedge} 6$ + z + 1'.

You can specify the generator polynomial as a character vector or as a binary numeric vector that lists the coefficients of the polynomial in descending order of powers. The first and last elements must equal 1 . Specify the length of this vector as $n+1$, where $n$ is the degree of the generator polynomial and must be even.

Lastly, you can specify the generator polynomial as a vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 . For example, $\left[\begin{array}{lllllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1\end{array}\right]$ and $\left[\begin{array}{lll}8 & 2 & 0\end{array}\right]$ represent the same polynomial, $g(z)=z^{8}+z^{2}+1$.

## InitialConditions

Initial conditions of shift register
Specify the initial values of the shift register as a binary numeric scalar or as binary numeric vector. The default is [ 0000001$]$. Set the vector length equal to the degree of the generator polynomial.

When you set this property to a vector value, each element of the vector corresponds to the initial value of the corresponding cell in the shift register.

When you set this property to a scalar value, that value specifies the initial conditions of all the cells of the shift register. The scalar, or at least one element of the specified vector, requires a nonzero value for the object to generate a nonzero sequence.

## Index

Sequence index
Specify the index to select a Kasami sequence of interest from the set of possible sequences. The default is 0 . Kasami sequences have a period equal to $N=2^{n}-1$, where $n$ indicates a nonnegative, even integer equal to the degree of the generator polynomial that you specify in the Polynomial on page 3-0 property.

There are two classes of Kasami sequences: those obtained from a small set and those obtained from a large set. You choose a Kasami sequence from the small set by setting this property to a numeric, scalar, integer value in the range [ $\left.0 \ldots .2^{n / 2}-2\right]$. You choose a sequence from the large set by setting this property to a numeric $1 \times 2$ integer vector $[k m]$ for $k$ in $\left[-2, \ldots, 2^{n}-2\right]$, and $m$ in $\left[-1, \ldots, 2^{n / 2}-2\right]$.

## Shift

Sequence offset from initial time
Specify the offset of the Kasami sequence from its starting point as a numeric, integer scalar value that can be positive or negative. The default is 0 . The Kasami sequence has a period of $N=2^{n}-1$, where $n$ is the degree of the generator polynomial that you specify in the Polynomial on page 30 property. The shift value is wrapped with respect to the sequence period.

## VariableSizeOutput

Enable variable-size outputs
Set this property to true to enable an additional input to the step method. The default is false. When you set this property to true, the enabled input specifies the output size of the Kasami sequence used for the step. The input value must be less than or equal to the value of the MaximumOutputSize property.

When you set this property to false, the SamplesPerFrame property specifies the number of output samples.

## MaximumOutputSize

Maximum output size
Specify the maximum output size of the Kasami sequence as a positive integer 2-element row vector. The second element of the vector must be 1 . The default is [10 1].

This property applies when you set the VariableSize0utput property to true.

## SamplesPerFrame

Number of output samples per frame
Specify the number of Kasami sequence samples that the step method outputs as a numeric, positive, integer scalar value. The default value is 1 .

When you set this property to a value of $M$, then the step method outputs $M$ samples of a Kasami sequence that has a period of $N=2^{n}-1$. The value $n$ equals the degree of the generator polynomial that you specify in the Polynomial on page 3-0 property.

## ResetInputPort

Enable generator reset input
Set this property to true to enable an additional input to the step method. The default is false. The additional input resets the states of the Kasami sequence generator to the initial conditions that you specify in the InitialConditions on page 3-0 property.

## OutputDataType

Data type of output
Specify the output data type as one of double | logical. The default is double.

## Methods

reset Reset states of Kasami sequence generator object
step Generate a Kasami sequence
Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

## Spread BPSK Data with a Kasami Sequence

Spread BPSK data with a Kasami sequence of length 255 by using the Kasami sequence System object.

Generate binary data and apply BPSK modulation.

```
data = randi([0 1],10,1);
modData = pskmod(data,2);
```

Create a Kasami sequence object of length 255 using generator polynomial $x^{8}+x^{7}+x^{4}+1$.
kasamiSequence $=$ comm.KasamiSequence('Polynomial', $\left.\begin{array}{llll}8 & 7 & 4 & 0\end{array}\right], \ldots$.
'InitialConditions',[0 0 0 0 0 0 0 1],'SamplesPerFrame', 255);

Generate the Kasami sequence and convert it to bipolar form.

```
kasSeq = kasamiSequence();
kasSeq = 2*kasSeq - 1;
```

Apply a gain of $1 / \sqrt{255}$ to ensure that the spreading operation does not increase the overall signal power.

```
kasSeq = kasSeq/sqrt(255);
```

Spread the BPSK data using the Kasami sequence.

```
spreadData = modData*kasSeq';
spreadData = spreadData(:);
```

Verify that the spread data sequence is 255 times longer than the input data sequence.

```
spreadingFactor = length(spreadData)/length(data)
spreadingFactor = 255
```

Verify that the spreading operation did not increase the signal power.

```
spreadSigPwr = sum(abs(spreadData).^2)/length(data)
spreadSigPwr = 1.0000
```

Change the generator polynomial of the Kasami sequence generator to $x^{8}+x^{3}+1$ after first releasing the object. Use the character representation of the polynomial.

```
release(kasamiSequence)
kasamiSequence.Polynomial = 'x^8 + x^3 + 1';
```

Generate a new sequence and convert it to bipolar form.

```
kasSeq = kasamiSequence();
kasSeq = 2*kasSeq - 1;
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Kasami Sequence Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the Sample time parameter.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

## reset

System object: comm.KasamiSequence
Package: comm
Reset states of Kasami sequence generator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the KasamiSequence object, H .

## step

System object: comm. KasamiSequence
Package: comm
Generate a Kasami sequence

## Syntax

$Y=\operatorname{step}(H)$
Y = step(H,RESET)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H})$ outputs a frame of the Kasami sequence in column vector Y . Specify the frame length with the SamplesPerFrame property. The Kasami sequence has a period of $N=2^{n}-1$, where $n$ is the degree of the generator polynomial that you specify in the Polynomial property.
$\mathrm{Y}=$ step ( $\mathrm{H}, \mathrm{RESET}$ ) uses RESET as the reset signal when you set the ResetInputPort property to true. The data type of the RESET input must be double precision or logical. RESET can be a scalar value or a column vector with a length equal to the number of samples per frame that you specify in the SamplesPerFrame property. When the RESET input is a non-zero scalar, the object resets to the initial conditions that you specify in the InitialConditions property. It then generates a new output frame. A column vector RESET input allows multiple resets within an output frame. A non-zero value at the $i$-th element of the vector causes a reset at the $i$-th output sample time.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.LDPCDecoder

Package: comm
Decode binary low-density parity-check (LDPC) code

## Description

The comm. LDPCDecoder System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see "Belief Propagation Decoding" on page 3-872.

To decode an LDPC-encoded signal:
1 Create the comm. LDPCDecoder object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

ldpcdecoder = comm. LDPCDecoder
ldpcdecoder $=$ comm. LDPCDecoder(parity)
ldpcdecoder $=$ comm. LDPCDecoder (__ , Name, Value)

## Description

ldpcdecoder = comm.LDPCDecoder creates a binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.
ldpcdecoder = comm.LDPCDecoder(parity) sets the ParityCheckMatrix property to parity and creates an LDPC decoder System object. The parity input must be specified as described by the ParityCheckMatrix property.
ldpcdecoder = comm.LDPCDecoder( $\qquad$ ,Name, Value) sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example,
comm.LDPCDecoder('DecisionMethod','Soft decision') configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type double. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## ParityCheckMatrix - Parity-check matrix

dvbs2ldpc(1/2) (default) | sparse binary matrix | nonsparse index matrix
Parity-check matrix, specified as a sparse ( $N-K$ )-by- $N$ binary-valued matrix. $N$ is the length of the received signal and must be in the range ( $0,2^{31}$ ). $K$ is the length of the uncoded message and must be less than $N$. The last ( $N-K$ ) columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, $\mathrm{gf}(2)$.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, $I$, that defines the row and column indices of the 1 s in the parity-check matrix such that sparse(I(:,1),I(:,2),1).

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the logical data type.

The default value uses the dvbs2ldpc function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S. 2 standard.
Example: dvbs2ldpc (R,'indices') configures the index matrix for the DVB-S. 2 standard, where $R$ is the code rate, and 'indices' specifies the output format of dvbs2ldpc as a two-column doubleprecision matrix that defines the row and column indices of the 1 s in the parity-check matrix.
Data Types: double | logical

## OutputValue - Output value format

'Information part' (default)|'Whole codeword'
Output value format, specified as one of these values:

- 'Information part' - The object outputs a $K$-by-1 column vector containing only the information-part of the received log-likelihood ratio vector. $K$ is the length of the uncoded message.
- 'Whole codeword' - The object outputs an $N$-by-1 column vector containing the whole loglikelihood ratio vector. $N$ is the length of the received signal.
$N$ and $K$ must align with the dimension of the $(N-K)$-by- $K$ parity-check matrix.

## Data Types: char

## DecisionMethod - Decision method

'Hard decision' (default)|'Soft decision'
Decision method used for decoding, specified as one of these values:

- 'Hard decision' - The object outputs decoded data of data type logical.
- 'Soft decision' - The object outputs log-likelihood ratios of data type double.

Data Types: char

## IterationTerminationCondition - Condition for iteration termination

'Maximum iteration count' (default)|'Parity check satisfied'

Condition for iteration termination, specified as one of these values:

- 'Maximum iteration count' - Decoding terminates after the number of iterations specified by the MaximumIterationCount property.
- 'Parity check satisfied ' - Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the MaximumIterationCount property.

Data Types: char

## MaximumIterationCount - Maximum number of decoding iterations <br> 50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.
Data Types: double
NumIterationsOutputPort - Output number of iterations executed
false (default) |true
Output number of iterations performed, specified as false or true. To output the number of iterations executed, set this property to true.
Data Types: logical

## FinalParityChecksOutputPort - Output final parity checks

false (default) | true
Output final parity checks, specified as false or true. To output the final calculated parity checks, set this property to true.

Data Types: logical

## Usage

## Syntax

$y=l d p c d e c o d e r(x)$
[y, numiter] = ldpcdecoder(x)
[y,parity] = ldpcdecoder(x)
[y, numiter, parity] = ldpcdecoder(x)

## Description

y = ldpcdecoder(x) decodes input data using an LDPC code based on the default parity-check matrix.
[y, numiter] = ldpcdecoder(x) returns the decoded data, $y$, and number of iterations performed, numiter. To use this syntax, set the NumIterationsOutputPort property to true.
[y,parity] = ldpcdecoder (x) returns the decoded data, y , and final parity checks, parity. To use this syntax, set the FinalParityChecksOutputPort property to true.
[y, numiter, parity] = ldpcdecoder(x) returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the NumIterationsOutputPort and FinalParityChecksOutputPort properties to true.

## Input Arguments

## x - Log-likelihood ratios

column vector
Log-likelihood ratios, specified as an $N$-by-1 column vector containing the soft-decision output from demodulation. $N$ is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first $K$ elements correspond to the information-part of the input message.

## Data Types: double

## Output Arguments

## y - Decoded data

column vector
Decoded data, returned as a column vector. The DecisionMethod property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the OutputValue property is set to 'Information part ', the output includes only the information-part of the received log-likelihood ratio vector.
- If the OutputValue property is set to 'Whole codeword ', the output includes the whole loglikelihood ratio vector.

Data Types: double | logical
numiter - Number of executed decoding iterations
positive integer
Number of executed decoding iterations, returned as a positive integer.

## Dependencies

To enable this output, set the NumIterationsOutputPort property to true.

## parity - Final parity checks

column vector
Final parity checks after decoding the input LDPC code, returned as an ( $N-K$ )-by- 1 column vector. $N$ is the number of bits in the LDPC codeword before modulation. $K$ is the length of the uncoded message.

## Dependencies

To enable this output, set the FinalParityChecksOutputPort property to true.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPCcoded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numEr\overline{rUnc;}
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
```

```
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.

```
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')
```

## Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

## Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.

For transmitted LDPC-encoded codeword $c=c_{0}, c_{1}, \ldots, c_{n-1}$, the input to the LDPC decoder is the loglikelihood ratio (LLR) value $L\left(c_{i}\right)=\log \left(\frac{\operatorname{Pr}\left(c_{i}=0 \mid \text { channel output for } c_{i}\right)}{\operatorname{Pr}\left(c_{i}=1 \mid \text { channel output for } c_{i}\right)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:
$L\left(r_{j i}\right)=2 \operatorname{atanh}\left(\prod_{i^{\prime} \in V_{j} j i} \tanh \left(\frac{1}{2} L\left(q_{i^{\prime} j}\right)\right)\right)$,
$L\left(q_{i j}\right)=L\left(c_{i}\right)+\sum_{j^{\prime} \in C_{i} \backslash j} L\left(r_{j^{\prime} i}\right)$, initialized as $L\left(q_{i j}\right)=L\left(c_{i}\right)$ before the first iteration, and
$L\left(Q_{i}\right)=L\left(c_{i}\right)+\sum_{j^{\prime} \in C_{i}} L\left(r_{j^{\prime} i}\right)$.
At the end of each iteration, $L\left(Q_{i}\right)$ contains the updated estimate of the LLR value for transmitted bit $c_{i}$. The value $L\left(Q_{i}\right)$ is the soft-decision output for $c_{i}$. If $L\left(Q_{i}\right)<0$, the hard-decision output for $c_{i}$ is 1 . Otherwise, the hard-decision output for $c_{i}$ is 0 .

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation $\left(H c^{\prime}=0\right)$ at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_{i} \backslash j$ and $V_{j} \backslash i$ are based on the parity-check matrix (PCM). Index sets $C_{i}$ and $V_{j}$ correspond to all nonzero elements in column $i$ and row $j$ of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for $i=5$ and $j=3$.

To avoid infinite numbers in the algorithm equations, $\operatorname{atanh}(1)$ and $\operatorname{atanh}(-1)$ are set to 19.07 and 19.07, respectively. Due to finite precision, MATLAB returns 1 for $\tanh (19.07)$ and -1 for $\tanh (-19.07)$.

## Functions

dvbs2ldpc

## Blocks

LDPC Decoder

## Introduced in R2012a

## comm.LDPCEncoder

Package: comm
Encode binary low-density parity-check (LDPC) code

## Description

The comm. LDPCEncoder System object applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

To encode a binary LDPC code:
1 Create the comm. LDPCEncoder object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

ldpcencoder = comm.LDPCEncoder
ldpcencoder = comm.LDPCEncoder(parity)
ldpcencoder = comm.LDPCEncoder(___ ,Name, Value)

## Description

ldpcencoder = comm.LDPCEncoder creates a binary LDPC encoder System object. This object performs LDPC encoding based on the default parity-check matrix.
ldpcencoder = comm.LDPCEncoder(parity) sets the ParityCheckMatrix property to parity and creates an LDPC encoder System object. The parity input must be specified as described by the ParityCheckMatrix property.
ldpcencoder = comm.LDPCEncoder (__ , Name, Value) sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, comm.LDPCEncoder('ParityCheckMatrix',sparse(I(:,1),I(:,2),1)) configures an LDPC encoder System object to encode data using the parity matrix sparse(I(:,1),I(:,2),1). Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## ParityCheckMatrix - Parity-check matrix

dvbs2ldpc (1/2) (default) | sparse binary matrix | nonsparse index matrix
Parity-check matrix, specified as a sparse ( $N-K$ )-by- $N$ binary-valued matrix. $N$ is the length of the output codeword vector, and must be in the range ( $0,2^{31}$ ). $K$ is the length of the uncoded message and must be less than $N$. The last $(N-K)$ columns in the parity-check matrix must be an invertible matrix in the Galois field of order $2, \mathrm{gf}(2)$.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, $I$, that defines the row and column indices of the 1 s in the parity-check matrix such that sparse(I(:,1),I(:,2),1).

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the logical data type.

The default value uses the dvbs2ldpc function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S. 2 standard.

## Note

- When the last $(N-K)$ columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.
- When the last $(N-K)$ columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.

Example: dvbs2ldpc (R, 'indices') configures the index matrix for the DVB-S. 2 standard, where R is the code rate, and 'indices ' specifies the output format of dvbs2ldpc as a two-column doubleprecision matrix that defines the row and column indices of the 1 s in the parity-check matrix.

Data Types: double | logical

## Usage

## Syntax

codeword = ldpcencoder(message)

## Description

codeword $=$ ldpcencoder(message) codes the input message using an LDPC code based on a parity-check matrix. The LDPC codeword output is a solution to the parity-check equation.

## Input Arguments

message - Input message
binary column vector

Input message, specified as a $K$-by- 1 column vector containing binary-valued elements. $K$ is the length of the uncoded message.

## Data Types: double | logical

## Output Arguments

## codeword - LDPC codeword

column vector
LDPC codeword, returned as an $N$-by- 1 column vector. $N$ is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first $K$ bits of the LDPC codeword output, and the parity check comprises the remaining $(N-K)$ bits.

## Data Types: double | logical

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

| step | Run System object algorithm |
| :--- | :--- |
| release | Release resources and allow changes to System object property values and input <br> characteristics |
| reset | Reset internal states of System object |

## Examples

## LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPCcoded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErr̄Unc = biterr(data,demód_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end
```

Plot the error statistics for uncoded and LDPC-coded data.
plot(snr,uncErrRate,snr,errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

## comm.LTEMIMOChannel

Package: comm
(To be removed) Filter input signal through LTE MIMO multipath fading channel

Note comm. LTEMIMOChannel will be removed in a future release. Use comm.MIMOChannel instead.

## Description

The comm. LTEMIMOChannel System object filters an input signal through an LTE multiple-input multiple-output (MIMO) multipath fading channel.

A specialization of the comm.MIMOChannel System object, the comm. LTEMIMOChannel System objects offers pre-set configurations for use with LTE link level simulations. In addition to the comm.MIMOChannel System object, the comm. LTEMIMOChannel System object also corrects the correlation matrix to be positive semi-definite, after rounding to 4 -digit precision. This System object models Rayleigh fading for each of its links.

To filter an input signal using an LTE MIMO multipath fading channel:
1 Define and set up your LTE MIMO multipath fading channel object. See "Construction" on page 3-880.
2 Call step to filter the input signal using an LTE MIMO multipath fading channel according to the properties of comm. LTEMIMOChannel. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. LTEMIMOChannel creates a 3GPP Long Term Evolution (LTE) Release 10 specified multiple-input multiple-output (MIMO) multipath fading channel System object, H. This object filters a real or complex input signal through the multipath LTE MIMO channel to obtain the channel impaired signal.

H = comm.LTEMIMOChannel (Name, Value) creates an LTE MIMO multipath fading channel object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Namel,Value1,...,NameN,ValueN).

## Properties

## SampleRate

Input signal sample rate (Hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is 30.72 MHz , as defined in the LTE specification.

## Profile

Channel propagation profile
Specify the propagation conditions of the LTE multipath fading channel as one of EPA $5 \mathrm{~Hz} \mid$ EVA 5 Hz |EVA 70 Hz |ETU 70 Hz |ETU 300 Hz , which are supported in the LTE specification Release 10. The default value of this property is EPA 5 Hz .

This property defines the delay profile of the channel to be one of EPA, EVA, and ETU. This property also defines the maximum Doppler shift of the channel to be $5 \mathrm{~Hz}, 70 \mathrm{~Hz}$, or 300 Hz . The Doppler spectrum always has a Jakes shape in the LTE specification. The EPA profile has seven paths. The EVA and ETU profiles have nine paths.

The following tables list the delay and relative power per path associated with each profile.
Extended Pedestrian A Model (EPA)

| Excess tap delay [ns] | Relative power [db] |
| :---: | :---: |
| 0 | 0.0 |
| 30 | -1.0 |
| 70 | -2.0 |
| 90 | -3.0 |
| 110 | -8.0 |
| 190 | -17.2 |
| 410 | -20.8 |

Extended Vehicular A Model (EVA)

| Excess tap delay [ns] | Relative power [db] |
| :---: | :---: |
| 0 | 0.0 |
| 30 | -1.5 |
| 150 | -1.4 |
| 310 | -3.6 |
| 370 | -0.6 |
| 710 | -9.1 |
| 1090 | -7.0 |
| 1730 | -12.0 |
| 2510 | -16.9 |

## Extended Typical Urban Model (ETU)

| Excess tap delay [ns] | Relative power [db] |
| :---: | :---: |
| 0 | -1.0 |

| Excess tap delay [ns] | Relative power [db] |
| :---: | :---: |
| 50 | -1.0 |
| 120 | -1.0 |
| 200 | 0.0 |
| 230 | 0.0 |
| 500 | 0.0 |
| 1600 | -3.0 |
| 2300 | -5.0 |
| 5000 | -7.0 |

## AntennaConfiguration

## Antenna configuration

Specify the antenna configuration of the LTE MIMO channel as one of $1 \times 2|2 \times 2| 4 \times 2 \mid 4 \times 4$. These configurations are supported in the LTE specification Release 10. The default value of this property is $2 \times 2$.

The property value is in the format of $N_{\mathrm{t}}$-by- $N_{\mathrm{r}}$. $N_{\mathrm{t}}$ represents the number of transmit antennas and $N_{\mathrm{r}}$ represents the number of receive antennas.

## CorrelationLevel

## Spatial correlation strength

Specify the spatial correlation strength of the LTE MIMO channel as one of Low | Medium | High. The default value of this property is Low. When you set this property to Low, the MIMO channel is spatially uncorrelated.

The transmit and receive spatial correlation matrices are defined from this property according to the LTE specification Release 10. See the Algorithms section for more information.

## AntennaSelection

Antenna selection
Specify the antenna selection scheme as one of $0 f f|T x| R x \mid T x$ and $R x$, where Tx represents transmit antennas and $R x$ represents receive antennas. When you select Tx and/or $R x$, additional input(s) are required to specify which antennas are selected for signal transmission. The default value of this property is Off.

## RandomStream

Source of random number stream
Specify the source of random number stream as one Global stream \| mt19937ar with seed. The default value of this property is Global stream. When you set this property to Global st ream, the current global random number stream is used for normally distributed random number generation. In this case, the reset method only resets the filters. If you set RandomStream to mt19937ar with seed, the object uses the mt19937ar algorithm for normally distributed random number generation. In this case, the reset method resets the filters and reinitializes the random number stream to the value of the Seed property.

## Seed

Initial seed of mt19937ar random number stream

Specify the initial seed of an mt19937ar random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is 73 . This property applies when you set the RandomStream property to mt19937ar with seed. The Seed reinitializes the mt19937ar random number stream in the reset method.

## NormalizePathGains

Normalize path gains (logical)
Set this property to true to normalize the fading processes so that the total power of the path gains, averaged over time, is 0 dB . The default value of this property is true. When you set this property to false, there is no normalization for path gains.

## NormalizeChannelOutputs

Normalize channel outputs (logical)
Set this property to true to normalize the channel outputs by the number of receive antennas. The default value of this property is true. When you set this property to false, there is no normalization for channel outputs.

## PathGains0utputPort

Enable path gain output (logical)
Set this property to true to output the channel path gains of the underlying fading process. The default value of this property is false.

## Methods

reset (To be removed) Reset states of the LTEMIMOChannel object
step (To be removed) Filter input signal through LTE MIMO multipath fading channel

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Configure MIMO Channel Object Using LTE MIMO Channel Object

Configure an equivalent MIMOChannel System Object using the LTEMIMOChannel System Object. Then, verify that the channel output and the path gain output from the two objects are the same.

Create a PSK Modulator System object ${ }^{\mathrm{TM}}$ to modulate randomly generated data.
pskModulator = comm. PSKModulator;
modData $=$ pskModulator(randi([0 pskModulator.Modulation0rder-1],2e3,1));

Split modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 1e3]).';
```

Create an LTEMIMOChannel System object with a 2-by-2 antenna configuration and a medium correlation level.

```
lteChan = comm.LTEMIMOChannel(...
    'Profile', 'EVA 5Hz',...
    'AntennaConfiguration', '2x2',...
    'CorrelationLevel', 'Medium',...
    'AntennaSelection', 'Off',...
    'RandomStream', 'mt19937ar with seed',...
    'Seed', 99,...
    'PathGainsOutputPort', true);
```

Warning: COMM.LTEMIMOCHANNEL will be removed in a future release. Use COMM.MIMOCHANNEL or LTEFAD
Filter the modulated data using the LTEMIMOChannel System object, lteChan.

```
[LTEChan0ut,LTEPathGains] = lteChan(channelInput);
```

Create an equivalent MIMOChannel System object, mimoChannel, using the properties of the LTEMIMOChannel System object, lteChan.

The KFactor, DirectPathDopplerShift and DirectPathInitialPhase properties only exist for the MIMOChannel System object. All other MIMOChannel System object properties also exist for the LTEMIMOChannel System object; however, some properties are hidden and read-only.

```
mimoChannel = comm.MIMOChannel( ...
    'SampleRate',lteChan.SampleRate, ...
    'PathDelays',lteChan.PathDelays, ...
    'AveragePathGains',lteChan.AveragePathGains, ...
    'NormalizePathGains',lteChan.NormalizePathGains, ...
    'FadingDistribution',lteChan.FadingDistribution, ...
    'MaximumDopplerShift',lteChan.MaximumDopplerShift, ...
    'DopplerSpectrum',lteChan.DopplerSpectrum, ...
    'SpatialCorrelationSpecification', ...
            lteChan.SpatialCorrelationSpecification, ...
    'SpatialCorrelationMatrix',lteChan.SpatialCorrelationMatrix, ...
    'AntennaSelection',lteChan.AntennaSelection, ...
    'NormalizeChannelOutputs',lteChan.NormalizeChannelOutputs, ...
    'RandomStream',lteChan.RandomStream, ...
    'Seed',lteChan.Seed, ...
    'PathGains0utputPort',lteChan.PathGains0utputPort);
```

Filter the modulated data using the equivalent mimoChannel object.

```
[MIMOChanOut, MIMOPathGains] = mimoChannel(channelInput);
```

Verify that the channel output and the path gain output from the two objects are the same.

```
sameChOutput = isequal(LTEChanOut,MIMOChanOut)
sameChOutput = logical
    1
```

samePathGains = isequal(LTEPathGains,MIMOPathGains)

```
samePathGains = logical
```

    1
    You can repeat the preceding process with AntennaConfiguration set to $4 \times 2$ or $4 \times 4$ and CorrelationLevel set to Medium or High for lteChan.

## Algorithms

This System object is a specialized implementation of the comm. MIMOChannel System object. For additional algorithm information, see the comm.MIMOChannel System object help page.

## Spatial Correlation Matrices

The following table defines the transmitter eNodeB correlation matrix.

|  | One Antenna | Two Antennas | Four Antennas |
| :---: | :---: | :---: | :---: |
| eNodeB Correlation | $R_{\text {eNB }}=1$ | $R_{e N B}=\left(\begin{array}{ll}1 & \alpha \\ \alpha^{*} & 1\end{array}\right)$ | $R_{\text {eNB }}=$ |
|  |  |  | $\left\|\begin{array}{cccc} 1 & \alpha^{1} / 9 & \alpha^{4} / 9 & \alpha \\ \alpha^{1 / 9 *} & 1 & \alpha^{1 / 9} & \alpha^{4} / 9 \\ \alpha^{4} / 9 * & \alpha^{1 / 9 *} & 1 & \alpha^{1 / 9} \\ \alpha^{*} & \alpha^{4} / 9 * & \alpha^{1 / 9 *} & 1 \end{array}\right\|$ |

The following table defines the receiver UE correlation matrix.

|  | One Antenna | Two Antennas | Four Antennas |
| :--- | :--- | :--- | :--- |
| UE Correlation | $R_{\text {UE }}=1$ | $R_{U E}=\left(\begin{array}{cc}1 & \beta \\ \beta^{*} & 1\end{array}\right)$ |  |
| $R_{U E}=$ |  |  |  |
|  |  |  |  |
|  |  |  | 1 $\beta^{1 / 9}$ $\beta^{4 / 9}$ $\beta$ <br> $\beta^{1 / 9 *}$ 1 $\beta^{1 / 9}$ $\beta^{4 / 9}$ <br> $\beta^{4 / 9 *}$ $\beta^{1 / 9 *}$ 1 $\beta^{1 / 9}$ <br> $\beta^{*}$ $\beta^{4 / 9 *}$ $\beta^{1 / 9 *}$ 1 |

The following table describes the $R_{\text {spat }}$ channel spatial correlation matrix between the transmitter and receiver antennas.

| Tx-by-Rx Configuration | Correlation Matrix |
| :---: | :---: |
| 1-by-2 | $R_{\text {spat }}=R_{U E}=\left[\begin{array}{cc}1 & \beta \\ \beta^{*} & 1\end{array}\right]$ |
| 2-by-2 | $\begin{aligned} & R_{\text {spat }}=R_{e N B} \otimes R_{U E}=\left[\begin{array}{cc} 1 & \alpha \\ \alpha^{*} & 1 \end{array}\right] \otimes\left[\begin{array}{cc} 1 & \beta \\ \beta^{*} & 1 \end{array}\right] \\ & =\left[\begin{array}{cccc} 1 & \beta & \alpha & \alpha \beta \\ \beta^{*} & 1 & \alpha \beta^{*} & \alpha \\ \alpha^{*} & \alpha^{*} \beta & 1 & \beta \\ \alpha^{*} \beta^{*} & \alpha^{*} & \beta^{*} & 1 \end{array}\right] \end{aligned}$ |
| 4-by-2 | $\begin{aligned} & R_{\text {spat }}=R_{e N B} \otimes R_{U E}=\left[\begin{array}{cccc} 1 & \alpha^{1 / 9} & \alpha^{4} / 9 & \alpha \\ \alpha^{1 / 9^{*}} & 1 & \alpha^{1 / 9} & \alpha^{4} / 9 \\ \alpha^{4} / 9^{*} & \alpha^{1 / 9^{*}} & 1 & \alpha^{1 / 9} \\ \alpha^{*} & \alpha^{4} / 9^{*} & \alpha^{1} / 9^{*} & 1 \end{array}\right] \\ & \otimes\left[\begin{array}{cc} 1 & \beta \\ \beta^{*} & 1 \end{array}\right] \end{aligned}$ |

| Tx-by-Rx Configuration | Correlation Matrix |
| :--- | :--- |
| 4-by-4 | $R_{\text {spat }}=R_{e N B} \otimes R_{U E}=\left[\begin{array}{cccc}1 & \alpha^{1 / 9} & \alpha^{4} / 9 & \alpha \\ \alpha^{1 / 9^{*}} & 1 & \alpha^{1 / 9} & \alpha^{4} / 9 \\ \alpha^{4} / 9^{*} & \alpha^{1 / 9^{*}} & 1 & \alpha^{1 / 9} \\ \alpha^{*} & \alpha^{4} / 9^{*} & \alpha^{1 / 9^{*}} & 1\end{array}\right]$ |
|  | $\otimes\left(\begin{array}{cccc}1 & \beta^{1 / 9} & \beta^{4 / 9} & \beta \\ \beta^{1 / 9 *} & 1 & \beta^{1 / 9} & \beta^{4 / 9} \\ \beta^{4} / 9 * & \beta^{1 / 9 *} & 1 & \beta^{1 / 9} \\ \beta^{*} & \beta^{4} / 9 * & \beta^{1 / 9 *} & 1\end{array}\right)$ |

## Spatial Correlation Correction

| Low Correlation |  | Medium Correlation |  | High Correlation |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\alpha$ | $\beta$ | $\alpha$ | $\beta$ | $\alpha$ | $\beta$ |
| 0 | 0 | 0.3 | 0.9 | 0.9 | 0.9 |

To insure the correlation matrix is positive semi-definite after round-off to 4 digit precision, this System object uses the following equation:

$$
R_{\text {high }}=\left[R_{\text {spatial }}+a I_{n}\right] /(1+a)
$$

Where
$\alpha$ represents the scaling factor such that the smallest value is used to obtain a positive semi-definite result.

For the 4 -by- 2 high correlation case, $\alpha=0.00010$.
For the 4-by-4 high correlation case, $\alpha=0.00012$.
The object uses the same method to adjust the 4-by-4 medium correlation matrix to insure the correlation matrix is positive semi-definite after rounding to 4 digit precision with $\alpha=0.00012$.

## reset

System object: comm. LTEMIMOChannel
Package: comm
(To be removed) Reset states of the LTEMIMOChannel object

Note comm. LTEMIMOChannel will be removed in a future release. Use comm.MIMOChannel instead.

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the LTEMIMOChannel object, H .
If you set the RandomStream property of H to Global stream, the reset method only resets the filters. If you set RandomStream to mt19937ar with seed, the reset method not only resets the filters but also reinitializes the random number stream to the value of the Seed property.

## step

System object: comm. LTEMIMOChannel
Package: comm
(To be removed) Filter input signal through LTE MIMO multipath fading channel

Note comm. LTEMIMOChannel will be removed in a future release. Use comm.MIMOChannel instead.

## Syntax

Y $=$ step (H,X)
[Y,PATHGAINS] = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ filters input signal X through an LTE MIMO multipath fading channel and returns the result in Y . The input X can be a double- or single-precision data type scalar, vector, or 2-D matrix with real or complex values. X is of size $N_{\mathrm{s}}$-by- $N_{\mathrm{t}}$. $N_{\mathrm{s}}$ represents the number of samples and $N_{\mathrm{t}}$ represents the number of transmit antennas that must match the AntennaConfiguration property setting of $\mathrm{H} . \mathrm{Y}$ is the output signal of size $N_{\mathrm{s}}$-by- $N_{\mathrm{r}} . N_{\mathrm{r}}$ represents the number of receive antennas that is specified by the AntennaConfiguration property of $\mathrm{H} . \mathrm{Y}$ contains complex values with same precision as input signal.
[ Y, PATHGAINS] $=\operatorname{step}(\mathrm{H}, \mathrm{X})$ returns the LTE MIMO channel path gains of the underlying fading process in PATHGAINS. This applies when you set the PathGainsOutputPort property to true. PATHGAINS is of size $N_{\mathrm{s}}$-by- $N_{\mathrm{p}}$-by- $N_{\mathrm{t}}$-by- $N_{\mathrm{r}}$. $N_{\mathrm{p}}$ represents the number of discrete paths of the channel implicitly defined by the Profile property of H. PATHGAINS contains complex values with same precision as input signal.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.MatrixDeinterleaver

Package: comm
(To be removed) Deinterleave input symbols using permutation matrix

## Compatibility

comm.MatrixDeinterleaver will be removed in a future release. Use matdeintrlv instead. For more information, see "Compatibility Considerations" on page 3-892.

## Description

The MatrixDeinterleaver object performs block deinterleaving by filling a matrix with the input symbols column by column and then sending the matrix contents to the output port row by row. The number of rows and number of columns properties set the dimensions of the matrix that the object uses internally for computations.

To deinterleave input symbols using a permutation vector:
1 Define and set up your matrix deinterleaver object. See "Construction" on page 3-891.
2 Call step to deinterleave the input signal according to the properties of comm. MatrixDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.MatrixDeinterleaver creates a matrix deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the matrix interleaver object.

H = comm.MatrixDeinterleaver(Name,Value) creates a matrix deinterleaver object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.MatrixDeinterleaver(N,M) creates a matrix deinterleaver object, H. This object has the NumRows property set to $\mathbf{N}$, the NumColumns property set to M .

## Properties

## NumRows

Number of rows of permutation matrix
Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3 .

## NumColumns

Number of columns of permutation matrix
Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4 .

## Methods

step (To be removed) Deinterleave input symbols using permutation matrix

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Matrix Interleaving and Deinterleaving

Create matrix interleaver and deinterleaver objects.

```
interleaver = comm.MatrixInterleaver('NumRows',2,'NumColumns', 5);
Warning: COMM.MATRIXINTERLEAVER will be removed in a future release. Use MATINTRLV instead. See
deinterleaver = comm.MatrixDeinterleaver('NumRows',2,'NumColumns', 5);
Warning: COMM.MATRIXDEINTERLEAVER will be removed in a future release. Use MATDEINTRLV instead.
```

Generate random data, interleave, and then deinterleave the data.

```
data = randi(7,10,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
ans = logical
    1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Deinterleaver block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

comm. MatrixDeinterleaver will be removed
Not recommended starting in R2019b
comm.MatrixDeinterleaver will be removed in a future release. Use matdeintrlv instead.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ restores the original ordering of the sequence, $X$, that was interleaved using a block interleaver. The object fills a permutation matrix with the input symbols column by column and outputs the matrix contents row by row in the output, Y . The input X must be a column vector of length equal to NumRows $\times$ NumColumns. The data type for $X$ can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MatrixInterleaver

Package: comm
(To be removed) Permute input symbols using permutation matrix

## Compatibility

comm.MatrixInterleaver will be removed in a future release. Use matintrlv instead. For more information, see "Compatibility Considerations" on page 3-896.

## Description

The MatrixInterleaver object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents column-by-column.

To perform block interleaving using a permutation matrix:
1 Define and set up your matrix interleaver object. See "Construction" on page 3-895.
2 Call step to interleave the input symbols according to the properties of comm. MatrixInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.MatrixInterleaver creates a matrix interleaver System object, H. This object permutes the input by filling a permutation matrix with the input symbols row by row. The object then outputs the matrix contents column by column.

H = comm.MatrixInterleaver(Name,Value) creates a matrix interleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).
$\mathrm{H}=$ comm. MatrixInterleaver( $\mathrm{N}, \mathrm{M}$ ) creates a matrix interleaver object, H . This object has the NumRows property set to N , the NumColumns property set to M .

## Properties

## NumRows

Number of rows of permutation matrix
Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3 .

## NumColumns

Number of columns of permutation matrix
Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4 .

## Methods

step (To be removed) Permute input symbols using permutation matrix

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Matrix Interleaving and Deinterleaving

Create matrix interleaver and deinterleaver objects.

```
interleaver = comm.MatrixInterleaver('NumRows',2,'NumColumns', 5);
Warning: COMM.MATRIXINTERLEAVER will be removed in a future release. Use MATINTRLV instead. See
deinterleaver = comm.MatrixDeinterleaver('NumRows',2,'NumColumns', 5);
Warning: COMM.MATRIXDEINTERLEAVER will be removed in a future release. Use MATDEINTRLV instead.
```

Generate random data, interleave, and then deinterleave the data.

```
data = randi(7,10,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
ans = logical
    1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Deinterleaver block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

## comm. MatrixInterleaver will be removed

Not recommended starting in R2019b
comm.MatrixInterleaver will be removed in a future release. Use matintrlv instead.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ permutes input sequence, $X$, and returns interleaved sequence, $Y$. The object fills a permutation matrix with the input symbols row by row and outputs the matrix contents column by column. The input $X$ must be a column vector of length NumRows $\times$ NumColumns and the data type can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.MatrixHelicalScanDeinterleaver

Package: comm
(To be removed) Deinterleave input symbols by filling a matrix along diagonals

## Compatibility

comm.MatrixHelicalScanDeinterleaver will be removed in a future release. Use helscandeintrlv instead. For more information, see "Compatibility Considerations" on page 3-901.

## Description

The MatrixHelicalScanDeinterleaver object performs block deinterleaving by filling a matrix with the input symbols helically and then outputs the matrix contents row by row. The number of rows and number of columns properties represent the dimensions of the matrix that the object uses internally for computations.

To deinterleave the input symbols by filling a matrix with the input symbols helically and then outputting the matrix contents row-by-row:

1 Define and set up your matrix helical scan deinterleaver object. See "Construction" on page 3899.

2 Call step to deinterleave the input signal according to the properties of comm. MatrixHelicalScanDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, x) and y $=$ obj (x) perform equivalent operations.

## Construction

H = comm. MatrixHelicalScanDeinterleaver creates a matrix helical scan deinterleaver object, $H$. This object restores the original ordering of a sequence that was interleaved using the matrix helical scan interleaver System object.
$H=$ comm. MatrixHelicalScanDeinterleaver(Name, Value) creates a matrix helical scan deinterleaver object, $H$, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Namel,Value1,...,NameN,ValueN).

## Properties

## NumRows

Number of rows of permutation matrix
Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is 64 .

## NumColumns

Number of columns of permutation matrix
Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

## StepSize

Slope of diagonals
Specify slope as a scalar integer between 0 and the value you specify in the NumRows on page 3-0 property. The default is 1 . The slope value indicates the amount by which the row index increases as the column index increases by 1 . When you set the value of this property to 0 , the object does not interleave and the output matches the input.

## Methods

step (To be removed) Deinterleave input symbols by filling a matrix along diagonals

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ restores the original ordering of the sequence, $X$. The object fills a permutation matrix with the input symbols in a helical fashion and output the contents row by row, and returns Y . The input X must be a NumRows $\times$ NumColumns long column vector and the data type can be numeric, logical, or fixed-point (fi objects). $Y$ has the same data type as $X$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MatrixHelicaIScanInterleaver

Package: comm
(To be removed) Permute input symbols by selecting matrix elements along diagonals

## Compatibility

comm.MatrixHelicalScanInterleaver will be removed in a future release. Use helscanintrlv instead. For more information, see "Compatibility Considerations" on page 3-905.

## Description

The MatrixHelicalScanInterleaver object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents helically. The number of rows and number of columns properties are the dimensions of the matrix that the object uses internally for computations.

To interleave the input signal by filling a matrix row-by-row with the input symbols and then outputting the matrix contents helically:

1 Define and set up your matrix helical scan interleaver object. See "Construction" on page 3-903.
2 Call step to interleave the input signal according to the properties of comm.MatrixHelicalScanInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

$\mathrm{H}=$ comm.MatrixHelicalScanInterleaver creates a matrix helical scan interleaver object, H . This object permutes the input by filling a permutation matrix with the input symbols row by row and then outputs the matrix contents helically.

H = comm.MatrixHelicalScanInterleaver(Name,Value) creates a matrix helical scan interleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## NumRows

Number of rows of permutation matrix
Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is 64 .

## NumColumns

Number of columns of permutation matrix
Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

## StepSize

Slope of diagonals
Specify slope as a scalar integer between 0 and the value you specify in the NumRows on page 3-0 property. The slope value represents the amount by which the row index increases as the column index increases by 1 . When you set the value of this property to 0 , the object does not interleave and the output matches the input. The default is 1 .

step will be removed in a future release. Use hel scanintrlv instead.

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ permutes input sequence, $X$, and returns interleaved sequence, $Y$. The input $X$ must be a NumRows $\times$ NumColumns long column vector and the data type can be numeric, logical, or fixed-point (fi objects). $Y$ has the same data type as $X$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MemorylessNonlinearity

Package: comm
Apply memoryless nonlinearity to complex baseband signal

## Description

The comm. MemorylessNonlinearity System object applies memoryless nonlinear impairments to a complex baseband signal. Use this System object to model memoryless nonlinear impairments caused by signal amplification in a radio frequency (RF) transmitter or receiver. For more information, see "Memoryless Nonlinear Impairments" on page 3-922.

Note All values of power assume a nominal impedance of 1 ohm .

To apply memoryless nonlinear impairments to a complex baseband signal:
1 Create the comm.MemorylessNonlinearity object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
mnl = comm.MemorylessNonlinearity
mnl = comm.MemorylessNonlinearity(Name,Value)
```

## Description

mnl = comm.MemorylessNonlinearity creates a memoryless nonlinearity System object that models RF nonlinear impairments.
mnl = comm.MemorylessNonlinearity(Name,Value) specifies properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, 'Method ', 'Saleh model ' sets the modeling method to the Saleh method.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Method - Nonlinearity modeling method

'Cubic polynomial' (default)|'Hyperbolic tangent'|'Saleh model'|'Ghorbani model'| 'Rapp model'|'Lookup table'

Nonlinearity modeling method, specified as 'Cubic polynomial', 'Hyperbolic tangent', 'Saleh model', 'Ghorbani model', 'Rapp model', or 'Lookup table'. For more information, see "Memoryless Nonlinear Impairments" on page 3-922.
Data Types: char | string

## InputScaling - Input signal scaling factor

0 (default) | numeric scalar
Input signal scaling factor in decibels, specified as a numeric scalar. This property scales the power gain of the input signal.

Tunable: Yes

## Dependencies

To enable this property, set the Method property to 'Saleh model' or 'Ghorbani model'.
Data Types: double

## LinearGain - Linear gain

0 (default) | numeric scalar
Linear gain in decibels, specified as a numeric scalar. This property scales the power gain of the output signal.

Tunable: Yes

## Dependencies

To enable this property, set the Method property to 'Cubic polynomial ', 'Hyperbolic tangent', or 'Rapp model'.
Data Types: double

## IIP3 - Third-order input intercept point

30 (default) | numeric scalar
Third-order input intercept point in dBm, specified as a numeric scalar.
Tunable: Yes
Dependencies
To enable this property, set the Method property to 'Cubic polynomial' or 'Hyperbolic tangent'.
Data Types: double

## AMPMConversion - AM/PM conversion factor

10 (default) | numeric scalar
AM/PM conversion factor in degrees per decibel, specified as a numeric scalar. For more information, see "Cubic Polynomial and Hyperbolic Tangent Model Methods" on page 3-924.

Tunable: Yes
Dependencies
To enable this property, set the Method property to 'Cubic polynomial' or 'Hyperbolic tangent'.

## Data Types: double

AMAMParameters - AM/AM parameters
$[2.15871 .1517] \mid[8.10811 .54136 .5202$-0.0718]| numeric row vector
AM/AM parameters used to compute the amplitude gain for an input signal, specified as a numeric row vector.

- When the Method property is set to 'Saleh model', this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is [2.1587 1.1517].
- When the Method property is set to 'Ghorbani model', this property must be a four-element vector that specifies $x_{1}, x_{2}, x_{3}$, and $x_{4}$ values. In this case, the default value is [8.1081 1.5413 $6.5202-0.0718]$.

For more information, see "Saleh Model Method" on page 3-924 and "Ghorbani Model Method" on page 3-925.

Tunable: Yes
Dependencies
To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.
Data Types: double

## AMPMParameters - AM/PM parameters

[4.0033 9.1040]|[4.6645 2.0965 10. 88 -0.003] | numeric row vector
AM/PM parameters used to compute the phase change for an input signal, specified as a numeric row vector.

- When the Method property is set to 'Saleh model', this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is [4.0033 9.1040].
- When the Method property is set to 'Ghorbani model', this property must be a four-element vector that specifies $y_{1}, y_{2}, y_{3}$, and $y_{4}$ values. In this case, the default value is [4.6645 2.0965 $10.88-0.003]$

For more information, see "Saleh Model Method" on page 3-924 and "Ghorbani Model Method" on page 3-925.

Tunable: Yes

## Dependencies

To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.

## Data Types: double

## PowerLowerLimit - Input power lower limit

10 (default) | numeric scalar

Input power lower limit in dBm , specified as a numeric scalar less than the PowerUpperLimit property value. The AM/PM conversion scales linearly for input power values in the range [PowerLowerLimit, PowerUpperLimit]. If the input signal power is below the input power lower limit, the phase shift resulting from AM/PM conversion is zero. For more information, see "Cubic Polynomial and Hyperbolic Tangent Model Methods" on page 3-924.

Tunable: Yes

## Dependencies

To enable this property, set the Method property is set to 'Cubic polynomial' or 'Hyperbolic tangent'.
Data Types: double
PowerUpperLimit - Input power upper limit
inf (default) | numeric scalar
Input power upper limit in dBm , specified as a numeric scalar greater than PowerLowerLimit. The $\mathrm{AM} / \mathrm{PM}$ conversion scales linearly for input power values in the range [PowerLowerLimit, PowerUpperLimit]. If the input signal power is above the input power upper limit, the phase shift resulting from AM/PM conversion is constant. For more information, see "Cubic Polynomial and Hyperbolic Tangent Model Methods" on page 3-924.

Tunable: Yes

## Dependencies

To enable this property, set the Method property is set to 'Cubic polynomial' or 'Hyperbolic tangent'.
Data Types: double

## OutputScaling - Output signal scaling factor <br> 0 (default) | numeric scalar

Output signal scaling factor in decibels, specified as a numeric scalar. This property scales the power gain of the output signal.

Tunable: Yes
Dependencies
To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.
Data Types: double

## Smoothness - Smoothness factor

0.5 (default) | numeric scalar

Smoothness factor, specified as a numeric scalar. For more information, see "Rapp Model Method" on page 3-926.

Tunable: Yes
Dependencies
To enable this property, set the Method property is set to 'Rapp model '.

## Data Types: double

## OutputSaturationLevel - Output saturation level

1 (default) | numeric scalar
Output saturation level, specified as a numeric scalar. For more information, see "Rapp Model Method" on page 3-926.

Tunable: Yes

## Dependencies

To enable this property, set the Method property is set to 'Rapp model '.

## Data Types: double

## Table - Amplifier characteristics lookup table

$N$-by- $\left[P_{\text {in }}, P_{\text {out }}, \Delta \Phi\right]$ numeric matrix
Amplifier characteristics lookup table, specified as an N -by-3 numeric matrix of measured power amplifier (PA) characteristics. Each row is of the form $\left[P_{\text {in }}, P_{\text {out }}, \Delta \Phi\right]$. $P_{\text {in }}$ specifies the PA input signal in $\mathrm{dBm}, P_{\text {out }}$ specifies the PA output signal in dBm , and $\Delta \Phi$ specifies the output phase shift in degrees. The default value is $[-25,5.16,-0.25 ;-20,10.11,-0.47 ;-15,15.11,-0.68 ;-10$, 20.05, -0.89; -5, 24.79, -1.22; 0, 27.64, 5.59; 5, 28.49, 12.03].

The measured PA characteristics defined by this property are used to compute the AM/AM (in $\mathrm{dBm} /$ dBm ) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in $\mathrm{dBm} / \mathrm{dBm}$ ) and AM/PM (in deg/dBm) values.

Note To determine appropriate $P_{\text {out }}$ and $\Delta \Phi$ for $P_{\text {in }}$ values outside the range of values specified in the Table property, the System objectapplies linear extrapolation from the first two or last two [ $P_{\text {in }}, P_{\text {out }}$, $\Delta \Phi$ ] rows of Table.

Tunable: Yes

## Dependencies

To enable this property, set the Method property is set to 'Lookup table'.
Data Types: double

## Usage

## Syntax

outsig $=m n l(i n s i g)$

## Description

outsig $=\mathrm{mnl}($ insig $)$ applies memoryless nonlinear impairments to the input RF baseband signal.

## Input Arguments

## insig - Input RF baseband signal

numeric scalar | numeric column vector
Input RF baseband signal, specified as a numeric scalar or numeric column vector. Values in this input must be complex.

```
Data Types: double
Complex Number Support: Yes
```

## Output Arguments

## outsig - Output RF baseband signal

numeric scalar | numeric column vector
Output RF baseband signal, returned as a numeric scalar or numeric column vector. The output is of the same data type as the input.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Apply Saleh Model of Power Amplifier Nonlinearity to 16-QAM Signal

Generate 16-QAM data with an average power of 10 mW and pass the data through a nonlinear power amplifier (PA).

```
M = 16;
data = randi([0 (M - 1)]',1000,1);
avgPow = 1e-2;
minD = avgPow2MinD(avgPow,M);
```

Create a memoryless nonlinearity System object, specifying the Saleh model method.

```
saleh = comm.MemorylessNonlinearity('Method','Saleh model');
```

Generate modulated symbols and pass them through the PA nonlinearity model.

```
modData = (minD/2).*qammod(data,M);
y = saleh(modData);
```

Generate a scatter plot of the results.

```
scatterplot(y)
```

Average power normalization of input signal.

```
function minD = avgPow2MinD(avgPow,M)
    % Average power to minimum distance
    nBits = log2(M);
    if (mod(nBits,2)==0)
        % Square QAM
        sf = (M - 1)/6;
    else
        % Cross QAM
        if (nBits>4)
            sf = ((31*M/32) - 1)/6;
        else
            sf = ((5*M/4) - 1)/6;
        end
    end
    minD = sqrt(avgPow/sf);
end
```

## Nonlinear Amplifier Gain Compression

Plot the gain compression of a nonlinear amplifier for a 16-QAM signal.

Specify the modulation order and samples per symbol parameters.
M = 16;
sps = 4;
Model a nonlinear amplifier, by creating a memoryless nonlinearity System object with a 30 dB thirdorder input intercept point. Create a raised cosine transmit filter System object.

```
amplifier = comm.MemorylessNonlinearity('IIP3',30);
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6, ...
    'OutputSamplesPerSymbol',sps, ...
    'Gain',sqrt(sps));
```

Specify the input power in dBm . Convert the input power to W and initialize the gain vector.

```
pindBm = -5:25;
pin = 10.^((pindBm-30)/10);
gain = zeros(length(pindBm),1);
```

Execute the main processing loop, which includes these steps.

- Generate random data symbols.
- Modulate the data symbols and adjust the average power of the signal.
- Filter the modulated signal.
- Amplify the signal.
- Measure the gain.

```
for k = 1:length(pin)
    data = randi([0 (M - 1)],1000,1);
    modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin(k));
    filtSig = txfilter(modSig);
    ampSig = amplifier(filtSig);
    gain(k) = 10*log10(var(ampSig)/var(filtSig));
end
```

Plot the amplifier gain as a function of the input signal power. The 1 dB gain compression point occurs for an input power of 18.5 dBm . To increase the point at which a 1 dB compression is observed, increase the third-order intercept point, amplifier. IIP3.

```
arrayplot = dsp.ArrayPlot('PlotType','Line','XLabel','Power In (dBm)', ...
    'XOffset',-5,'YLimits',[-5 5]);
arrayplot(gain)
```

Processing

## Distort 16-QAM Signal with Custom Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics to a 16-QAM signal by setting the Method property to 'Lookup table'.

Define parameters for the modulation order, samples per symbol, and input power. Create random data.

M = 16; \% Modulation order
sps $=4$; \% Samples per symbol
pindBm $=-2$; \% Input power
pin = 10.^((pindBm-30)/10); \% power in Watts
data $=$ randi([0 (M - 1)],1000,1);
refdata = 0:M-1;
refconst $=$ qammod(refdata, $M$, 'UnitAveragePower',true);
Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```
amplifier = comm.MemorylessNonlinearity('Method','Lookup table');
```

txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps, 'Gain', sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4,'ReferenceConstellation', refconst
'Title','Amplified/Distorted Signal');

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```
modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);
```

Compute input and output signal levels and the phase shift.

```
poutdBm = (20*log10(abs(ampSig))) + 30;
simulated_pindBm = (20*log10(abs(filtSig))) + 30;
phase = angle(ampSig.*conj(filtSig))*180/pi;
```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

```
figure
set(gcf,'units','normalized','position',[.25 1/3 . 5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2),'.','Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristics');
leglabels = {'Simulated results','Measurement'};
legend (leglabels,'Location','north');
subplot(1,2,2)
plot(simulated_pindBm,phase,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3),'.','Markersize',15);
legend (leglabels,'Location','north');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (degrees)');
grid on; title('AM/PM Characteristics');
```

Generate a constellation diagram of the amplified signal and reference constellation. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the reference constellation.

```
constellation(ampSig)
```

## Distort 16-QAM Signal with Measured Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics to a 16-QAM signal by setting the Method property to 'Lookup table'.

Define parameters for the modulation order, samples per symbol, and input power. Create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -8; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 (M - 1)],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
paChar = pa_performance_characteristics();
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```
amplifier = comm.MemorylessNonlinearity('Method','Lookup table','Table',paChar);
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4, ...
    'Title','Amplified/Distorted Signal','NumInputPorts',2, ...
    'ReferenceConstellation', refconst,'ShowLegend',true, ...
    'ChannelNames',{'Filtered signal','Amplified signal'});
```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```
modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);
```

Compute input and output signal levels and the phase shift.

```
poutdBm = (20*log10(abs(ampSig))) + 30;
simulated_pindBm = (20*log10(abs(filtSig))) + 30;
phase = angle(ampSig.*conj(filtSig))*180/pi;
```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

```
figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2),'.','Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristics');
leglabel = {'Simulated results','Measurement'};
legend (leglabel,'Location','south');
subplot(1,2,2)
plot(simulated_pindBm,phase,'.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3),'.','Markersize',15);
legend (leglabel,'Location','south');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (degrees)');
grid on;
title('AM/PM Characteristics');
```

For the purpose of constellation comparison, normalize the amplified signal and the filtered signal. Generate a constellation diagram of the filtered signal and amplified signal. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the filtered constellation.

```
filtSig = filtSig/mean(abs(filtSig)); % Normalized filtered signal
ampSig = ampSig/mean(abs(ampSig)); % Normalized amplified signal
constellation(filtSig,ampSig)
```

The pa_performance_characteristics helper function calculates the amplifier performance characteristics. The data is extracted from figure 4 of Hammi, Oualid, et al. "Power amplifiers' model assessment and memory effects intensity quantification using memoryless post-compensation technique." IEEE Transactions on Microwave Theory and Techniques 56.12 (2008): 3170-3179.
function paChar = pa_performance_characteristics()
The operating specification for the LDMOS-based Doherty amplifier are:

- A frequency of 2110 MHz
- A peak power of 300 W
- A small signal gain of 61 dB

Each row in HAV08_Table specifies Pin (dBm), gain (dB), phase shift (degrees).
HAV08 Table =...

Convert the second column of the HAV08_Table from gain to Pout for use by the memoryless nonlinearity System object.

```
paChar = HAV08_Table;
paChar(:,2) = paChar(:,1) + paChar(:,2);
end
```

## More About

## Memoryless Nonlinear Impairments

Memoryless nonlinear impairments distort the input signal amplitude and phase. The amplitude distortion is amplitude-to-amplitude modulation (AM/AM) and the phase distortion is amplitude-tophase modulation (AM/PM).

| Model Method | Memoryless Nonlinear Impairment |
| :--- | :--- |
| Cubic polynomial | AM/AM and AM/PM |
| Hyperbolic tangent |  |
| Saleh model |  |
| Ghorbani model | AM/AM only |
| Rapp model |  |

Model Method
Lookup table

## Memoryless Nonlinear Impairment

Applies impairment according to $\left[P_{\text {in }}, P_{\text {out }}, \Delta \Phi\right]$ amplifier characteristics specified by the Table property

The modeled impairments apply the AM/AM and AM/PM distortions differently, according to the model method you specify. The models apply the memoryless nonlinear impairment to the input signal by following these steps.

1 Multiply the signal by an input gain factor.

Note You can normalize the signal to 1 by setting the input scaling gain to the inverse of the input signal amplitude.
2 Split the complex signal into its magnitude and angle components.
3 Apply an AM/AM distortion to the magnitude of the signal, according to the selected model method, to produce the magnitude of the output signal.
4 Apply an AM/PM distortion to the phase of the signal, according to the selected model method, to produce the angle of the output signal.

Note This step does not apply for the Rapp model.
5 Combine the new magnitude and angle components into a complex signal. Then, multiply the result by an output gain factor.

The first four model methods (cubic polynomial, hyperbolic tangent, Saleh model, and Ghorbani model) apply AM/AM and AM/PM impairments as shown in this figure.

The Rapp model method applies AM/AM distortion as shown in this figure.

The lookup table method uses the power amplifier (PA) characteristics lookup table, specified as an $N$-by-3 numeric matrix of measured power amplifier (PA) characteristics. Each row is of the form [ $P_{\text {in }}$,
$\left.P_{\text {out }}, \Delta \Phi\right] . P_{\text {in }}$ specifies the PA input signal in $\mathrm{dBm}, P_{\text {out }}$ specifies the PA output signal in dBm , and $\Delta \Phi$ specifies the output phase shift in degrees. The measured PA characteristics defined by the Table property are used to compute the AM/AM (in $\mathrm{dBm} / \mathrm{dBm}$ ) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in $\mathrm{dBm} / \mathrm{dBm}$ ) and $\mathrm{AM} / \mathrm{PM}$ (in deg/dBm) values.

Note To determine appropriate $P_{\text {out }}$ and $\Delta \Phi$ for $P_{\text {in }}$ values outside the range of values specified in the Table property, the System objectapplies linear extrapolation from the first two or last two [ $P_{\text {in }}, P_{\text {out }}$, $\Delta \Phi]$ rows of Table.

## Cubic Polynomial and Hyperbolic Tangent Model Methods

This figure shows the AM/PM conversion behavior for the cubic polynomial and hyperbolic tangent model methods.

The AM/PM conversion scales linearly with an input power value between the lower and upper limits of the input power level. Outside this range, the AM/PM conversion is constant at the values corresponding to the lower and upper input power limits, which are zero and (AM/PM conversion) $\times$ (upper input power limit - lower input power limit), respectively.

## Saleh Model Method

This figure shows the AM/AM behavior (output voltage versus input voltage for the AM/AM distortion) and the $\mathrm{AM} / \mathrm{PM}$ behavior (output phase versus input voltage for the AM/PM distortion) for the Saleh model method.

The AM/AM parameters, $\alpha_{\text {AMAM }}$ and $\beta_{\text {AMAM }}$, are used to compute the amplitude distortion of the input signal by using

$$
F_{\mathrm{AMAM}}(u)=\frac{\alpha_{\mathrm{AMAM}} \times u}{1+\beta_{\mathrm{AMAM}} \times u^{2}},
$$

where $u$ is the magnitude of the scaled signal.
The AM/PM parameters, $\alpha_{\text {AMPM }}$ and $\beta_{\text {AMPM }}$, are used to compute the phase distortion of the input signal by using

$$
F_{\mathrm{AMPM}}(u)=\frac{\alpha_{\mathrm{AMPM}} \times u^{2}}{1+\beta_{\mathrm{AMPM}} \times u^{2}}
$$

where $u$ is the magnitude of the scaled signal. The $\alpha$ and $\beta$ parameters for $\mathrm{AM} / \mathrm{AM}$ and $\mathrm{AM} / \mathrm{PM}$ are similarly named but distinct.

## Ghorbani Model Method

The Ghorbani model method applies AM/AM and AM/PM distortion as described in this section.
The AM/AM parameters $\left(x_{1}, x_{2}, x_{3}\right.$, and $\left.x_{4}\right)$ are used to compute the amplitude distortion of the input signal by using

$$
F_{\mathrm{AMAM}}(u)=\frac{x_{1} u^{x_{2}}}{1+x_{3} u^{x_{2}}}+x_{4} u
$$

where $u$ is the magnitude of the scaled signal.
The AM/PM parameters ( $y_{1}, y_{2}, y_{3}$, and $y_{4}$ ) are used to compute the phase distortion of the input signal by using

$$
F_{\mathrm{AMPM}}(u)=\frac{y_{1} u^{y_{2}}}{1+y_{3} u^{y_{2}}}+y_{4} u
$$

where $u$ is the magnitude of the scaled signal.

## Rapp Model Method

The Rapp model method applies AM/AM distortion as described in this section. The Rapp model does not apply AM/PM distortion to the input signal.

The smoothness factor and output saturation level are used to compute the amplitude distortion of the input signal given by

$$
F_{\mathrm{AMAM}}(u)=\frac{u}{\left(1+\left(\frac{u}{O_{\mathrm{sat}}}\right)^{2 \mathrm{~S}}\right)^{1 / 2 \mathrm{~S}}}
$$

where

- $u$ is the magnitude of the scaled signal.
- $S$ is the smoothness factor.
- $O_{\text {sat }}$ is the output saturation level.

## Package: comm

Measure modulation error ratio

## Description

The comm. MER (modulation error ratio) object measures the signal-to-noise ratio (SNR) in digital modulation applications. You can use MER measurements to determine system performance in communications applications. For example, determining whether a DVB-T system conforms to applicable radio transmission standards requires accurate MER measurements. The block measures all outputs in dB .

To measure modulation error ratio:
1 Define and set up your MER object. See "Construction" on page 3-928.
2 Call step to measure the modulation error ratio according to the properties of comm.MER. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

MER = comm. MER creates a modulation error ratio (MER) System object, MER. This object measures the signal-to-noise ratio (SNR) in digital modulation applications.

MER = comm.MER(Name,Value) creates an MER object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Example: MER = comm.MER('ReferenceSignalSource','Estimated from reference constellation' ) creates an object, MER, that measures the MER of a received signal by using a reference constellation.

## Properties

## ReferenceSignalSource

Reference signal source
Reference signal source, specified as either 'Input port' (default) or 'Estimated from reference constellation'. To provide an explicit reference signal against which the input signal is measured, set this property to 'Input port'. To measure the MER of the input signal against a reference constellation, set this property to 'Estimated from reference constellation'.

## ReferenceConstellation

Reference constellation
Reference constellation, specified as a vector. This property is available when the ReferenceSignalSource property is 'Estimated from reference constellation'.

The default is [0.7071-0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + $0.7071 \mathrm{i}]$, which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16QAM signal, you can use qammod $(0: 15,16)$.

## MeasurementIntervalSource

Measurement interval source
Measurement interval source, specified as one of the following: ' Input length' (default), 'Entire history','Custom', or 'Custom with periodic reset'. This property affects the RMS and maximum MER outputs only.

- To calculate MER using only the current samples, set this property to 'Input length '.
- To calculate MER for all samples, set this property to 'Entire history'.
- To calculate MER over an interval you specify and to use a sliding window, set this property to 'Custom'.
- To calculate MER over an interval you specify and to reset the object each time the measurement interval is filled, set this property to 'Custom with periodic reset'.

## MeasurementInterval

Measurement interval
Measurement interval over which the MER is calculated, specified in samples as a real positive integer. This property is available when MeasurementIntervalSource is 'Custom' or 'Custom with periodic reset'. The default is 100 .

## AveragingDimensions

## Averaging dimensions

Averaging dimensions, specified as a positive integer or row vector of positive integers. This property determines the dimensions over which the averaging is performed. For example, to average across the rows, set this property to 2 . The default is 1 .

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between step calls. For example, if the input has size [ $\begin{array}{ll}4 & 3\end{array}$ ] and Averaging dimensions is [13], the output size is [lll 131 1], and the second dimension must remain fixed at 3.

## MinimumMEROutputPort

Minimum MER measurement output port
Minimum MER measurement output port, specified as a logical scalar. To create an output port for minimum MER measurements, set this property to true. The default is false.

## XPercentileMEROutputPort

$X$-percentile MER measurement output port
$X$-percentile MER measurement output port, specified as a logical scalar. To create an output port for $X$-percentile MER measurements, set this property to true. The $X$-percentile MER measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is false.

## XPercentileValue

$X$-percentile value
$X$-percentile value above which $X \%$ of the MER measurements fall, specified as a real scalar from 0 to 100. This property applies when XPercentileMEROutputPort is true. The default is 95.

## SymbolCountOutputPort

Symbol count output port
Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the $X$-percentile MER measurements, set this property to true. This property is available when XPercentileMEROutputPort property is true. The default is false.

## Methods

| reset | Reset states of MER measurement object |
| :--- | :--- |
| step | Measure modulation error ratio |

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- |

## Examples

## Measure MER of Noisy 16-QAM Modulated Signal

Create an MER object which outputs minimum MER, 90 -percentile MER, and the number of symbols.

```
mer = comm.MER('MinimumMEROutputPort',true, ...
    'XPercentileMEROutputPort',true,'XPercentileValue',90,...
    'SymbolCountOutputPort',true);
```

Generate random data. Apply 16-QAM modulation having unit average power. Pass the signal through an AWGN channel.

```
data = randi([0 15],1000,1);
refsym = qammod(data,16,'UnitAveragePower',true);
rxsym = awgn(refsym,20);
```

Determine the RMS, minimum, and 90th percentile MER values.

```
[MERdB,MinMER,PercentileMER,NumSym] = mer(refsym,rxsym)
```

```
MERdB = 20.1071
MinMER = 11.4248
PercentileMER = 16.5850
NumSym = 1000
```

## Measure MER Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an MER object. Measure the MER using the transmitted signal as the reference.

```
mer = comm.MER;
mer1 = mer(txSig,rxSig);
```

Release the MER object. Set the object to use a reference constellation for making MER measurements.

```
release(mer)
mer.ReferenceSignalSource = 'Estimated from reference constellation';
mer.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the MER using only the received signal as an input. Verify that it matches the result obtained with a reference signal.

```
mer2 = mer(rxSig);
[mer1 mer2]
ans = 1\times2
    30.0271 30.0271
```

## Measure MER Using Custom Measurement Interval

Measure the MER of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames, $M$, and the number of subframes per frame, $K$.
$M=2 ;$
K = 5;
Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen
frmLen = 500
```

Create an MER object. Configure the object to use a custom measurement interval equal to the frame length.

```
mer1 = comm.MER('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);
```

Configure the object to measure MER using an 8-PSK reference constellation.

```
merl.ReferenceSignalSource = 'Estimated from reference constellation';
merl.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an MER object, and configure it use a 500 -symbol measurement interval with a periodic reset. Configure the object to measure MER using an 8-PSK reference constellation.

```
mer2 = comm.MER('MeasurementIntervalSource','Custom with periodic reset', ...
    'MeasurementInterval',frmLen);
mer2.ReferenceSignalSource = 'Estimated from reference constellation';
mer2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the MER and signal-to-noise arrays.

```
merNoReset = zeros(K,M);
merReset = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the MER for a noisy 8-PSK signal using both objects. The SNR is increases by 1 dB from subframe to subframe. For merNoReset, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire data frame is used as the basis for the estimate. For merReset, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*K+7;
        rxSig = awgn(txSig,snrdB(k,m));
        merNoReset(k,m) = merl(rxSig);
        merReset(k,m) = mer2(rxSig);
    end
end
```

Display the MER measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the MER object resets after the first frame so that the calculated MER values more accurately reflect the current SNR.

```
stairs(snrdB(:),[merNoReset(:) merReset(:)])
xlabel('SNR (dB)')
ylabel('MER (%)')
legend('No Reset','Periodic Reset')
```

## Measure MER Across Different Dimensions

Create OFDM modulator and demodulator objects.
ofdmmod = comm.0FDMModulator('FFTLength', 32,'NumSymbols',4);
ofdmdemod = comm.OFDMDemodulator('FFTLength', 32,'NumSymbols',4);
Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1)
numSC = 21
numSym = ofdmDims.DataInputSize(2)
numSym = 4
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
modSig = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(modSig);
rxSig = awgn(txSig,10,'measured');
demodSig = ofdmdemod(rxSig);
```

Create an MER object, where the result is averaged over the subcarriers. Measure the MER. There are four entries corresponding to each of the 4 OFDM symbols.

```
mer = comm.MER('AveragingDimensions',1);
modErrorRatio = mer(demodSig,modSig)
modErrorRatio = 1×4
    11.2338 12.5315 12.8882 12.7015
```

Overwrite the MER object, where the result is averaged over the OFDM symbols. Measure the MER. There are 21 entries corresponding to each of the 21 subcarriers.

```
mer = comm.MER('AveragingDimensions',2);
modErrorRatio = mer(demodSig,modSig)
modErrorRatio = 21×1
    10.8054
    14.9655
    14.5721
    13.6024
    13.0132
    12.1391
    10.4012
        9.5017
        8.8055
    13.3824
```

Measure the MER and average over both the subcarriers and the OFDM symbols.

```
mer = comm.MER('AveragingDimensions',[1 2]);
modErrorRatio = mer(demodSig,modSig)
modErrorRatio = 12.2884
```

## Algorithms

MER is a measure of the SNR in a modulated signal calculated in dB. The MER over $N$ symbols is

## $\operatorname{MER}=10 \cdot \log _{10}\left(\frac{\sum_{n=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}{\sum_{n=1}^{N}\left(e_{k}\right)}\right) \mathrm{dB}$,

The MER for the $k$ th symbol is

$$
M E R_{k}=10 * \log _{10}\left(\frac{\frac{1}{N} \sum_{n=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}{e_{k}}\right) \mathrm{dB} .
$$

The minimum MER represents the minimum MER value in a burst, or
$M E R_{\text {min }}=\min _{k \in[1, \ldots, N]}\left\{M E R_{k}\right\}$,
where:

- $e_{k}=e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}$
- $I_{k}=$ In-phase measurement of the $k$ th symbol in the burst
- $Q_{k}=$ Quadrature phase measurement of the $k$ th symbol in the burst
- $I_{k}$ and $Q_{k}$ represent ideal (reference) values. $\tilde{I}_{k}$ and $\widetilde{Q}_{k}$ represent measured (received) symbols.

The block computes the $X$-percentile MER by creating a histogram of all the incoming $M E R_{k}$ values. The output provides the MER value above which X\% of the MER values fall.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\text {TM }}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Introduced in R2012a

## reset

System object: comm.MER
Package: comm
Reset states of MER measurement object

## Syntax

reset (H)

## Description

reset $(H)$ resets the states of the MER object, H .

## step

System object: comm.MER
Package: comm
Measure modulation error ratio

## Syntax

MERDB= step(MER,REFSYM,RXSYM)
MERDB = step(MER,RXSYM)
$\qquad$ ,MINMER] = step( )
[___, XMER] = step( $\qquad$
[___, NUMSYM] = step(___)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

MERDB= step (MER,REFSYM, RXSYM) returns the measured MER, MERDB, of the received signal RXSYM, based on reference signal REFSYM. MER values are measured in dB.

REFSYM. REFSYM and RXSYM inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type double. To set the interval over which the MER is measured, use the MeasurementIntervalSource and MeasurementInterval properties.

MERDB = step(MER, RXSYM) returns the measured MER of received signal RXSYM based on a reference signal specified in the ReceivedConstellation property.
[ ___ , MINMER] = step (___ ) returns the minimum MER, MINMER, given either of the two previous syntaxes.

To return minimum MER, set the MinimumMEROutputPort property to true. To set the interval over which MINMER is measured, use the MeasurementIntervalSource and MeasurementInterval properties.

$$
\left[\__{\ldots}, X M E R\right]=\operatorname{step}(\ldots \quad) \text { returns the } X \text {-percentile MER, XMER. }
$$

To return the $X$-percentile MER, set the XPercentileMEROutputPort property to true. XMER is the MER above which $X \%$ of the measurements fall, where $X$ is set by the XPercentileValue property. XMER is measured using all the input frames since the last reset.
[ ___ ,NUMSYM] = step( $\qquad$ ) returns the number of symbols, NUMSYM, used to calculate the $X$ percentile MER.

To return NUMSYM, set the SymbolCountOutputPort to true. NUMSYM is measured using all the input frames since the last reset.

Note MER specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MIMOChannel

Package: comm
Filter input signal through MIMO multipath fading channel

## Description

A comm.MIMOChannel object filters an input signal through a multiple-input/multiple-output (MIMO) multipath fading channel. This object models both Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 3-963 section.

To filter an input signal through a MIMO multipath fading channel:
1 Create the comm. MIMOChannel object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

mimochan $=$ comm.MIMOChannel
mimochan $=$ comm.MIMOChannel (Name, Value)

## Description

mimochan $=$ comm.MIMOChannel creates a multiple-input multiple-output (MIMO) frequencyselective or frequency-flat fading channel System object. This object filters a real or complex input signal through the multipath MIMO channel to obtain the channel-impaired signal.
mimochan = comm.MIMOChannel (Name, Value) sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Example: comm.MIMOChannel('SampleRate', 2)

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## SampleRate - Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

## Data Types: double

## PathDelays - Discrete path delay

0 (default) | scalar | row vector
Discrete path delay in seconds, specified as a scalar or row vector.

- When you set PathDelays to a scalar, the MIMO channel is frequency flat.
- When you set PathDelays to a vector, the MIMO channel is frequency selective.

Data Types: double
AveragePathGains - Average path gains (dB)
0 (default) | scalar | row vector
Average path gains in decibels, specified as a scalar or row vector. AveragePathGains must have the same size as PathDelays.
Data Types: double

## NormalizePathGains - Normalize path gains <br> true (default) | false

Normalize path gains, specified as true or false.

- When you set this property to true, the fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB .
- When you set this property to false, there is no normalization on path gains.

The average powers of the path gains are specified by the AveragePathGains property.
Data Types: logical

## FadingDistribution - Fading distribution

'Rayleigh' (default) | 'Rician'
Fading distribution to use for the channel, specified as 'Rayleigh' or 'Rician'.
Data Types: char

## KFactor - K-factor of Rician fading channel

3 (default) | positive scalar | row vector
K-factor of a Rician fading channel, specified as a positive scalar or a 1-by- $N_{\mathrm{P}}$ vector of positive-valued elements. $N_{P}$ equals number of path delays specified by the PathDelays property.

- If you set KFactor to a scalar, the first discrete path is a Rician fading process with a Rician Kfactor of KFactor. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set KFactor to a row vector, the discrete path corresponding to a positive element of the KFactor vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to a zero-valued element of the KFactor vector is a Rayleigh fading process.

## Dependencies

This property applies when FadingDistribution is Rician.
Data Types: double

## DirectPathDopplerShift - Doppler shifts for line-of-sight components (Hz)

0 (default) | scalar | row vector
Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This property must have the same size as KFactor.

- If you set DirectPathDopplerShift to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set DirectPathDopplerShift to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of DirectPathDopplerShift that correspond to positive elements in the KFactor vector.

## Dependencies

This property applies when FadingDistribution is Rician.
Data Types: double

## DirectPathInitialPhase - Initial phases for line-of-sight components (Radians) <br> 0 (default) | scalar | row vector

Initial phases for the line-of-sight components of the Rician fading channel in radians, specified as a scalar or row vector. This property must have the same size as KFactor.

- If you set DirectPathInitialPhase to a scalar, it represents the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set DirectPathInitialPhase to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the elements of DirectPathInitialPhase that correspond to positive elements in the KFactor vector.

## Dependencies

This property applies when FadingDistribution is Rician.
Data Types: double

## MaximumDopplerShift - Maximum Doppler shift for all channel paths (Hz)

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.
The Doppler shift applies to all channel paths. When you set this property to 0, the channel remains static for the entire input. You can use the reset object function to generate a new channel realization.

MaximumDopplerShift must be smaller than (SampleRate/10)/f for each path, where $f_{\mathrm{c}}$ represents the cutoff frequency factor of the path. For more information on the cutoff frequency, see Cutoff Frequency Factor on page 3-964.
Data Types: double

## DopplerSpectrum - Doppler spectrum shape for all channel paths

doppler('Jakes') (default)|doppler('Flat')|doppler('Rounded', ....)|
doppler('Bell', ...)|doppler('Asymmetric Jakes', ...)|doppler('Restricted
Jakes', ...)|doppler('Gaussian', ...)|doppler('BiGaussian', ...)
Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the doppler function or a 1-by- $N_{\mathrm{P}}$ cell array of such structures. The default value of this property is the Jakes Doppler spectrum (doppler('Jakes')).

- If you assign a single call to doppler, all paths have the same specified Doppler spectrum.
- If you assign a 1 -by- $N_{\mathrm{P}}$ cell array of calls to doppler using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case, $N_{\mathrm{P}}$ equals the value of the PathDelays property.

The maximum Doppler shift value necessary to specify the Doppler spectrum/spectra is given by the MaximumDopplerShift property.

## Dependencies

This property applies when MaximumDopplerShift is greater than zero.
If you assign the FadingTechnique property to 'Sum of sinusoids' ', you must set
DopplerSpectrum to doppler('Jakes').

## SpatialCorrelationSpecification - Spatial correlation specification

'Separate Tx Rx' (default)|'None'| 'Combined'
Spatial correlation specification, specified as 'Separate Tx Rx', 'None', or 'Combined'.

- Choose 'Spatial Tx Rx' to separately specify the transmit and receive spatial correlation matrices from which the number of transmit antenna ( $N_{\mathrm{T}}$ ) and number of receive antennas ( $N_{\mathrm{R}}$ ) are derived.
- Choose 'None ' to specify the number of transmit and receive antennas.
- Choose 'Combined ' to specify a single correlation matrix for the whole channel, from which the product of $N_{\mathrm{T}}$ and $N_{\mathrm{R}}$ is derived.

Data Types: char

## NumTransmitAntennas - Number of transmit antennas

2 (default) | positive integer
Number of transmit antennas, specified as a positive integer.

## Dependencies

This property applies when SpatialCorrelationSpecification is 'None ' or 'Combined'.
Data Types: double

## NumReceiveAntennas - Number of receive antennas

2 (default) | positive integer
Number of receive antennas, specified as a positive integer.

## Dependencies

This property applies when SpatialCorrelationSpecification is 'None ' or 'Combined'.

## Data Types: double

## TransmitCorrelationMatrix - Spatial correlation of transmitter [1 0; 0 1] (default) | matrix | 3-D array

Specify the spatial correlation of the transmitter as an $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$ matrix or $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$-by- $N_{\mathrm{P}}$ array. $N_{\mathrm{T}}$ is the number of transmit antennas, and $N_{\mathrm{P}}$ equals the value of the PathDelays property.

- If PathDelays is a scalar, the channel is frequency-flat, and TransmitCorrelationMatrix is an $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$ Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If PathDelays is a vector, the channel is frequency selective, and you can specify TransmitCorrelationMatrix as a matrix. Each path has the same transmit spatial correlation matrix.
- Alternatively, you can specify TransmitCorrelationMatrix as an $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$-by- $N_{\mathrm{P}}$ array, where each path can have its own different transmit spatial correlation matrix.

## Dependencies

This property applies when you set the SpatialCorrelationSpecification property to 'Separate Tx Rx'.

## Data Types: double

Complex Number Support: Yes

## ReceiveCorrelationMatrix - Spatial correlation of receiver

[1 0; 0 1] (default)| matrix|3-D array
Specify the spatial correlation of the receiver as an $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$ matrix or $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$-by- $N_{\mathrm{P}}$ array. $N_{\mathrm{R}}$ is the number of receive antennas, and $N_{\mathrm{P}}$ equals the value of the PathDelays property.

- If PathDelays is a scalar, the channel is frequency flat, and ReceiveCorrelationMatrix is an $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$ Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If PathDelays is a vector, the channel is frequency selective, and you can specify ReceiveCorrelationMatrix as a matrix. Each path has the same receive spatial correlation matrix.
- Alternatively, you can specify ReceiveCorrelationMatrix as an $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$-by- $N_{\mathrm{P}}$ array, where each path can have its own different receive spatial correlation matrix.

## Dependencies

This property applies when you set the SpatialCorrelationSpecification property to 'Separate Tx Rx'.

Data Types: double
Complex Number Support: Yes

## SpatialCorrelationMatrix - Combined spatial correlation matrix

 [1000; 0100 0; $0010 ; 0001]$ (default) $\mid$ matrix $\mid$ 3-D arrayCombined spatial correlation matrix, specified as an $N_{T R}$-by- $N_{\mathrm{TR}}$ matrix or $N_{\mathrm{TR}}$-by- $N_{\mathrm{TR}}$-by- $N_{\mathrm{P}}$ array, where $N_{\mathrm{TR}}=\left(N_{\mathrm{T}} \times N_{\mathrm{R}}\right)$, and $N_{\mathrm{P}}$ equals the value of the PathDelays property.

- If PathDelays is a scalar, the channel is frequency flat, and SpatialCorrelationMatrix is an $N_{T R}-$-by- $N_{\text {TR }}$ Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If PathDelays is a vector, the channel is frequency selective, and you can specify SpatialCorrelationMatrix as a matrix. Each path has the same spatial correlation matrix.
- Alternatively, you can specify SpatialCorrelationMatrix as an $N_{\mathrm{TR}}$-by- $N_{\mathrm{TR}}$-by- $N_{\mathrm{P}}$ array, where each path can have its own different combined spatial correlation matrix.

## Dependencies

This property applies when you set the SpatialCorrelationSpecification property to 'Combined '.
Data Types: double

## AntennaSelection - Antenna selection scheme

'Off' (default)|'Tx'|'Rx'|'Tx and Rx'
Antenna selection scheme, specified as 'Off', 'Tx', 'Rx', or 'Tx and Rx'.
Tx represents transmit antennas and $R x$ represents receive antennas. When you configure any antenna selection other than the default setting, the object requires one or more inputs to specify which antennas are selected for signal transmission. For more information, see Antenna Selection on page 3-964.
Data Types: char

## NormalizeChannelOutputs - Normalize channel outputs <br> true (default) | false

Normalize channel outputs, specified as true or false.

- When you set this property to true, channel outputs are normalized by the number of receive antennas.
- When you set this property to false, channel outputs are not normalized.

Data Types: logical
FadingTechnique - Channel model fading technique
'Filtered Gaussian noise' (default)|'Sum of sinusoids'
Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char
NumSinusoids - Number of sinusoids used
48 (default) | positive integer
Number of sinusoids used to model the fading process, specified as a positive integer.

## Dependencies

This property applies when FadingTechnique is 'Sum of sinusoids'.
Data Types: double

## InitialTimeSource - Source to control start time of fading process <br> 'Property' (default)|'Input port'

Source to control the start time of the fading process, specified as 'Property ' or 'Input port'.

- 'Property ' -- Use the InitialTime property to set the initial time offset.
- 'Input port' -- Specify the start time of the fading process by using the initialtime input to the object. The input value can change in consecutive calls to the object.

## Dependencies

This property applies when FadingTechnique is 'Sum of sinusoids'.

## InitialTime - Initial time offset

0 (default) | nonnegative scalar
Initial time offset for the fading model in seconds, specified as a nonnegative scalar.
When InitialTime is not a multiple of $1 /$ SampleRate, it is rounded up to the nearest sample position.

## Dependencies

This property applies when the FadingTechnique property is set to 'Sum of sinusoids ' and the InitialTimeSource property is set to 'Property'.
Data Types: double

## RandomStream - Source of random number stream

'Global stream' (default)|'mt19937ar with seed'
Source of the random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- 'Global stream' -- The current global random number stream is used for normally distributed random number generation. In this case, the reset object function resets the filters only.
- 'mt19937ar with seed' -- The mt19937ar algorithm is used for normally distributed random number generation. In this case, the reset object function resets the filters and also reinitializes the random number stream to the value of the Seed property.

## Data Types: char

## Seed - Initial seed of mt19937ar random number stream

73 (default) | nonnegative integer
Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. When the reset object function is called, the mt19937ar random number stream is reinitialized to the Seed value.

## Dependencies

This property applies when you set the RandomStream property to 'mt19937ar with seed'.

## PathGains0utputPort - Option to output path gains

false (default) | true

Option to output path gains, specified as false or true. Set this property to true to output the channel path gains of the underlying fading process.

## Data Types: logical

## Visualization - Channel visualization

'Off' (default)|'Impulse response'|'Frequency response'|'Impulse and frequency responses'|'Doppler spectrum'

Channel visualization preference, specified as 'Off', 'Impulse response', 'Frequency response','Impulse and frequency responses', or 'Doppler spectrum'. When visualization is on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

## Dependencies

Visualization applies only when the FadingTechnique property is set to 'Filtered Gaussian noise'.

## AntennaPairsToDisplay - Transmit-receive antenna pair to display

[1 1] (default) | row vector
Transmit-receive antenna pair to display, specified as a 1-by-2 vector, where the first element corresponds to the desired transmit antenna and the second element corresponds to the desired receive antenna. At this time, only a single pair can be displayed.

## Dependencies

This property applies when Visualization is not Off.

## PathsForDopplerDisplay - Path for which the Doppler spectrum is displayed <br> 1 (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to $N_{\mathrm{P}}$, where $N_{\mathrm{P}}$ equals the value of the PathDelays property.

## Dependencies

This property applies when Visualization is set to 'Doppler spectrum'.

## SamplesToDisplay - Percentage of samples to display <br> 25\% (default) | 10\% | 50\% | 100\%

Percentage of samples to display, specified as $10 \%, 25 \%, 50 \%$, or $100 \%$. Increasing the percentage improves display accuracy at the expense of simulation speed.

## Dependencies

This property applies when Visualization is 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

## Usage

## Syntax

```
outsignal = mimochan(insignal)
```

```
outsignal = mimochan(insignal,seltx)
outsignal = mimochan(insignal,selrx)
outsignal = mimochan(insignal,seltx,selrx)
outsignal = mimochan( ___,initialtime)
[outsignal,pathgains] = mimochan(
```

$\qquad$

```
Description
```

outsignal $=$ mimochan(insignal) filters the input signal through the MIMO fading channel specified by mimochan and returns the result in outsignal.
outsignal $=$ mimochan(insignal, seltx) turns on the transmit antennas selected by seltx for channel processing.

This syntax applies when you set the AntennaSelection property of the object to 'Tx'.
For example, to select the first and third transmit antenna index as active:

```
mimochan = comm.MIMOChannel('AntennaSelection','Tx');
seltx = [1 0 1];
outsignal = mimochan(insignal,seltx);
```

outsignal $=$ mimochan(insignal, selrx) turns on receive antennas, selected by selrx for
channel processing.

This syntax applies when you set the AntennaSelection property of the object to ' Rx '.
For example, to select the second receive antenna index as active:

```
mimochan = comm.MIMOChannel('AntennaSelection','Rx');
selrx = [0 1];
outsignal = mimochan(insignal,selrx);
```

outsignal = mimochan(insignal, seltx, selrx) turns on transmit and receive antennas,
selected by seltx and selrx for channel processing.

This syntax applies when you set the AntennaSelection property of the object to ' $T x$ and $R x$ '.
For example:

```
mimochan = comm.MIMOChannel('AntennaSelection','Tx and Rx');
seltx = [ll 1];
selrx = [0 1];
outsignal = mimochan(insignal,selrx);
```

outsignal = mimochan(
$\qquad$ , initialtime) specifies a start time for the fading process.

This syntax applies when you set the FadingTechnique property of the object to 'Sum of sinusoids' and the InitialTimeSource property of the object to 'Input port'. The syntax supports input options from prior syntaxes.
[outsignal,pathgains] = mimochan( $\qquad$ ) also returns the MIMO channel path gains for antenna selection schemes. The syntax supports input options from prior syntaxes.

## Input Arguments

## insignal - Input signal

scalar | vector | matrix
Input signal, specified as a scalar, an $N_{\mathrm{S}}$ element column vector, an $N_{\mathrm{S}}$-by- $N_{\mathrm{T}}$ matrix, or an $N_{\mathrm{S}}$-by- $N_{\mathrm{ST}}$ matrix.

- $N_{\mathrm{S}}$ is the number of samples.
- $N_{\mathrm{T}}$ is the number of transmit antennas. $N_{\mathrm{T}}$ is determined by the TransmitCorrelationMatrix or NumTransmitAntennas property values of the object.
- $N_{\mathrm{ST}}$ is the number of selected transmit antennas, as determined by the number of elements set to 1 in the vector provided to the seltx input.

The number of transmit antennas is determined by the TransmitCorrelationMatrix or NumTransmitAntennas property values of the object.
Data Types: double \| single
Complex Number Support: Yes

## seltx - Select active transmit antennas

binary vector
Select active transmit antennas, specified as a 1-by- $N_{T}$ binary vector. $N_{T}$ represents the number of transmit antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

Data Types: double

## selrx - Select active receive antennas

binary vector
Select active receive antennas, specified as a 1-by- $N_{\mathrm{R}}$ binary vector. $N_{\mathrm{R}}$ represents the number of receive antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

Data Types: double

## initialtime - Initial time offset

0 (default) | nonnegative scalar
Initial time offset for the fading model in seconds, specified as a nonnegative scalar.
The initial time offset must be greater than the last frame end time. When initialtime is not a multiple of $1 /$ SampleRate, it is rounded up to the nearest sample position.
Data Types: double

## Output Arguments

## outsignal - Output signal

matrix
Output data signal, returned as an $N_{\mathrm{S}}$-by- $N_{\mathrm{R}}$ or $N_{\mathrm{S}}$-by- $N_{\mathrm{SR}}$ matrix.

- $N_{\mathrm{S}}$ is the number of samples.
- $\quad N_{\mathrm{R}}$ is the number of receive antennas. $N_{\mathrm{R}}$ is determined by the ReceiveCorrelationMatrix or NumReceiveAntennas property values of the object.
- $N_{\mathrm{SR}}$ is the number of selected receive antennas, as determined by the number of elements set to 1 in the vector provided to the selrx input.

## pathgains - Output path gains

4-D array
Output path gains, returned as an $N_{\mathrm{S}}$-by- $N_{\mathrm{P}}$-by- $N_{\mathrm{T}}$-by- $N_{\mathrm{R}}$ array with NaN values for the unselected transmit-receive antenna pairs.

- $N_{\mathrm{S}}$ is the number of samples.
- $N_{P}$ equals the value of the PathDelays property.
- $\quad N_{\mathrm{T}}$ is the number of transmit antennas.
- $\quad N_{\mathrm{R}}$ is the number of receive antennas.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Specific to comm.MIMOChannel

info Characteristic information about fading channel object

## Common to All System Objects

| step | Run System object algorithm <br> release |
| :--- | :--- |
| Release resources and allow changes to System object property values and input <br> characteristics |  |
| reset | Reset internal states of System object |

## Note

- If you set the RandomStream property of the object to 'Global stream' , the reset object function resets the filters only.
- If you set RandomStream to 'mt19937ar with seed', the reset object function resets the filters and also reinitializes the random number stream to the value of the Seed property.

## Examples

## Pass QPSK Data Through 4-by-2 MIMO Channel

Create a 4 -by-2 MIMO channel by using the MIMO channel System object. Pass modulated and spatially encoded data through the channel.

Generate QPSK-modulated data.

```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Create an orthogonal space-time block encoder to encode the modulated data into four spatially separated streams. Encode the data.

```
ostbc = comm.OSTBCEncoder('NumTransmitAntennas',4,'SymbolRate',1/2);
txSig = ostbc(modData);
```

Create a MIMO channel object, using name-value pairs to set the properties. The channel consists of two paths with a maximum Doppler shift of 5 Hz . Set the SpatialCorrelationSpecification property to 'None', which requires that you specify the number of transmit and receive antennas. Set the number of transmit antennas to 4 and the number of receive antennas to 2 .

```
mimochannel = comm.MIMOChannel(...
    'SampleRate',1000, ...
    'PathDelays',[0 2e-3], ...
    'AveragePathGains',[0 -5], ...
    'MaximumDopplerShift',5, ...
    'SpatialCorrelationSpecification','None', ...
    'NumTransmitAntennas',4, ...
    'NumReceiveAntennas',2);
```

Pass the modulated and encoded data through the MIMO channel.

```
rxSig = mimochannel(txSig);
```

Create a time vector, $t$, to use for plotting the power of the received signal.

```
ts = 1/mimochannel.SampleRate;
t = (0:ts:(size(txSig,1)-1)*ts)';
```

Calculate and plot the power of the signal received by antenna 1.

```
pwrdB = 20*log10(abs(rxSig(:,1)));
plot(t,pwrdB)
xlabel('Time (s)')
ylabel('Power (dBW)')
```

## Examine Spatial Correlation Characteristics of 2-by-2 Rayleigh Fading Channel

Without specifying antenna selection, filter PSK-modulated data through a 2-by-2 Rayleigh fading channel and examine the spatial correlation characteristics of the channel realization. Use the release object function to unlock the object to set the AntennaSelection property to 'Tx and $R x$ ' and then confirm the unselected transmit-receive antenna pairs.

## Examine Spatial Correlation Characteristics Without Specifying Antenna Selection

Create a PSK modulator System object ${ }^{\mathrm{TM}}$ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],1e5,1));
```

Split the modulated data into two spatial streams.
channelInput = reshape(modData,[2 5e4]).';
Create a 2-by-2 MIMO channel System object with two discrete paths. Each path has different transmit and receive correlation matrices, specified by the TransmitCorrelationMatrix and ReceiveCorrelationMatrix properties.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, 'PathDelays',[0 1e-3], ...
    'AveragePathGains',[3 5], 'NormalizePathGains',false, 'MaximumDopplerShift',5, ...
```

```
'TransmitCorrelationMatrix',cat(3,eye(2),[1 0.1;0.1 1]), ...
'ReceiveCorrelationMatrix',cat(3,[1 0.2;0.2 1],eye(2)), ...
'RandomStream','mt19937ar with seed', 'Seed',33, 'PathGainsOutputPort',true);
```

Filter the modulated data using the MIMO channel object.

```
[~,pathGains] = mimoChan(channelInput);
```

The transmit spatial correlation for the first discrete path at the first receive antenna is specified as an identity matrix in the TransmitCorrelationMatrix property. Confirm that the channel output pathGains exhibits the same statistical characteristics by using the corrcoef function.

```
disp('Tx spatial correlation, first path, first Rx:');
Tx spatial correlation, first path, first Rx:
disp(corrcoef(squeeze(pathGains(:,1,:,1))));
1.0000 + 0.0000i 0.0357 - 0.0253i
0.0357 + 0.0253i 1.0000 + 0.0000i
```

The transmit spatial correlation for the second discrete path at the second receive antenna is specified as [1 0.1;0.1 1] in the TransmitCorrelationMatrix property. Confirm that the channel output pathGains exhibits the same statistical characteristics.

```
disp('Tx spatial correlation, second path, second Rx:');
Tx spatial correlation, second path, second Rx:
disp(corrcoef(squeeze(pathGains(:,2,:,2))));
    1.0000 + 0.0000i 0.0863 + 0.0009i
    0.0863-0.0009i 1.0000 + 0.0000i
```

The receive spatial correlation for the first discrete path at the second transmit antenna is specified as [10.2;0.2 1] in the ReceiveCorrelationMatrix property. Confirm that the channel output pathGains exhibits the same statistical characteristics.

```
disp('Rx spatial correlation, first path, second Tx:');
Rx spatial correlation, first path, second Tx:
disp(corrcoef(squeeze(pathGains(:,1,2,:))));
    1.0000 + 0.0000i 0.2236 + 0.0550i
    0.2236 - 0.0550i 1.0000 + 0.0000i
```

The receive spatial correlation for the second discrete path at the first transmit antenna is specified as an identity matrix in the ReceiveCorrelationMatrix property. Confirm that the channel output pathGains exhibits the same statistical characteristics.

```
disp('Rx spatial correlation, second path, first Tx:');
Rx spatial correlation, second path, first Tx:
disp(corrcoef(squeeze(pathGains(:,2,1,:))));
    1.0000 + 0.0000i -0.0088 - 0.0489i
    -0.0088 + 0.0489i 1.0000 + 0.0000i
```

## Examine Spatial Correlation Characteristics Specifying Antenna Selection

Enable transmit and receive antenna selection for the mimoChan object. The input frame size is shortened to 100.

```
release(mimoChan);
mimoChan.AntennaSelection = 'Tx and Rx';
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],100,1));
```

Select the first transmit antenna and second receive antenna.

```
[channelOutput,pathGains] = mimoChan(modData,[1 0],[0 1]);
```

Confirm that the path gains that MATLAB® returns have NaN values for the unselected transmitreceive antenna pairs.

```
disp('Return 1 if the path gains for the second transmit antenna are NaN:');
Return 1 if the path gains for the second transmit antenna are NaN:
disp(isequal(isnan(squeeze(pathGains(:,:,2,:))), ones(100,2,2)));
    1
disp('Return l if the path gains for the first receive antenna are NaN:');
Return 1 if the path gains for the first receive antenna are NaN:
disp(isequal(isnan(squeeze(pathGains(:,:,:,1))), ones(100,2,2)));
    1
```

## Display Impulse and Frequency Responses of Frequency Selective Channel

Create a frequency selective MIMO channel and display its impulse and frequency responses.
Set the sample rate to 10 MHz and specify path delays and gains using the extended vehicular A (EVA) channel parameters. Set the maximum Doppler shift to 70 Hz .

```
fs = 10e6; % Hz
pathDelays = [0 30 150 310 370 710 1090 1730 2510]*1e-9; % sec
avgPathGains =[[0-1.5 -1.4 -3.6 -0.6 -9.1 -7 -12 -16.9]; % dB
fD = 70; % Hz
```

Create a 2 x 2 MIMO channel System object with the previously defined parameters and set the Visualization property to Impulse and frequency responses using name-value pairs. By default, the antenna pair corresponding to transmit antenna 1 and receive antenna 1 will be displayed.

```
mimoChan = comm.MIMOChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data and pass it through the MIMO channel. The impulse response plot allows you to easily identify the individual paths and their corresponding filter coefficients. The frequency selective nature of the EVA channel is shown by the frequency response plot.

```
x = randi([0 1],1000,2);
y = mimoChan(x);
```

Processing

Release mimoChan and set the AntennaPairsToDisplay property to [2 1] to view the antenna pair corresponding to transmit antenna 2 and receive antenna 1. It is necessary to release the object as the property is non-tunable.
release(mimoChan)
mimoChan.AntennaPairsToDisplay = [2 1];
$y=$ mimoChan $(x)$;

Processing

## Display Doppler for $\mathbf{2 x} \mathbf{2}$ MIMO Channel

Create and visualize the Doppler spectra of a MIMO channel having two paths.
Construct a cell array of Doppler structures to be used in creating the channel. The Doppler spectrum of the first path is set to have a bell shape while the second path is set to be flat.

```
dp{1} = doppler('Bell');
dp{2} = doppler('Flat');
```

Create a default 2 x 2 MIMO channel with two paths and a 100 Hz maximum Doppler shift using namevalue pairs. Set the Visualization property to Doppler spectrum and set
PathsForDopplerDisplay to 1. The Doppler spectrum of the first path will be displayed.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, ...
    'PathDelays',[0 0.002], ...
    'AveragePathGains',[0 -3], ...
    'MaximumDopplerShift',100, ...
    'DopplerSpectrum',dp, ...
    'Visualization','Doppler spectrum', ...
    'PathsForDopplerDisplay',1);
```

Pass random data through the MIMO channel to generate the Doppler spectrum of the first path. Since the Doppler spectrum plot only updates when its buffer is filled, the mimoChan function is invoked multiple times to improve the accuracy of the estimate. Observe that the spectrum has a bell shape and that its minimum and maximum frequencies fall within the limits set by MaximumDopplerShift.

```
for k = 1:25
    x = randi([0 1],10000,2);
    y = mimoChan(x);
end
```

Release mimoChan and set the PathsForDopplerDisplay property to 2. It is necessary to release the object as the property is non-tunable. Call the function multiple times to display the Doppler spectrum of the second path. Observe that the spectrum is flat.

```
release(mimoChan)
mimoChan.PathsForDopplerDisplay = 2;
for k = 1:25
    x = randi([0 1],10000,2);
    y = mimoChan(x);
end
```

## Model MIMO Channel Using Sum-of-Sinusoids Technique

Create a MIMO channel object and pass data through it using the sum-of-sinusoids technique. The example demonstrates how the channel state is maintained in cases in which data is discontinuously transmitted.

Define the overall simulation time and three time segments for which data will be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One 1000 -sample, continuous data sequence is transmitted at time 0 . Three 100 -sample data packets are transmitted at time 0.1 s , 0.4 s , and 0.7 s .

```
t0 = 0:0.001:0.999; % Transmission 0
t1 = 0.1:0.001:0.199; % Transmission 1
t2 = 0.4:0.001:0.499; % Transmission 2
t3 = 0.7:0.001:0.799; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],1000,2); % 1000 samples
d1 = randi([0 1],100,2); % 100 samples
```

```
d2 = randi([0 1],100,2); % 100 samples
d3 = randi([0 1],100,2); % 100 samples
```

Create a flat fading 2 x 2 MIMO channel System object with the Sum of sinusoids fading technique. So that results can be repeated, specify a seed using a name-value pair. As the InitialTime property is not specified, the fading channel will be simulated from time 0 . Enable the path gains output port.

```
mimoChan1 = comm.MIMOChannel('SampleRate',1000, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the MIMO channel System object. Set the InitialTimeSource property to Input port so that the fading channel offset time can be specified as an input argument to the mimoChan function.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first channel object, mimoChan1. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.
[ $\sim, \mathrm{pg} 0]=$ mimoChan1(d0);
Pass random data through the second channel object, mimoChan2, where the initial time offsets are provided as input arguments.
$[\sim, \mathrm{pg} 1]=$ mimoChan2 $(\mathrm{d} 1,0.1) ;$
$[\sim, \mathrm{pg} 2]=$ mimoChan2 $(\mathrm{d} 2,0.4) ;$
$[\sim, \mathrm{pg} 3]=$ mimoChan2 $(\mathrm{d} 3,0.7) ;$
Compare the number of samples processed by the two channels using the info method. You can see that 1000 samples were processed by mimoChan1 while only 300 were processed by mimoChan2.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
ans = 1\times2
    1000
    300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. Observe that the gains for the three segments perfectly match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```

## Calculate Execution Time Advantage Using Sum of Sinusoids

Demonstrate the advantage of using the sum of sinusoids fading technique when simulating a channel with burst data.

Set the simulation parameters such that the sampling rate is 100 kHz , the total simulation time is 100 seconds, and the duty cycle for the burst data is $25 \%$.

```
fs = 1e5; % Hz
tsim = 100; % seconds
dutyCycle = 0.25;
```

Create a flat fading $2 \times 2$ MIMO channel object using the default Filtered Gaussian noise technique.

```
fgn = comm.MIMOChannel('SampleRate',fs);
```

Create a similar MIMO channel object using the Sum of sinusoids technique where the fading process start times are given as an input argument.

```
sos = comm.MIMOChannel('SampleRate',fs, ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',48, ...
    'InitialTimeSource','Input port');
```

Run a continuous sequence of random bits through the filtered Gaussian noise MIMO channel object. Use the tic/toc stopwatch timer functions to measure the execution time of the function call.

```
tic
y = fgn(randi([0 1],fs*tsim,2));
tFGN = toc;
```

To transmit a data burst each second, pass random bits through the sum of sinusoids MIMO channel object by calling the sos function inside of a for loop. Use the tic/toc stopwatch timer to measure the execution time.

```
tic
for k = 1:tsim
    z = sos(randi([0 1],fs*dutyCycle,2),0.5+(k-1));
end
tSOS = toc;
```

Compare the ratio of the sum of sinusoids execution time to the filtered Gaussian noise execution time. The ratio is less than one, which indicates that the sum of sinusoids technique is faster.

```
tSOS/tFGN
```

ans $=0.2912$

## Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all $\left(N_{T} \times N_{R}\right)$ links of the MIMO channel. Each link comprises all multipaths for that link.

## The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$
R_{H}=E\left[R_{t} \otimes R_{r}\right]
$$

- The $\otimes$ symbol represents the Kronecker product.
- $R_{\mathrm{t}}$ represents the correlation matrix at the transmit side: $R_{t}=E\left[H^{H} H\right]$, of size $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$.
- $R_{\mathrm{r}}$ represents the correlation matrix at the receive side: $R_{r}=E\left[H H^{H}\right]$, of size $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$.

You can obtain a realization of the MIMO channel matrix as:

$$
H=R_{r}^{\frac{1}{2}} A R_{t}^{\frac{1}{2}}
$$

$A$ is an $N_{\mathrm{R}}$-by- $N_{\mathrm{T}}$ matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

## Cutoff Frequency Factor

The cutoff frequency factor, $f_{c}$, is determined for different Doppler spectrum types.

- For any Doppler spectrum type other than Gaussian and biGaussian, $f_{c}$ equals 1.
- For a doppler('Gaussian') spectrum type, $f_{\mathrm{c}}$ equals NormalizedStandardDeviation $\times \sqrt{2 \log 2}$.
- For a doppler('BiGaussian') spectrum type:
- If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0 , then $f_{c}$ equals NormalizedStandardDeviation (1) $\times \sqrt{2 \log 2}$.
- If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0 , then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation (2) $\times \sqrt{2 \log 2}$.
- If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation(1) $\times \sqrt{2 \log 2}$.
- In all other cases, $f_{\mathrm{c}}$ equals 1 .

## Antenna Selection

When the object is in antenna selection mode, it uses the following algorithms to process an input signal:

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the non-selected links are populated with NaN .
- The spatial correlation only applies to the selected transmit and/or receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. In other words, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

## comm.MLSEEqualizer

Package: comm
Equalize using maximum likelihood sequence estimation

## Description

The MLSEEqualizer object uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The object processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal. This processing uses an estimate of the channel modeled as a finite impulse response (FIR) filter.

To equalize a linearly modulated signal and output the maximum likelihood sequence estimate:
1 Define and set up your maximum likelihood sequence estimate equalizer object. See "Construction" on page 3-966.
2 Call step to equalize a linearly modulated signal and output the maximum likelihood sequence estimate according to the properties of comm.MLSEEqualizer. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.MLSEEqualizer creates a maximum likelihood sequence estimation equalizer (MLSEE) System object, H. This object uses the Viterbi algorithm and a channel estimate to equalize a linearly modulated signal that has been transmitted through a dispersive channel.

H = comm.MLSEEqualizer(Name,Value) creates an MLSEE object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.MLSEEqualizer(CHANNEL, Name, Value) creates an MLSEE object, H. This object has the Channel property set to CHANNEL, and the other specified properties set to the specified values.

## Properties

## ChannelSource

Source of channel coefficients
Specify the source of the channel coefficients as one of Input port | Property. The default is Property.

## Channel

Channel coefficients

Specify the channel as a numeric, column vector containing the coefficients of an FIR filter. The default is $[1 ; 0.7 ; 0.5 ; 0.3]$. The length of this vector determines the memory length of the channel. This must be an integer multiple of the samples per symbol, that you specify in the SamplesPerSymbol on page 3-0 property. This property applies when you set the ChannelSource on page 3-0 property to Property.

## Constellation

Input signal constellation
Specify the constellation of the input modulated signal as a complex vector. The default is [ $1+1 \mathrm{i}$ -1+1i -1-1i 1-1i].

## TracebackDepth

Traceback depth of Viterbi algorithm
Specify the number of trellis branches (the number of symbols), the Viterbi algorithm uses to construct each traceback path. The default is 21 . The traceback depth influences the decoding accuracy and delay. The decoding delay represents the number of zero symbols that precede the first decoded symbol in the output. When you set the TerminationMethod on page 3-0 property to Continuous, the decoding delay equals the number of zero symbols of this property. When you set the TerminationMethod property to Truncated, there is no output delay.

## TerminationMethod

Termination method of Viterbi algorithm
Specify the termination method of the Viterbi algorithm as one of Continuous | Truncated. The default is Truncated. When you set this property to Continuous, the object initializes the Viterbi algorithm metrics of all the states to 0 in the first call to the step method. Then, the object saves its internal state metric at the end of each frame, for use with the next frame. When you set this property to Truncated, the object resets at every frame. The Viterbi algorithm processes each frame of data independently, resetting the state metric at the end of each frame. The traceback path always starts at the state with the minimum metric. The initialization of the state metrics depends on whether you specify a preamble or postamble. If you set the PreambleSource on page 3-0 property to None, the object initializes the metrics of all the states to 0 at the beginning of each data frame. If you set the PreambleSource property to Property, the object uses the preamble that you specify at the Preamble on page 3-0 property, to initialize the state metrics at the beginning of each data frame. When you specify a preamble, the traceback path ends at one of the states represented by that preamble. If you set the PostambleSource on page 3-0 property to None, the traceback path starts at the state with the smallest metric. If you set the PostambleSource property to Property, the traceback path begins at the state represented by the postamble that you specify at the Postamble on page 3-0 property. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble. The decoder then begins traceback decoding at that state. When you set this property to Truncated, the step method input data signal must contain at least TracebackDepth on page 30 symbols, not including an optional preamble.

## ResetInputPort

Enable equalizer reset input
Set this property to true to enable an additional input to the step method. The default is false. When this input is a nonzero, double-precision or logical scalar value, the object resets the states of
the equalizer. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

## PreambleSource

Source of preamble
Specify the source of the preamble that is expected to precede the input signal. Choose from None |
Property. The default is None. Set this property to Property to specify a preamble using the Preamble on page 3-0 property. This property applies when you set the TerminationMethod on page 3-0 property to Truncated.

## Preamble

Preamble that precedes input signals
Specify a preamble that is expected to precede the data in the input signal as an integer, row vector. The default is [ $\left.\begin{array}{llll}0 & 3 & 2 & 1\end{array}\right]$. The values of the preamble should be between 0 and $M-1$, where $M$ is the length of the signal constellation that you specify in the Constellation on page 3-0 property. An integer value of $k-1$ in the vector corresponds to the $k$-th entry in the vector stored in the Constellation property. This property applies when you set the TerminationMethod on page 30 property to Truncated and the PreambleSource on page 3-0 property to Property.

## PostambleSource

Source of postamble
Specify the source of the postamble that is expected to follow the input signal. Choose from None | Property. The default is None. Set this property to Property to specify a postamble in the Postamble on page 3-0 property. This property applies when you set the TerminationMethod on page 3-0 property to Truncated.

## Postamble

Postamble that follows input signals
Specify a postamble that is expected to follow the data in the input signal as an integer row vector. The default is [ $\left.\begin{array}{llll}0 & 2 & 3 & 1\end{array}\right]$. The values of the postamble should be between 0 and $M-1$. In this case, $M$ indicates the length of the Constellation on page 3-0 property. An integer value of $k-1$ in the vector corresponds to the $k$-th entry in the vector specified in the Constellation property. This property applies when you set the TerminationMethod on page 3-0 property to Truncated and

## SamplesPerSymbol

Number of samples per symbol
Specify the number of samples per symbol in the input signal as an integer scalar value. The default is 1 .

## Examples

## MLSE Equalize QPSK Signal Through Dispersive Channel

This example shows how to use an MLSE equalizer to remove the effects of a frequency-selective channel.

Specify static channel coefficients.

```
chCoeffs = [.986; .845; .237; .12345+.31i];
```

Create an MLSE equalizer object. Create an error rate calculator object.

```
mlse = comm.MLSEEqualizer('TracebackDepth',10,\ldots.
    'Channel',chCoeffs,'Constellation',pskmod(0:3,4,pi/4));
errorRate = comm.ErrorRate;
```

The main processing loop includes these steps:

- Data generation
- QPSK modulation
- Channel filtering
- Signal equalization
- QPSK demodulation
- Error computation
for $n=1: 50$
data= randi([0 3],100,1);
modSignal = pskmod(data,4,pi/4,'gray');
\% Introduce channel distortion.
chanOutput = filter(chCoeffs,1,modSignal);
\% Equalize the channel output and demodulate.
eqSignal = mlse(chanOutput);
demodData = pskdemod(eqSignal,4,pi/4,'gray');
\% Compute BER.
errorStats = errorRate(data,demodData);
end

Display the bit error rate and the number of errors.

```
ber = errorStats(1)
numErrors = errorStats(2)
ber =
    0
numErrors =
    0
```

Plot the signal constellation prior to equalization.
constDiagram = comm. ConstellationDiagram; constDiagram( chanOutput)

Plot the signal constellation after equalization.
constDiagram(eqSignal)

The equalized symbols align perfectly with the QPSK reference constellation.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MLSE Equalizer block reference page. The object properties correspond to the block parameters.

## reset

System object: comm.MLSEEqualizer
Package: comm
Reset states of MLSEE object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the MLSEEqualizer object, H .

## step

System object: comm.MLSEEqualizer
Package: comm
Equalize using maximum likelihood sequence estimation

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )
Y = step(H,X,CHANNEL)
Y = step(H,X,RESET)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ equalizes the linearly modulated data input, X , using the Viterbi algorithm. The step method outputs $Y$, the maximum likelihood sequence estimate of the signal. Input $X$ must be a column vector of data type double or single.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{CHANNEL})$ uses CHANNEL as the channel coefficients when you set the ChannelSource property to 'Input port'. The channel coefficients input, CHANNEL, must be a numeric, column vector containing the coefficients of an FIR filter in descending order of powers of $z$. The length of this vector is the channel memory, which must be an integer multiple of the samples per input symbol specified in the SamplesPerSymbol property.
$Y=$ step ( $\mathrm{H}, \mathrm{X}, \mathrm{RESET}$ ) uses RESET as the reset signal when you set the TerminationMethod property to 'Continuous' and the ResetInputPort property to true. The object resets when RESET has a non-zero value. RESET must be a double precision or logical scalar. You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties. For example, $\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{CHANNEL}$, RESET $)$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MSKDemodulator

Package: comm
Demodulate using MSK method and the Viterbi algorithm

## Description

The comm.MSKDemodulator object demodulates a signal that was modulated using the minimum shift keying method. The object expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. The initial phase offset property sets the initial phase of the modulated waveform.

To demodulate a signal that was modulated using minimum shift keying:
1 Define and set up your MSK demodulator object. See "Construction" on page 3-975.
2 Call step to demodulate the signal according to the properties of comm.MSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.MSKDemodulator creates a demodulator System object, H. This object demodulates the input minimum shift keying (MSK) modulated data using the Viterbi algorithm.

H = comm.MSKDemodulator(Name, Value) creates an MSK demodulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer values. The default is false.
When you set this property to false, the step method outputs a column vector with a length equal to $N /$ SamplesPerSymbol on page 3-0.$N$ represents the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are -1 or 1 .

When you set the BitOutput on page 3-0 property to true, the step method outputs a binary column vector with a length equal to N/SamplesPerSymbol. The vector elements are bit values of 0 or 1 .

## InitialPhaseOffset

Initial phase offset
Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is 0 .

## SamplesPerSymbol

Number of samples per input symbol
Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is 8 .

## TracebackDepth

Traceback depth for Viterbi algorithm
Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The default is 16 . The value of this property is also the output delay This value indicates number of zero symbols that precede the first meaningful demodulated symbol in the output.

## OutputDataType

Data type of output
Specify the output data type as one of int8|int16|int32|double, when you set the Bit0utput on page 3-0 property to false. The default is double.

When you set the BitOutput property to true, specify the output data type as one of logical| double.

## Methods

reset Reset states of the MSK demodulator object
step Demodulate using MSK method and the Viterbi algorithm

## Common to All System Objects

release Allow System object property value changes

## Examples

## Demodulate an MSK signal with bit inputs and phase offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a
% phase offset of pi/4.
    hMod = comm.MSKModulator('BitInput', true, ...
    'InitialPhaseOffset', pi/4);
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.MSKDemodulator('Bit0utput', true, ...
```

'InitialPhaseOffset', pi/4);
\% Create an error rate calculator, account for the delay caused by the Viterbi algorithm hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
for counter = 1:100
\% Transmit 100 3-bit words
data $=$ randi([0 1],300,1);
modSignal = step(hMod, data);
noisySignal = step(hAWGN, modSignal);
receivedData $=$ step(hDemod, noisySignal);
errorStats $=$ step(hError, data, receivedData);
end
fprintf('Error rate $=\% f \backslash n N u m b e r ~ o f ~ e r r o r s ~=~ \% d \backslash n ', ~ . . . ~$ errorStats(1), errorStats(2))

Error rate $=0.000000$
Number of errors $=0$

## Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1 .

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 - 1.0000i
    -1.0000 + 0.0000i
    0.0000 + 1.0000i
    1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5×1
            0
    -1.5708
    -3.1416
    -4.7124
    -6.2832
```

A sequence of zeros causes the phase to shift by $-\Pi / 2$ between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 + 1.0000i
    -1.0000 - 0.0000i
    0.0000 - 1.0000i
    1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5x1
```

    0
    1.5708
3.1416
4.7124
6.2832

A sequence of ones causes the phase to shift by $+\pi / 2$ between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is $\pi / 2$, which is a modulation index of 0.5 .

## Extended Capabilities

## Description

reset $(\mathrm{H})$ resets the states of the MSKDemodulator object, H .

## step

System object: comm.MSKDemodulator
Package: comm
Demodulate using MSK method and the Viterbi algorithm

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the MSK demodulator System object, H , and returns Y. X must be a double or single precision column vector with a length equal to an integer multiple of the number of samples per symbol you specify in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.MSKModulator

Package: comm
Modulate using MSK method

## Description

The MSKModulator object modulates using the minimum shift keying method. The output is a baseband representation of the modulated signal. The initial phase offset property sets the initial phase of the output waveform, measured in radians.

To modulate a signal using minimum shift keying:
1 Define and set up your MSK modulator object. See "Construction" on page 3-981.
2 Call step to modulate the signal according to the properties of comm.MSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm.MSKModulator creates a modulator System object, H. This object modulates the input signal using the minimum shift keying (MSK) modulation method.

H = comm.MSKModulator(Name, Value) creates an MSK modulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false.
When you set the BitInput on page 3-0 property to false, the step method input must be a column vector with a double-precision or signed integer data type and of values equal to -1 or 1 .

When you set the BitInput property to true, the step method input requires double-precision or logical data type column vector of 0 s and 1 s .

## InitialPhaseOffset

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is 0 .

## SamplesPerSymbol

Number of samples per output symbol
Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is 8 . The upsampling factor indicates the number of output samples that the step method produces for each input sample.

## OutputDataType

Data type of output
Specify output data type as one of double | single. The default is double.

## Methods

| reset | Reset states of the MSK modulator object |
| :--- | :--- |
| step | Modulate using MSK method |

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- |

## Examples

## Modulate an MSK signal with bit inputs and phase offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a
% phase offset of pi/4.
    hMod = comm.MSKModulator('BitInput', true, ...
            'InitialPhaseOffset', pi/4);
        hAWGN = comm.AWGNChannel('NoiseMethod', ...
            'Signal to noise ratio (SNR)','SNR',0);
        hDemod = comm.MSKDemodulator('BitOutput', true, ...
                            'InitialPhaseOffset', pi/4);
    % Create an error rate calculator, account for the delay caused by the Viterbi algorithm
        hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
        for counter = 1:100
            % Transmit 100 3-bit words
            data = randi([0 1],300,1);
            modSignal = step(hMod, data);
            noisySignal = step(hAWGN, modSignal);
            receivedData = step(hDemod, noisySignal);
            errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
Error rate = 0.000000
Number of errors = 0
```

## Map Binary Data to GMSK Signal

This example illustrates the mapping of binary sequences of zeros and ones to the output of a GMSK modulator. The relationship also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs. Specify the pulse length and samples per symbol to be 1.

```
gmsk = comm.GMSKModulator('BitInput',true,'PulseLength',1,'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 - 1.0000i
    -1.0000 + 0.0000i
    0.0000 + 1.0000i
    1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
theta = 5×1
    0
    -1.5708
    -3.1416
    -4.7124
    -6.2832
```

A sequence of zeros causes the phase to shift by $-\Pi / 2$ between samples.
Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmsk)
x = ones(5,1);
y = gmsk(x)
y = 5x1 complex
    1.0000 + 0.0000i
    -0.0000 + 1.0000i
    -1.0000 - 0.0000i
    0.0000 - 1.0000i
    1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the unwrap function to better show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1
```

0
1.5708
3.1416
4.7124
6.2832

A sequence of ones causes the phase to shift by $+\Pi / 2$ between samples.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is $\Pi / 2$, which is a modulation index of 0.5 .

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the MSKModulator object, H .

## step

System object: comm.MSKModulator
Package: comm
Modulate using MSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the MSK modulator object, H . It returns the baseband modulated output, $Y$. Depending on the value of the BitInput property, input $X$ can be a double precision, signed integer, or logical column vector. The length of output vector, Y , is equal to the number of input samples times the number of samples per symbol you specify in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.MSKTimingSynchronizer

Package: comm
Recover symbol timing phase using fourth-order nonlinearity method

## Description

The MSKTimingSynchronizer object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This object implements a general non-data-aided feedback method that is independent of carrier phase recovery. This method requires prior compensation for the carrier frequency offset. This object is suitable for systems that use baseband minimum shift keying (MSK) modulation.

To recover the symbol timing phase of the input signal:
1 Define and set up your MSK timing synchronizer object. See "Construction" on page 3-987.
2 Call step to recover the symbol timing phase of the input signal according to the properties of comm.MSKTimingSynchronizer. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm.MSKTimingSynchronizer creates a timing phase synchronizer System object, H. This object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method.
$\mathrm{H}=$ comm.MSKTimingSynchronizer(Name, Value) creates an MSK timing synchronizer object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## SamplesPerSymbol

Number of samples representing each symbol
Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar greater than 1 . The default is 4 .

## ErrorUpdateGain

Error update step size
Specify the step size for updating successive timing phase estimates as a positive, real scalar value. The default is 0.05 . Typically, this number is less than $1 /$ SamplesPerSymbol on page 3-0 , which corresponds to a slowly varying timing phase. This property is tunable.

## ResetInputPort

Enable synchronization reset input
Set this property to true to enable resetting the timing phase recovery process based on an input argument value. The default is false.

When you set this property to true, you must specify a reset input value to the step method.
When the reset input is a nonzero value, the object restarts the timing phase recovery process. When you set this property to false, the object does not restart.

## ResetCondition

Condition for timing phase recovery reset
Specify the conditions to reset the timing phase recovery process as one of Never | Every frame. The default is Never.

When you set this property to Never, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to Every frame, the timing phase recovery restarts at the start of each frame of data. Thus, each time the object calls the step method. This property applies when you set the ResetInputPort on page 3-0 property to false.

## Methods

reset Reset states of MSK timing phase synchronizer object
step Recover symbol timing phase using fourth-order nonlinearity method

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Recover Timing Phase of MSK Signal

Create MSK modulator, variable fractional delay, and MSK timing synchronizer System objects.

```
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',14);
timing0ffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
mskTimingSync = comm.MSKTimingSynchronizer('SamplesPerSymbol',14,'ErrorUpdateGain', 0.05);
```

Main processing loop.

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = mskMod(data); % Modulate data
```

```
% Apply timing offset error.
impairedData = varDelay(modData,timingOffset*14);
% Perform timing phase recovery.
[~,phase] = mskTimingSync(impairedData);
phEst(i) = phase(1)/14;
```

end

Plot the results.

```
plot(1:50,[0.2*ones(50,1) phEst]);
legend( 'Original','Estimated')
title('Original and Estimated timing phases');
```

Original and Estimated timing phases

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the Modulation type parameter set to MSK.
- The Reset parameter corresponds to the ResetInputPort on page 3-0 and ResetCondition on page 3-0 properties.

System object: comm.MSKTimingSynchronizer
Package: comm
Recover symbol timing phase using fourth-order nonlinearity method

## Syntax

[Y,PHASE] = step(H,X)
[Y,PHASE] = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
[ $\mathrm{Y}, \mathrm{PHASE}$ ] = step $(\mathrm{H}, \mathrm{X})$ recovers the timing phase and returns the time-synchronized signal, Y , and the estimated timing phase, PHASE, for input signal X . X must be a double or single precision complex column vector.
[ $\mathrm{Y}, \mathrm{PHASE}]=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})$ restarts the timing phase recovery process when you input a reset signal, $R$, that is non-zero. $R$ must be a logical or double scalar. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MultiplexedDeinterleaver

Package: comm
Deinterleave input symbols using set of shift registers with specified delays

## Description

The MultiplexedDeinterleaver object restores the original ordering of a sequence that was interleaved using the General Multiplexed Interleaver object.

To deinterleave the input symbols:
1 Define and set up your multiplexed deinterleaver object. See "Construction" on page 3-993.
2 Call step to restore the original ordering of the input sequence according to the properties of comm.MultiplexedDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.MultiplexedDeinterleaver creates a multiplexed deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the multiplexed interleaver System object.

H = comm.MultiplexedDeinterleaver(Name, Value) creates a multiplexed deinterleaver object, H , with each specified property set to the specified value. You can specify additional namevalue pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## Delay

Interleaver delay
Specify the lengths of the shift registers as an integer column vector. The default is $[2 ; 0 ; 1 ; 3 ; 10]$.

## InitialConditions

Initial conditions of shift registers
Specify the initial values in each shift register as a numeric scalar value or a column vector. The default is 0 . When you set this property to a column vector, the vector length must equal the value of the Delay on page 3-0 property. This vector contains initial conditions, where the $i$-th initial condition is stored in the ith shift register.

## Methods

reset Reset states of the multiplexed deinterleaver object
step Deinterleave input symbols using a set of shift registers with specified delays

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- |

## Examples

## Multiplexed Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.MultiplexedInterleaver('Delay',[1; 0; 2; 1]);
deinterleaver = comm.MultiplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and deinterleaver.

```
[dataIn,dataOut] = deal([]); % Initialize data arrays
for k = 1:50
    data = randi([0 7],20,1); % Generate data sequence
    intData = interleaver(data); % Interleave sequence
    deIntData = deinterleaver(intData); % Deinterleave sequence
    dataIn = cat(1,dataIn,data); % Save original data
    dataOut = cat(1,dataOut,deIntData); % Save deinterleaved data
end
```

Determine the delay through the interleaver and deinterleaver.

```
intlvrDelay = finddelay(dataIn,dataOut)
intlvrDelay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-intlvrDelay),data0ut(intlvrDelay+1:end))
ans = logical
    1
```

## Syntax

reset (H)

## Description

reset $(H)$ resets the states of the MultiplexedDeinterleaver object, H .

## step

System object: comm.MultiplexedDeinterleaver
Package: comm
Deinterleave input symbols using a set of shift registers with specified delays

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ restores the original ordering of the sequence, $X$, that was interleaved using a multiplexed interleaver and returns $Y$. The input $X$ must be a column vector. The data type for $X$ can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X . The multiplexed deinterleaver object uses N shift registers, where N is the number of elements in the vector specified by the Delay property. When a new input symbol enters the deinterleaver, a commutator switches to a new register. The new symbol shifts in while the oldest symbol in that register is shifted out. When the commutator reaches the Nth register, upon the next new input, it returns to the first register. The multiplexed deinterleaver associated with a multiplexed interleaver has the same number of registers as the interleaver. The delay in a particular deinterleaver register depends on the largest interleaver delay minus the interleaver delay for the given register.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.MultiplexedInterleaver

Package: comm
Permute input symbols using set of shift registers with specified delays

## Description

The MultiplexedInterleaver object permutes the symbols in the input signal. Internally, the object uses a set of shift registers, each with its own delay value.

To permute the symbols in the input signal:
1 Define and set up your multiplexed interleaver object. See "Construction" on page 3-998.
2 Call step to interleave the input signal according to the properties of comm.MultiplexedInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $\mathrm{y}=$ step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.MultiplexedInterleaver creates a multiplexed interleaver System object, H. This object permutes the symbols in the input signal using a set of shift registers with specified delays.

H = comm.MultiplexedInterleaver(Name, Value) creates a multiplexed interleaver object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## Delay

Interleaver delay
Specify the lengths of the shift registers as an integer column vector. The default is $[2 ; 0 ; 1 ; 3 ; 10]$.

## InitialConditions

Initial conditions of shift registers
Specify the initial values in each shift register as a numeric scalar value or a column vector. The default is 0 . When you set this property to a column vector, the length must equal the value of the Delay on page 3-0 property. This vector contains initial conditions, where the $i$-th initial condition is stored in the $i$-th shift register.

## Methods

reset Reset states of the multiplexed interleaver object
step Permute input symbols using a set of shift registers with specified delays

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- |

## Examples

## Multiplexed Interleaving and Deinterleaving

Create interleaver and deinterleaver objects.

```
interleaver = comm.MultiplexedInterleaver('Delay',[1; 0; 2; 1]);
deinterleaver = comm.MultiplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and deinterleaver.

```
[dataIn,dataOut] = deal([]); % Initialize data arrays
for k = 1:50
    data = randi([0 7],20,1); % Generate data sequence
    intData = interleaver(data); % Interleave sequence
    deIntData = deinterleaver(intData); % Deinterleave sequence
    dataIn = cat(1,dataIn,data); % Save original data
    dataOut = cat(1,dataOut,deIntData); % Save deinterleaved data
end
```

Determine the delay through the interleaver and deinterleaver.

```
intlvrDelay = finddelay(dataIn,dataOut)
intlvrDelay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-intlvrDelay),data0ut(intlvrDelay+1:end))
ans = logical
    1
```

Copyright 2012 The MathWorks, Inc.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General Multiplexed Interleaver block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

See Also<br>comm.ConvolutionalInterleaver|comm.MultiplexedDeinterleaver Introduced in R2012a

## reset

System object: comm.MultiplexedInterleaver
Package: comm
Reset states of the multiplexed interleaver object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the MultiplexedInterleaver object, H .

## step

System object: comm.MultiplexedInterleaver
Package: comm
Permute input symbols using a set of shift registers with specified delays

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ permutes input sequence, X , and returns interleaved sequence, Y . The input X must be a column vector and the data type can be numeric, logical, or fixed-point (fi objects). $Y$ has the same data type as X . The multiplexed interleaver object consists of N registers, each with a specified delay. With each new input symbol, a commutator switches to a new register and the new symbol is shifted in while the oldest symbol in that register is shifted out. When the commutator reaches the Nth register, upon the next new input, it returns to the first register.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.OQPSKDemodulator

Package: comm
Demodulation using OQPSK method

## Description

The comm.OQPSKDemodulator object applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see "Pulse Shaping Filter" on page 3-1009. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see "Modulation Delays" on page 3-1009.

To demodulate a signal that is OQPSK modulated:
1 Create the comm.0QPSKDemodulator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
oqpskdemod = comm.OQPSKDemodulator
oqpskdemod = comm.OQPSKDemodulator(mod)
oqpskdemod = comm.OQPSKDemodulator(Name,Value)
oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)
```

## Description

oqpskdemod $=$ comm.OQPSKDemodulator creates a demodulator System object. This object can jointly match-filter and decimate a waveform, and demodulate it using the offset quadrature phase shift keying (OQPSK) method.
oqpskdemod = comm.OQPSKDemodulator(mod) creates a demodulator System object with symmetric configuration to the OQPSK modulator object, mod.
oqpskdemod = comm.OQPSKDemodulator(Name, Value) sets properties using one or more namevalue pairs. Enclose each property name in single quotes.
Example: comm.OQPSKDemodulator('Bit0utput', true)
oqpskdemod $=$ comm.OQPSKDemodulator(phase, Name, Value) sets the PhaseOffset property of the created object to phase and sets any other specified Name, Value pairs.
Example: comm.0QPSKDemodulator(0.5*pi,'SamplesPerSymbol' , 2)

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## PhaseOffset - Phase of zeroth point of signal constellation

0 (default) | scalar
Phase of zeroth point of the signal constellation in radians, specified as a scalar.
Example: 'PhaseOffset ' , 0 aligns the OQPSK signal constellation points on the axes, $\{(1,0),(0, j)$, $(-1,0),(0,-j)\}$.

## Data Types: double

## BitOutput - Option to output data as bits

false (default) | true
Option to output data as bits, specified as false or true.

- When you set this property to false, the object outputs a column vector of integer values with a length equal to the number of demodulated symbols. The output values are integer representations of two bits and range from 0 to 3 .
- When you set this property to true, the object outputs a binary column vector of bit values. The output vector length is twice as long as the number of input symbols.

## Data Types: logical

## SymbolMapping - Signal constellation bit mapping

'Gray' (default) | 'Binary | custom 4-element numeric vector of integers with values from 0 to 3
Signal constellation bit mapping, specified as 'Gray ', 'Binary', or a custom 4-element numeric vector of integers with values from 0 to 3 .

$\left.\begin{array}{|l|c|l|l|l|}\hline \text { Setting } & \begin{array}{l}\text { Constellation } \\ \text { Mapping for Integers }\end{array} & \begin{array}{l}\text { Constellation } \\ \text { Mapping for Bits }\end{array} & \text { Comment } \\ \hline \begin{array}{l}\text { Custom 4-element } \\ \text { numeric vector of } \\ \text { integers with values } \\ \text { from 0 to 3 }\end{array} & \text { b } & \text { a } & \text { de2bi(b) } & \text { de2bi(a) }\end{array} \begin{array}{l}\text { Elements [a b c d] must } \\ \text { be composed of the set } \\ \text { of values [0, 1, 2, 3] in } \\ \text { any order. }\end{array}\right]$

## Data Types: char | double

## PulseShape - Filtering pulse shape

'Half sine' (default)|'Normal raised cosine'|'Root raised cosine'|'Custom'
Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine'|'Root raised cosine', or 'Custom'.

Data Types: char

## RolloffFactor - Raised cosine filter rolloff factor

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1 .

## Dependencies

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.
Data Types: double

## FilterSpanInSymbols - Filter length

10 (default) | scalar
Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

## Dependencies

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.
Data Types: double
FilterNumerator - Filter numerator
[0.7071 0.7071] (default)| row vector
Filter numerator, specified as a row vector.

## Dependencies

This property applies when PulseShape is 'Custom'.
Data Types: double

## SamplesPerSymbol - Number of samples per symbol <br> 4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

## OutputDataType - Data type assigned to output

'double' (default)|'single'|'uint8'
Data type assigned to output, specified as 'double', 'single', or 'uint8'.
Data Types: char

## Usage

## Syntax

outsignal = oqpskdemod(waveform)

## Description

outsignal = oqpskdemod(waveform) returns the demodulated output signal. The object produces one output symbol for each input pulse.

## Input Arguments

## waveform - Received waveform

scalar | column vector
Received waveform, specified as a complex scalar or column vector.
Data Types: double
Complex Number Support: Yes

## Output Arguments

## outsignal - Demodulated signal

integer vector | bit vector
Demodulated signal, returned as an $N_{\mathrm{S}}$-element integer vector or bit vector, where $N_{\mathrm{S}}$ is the number of samples.

The received waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol. The setting of the BitOutput property determines the interpretation of the received waveform.
Data Types: double

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the ReceiveDelay property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 3.3336e-05
numErrors = errorStats(2)
numErrors = 1
numBits = errorStats(3)
numBits = 29998
```

## OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

## System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data
modulator = comm.OQPSKModulator('BitInput',true,'SamplesPerSymbol',sps,'PulseShape','Root raised
demodulator = comm.OQPSKDemodulator(modulator);
Waveform transmission and reception
```

Use the modulator object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform, snr);
```

Use the demodulator object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
```

[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))
ber $=0$

## Soft-Decision OQPSK Modulation-Demodulation

Use the qamdemod function to simulate soft decision output for OQPSK-modulated signals.
Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

## Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse,'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the qamdemod function. Align symbol mapping of qamdemod with the symbol mapping used by the comm.0QPSKModulator, then demodulate the signal.
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');

## More About

## Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

| Pulse Shape | Input/Output Data (*) | End-to-End Delay Incurred by <br> ay an OQPSK Modulator- <br> Demodulator Object Pair (in <br> samples) |
| :--- | :--- | :--- |
| 'Half sine' or 'Custom' | Integer | 1 |
|  | Bit | 2 |
| 'Normal raised cosine' or <br> 'Root raised cosine' | Integer | FilterSpanInSymbols |
|  | Bit | 2*FilterSpanInSymbols |
| (*) Set the data type property (BitInput for modulation or BitOutput for demodulation) to <br> false for integer data and true for bit data. |  |  |

## Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{Tm}}$.
Usage notes and limitations:

## Introduced in R2012a

## comm.OQPSKModulator

Package: comm
Modulation using OQPSK method

## Description

The comm.OQPSKModulator object modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the output waveform. For more information, see "Pulse Shaping Filter" on page 3-1018. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see "Modulation Delays" on page 3-1017.

To modulate a signal using offset quadrature phase shift keying:
1 Create the comm.0QPSKModulator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

oqpskmod = comm.OQPSKModulator
oqpskmod = comm.OQPSKModulator(demod)
oqpskmod = comm.OQPSKModulator(Name,Value)
oqpskmod = comm.OQPSKModulator(phase, Name, Value)

## Description

oqpskmod = comm.OQPSKModulator creates a modulator System object. This object applies offset quadrature phase shift keying (OQPSK) modulation and pulse shape filtering to the input signal.
oqpskmod $=$ comm.OQPSKModulator(demod) creates a modulator System object with symmetric configuration to the OQPSK demodulator object, demod.
oqpskmod = comm.OQPSKModulator(Name,Value) sets properties using one or more name-value pairs. Enclose each property name in single quotes.
Example: comm.OQPSKModulator('BitInput',true)
oqpskmod = comm.OQPSKModulator(phase, Name, Value) sets the PhaseOffset property of the created object to phase and sets any other specified Name, Value pairs.

Example: comm.0QPSKModulator(0.5*pi, 'SymbolMapping ', 'Binary')

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## PhaseOffset - Phase of zeroth point of signal constellation

0 (default) | scalar
Phase of zeroth point of the signal constellation in radians, specified as a scalar.
Example: 'PhaseOffset ' , 0 aligns the OQPSK signal constellation points on the axes, $\{(1,0),(0, j)$, $(-1,0),(0,-j)\}$.

## Data Types: double

## BitInput - Option to provide input in bits

false (default) | true
Option to provide input in bits, specified as false or true.

- When this property is set to false, the input values must be integer representations of two-bit input segments and range from 0 to 3 .
- When this property is set to true, the input must be a binary vector of even length. Element pairs are binary representations of integers.

## Data Types: logical

## SymbolMapping - Signal constellation bit mapping

'Gray' (default) | 'Binary | custom 4-element numeric vector of integers with values from 0 to 3
Signal constellation bit mapping, specified as 'Gray ', 'Binary ', or a custom 4-element numeric vector of integers with values from 0 to 3 .

| Setting | Constellation <br> Mapping for Integers | Constellation <br> Mapping for Bits | Comment |  |  |
| :--- | :---: | :---: | :---: | :---: | :--- |
| Gray | 1 | 0 | 01 | 00 | The signal constellation <br> mapping is Gray- <br> encoded. |
| 3 | 2 | 11 | 10 |  |  |
| Binary | 1 | 0 | 01 | 00 | The signal constellation <br> mapping for the input <br> integer m $(0 \leq \mathrm{m} \leq 3)$ is |

$\left.\begin{array}{|l|c|c|l|l|}\hline \text { Setting } & \begin{array}{l}\text { Constellation } \\ \text { Mapping for Integers }\end{array} & \begin{array}{l}\text { Constellation } \\ \text { Mapping for Bits }\end{array} & \text { Comment } \\ \hline \begin{array}{l}\text { Custom 4-element } \\ \text { numeric vector of } \\ \text { integers with values } \\ \text { from 0 to 3 }\end{array} & \text { b } & \text { a } & \text { de2bi(b) } & \text { de2bi(a) }\end{array} \begin{array}{l}\text { dements [a b c d] must } \\ \text { be composed of the set } \\ \text { of values [0, 1, 2, 3] in } \\ \text { any order. }\end{array}\right]$

## Data Types: char | double

## PulseShape - Filtering pulse shape

'Half sine' (default)|'Normal raised cosine'|'Root raised cosine'|'Custom'
Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine', 'Root raised cosine', or 'Custom'.

Data Types: char

## RolloffFactor - Raised cosine filter rolloff factor

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1 .

## Dependencies

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.
Data Types: double

## FilterSpanInSymbols - Filter length

10 (default) | scalar
Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

## Dependencies

This property applies when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.
Data Types: double
FilterNumerator - Filter numerator
[0.7071 0.7071] (default)| row vector
Filter numerator, specified as a row vector.

## Dependencies

This property applies when PulseShape is 'Custom'.
Data Types: double

## SamplesPerSymbol - Number of samples per symbol <br> 4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

## OutputDataType - Data type assigned to output

'double' (default)|'single'
Data type assigned to output, specified as 'double' or 'single'.
Data Types: char

## Usage

## Syntax

```
waveform = oqpskmod(insignal)
```

## Description

waveform = oqpskmod(insignal) returns baseband-modulated output. The output waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol.

## Input Arguments

## insignal - Input signal

integer column vector | bit column vector
Input signal, specified as an $N_{\mathrm{S}}$-element column vector of integers or bits, where $N_{\mathrm{S}}$ is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.
Data Types: double

## Output Arguments

## waveform - Output waveform

vector
Output waveform, returned as a vector. The output waveform is pulse-shaped according to the configuration properties PulseShape and SamplesPerSymbol.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('Bit0utput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the ReceiveDelay property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

ber $=3.3336 \mathrm{e}-05$
numErrors $=$ errorStats(2)
numErrors $=1$
numBits = errorStats(3)
numBits = 29998

## Create OQPSK Modulator Using Demodulator

Use an OQPSK demodulator object to initialize an OQPSK modulator object while creating it.
Create an OQPSK demodulator, assigning it a phase offset of $\frac{1}{2} \Pi$.

```
phase = 0.5*pi;
oqpskdemod = comm.OQPSKDemodulator(phase)
oqpskdemod =
    comm.OQPSKDemodulator with properties:
    Modulation
            PhaseOffset: 1.5708
            SymbolMapping: 'Gray'
                BitOutput: false
    Filtering
            PulseShape: 'Half sine'
        SamplesPerSymbol: 4
            OutputDataType: 'double'
```

Use the demodulator object to initialize an OQPSK modulator while creating it.

```
oqpskmod = comm.OQPSKModulator(oqpskdemod)
oqpskmod =
    comm.OQPSKModulator with properties:
    Modulation
                PhaseOffset: 1.5708
            SymbolMapping: 'Gray'
                BitInput: false
    Filtering
            PulseShape: 'Half sine'
        SamplesPerSymbol: 4
            OutputDataType: 'double'
```

## OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

## System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data
modulator = comm.OQPSKModulator('BitInput',true,'SamplesPerSymbol',sps,'PulseShape','Root raised
demodulator = comm.0QPSKDemodulator(modulator);
Waveform transmission and reception
```

Use the modulator object to apply OQPSK modulation and transmit filtering to the input data.
oqpskWaveform = modulator(bits);

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform, snr);
```

Use the demodulator object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))
ber = 0
```

## Soft-Decision OQPSK Modulation-Demodulation

Use the qamdemod function to simulate soft decision output for OQPSK-modulated signals.
Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

## Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse,'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the qamdemod function. Align symbol mapping of qamdemod with the symbol mapping used by the comm.0QPSKModulator, then demodulate the signal.
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');

## More About

## Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with
received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

| Pulse Shape | Input/Output Data (*) | End-to-End Delay Incurred by <br> ay an OQPSK Modulator- <br> Demodulator Object Pair (in <br> samples) |
| :--- | :--- | :--- |
| 'Half sine' or 'Custom' | Integer | 1 |
|  | Bit | 2 |
| 'Normal raised cosine' or <br> 'Root raised cosine' | Integer | FilterSpanInSymbols |
|  | Bit | 2*FilterSpanInSymbols |
| (*) Set the data type property (BitInput for modulation or BitOutput for demodulation) to <br> false for integer data and true for bit data. |  |  |

## Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

## comm.OSTBCCombiner

Package: comm
Combine inputs using orthogonal space-time block code

## Description

The OSTBCCombiner object combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC. The input channel estimate does not need to be constant and can vary at each call to the step method. The combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner object in a MIMO communications system.

To combine input signals and extract the soft information of the symbols encoded by an OSTBC:
1 Define and set up your OSTBC combiner object. See "Construction" on page 3-1019.
2 Call step to Combine inputs using an orthogonal space-time block code according to the properties of comm. OSTBCCombiner. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. OSTBCCombiner creates an orthogonal space-time block code (OSTBC) combiner System object, H . This object combines the input signal (from all of the receive antennas) with the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC.

H = comm.OSTBCCombiner(Name, Value) creates an OSTBC Combiner object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. OSTBCCombiner ( $\mathrm{N}, \mathrm{M}$, Name, Value) creates an OSTBC Combiner object, H. This object has the NumTransmitAntennas property set to N , the NumReceiveAntennas property set to N , and the other specified properties set to the specified values.

## Properties

## NumTransmitAntennas

Number of transmit antennas
Specify the number of antennas at the transmitter as $2|3| 4$. The default is 2 .

## SymbolRate

Symbol rate of code

Specify the symbol rate of the code as $3 / 4 \mid 1 / 2$. The default is $3 / 4$. This property applies when the NumTransmitAntennas on page 3-0 property is greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

## NumReceiveAntennas

Number of receive antennas
Specify the number of antennas at the receiver as a double-precision, real, scalar integer value from 1 to 8 . The default is 1 .

## Fixed-Point Properties

## RoundingMethod

Rounding of fixed-point numeric values
Specify the rounding method as Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero. The default is Floor.

## OverflowAction

Action when fixed-point numeric values overflow
Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property specifies the action to be taken in case of overflow. Such overflow occurs if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

## ProductDataType

Data type of product
Specify the product data type as one of Full precision | Custom. The default is Full precision.

## CustomProductDataType

Fixed-point data type of product
Specify the product fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype ([],32,16). This property applies when you set the ProductDataType property to Custom.

## AccumulatorDataType

Data type of accumulator
Specify the accumulator data type as Full precision | Same as product | Custom. The default is Full precision.

## CustomAccumulatorDataType

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype([],32,16). This property applies when you set the AccumulatorDataType property to Custom.

## EnergyProductDataType

Data type of energy product
Specify the complex energy product data type as one of Full precision | Same as product Custom. The default is Full precision. This property sets the data type of the complex product in the denominator to calculate the total energy in the MIMO channel.

## CustomEnergyProductDataType

Fixed-point data type of energy product
Specify the energy product fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype([],32,16). This property applies when you set the EnergyProductDataType property to Custom.

## EnergyAccumulatorDataType

Data type of energy accumulator
Specify the energy accumulator data type as one of Full precision| Same as energy product |Same as accumulator|Custom. The default is Full precision. This property sets the data type of the summation in the denominator to calculate the total energy in the MIMO channel.

## CustomEnergyAccumulatorDataType

Fixed-point data type of energy accumulator
Specify the energy accumulator fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype([],32,16). This property applies when you set the EnergyAccumulatorDataType property to Custom.

## DivisionDataType

Data type of division
Specify the division data type as one of Same as accumulator|Custom. The default is Same as accumulator. This property sets the data type at the output of the division operation. The setting normalizes diversity combining by the total energy in the MIMO channel.

## CustomDivisionDataType

Fixed-point data type of division
Specify the division fixed-point type as a scaled numerictype object with a signedness of Auto. The default is numerictype([],32,16). This property applies when you set the DivisionDataType property to Custom.

## Examples

## Encode with OSTBC and Calculate Errors

Determine the bit error rate for a QSPK signal employing OSTBC encoding when transmitted through a $4 x 2$ MIMO channel. Perfect channel estimation is assumed to be used by the OSTBC combiner.

Define the system parameters.

```
numTx = 4; % Number of transmit antennas
numRx = 2; % Number of receive antennas
Rs = le6; % Sampling rate (Hz)
tau = [0 2e-6]; % Path delays (sec)
pdb = [0 -10]; % Average path gains (dB)
maxDopp = 30; % Maximum Doppler shift (Hz)
numBits = 12000; % Number of bits
SNR = 6; % Signal-to-noise ratio (dB)
```

Set the random number generator to its default state to ensure repeatable results.

```
rng default
```

Create a QPSK modulator System object ${ }^{\text {mp }}$. Set the BitInput property to true and the SymbolMapping property to Gray.

```
hMod = comm.QPSKModulator(...
    'BitInput',true,...
    'SymbolMapping','Gray');
```

Create a corresponding QPSK demodulator System object. Set the SymbolMapping property to Gray and the BitOutput property to true.

```
hDemod = comm.QPSKDemodulator(...
    'SymbolMapping','Gray',...
    'BitOutput',true);
```

Create an OSTBC encoder and combiner pair, where the number of antennas is specified in the system parameters.

```
hOSTBCEnc = comm.OSTBCEncoder(...
    'NumTransmitAntennas',numTx);
hOSTBCComb = comm.OSTBCCombiner(...
    'NumTransmitAntennas',numTx,...
    'NumReceiveAntennas',numRx);
```

Create a flat 4x2 MIMO Channel System object, where the channel characteristics are set using name-value pairs. The path gains are made available to serve as a perfect channel estimate for the OSTBC combiner.

```
hChan = comm.MIMOChannel(...
    'SampleRate',Rs,...
    'PathDelays',tau,...
    'AveragePathGains',pdb,...
    'MaximumDopplerShift',maxDopp,...
    'SpatialCorrelationSpecification','None',...
    'NumTransmitAntennas',numTx,...
    'NumReceiveAntennas',numRx,...
    'PathGains0utputPort',true);
```

Create an AWGN channel System object in which the noise method is specified as a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)',...
    'SNR',SNR,...
    'SignalPower',1);
```

Generate a random sequence of bits.
data $=$ randi([0 1],numBits,1);
Apply QPSK modulation.
modData $=$ step(hMod,data);
Encode the modulated data using the OSTBC encoder object.
encData $=$ step(hOSTBCEnc,modData);
Transmit the encoded data through the MIMO channel and add white noise by using the step functions of the MIMO and AWGN channel objects, respectively.

```
[chanOut,pathGains] = step(hChan,encData);
rxSignal = step(hAWGN,chanOut);
```

Sum the pathGains array along the number of paths (2nd dimension) to form the channel estimate. Apply the squeeze function to make its dimensions conform with those of rxSignal.

```
chEst = squeeze(sum(pathGains,2));
```

Combine the received MIMO signal and its channel estimate using the step function of the OSTBC combiner object. Demodulate the combined signal.

```
combinedData = step(h0STBCComb,rxSignal,chEst);
receivedData = step(hDemod,combinedData);
```

Compute the number of bit errors and the bit error rate.

```
[numErrors,ber] = biterr(data,receivedData)
numErrors = 11
ber = 9.1667e-04
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Combiner block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

comm. OSTBCEncoder

## Introduced in R2012a

## step

System object: comm.OSTBCCombiner
Package: comm
Combine inputs using orthogonal space-time block code

## Syntax

Y = step(H,X,CEST)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X, C E S T)$ combines the received data, $X$, and the channel estimate, CEST, to extract the symbols encoded by an OSTBC. Both X and CEST are complex-valued and of the same data type, which can be double, single, or signed fixed point with power-of-two slope and zero bias. When the step method input X has double or single precision, the output, Y , has the same data type as the input. The input channel estimate can remain constant or can vary during each codeword block transmission. The combining algorithm uses the estimate only for the first symbol period per codeword block.

The time domain length, $T /$ SymbolRate, must be a multiple of the codeword block length. $T$ is the output symbol sequence length in the time domain. Specifically, when you set the NumTransmitAntennas property to 2, $T /$ SymbolRate must be a multiple of two. When you set the NumTransmitAntennas property greater than 2, T/SymbolRate must be a multiple of four. For an input of $T /$ SymbolRate rows by NumReceiveAntennas columns, the input channel estimate, CEST, must be a matrix of size $T /$ SymbolRateby NumTransmitAntennas by NumReceiveAntennas. In this case, the extracted symbol data, Y , is a column vector with $T$ elements. Input matrix size can be $F$ by $T /$ SymbolRate by NumReceiveAntennas, where $F$ is an optional dimension (typically frequency domain) over which the combining calculation is independent. In this case, the input channel estimate, CEST, must be a matrix of size F by $T /$ SymbolRate by NumTransmitAntennas by NumReceiveAntennas. The extracted symbol data, Y , is an $F$ rows by $T$ columns matrix.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.OSTBCEncoder

Package: comm
Encode input using orthogonal space-time block code

## Description

The OSTBCEncoder object encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

To encode an input symbol sequence using an orthogonal space-time block code:
1 Define and set up your OSTBC encoder object. See "Construction" on page 3-1026.
2 Call step to encode an input symbol sequence according to the properties of comm. OSTBCEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $\mathrm{y}=$ step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. OSTBCEncoder creates an orthogonal space-time block code (OSTBC) encoder System object, H. This object maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

H = comm. OSTBCEncoder (Name, Value) creates an OSTBC encoder object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. OSTBCEncoder(N,Name, Value) creates an OSTBC encoder object, H. This object has the NumTransmitAntennas property set to N , and the other specified properties set to the specified values.

## Properties

## NumTransmitAntennas

Number of transmit antennas
Specify the number of antennas at the transmitter as $2|3| 4$. The default is 2 .

## SymbolRate

Symbol rate of code

Specify the symbol rate of the code as one of $3 / 4 \mid 1 / 2$. The default is $3 / 4$. This property applies when you set the NumTransmitAntennas on page 3-0 property to greater than 2. For 2 transmit antennas, the symbol rate defaults to 1 .

## Fixed-Point Properties

## OverflowAction

Action when fixed-point numeric values overflow
Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property specifies the action to be taken in the case of an overflow. Such overflow occurs when the magnitude of a fixedpoint calculation result does not fit into the range of the data type and scaling that stores the result.

## Examples

## Encode BPSK Modulated Data with OSTBC

Generate random binary data, modulate using the BPSK modulation scheme, and encode the modulated data using OSTBC.

Generate an 8 -by- 1 vector of random binary data.

```
data = randi([0 1],8,1);
```

Create BPSK Modulator System object and modulated the data using the step function.

```
bpskMod = comm.BPSKModulator;
modData = bpskMod(data);
```

Create an OSTBC Encoder and encode the modulated signal. As the default number of transmit antennas is 2 , you can see that encData is an 8 -by- 2 vector.

```
ostbcEnc = comm.OSTBCEncoder;
encData = ostbcEnc(modData)
encData = 8\times2 complex
    -1.0000 + 0.0000i -1.0000 + 0.0000i
    1.0000 + 0.0000i -1.0000 - 0.0000i
    1.0000 + 0.0000i -1.0000 + 0.0000i
    1.0000 + 0.0000i 1.0000 + 0.0000i
    -1.0000 + 0.0000i 1.0000 + 0.0000i
    -1.0000 + 0.0000i -1.0000 - 0.0000i
    1.0000 + 0.0000i -1.0000 + 0.0000i
    1.0000 + 0.0000i 1.0000 + 0.0000i
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Encoder block reference page. The object properties correspond to the block parameters.

When this object processes variable-size signals:

- If the input signal is a column vector, the first dimension can change, but the second dimension must remain fixed at 1.
- If the input signal is a matrix, both dimensions can change.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{Tm}}$.
Usage notes and limitations:

Package: comm
Encode input using orthogonal space-time block code

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X)$ encodes the input data, $X$, using OSTBC encoder object, $H$. The input is a complexvalued column vector or matrix of data type double, single, or signed fixed-point with power-of-two slope and zero bias. The step method output, Y , is the same data type as the input data. The time domain length, $T$, of $X$ must be a multiple of the number of symbols in each codeword matrix.
Specifically, when you set the NumTransmitAntennas property is 2 or the SymbolRate property is $1 / 2, T$ must be a multiple of two and when the SymbolRate property to $3 / 4, T$ must be a multiple of three. For a time or spatial domain input of $T$ rows by one column, the encoded output data, Y , is a ( $T /$ SymbolRate)-by-NumTransmitAntennas matrix. The input matrix size can be $F$ rows by $T$ columns, where $F$ is the additional dimension (typically the frequency domain) over which the encoding calculation is independent. In this case, the output is an F-by-(T/SymbolRate)-byNumTransmitAntennas matrix.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.OVSFCode

Package: comm
Generate OVSF code

## Description

The OVSFCode object generates an orthogonal variable spreading factor (OVSF) code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. They are primarily used to preserve orthogonality between different channels in a communication system.

To generate an OVSF code:
1 Define and set up your OVSF code object. See "Construction" on page 3-1030.
2 Call step to generate an OVSF code according to the properties of comm. OVSFCode. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.OVSFCode creates an orthogonal variable spreading factor (OVSF) code generator System object, H. This object generates an OVSF code.

H = comm. OVSFCode(Name, Value) creates an OVSF code generator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## SpreadingFactor

Length of generated code
Specify the length of the generated code as an integer scalar value with a power of two. The default is 64 .

## Index

Index of code of interest
Specify the index of the desired code from the available set of codes that have the spreading factor specified in the SpreadingFactor on page 3-0 property. This property must be an integer scalar in the range 0 to SpreadingFactor-1. The default is 60 .

OVSF codes are defined as the rows of an $n$-by- $n$ matrix, $C n$, where $n$ is the value specified in the SpreadingFactor property.

You can define the matrix Cn recursively as follows:
First, define $C 1=$ [1].
Next, assume that $C n$ is defined and let $C n(k)$ denote the $k$-th row of $C n$.
Then, $C 2 n=[C n(0) C n(0) ; C n(0)-C n(0) ; \ldots$; $C n(n-1) C n(n-1) ; C n(n-1)-C n(n-1)]$.
$C n$ is only defined for values of $n$ that are a power of 2 . Set this property to a value of $k$ to choose the $k$-th row of the $C$ matrix as the code of interest.

## SamplesPerFrame

Number of output samples per frame
Specify the number of OVSF code samples that the step method outputs as a numeric, positive, integer scalar value. The default is 1 . If you set this property to a value of $M$, then the step method outputs $M$ samples of an OVSF code of length $N . N$ is the length of the OVSF code that you specify in the SpreadingFactor on page 3-0 property.

## OutputDataType

Data type of output
Specify output data type as one of double \| int8. The default is double.

## Methods

reset Reset states of OVSF code generator object
step Generate OVSF code

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

Generate 10 samples of an OVSF code with a spreading factor of 64 .

```
hOVSF = comm.OVSFCode('SamplesPerFrame', 10,'SpreadingFactor',64);
seq = step(hOVSF)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OVSF Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the Sample time parameter.

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = $\underline{\text { step }(o b j, x) \text { and } y=o b j(x) \text { perform equivalent operations. }}$
$\mathrm{Y}=$ step (H) outputs a frame of the OVSF code in column vector Y . Specify the frame length with the SamplesPerFrame property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.PAMDemodulator

Package: comm
(Not recommended) Demodulate using M-ary PAM method

Note comm. PAMDemodulator is not recommended. Use pamdemod instead.

## Description

The PAMDemodulator object demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using M-ary pulse amplitude modulation:
1 Define and set up your PAM demodulator object. See "Construction" on page 3-1034.
2 Call step to demodulate the signal according to the properties of comm. PAMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. PAMDemodulator creates a demodulator System object, H. This object demodulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

H = comm. PAMDemodulator(Name, Value) creates an M-PAM demodulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. PAMDemodulator(M,Name, Value) creates an M-PAM demodulator object, H. This object has the Modulation0rder property set to $M$, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4 . When you set the BitOutput on page 3-0 property to false, this value must be even. When you set the BitOutput property to true, this value requires an integer power of two.

## BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is false.
When you set this property to true the step method outputs a column vector of bit values with length equal to $\log 2$ (ModulationOrder on page 3-0 ) times the number of demodulated symbols.

When you set this property to false, the step method outputs a column vector, with length equal to the input data vector. This value contains integer symbol values between 0 and ModulationOrder1.

## SymbolMapping

Constellation encoding
Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses a Gray-encoded signal constellation.
When you set this property to Binary, the integer $m$, between $0 \leq m \leq$ (ModulationOrder-1) maps to the complex value $2 m$-ModulationOrder +1 .

## NormalizationMethod

Constellation normalization method
Specify the method used to normalize the signal constellation as one of Minimum distance between symbols|Average power|Peak power. The default is Minimum distance between symbols.

## MinimumDistance

Minimum distance between symbols
Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2 . This property applies when you set the NormalizationMethod on page 30 property to Minimum distance between symbols.

## AveragePower

Average power of constellation
Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Average power.

## PeakPower

Peak power of constellation
Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Peak power.

## OutputDataType

Data type of output

Specify the output data type as one of Full precision | Smallest unsigned integer|double | single | int8|uint8|int16|uint16|int32|uint32. The default is Full precision.

When you set this property to Full precision, and the input data type is single or double precision, the output data has the same data type that of the input.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType on page 3-0 property to Smallest unsigned integer.

When you set the BitOutput on page 3-0 property to true, then logical data type becomes a valid option.

## Fixed-Point Properties

## FullPrecisionOverride

Full precision override for fixed-point arithmetic
Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for FixedPoint System Objects" on page 3-1038.

## DenormalizationFactorDataType

Data type of denormalization factor
Specify the denormalization factor data type as one of Same word length as input | Custom. The default is Same word length as input.

## CustomDenormalizationFactorDataType

Fixed-point data type of denormalization factor
Specify the denormalization factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype ([],16). This property applies when you set the DenormalizationFactorDataType on page 3-0 property to Custom.

## ProductDataType

Data type of product
Specify the product data type as one of Full precision | Custom. The default is Full precision. When you set this property to Full precision the object calculates the full-precision product word and fraction lengths. This property applies when you set the FullPrecisionOverride on page 3-0 property to false.

## CustomProductDataType

Fixed-point data type of product
Specify the product fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],32). This property applies when you set the
FullPrecisionOverride on page 3-0 property to false and the ProductDataType on page 3-
0 property to Custom.

## ProductRoundingMethod

Rounding of fixed-point numeric value of product
Specify the product rounding method as one of Ceiling | Convergent | Floor | Nearest | Round |
Simplest | Zero. The default is Floor. This property applies when the object is not in a full precision configuration

## ProductOverflowAction

Action when fixed-point numeric value of product overflows
Specify the product overflow action as one of Wrap | Saturate. The default is Wrap. This property applies when the object is not in a full precision configuration.

## SumDataType

Data type of sum
Specify the sum data type as one of Full precision | Same as product | Custom. The default is Full precision. When you set this property to Full precision, the object calculates the fullprecision sum word and fraction lengths. This property applies when you set the FullPrecisionOverride on page 3-0 property to false

## CustomSumDataType

Fixed-point data type of sum
Specify the sum fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],32). This property applies when you set the FullPrecisionOverride on page 3-0 property to false and the SumDataType on page 3-0 property to Custom.

## Methods

$$
\begin{array}{ll}
\text { constellation } & \text { (Not recommended) Calculate or plot ideal signal constellation } \\
\text { step } & \text { (Not recommended) Demodulate using M-ary PAM method }
\end{array}
$$

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

Modulate and demodulate a signal using 16-PAM modulation.

```
hMod = comm.PAMModulator(16);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
                        'Signal to noise ratio (SNR)', ...
                            'SNR',20, 'SignalPower', 85);
hDemod = comm.PAMDemodulator(16);
%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 hMod.ModulationOrder-1],50,1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

## Compatibility Considerations

## comm. PAMDemodulator is not recommended

comm. PAMDEmodulator is not recommended. Use pamdemod instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.
%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.
%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

## More About

## Full Precision for Fixed-Point System Objects

FullPrecisionOverride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to true, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to false.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Demodulator
Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## C/C++ Code Generation

Constellation: 4-PAM,Gray Mapping,Min.Dist=2

## step

System object: comm. PAMDemodulator
Package: comm
(Not recommended) Demodulate using M-ary PAM method

Note comm. PAMDemodulator is not recommended. Use pamdemod instead.

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

Y = step ( $\mathrm{H}, \mathrm{X}$ ) demodulates data, X , with the M-PAM demodulator System object, H , and returns Y . Input $X$ must be a scalar or column vector. The data type of the input can be double or single precision, signed integer, or signed fixed point (fi objects). Depending on the BitOutput property value, output $Y$ can be integer or bit valued.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.PAMModulator

Package: comm
(Not recommended) Modulate using M-ary PAM method

Note comm. PAMModulator is not recommended. Use pammod instead.

## Description

The PAMModulator object modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The M -ary number parameter, M , represents the number of points in the signal constellation and requires an even integer.

To modulate a signal using M-ary pulse amplitude modulation:
1 Define and set up your PAM modulator object. See "Construction" on page 3-1043.
2 Call step to modulate the signal according to the properties of comm. PAMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. PAMModulator creates a modulator System object, H. This object modulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

H = comm.PAMModulator(Name,Value) creates an M-PAM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. PAMModulator(M,Name, Value) creates an M-PAM modulator object, H. This object has the ModulationOrder property set to $M$ and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the BitInput on page 3-0 property to false, ModulationOrder must be even. When you set the BitInput property to true, ModulationOrder must be an integer power of two.

## BitInput

Assume bit inputs
Specify whether the input is in bits or integers. The default is false.
When you set this property to true, the step method input requires a column vector of bit values whose length is an integer multiple of $\log 2$ (ModulationOrder on page 3-0 ). This vector contains bit representations of integers between 0 and ModulationOrder-1.

When you set this property to false, the step method input must be a column vector of integer symbol values between 0 and ModulationOrder-1.

## SymbolMapping

Constellation encoding
Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) input bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses a Gray-encoded signal constellation.
When you set this property to Binary, the input integer $m$, between $0 \leq m \leq$ ModulationOrder-1) maps to the complex value $2 m$-ModulationOrder +1 .

## NormalizationMethod

Constellation normalization method
Specify the method used to normalize the signal constellation as one of Minimum distance between symbols|Average power|Peak power. The default is Minimum distance between symbols.

## MinimumDistance

Minimum distance between symbols
Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2 . This property applies when you set the NormalizationMethod on page 30 property to Minimum distance between symbols.

## AveragePower

Average power of constellation
Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Average power.

## PeakPower

Peak power of constellation
Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Peak power.

## OutputDataType

Data type of output
Specify the output data type as one of double | single | Custom. The default is double.

## Fixed-Point Properties

## CustomOutputDataType

Fixed-point data type of output
Specify the output fixed-point type as a numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the OutputDataType on page 3-0 property to Custom.

## Methods

| constellation | (Not recommended) Calculate or plot ideal signal constellation |
| :--- | :--- |
| step | (Not recommended) Modulate using M-ary PAM method |

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

Modulate data using 16-PAM modulation, and visualize the data in a scatter plot.

```
% Create binary data for 100, 4-bit symbols
data = randi([0 1],400,1);
% Create a 16-PAM modulator System object with bits as inputs and
% Gray-coded signal constellation
hModulator = comm.PAMModulator(16,'BitInput',true);
% Modulate and plot the data
modData = step(hModulator, data);
constellation(hModulator)
```

## Compatibility Considerations

## comm. PAMModulator is not recommended

comm. PAMModulator is not recommended. Use pammod instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.
%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.
```

\%\% Using PAM modulation and demodulation functions yNew $=$ pammod $(x, M)$; \% Modulate.
\% ... channel filtering ...
zNew $=$ pamdemod(y,M); \% Demodulate.

## Algorithms

## step

System object: comm. PAMModulator
Package: comm
(Not recommended) Modulate using M-ary PAM method

Note comm. PAMModulator is not recommended. Use pammod instead.

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the M -PAM modulator System object, H . It returns the baseband modulated output, Y . Depending on the value of the BitInput property, input X can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.PhaseFrequencyOffset

Package: comm
Apply phase and frequency offsets to input signal

## Description

The PhaseFrequencyOffset object applies phase and frequency offsets to an incoming signal.
To apply phase and frequency offsets to the input signal:
1 Define and set up your phase frequency offset object. See "Construction" on page 3-1050.
2 Call step to apply phase and frequency offsets to the input signal according to the properties of comm. PhaseFrequency0ffset. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

$\mathrm{H}=$ comm. PhaseFrequencyOffset creates a phase and frequency offset System object, H. This object applies phase and frequency offsets to an input signal.

H = comm. PhaseFrequencyOffset (Name, Value) creates a phase and frequency offset object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## PhaseOffset

Phase offset
Specify the phase offset in degrees. The default is 0 . If the step method input is an $M$-by- $N$ matrix, the PhaseOffset on page 3-0 property can be set to a numeric scalar, an $M$-by-1, or 1-by- $N$ numeric vector, or an $M$-by- $N$ numeric matrix.

When you set the PhaseOffset property to a scalar value, the object applies the constant specified phase offset to each column of the input matrix.

When you set this property to an $M$-by-1 vector, the object applies time varying phase offsets, specified in the vector of this property, to each column of the input to the step method.

When you set this property to a 1 -by- $N$ vector, the object applies the $i$-th constant phase offset of this property to the $i$-th column of the input to the step method.

When you set this property to an $M$-by- $N$ matrix, the object applies the $i$-th time varying phase offsets, specified in the $i$-th column of this property, to the $i$-th column of the input to the step method. This property is tunable.

## FrequencyOffsetSource

Source of frequency offset
Specify the source of the frequency offset as one of Property | Input port. The default is Property. If you set this property to Property, you can specify the frequency offset using the FrequencyOffset on page 3-0 property. If you set this property to Input port, you specify the frequency offset as a step method input.

## FrequencyOffset

Frequency offset
Specify the frequency offset in Hertz. The default is 0 . If the step method input is an $M$-by- $N$ matrix, then the Frequency $0 f f$ set on page 3-0 property is a numeric scalar, an $M$-by-1, or 1-by- $N$ numeric vector, or an $M$-by- $N$ numeric matrix.

This property applies when you set the FrequencyOffsetSource on page 3-0 property to Property.

When you set this property to a scalar value, the object applies the constant specified frequency offset to each column of the input to the step method.

When you set this property to an $M$-by-1 vector, the object applies time-varying frequency offsets. These offsets are specified in the property, to each column of the input to the step method.

When you set this property to a 1-by- $N$ vector, the object applies the $i$-th constant frequency offset in this property to the $i$-th column of the input to the step method.

When you set this property to an $M$-by- $N$ matrix, the object applies the $i$-th time varying frequency offset. This offset is specified in the $i$-th column of this property and to the $i$-th column of input to the step method. This property is tunable.

## SampleRate

Sample rate
Specify the sample rate of the input samples in seconds as a double-precision, real, positive scalar value. The default is 1 .

SampleRate = Input Vector Size / Simulink Sample Time

## Methods

step Apply phase and frequency offsets to input signal

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Introduce Phase Offset to 16-QAM Signal

Introduce a phase offset to a $16-\mathrm{QAM}$ signal and view its effect on the constellation.
Create a phase frequency offset System object ${ }^{\mathrm{TM}}$. Set the phase offset to 30 degrees.
pfo = comm. PhaseFrequencyOffset('PhaseOffset', 30);
Generate random symbols and apply 16-QAM modulation.

```
M = 16;
data = (0:M-1)';
modData = qammod(data,M);
```

Plot the 16-QAM constellation.
scatterplot(modData);
title(' Original Constellation')
$x \lim ([-55])$
ylim([-5 5])

Introduce a phase offset using pfo and plot the offset constellation. Note that it has been shifted 30 degrees.

```
impairedData = pfo(modData);
scatterplot(impairedData);
title('Constellation after phase offset')
xlim([-5 5])
ylim([-5 5])
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Phase/Frequency Offset block reference page. The object properties correspond to the block parameters, except: The object provides a SampleRate on page 3-0 property, which you must specify. The block senses the sample time of the signal and therefore does not have a corresponding parameter.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

comm. MemorylessNonlinearity | comm. PhaseNoise | comm. ThermalNoise

Introduced in R2012a

## step

System object: comm. PhaseFrequency0ffset
Package: comm
Apply phase and frequency offsets to input signal

## Syntax

$Y=\operatorname{step}(H, X)$
Y = step(H,X,FRQ)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ applies phase and frequency offsets to input X , and returns Y . The input X is a double or single precision matrix $X$, of dimensions MxN. M is the number of time samples in the input signals and N is number of channels. Both M and N can be equal to 1 . The object adds phase and frequency offsets independently to each column of $X$. The data type and dimensions of $X$ and $Y$ are the same.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{FRQ})$ uses FRQ as the frequency offset that the object applies to input X when you set the FrequencyOffsetSource property to 'Input port'. When the X input is an MxN matrix, the value for FRQ can be a numeric scalar, an Mx1 or 1 xN numeric vector, or an MxN numeric matrix. When the FRQ input is a scalar, the object applies a constant frequency offset, FRQ, to each column of $X$. When the FRQ input is an Mx1 vector, the object applies time varying frequency offsets, which are specified in the FRQ vector, to each column of $X$. When the FRQ input is a 1 xN vector, the object applies the ith constant frequency offset in FRQ to the ith column of $X$. When the FRQ input is an MxN matrix, the object applies the ith time varying frequency offsets, specified in the ith column of FRQ, to the ith column of $X$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.PhaseNoise

Package: comm
Apply phase noise to baseband signal

## Description

The comm. PhaseNoise System object adds phase noise to a complex signal. This object emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The object generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see "Algorithms" on page 3-1060.

To add phase noise using a comm. PhaseNoise object:
1 Create the comm. PhaseNoise object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

phznoise = comm.PhaseNoise
phznoise = comm.PhaseNoise(Name,Value)
phznoise = comm.PhaseNoise(level,offset,samplerate)

## Description

phznoise $=$ comm. PhaseNoise creates a phase noise System object with default property values.
phznoise $=$ comm. PhaseNoise(Name, Value) creates a phase noise object with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).
phznoise $=$ comm. PhaseNoise(level, offset, samplerate) creates a phase noise object with the phase noise level, frequency offset, and sample rate properties specified as value-only arguments. When specifying a value-only argument, you must specify all preceding value-only arguments.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Level - Phase noise level

## [-60 -80] (default) | vector of negative scalars

Phase noise level in decibels relative to carrier per hertz ( $\mathrm{dBc} / \mathrm{Hz}$ ), specified as a vector of negative scalars. The Level and Frequency0ffset properties must have the same length.
Data Types: double
Frequency0ffset - Frequency offset
[20 200] (default) | vector of positive increasing values
Frequency offset in Hz , specified as a vector of positive increasing values. The Level and Frequency0ffset properties must have the same length.
Data Types: double

## SampleRate - Sample rate

1024 (default) | positive scalar
Sample rate in samples per second, specified as a positive scalar. To avoid aliasing, the sample rate must be greater than twice the largest value specified by Frequency0ffset.
Data Types: double

## RandomStream - Source of random stream

'Global stream' (default)|'mt19937ar with seed'
Source of the random stream, specified as 'Global stream' or 'mt19937ar with seed'. If RandomStream is set to 'mt19937ar with seed', the mt19937ar algorithm is used for normally distributed random number generation, in which case the reset method reinitializes the random number stream to the value of the Seed property.
Data Types: char | string

## Seed - Initial seed

2137 (default) | positive scalar less than $2^{32}$
Initial seed for RandomStream, specified as a positive scalar less than $2^{32}$.

## Dependencies

To enable this property, set RandomStream to 'mt19937ar with seed'.

## Data Types: double

## Usage

## Syntax

out = phznoise(in)

## Description

out $=$ phznoise(in) adds phase noise, specified by the phznoise System object, to the input signal. The result is returned in out.

## Input Arguments

## in - Input signal

complex column vector
Input signal, specified as an $N_{\mathrm{S}}$-by-1 vector of complex values. $N_{\mathrm{S}}$ is the number of samples.
Data Types: double
Complex Number Support: Yes

## Output Arguments

out - Output signal
column vector
Output signal, returned as an $N_{\mathrm{S}}$-by-1 vector of complex values. $N_{\mathrm{S}}$ equals the number of samples in the input signal.
Data Types: double
Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Specific to comm.PhaseNoise

visualize Visualize spectrum mask of phase noise

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Phase Noise Effects on 16-QAM Signal

Add a phase noise vector and frequency offset vector to a 16-QAM signal. Then plot the signal.
Create a phase noise System object.

```
pnoise = comm.PhaseNoise('Level',-50,'Frequency0ffset',20);
```

Generate modulated symbols.

```
M = 16; % From 16-QAM
data = randi([0 M-1],1000,1);
modData = qammod(data,M);
```

Use pnoise to apply phase noise. Plot the impaired data.
y = pnoise(modData);
scatterplot(y)

## Phase Noise Effects on Signal Spectrum

Create a sine wave generator having a carrier frequency of 100 Hz , a sample rate of 1000 Hz , and a frame size of 10,000 samples.

```
sinewave = dsp.SineWave('Frequency',100,'SampleRate',1000, ...
    'SamplesPerFrame',1e4,'Complex0utput',true);
```

Create a phase noise object. Specify the phase noise level to be ? $40 \mathrm{dBc} / \mathrm{Hz}$ for a 100 Hz offset and ? $70 \mathrm{dBc} / \mathrm{Hz}$ for a 200 Hz offset.

```
pnoise = comm.PhaseNoise('Level',[-40 -70],'Frequency0ffset',[100 200], ...
    'SampleRate',1000);
```

Create a spectrum analyzer.

```
spectrum = dsp.SpectrumAnalyzer('NumInputPorts',2,'SampleRate',1000, ...
```

    'SpectralAverages',10,'PowerUnits','dBW');
    Generate a sine wave and add phase noise to it. Plot the spectrum of the sine wave and the noisy signal.
$x=$ sinewave();
y = pnoise(x);
$\operatorname{spectrum}(x, y)$

The phase noise is ? 40 dBW within $\pm 100 \mathrm{~Hz}$ of the carrier. The phase noise is $? 70 \mathrm{~dB}$ below the carrier for offsets greater than 200 Hz .

## Algorithms

The output signal, $y_{k}$, is related to input sequence $x_{k}$ by $y_{k}=x_{k} e^{j \varphi_{k},}$ where $\varphi_{k}$ is the phase noise. The phase noise is filtered Gaussian noise such that $\varphi_{\mathrm{k}}=f\left(n_{\mathrm{k}}\right)$, where $n_{\mathrm{k}}$ is the noise sequence and $f$ represents a filtering operation.

To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a 1/f characteristic that passes through the specified point.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across $\log 10(f)$. It is flat from DC to the lowest frequency offset, and from the highest frequency offset to half the sample rate.

## IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$
\lambda=\sqrt{2 \pi f_{o f f s e t} 10^{L / 10}}
$$

where $f_{\text {offset }}$ is the frequency offset in Hz and $L$ is the phase noise level in $\mathrm{dBc} / \mathrm{Hz}$. The denominator coefficients, $\gamma_{i}$, are recursively determined as

$$
\gamma_{i}=(i-2.5) \frac{\gamma_{i-1}}{i-1},
$$

where $\gamma_{1}=1, i=\left\{1,2, \ldots, N_{\mathrm{t}}\right\}$, and $N_{\mathrm{t}}$ is the number of filter coefficients. $N_{\mathrm{t}}$ is a power of 2 , from $2^{7}$ to $2^{19}$. The value of $N_{\mathrm{t}}$ grows as the phase noise offset decreases towards 0 Hz .

## FIR Filter

For the FIR filter, the phase noise level is determined through $\log 10(f)$ interpolation for frequency offsets over the range [df, $f_{\mathrm{s}} / 2$ ], where $d f$ is the frequency resolution and $f_{\mathrm{s}}$ is the sample rate. The phase noise is flat from 0 Hz to the smallest frequency offset, and from the largest frequency offset to $f_{\mathrm{s}} / 2$. The frequency resolution is equal to $\frac{f_{s}}{2}\left(\frac{1}{N_{t}}\right)$, where $N_{\mathrm{t}}$ is the number of coefficients, and is a power of 2 less than or equal to $2^{16}$. If $N_{\mathrm{t}}<2^{8}$, a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases $N_{\mathrm{t}}$ until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.
- The maximum number of FIR filter taps is $2^{16}$.

## comm.PNSequence

Package: comm
Generate a pseudo-noise (PN) sequence

## Description

The PNSequence object generates a sequence of pseudorandom binary numbers using a linearfeedback shift register (LFSR). This object implements LFSR using a simple shift register generator (SSRG, or Fibonacci) configuration. Pseudo-noise sequences are typically used for pseudorandom scrambling and in direct-sequence spread-spectrum systems.

To generate a PN sequence:
1 Create the comm. PNSequence object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

pnSequence $=$ comm. PNSequence pnSequence = comm. PNSequence(Name, Value)

## Description

pnSequence $=$ comm. PNSequence creates a pseudo-noise (PN) sequence generator System object. This object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR).
pnSequence = comm. PNSequence(Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Polynomial - Generator polynomial

' z^6 + z + 1' (default) | polynomial character vector | binary row vector | integer vector

Generator polynomial that determines the shift register's feedback connections, specified as one of these:

- A polynomial character vector that includes the number 1.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The first and last entries must be 1 . The length of this vector is $N+1$, where $N$ is the degree of the generator polynomial.
- A vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 .

For more information, see "Character Representation of Polynomials".
Example: ' $z^{\wedge} 8+z^{\wedge} 2+1^{\prime},\left[\begin{array}{llllllll}1 & 0 & 0 & 0 & 1 & 0 & 1\end{array}\right]$, and $[8200]$ represent the same polynomial, $p(z)=z^{8}+z^{2}+1$.
Data Types: double | char

## InitialConditionsSource - Source of initial conditions <br> 'Property' (default)|'Input port'

Source of the initial conditions that determines the start of the PN sequence, specified as one of these:

- 'Property ' - Specify PN sequence generator initial conditions as a binary scalar or binary vector using the InitialConditions property.
- 'Input port ' - Specify PN sequence generator initial conditions by using an additional input argument, when calling the object. The object accepts a binary scalar or binary vector input. The length of the input must equal the degree of the generator polynomial that the Polynomial property specifies.
Data Types: char

## InitialConditions - Initial conditions of shift register

[0 0 0 0 0 1] (default) | binary scalar | binary vector
Initial conditions of shift register when the simulation starts, specified as a binary scalar or binary vector.

If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial. If you set this property to a scalar, the initial conditions of all the cells of the shift register are the specified scalar value.

The scalar, or at least one element of the specified vector, must be nonzero for the object to generate a nonzero sequence.

## Dependencies

This property is available when InitialConditionsSource is set to 'Property '.
Data Types: double

## MaskSource - Source of mask to shift PN sequence

'Property' (default)|'Input port'
Source of the mask that determines the shift of the PN sequence, specified as one of these:

- 'Property ' - Specify the mask as an integer scalar or binary vector using the Mask property.
- 'Input port' - Specify the mask by using an additional input argument, when calling the object. The mask can only be specified as a binary vector, whose length must equal the degree of the generator polynomial that the Polynomial property specifies.

## Data Types: char

## Mask - Mask to shift PN sequence

0 (default) | integer scalar | binary vector
Mask that determines how the PN sequence is shifted from its starting point, specified as an integer scalar or a binary vector.

When you set this property to an integer scalar, the value is the length of the shift. A scalar shift can be positive or negative. When the PN sequence has a period of $N=2^{n}-1$, where $n$ is the degree of the generator polynomial that the Polynomial property specifies, the object wraps shift values that are negative or greater than $N$.

When you set this property to a binary vector, its length must equal the degree of the generator polynomial that the Polynomial specifies. For more information, see "Shifting PN Sequence Starting Point" on page 3-1072.

The mask vector can be calculated using the shift2mask function.

## Dependencies

This property is available when MaskSource is set to 'Property '.

## VariableSizeOutput - Enable variable-size outputs

false (default) | true
Set this property to true to enable variable-size outputs by using an additional input argument when calling the object. The enabled input specifies the output size of the PN sequence. The input value must be less than or equal to the value of the MaximumOutputSize property.

When you set this property to false, the SamplesPerFrame property specifies the number of output samples.

## MaximumOutputSize - Maximum output size

[10 1] (default)|two-element row vector
Maximum output size, specified as a positive integer two-element row vector that denotes the maximum output size of the PN sequence. The second element of the vector must be 1.
Example: [10 1] gives a 10-by-1 maximum sized output signal.

## Dependencies

This property is available when VariableSizeOutput is set to true.

## SamplesPerFrame - Number of samples output per frame

1 (default) | positive integer
Number of samples output per frame by the PN sequence object, specified as a positive integer. If you set this property to a value of $M$, then the object outputs $M$ samples of a PN sequence that has a
period of $N=2^{n}-1$, where $n$ represents the degree of the generator polynomial that the Polynomial specifies.

If you set the BitPackedOutput property to false, the samples are bits from the PN sequence. If you set the BitPackedOutput property to true, then the output corresponds to SamplesPerFrame groups of bit-packed samples.

## ResetInputPort - Enable generator reset input

false (default) |true
Set this property to true to enable PN sequence generator reset by using an additional input argument when calling the object. This input resets the states of the PN sequence generator to the initial conditions specified in the InitialConditions property. For more information, see "Resetting a Signal" on page 3-1072.

## Dependencies

This property is available when InitialConditionsSource is set to 'Property '.

## BitPackedOutput - Output bit-packed words

false (default) | true
Option to output bit-packed words, specified as false or true. Set this property to true to enable bit-packed outputs. The first bit from the left in the bit-packed word is considered the most significant bit.

When BitPackedOutput is true, the object outputs a column vector of length $M$, which contains integer representations of bit words of length $P . M$ is the number of samples per frame specified in the SamplesPerFrame property. $P$ is the size of the bit-packed words specified in the NumPackedBits property.

## NumPackedBits - Number of bits per bit-packed word

## 8 (default) | integer

Number of bits packed into each output data word, specified as an integer in the range [1, 32].

## Dependencies

This property is available when BitPackedOutput is set to true.

## SignedOutput - Output signed bit-packed words

false (default) | true
Set this property to true to obtain signed, bit-packed, output words. In this case, a 1 in the most significant bit (sign bit) indicates a negative value. The property indicates negative numbers in a two's complement format.

## Dependencies

This property is available when BitPackedOutput is set to true.

## OutputDataType - Data type of output

'double' (default)|'logical'|'Smallest unsigned integer'|'Smallest integer'
Output data type, specified as one of these:

- When BitPackedOutput is set to false, OutputDataType can be 'double', 'logical', or 'Smallest unsigned integer'.
- When BitPackedOutput is set to true, OutputDataType can be 'double' or 'Smallest integer'.

Note You must have a Fixed-Point Designer user license to use this property in 'Smallest unsigned integer' or 'Smallest integer' mode.

## Dependencies

The valid settings for OutputDataType depends on the setting of BitPackedOutput.

## Usage

## Syntax

```
outSequence = pnSequence()
outSequence = pnSequence(initCond)
outSequence = pnSequence(maskVec)
outSequence = pnSequence(outputSize)
outSequence = pnSequence(reset)
```

## Description

outSequence $=$ pnSequence () outputs a frame of the PN sequence. Specify the frame length with the SamplesPerFrame property. The PN sequence has a period of $N=2^{n}-1$, where $n$ is the degree of the generator polynomial that you specify in the Polynomial property.

You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties.
outSequence $=$ pnSequence(initCond) provides an additional input with values specifying the initial conditions of the linear-feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to 'Input port'.
outSequence $=$ pnSequence(maskVec) provides an additional input specifying the mask vector that determines how the PN sequence is shifted from its starting point.

This syntax applies when you set the MaskSource property of the object to 'Input port '.
outSequence $=$ pnSequence(outputSize) provides an additional input specifying the output size of the PN sequence.

This syntax applies when you set the VariableSize0utput property of the object to true.
outSequence $=$ pnSequence (reset) provides an additional input indicating whether to reset the PN sequence generator.

This syntax applies when you set InitialConditionsSource to 'Property' and ResetInputPort to true.

## Input Arguments

## initCond - Initial register conditions

binary scalar | binary vector
Initial conditions of the shift register when the simulation starts, specified as a binary scalar or binary vector. When you set initCond to a binary vector, the length of the vector must equal the degree of the Polynomial property. The scalar, or at least one element of initCond, must be nonzero for the object to generate a nonzero sequence.
 for a PN sequence generator specified by a generator polynomial of degree 3 .
Data Types: double
maskVec - Mask vector
binary vector
Mask that determines how the PN sequence is shifted from its starting point, specified as a binary vector. The length of the vector must equal the degree of the Polynomial property.

## outputSize - Output size of the PN sequence

scalar | two-element row vector
Output size of the PN sequence, specified as a scalar or two-element row vector. When you set outputSize to a two-element row vector, the second element must be equal to 1 .

## reset - Reset PN sequence generator

scalar | column vector
When you specify reset as a scalar, the object resets to the initial conditions specified in the InitialConditions property and generates a new output frame.

When you specify reset as a column vector, the length of the vector must equal the number of samples per frame specified in SamplesPerFrame. A column vector input allows multiple resets within an output frame. A non-zero value at the ith element of the vector will cause a reset at the ith element of the generated PN sequence.

## Output Arguments

## outSequence - PN Sequence

column vector
PN sequence generated by the object, returned as a column vector.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Generate Maximal Length PN Sequences

Generate a 14 -sample frame of a maximal length PN sequence given generator polynomial, $x^{3}+x^{2}+1$.

Generate PN sequence data by using the comm. PNSequence object. The sequence repeats itself as it contains 14 samples while the maximal sequence length is only 7 samples $\left(2^{3}-1\right)$.

```
pnSequence = comm.PNSequence('Polynomial',[3 2 0], ...
    'SamplesPerFrame',14,'InitialConditions',[0 0 1]);
x1 = pnSequence();
[x1(1:7) x1(8:14)]
ans = 7\times2
    1 1
    0 0
    0 0
    1
    1 1
    1 1
    0 0
```

Create another maximal length sequence based on the generator polynomial, $x^{4}+x+1$. As it is a fourth order polynomial, the sequence repeats itself after 15 samples $\left(2^{4}-1\right)$.

```
pnSequence2 = comm.PNSequence('Polynomial','x^4+x+1', ...
    'InitialConditions',[0 0 0 1],'SamplesPerFrame',30);
x2 = pnSequence2();
[x2(1:15) x2(16:30)]
ans = 15\times2
\begin{tabular}{ll}
1 & 1 \\
0 & 0 \\
0 & 0 \\
0 & 0 \\
1 & 1 \\
0 & 0 \\
0 & 0 \\
1 & 1 \\
1 & 1 \\
0 & 0
\end{tabular}
```

## Generate Galois Linear-Feedback Shift Register Output

The comm. PNSequence system object implements a linear-feedback shift register (LFSR) using a simple shift register generator (SSRG, or Fibonacci configuration). This configuration differs from the modular shift register generator (MSRG, or Galois configuration) by a phase difference, that can be determined empirically from the system object.

This phase difference can be specified as the Mask parameter for the comm. PNSequence system object to generate the equivalent MSRG configuration output. The block diagram represents the implementation of a 5-bit LFSR in the Galois (MSRG) configuration.

Load the file GaloisLFSR. The file contains the following variables that define the properties and output PN sequence of the 5 -bit Galois LFSR:

- polyVec: Generator polynomial
- polySize: Degree of the generator polynomial
- initStates: Initial conditions of the shift register
- maskVar: Mask to shift the PN sequence
- pn_msrg: Output PN sequence of maximal length, from the 5-bit Galois LFSR
load GaloisLFSR
Generate PN sequence data by using the comm. PNSequence object with the same set of properties used to implement the 5-bit Galois LFSR. Compare this PN sequence with the output of the 5-bit Galois LFSR. The two sequences differ by a phase shift.

```
pnSequence = comm.PNSequence('Polynomial',polyVec,'InitialConditions',initStates,...
    'Mask',maskVar,'SamplesPerFrame',2^polySize-1);
pn = pnSequence();
isequal(pn,pn_msrg)
ans = logical
    0
```

Compute the phase shift between the two configurations. Set the value of the Mask property based on this phase shift.

```
for i = 1:length(pn)
    exp_pn = [pn(i:end);pn(1:(i-1))];
    if isequal(exp_pn,pn_msrg)
```

```
        break
    end
end
maskVar = i-1;
```

Generate PN sequence data by using the comm. PNSequence system object with the modifed Mask property value. Compare this sequence with the output of the 5-bit Galois LFSR. The two sequences are now equal.

```
pnSequence_mod = comm.PNSequence('Polynomial',polyVec,'InitialConditions',initStates,...
    'Mask',maskVar,'SamplesPerFrame',2^polySize-1);
pn_mod = pnSequence_mod();
isequal(pn_mod,pn_msrg)
ans = logical
    1
```

## Algorithms

## Simple Shift Register Generator

A linear-feedback shift register (LFSR), implemented as a simple shift register generator (SSRG), is used to generate PN sequences. This type of shift register is also known as a Fibonacci implementation.

The Polynomial property determines the feedback connections of the shift register. It is a primitive binary polynomial in $z, g_{\mathrm{r}} z^{\mathrm{r}}+g_{\mathrm{r}-1} z^{r-1}+g_{r-2} z^{r-2}+\ldots+g_{0}$. For the coefficient, $g_{k=0}$ to $r$, the coefficient $g_{k}$ is 1 if there is a connection from the kth register to the adder. The leading term, $g_{r}$, and the constant term, $g_{0}$, of the Polynomial property must be 1 because the polynomial must be primitive. The InitialConditions property specifies the initial values of the registers. For example, the following
table indicates two sets of parameter values that correspond to a generator polynomial of $p(z)=z^{8}+$ $z^{2}+1$.

| Quantity | Example 1 | Example 2 |
| :---: | :---: | :---: |
| Polynomial | g1 = [1 0 0 0 0 0 1 0 1] |  |
| Degree of generator polynomial | 8 , which is length(g1)-1 | 8 |
| InitialConditions | [10 0 0 0 0 1 0] | [1 0 0 0 0 0 1 0] |

At each step, all $r$ registers in the generator update their values according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The output of the LFSR reflects the sum of all connections in the $m$ mask vector.

The Mask property, $m$, determines the shift of the PN sequence starting point. For more information, see "Shifting PN Sequence Starting Point" on page 3-1072.

## Shifting PN Sequence Starting Point

To shift the starting point of the PN sequence, specify the Mask property as:

- An integer representing the length of the shift.

The default Mask setting of 0 corresponds to no shift. As illustrated in the LFSR shift register diagram in "Simple Shift Register Generator" on page 3-1071, there is no shift when the only connection is along the arrow labeled $m_{0}$.

This table shows the shift that occurs when you set Mask to 0 versus a positive integer $d$.

|  | T = 0 | T = 1 | T = 2 | $\cdots$ | T = d | T = d+1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Shift $=0$ | $x_{0}$ | $x_{1}$ | $x_{2}$ | $\ldots$ | $x_{d}$ | $x_{d+1}$ |
| Shift $=d$ | $x_{d}$ | $x_{d+1}$ | $x_{d+2}$ | $\ldots$ | $x_{2 d}$ | $x_{2 d+1}$ |

- A binary vector whose length is equal to the degree of the generator polynomial. The LFSR shift register diagram in "Simple Shift Register Generator" on page 3-1071 shows Mask specified as a mask vector, $m$. The binary vector must have $N$ elements, where $N$ is the degree of the generator polynomial. To calculate the mask vector, use the shift2mask function.

The binary vector corresponds to a polynomial in $z, m_{r-1} z^{r-1}+m_{r-2} z^{r-2}+\ldots+m_{1} z+m_{0}$, of degree at most $r-1$. The mask vector that corresponds to a shift of $d$ is the vector that represents $m(z)=$ $z^{d}$ modulo $g(z)$, where $g(z)$ is the generator polynomial.

For example, if the degree of the generator polynomial is 4 , then the mask vector that corresponds to $d=2$ is [ $\left.\begin{array}{lll}0 & 1 & 0\end{array}\right]$ ], which represents the polynomial $m(z)=z^{2}$.

## Resetting a Signal

To reset the PN generator sequence, you must first set the ResetInputPort property to true. Suppose that the system object generates a PN sequence of [ $\left.\begin{array}{llllllll}1 & 0 & 0 & 1 & 1 & 0 & 1 & 1\end{array}\right]$ when there is no reset. When the reset signal [0001] is passed as an input argument to the object, the PN sequence is reset at the fourth bit, because the fourth bit of the reset signal is a 1 .

## Sequences of Maximum Length

To generate a maximum length sequence for a generator polynomial that has the degree $r$, set Polynomial to a value from the following table. The maximum sequence length is $2^{r}-1$.

| r | Generator Polynomial | r | Generator Polynomial | r | Generator Polynomial | r | Generator Polynomial |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | $\left[\begin{array}{lll}2 & 1 & 0\end{array}\right]$ | 15 | $\left[\begin{array}{lll}15 & 14 & 0\end{array}\right]$ | 28 | $\left[\begin{array}{lll}28 & 25 & 0\end{array}\right]$ | 41 | [41 3 0] |
| 3 | $\left[\begin{array}{lll}3 & 2 & 0\end{array}\right]$ | 16 | $\left[\begin{array}{lllll}16 & 15 & 13 & 4 & 0\end{array}\right]$ | 29 | $\left[\begin{array}{llll}29 & 27 & 0\end{array}\right]$ | 42 | $\left[\begin{array}{lllll}42 & 23 & 22 & 1 & 0\end{array}\right]$ |
| 4 | $\left[\begin{array}{lll}4 & 3 & 0\end{array}\right]$ | 17 | $\left[\begin{array}{llll}17 & 14 & 0\end{array}\right]$ | 30 | $\left[\begin{array}{llllll}30 & 29 & 28 & 7 & 0\end{array}\right]$ | 43 | $\left[\begin{array}{lllll}43 & 6 & 4 & 3 & 0\end{array}\right]$ |
| 5 | $\left[\begin{array}{lll}5 & 3 & 0\end{array}\right]$ | 18 | [18 11-1] | 31 | $\left[\begin{array}{lll}31 & 28 & 0\end{array}\right]$ | 44 | [44 6 5 2 0] |
| 6 | [6 5 0] | 19 | $\begin{array}{llll} {\left[\begin{array}{llll} {[19} & 18 & 17 & 14 \\ 0] \end{array}\right.} & & \\ \hline \end{array}$ | 32 | $\begin{array}{lllll} \hline\left[\begin{array}{llll} 32 & 31 & 30 & 10 \\ 01 \end{array}\right. & & \end{array}$ | 45 | [45 4 31100$]$ |
| 7 | $\left[\begin{array}{lll}7 & 6 & 0\end{array}\right]$ | 20 | [20 17 0] | 33 | $\left[\begin{array}{lll}33 & 20 & 0\end{array}\right]$ | 46 | $\left[\begin{array}{lllll}46 & 21 & 10 & 1 & 0\end{array}\right]$ |
| 8 | [86 6 5 4 0] | 21 | $\left[\begin{array}{llll}21 & 19 & 0\end{array}\right]$ | 34 | $\left[\begin{array}{lllll}34 & 15 & 14 & 1 & 0\end{array}\right]$ | 47 | [47 14 0] |
| 9 | [9 500$]$ | 22 | $\left[\begin{array}{lll}22 & 21 & 0\end{array}\right]$ | 35 | [35 2 0] | 48 | [482827 100 |
| 10 | [10 7 0] | 23 | $\left[\begin{array}{lll}23 & 18 & 0\end{array}\right]$ | 36 | [36 11-1] | 49 | [49 9 0] |

## comm.PreambleDetector

Package: comm
Detect preamble in data

## Description

The comm. PreambleDetector System object detects a preamble in an input data sequence. A preamble is a set of symbols or bits used in packet-based communication systems to indicate the start of a packet. The preamble detector object finds the location corresponding to the end of the preamble.

To detect a preamble in an input data sequence:
1 Create a comm. PreambleDetector object and set the properties of the object.
2 Call step to detect the presence of a preamble.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

prbdet = comm. PreambleDetector creates a preamble detector object, prbdet, using the default properties.
prbdet = comm.PreambleDetector(Name,Value) specifies additional properties using Name, Value pairs. Unspecified properties have default values.
prbdet $=$ comm. PreambleDetector(prb,Name,Value) specifies the preamble, prb in addition to those properties specified by using Name, Value pairs.

## Example:

prbdet = comm.PreambleDetector('Input','Bit','Detections','First');

## Properties

## Input - Type of input data <br> 'Symbol' (default)|'Bit'

Type of input data, specified as 'Symbol' or 'Bit'. For binary inputs, set this parameter to 'Bit '. For all other inputs, set this parameter to 'Symbol '. Symbol data can be of data type single or double while bit data can, in addition, support the Boolean, int8, and uint8 data types.

## Preamble - Preamble sequence

[1+1i; 1-1i] (default) | column vector

Preamble sequence, specified as a real or complex column vector. The object uses this sequence to detect the presence of the preamble in the input data. If Input is 'Bit', the preamble must be a binary sequence. If Input is 'Symbol ', the preamble can be any real or complex sequence.

## Data Types: double | single | logical | int8|uint8

## Threshold - Detection threshold

3 (default) | nonnegative scalar
Detection threshold, specified as a nonnegative scalar. When the computed detection metric is greater than or equal to Threshold, the preamble is detected. This property is available when Input is set to 'Symbol'. Tunable.

## Detections - Number of preambles to detect

'All' (default)|'First'
Number of preambles to detect, specified as 'All' or 'First'.

- 'All' - Detects all the preambles in the input data sequence.
- 'First' - Detect only the first preamble in the input data sequence.

## Methods

$$
\text { reset } \quad \text { Reset states of preamble detector object }
$$

step Detect preamble in data
Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

## Detect Preamble from Binary Data Sequence

Specify a six-bit preamble.
prb = [1 00101$]$ ';
Create a preamble detector object using preamble prb and taking bit inputs.
prbdet = comm. PreambleDetector(prb,'Input','Bit');
Generate a binary data sequence containing two preambles and using random bits to represent the data fields.

```
pkt = [prb; randi([0 1],10,1); prb; randi([0 1],10,1)];
```

Locate the indices of the two preambles. The indices correspond to the end of the preambles.

```
idx = prbdet(pkt)
idx = 2x1
```

The detector correctly identified indices 6 and 22 as the end of the two preambles inserted in the sequence.

## Detect Preamble in Noisy QPSK Signal

Create a preamble and apply QPSK modulation.

```
p1 = [00 1 2 3 3 3 2 1 0]';
p = [p1; p1];
prb = pskmod(p,4,pi/4,'gray');
```

Create a comm. PreambleDetector object using preamble prb.
prbdet $=$ comm. PreambleDetector (prb)
prbdet =
comm. PreambleDetector with properties:
Input: 'Symbol'
Preamble: [16x1 double]
Threshold: 3
Detections: 'All'

Generate a sequence of random symbols. The first sequence represents the last 20 symbols from a previous packet. The second sequence represents the symbols from the current packet.

```
d1 = randi([0 3],20,1);
d2 = randi([0 3],100,1);
```

Modulate the two sequences.

```
x1 = pskmod(d1,4,pi/4,'gray');
```

x2 = pskmod(d2,4,pi/4,'gray');

Create a sequence of modulated symbols consisting of the remnant of the previous packet, the preamble, and the current packet.
y = [x1; prb; x2];
Add white Gaussian noise.
$z=\operatorname{awgn}(y, 10) ;$
Determine the preamble index and the detection metric.
[idx, detmet] = prbdet(z);
Calculate the number of elements in idx. Because the number of elements is greater than one, the detection threshold is too low.
numel(idx)
ans $=80$

Display the five largest detection metrics.

```
detmetSort = sort(detmet,'descend');
detmetSort(1:5)
ans = 5*1
    16.3115
    13.6900
    10.5698
        9.1920
        8.9706
```

Increase the threshold and determine the preamble index.

```
prbdet.Threshold = 15;
```

idx = prbdet(z)
$i d x=36$

The result of 36 corresponds to the sum of the preamble length (16) and the remaining samples in the previous packet (20). This indicates that the preamble has been successfully detected.

## Algorithms

## Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

## Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples match the preamble, the filter output reaches its peak. The index of the peak corresponds to the end of the preamble sequence in the input data. See Discrete FIR Filter for further information on the FIR filter algorithm.

The cross-correlation values that are greater than or equal to the specified threshold are reported as peaks.

- If the detection threshold is too low, the algorithm will detect false peaks, or, in the extreme case, detect as many detected peaks as there are input samples.
- If the detection threshold is too high, the algorithm will miss detecting peaks, or, in the extreme case, detect no peaks.

Consequently, the selection of the detection threshold is critical.

## reset

System object: comm. PreambleDetector
Package: comm
Reset states of preamble detector object

## Syntax

reset(prbdet)

## Description

reset (prbdet) resets the states of the PreambleDetector object, prbdet.
Introduced in R2016b

## step

System object: comm. PreambleDetector<br>Package: comm<br>Detect preamble in data

## Syntax

idx = step(prbdet,x)
[idx, detmet] = step(prbdet, $x$ )
idx = prbdet(x)
[idx, detmet] = prbdet(x)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.
idx $=\operatorname{step}(p r b d e t, x)$ returns the location of the end of the preamble in data sequence $x$, using preamble detector prbdet. The index is of data type double.
[idx, detmet] = step(prbdet,x) also returns the detection metric, detmet. This syntax is available when the Input property is 'Symbol' . detmet has the same dimensions and data type as x .

The output, detmet, is determined by one of these algorithms:

- If either the preamble or input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input signal.
- If both the preamble and input data are real, the detection metric is the cross-correlation of the preamble and the input signal.
$i d x=\operatorname{prbdet}(x)$ is equivalent to the first syntax.
[idx, detmet] = prbdet(x) is equivalent to the second syntax.

Note prbdet specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## Introduced in R2016b

## comm.PSKCoarseFrequencyEstimator

Package: comm
(To be removed) Estimate frequency offset for PSK signal

Note will be removed in a future release. Use comm. CoarseFrequencyCompensator instead.

## Description

The PSKCoarseFrequencyEstimator System object estimates frequency offset for a PSK signal.
To estimate frequency offset for a PSK signal:
1 Define and set up your PSK coarse frequency estimator object. See "Construction" on page 31082.

2 Call step to estimate frequency offset for a PSK signal according to the properties of comm. PSKCoarseFrequencyEstimator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. PSKCoarseFrequencyEstimator creates a PSK coarse frequency offset estimator object, H . This object uses an open-loop technique to estimate the carrier frequency offset in a received PSK signal.

H = comm. PSKCoarseFrequencyEstimator(Name,Value) creates a PSK coarse frequency offset estimator object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## ModulationOrder

Modulation order the object uses
Specify the modulation order of the PSK signal as a positive, real scalar of data type double. This value must be a positive power of 2 . The default is 4 .

## Algorithm

Estimation algorithm to object uses
Specify the estimation algorithm as one of FFT-based or Correlation-based. The default is FFTbased.

## FrequencyResolution

Desired frequency resolution ( Hz )
Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length used to perform spectral analysis, and must be less than or equal to half the SampleRate on page 3-0 property. This property applies only if the Algorithm property is FFT-based. The default is 0.001 .

## MaximumOffset

Maximum measurable frequency offset ( Hz )
Specify the maximum measurable frequency offset as a positive, real scalar of data type double. The default is 0.05 .

The value of this property must be less than SampleRate on page 3-0 / ModulationOrder on page 3-0 . It is recommended that MaximumOffset on page 3-0 be less than or equal to SampleRate on page 3-0 /(4*ModulationOrder on page 3-0 ). This property is active only if the Algorithm property is Correlation-based.

## SampleRate

Sample rate (Hz)
Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1 .

## Methods

reset (To be removed) Reset states of the PSKCoarseFrequencyEstimator object
step (To be removed) Estimate frequency offset for PSK signal

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Compare Frequency Offset Estimation and Correction Methods for QPSK Signal

Estimate and correct for a frequency offset in a QPSK signal using the recommended comm. CoarseFrequencyCompensator System object. Compare frequency correction results to a workflow using the comm. PSKCoarseFrequencyEstimator System object.

Set example parameters.

```
nSym = 2048; % Number of input symbols
M = 4; % Modulation order
fs = 80000; % Sampling frequency (Hz)
freqRez = 1; % Frequency resolution (Hz)
freqOff = -2000; % Frequency offset
```

Create System objects for these operations:

```
% Square root raised cosine transmit filter
txfilter = comm.RaisedCosineTransmitFilter;
% Phase frequency offset - one to apply a frequency offset and a second
% that takes the frequency offset estimate as an input to correct the
% offset.
pfo = comm.PhaseFrequency0ffset('Frequency0ffset',freq0ff, ...
    SampleRate',fs);
pfoCorrect = comm. PhaseFrequency0ffset(...
    'Frequency0ffsetSource','Input port', ...
    'SampleRate',fs);
% PSK coarse frequency estimator
frequencyEst = comm.PSKCoarseFrequencyEstimator(...
    'SampleRate',fs,'FrequencyResolution',freqRez);
Warning: comm.PSKCoarseFrequencyEstimator will be removed in a future release.
Use comm.CoarseFrequencyCompensator instead.
% Coarse frequency compensatator
freqComp = comm.CoarseFrequencyCompensator('Modulation','QPSK', ...
        'SampleRate',fs,'FrequencyResolution',freqRez);
```

Generate a QPSK signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
data = randi([0 M-1],nSym,1);
modData = pskmod(data,M,pi/4); % Generate QPSK signal
txFiltData = txfilter(modData); % Apply Tx filter
offsetData = pfo(txFiltData); % Apply frequency offset
rxData = awgn(offsetData,25); % Pass through AWGN channel
```

This example does not apply receive filtering. In general, when the frequency offset is high, it is beneficial to apply coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

Compare the results for estimating and correcting the frequency offset by:

- Using the frequencyEst object to estimate the frequency offset and pfoCorrect to compensate for the frequency offset.
- Using the freqComp object estimate and apply compensation to the signal.

Observe the frequency offset estimate returned by both estimation methods.

```
estFreq0ffset1
estFreq0ffset2
estFreqOffset1 =
    -2.0000e+03
estFreq0ffset2 =
    -2.0000e+03
```

Confirm the maximum resulting difference between the two compensation methods is negligible.

```
max(compensatedData1-compensatedData2)
```

reset $(\mathrm{H})$ resets the internal states of the PSKCoarseFrequencyEstimator object, H .

## step

System object: comm.PSKCoarseFrequencyEstimator
Package: comm
(To be removed) Estimate frequency offset for PSK signal

Note comm. PSKCoarseFrequencyEstimator will be removed in a future release. Use comm. CoarseFrequencyCompensator instead.

## Syntax

Y $=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ estimates the carrier frequency offset of the input $X$ and returns the result in $Y . X$ must be a complex column vector of data type double. The step method outputs the estimate Y as a scalar of type double.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.PSKDemodulator

Package: comm
Demodulate using M-ary PSK method

## Description

The PSKDemodulator object demodulates an input signal using the M-ary phase shift keying (MPSK) method.

To demodulate a signal that was modulated using phase shift keying:
1 Define and set up your PSK demodulator object. See "Construction" on page 3-1088.
2 Call step to demodulate the signal according to the properties of comm. PSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm.PSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

H = comm. PSKDemodulator(Name, Value) creates an M-PSK demodulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. PSKDemodulator(M, PHASE,Name, Value) creates an M-PSK demodulator object, H. This object has the ModulationOrder property set to M, the PhaseOffset property set to PHASE, and the other specified properties set to the specified values. M and PHASE are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8 .

## PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar value. The default is pi/8.

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values. The default is false. When you set this property to true, the step method outputs a column vector of bit values. The length of this vector equals $\log 2$ (ModulationOrder on page 3-0 ) times the number of demodulated symbols. When you set this property to false, the step method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between 0 and ModulationOrder-1.

## SymbolMapping

Constellation encoding
Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) bits to the corresponding symbol. Choose from Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the integer $m$ must be in the range [0, (ModulationOrder-1)] and maps to the complex value $\exp (j \square$ PhaseOffset on page 3-0 $\quad+j 2 \pi m / M o d u l a t i o n 0 r d e r)$. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping on page 3-0 property.

## CustomSymbolMapping

Custom constellation encoding
Specify a custom constellation symbol mapping vector. The default is $0: 7$. This property requires a row or column vector with a size of Modulation0rder on page 3-0 . This vector must have unique integer values in the range [0, Modulation0rder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of $0+$ PhaseOffset on page 3-0 , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of $-\Pi /$ ModulationOrder + PhaseOffset. This property applies when you set the SymbolMapping on page 3-0 property to Custom.

## DecisionMethod

Demodulation decision method
Specify the decision method the object uses as Hard decision|Log-likelihood ratio| Approximate log-likelihood ratio. The default is Hard decision. When you set the BitOutput on page 3-0 property to false, the object always performs hard decision demodulation. This property applies when you set the BitOutput property to true.

## VarianceSource

## Source of noise variance

Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate loglikelihood ratio.

## Variance

Noise variance
Specify the variance of the noise as a positive, real scalar value. The default is 1 . If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, use approximate LLR instead because the algorithm for that option does not compute exponentials. This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Log-likelihood ratio, or Approximate log-likelihood ratio, and the VarianceSource on page 3-0 property to Property. This property is tunable.

## OutputDataType

Data type of output
Specify the output data type as Full precision|Smallest unsigned integer|double| single | int8|uint8|int16|uint16|int32|uint32. The default is Full precision. This property applies when you set the Bit0utput on page 3-0 property to false. It also applies when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. In this second case, when the OutputDataType on page 3-0 property is set to Full precision, the input data type is single- or double-precision, the output data has the same data type as the input. . When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer.

When you set BitOutput to true and the DecisionMethod property to Hard Decision, then logical data type becomes a valid option. If you set the BitOutput property to true and the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio, the output data has the same data type as the input. In this case, the data type must be single- or double-precision.

## Fixed-Point Properties

## DerotateFactorDataType

## Data type of derotate factor

Specify the derotate factor data type as Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on page 3-0 property to false. It also applies when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when the ModulationOrder on page 3-0 property is 2,4 , or 8 . The step method input must also have a fixed-point type, and the PhaseOffset on page 3-0 property must have a nontrivial value. For ModulationOrder $=2$, the phase offset is trivial if that value is a multiple of $\pi / 2$. For ModulationOrder $=4$, the phase offset is trivial if that value is an even multiple of $\pi / 4$. For Modulation0rder $=8$, there are no trivial phase offsets.

## CustomDerotateFactorDataType

Fixed-point data type of derotate factor
Specify the derotate factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype ( $[\mathrm{l}, 16$ ). This property applies when you set the

DerotateFactorDataType on page 3-0
property to Custom. The word length must be a value between 2 and 128.

## Examples

## 16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects ${ }^{\mathrm{TM}}$ in which custom symbol mapping is used. Estimate the BER in an AWGN channel and compare the performance with that of a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values which fall between 0 and 15 .

```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16 -PSK modulator and demodulator pair having custom symbol mapping defined by the array, custMap.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...
    'SymbolMapping','Custom', ...
    'CustomSymbolMapping',custMap);
pskDemodulator = comm.PSKDemodulator(16,'BitOutput',true, ...
    'SymbolMapping','Custom', ...
    'CustomSymbolMapping',custMap);
```

Display the modulator constellation.

```
constellation(pskModulator)
```

Create an AWGN channel System object for use with 16 -ary data.
awgnChannel = comm.AWGNChannel('BitsPerSymbol', log2(16));
Create an error rate object to track the BER statistics.
errorRate = comm.ErrorRate;
Initialize the simulation vectors. The Eb/No is varied from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for k = 1:length(ebnoVec)
    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(k);
    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1],4000,1);
```

```
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data,rxData);
    end
    % Save the BER data
    ber(k) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using berawgn.
berTheory = berawgn(ebnoVec,'psk',16,'nondiff');
Plot the simulated and theoretical results. Because the simulated results rely on 16-PSK modulation that does not use Gray codes, the performance is not as good as that predicted by theory.

```

constellation(demod)
```

## step

System object: comm. PSKDemodulator
Package: comm
Demodulate using M-ary PSK method

## Syntax

$Y=\operatorname{step}(H, X)$
Y = step(H,X,VAR)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

Y = step ( $\mathrm{H}, \mathrm{X}$ ) demodulates data, X , with the PSK demodulator System object, H , and returns Y . Input $X$ must be a scalar or a column vector with double or single precision data type. If the value of the ModulationOrder property is less than or equal to 8 and you set BitOutput to false, or when you set the DecisionMethod property to Hard Decision and BitOutput to true, the object accepts an input with a signed integer data type or signed fixed point (fi objects). Depending on the BitOutput property value, output $Y$, can be integer or bit valued.
$Y=\operatorname{step}(H, X, V A R)$ uses soft decision demodulation and noise variance VAR. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to Approximate log-likelihood ratio or Log-likelihood ratio, and the VarianceSource property to Input port. The data type of input VAR must be double or single precision.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.PSKModulator

Package: comm
Modulate using M-ary PSK method

## Description

The PSKModulator object modulates using the M-ary phase shift keying method. The output is a baseband representation of the modulated signal. The M-ary number parameter, M , is the number of points in the signal constellation.

To modulate a signal using phase shift keying:
1 Define and set up your PSK modulator object. See "Construction" on page 3-1107.
2 Call step to modulate the signal according to the properties of comm. PSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = $\underline{\text { step }(o b j, x) \text { and } y=o b j(x) \text { perform equivalent operations. }}$

## Construction

H = comm. PSKModulator creates a modulator System object, H. This object modulates the input signal using the M-ary phase shift keying (M-PSK) method.

H = comm. PSKModulator(Name,Value) creates an M-PSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. PSKModulator(M,PHASE,Name, Value) creates an M-PSK modulator object, H. This object has the ModulationOrder property set to M, the PhaseOffset property set to PHASE, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8 .

## PhaseOffset

Phase of zeroth point of constellation
Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar value. The default is $\mathrm{pi} / 8$.

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. When you set this property to true, the step method input must be a column vector of bit values. This vector must have a length that is an integer multiple of $\boldsymbol{\operatorname { l o g }} 2$ (Modulation0rder on page 3-0 ). This vector contains bit representations of integers between 0 and ModulationOrder-1. When you set the BitInput on page 3-0 property to false, the step method input must be a column vector of numeric data type integer symbol values. These values must be between 0 and ModulationOrder-1. The default is false.

## SymbolMapping

Constellation encoding
Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) input bits to the corresponding symbol as one of Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the integer $m$ must be in the range [ 0 , (Modulation0rder-1)] and maps to the complex value $\exp (j \square$ PhaseOffset on page 3-0 $\quad+j 2 \pi m / M o d u l a t i o n 0 r d e r)$. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping on page 3-0 property.

## CustomSymbolMapping

Custom constellation encoding
Specify a custom constellation symbol mapping vector. This property requires a row or column vector of size ModulationOrder on page 3-0 and must have unique integer values in the range [0, Modulation0rder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of $0+$ Phase 0 ffset on page 3-0 , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of $-\Pi /$ ModulationOrder + PhaseOffset. This property applies when you set the SymbolMapping on page 3-0 property to Custom. The default is $0: 7$.

## OutputDataType

Data type of output
Specify the output data type as double | single | Custom. The default is double.

## Fixed-Point Properties

## CustomOutputDataType

Fixed-point data type of output
Specify the output fixed-point type as a numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the OutputDataType on page 3-0 property to Custom.

## Methods

| constellation | Calculate or plot ideal signal constellation |
| :--- | :--- |
| step | Modulate using M-ary PSK method |

## Common to All System Objects

release Allow System object property value changes

## Examples

## Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to observe the effects of noise.

Create a PSK modulator System object ${ }^{\mathrm{Tm}}$. The default modulation order for the PSK modulator object is 8 .
pskModulator = comm.PSKModulator;
Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an AWGN channel.
channel = comm. AWGNChannel('EbNo',20, 'BitsPerSymbol',3);
Transmit the signal through the AWGN channel.
channelOutput = channel(modData);
Plot the noiseless and noisy data using scatter plots to observe the effects of noise.

```
scatterplot(modData)
```

Change the EbNo property to 10 dB to increase the noise. channel.EbNo = 10;

Pass the modulated data through the AWGN channel.
channelOutput = channel(modData);
Plot the channel output. You can see the effects of increased noise.
scatterplot(channelOutput)

## Algorithms

The block outputs a baseband signal by mapping input bits or integers to complex symbols according to the following:

$$
s_{n}(t)=\exp \left(j \Pi\left(\frac{2 n+1}{M}\right)\right) ; \quad n \in\{0,1, \ldots, M-1\} .
$$

This applies when a natural binary ordering is used. Another common mapping is Gray coding, which has the advantage that only one bit changes between adjacent constellation points. This results in better bit error rate performance. For 8-PSK modulation with Gray coding, the mapping between the input and output symbols is shown.

| Input | Output |
| :--- | :--- |
| 0 | $0(000)$ |
| 1 | $1(001)$ |
| 2 | $3(011)$ |
| 3 | $2(010)$ |
| 4 | $6(110)$ |
| 5 | $7(111)$ |
| 6 | $5(101)$ |

| Input | Output |
| :--- | :--- |
| 7 | $4(100)$ |

The corresponding constellation diagram follows.

When the input signal is composed of bits, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $\log _{2}(M)$ bits.

## step

System object: comm. PSKModulator
Package: comm
Modulate using M-ary PSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the PSK modulator System object, H . It returns the baseband modulated output, Y. Depending on the value of the BitInput property, input X can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.PSKTCMDemodulator

Package: comm
Demodulate convolutionally encoded data mapped to M-ary PSK signal constellation

## Description

The PSKTCMDemodulator object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

To demodulate a signal that was modulated using trellis-coded modulation:
1 Define and set up your PSK TCM demodulator object. See "Construction" on page 3-1119.
2 Call step to demodulate the signal according to the properties of comm. PSKTCMDemodulator.
The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm. PSKTCMDemodulator creates a trellis-coded, M-ary phase shift, keying (PSK TCM) demodulator System object, H. This object demodulates convolutionally encoded data that has been mapped to an M-PSK constellation.

H = comm. PSKTCMDemodulator(Name, Value) creates a PSK TCM demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. PSKTCMDemodulator(TRELLIS,Name, Value) creates a PSK TCM demodulator System object, H . This object has the TrellisStructure property set to TRELLIS and the other specified properties set to the specified values.

## Properties

## TrellisStructure

Trellis structure of convolutional code
Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check whether the trellis structure is valid. The default is the result of poly2trellis([1 3], [1 0 0; 0 5 2]).

## TerminationMethod

Termination method of encoded frame

Specify the termination method as one of Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use Continuous mode.

When you set this property to Truncated, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set property to Terminated, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

## TracebackDepth

Traceback depth for Viterbi decoder
Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the TerminationMethod on page 3-0 property to Continuous, the decoding delay consists of TracebackDepth zero symbols or TracebackDepth $\times$ K zero bits for a rate $K / N$ convolutional code.

When you set the TerminationMethod property to Truncated or Terminated, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

## ResetInputPort

Enable demodulator reset input
Set this property to true to enable an additional input to the step method. The default is false. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4,8 , or 16 . The default is 8 . The ModulationOrder on page 3-0 property value must equal the number of possible input symbols to the convolutional decoder of the PSK TCM demodulator object. The ModulationOrder property must equal $2^{N}$ for a rate $K / N$ convolutional code.

## OutputDataType

Data type of output
Specify output data type as logical | double. The default is double.

## Methods

reset Reset states of the PSK TCM demodulator object
step Demodulate convolutionally encoded data mapped to M-ary PSK constellation

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Demodulate Noisy PSK QAM Data

Modulate and demodulate data using 8-PSK TCM modulation in an AWGN channel. Estimate the resulting error rate.

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create modulator and demodulator System objects ${ }^{\mathrm{TM}}$ using trellis, t , having modulation order 8.

```
hMod = comm.PSKTCMModulator(t,'ModulationOrder',8);
hDemod = comm.PSKTCMDemodulator(t,'Modulation0rder',8, ...
    'TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    SNR',7);
```

Create an error rate calculator with delay in bits equal to TracebackDepth times the number of bits per symbol.

```
hError = comm.ErrorRate('ReceiveDelay',...
    hDemod.TracebackDepth*log2(t.numInputSymbols));
```

Generate random binary data and modulate with 8-PSK TCM. Pass the modulated signal through the AWGN channel and demodulate. Calculate the error statistics.

```
for counter = 1:10
    % Transmit frames of 250 2-bit symbols
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate error statistics
    errorStats = step(hError,data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1),errorStats(2))
Error rate = 2.17e-02
Number of errors = 108
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{Tm}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

Introduced in R2012a

## reset

System object: comm. PSKTCMDemodulator
Package: comm
Reset states of the PSK TCM demodulator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the PSKTCMDemodulator object, H .

## step

System object: comm. PSKTCMDemodulator
Package: comm
Demodulate convolutionally encoded data mapped to M-ary PSK constellation

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )
Y = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates the PSK modulated input data, X , and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. X must be a complex, double or single precision column vector. The step method outputs a demodulated, binary data column vector, Y. When the convolutional encoder represents a rate $K / N$ code, the length of the output vector is $K \times$ $L$, where $L$ is the length of the input vector, $X$.
$Y=\operatorname{step}(H, X, R)$ resets the decoder to the all-zeros state when you input a reset signal, $R$ that is non-zero. R must be a double precision or logical, scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.PSKTCMModulator

Package: comm
Convolutionally encode binary data and map using M-ary PSK signal constellation

## Description

The PSKTCMModulator object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and then mapping the result to a PSK signal constellation.

To modulate a signal using trellis-coded modulation:
1 Define and set up your PSK TCM modulator object. See "Construction" on page 3-1125.
2 Call step to modulate the signal according to the properties of comm. PSKTCMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm.PSKTCMModulator creates a trellis-coded M-ary phase shift keying (PSK TCM) modulator System object, H. This object convolutionally encodes a binary input signal and maps the result to an M-PSK constellation.

H = comm.PSKTCMModulator(Name, Value) creates a PSK TCM encoder object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. PSKTCMModulator(TRELLIS,Name, Value) creates a PSK TCM encoder object, H. This object has the TrellisStructure property set to TRELLIS and the other specified properties set to the specified values.

## Properties

## TrellisStructure

Trellis structure of convolutional code
Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check whether a trellis structure is valid. The default is the result of poly2trellis([1 3], [1 0 0; 0 5 2]).

## TerminationMethod

Termination method of encoded frame

Specify the termination method as one of Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to Truncated, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to Terminated, the object treats each input vector independently. However, for each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate $K / N$ code, the step method outputs the vector with a length given by $y=N \times(L+S) / K$, where $S=$ constraintLength-1 (or, in the case of multiple constraint lengths, $S=$ $\operatorname{sum}($ constraintLength(i)-1)). $L$ indicates the length of the input to the step method.

## ResetInputPort

Enable modulator reset input
Set this property to true to enable an additional input to the step method. The default is false. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4,8 , or 16 . The default is 8 . The value of the ModulationOrder on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the PSK TCM modulator. Thus, the value for the ModulationOrder property must equal $2^{N}$ for a rate $K / N$ convolutional code.

## OutputDataType

Data type of output
Specify the output data type as one of double | single. The default is double.

## Methods

reset Reset states of the PSK TCM modulator object
step Convolutionally encode binary data and map using M-ary PSK constellation

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Modulate Data Using 8-PSK TCM Modulation

Modulate random data using 8-PSK TCM modulation and display the constellation diagram.
Create binary data.
data $=$ randi([0 1],1000,1);
Define a trellis structure with four input symbols and eight output symbols.
t = poly2trellis([5 4],[23 35 0; 05 13]);
Create an 8-PSK TCM modulator object using the trellis structure variable, t .
hMod $=$ comm.PSKTCMModulator(t,'ModulationOrder',8);
Modulate and plot the data.

```
modData = step(hMod,data);
```

scatterplot(modData);

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## step

System object: comm. PSKTCMModulator
Package: comm
Convolutionally encode binary data and map using M-ary PSK constellation

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )
Y = step(H,X,R)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ convolutionally encodes and modulates the input binary data column vector, X , and returns the encoded and modulated data, $\mathrm{Y} . \mathrm{X}$ must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate $K / N$ code, the length of the input vector, X , must be $K \times L$, for some positive integer $L$. The step method outputs a complex column vector, $Y$, of length $L$.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})$ resets the encoder of the PSK TCM modulator object to the all-zeros state when you input a reset signal, $R$, that is non-zero. $R$ must be a double precision or logical scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

# comm.QAMCoarseFrequencyEstimator 

Package: comm
(To be removed) Estimate frequency offset for QAM signal

Note comm. QAMCoarseFrequencyEstimator will be removed in a future release. Use comm. CoarseFrequencyCompensator instead.

## Description

The QAMCoarseF requencyEstimator System object estimates frequency offset for a QAM signal.
To estimate frequency offset for a QAM signal:
1 Define and set up your QAM Coarse Frequency Estimator object. See "Construction" on page 31131.

2 Call step to estimate frequency offset for a QAM signal according to the properties of comm. QAMCoarseFrequencyEstimator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. QAMCoarseFrequencyEstimator creates a rectangular QAM coarse frequency offset estimator object, H. This object uses an open-loop, FFT-based technique to estimate the carrier frequency offset in a received rectangular QAM signal.

H = comm. QAMCoarseFrequencyEstimator(Name,Value) creates a rectangular QAM coarse frequency offset estimator object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## FrequencyResolution

Desired frequency resolution (Hz)
Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length that the object uses to perform spectral analysis. The value for this property must be less than or equal to half the SampleRate on page 30 property. The default is 0.001 .

## SampleRate

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1 .

## Methods

reset (To be removed) Reset states of the QAMCoarseFrequencyEstimator object
step (To be removed) Estimate frequency offset for QAM signal

## Common to All System Objects

release Allow System object property value changes

## Examples

## Compare Frequency Offset Estimation and Correction Methods for 16-QAM Signal

Estimate and correct for a frequency offset in a 16-QAM signal using the recommended comm. CoarseFrequencyCompensator System object. Compare frequency correction results to a workflow using the comm. QAMCoarseFrequencyEstimator System object.

Set example parameters.

```
nSym = 2048; % Number of input symbols
M = 16; % Modulation order
fs = 80000; % Sampling frequency (Hz)
freqRez = 1; % Frequency resolution (Hz)
freqOff = -3000; % Frequency offset
```

Create System objects for these operations:

```
% Square root raised cosine transmit filter
txfilter = comm.RaisedCosineTransmitFilter;
% Phase frequency offset - one to apply a frequency offset and a
% second that takes the frequency offset estimate as an input to correct
% the offset.
pfo = comm.PhaseFrequency0ffset('Frequency0ffset',freq0ff, ...
    'SampleRate',fs);
pfoCorrect = comm.PhaseFrequencyOffset(...
    'FrequencyOffsetSource','Input port', ...
    'SampleRate',fs);
% QAM coarse frequency estimator
frequencyEst = comm.QAMCoarseFrequencyEstimator(...
    'SampleRate',fs, ...
    'FrequencyResolution' ,freqRez);
Warning: comm.QAMCoarseFrequencyEstimator will be removed in a future release.
Use comm.CoarseFrequencyCompensator instead.
% Coarse frequency compensatator
freqComp = comm.CoarseFrequencyCompensator('Modulation','QAM', ...
    'SampleRate',fs,'FrequencyResolution',freqRez);
```

Generate a 16-QAM signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

## data = randi([0 M-1],nSym,1);

modData $=$ qammod(data, M,'UnitAveragePower',true); \% Generate QAM signal
txFiltData $=$ txfilter(modData);
\% Apply Tx filter
offsetData $=$ pfo(txFiltData);
\% Apply frequency offset
rxData = awgn(offsetData,25,'measured'); \% Pass through AWGN channel
This example does not apply receive filtering. In general, when the frequency offset is high, it is beneficial to apply coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

Compare the results for estimating and correcting the frequency offset by:

- Using the frequencyEst object to estimate the frequency offset and pfoCorrect to compensate for the frequency offset.
- Using the freqComp object estimate and apply compensation to the signal.

Observe the frequency offset estimate returned by both estimation methods.

```
estFreq0ffset1
estFreqOffset2
estFreq0ffset1 =
    -3.0000e+03
estFreqOffset2 =
    -3.0000e+03
```

Confirm the maximum resulting difference between the two compensation methods is negligible.

```
max(compensatedData1-compensatedData2)
ans =
    -1.3051e-13 - 1.7614e-13i
```

reset $(\mathrm{H})$ resets the internal states of the QAMCoarseFrequencyEstimator object, H .

## step

System object: comm.PSKCoarseFrequencyEstimator Package: comm
(To be removed) Estimate frequency offset for QAM signal

Note comm. QAMCoarseFrequencyEstimator will be removed in a future release. Use comm. CoarseFrequencyCompensator instead.

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ estimates the carrier frequency offset of the input $X$ and returns the result in $Y . X$ must be a complex column vector of data type double. The step method outputs the estimate Y as a scalar of type double.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.QPSKDemodulator

Package: comm
Demodulate using QPSK method

## Description

The QPSKDemodulator object demodulates a signal that was modulated using the quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature phase shift keying:
1 Define and set up your QPSK demodulator object. See "Construction" on page 3-1137.
2 Call step to demodulate the signal according to the properties of comm. QPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = $\operatorname{step}(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm. QPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the quadrature phase shift keying (QPSK) method.

H = comm.QPSKDemodulator(Name,Value) creates a QPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. QPSKDemodulator(PHASE, Name, Value) creates a QPSK demodulator object, H. This object has the PhaseOffset property set to PHASE, and the other specified properties set to the specified values.

## Properties

## PhaseOffset

Phase of zeroth point in constellation
Specify the phase offset of the zeroth point in the constellation, in radians, as a real scalar value. The default is $\mathrm{pi} / 4$.

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values.

When you set this property to true, the step method outputs a column vector of bit values with length equal to twice the number of demodulated symbols.

When you set this property to false, the step method outputs a column vector with length equal to the input data vector. This vector contains integer symbol values between 0 and 3 . The default is false.

## SymbolMapping

## Constellation encoding

Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of Binary | Gray. The default is Gray.

When you set this property to Gray, the object uses a Gray-encoded signal constellation.
When you set this property to Binary, the integer $m$, between $0 \leq m \leq 3$ maps to the complex value $\boldsymbol{\operatorname { e x p }}(j \times$ PhaseOffset on page 3-0 $\quad+j \times 2 \pi \times m / 4$ ).

## DecisionMethod

Demodulation decision method
Specify the decision method the object uses as Hard decision | Log-likelihood ratio | Approximate log-likelihood ratio. The default is Hard decision.

When you set the BitOutput on page 3-0 property to false, the object always performs hard decision demodulation. This property applies when you set the Bit0utput property to true.

## VarianceSource

Source of noise variance
Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate loglikelihood ratio.

## Variance

Noise variance
Specify the variance of the noise as a positive, real scalar value. The default is 1 . If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, use approximate LLR is because that option's algorithm does not compute exponentials.

This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate loglikelihood ratio, and the VarianceSource on page 3-0 property to Property.This property is tunable.

## OutputDataType

Data type of output
Specify the output data type as Full precision | Smallest unsigned integer|double| single | int8|uint8 | int16|uint16|int32|uint32. The default is Full precision.

This property applies when you set the BitOutput on page 3-0 property to false. The property also applies when you set the BitOutput property to true and the DecisionMethod on page 30 property to Hard decision. In this second case, when the OutputDataType on page 3-0 property is set to Full precision, and the input data type is single or double precision, the output data has the same as that of the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer.

When you set BitOutput to true and the DecisionMethod property to Hard Decision, then logical data type becomes a valid option.

When you set the BitOutput property to true and the DecisionMethod property to Loglikelihood ratio or Approximate log-likelihood ratio, the output data type is the same as that of the input. In this case, that data type can only be single or double precision.

## Fixed-Point Properties

## DerotateFactorDataType

Data type of derotate factor
Specify derotate factor data type as one of Same word length as input | Custom. The default is Same word length as input.

This property applies when you set the BitOutput on page 3-0 property to false. The property also applies when you set the Bit0utput property to true and the DecisionMethod on page 30 property to Hard decision. The object uses the derotate factor in the computations only when the step method input is a fixed-point type and the Phase 0 ff fet on page 3-0 property has a value that is not an even multiple of pi/4.

## CustomDerotateFactorDataType

Fixed-point data type of derotate factor
Specify the derotate factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype ( []$, 16$ ). This property applies when you set the DerotateFactorDataType on page 3-0 property to Custom.

## Methods

## Examples

Plot QPSK Reference Constellation
Create a QPSK modulator.
mod = comm.QPSKModulator;
Determine the reference constellation points.

```
refC = constellation(mod)
refC = 4×1 complex
    0.7071 + 0.7071i
    -0.7071 + 0.7071i
    -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Create a PSK demodulator having 0 phase offset.
demod = comm.QPSKDemodulator('PhaseOffset',0);
Plot its reference constellation. The constellation method works for both modulator and demodulator objects.

```
constellation(demod)
```

## BER Estimate of QPSK Signal

Create a QPSK modulator and demodulator pair that operate on bits.
qpskModulator = comm.QPSKModulator('BitInput',true);
qpskDemodulator $=$ comm.QPSKDemodulator('Bit0utput', true);
Create an AWGN channel object and an error rate counter.
channel = comm. AWGNChannel('EbNo',4,'BitsPerSymbol', 2);
errorRate = comm.ErrorRate;
Generate random binary data and apply QPSK modulation.

```
data = randi([0 1],1000,1);
txSig = qpskModulator(data);
```

Pass the signal through the AWGN channel and demodulate it.

```
rxSig = channel(txSig);
rxData = qpskDemodulator(rxSig);
```

Calculate the error statistics. Display the BER.

```
errorStats = errorRate(data,rxData);
```

errorStats(1)
ans $=0.0100$

## Algorithms

This object implements the algorithm, inputs, and outputs described on the QPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

```

## step

System object: comm. QPSKDemodulator
Package: comm
Demodulate using QPSK method

## Syntax

$Y=\operatorname{step}(H, X)$
Y = step(H,X,VAR)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the QPSK demodulator System object, H , and returns Y . Input X must be a scalar or a column vector with double or single precision data type. When you set the BitOutput property to false, or when you set the DecisionMethod property to Hard decision and the BitOutput property to true, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the BitOutput property value, output $Y$ can be integer or bit valued.

Y = step( $H, X$, VAR) uses soft decision demodulation and noise variance VAR. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to Approximate log-likelihood ratioor Log-likelihood ratio, and the VarianceSource property to Input port. The data type of input VAR must be double or single precision.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.QPSKModulator

Package: comm
Modulate using QPSK method

## Description

The comm. QPSKModulator object modulates using the quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To apply QPSK modulation:
1 Create the comm.QPSKModulator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
qpskmod = comm.QPSKModulator
qpskmod = comm.QPSKModulator(Name,Value)
qpskmod = comm.QPSKModulator(phase,Name,Value)
Description
```

qpskmod = comm.QPSKModulator creates a modulator System object. Use this object to modulate the input signal using the quadrature phase shift keying (QPSK) method.
qpskmod = comm. QPSKModulator(Name,Value) creates a QPSK modulator object, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).
qpskmod = comm.QPSKModulator(phase,Name,Value) creates a QPSK modulator object, qpskmod. This object has the PhaseOffset property set to phase and the other specified properties set to the specified values. Specify phase in radians.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## PhaseOffset - Phase offset of zeroth point in constellation <br> pi/4 (default) | numeric scalar

Phase of zeroth point of the signal constellation in radians, specified as a numeric scalar.
Example: 'PhaseOffset ' , 0 aligns the QPSK signal constellation points on the axes, $\{(1,0),(0, j)$, $(-1,0),(0,-j)\}$.
Data Types: double

## BitInput - Option to provide input in bits

false (default) | true
Option to provide input in bits, specified as false or true.

- When this property is set to false, the input values must be integer representations of two-bit input segments and range from 0 to 3 .
- When this property is set to true, the input must be a binary vector of even length. Element pairs are binary representations of integers.

## Data Types: logical

## SymbolMapping - Signal constellation bit mapping

'Gray ' (default) |'Binary'
Constellation encoding
Signal constellation bit mapping, specified as 'Gray' or 'Binary'.

| Setting | Constellation Mapping for Integers |  | Constellation Mapping for Bits |  | Comment |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Gray | 1 | 0 | 01 | 00 | The signal constellation mapping is Grayencoded. |
|  | 3 | 2 | 11 | 10 |  |
| Binary | 1 2 | 0 3 | 01 10 | 00 <br> 11 | The signal constellation mapping for the input integer $m(0 \leq m \leq 3)$ is the complex value $\mathrm{e}^{\left(\mathrm{j}^{*} \text { (Phaseoffset) }+\right.}$ ${ }^{\left.\mathrm{j} * 2 *_{n} * m / 4\right)}$. |

## Data Types: char

## OutputDataType - Data type assigned to output

'double' (default)|'single'|'Custom'
Data type assigned to output, specified as 'double', 'single', or 'Custom'.
Data Types: char

## Fixed-Point Properties

## CustomOutputDataType - Fixed-point data type of output

numerictype([],16) (default)| numerictype object
Fixed-point data type of output, specified as a numerictype object with a signedness of Auto. This property applies when you set the OutputDataType on page 3-0 property to Custom.

## Dependencies

This property applies when you set the OutputDataType property to 'Custom'.

## Usage

## Syntax

```
waveform = qpskmod(insignal)
```

## Description

waveform = qpskmod(insignal) returns baseband-modulated output.

## Input Arguments

## insignal - Input signal

integer column vector | bit column vector
Input signal, specified as an $N_{\mathrm{S}}$-element column vector of integers or bits, where $N_{\mathrm{S}}$ is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.
Data Types: double |int8|logical|fi
Output Arguments
waveform - Output waveform
numeric vector
Output waveform, returned as a complex-valued numeric vector.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Specific to comm. QPSKModulator

constellation Calculate or plot ideal signal constellation

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Plot QPSK Reference Constellation

Create a QPSK modulator.
$\bmod =$ comm.QPSKModulator;
Determine the reference constellation points.

```
refC = constellation(mod)
refC = 4×1 complex
    0.7071 + 0.7071i
    -0.7071 + 0.7071i
    -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation.
constellation(mod)

Constellation: QPSK,Gray Mapping,PhaseOffset=0.7854rad

Create a PSK demodulator having 0 phase offset.
demod $=$ comm.QPSKDemodulator('PhaseOffset',0);
Plot its reference constellation. The constellation method works for both modulator and demodulator objects.

```
constellation(demod)
```

## Phase Noise on QPSK Signal

Create a QPSK modulator object and a phase noise object.
qpskModulator $=$ comm. QPSKModulator;
phNoise = comm.PhaseNoise('Level',-55,'FrequencyOffset',20,'SampleRate',1000);
Generate random QPSK data. Pass the signal through the phase noise object.

```
d = randi([0 3],1000,1);
x = qpskModulator(d);
y = phNoise(x);
```

Display the constellation diagram of the QPSK signal. The phase noise has introduced a rotational distortion on the constellation diagram.

```
constDiagram = comm.ConstellationDiagram;
constDiagram(y)
```

## Create QPSK Modulator Object with Bit Input

Create QPSK modulator object setting the BitInput property to true. Display the properties.
qpskmod = comm.QPSKModulator('BitInput',true)
qpskmod =
comm.QPSKModulator with properties:
PhaseOffset: 0.7854
BitInput: true
SymbolMapping: 'Gray'
OutputDataType: 'double'

Determine the reference constellation points.

```
refC = constellation(qpskmod)
refC = 4×1 complex
    0.7071 + 0.7071i
    -0.7071 + 0.7071i
    -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation. Since BitInput is true, the constellation symbols are label with bit values. constellation(qpskmod)

Constellation: QPSK,Gray Mapping,PhaseOffset=0.7854rad

Create QPSK modulator object with default properties settings. Display the properties.
qpskmod2 $=$ comm.QPSKModulator
qpskmod2 =
comm.QPSKModulator with properties:
PhaseOffset: 0.7854 BitInput: false
SymbolMapping: 'Gray'
OutputDataType: 'double'

Plot constellation with default settings. Since BitInput is false, the constellation symbols are label with integer values.

## comm.RaisedCosineReceiveFilter

Package: comm
Apply pulse shaping by decimating signal using raised cosine filter

## Description

The Raised Cosine Receive Filter System object applies pulse-shaping by decimating an input signal using a raised cosine FIR filter.

To decimate the input signal:
1 Define and set up your raised cosine receive filter object. See "Construction" on page 3-1156.
2 Call step to decimate the input signal according to the properties of comm.RaisedCosineReceiveFilter. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm.RaisedCosineReceiveFilter returns a raised cosine receive filter System object, H, which decimates the input signal. The filter uses an efficient polyphase FIR decimation structure and has unit energy.

H = comm.RaisedCosineReceiveFilter(PropertyName,PropertyValue, ...) returns a raised cosine receive filter object, H , with each specified property set to the specified value.

## Properties

## Shape

Filter shape
Specify the filter shape as one of Normal or Square root. The default is Square root.

## RolloffFactor

Rolloff factor
Specify the rolloff factor as a scalar between 0 and 1 . The default is 0.2 .

## FilterSpanInSymbols

Filter span in symbols

Specify the number of symbols the filter spans as an integer-valued positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the object truncates the impulse response to the value you specify for this property.

## InputSamplesPerSymbol

Input samples per symbol
Specify the number of input samples that represent a symbol. The default is 8 . This property accepts an integer-valued, positive double or single scalar value. The raised cosine filter has (FilterSpanInSymbols x InputSamplesPerSymbol + 1) taps.

## DecimationFactor

## Decimation factor

Specify the factor by which the object reduces the sampling rate of the input signal. The default value is 8 . This property accepts a positive integer scalar value between 1 and InputSamplesPerSymbol. The value must evenly divide into InputSamplesPerSymbol. The number of input rows must be a multiple of the decimation factor. If you set DecimationFactor to 1 , then the object only applies filtering without downsampling.

## Decimation0ffset

Specify the number of filtered samples the System object discards before downsampling. The default is 0 . This property accepts an integer valued scalar between 0 and DecimationFactor - 1 .

## Gain

Linear filter gain
Specify the linear gain of the filter as a positive numeric scalar. The default is 1 . The object designs a raised cosine filter that has unit energy, and then applies the linear gain to obtain final tap values.

## Methods

| coeffs | Returns coefficients for filters |
| :--- | :--- |
| reset | Reset internal states of System object |
| step | Output decimated values of input signal |

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Filter Signal Using Square Root Raised Cosine Receive Filter

Filter the output of a square root raised cosine transmit filter using a matched square root raised cosine receive filter. The input signal has eight samples per symbol.

Create a raised cosine transmit filter and set the OutputSamplesPerSymbol property to 8.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',8);
```

Create a raised cosine receive filter and set the InputSamplesPerSymbol property to 8 and the DecimationFactor property to 8 .

```
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',8, ...
    'DecimationFactor',8);
```

Use the coeffs function to determine the filter coefficients for both filters.

```
txCoef = coeffs(txfilter);
rxCoef = coeffs(rxfilter);
```

Launch the filter visualization tool and display the magnitude responses of the two filters. Observe that they have identical responses.

```
fvtool(txCoef.Numerator,1,rxCoef.Numerator,1);
legend('Tx Filter','Rx Filter')
```

Generate a random bipolar signal and then interpolate.

```
preTx = 2*randi([0 1],100,1) - 1;
y = txfilter(preTx);
```

Decimate the signal using the raised cosine receive filter System object.

```
postRx = rxfilter(y);
```

The filter delay is equal to the FilterSpanInSymbols property. Adjust for the delay to compare the pre-Tx filter signal with the post-Rx filter signal.

```
delay = txfilter.FilterSpanInSymbols;
x = (1:(length(preTx)-delay));
plot(x,preTx(1:end-delay),x,postRx(delay+1:end))
legend('Pre-Tx Filter','Post-Rx Filter')
```

You can see that the two signals overlap one another since the receive filter is matched to the transmit filter.

## Specify Filter Span of Raised Cosine Receive Filter

Decimate a bipolar signal using a square root raised cosine filter whose impulse response is truncated to six symbol durations.

Create a raised cosine transmit filter and set the FilterSpanInSymbols property to 6. The object truncates the impulse response to six symbols.
txfilter = comm. RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
Generate a random bipolar signal and filter it using txfilter.
$x=2 * r a n d i([01], 25,1)-1 ;$
y = txfilter(x);

Create a matched raised cosine receive filter System object.
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',6);
Launch the filter visualization tool to show the impulse response of the receive filter.
fvtool(rxfilter,'Analysis','impulse')

Filter the output signal from the transmit filter using the matched receive filter object, rxfilter. $r=r x f i l t e r(y) ;$

Plot the interpolated signal. Because of the filter span, there is a delay of six symbols before data passes through the filter.
stem(r)

## Raised Cosine Receive Filter with Unity Passband Gain

Create a raised cosine receive filter with unity passband gain.
Create a raised cosine receive filter System object ${ }^{\mathrm{TM}}$. Obtain the filter coefficients using the coeffs function.

```
rxfilter = comm.RaisedCosineReceiveFilter;
b = coeffs(rxfilter);
```

A filter with unity passband gain has filter coefficients such that the sum of coefficients is 1. Therefore, set the Gain property to the inverse of the sum of b.Numerator.

```
rxfilter.Gain = 1/sum(b.Numerator);
```

Verify that the sum of the coefficients from the resulting filter equal 1.

```
bNorm = coeffs(rxfilter);
sum(bNorm.Numerator)
ans = 1.0000
```

Plot the frequency response of the filter. Note that it shows a passband gain of 0 dB , which is unity gain.

```
fvtool(rxfilter)
```

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

comm.RaisedCosineTransmitFilter|rcosdesign

## Introduced in R2013b

## coeffs

System object: comm.RaisedCosineReceiveFilter
Package: comm
Returns coefficients for filters

## Syntax

S = coeffs (H)
S = coeffs(H,'Arithmetic',ARITH,...)

## Description

S = coeffs (H) Returns the coefficients of filter System object, H, in the structure S.
S = coeffs(H,'Arithmetic',ARITH, ...) analyzes the filter System object, H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of double, single, or fixed. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The coeffs method returns the quantized filter coefficients when you set ARITH to single or fixed.

## reset

System object: comm.RaisedCosineReceiveFilter
Package: comm
Reset internal states of System object

## Syntax

reset (OBJ)

## Description

reset (OBJ) resets the internal states of System object OBJ to their initial values.

## step

System object: comm. RaisedCosineReceiveFilter
Package: comm
Output decimated values of input signal

## Syntax

Y = step(H, X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.

Y = step ( $\mathrm{H}, \mathrm{X}$ ) outputs the decimated values, Y , of the input signal X . The System object treats the input matrix $\mathrm{K}_{\mathrm{i}}$-by- N as N independent channels. The System object filters each channel over time and generates a $\mathrm{K}_{0}$-by- N output matrix. $\mathrm{K}_{0}=\mathrm{K}_{\mathrm{i}} / \mathrm{M}$ where M represents the decimation factor. The System object supports real and complex floating-point inputs.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.RaisedCosineTransmitFilter

Package: comm
Apply pulse shaping by interpolating signal using raised cosine filter

## Description

The Raised Cosine Transmit Filter System object applies pulse-shaping by interpolating an input signal using a raised cosine FIR filter.

To interpolate the input signal:
1 Define and set up your raised cosine transmit filter object. See "Construction" on page 3-1166.
2 Call step to interpolate the input signal according to the properties of comm.RaisedCosineTransmitFilter. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

H = comm.RaisedCosineTransmitFilter returns a raised cosine transmit filter System object, H, which interpolates an input signal using a raised cosine FIR filter. The filter uses an efficient polyphase FIR interpolation structure and has unit energy.

H = comm.RaisedCosineTransmitFilter(PropertyName, PropertyValue, ...) returns a raised cosine transmit filter object, H , with each specified property set to the specified value.

## Properties

## Shape

Filter shape
Specify the filter shape as one of Normal or Square root. The default is Square root.

## RolloffFactor

Rolloff factor
Specify the rolloff factor as a scalar between 0 and 1 . The default is 0.2 .

## FilterSpanInSymbols

Filter span in symbols

Specify the number of symbols the filter spans as an integer-valued, positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the object truncates the impulse response to the value you specify for this property.

## OutputSamplesPerSymbol

Output samples per symbol
Specify the number of output samples for each input symbol. The default is 8 . This property accepts an integer-valued, positive scalar value. The raised cosine filter has (FilterSpanInSymbols x OutputSamplesPerSymbol +1) taps.

## Gain

Linear filter gain
Specify the linear gain of the filter as a positive numeric scalar. The default is 1 . The object designs a raised cosine filter that has unit energy, and then applies the linear gain to obtain final tap values.

## Methods

| coeffs | Returns coefficients for filters |
| :--- | :--- |
| reset | Reset internal states of System object |
| step | Output interpolated values of input signal |

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Interpolate Signal Using Square Root Raised Cosine Filter

This example shows how to interpolate a signal using the comm. RaisedCosineTransmitFilter System object and to display its spectrum.

Create a square root raised square root cosine transmit filter object. You can see that its default settings are such that the filter has a square root shape and that there are 8 samples per symbol.

```
txfilter = comm.RaisedCosineTransmitFilter
txfilter =
    comm.RaisedCosineTransmitFilter with properties:
                            Shape: 'Square root'
            RolloffFactor: 0.2000
        FilterSpanInSymbols: 10
        OutputSamplesPerSymbol: 8
                            Gain: 1
```

Generate random bipolar data.
data $=2 *$ randi([0 1],10000,1) - 1;
Filter the data by using the RRC filter.
filteredData $=$ txfilter(data);
To view the spectrum of the filtered signal, create a spectrum analyzer object with a sample rate of 1000 Hz.
spectrumAnalyzer = dsp.SpectrumAnalyzer('SampleRate',1000);
View the spectrum of the filtered signal using the spectrum analyzer.
spectrumAnalyzer(filteredData)

## Specify Filter Span of Raised Cosine Transmit Filter

This example shows to create an interpolated signal from a square root raised cosine filter that is truncated to six symbol durations.

Create a raised cosine filter and set the FilterSpanInSymbols to 6. The object truncates the impulse response to six symbols.
txfilter = comm. RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
Launch the filter visualization tool to show the impulse response.

```
fvtool(txfilter)
```

Generate random bipolar data and pass it through the filter.
$x=2 * r a n d i([01], 96,1)-1 ;$
$y=$ txfilter(x);
Plot the interpolated signal.
plot(y)
grid on

## Raised Cosine Transmit Filter with Unity Passband Gain

This example shows how to create a raised cosine transmit filter with unity passband gain.
Generate a filter with unit energy. You can obtain the filter coefficients using the coeffs function.
txfilter = comm.RaisedCosineTransmitFilter;
b = coeffs(txfilter);
Plot the filter response. You can see that its gain is greater than unity (more than 0 dB ).

A filter with unity passband gain has filter coefficients that sum to 1 . Set the Gain property to the inverse of the sum of $b$.Numerator
txfilter.Gain = 1/sum(b.Numerator);
Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);
sum(bNorm.Numerator)
ans = 1.0000
```

Plot the filter frequency response. Note that it shows a passband gain of 0 dB .

```
fvtool(txfilter)
```

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.

## Syntax

S = coeffs (H)
S = coeffs(H,'Arithmetic',ARITH,...)

## Description

S = coeffs (H) Returns the coefficients of filter System object, H, in the structure S.
S = coeffs(H,'Arithmetic', ARITH, ...) analyzes the filter System object, H, based on the arithmetic specified in the ARITH input. ARITH can be set to one of double, single, or fixed. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The coeffs method returns the quantized filter coefficients when you set ARITH to single or fixed.

## reset

System object: comm.RaisedCosineTransmitFilter
Package: comm
Reset internal states of System object

## Syntax

reset(OBJ)

## Description

reset (OBJ) resets the internal states of System object OBJ to their initial values.

## step

System object: comm.RaisedCosineTransmitFilter
Package: comm
Output interpolated values of input signal

## Syntax

Y = step(H, X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ outputs the interpolated values, Y , of the input signal X . The System object treats the input matrix $\mathrm{K}_{\mathrm{i}}$-by- N as N independent channels. The object interpolates each channel over the first dimension and then generates a $\mathrm{K}_{0}$-by- N output matrix. In the output matrix, $\mathrm{K}_{0}=\mathrm{K}_{\mathrm{i}}{ }^{*} \mathrm{~L}$, where L represents the output samples per symbol. The object supports real and complex floating-point inputs.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.RayleighChannel

Package: comm
Filter input signal through multipath Rayleigh fading channel

## Description

The comm.RayleighChannel System object filters an input signal through a multipath Rayleigh fading channel. For more information on fading model processing, see Methodology for Simulating Multipath Fading Channels.

To filter an input signal using a multipath Rayleigh fading channel:
1 Create the comm. RayleighChannel object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

rayleighchan = comm. RayleighChannel
rayleighchan = comm.RayleighChannel(Name,Value)

## Description

rayleighchan = comm.RayleighChannel creates a frequency-selective or frequency-flat multipath Rayleigh fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain the channel-impaired signal.
rayleighchan = comm.RayleighChannel(Name,Value) sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, comm. RayleighChannel('SampleRate', 2) sets the input signal sample rate to 2 .

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## SampleRate - Input signal sample rate

1 (default) | positive scalar
Input signal sample rate in Hz , specified as a positive scalar.

## Data Types: double

## PathDelays - Discrete path delay

0 (default) | numeric scalar | numeric row vector
Discrete path delay in seconds, specified as a numeric scalar or numeric row vector.

- When PathDelays is a scalar, the channel is frequency flat.
- When PathDelays is a vector, the channel is frequency selective.

## Data Types: double

## AveragePathGains - Average of the discrete paths

0 (default) | numeric scalar | numeric row vector
Average gains of the discrete paths in decibels, specified as a numeric scalar or numeric row vector. AveragePathGains must be of the same size as the PathDelays property.

## Data Types: double

## NormalizePathGains - Normalize average path gains to $\mathbf{0} \mathbf{d B}$

true or 1 (default) | false or 0
Normalize average path gains to 0 dB , specified as a logical 1 (true) or 0 (false).

- When NormalizePathGains is true, the fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB .
- When NormalizePathGains is false, the total power of the path gains is not normalized.

## Data Types: logical

MaximumDopplerShift - Maximum Doppler shift for all channel paths
0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.
The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the reset object function to generate a new channel realization. The MaximumDopplerShift property value must be smaller than SampleRate $/ 10 / f_{c}$ for each path. $f_{c}$ represents the cutoff frequency factor of the path. For most Doppler spectrum types, the value of $f_{\mathrm{c}}$ is 1 . For Gaussian and biGaussian Doppler spectrum types, $f_{\mathrm{c}}$ is dependent on the Doppler spectrum structure fields. For more details about how $f_{\mathrm{c}}$ is defined, see "Cutoff Frequency Factor" on page 3-1188.
Data Types: double

## DopplerSpectrum - Doppler spectrum shape for all channel paths

doppler('Jakes') (default) | Doppler spectrum structure | 1-by- $N_{P}$ cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- $N_{P}$ cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the doppler function. $N_{\mathrm{P}}$ is the number of discrete delay paths, that is, the length of the PathDelays property.

- When DopplerSpectrum is defined by a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When DopplerSpectrum is defined by a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Options for the spectrum type are specified by the specType input to the doppler function. If you set the FadingTechnique property to 'Sum of sinusoids', you must set DopplerSpectrum to doppler('Jakes').

## Dependencies

To enable this property, set the MaximumDopplerShift property to a positive value. The MaximumDopplerShift property defines the maximum Doppler shift value permitted when specifying the Doppler spectrum.

## Data Types: struct | cell

## FadingTechnique - Channel model fading technique

```
'Filtered Gaussian noise' (default)|'Sum of sinusoids'
```

Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char|string

## NumSinusoids - Number of sinusoids used

48 (default) | positive integer
Number of sinusoids used to model the fading process, specified as a positive integer.

## Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

## Data Types: double

## InitialTimeSource - Source to control start time of fading process <br> 'Property' (default)|'Input port'

Source to control the start time of the fading process, specified as 'Property ' or 'Input port '.

- When InitialTimeSource is set to 'Property', use the InitialTime property to set the initial time offset.
- When InitialTimeSource is set to 'Input port', specify the start time of the fading process by using the itime input to the System object. The input value can change in consecutive calls to the System object.

## Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

## Data Types: string | char

## InitialTime - Initial time offset

0 (default) | nonnegative scalar

Initial time offset, in seconds, for the fading model, specified as a nonnegative scalar. InitialTime must be greater than end time of the last frame. InitialTime is rounded up to the nearest sample position when it is not a multiple of 1/SampleRate.

## Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Property'.

Data Types: double

## RandomStream - Source of random number stream

'Global stream' (default)|'mt19937ar with seed'
Source of random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- 'Global stream' - The current global random number stream is used for normally distributed random number generation. In this case, the reset object function resets the channel filters only.
- 'mt19937ar with seed' - The mt19937ar algorithm is used for normally distributed random number generation. In this case, the reset object function resets the channel filters and reinitializes the random number stream to the value of the Seed property.

## Data Types: string | char

## Seed - Initial seed of mt19937ar random number stream

73 (default) | nonnegative integer
Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. When the reset object function is called, the mt19937ar random number stream is reinitialized to the Seed property value.

## Dependencies

To enable this property, set the RandomStream property to 'mt19937ar with seed'.
Data Types: double

## PathGainsOutputPort - Option to output path gains

false or 0 (default) | true or 1
Option to output path gains, specified as 0 (false) or 1 (true). Set this property to 1 (true) to output the channel path gains of the underlying fading process.
Data Types: logical

## Visualization - Channel visualization

```
'Off'(default)|'Impulse response'|'Frequency response'|'Impulse and frequency
``` responses'|'Doppler spectrum'

Channel visualization, specified as 'Off','Impulse response','Frequency response', 'Impulse and frequency responses', or 'Doppler spectrum'. For more information, see "Channel Visualization" on page 3-1188.

Data Types: string | char

\section*{SamplesToDisplay - Percentage of samples to display '25\%' (default)|'10\%'|'50\%' | '100\%'}

Percentage of samples to display, specified as ' \(25 \%\) ', ' \(10 \%\) ', ' \(50 \%\) ', or ' \(100 \%\) '. Displaying fewer samples improves (decreases) the display update rate at the expense of decreasing the visualized precision.

\section*{Dependencies}

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: string |char

\section*{PathsForDopplerDisplay - Path for Doppler display}

1 (default) | positive integer
Path for Doppler display, specified as a positive integer. Use this property to select the discrete path used in constructing a Doppler spectrum plot. The specified path must be an element of \(\{1,2, \ldots\), \(\left.N_{\mathrm{P}}\right\}\). In this set, \(N_{\mathrm{P}}\) is the number of discrete delay paths, that is, the length of the PathDelays property value.

\section*{Dependencies}

To enable this property, set the Visualization property to 'Doppler spectrum'.
Data Types: double

\section*{Usage}

\section*{Syntax}
```

y = rayleighchan(x)
[y,pathgains] = rayleighchan(x)
___ = rayleighchan(x,itime)

```

\section*{Description}
\(y=\) rayleighchan( \(x\) ) filters input signal \(x\) through a multipath Rayleigh fading channel and returns the output signal in y .
[y, pathgains] = rayleighchan (x) returns the channel path gains of the underlying multipath Rayleigh fading process in pathgains. To enable this syntax set the PathGainsOutputPort property set to 1 (true).
= rayleighchan(x,itime) passes data through the multipath Rayleigh fading channel beginning at the initial time specified by itime. To enable this syntax, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Input port'.

\section*{Input Arguments}

\section*{x - Input signal}
\(N_{\mathrm{S}}\)-by-1 numeric vector
Input signal, specified as an \(N_{\mathrm{S}}\)-by-1 numeric vector, where \(N_{\mathrm{S}}\) is the number of samples.
Data Types: single | double
Complex Number Support: Yes

\section*{itime - Initial time}

0 | nonnegative scalar
Initial time in seconds, specified as a nonnegative scalar. The itime input must be greater than the end time of the last frame. When itime is not a multiple of \(1 /\) SampleRate, it is rounded up to the nearest sample position.
Data Types: single | double

\section*{Output Arguments}
y - Output signal
\(N_{\mathrm{S}}\)-by-1 numeric vector
Output signal, returned as an \(N_{S}\)-by-1 numeric vector of complex values with the same data precision as the input signal x . \(N_{\mathrm{S}}\) is the number of samples.

\section*{pathgains - Path gains}
\(N_{\mathrm{S}}\)-by- \(N_{\mathrm{P}}\) numeric array
Path gains, returned as an \(N_{\mathrm{S}}\)-by- \(N_{\mathrm{P}}\) array. \(N_{\mathrm{S}}\) is the number of samples. \(N_{\mathrm{P}}\) is the number of discrete delay paths, that is, the length of the PathDelays property value. pathgains contains complex values with the same precision as the input signal x .

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
```

release(obj)

```

\section*{Specific to comm.RayleighChannel}
info Characteristic information about fading channel object

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Produce Same Rayleigh Channel Outputs Using Two Random Number Generation Methods}

This example shows how to produce the same multipath Rayleigh fading channel response by using two different methods for random number generation. The multipath Rayleigh fading channel System object \({ }^{\mathrm{TM}}\) includes two methods for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from these two methods.

Create a PSK modulator System object to modulate randomly generated data.
```

pskModulator = comm.PSKModulator;
channelInput = pskModulator(randi([0 pskModulator.ModulationOrder-1],1024,1));

```

Create a multipath Rayleigh fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 22.
```

rayleighchan = comm.RayleighChannel(...
'SampleRate',10e3, ...
'PathDelays',[0 1.5e-4], ...
'AveragePathGains',[2 3], ...
'NormalizePathGains',true, ...
'MaximumDopplerShift',30, ...
'DopplerSpectrum',{doppler('Gaussian',0.6),doppler('Flat')}, ...
'RandomStream','mt19937ar with seed', ...
'Seed',22, ...
'PathGains0utputPort',true);

```

Filter the modulated data by using the multipath Rayleigh fading channel System object.
```

[chanOut1,pathGains1] = rayleighchan(channelInput);

```

Set the System object to use the global stream for random number generation.
```

release(rayleighchan);
rayleighchan.RandomStream = 'Global stream';

```

Set the global stream to have the same seed that was specified when creating the multipath Rayleigh fading channel System object.
```

rng(22)

```

Filter the modulated data by using the multipath Rayleigh fading channel System object again.
```

[chanOut2,pathGains2] = rayleighchan(channelInput);

```

Verify that the channel and path gain outputs are the same for each of the two methods.
```

isequal(chanOut1,chanOut2)
ans = logical
1
isequal(pathGains1,pathGains2)
ans = logical
1

```

\section*{Display Impulse and Frequency Responses of Multipath Rayleigh Fading Channel}

This example shows how to create a frequency-selective multipath Rayleigh fading channel System object and display its impulse and frequency responses.

Set the sample rate to 3.84 MHz . Specify path delays and gains by using the ITU pedestrian B channel configuration. Set the maximum Doppler shift to 50 Hz .
```

fs = 3.84e6; % Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % sec
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
fD = 50; % Hz

```

Create a multipath Rayleigh fading channel System object by using the previously defined properties and to visualize the impulse response and frequency response plots.
rayleighchan = comm. RayleighChannel('SampleRate',fs, ...
'PathDelays', pathDelays,
'AveragePathGains',avgPathGains, ...
'MaximumDopplerShift',fD, ...
'Visualization','Impulse and frequency responses');
Generate random binary data and pass it through the multipath Rayleigh fading channel. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.
```

x = randi([0 1],1000,1);
y = rayleighchan(x);

```

\section*{Model Multipath Rayleigh Fading Channel by Using Sum-of-Sinusoids Technique}

The example shows how the channel state is maintained in cases in which data is discontinuously transmitted. Create a multipath Rayleigh fading channel System object and pass data through it using the sum-of-sinusoids technique.

Set the channel properties.
```

fs = 1000; % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5; % Maximum Doppler shift (Hz)
ns = 1000; % Number of samples
nsdel = 100; % Number of samples for delayed paths

```

Define the overall simulation time and three time segments for which data is to be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One \(1000-\) sample continuous data sequence is transmitted at time 0 . Three 100 -sample data packets are transmitted at times \(0.1 \mathrm{~s}, 0.4\) s , and 0.7 s , respectively.
```

to0 = 0.0;
tol = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs; % Transmission 0
t1 = tol+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3

```

Generate random binary data corresponding to the previously defined time intervals.
```

d0 = randi([0 1],ns,1);
d1 = randi([0 1],nsdel,1);
d2 = randi([0 1],nsdel,1);
d3 = randi([0 1],nsdel,1);

```

Create a frequency-flat multipath Rayleigh fading System object, specifying the sum-of-sinusoids fading technique. So that results can be repeated, specify a seed value. Use the default
InitialTime property setting so that the fading channel will be simulated from time 0 . Enable the path gains output.
```

rayleighchan1 = comm.RayleighChannel('SampleRate',fs, ...
'MaximumDopplerShift',5, ...
'RandomStream','mt19937ar with seed', ...
'Seed',17, ...
'FadingTechnique','Sum of sinusoids', ...
'PathGains0utputPort',true);

```

Create a clone of the multipath Rayleigh fading channel System object. Set the source for initial time so that the fading channel offset time can be specified as an input argument when using the System object.
```

rayleighchan2 = clone(rayleighchan1);
rayleighchan2.InitialTimeSource = 'Input port';

```

Pass random binary data through the first multipath Rayleigh fading channel System object, rayleighchan1. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.
```

[~,pg0] = rayleighchan1(d0);

```

Pass random data through the second multipath Rayleigh fading channel System object, rayleighchan2, where the initial time offsets are provided as input arguments.
```

[~,pg1] = rayleighchan2(d1,to1);
[~,pg2] = rayleighchan2(d2,to2);
[~,pg3] = rayleighchan2(d3,to3);

```

Compare the number of samples processed by the two channels by using the info object function. The rayleighchan1 object processed 1000 samples, while the rayleighchan2 object only processed 300 samples.
```

G = info(rayleighchan1);
H = info(rayleighchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
ans = 1\times2

```

Convert the path gains into decibels.
```

pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));

```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is suited to the simulation of packetized data, as the channel characteristics are maintained even when data is not transmitted.
```

plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continous and Discontinuous Transmission Path Gains')

```

\section*{Use Info Method to Reproduce Multipath Rayleigh Fading Channel Response}

The example show how to use the ChannelFilterCoefficients property returned by the info object function of the comm. RayleighChannel System object to reproduce the multipath Rayleigh fading channel output.

Create a multipath Rayleigh fading channel System object, defining two paths and specifying data to pass through the channel.
```

rayleighchan = comm.RayleighChannel('SampleRate',1000,'PathDelays',[0 1.5e-3], ...
'AveragePathGains',[0 -3],'PathGainsOutputPort',true)
rayleighchan =
comm.RayleighChannel with properties:
SampleRate: 1000
PathDelays: [0 0.0015]
AveragePathGains: [0 -3]
NormalizePathGains: true
MaximumDopplerShift: 1.0000e-03
DopplerSpectrum: [1x1 struct]
Show all properties
data = randi([0 1],600,1);

```

Pass data through the channel. Assign the ChannelFilterCoefficients property value to the variable coeff.
```

[chanout1,pg] = rayleighchan(data);
chaninfo = info(rayleighchan)
chaninfo = struct with fields:
ChannelFilterDelay: 6
ChannelFilterCoefficients: [2x16 double]
NumSamplesProcessed: 600

```
coeff = chaninfo. ChannelFilterCoefficients;

Calculate the fractional delayed input signal at the path delay locations stored in coeff.
```

Np = length(rayleighchan.PathDelays);
fracdelaydata = zeros(size(data,1),Np);
for ii = 1:Np
fracdelaydata(:,ii) = filter(coeff(ii,:),1,data);
end

```

Apply the path gains and sum the results for all paths.
```

chanout2 = sum(pg .* fracdelaydata,2);

```

Compare the output of the multipath Rayleigh fading channel System object to the output reproduced using the path gains and the ChannelFilterCoefficients property of the multipath Rayleigh fading channel System object.
isequal(chanout1, chanout2)
```

ans = logical

```
    1

\section*{More About}

\section*{Cutoff Frequency Factor}

The cutoff frequency factor, \(f_{\mathrm{c}}\), is determined for different Doppler spectrum types.
- For any Doppler spectrum type other than Gaussian and biGaussian, \(f_{\mathrm{c}}\) equals 1.
- For a doppler('Gaussian') spectrum type, \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation \(\times \sqrt{2 \log 2}\).
- For a doppler('BiGaussian') spectrum type:
- If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation(1) \(\times \sqrt{2 \log 2}\).
- If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation (2) \(\times \sqrt{2 \log 2}\).
- If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation(1) \(\times \sqrt{2 \log 2}\).
- In all other cases, \(f_{\mathrm{c}}\) equals 1 .

\section*{Channel Visualization}

The comm. RayleighChannel System object enables visualization of the channel impulse response, frequency response, and Doppler spectrum.

\section*{Note}
- The displayed and specified path gain locations can differ by as much as \(5 \%\) of the input sample time.
- The visualization display speed is controlled by the combination of the SamplesToDisplay property and the Playback > Reduce Updates to Improve Performance scope menu item. Reducing the percentage of samples to display and enabling reduced updates can speed up the rendering of the visualization scope.
- After the visualization scopes are manually closed, calls to the System object are executed at its normal speed.
- Code generation is available only when the Visualization property is set to 'Off'.

\section*{Impulse Response}

The impulse response scope displays the path gains, channel filter coefficients, and interpolated path gains. The path gains occur at time instances which correspond to the specified PathDelays property and might not be aligned with the input sampling time. The channel filter coefficients are used to model the channel. They are interpolated from the actual path gains and are aligned with the
input sampling time. In cases in which the path gains are aligned with the sampling time, the path gains overlap the filter coefficients. Sinc interpolation is used to connect the channel filter coefficients and is shown as the interpolated path gains. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the upper-left corner of the scope.

The impulse response plot shares the same toolbar and menus as the dsp.ArrayPlot System object.
When the specified path gains align with the sample rate, the path gains and the channel filter coefficients overlap. In this figure the impulse response shows the path gains overlap the filter coefficients.

If the specified path gains are not aligned with the sample rate, the path gains and the channel filter coefficients do not overlap. In this figure, the filter coefficients are equally distributed. The path gains do not overlap with the channel filter coefficients because the path gains are not aligned with the sample rate.

This figure shows the impulse response for a frequency-flat channel. In this case, the interpolated path gains are not displayed.

\section*{Frequency response}

The frequency response scope displays the multipath Rayleigh fading channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the dsp. SpectrumAnalyzer System object.

The y-axis limits of the plot are computed based on the NormalizePathGains and AveragePathGains properties of the comm. RayleighChannel System object.

This table shows other selected default spectrum settings. These settings can be changed from their default values by using the View > Spectrum Settings menu.
\begin{tabular}{|l|l|}
\hline Spectrum Settings & Value \\
\hline Main options \(>\) Type & Power \\
\hline Main options \(>\) Window length & Channel filter length \\
\hline Main options \(>\) NFFT & 512 \\
\hline Window options \(>\) Window & Rectangular \\
\hline Trace options \(>\) Units & dBW \\
\hline
\end{tabular}

This figure shows the frequency response plot for a frequency selective channel.

\section*{Doppler Spectrum}

The Doppler spectrum plot displays the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a line for the case of nonstatic channels and as a point for static channels. The empirical data is shown as * symbols. Before the empirical plot is updated, the internal buffer must be completely filled with filtered Gaussian samples. The empirical plot is the running mean of the spectrum calculated from each full buffer. For nonstatic channels, the number of input samples needed before the next update is displayed in the upper-left corner of the plot. The number of samples needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text "Reset fading channel for next update" is displayed.

\section*{comm.RBDSWaveformGenerator}

Package: comm
Generate RDS/RBDS waveform

\section*{Description}

The comm.RBDSWaveformGenerator System object generates configurable standard-compliant baseband RDS/RBDS waveforms in MATLAB. RDS/RBDS waveforms supplement FM radio stations with additional textual information, such as song title, artist name, and station description. The RDS/ RBDS signal lies in the \(57-\mathrm{kHz}\) band of the baseband FM radio signal.

Use this object to generate a waveform containing RadioText Plus (RT+) information and register a custom encoding implementation for an Open Data Application (ODA). You can also specify the time, data, and the program type. The object supports short, scrolling 8-character text, and longer 32character or 64 -character text.

To generate baseband RDS/RBDS waveforms:
1 Create a comm.RBDSWaveformGenerator object and set the properties of the object.
2 Call step to generate the waveform.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((\mathrm{obj}, \mathrm{x})\) and \(\mathrm{y}=\mathrm{obj}(\mathrm{x})\) perform equivalent operations.

\section*{Construction}
rbdsgen = comm.RBDSWaveformGenerator creates an RDS/RBDS waveform generator object, rbdsgen, using the default properties.
rbdsgen = comm.RBDSWaveformGenerator(Name,Value) specifies additional properties using Name, Value pairs. Unspecified properties have default values.

\section*{Example:}
```

rbdsgen = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...
'SendRadioTextPlus',true);

```

\section*{Properties}

If a property is listed as tunable, then you can change its value even when the object is locked.

\section*{SamplesPerSymbol - Number of samples per symbol}

10 (default) | positive even integer
Number of samples per symbol (bit), specified as a positive even integer. Half of the samples represent one amplitude level of Manchester coding. The other half of the samples represent the opposite level.

\section*{GroupsPerFrame - Number of groups per output frame}

10 (default) | scalar integer
Number of groups per output frame, specified as a scalar integer. Each group is 104 symbols (bits) long.

\section*{RadioText - Long text conveyed with type 2A groups}
'Long text' (default)| character vector
Radio text conveyed with type 2A groups, specified as a character vector that is up to 64 characters long. The object transmits the specified text four characters at a time, using type 2A groups.

Tunable: Yes
ProgramServiceName - Label of the program service
'ShortTxt' (default) | character vector
Label of the program service, specified as a character vector that is up to eight characters long. This information is conveyed as a short text with type 0A groups, two characters at a time.

Tunable: Yes

\section*{ProgramIdentificationCode - Program identification code}
[0000000000000000] (default) | 16-bit row vector
Program identification (PI) code, specified as a 16 -bit row vector. In North America, the PI code conveys the call letters of the station. Example call letters include 'WABC' and 'KXYZ'.

To generate North American PI codes for a station's call letters, use the callLettersToPICode method.

\section*{ProgramType - Program type \\ 'No program type or undefined' (default)|character vector}

Program type, specified as a character vector containing one of the 31 values allowed by the RDS/ RBDS standard. For a list of program types that the RDS/RBDS standard allows in North America, see [1].

Tunable: Yes

\section*{ProgramTypeName - Program type name}

\section*{' ' (default) | character vector}

Program type name, specified as a character vector that is up to eight characters long. This text further characterizes the program type, such as 'Football' for the program type 'Sports '. The object conveys the program type name using type 10A groups. If this property is empty, then no 10A groups are generated.

Tunable: Yes

\section*{SendDateTime - Option to advertise date and time \\ false (default) | true}

Option to advertise the date and time, specified as either false or true. When you set this property to true, one 4A group is periodically generated every 685 groups (once a minute).

\section*{AlternativeFrequencies - Alternative frequencies}
[] (default) | numeric row vector
Alternative frequencies, specified as a numeric row vector in MHz. This information is conveyed with type 0A groups. It indicates other transmitters broadcasting the same program in the same or adjacent reception areas. With this information, receivers can switch to a different frequency with better reception.

\section*{SendRadioTextPlus - Option to send RT+ information}
false (default) | true
Option to transmit RadioText Plus (RT+) information, specified as a scalar logical. When you set this property to true, the RT+ ODA information is advertised with type 3A groups. In addition, the RT+ content types, specified in RadioTextType1, RadioTextType2, and the two RT+ substrings indexed by RadioTextIndices are conveyed with the open-format type 11A group.

\section*{RadioTextType1 - Content type of first RT+ substring}
'Item.Artist' (default)| character vector
Content type of the first RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

\section*{RadioTextType2 - Content type of second RT+ substring}
'Item.Title' (default)| character vector
Content type of the second RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

\section*{RadioTextIndices - Start and end indices of RT+ substrings}
[1 2; 3 4] (default) | 2-by-2 matrix of positive integers
Start and end indices of RT+ substrings, specified as a 2-by-2 matrix of positive integers. The first column indexes the beginning of each RT+ substring. The second column indexes the end of each substring.

Tunable: Yes

\section*{Methods}
\begin{tabular}{ll} 
callLettersToPICode & Convert North-American call letters to binary PI code \\
registerODA & Register a custom encoding implementation for an ODA \\
reset & Reset states of RBDS waveform generator object \\
step & Generate RDS/RBDS waveform
\end{tabular}

\section*{Examples}

\section*{Generate a Basic RBDS Waveform}

Generate a basic RBDS waveform, FM modulate the waveform with an audio signal, and then demodulate the waveform.

Each frame of the RBDS waveform contains 19 groups, with a group length of 104 bits (symbols) each. Set the number of samples per RBDS symbol to 10. Therefore, the number of samples in each frame of RBDS waveform is \(104 \times 10 \times 19=19,760\). According to the RBDS standard, the bit rate is 1187.5 Hz . So, the RBDS sample rate \(=1187.5 \mathrm{x}\) samples per RBDS symbol. Set the audio frame rate to \(40 \times 1187.5=47,500\).
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate \(=40 * 1187.5\);
rbdsRate = 1187.5*sps;
outRate \(=4 * 57000\);
afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRa
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);
fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
'Stereo',true, 'RBDS',true, 'RBDSSamplesPerSymbol',sps);
fmDemod = comm. FMBroadcastDemodulator('SampleRate',outRate,...
'Stereo',true, 'RBDS',true, 'PlaySound',true);
scope = dsp.TimeScope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
Get the audio input and generate the RBDS waveform. FM modulate the stereo audio with the RBDS waveform, add noise, and FM demodulate the audio and RBDS waveforms. View the demodulated RBDS waveform in the time scope.
```

for idx = 1:7
input = afr(); % get current audio input
rbdsWave = rbds(); % generate RBDS info at the same configured rate
yFM = fmMod([input input], rbdsWave); % FM modulate stereo audio with RBDS info
rcv = awgn(yFM, 40); % add noise
[audioRcv, rbdsRcv] = fmDemod(rcv); % FM demodulate the audio and RBDS waveforms
scope(rbdsRcv);
end

```

\section*{Generate RBDS Waveform with RadioText Plus Information}

Create a comm.RBDSWaveformGenerator System object \({ }^{\mathrm{TM}}\) with 20 groups per frame and 10 samples per symbol. Add the Radio Text plus (RT+) information, such as artist name and song, title, to the waveform. Indicate the start and end of the RT+ substrings by using the RadioTextIndices property.
```

rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...
'SendRadioTextPlus', true);
rbds.RadioText = 'MyArtist - MySongTitle';
rbds.RadioTextType1 = 'Item.Artist';
rbds.RadioTextType2 = 'Item.Title';
rbds.RadioTextIndices = [1 8; 12 22];
for idx = 1:10
rbds.step();
end

```

\section*{Register a Custom Encoding Implementation}

Register a custom encoding implementation for an Open Data Application (ODA) by using the registerODA method of the comm. RBDSWaveformGenerator System object \({ }^{\mathrm{TM}}\). Set the ODA ID to 'CD46' , which is the ID for the traffic message channel. The allocated group type is 8A.
```

rbds = comm.RBDSWaveformGenerator();
odaID = 'CD46';
allocatedGroupType = '8A';

```

This example uses the following templates as a starting point for custom encoding implementation.
```

mainProcessingFcn = @CustomODAEncodingMain;
fcn3A = @CustomODAEncoding3A;
registerODA(rbds,odaID,allocatedGroupType,mainProcessingFcn,fcn3A);
s = info(rbds);
s.0DAMap
ans=2\times1 struct array with fields:
ID
GroupType
FunctionMain
Function3A

```

\section*{Configure RBDS Waveforms with Date and Time Information}

Generate RBDS waveform with date and time information, the program type, and alternative frequencies. The comm.RBDSWaveformGenerator object uses type 4A groups for date and time information, type 10A groups for the program type information, and type 0A groups for alternative frequencies. View the waveform in a spectrum analyzer.
```

rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',1000);
scope = dsp.SpectrumAnalyzer('SampleRate',1187.5*rbds.SamplesPerSymbol,'YLimits',[-140 20]);
rbds.SendDateTime = true; % send type 4A groups
rbds.ProgramType = 'Sports';
rbds.ProgramTypeName = 'Football'; % send type 10A groups
rbds.AlternativeFrequencies = [99.1 102.5]; % info sent in type 0A groups
wave = rbds.step();
scope(wave)

```

\section*{Algorithms}
comm.RBDSWaveformGenerator generates waveforms according to the RDS/RBDS standard [1]. The RDS/RBDS standard consists of three layers: physical layer, data-link layer, and session and application layer.

\section*{Physical Layer}

The physical layer (first layer) converts the data-link bits to an analog waveform by conducting differential encoding and biphase symbol encoding (Manchester encoding) and pulse-shaping filtering.

\section*{Data-Link Layer}

The data-link layer (second layer) performs \((26,16)\) cyclic encoding shortened from \((341,331)\) encoding [1]. The second layer is responsible for error detection, error correction, and the establishment of group-level synchronization. Each group of RDS/RBDS frames contains four blocks of 26 bits (that is 104 bits) each. Each block contains an information word and a check word. Each information word contains 16 bits, and each check word contains 10 bits.

Here is the baseband coding structure for the RDS/RBDS waveform. For more details, see [1].

For each block, a unique offset word is modulo-2 added to the checkword bits. The added offset word provides a group and block synchronization system in the receiver (decoder). Because the addition of the offset is reversible in the decoder, the normal additive error-correcting and detecting properties of the basic code are unaffected.

\section*{Session and Application Layer}

The first block in every group contains a program identification (PI) code. The first four bits of the second block of every group are allocated to a four-bit code. This code specifies the application of the group. Groups are referred to as types \(0-15\) according to the binary weighting \(\mathrm{A}_{3}=8, \mathrm{~A}_{2}=4, \mathrm{~A}_{1}=2\), \(A_{0}=1\). The fifth bit of the second block, \(B_{0}\), defines the version of the application. If \(B_{0}=0\), the version of the group is A. The PI code in this version is inserted into block 1 only. Example group types include 0A, 1A, 2A, 3A, and 4A.

The Program Type code and Traffic Program Identification (PI) occupy fixed locations in block 2 of every group.

\section*{Group Types}
\begin{tabular}{|c|c|c|c|c|c|l|}
\hline \multirow{2}{*}{\begin{tabular}{c} 
Group \\
Type
\end{tabular}} & \multicolumn{5}{|c|}{ Group Type Code/Version } & \multirow{2}{*}{ Description } \\
\cline { 2 - 5 } & \(\mathrm{A}_{3}\) & \(\mathrm{~A}_{2}\) & \(\mathrm{~A}_{1}\) & \(\mathrm{~A}_{0}\) & \(\mathrm{~B}_{0}\) & \\
\hline OA & 0 & 0 & 0 & 0 & 0 & \begin{tabular}{l} 
Basic station information. Short, usually scrolling text, up to 8 characters long. \\
Transmitted 2 characters at a time.
\end{tabular} \\
\hline 2 A & 0 & 0 & 1 & 0 & 0 & \begin{tabular}{l} 
Radio text. Long text, up to 64 characters long. Transmitted 4 characters at a \\
time.
\end{tabular} \\
\hline 3 A & 0 & 0 & 1 & 1 & 0 & \begin{tabular}{l} 
Specification of used Open Data Applications and their allocation group type. \\
Example: Radio Text Plus information is sent using 11A group.
\end{tabular} \\
\hline 4 A & 0 & 1 & 0 & 0 & 0 & \begin{tabular}{l} 
Date and time. Optional group that can be transmitted once in every 685 \\
groups (once a minute).
\end{tabular} \\
\hline 10 A & 1 & 0 & 1 & 0 & 0 & Program type name. Example: Football for ProgramType \(=\) 'Sports'. \\
\hline 11 A & 1 & 0 & 1 & 1 & 0 & Open Data Applications. Example: RadioText Plus (RT+). \\
\hline
\end{tabular}

System object: comm. RBDSWaveformGenerator
Package: comm
Convert North-American call letters to binary PI code

\section*{Syntax}
picode = callLettersToPICode(rbdsgen, callLetters)

\section*{Description}
picode = callLettersToPICode(rbdsgen, callLetters) returns the 16-bit program identification (PI) code that corresponds to callLetters. Acceptable call letter formats are 3character or 4 -character vectors beginning with ' \(K\) ' or ' \(W\) '.

Introduced in R2017a

\section*{registerODA}

System object: comm. RBDSWaveformGenerator
Package: comm
Register a custom encoding implementation for an ODA

\section*{Syntax}
registerODA(rbdsgen, odaID, group, handleMain, handle3A)

\section*{Description}
registerODA (rbdsgen, odaID, group, handleMain, handle3A) associates the Open Data Application (ODA) specified by the hexadecimal ID odaID, with the type group groups generated by rbdsgen. The four 16-bit information words of these groups are generated by the function handle handleMain. The third information word of type 3A groups, which is ODA-specific, is generated by the function handle handle3A.

\section*{reset}

System object: comm.RBDSWaveformGenerator
Package: comm
Reset states of RBDS waveform generator object

\section*{Syntax}
reset(rbdsgen)

\section*{Description}
reset (rbdsgen) resets the states of the RBDSWaveformGenerator object, rbdsgen.
Introduced in R2017a

\section*{step}

System object: comm.RBDSWaveformGenerator
Package: comm
Generate RDS/RBDS waveform

\section*{Syntax}
y = step(rbdsgen)

\section*{Description}

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(y=\) step(rbdsgen) outputs a frame of the baseband RDS/RBDS waveform in column vector y . The waveform contains the number of 104-bit groups, specified in the GroupsPerFrame property of the object. Each symbol is oversampled according to the SamplesPerSymbol property. Thus, the output length is SamplesPerSymbol \(\times 104 \times\) GroupsPerFrame samples. The object uses an internal scheduler to determine the order and frequency of the transmitted group types.

Note rbdsgen specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{Introduced in R2017a}

\section*{comm.RectangularQAMDemodulator}

Package: comm
(To be removed) Demodulate using rectangular QAM signal constellation

Note comm. RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead. For more information, see "Compatibility Considerations".

\section*{Description}

The RectangularQAMDemodulator object demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

To demodulate a signal that was modulated using quadrature amplitude modulation:
1 Define and set up your rectangular QAM demodulator object. See "Construction" on page 31207.

2 Call step to demodulate the signal according to the properties of comm. RectangularQAMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = \(\underline{\text { step }(o b j, x) \text { and } y=o b j(x) \text { perform equivalent operations. }}\)

\section*{Construction}

H = comm.RectangularQAMDemodulator creates a demodulator System object, H. This object demodulates the input signal using the rectangular quadrature amplitude modulation (QAM) method.

H = comm.RectangularQAMDemodulator(Name, Value) creates a rectangular QAM demodulator object, H , with each specified property set to the specified value. You can specify additional namevalue pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.RectangularQAMDemodulator(M,Name,Value) creates a rectangular QAM demodulator object, H . This object has the ModulationOrder property set to M , and the other specified properties set to the specified values.

\section*{Properties}

\section*{ModulationOrder}

Number of points in signal constellation
Specify the number of points in the signal constellation as scalar value with a positive, integer power of two. The default is 16 .

\section*{PhaseOffset}

Phase offset of constellation
Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0 .

\section*{BitOutput}

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values. When you set this property to true the step method outputs a column vector of bit values whose length equals \(\boldsymbol{\operatorname { l o g }} 2\) (ModulationOrder on page 3-0 \(\quad\) ) times the number of demodulated symbols. When you set this property to false, the step method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between 0 and Modulation0rder-1. The default is false.

\section*{SymbolMapping}

\section*{Constellation encoding}

Specify how the object maps an integer or group of \(\boldsymbol{\operatorname { l o g } 2}\) (ModulationOrder on page 3-0 ) bits to the corresponding symbol as one of Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-coded signal constellation. When you set this property to Binary, the object uses a natural binary-coded constellation. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping on page 3-0 property.

\section*{CustomSymbolMapping}

\section*{Custom constellation encoding}

Specify a custom constellation symbol mapping vector. The default is \(0: 15\). This property is a row or column vector with a size of ModulationOrder on page 3-0 and with unique integer values in the range [0, Modulation0rder-1]. The values must be of data type double. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the SymbolMapping on page 3-0 property to Custom.

\section*{NormalizationMethod}

Constellation normalization method
Specify the method used to normalize the signal constellation as Minimum distance between symbols|Average power|Peak power. The default is Minimum distance between symbols.

\section*{MinimumDistance}

Minimum distance between symbols
Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2 . This property applies when you set the NormalizationMethod on page 30 property to Minimum distance between symbols.

\section*{AveragePower}

Average power of constellation
Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Average power.

\section*{PeakPower}

Peak power of constellation
Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Peak power.

\section*{DecisionMethod}

Demodulation decision method
Specify the decision method the object uses as Hard decision | Log-likelihood ratio| Approximate log-likelihood ratio. The default is Hard decision. When you set the BitOutput on page 3-0 property to false the object always performs hard-decision demodulation. This property applies when you set the BitOutput property to true.

\section*{VarianceSource}

Source of noise variance
Specify the source of the noise variance as Property | Input port. The default is Property. This property applies when you set the BitOutput on page 3-0 property to true and the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate loglikelihood ratio.

\section*{Variance}

Noise variance
Specify the variance of the noise as a positive, real scalar value. The default is 1 . If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield Inf or -Inf. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the BitOutput on page 3-0 property to true, the DecisionMethod on page 3-0 property to Log-likelihood ratio or Approximate log-likelihood ratio, and the VarianceSource on page 3-0 property to Property. This property is tunable.

\section*{OutputDataType}

Data type of output
Specify the output data type as Full precision|Smallest unsigned integer|double| single | int8|uint8| int16|uint16|int32|uint32. The default is Full precision.

This property applies only when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard
decision. In this case, when the OutputDataType on page 3-0 property is set to Full precision, and the input data type is single- or double-precision, the output data has the same data type as the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer.

When you set the BitOutput property to true and the DecisionMethod property to Hard Decision, then logical data type becomes a valid option.

When you set the BitOutput property to true and the DecisionMethod property to Loglikelihood ratio or Approximate log-likelihood ratio, the output data type is the same as that of the input. In this case, that data type can only be single- or double-precision.

\section*{Fixed-Point Properties}

\section*{FullPrecisionOverride}

Full precision override for fixed-point arithmetic
Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for FixedPoint System Objects" on page 3-1212.

\section*{DerotateFactorDataType}

Data type of derotate factor
Specify the derotate factor data type as Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on page 3-0 property to false, or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when the step method input is of a fixed-point type and the PhaseOffset on page 3-0
property has a value that is not a multiple of \(\Pi / 2\).

\section*{CustomDerotateFactorDataType}

Fixed-point data type of derotate factor
Specify the derotate factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype ( \([\mathrm{l}, 16\) ). This property applies when you set the DerotateFactorDataType on page 3-0 property to Custom.

\section*{DenormalizationFactorDataType}

Data type of denormalization factor
Specify the denormalization factor data type as Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput on
page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

\section*{CustomDenormalizationFactorDataType}

Fixed-point data type of denormalization factor
Specify the denormalization factor fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the DenormalizationFactorDataType on page 3-0 property to Custom.

\section*{ProductDataType}

Data type of product
Specify the product data type as Full precision | Custom. The default is Full precision. This property applies when you set the Bit0utput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

\section*{CustomProductDataType}

Fixed-point data type of product
Specify the product fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],32). This property applies when you set the ProductDataType on page 3-0 property to Custom.

\section*{ProductRoundingMethod}

Rounding of fixed-point numeric value of product
Specify the product rounding method as Ceiling | Convergent | Floor | Nearest | Round |
Simplest | Zero. The default is Floor. This property applies when the object is not in a full precision configuration, when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

\section*{ProductOverflowAction}

Action when fixed-point numeric value of product overflows
Specify the product overflow action as Wrap | Saturate. The default is Wrap. This property applies when the object is not in a full precision configuration, when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

\section*{SumDataType}

Data type of sum
Specify the sum data type as Full precision | Same as product | Custom. The default is Full precision. This property applies when you set the FullPrecisionOverride on page 3-0 property to false, when you set the BitOutput on page 3-0 property to false or when you set the BitOutput property to true and the DecisionMethod on page 3-0 property to Hard decision.

\section*{CustomSumDataType}

Fixed-point data type of sum
Specify the sum fixed-point type as an unscaled numerictype object with a signedness of Auto. The default is numerictype([],32). This property applies when you set the FullPrecisionOverride on page 3-0 property to false or when you set the SumDataType on page 3-0 property Custom.

\section*{Methods}
constellation (To be removed) Calculate or plot ideal signal constellation
step (To be removed) Demodulate using rectangular QAM method

\section*{Common to All System Objects}
\begin{tabular}{l|l} 
release & Allow System object property value changes \\
\hline
\end{tabular}

\section*{More About}

\section*{Full Precision for Fixed-Point System Objects}

FullPrecisionOverride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to true, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to false.

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

\section*{Compatibility Considerations}
comm. RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead.
Not recommended starting in R2018b
Constellation normalization by PeakPower and AveragePower (other than unit average power) as supported by comm. RectangularQAMModulator and comm. RectangularQAMDemodulator is not inherently provided by functions. This code shows you how to perform peak power and average power normalization using qammod and qamdemod functions.

\section*{Extended Capabilities}

\section*{C/C++ Code Generation}

Generate C and \(\mathrm{C}++\) code using MATLAB® \({ }^{\circledR}\) Coder \(^{\mathrm{TM}}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{See Also}

\section*{Functions}
genqamdemod | qamdemod

\section*{Objects}
comm.GeneralQAMDemodulator
Introduced in R2012a

3-1222

\section*{constellation}

System object: comm.RectangularQAMDemodulator
Package: comm
(To be removed) Calculate or plot ideal signal constellation

Note comm. RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead.

\section*{Syntax}
y = constellation(h)
constellation(h)

\section*{Description}
\(y=\) constellation(h) returns the numerical values of the constellation.
constellation(h) generates a constellation plot for the object.

\section*{Examples}

\section*{Plot QAM Reference Constellations}

Plot QAM reference constellation using the qammod and qamdemod functions. Show that the ' PlotConstellation, true' Name,Value pair property works for both qammod and qamdemod functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.
```

M = 16; % For 16-QAM
refSym = (0:M-1)';

```

Plot the reference constellation using the qammod function.
qammod(refSym, M, 'PlotConstellation',true);

The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify 'InputType', 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of \(\log 2\) (M). Tranpose the input vector so that the input symbols map to the column vectors.
```

biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');

```

Replot the reference constellation using binary-coded symbol ordering.
biRefSym = de2bi(refSym);
qammod(biRefSym', M, 'bin','PlotConstellation',true,'InputType','bit');

Create symbols for a 64-QAM modulator.
\(M=64\); For 64-QAM
refSym = (0:M-1);
Plot the reference constellation using the qamdemod function.
qamdemod(refSym, M, 'PlotConstellation', true);

\section*{step}

System object: comm.RectangularQAMDemodulator Package: comm
(To be removed) Demodulate using rectangular QAM method

Note comm. RectangularQAMDemodulator will be removed in a future release. Use qamdemod instead.

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)
\(Y=\operatorname{step}(H, X, V A R)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(Y=\) step \((H, X)\) demodulates the input data, \(X\), with the rectangular QAM demodulator System object, \(H\), and returns, Y . Input X must be a scalar or a column vector with double or single precision data type. When ModulationOrder is an even power of two and you set the BitOutput property to false or, when you set the DecisionMethod to Hard decision and the BitOutput property to true, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the BitOutput property value, output \(Y\) can be integer or bit valued.

Y = step( \(H, X\), VAR) uses soft decision demodulation and noise variance VAR. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to Approximate log-likelihood ratioor Log-likelihood ratio, and the VarianceSource property to Input port. The data type of input VAR must be double or single precision.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.RectangularQAMModulator}

Package: comm
(To be removed) Modulate using rectangular QAM signal constellation

Note comm. RectangularQAMModulator will be removed in a future release. Use qammod instead. For more information, see "Compatibility Considerations".

\section*{Description}

The RectangularQAMModulator object modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal.

To modulate a signal using quadrature amplitude modulation:
1 Define and set up your rectangular QAM modulator object. See "Construction" on page 3-1229.
2 Call step to modulate the signal according to the properties of comm. RectangularQAMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. RectangularQAMModulator creates a modulator object, \(H\). This object modulates the input using the rectangular quadrature amplitude modulation (QAM) method.

H = comm.RectangularQAMModulator(Name,Value) creates a rectangular QAM modulator object, H , with each specified property set to the specified value. You can specify additional namevalue pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.RectangularQAMModulator(M,Name,Value) creates a rectangular QAM modulator object, H . This object has the ModulationOrder property set to \(M\), and the other specified properties set to the specified values.

\section*{Properties}

\section*{ModulationOrder}

Number of points in signal constellation
Specify the number of points in the signal constellation as scalar value that is a positive integer power of two. The default is 16 .

\section*{PhaseOffset}

Phase offset of constellation
Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0 .

\section*{BitInput}

Assume bit inputs
Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input requires a column vector of bit values. The length of this vector must an integer multiple of \(\log 2\) (ModulationOrder on page 3-0 ). This vector contains bit representations of integers between 0 and ModulationOrder-1. When you set this property to false, the step method input must be a column vector of integer symbol values between 0 and ModulationOrder-1.

\section*{SymbolMapping}

Constellation encoding
Specify how the object maps an integer or group of \(\log 2\) (ModulationOrder on page 3-0 ) input bits to the corresponding symbol as Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the System object uses a Gray-coded signal constellation. When you set this property to Binary, the object uses a natural binary-coded constellation. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping on page 30 property.

\section*{CustomSymbolMapping}

Custom constellation encoding
Specify a custom constellation symbol mapping vector. The default is \(0: 15\). This property is a row or column vector with a size of ModulationOrder on page 3-0 . This vector has unique integer values in the range [0, ModulationOrder-1]. These values must be of data type double. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottomrightmost point. This property applies when you set the SymbolMapping on page 3-0 property to Custom.

\section*{NormalizationMethod}

Constellation normalization method
Specify the method used to normalize the signal constellation as Minimum distance between symbols|Average power|Peak power. The default is Minimum distance between symbols.

\section*{MinimumDistance}

Minimum distance between symbols
Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2 . This property applies when you set the NormalizationMethod on page 30 property to Minimum distance between symbols.

\section*{AveragePower}

Average power of constellation
Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 3-
0 property to Average power.

\section*{PeakPower}

Peak power of constellation
Specify the maximum power of the symbols in the constellation as a positive real, numeric scalar value. The default is 1 . This property applies when you set the NormalizationMethod on page 30 property to Peak power.

\section*{OutputDataType}

Data type of output
Specify the output data type as double \| single \| Custom. The default is double.

\section*{Fixed-Point Properties}

\section*{Custom0utputDataType}

Fixed-point data type of output
Specify the output fixed-point type as a numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the OutputDataType on page 3-0 property to Custom.

\section*{Methods}
constellation (To be removed) Calculate or plot ideal signal constellation
step (To be removed) Modulate using rectangular QAM method

\section*{Common to All System Objects}
release \(\quad\) Allow System object property value changes

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM
Modulator Baseband block reference page. The object properties correspond to the block parameters.

\section*{Compatibility Considerations}
comm. RectangularQAMModulator will be removed in a future release. Use qammod instead. Not recommended starting in R2018b

Constellation normalization by PeakPower and AveragePower (other than unit average power) as supported by comm. RectangularQAMModulator and comm. RectangularQAMDemodulator is not
inherently provided by functions. This code shows you how to perform peak power and average power normalization using qammod and qamdemod functions.

Objects
comm.GeneralQAMModulator
Introduced in R2012a

\section*{constellation}

System object: comm.RectangularQAMModulator
Package: comm
(To be removed) Calculate or plot ideal signal constellation

Note comm. RectangularQAMModulator will be removed in a future release. Use qammod instead.

\section*{Syntax}
\(\mathrm{y}=\) constellation(h)
constellation(h)

\section*{Description}
\(y=\) constellation(h) returns the numerical values of the constellation.
constellation(h) generates a constellation plot for the object.

\section*{Examples}

\section*{Plot QAM Reference Constellations}

Plot QAM reference constellation using the qammod and qamdemod functions. Show that the ' PlotConstellation, true' Name,Value pair property works for both qammod and qamdemod functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.
```

M = 16; % For 16-QAM
refSym = (0:M-1)';

```

Plot the reference constellation using the qammod function.
qammod(refSym,M, 'PlotConstellation',true);

The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify 'InputType', 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of log2 (M). Tranpose the input vector so that the input symbols map to the column vectors.
```

biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');

```

Replot the reference constellation using binary-coded symbol ordering.
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');

Create symbols for a 64-QAM modulator.
\(M=64\); For 64-QAM
refSym = (0:M-1);
Plot the reference constellation using the qamdemod function.
qamdemod(refSym, M, 'PlotConstellation', true) ;

\section*{step}

System object: comm. RectangularQAMModulator
Package: comm
(To be removed) Modulate using rectangular QAM method

Note comm. RectangularQAMModulator will be removed in a future release. Use qammod instead.

\section*{Syntax}

Y = step(H,X)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})\) modulates input data, X , with the rectangular QAM modulator object, H . It returns the baseband modulated output, Y . Depending on the value of the BitInput property, input X can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.RectangularQAMTCMDemodulator}

\section*{Package: comm}

Demodulate convolutionally encoded data mapped to rectangular QAM signal constellation

\section*{Description}

The RectangularQAMTCMDemodulator object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a rectangular QAM signal constellation.

To demodulate convolutionally encoded data mapped to a rectangular QAM signal constellation:
1 Define and set up your rectangular QAM TCM demodulator object. See "Construction" on page 31248.

2 Call step to demodulate the signal according to the properties of comm.RectangularQAMTCMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. RectangularQAMTCMDemodulator creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) demodulator System object, H. This object demodulates convolutionally encoded data that has been mapped to a rectangular QAM constellation.

H = comm.RectangularQAMTCMDemodulator(Name, Value) creates a rectangular, QAM TCM, demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.RectangularQAMTCMDemodulator(TRELLIS,Name,Value) creates a rectangular QAM TCM demodulator object, H. This object has the TrellisStructure property set to TRELLIS, and the other specified properties set to the specified values.

\section*{Properties}

\section*{TrellisStructure}

Trellis structure of convolutional code
Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check whether a structure is a valid trellis. The default is the result of poly2trellis([3 1 1], [ \(5200 ; 0010 ; 0001])\).

\section*{TerminationMethod}

Termination method of encoded frame
Specify the termination method as Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, you should use Continuous mode.

When you set this property to Truncated, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to Terminated, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

\section*{TracebackDepth}

Traceback depth for Viterbi decoder
Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the TerminationMethod property to Continuous, the decoding delay consists of TracebackDepth zero symbols or TracebackDepth \(\times K\) zero bits for a rate \(K / N\) convolutional code.

When you set the TerminationMethod property to Truncated or Terminated, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

\section*{ResetInputPort}

Enable demodulator reset input
Set this property to true to enable an additional input to the step method. The default is false. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the TerminationMethod property to Continuous.

\section*{ModulationOrder}

Number of points in signal constellation
Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be \(4,8,16,32\), or 64 . The default is 16. The ModulationOrder property value must equal the number of possible input symbols to the convolutional decoder of the rectangular QAM TCM demodulator object. The ModulationOrder must equal \(2^{N}\) for a rate \(K / N\) convolutional code.

\section*{OutputDataType}

Data type of output
Specify output data type as logical | double. The default is double.

\section*{Methods}
reset Reset states of the rectangular QAM TCM demodulator object
step Demodulate convolutionally encoded data mapped to rectangular QAM constellation
Common to All System Objects
release \(\quad\) Allow System object property value changes

\section*{Examples}

\section*{Modulate and Demodulate Using Rectangular 16-QAM TCM}

Modulate and demodulate data using 16-QAM TCM in an AWGN channel. Estimate the BER.
Create QAM TCM modulator and demodulator System objects \({ }^{\mathrm{TM}}\).
hMod \(=\) comm.RectangularQAMTCMModulator;
hDemod = comm.RectangularQAMTCMDemodulator('TracebackDepth',16);
Create an AWGN channel object.
hAWGN = comm.AWGNChannel('EbNo',5);
Determine the delay through the QAM TCM demodulator. The demodulator uses the Viterbi algorithm to decode the TCM signal that was modulated using rectangular QAM. To accurately calculate the bit error rate, the delay through the decoder must be known.
```

bitsPerSymbol = log2(hDemod.TrellisStructure.numInputSymbols);

```
delay \(=\) hDemod.TracebackDepth*bitsPerSymbol;

Create an error rate calculator object with the ReceiveDelay property set to delay.
```

hErrorCalc = comm.ErrorRate('ReceiveDelay',delay);

```

Generate binary data and modulate with 16-QAM TCM. Pass the signal through an AWGN channel and demodulate. Calculate the error statistics. The loop runs until either 100 bit errors are encountered or 1 e 7 total bits are transmitted.
```

% Initialize the error results vector.
errStats = [0 0 0];
while errStats(2) < 100 \&\& errStats(3) < le7
% Transmit frames of 200 3-bit symbols
txData = randi([0 1],600,1);
% Modulate
txSig = step(hMod,txData);
% Pass through AWGN channel
rxSig = step(hAWGN,txSig);
% Demodulate
rxData = step(hDemod,rxSig);
% Collect error statistics
errStats = step(hErrorCalc,txData,rxData);
end

```

Display the error data.
```

fprintf('Error rate = %4.2e\nNumber of errors = %d\n', ...
errStats(1),errStats(2))
Error rate = 1.94e-03
Number of errors = 100

```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Decoder block reference page. The object properties correspond to the block parameters.

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and \(\mathrm{C}++\) code using MATLAB® Coder \(^{\mathrm{TM}}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{See Also}
comm. GeneralQAMTCMDemodulator | comm.RectangularQAMTCMModulator | comm.ViterbiDecoder

\section*{Introduced in R2012a}

\section*{reset}

System object: comm.RectangularQAMTCMDemodulator
Package: comm
Reset states of the rectangular QAM TCM demodulator object

\section*{Syntax}
reset (H)

\section*{Description}
reset \((\mathrm{H})\) resets the states of the RectangularQAMTCMDemodulator object, H .

\section*{step}

System object: comm. RectangularQAMTCMDemodulator
Package: comm
Demodulate convolutionally encoded data mapped to rectangular QAM constellation

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)
Y = step (H, X,R)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})\) demodulates the rectangular QAM modulated input data, X , and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. X must be a complex, double or single precision column vector. The step method outputs a demodulated, binary data column vector, Y . When the convolutional encoder represents a rate \(\mathrm{K} / \mathrm{N}\) code, the length of the output vector is \(\mathrm{K}^{*} \mathrm{~L}\), where L is the length of the input vector, X .
\(Y=\operatorname{step}(H, X, R)\) resets the decoder to the all-zeros state when you input a reset signal, \(R\) that is non-zero. R must be a double precision or logical, scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.RectangularQAMTCMModulator}

\section*{Package: comm}

Convolutionally encode binary data and map using rectangular QAM signal constellation

\section*{Description}

The RectangularQAMTCMModulator object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a rectangular QAM signal constellation.

To convolutionally encode binary data and map the result using a rectangular QAM constellation:
1 Define and set up your rectangular QAM TCM modulator object. See "Construction" on page 31254.

2 Call step to modulate the signal according to the properties of comm. RectangularQAMTCMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. RectangularQAMTCMModulator creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) System object, H. This object convolutionally encodes a binary input signal and maps the result to a rectangular QAM constellation.

H = comm.RectangularQAMTCMModulator(Name, Value) creates a rectangular QAM TCM modulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.RectangularQAMTCMModulator(TRELLIS,Name,Value) creates a rectangular QAM TCM modulator object, H . This object has the TrellisStructure property set to TRELLIS and the other specified properties set to the specified values.

\section*{Properties}

\section*{TrellisStructure}

Trellis structure of convolutional code
Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check whether a structure is a valid trellis. The default is the result of poly2trellis([3 1 1], [ \(5200 ; 0010 ; 0001])\).

\section*{TerminationMethod}

Termination method of encoded frame
Specify the termination method as Continuous | Truncated | Terminated. The default is Continuous.

When you set this property to Continuous, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to Truncated, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to Terminated, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate \(K / N\) code, the step method outputs the vector with a length given by \(y=N \times(L+S) / K\), where \(S=\) constraintLength-1 (or, in the case of multiple constraint lengths, \(S=\) \(\operatorname{sum}(\) constraintLength(i)-1)). \(L\) is the length of the input to the step method.

\section*{ResetInputPort}

Enable modulator reset input
Set this property to true to enable an additional input to the step method. The default is false. When you set the reset input to the step method to a nonzero value, the object resets the encoder to the allzeros state. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

\section*{ModulationOrder}

Number of points in signal constellation
Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to \(4,8,16,32\), or 64 . The default is 16 . The value of the ModulationOrder on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the QAM TCM modulator. Thus, the value for the ModulationOrder property must equal \(2^{N}\) for a rate \(K / N\) convolutional code.

\section*{OutputDataType}

Data type of output
Specify the output data type as one of double | single. The default is double.

\section*{Methods}
reset Reset states of the rectangular QAM TCM modulator object
step Convolutionally encode binary data and map using rectangular QAM constellation
Common to All System Objects
\begin{tabular}{|l|ll}
\hline release & Allow System object property value changes
\end{tabular}

\section*{Examples}

\section*{Modulate Data Using Rectangular QAM TCM}

Modulate data using rectangular 16-QAM TCM modulation and display the scatter plot.
Generate random binary data. The length of the data vector must be an integer multiple of the number of input streams into the encoder, \(\log 2(8)=3\).
```

data = randi([0 1],3000,1);

```

Create a modulator System object \({ }^{T M}\) and use its step function to modulate the data.
hMod = comm.RectangularQAMTCMModulator;
modData \(=\) step(hMod,data);
Plot the modulated data.
scatterplot(modData)

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Encoder block reference page. The object properties correspond to the block parameters.

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and \(\mathrm{C}++\) code using MATLAB® Coder \(^{\text {™ }}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{See Also}
comm. ConvolutionalEncoder | comm.GeneralQAMTCMModulator |
comm. RectangularQAMTCMDemodulator

Introduced in R2012a

\section*{reset}

System object: comm.RectangularQAMTCMModulator
Package: comm
Reset states of the rectangular QAM TCM modulator object

\section*{Syntax}
reset (H)

\section*{Description}
reset \((\mathrm{H})\) resets the states of the RectangularQAMTCMModulator object, H.

\section*{step}

System object: comm. RectangularQAMTCMModulator
Package: comm
Convolutionally encode binary data and map using rectangular QAM constellation

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)
Y = step(H,X,R)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\) step \((\mathrm{H}, \mathrm{X})\) convolutionally encodes and modulates the input data numeric or logical column vector X , and returns the encoded and modulated data, Y . X must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate \(K / N\) code, the length of the input vector, \(X\), must be \(K \times L\), for some positive integer \(L\). The step method outputs a complex column vector, \(Y\), of length \(L\).
\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})\) resets the encoder of the rectangular QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, R. R must be a double precision or logical, scalar integer. This syntax applies when you set the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.RicianChannel}

Package: comm
Filter input signal through multipath Rician fading channel

\section*{Description}

The comm.RicianChannel System object filters an input signal through a multipath Rician fading channel. For more information on fading model processing, see Methodology for Simulating Multipath Fading Channels.

To filter an input signal using a multipath Rician fading channel:
1 Create the comm. RicianChannel object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
ricianlchan = comm.RicianChannel
ricianlchan = comm.RicianChannel(Name, Value)

\section*{Description}
ricianlchan = comm.RicianChannel creates a frequency-selective or frequency-flat multipath Rician fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain the channel-impaired signal.
ricianlchan = comm.RicianChannel (Name, Value) sets properties using one or more namevalue pair arguments. Enclose each property name in quotes. For example, comm.RicianChannel('SampleRate', 2) sets the input signal sample rate to 2 .

\section*{Properties}

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

\section*{SampleRate - Input signal sample rate}

1 (default) | positive scalar
Input signal sample rate in Hz , specified as a positive scalar.

\section*{Data Types: double}

\section*{PathDelays - Discrete path delay}

0 (default) | numeric scalar | numeric row vector
Discrete path delay in seconds, specified as a numeric scalar or numeric row vector.
- When PathDelays is a scalar, the channel is frequency flat.
- When PathDelays is a vector, the channel is frequency selective.

\section*{Data Types: double}

\section*{AveragePathGains - Average of the discrete paths}

0 (default) | numeric scalar | numeric row vector
Average gains of the discrete paths in decibels, specified as a numeric scalar or numeric row vector. AveragePathGains must be of the same size as the PathDelays property.

\section*{Data Types: double}

\section*{NormalizePathGains - Normalize average path gains to \(\mathbf{0} \mathbf{d B}\)}
true or 1 (default) | false or 0
Normalize average path gains to 0 dB , specified as a logical 1 (true) or 0 (false).
- When NormalizePathGains is true, the fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB .
- When NormalizePathGains is false, the total power of the path gains is not normalized.

Data Types: logical

\section*{KFactor - Rician \(K\)-factor}

3 (default) | positive scalar | row vector of nonnegative values
Rician \(K\)-factor, specified as a positive scalar or row vector of nonnegative values. The vector must be the same length as the PathDelays property value.
- When KFactor is a scalar, the first discrete path is a Rician fading process with a Rician \(K\)-factor of KFactor. Any remaining discrete paths are independent Rayleigh fading processes.
- When KFactor is a row vector, the discrete path corresponding to a positive element of the KFactor vector is a Rician fading process with a Rician \(K\)-factor specified by that element. The discrete path corresponding to any zero-valued elements of the KFactor vector are Rayleigh fading processes. At least one element value must be nonzero.

\section*{Data Types: double}

\section*{DirectPathDopplerShift - Doppler shift}

0 (default) | numeric scalar | numeric row vector
Doppler shift of the line-of-sight components of a multipath Rician fading channel, specified as a numeric scalar or numeric row vector. Units are in hertz. The DirectPathDopplerShift property must be of the same size as the KFactor property.
- When DirectPathDopplerShift is a scalar, the value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process.
- When DirectPathDopplerShift is a row vector, the discrete path corresponding to a positive element of the KFactor vector is a Rician fading process. The corresponding element of DirectPathDopplerShift specifies the line-of-sight component Doppler shift of that discrete path.

\section*{Data Types: double}

\section*{DirectPathInitialPhase - Initial phase}

0 (default) | numeric scalar | numeric row vector
Initial phase of the line-of-sight components of a multipath Rician fading channel, specified as a numeric scalar or numeric row vector. Units are in radians. The DirectPathInitialPhase property must be of the same size as the KFactor property.
- When DirectPathInitialPhase is a scalar, the value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process.
- When DirectPathInitialPhase is a row vector, the discrete path corresponding to a positive element of the KFactor vector is a Rician fading process. The corresponding element of DirectPathInitialPhase specifies the line-of-sight component initial phase of that discrete path.

Data Types: double

\section*{MaximumDopplerShift - Maximum Doppler shift for all channel paths}
0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.
The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the reset object function to generate a new channel realization. The MaximumDopplerShift property value must be smaller than SampleRate \(/ 10 / f_{\mathrm{c}}\) for each path. \(f_{\mathrm{c}}\) represents the cutoff frequency factor of the path. For most Doppler spectrum types, the value of \(f_{\mathrm{c}}\) is 1 . For Gaussian and biGaussian Doppler spectrum types, \(f_{\mathrm{c}}\) is dependent on the Doppler spectrum structure fields. For more details about how \(f_{\mathrm{c}}\) is defined, see "Cutoff Frequency Factor" on page 3-1273.

Data Types: double

\section*{DopplerSpectrum - Doppler spectrum shape for all channel paths}
doppler('Jakes') (default) | Doppler spectrum structure | 1-by- \(N_{\mathrm{P}}\) cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- \(N_{\mathrm{P}}\) cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the doppler function. \(N_{\mathrm{P}}\) is the number of discrete delay paths, that is, the length of the PathDelays property.
- When DopplerSpectrum is defined by a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When DopplerSpectrum is defined by a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Options for the spectrum type are specified by the specType input to the doppler function. If you set the FadingTechnique property to 'Sum of sinusoids', you must set DopplerSpectrum to doppler('Jakes').

\section*{Dependencies}

To enable this property, set the MaximumDopplerShift property to a positive value. The MaximumDopplerShift property defines the maximum Doppler shift value permitted when specifying the Doppler spectrum.

Data Types: struct | cell
FadingTechnique - Channel model fading technique
'Filtered Gaussian noise' (default)|'Sum of sinusoids'
Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char | string
NumSinusoids - Number of sinusoids used
48 (default) | positive integer
Number of sinusoids used to model the fading process, specified as a positive integer.

\section*{Dependencies}

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.
```

Data Types: double

```

\section*{InitialTimeSource - Source to control start time of fading process}
'Property' (default)|'Input port'
Source to control the start time of the fading process, specified as 'Property' or 'Input port'.
- When InitialTimeSource is set to 'Property', use the InitialTime property to set the initial time offset.
- When InitialTimeSource is set to 'Input port', specify the start time of the fading process by using the itime input to the System object. The input value can change in consecutive calls to the System object.

\section*{Dependencies}

This property applies when the FadingTechnique property to 'Sum of sinusoids'.
Data Types: string | char

\section*{InitialTime - Initial time offset}

0 (default) | nonnegative scalar
Initial time offset, in seconds, for the fading model, specified as a nonnegative scalar. InitialTime must be greater than end time of the last frame. InitialTime is rounded up to the nearest sample position when it is not a multiple of \(1 /\) SampleRate.

\section*{Dependencies}

To enable this property, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Property'.
Data Types: double

\section*{RandomStream - Source of random number stream}
'Global stream' (default)|'mt19937ar with seed'
Source of random number stream, specified as 'Global stream' or 'mt19937ar with seed'.
- 'Global stream' - The current global random number stream is used for normally distributed random number generation. In this case, the reset object function resets the channel filters only.
- 'mt19937ar with seed' - The mt19937ar algorithm is used for normally distributed random number generation. In this case, the reset object function resets the channel filters and reinitializes the random number stream to the value of the Seed property.

Data Types: string | char

\section*{Seed - Initial seed of mt19937ar random number stream}

73 (default) | nonnegative integer
Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. When the reset object function is called, the mt19937ar random number stream is reinitialized to the Seedproperty value.

\section*{Dependencies}

This property applies when you set the RandomStream property to 'mt19937ar with seed'.
Data Types: double

\section*{PathGainsOutputPort - Option to output path gains \\ false or 0 (default) | true or 1}

Option to output path gains, specified as 0 (false) or 1 (true). Set this property to 1 (true) to output the channel path gains of the underlying fading process.

\section*{Data Types: logical}

\section*{Visualization - Channel visualization}
'Off' (default)|'Impulse response'|'Frequency response'|'Impulse and frequency responses'|'Doppler spectrum'

Channel visualization, specified as 'Off', 'Impulse response', 'Frequency response', 'Impulse and frequency responses', or 'Doppler spectrum'. For more information, see "Channel Visualization" on page 3-1273.
Data Types: string | char

\section*{SamplesToDisplay - Percentage of samples to display}
```

'25%'(default)|'10%'|'50%'| '100%'

```

Percentage of samples to display, specified as ' \(25 \%\) ', ' \(10 \%\) ', ' \(50 \%\) ' , or ' \(100 \%\) '. Displaying fewer samples improves (decreases) the display update rate at the expense of decreasing the visualized precision.

\section*{Dependencies}

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.
Data Types: string|char

\section*{PathsForDopplerDisplay - Path for Doppler display \\ 1 (default) | positive integer}

Path for Doppler display, specified as a positive integer. Use this property to select the discrete path used in constructing a Doppler spectrum plot. The specified path must be an element of \(\{1,2, \ldots\), \(N_{\mathrm{P}}\) \}. In this set, \(N_{\mathrm{P}}\) is the number of discrete delay paths, that is, the length of the PathDelays property value.

\section*{Dependencies}

To enable this property, set the Visualization property to 'Doppler spectrum'.
Data Types: double

\section*{Usage}

\section*{Syntax}
\(y=r a y l e i g h c h a n(x)\)
[y, pathgains] = rayleighchan \((x)\)
_ = rayleighchan(x,itime)

\section*{Description}
\(y=\) rayleighchan( \(x\) ) filters input signal \(x\) through a multipath Rician fading channel and returns the output signal in y .
[y,pathgains] = rayleighchan(x) returns the channel path gains of the underlying multipath Rician fading process in pathgains. To enable this syntax set the PathGainsOutputPort property set to 1 (true).
\(=\) rayleighchan (x,itime) passes data through the multipath Rician fading channel beginning at the initial time specified by itime. To enable this syntax, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Input port'.

\section*{Input Arguments}

\section*{x - Input signal}
\(N_{\mathrm{S}}\)-by-1 numeric vector
Input signal, specified as an \(N_{\mathrm{S}}\)-by-1 numeric vector, where \(N_{\mathrm{S}}\) is the number of samples.
Data Types: single | double
Complex Number Support: Yes

\section*{itime - Initial time}

0 | nonnegative scalar
Initial time in seconds, specified as a nonnegative scalar. The itime input must be greater than the end time of the last frame. When itime is not a multiple of \(1 /\) SampleRate, it is rounded up to the nearest sample position.
Data Types: single | double

\section*{Output Arguments}
y - Output signal
\(N_{\mathrm{S}}\)-by-1 numeric vector
Output signal, returned as an \(N_{\mathrm{S}}\)-by-1 numeric vector of complex values with the same data precision as the input signal x . \(N_{\mathrm{S}}\) is the number of samples.

\section*{pathgains - Path gains}
\(N_{\mathrm{S}}\)-by- \(N_{\mathrm{P}}\) numeric array
Path gains, returned as an \(N_{\mathrm{S}}\)-by- \(N_{\mathrm{P}}\) array. \(N_{\mathrm{S}}\) is the number of samples. \(N_{\mathrm{P}}\) is the number of discrete delay paths, that is, the length of the PathDelays property value. pathgains contains complex values with the same precision as the input signal x .

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
```

release(obj)

```

\section*{Specific to comm.RicianChannel}
info Characteristic information about fading channel object

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Produce Same Rician Channel Outputs Using two Random Number Generation Methods}

This example shows how to produce the same multipath Rician fading channel response by using two different methods for random number generation. The multipath Rician fading channel System object \({ }^{\text {TM }}\) includes two methods for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from the two methods.

Create a PSK modulator System object to modulate randomly generated data.
pskModulator \(=\) comm. PSKModulator;
channelInput \(=\) pskModulator(randi([0 pskModulator.Modulation0rder-1],1024,1));
Create a multipath Rician fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 73 .
```

ricianchan = comm.RicianChannel(...
'SampleRate',1e6,...
'PathDelays',[0.0 0.5 1.2]*1e-6,...

```
```

'AveragePathGains',[0.1 0.5 0.2],...
'KFactor',2.8,...
'DirectPathDopplerShift',5.0,...
'DirectPathInitialPhase',0.5,...
'MaximumDopplerShift',50,...
'DopplerSpectrum',doppler('Bell', 8),...
'RandomStream','mt19937ar with seed', ...
'Seed',73, ...
'PathGains0utputPort',true);

```

Filter the modulated data by using the multipath Rician fading channel System object.
```

[RicianChanOut1, RicianPathGains1] = ricianchan(channelInput);

```

Set the System object to use the global stream for random number generation.
```

release(ricianchan);
ricianchan.RandomStream = 'Global stream';

```

Set the global stream to have the same seed that was specified when creating the multipath Rician fading channel System object.
```

rng(73)

```

Filter the modulated data by using the multipath Rician fading channel System object again.
```

[RicianChanOut2,RicianPathGains2] = ricianchan(channelInput);

```

Verify that the channel and path gain outputs are the same for each of the two methods.
```

isequal(RicianChan0ut1,RicianChan0ut2)
ans = logical
1

```
isequal(RicianPathGains1,RicianPathGains2)
ans = logical
    1

\section*{Display Impulse and Frequency Responses of Multipath Rician Fading Channel}

This example shows how to create a frequency-selective multipath Rician fading channel and display its impulse and frequency responses.

Set the sample rate to 3.84 MHz . Specify path delays and gains by using the ITU pedestrian B channel configuration. Set the Rician K-factor to 10 and the maximum Doppler shift to 50 Hz .
```

fs = 3.84e6; % Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % sec
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
fD = 50; % Hz

```

Create a multipath Rician fading channel System object by using the previously defined properties and to visualize the impulse response and frequency response plots.
```

ricianChan = comm.RicianChannel('SampleRate',fs, ...
'PathDelays',pathDelays,
'AveragePathGains',avgPathGains, ...
'KFactor',10, ...
'MaximumDopplerShift',fD, ...
'Visualization','Impulse and frequency responses');

```

Generate random binary data and pass it through the multipath Rician fading channel. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.
```

x = randi([0 1],1000,1);
y = ricianChan(x);

```

\section*{Model a Rician Channel Using Sum-of-Sinusoids Technique}

The example shows how the channel state is maintained in cases in which data is discontinuously transmitted. Create a Rician channel object and pass data through it using the sum-of-sinusoids technique.

Set the channel properties.
```

fs = 1000; % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5; % Maximum Doppler shift (Hz)
ns = 1000; % Number of samples
nsdel = 100; % Number of samples for delayed paths

```

Define the overall simulation time and three time segments for which data is to be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One 1000 -sample continuous data sequence is transmitted at time 0 . Three 100 -sample data packets are transmitted at times \(0.1 \mathrm{~s}, 0.5\) s , and 0.8 s , respectively.
```

to0 = 0.0;
tol = 0.1;
to2 = 0.5;
to3 = 0.8;
t0 = (to0:ns-1)/fs; % Transmission 0
t1 = tol+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3

```

Generate random binary data corresponding to the previously defined time intervals.
```

d0 = randi([0 1],ns,1);
d1 = randi([0 1],nsdel,1);
d2 = randi([0 1],nsdel,1);
d3 = randi([0 1],nsdel,1);

```

Create a frequency-flat multipath Rician fading System object, specifying the sum-of-sinusoids fading technique. So that results can be repeated, specify a seed value. Use the default InitialTime property setting so that the fading channel will be simulated from time 0 . Enable the path gains output.
```

ricianchan1 = comm.RicianChannel('SampleRate',fs, ...
'MaximumDopplerShift',5, ...
'RandomStream','mt19937ar with seed', ...
'Seed',17, ...
'FadingTechnique','Sum of sinusoids', ...
'PathGains0utputPort',true);

```

Create a clone of the multipath Rician fading channel System object. Set the source for initial time so that the fading channel offset time can be specified as an input argument when using the System object.
```

ricianchan2 = clone(ricianchan1);
ricianchan2.InitialTimeSource = 'Input port';

```

Pass random binary data through the first multipath Rician fading channel System object, ricianchan1. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.
```

[~,pg0] = ricianchan1(d0);

```

Pass random data through the second multipath Rician fading channel System object, ricianchan2, where the initial time offsets are provided as input arguments.
```

[~,pg1] = ricianchan2(d1,to1);
[~,pg2] = ricianchan2(d2,to2);
[~,pg3] = ricianchan2(d3,to3);

```

Compare the number of samples processed by the two channels by using the info object function. The ricianchan 1 object processed 1000 samples, while the ricianhan2 object only processed 300 samples.
```

G = info(ricianchan1);
H = info(ricianchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
ans = 1\times2

```

Convert the path gains into decibels.
```

pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));

```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is suited to the simulation of packetized data, as the channel characteristics are maintained even when data is not transmitted.
```

plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continous and Discontinuous Transmission Path Gains')

```

\section*{Use Info Method to Reproduce Multipath Rican Fading Channel Response}

The example show how to use the ChannelFilterCoefficients property returned by the info object function of the comm. RicianChannel System object to reproduce the multipath Rician fading channel output.

Create a multipath Rician fading channel System object, defining two paths and specifying data to pass through the channel.
```

ricianchan = comm.RicianChannel('SampleRate',1000,'PathDelays',[0 1e-3], ...
'AveragePathGains',[0 -2],'PathGainsOutputPort',true)
ricianchan =
comm.RicianChannel with properties:
SampleRate: 1000
PathDelays: [0 1.0000e-03]
AveragePathGains: [0 -2]
NormalizePathGains: true
KFactor: 3
DirectPathDopplerShift: 0
DirectPathInitialPhase: 0
MaximumDopplerShift: 1.0000e-03
DopplerSpectrum: [1x1 struct]
Show all properties
data = randi([0 1],600,1);

\section*{More About}

\section*{Cutoff Frequency Factor}

The cutoff frequency factor, \(f_{c}\), is determined for different Doppler spectrum types.
- For any Doppler spectrum type other than Gaussian and biGaussian, \(f_{\mathrm{c}}\) equals 1.
- For a doppler('Gaussian') spectrum type, \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation \(\times \sqrt{2 \log 2}\).
- For a doppler('BiGaussian') spectrum type:
- If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then \(f_{c}\) equals NormalizedStandardDeviation (1) \(\times \sqrt{2 \log 2}\).
- If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0 , then \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation (2) \(\times \sqrt{2 \log 2}\).
- If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then \(f_{\mathrm{c}}\) equals NormalizedStandardDeviation(1) \(\times \sqrt{2 \log 2}\).
- In all other cases, \(f_{\mathrm{c}}\) equals 1.

\section*{Channel Visualization}

The comm.RicianChannel System object enables visualization of the channel impulse response, frequency response, and Doppler spectrum.

\section*{Note}
- The displayed and specified path gain locations can differ by as much as \(5 \%\) of the input sample time.
- The visualization display speed is controlled by the combination of the SamplesToDisplay property and the Playback > Reduce Updates to Improve Performance scope menu item. Reducing the percentage of samples to display and enabling reduced updates can speed up the rendering of the visualization scope.
- After the visualization scopes are manually closed, calls to the System object are executed at its normal speed.
- Code generation is available only when the Visualization property is set to ' \(0 f f^{\prime}\) '.

\section*{Impulse Response}

The impulse response scope displays the path gains, channel filter coefficients, and interpolated path gains. The path gains occur at time instances which correspond to the specified PathDelays property and might not be aligned with the input sampling time. The channel filter coefficients are
used to model the channel. They are interpolated from the actual path gains and are aligned with the input sampling time. In cases in which the path gains are aligned with the sampling time, the path gains overlap the filter coefficients. Sinc interpolation is used to connect the channel filter coefficients and is shown as the interpolated path gains. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the upper-left corner of the scope.

The impulse response plot shares the same toolbar and menus as the dsp.ArrayPlot System object.
When the specified path gains align with the sample rate, the path gains and the channel filter coefficients overlap. In this figure the impulse response shows the path gains overlap the filter coefficients.

If the specified path gains are not aligned with the sample rate, the path gains and the channel filter coefficients do not overlap. In this figure, the filter coefficients are equally distributed. The path gains do not overlap with the channel filter coefficients because the path gains are not aligned with the sample rate.

This figure shows the impulse response for a frequency-flat channel. In this case, the interpolated path gains are not displayed.

Frequency response
The frequency response scope displays the multipath Rayleigh fading channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the dsp. SpectrumAnalyzer System object.

The y-axis limits of the plot are computed based on the NormalizePathGains and AveragePathGains properties of the comm. RicianChannel System object.

This table shows other selected default spectrum settings. These settings can be changed from their default values by using the View > Spectrum Settings menu.
\begin{tabular}{|l|l|}
\hline Spectrum Settings & Value \\
\hline Main options \(>\) Type & Power \\
\hline Main options \(>\) Window length & Channel filter length \\
\hline Main options \(>\) NFFT & 512 \\
\hline Window options \(>\) Window & Rectangular \\
\hline Trace options \(>\) Units & dBW \\
\hline
\end{tabular}

This figure shows the frequency response plot for a frequency selective channel.

\section*{Doppler Spectrum}

The Doppler spectrum plot displays the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a line for the case of nonstatic channels and as a point for static channels. The empirical data is shown as * symbols. Before the empirical plot is updated, the internal buffer must be completely filled with filtered Gaussian samples. The empirical plot is the running mean of the spectrum calculated from each full buffer. For nonstatic channels, the number of input samples needed before the next update is displayed in the upper-left corner of the plot. The number of samples needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text "Reset fading channel for next update" is displayed.

\section*{comm.RSDecoder}

Package: comm
Decode data using Reed-Solomon decoder

\section*{Description}

The RSDecoder object recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the property values for this object should match the property values in the corresponding RS Encoder object.

To decode data using a Reed-Solomon decoding scheme:
1 Define and set up your Reed-Solomon decoder object. See "Construction" on page 3-1279.
2 Call step to decode data according to the properties of comm. RSDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
dec \(=\) comm.RSDecoder creates a block decoder System object, dec. This object performs ReedSolomon (RS) decoding.
dec \(=\) comm.RSDecoder( \(\mathrm{N}, \mathrm{K}\) ) creates an RS decoder object, dec with the CodewordLength property set to N and the MessageLength property set to K .
dec \(=\) comm.RSDecoder( \(\mathrm{N}, \mathrm{K}, \mathrm{GP}\) ) creates an RS decoder object, dec with the CodewordLength property set to N , the MessageLength property set to K , and the GeneratorPolynomial property set to GP.
dec \(=\) comm.RSDecoder(N,K,GP,S) creates an RS decoder object, dec with the CodewordLength property set to N , the MessageLength property set to K, the GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.
dec \(=\) comm.RSDecoder(N,K,GP,S,Name,Value) creates an RS decoder object, dec with the CodewordLength property set to \(N\), the MessageLength property set to K, the
GeneratorPolynomial property set to GP, and each specified property Name set to the specified Value.
dec \(=\) comm.RSDecoder(Name, Value) creates an RS decoder object, dec, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

Note The input and output signal lengths are listed in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88 on the comm. BCHDecoder reference page.

\section*{BitInput}

Assume that input is bits
Specify whether the input comprises bits or integers. The default is false.
When you set this property to false, the step method input data value must be a numeric, column vector of integers. The step method outputs an encoded data output vector. The output result is a column vector of integers. Each symbol that forms the input message and output codewords is an integer between 0 and \(2^{\mathrm{M}}-1\). These integers correspond to an element of the finite Galois field \(g f\left(2^{\mathrm{M}}\right) . M\) is the degree of the primitive polynomial that you specify with the PrimitivePolynomialSource on page 3-0 and PrimitivePolynomial on page 3-0 properties.

When you set this property to true, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

\section*{CodewordLength}

Codeword length
Specify the codeword length of the RS code in symbols as a double-precision, positive, integer scalar value. The default is 7 .

For a full-length RS code, the value of this property must be \(2^{M}-1\), where \(M\) is an integer such that \(3 \leq\) \(M \leq 16\).

\section*{MessageLength}

Message length
Specify the message length in symbols as a double-precision positive integer scalar value. The default is 3 .

\section*{ShortMessageLengthSource}

Short message length source
Specify the source of the shortened message as Auto or Property. When this property is set to Auto, the RS code is defined by the CodewordLength on page 3-0 , MessageLength on page 3-0 , GeneratorPolynomial on page 3-0 , and PrimitivePolynomial on page 3-
0 properties.
When ShortMessageLengthSource is set to Property, you must specify the ShortMessageLength on page 3-0 property, which is used with the other properties to define the RS code. The default is Auto.

\section*{ShortMessageLength}

Shortened message length
Specify the length of the shortened message in symbols as a double-precision positive integer scalar whose value must be less than or equal to MessageLength on page 3-0

When ShortMessageLength < MessageLength, the RS code is shortened. The default is 3 .

\section*{GeneratorPolynomialSource}

Source of generator polynomial
Specify the source of the generator polynomial as Auto or Property. The default is Auto.
When you set this property to Auto, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the PrimitivePolynomialSource on page 3-0 property.

When you set this property to Auto, the object automatically chooses the generator polynomial. The object calculates the generator polynomial based on the value of the PrimitivePolynomial on page 3-0 property.

When you set this property to Property, you must specify a generator polynomial using the GeneratorPolynomial on page 3-0 property.

\section*{GeneratorPolynomial}

Generator polynomial
Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois field row vector whose entries are in the range from 0 to \(2^{M}-1\) and represent a generator polynomial in descending order of powers. The length of the generator polynomial must be CodewordLength-MessageLength+1. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property.

The default is the result of \(\operatorname{rsgenpoly}(7,3,[],[], ' d o u b l e ')\), which corresponds to \(\left[\begin{array}{llll}1 & 3 & 1 & 2\end{array}\right.\) \(3]\).

When you use this object to generate code, you must set the generator polynomial to a doubleprecision integer row vector.

\section*{CheckGeneratorPolynomial}

Enable generator polynomial checking
Set this property to true to perform a generator polynomial check. The default is true. This check verifies that the specified generator polynomial is valid.

For larger codes, disabling the check accelerates processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property.

\section*{PrimitivePolynomialSource}

Source of primitive polynomial

Specify the source of the primitive polynomial as Auto or Property. The default is Auto.
When you set this property to Auto, the object uses a primitive polynomial of degree \(M=\) ceil \((\log 2\) (CodewordLength on page 3-0 +1\()\) ).

When you setPrimitivePolynomialSource to Property, you must specify a polynomial using PrimitivePolynomial on page 3-0

\section*{PrimitivePolynomial}

Primitive polynomial
Specify the primitive polynomial that defines the finite field \(\mathrm{gf}\left(2^{M}\right)\) corresponding to the integers that form messages and codewords. The default is the result of fliplr(de2bi(primpoly(3))), which is \(\left[\begin{array}{llll}1 & 0 & 1 & 1\end{array}\right]\) or the polynomial \(x^{3}+x+1\). Specify this property as a double-precision, binary, row vector that represents a primitive polynomial over \(\mathrm{GF}(2)\) of degree \(M\) in descending order of powers. This property applies when you set PrimitivePolynomialSource on page 3-0 to Property.

\section*{PuncturePatternSource}

Source of puncture pattern
Specify the source of the puncture pattern as None or Property. The default is None.
If you set this property to None, the object does not apply puncturing to the code. If you set it to Property, the object punctures the code based on a puncture pattern vector specified in PuncturePattern on page 3-0

\section*{PuncturePattern}

Puncture pattern vector
Specify the pattern used to puncture the encoded data as a double-precision, binary column vector of length (CodewordLength on page 3-0 -MessageLength on page 3-0 ). The default is [ones \((2,1)\); zeros \((2,1)\) ]. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword. This property applies when you set PuncturePatternSource on page 3-0 to Property.

\section*{ErasuresInputPort}

Enable erasures input
Set this property to true to specify a vector of erasures as an input to the step method. The default is false. The erasures input must be a double-precision or logical binary column vector that indicates which symbols of the input codewords to erase.

The length of the erasures vector is explained in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88.

When this property is set to false, the object assumes no erasures.

\section*{NumCorrectedErrorsOutputPort}

Enable number of corrected errors output

Set this property to true to obtain the number of corrected errors as an output to the step method. The default is true. A nonnegative value in the \(i\)-th element of the error output vector, denotes the number of corrected errors in the \(i\)-th input codeword. A value of -1 in the \(i\)-th element of the error output vector indicates that a decoding error occurred for that codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the RS code.

\section*{OutputDataType}

Data type of output
Specify the output data type as Same as input, double, or logical. The default is Same as input. This property applies when you set BitInput on page 3-0 to true.

\section*{Methods}
step Decode data using a Reed-Solomon decoder

\section*{Common to All System Objects}
release Allow System object property value changes

\section*{Examples}

\section*{Transmit an RS-encoded, 8-DPSK-modulated symbol stream}

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.
```

    enc = comm.RSEncoder;
    mod = comm.DPSKModulator('BitInput',false);
    chan = comm.AWGNChannel(...
        'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
    demod = comm.DPSKDemodulator('BitOutput',false);
    hDdecec = comm.RSDecoder;
    errorRate = comm.ErrorRate('ComputationDelay',3);
    for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
    end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
errorStats(1), errorStats(2))
Error rate = 0.115578
Number of errors = 69

```

\section*{Transmit a Shortened RS-encoded, 256-QAM-modulated Symbol Stream}

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.
Set the parameters for the Reed-Solomon code, where \(N\) is the codeword length, \(K\) is the nominal message length, and S is the shortened message length. Set the modulation order, M , and the number of frames, L.
\(\mathrm{N}=255\);
\(K=239\);
S = 188;
M = 256;
L = 50;
Create an AWGN channel System object and an error rate System object.
```

awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);

```

Create the Reed-Solomon generator polynomial from the DVB-T standard.
```

gp = rsgenpoly(N,K,[],0);

```

Create a Reed-Solomon encoder and decoder pair using the shortened message length, S, and the DVB-T generator polynomial, gp.
```

enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);

```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.
```

for counter = 1:L
data = randi([0 1],S,log2(M));
encodedData = step(enc,bi2de(data));
modSignal = qammod(encodedData,M,'UnitAveragePower',true);
rxSignal = awgnChan(modSignal);
demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
rxBits = dec(demodSignal);
dataOut = de2bi(rxBits);
errorStats = errorRate(data(:),data0ut(:));
end

```

Display the error rate and number of errors.
```

fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
errorStats(1), errorStats(2))
Error rate = 2.01e-02
Number of errors = 1509

```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and \(\mathrm{C}++\) code using MATLAB® \({ }^{\circledR}\) Coder \(^{\mathrm{TM}}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\author{
See Also \\ comm. BCHDecoder | comm.RSEncoder | primpoly | rsdec | rsgenpoly Introduced in R2012a
}

\section*{step}

System object: comm.RSDecoder
Package: comm
Decode data using a Reed-Solomon decoder

\section*{Syntax}
[Y,ERR] = step( \(\mathrm{H}, \mathrm{X}\) )
Y = step ( \(\mathrm{H}, \mathrm{X}\) )
Y \(=\operatorname{step}(H, X, E R A S U R E S)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
[ \(\mathrm{Y}, \mathrm{ERR}\) ] \(=\operatorname{step}(\mathrm{H}, \mathrm{X})\) decodes the encoded input data, X , into the output vector Y and returns the number of corrected symbols in output vector ERR. The value of the BitInput property determines whether X is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the step function equal the values listed in the table in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88. This syntax applies when you set the NumCorrectedErrorsOutputPort property to true. A value of -1 in the \(i\)-th element of the error output vector indicates that a decoding error occurred for that codeword.
\(\mathrm{Y}=\) step \((\mathrm{H}, \mathrm{X})\) decodes the encoded data, X , into the output vector Y . This syntax applies when you set the NumCorrectedErrors0utputPort property to false.
\(\mathrm{Y}=\mathrm{step}(\mathrm{H}, \mathrm{X}\), ERASURES) uses the binary column input vector, ERASURES, to erase the symbols of the input codewords. The elements in ERASURES must be of data type double or logical. Values of 1 in the ERASURES vector correspond to erased symbols, and values of 0 correspond to non-erased symbols. This syntax applies when you set the ErasuresInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.RSEncoder}

Package: comm
Encode data using Reed-Solomon encoder

\section*{Description}

The RSEncoder object creates a Reed-Solomon code with message and codeword lengths you specify.
To encode data using a Reed-Solomon encoding scheme:
1 Define and set up your Reed-Solomon encoder object. See "Construction" on page 3-1287.
2 Call step to encode data according to the properties of comm. RSEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
enc \(=\) comm.RSEncoder creates a block encoder System object, enc. This object performs ReedSolomon (RS) encoding.
enc \(=\) comm.RSEncoder( \(N, K\) ) creates an RS encoder object, enc, with the CodewordLength property set to N and the MessageLength property set to K .
enc = comm.RSEncoder(N,K,GP) creates an RS encoder object, enc, with the CodewordLength property set to N , the MessageLength property set to K , and the GeneratorPolynomial property set to GP.
enc = comm.RSEncoder(N,K,GP,S) creates an RS encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.
enc \(=\) comm.RSEncoder(N,K,GP,S,Name, Value) creates an RS encoder object, enc, with the CodewordLength property set to N , the MessageLength property set to K , the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.
enc = comm.RSEncoder(Name, Value) creates an RS encoder object, enc, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

Note The input and output signal lengths are listed in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88 on the comm. BCHDecoder reference page.

\section*{BitInput}

Assume that input is bits
Specify whether the input comprises bits or integers. The default is false.
When you set this property to false, the step method input data value must be a numeric, column vector of integers. Each symbol that forms the input message and output codewords is an integer between 0 and \(2^{M}-1\). These integers correspond to an element of the finite Galois field \(g f\left(2^{M}\right) . M\) is the degree of the primitive polynomial that you specify with the PrimitivePolynomialSource on page 3-0 and PrimitivePolynomial on page 3-0 properties.

When you set this property to true, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

\section*{CodewordLength}

\section*{Codeword length}

Specify the codeword length of the RS code as a double-precision positive integer scalar value. The default is 7 .

For a full-length RS code, the value of this property must be \(2^{M}-1\), where \(M\) is an integer such that 3 \(\leq M \leq 16\).

\section*{MessageLength}

\section*{Message length}

Specify the message length as a double-precision positive integer scalar value. The default is 3 .

\section*{ShortMessageLengthSource}

Short message length source
Specify the source of the shortened message as Auto or Property. When this property is set to Auto, the RS code is defined by the CodewordLength on page 3-0 , MessageLength on page 3-0 , GeneratorPolynomial on page 3-0 , and PrimitivePolynomial on page 3-
0 properties. When ShortMessageLengthSource is set to Property, you must specify the ShortMessageLength on page 3-0 property, which is used with the other properties to define the RS code. The default is Auto.

\section*{ShortMessageLength}

Shortened message length
Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to MessageLength on page 3-0
When ShortMessageLength < MessageLength, the RS code is shortened. The default is 3 .

\section*{GeneratorPolynomialSource}

Source of generator polynomial
Specify the source of the generator polynomial as Auto or Property. The default is Auto.

When you set this property to Auto, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the PrimitivePolynomial on page 3-0 property.

When you set GeneratorPolynomialSource to Property, you must specify a generator polynomial using the GeneratorPolynomial on page 3-0 property.

\section*{GeneratorPolynomial}

\section*{Generator polynomial}

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois row vector. The Galois row vector entries must be in the range from 0 to \(2^{M}-1\). These entries must represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field \(\mathrm{gf}\left(2^{M}\right)\), represented in integer format. The length of the generator polynomial must be CodewordLength on page 3-0 \(\quad\) - MessageLength on page 3-0 +1 .

The default is the result of rsgenpoly(7,3,[],[],'double'), which evaluates to a GF( \(2^{3}\) ) array with elements [lllll \(\left.\begin{array}{llll}1 & 3 & 1 & 2\end{array}\right]\). This property applies when you set GeneratorPolynomialSource on page 3-0 to Property.

\section*{CheckGeneratorPolynomial}

Enable generator polynomial checking
Set this property to true to perform a generator polynomial check. The default is true. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to false. This property applies when GeneratorPolynomialSource on page 3-0 is set to Property.

\section*{PrimitivePolynomialSource}

Source of primitive polynomial
Specify the source of the primitive polynomial as Auto or Property. The default is Auto.
When you set this property to Auto, the object uses a primitive polynomial of degree \(M=\) ceil(log2(CodewordLength on page 3-0 +1)).

When you set this property to Property, you must specify a polynomial using the PrimitivePolynomial on page 3-0 property.

\section*{PrimitivePolynomial}

\section*{Primitive polynomial}

Specify the primitive polynomial that defines the finite field \(\mathrm{gf}\left(2^{M}\right)\) corresponding to the integers that form messages and codewords. Specify this property as a double-precision, binary row vector that represents a primitive polynomial over \(\mathrm{gf}(2)\) of degree \(M\) in descending order of powers.

If CodewordLength on page 3-0 is less than \(2^{M}-1\), the object uses a shortened RS code. The

This property applies when you set PrimitivePolynomialSource on page 3-0 to Property.

\section*{PuncturePatternSource}

Source of puncture pattern
Specify the source of the puncture pattern as None or Property. The default is None.
If you set this property to None, the object does not apply puncturing to the code. If you set this property to Property, the object punctures the code based on a puncture pattern vector specified in the PuncturePattern on page 3-0 property.

\section*{PuncturePattern}

Puncture pattern vector
Specify the pattern used to puncture the encoded data as a double-precision, binary column vector with a length of (CodewordLength on page 3-0 - MessageLength on page 3-0 ). The default is [ones \((2,1)\); zeros \((2,1)\) ]. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword. This property applies when you set the PuncturePatternSource on page 3-0 property to Property.

\section*{OutputDataType}

Data type of output
Specify the output data type as Same as input, double, or logical. The default is Same as input. This property applies when you set the BitInput on page 3-0 property to true.

\section*{Methods}
step Encode data using a Reed-Solomon encoder

\section*{Common to All System Objects}
release \(\quad\) Allow System object property value changes

\section*{Examples}

\section*{Transmit an RS-encoded, 8-DPSK-modulated symbol stream}

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.
```

enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('Bit0utput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);
for counter = 1:20
data = randi([0 7], 30, 1);
encodedData = step(enc, data);

```
```

    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
errorStats(1), errorStats(2))
Error rate = 0.115578
Number of errors = 69

```

\section*{Transmit a Shortened RS-encoded, 256-QAM-modulated Symbol Stream}

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where N is the codeword length, K is the nominal message length, and S is the shortened message length. Set the modulation order, M , and the number of frames, L.
\(\mathrm{N}=255\);
K = 239;
S = 188;
M = 256;
L = 50;
Create an AWGN channel System object and an error rate System object.
```

awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);

```

Create the Reed-Solomon generator polynomial from the DVB-T standard.
gp = rsgenpoly(N,K,[],0);
Create a Reed-Solomon encoder and decoder pair using the shortened message length, S , and the DVB-T generator polynomial, gp.
```

enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);

```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.
```

for counter = 1:L
data = randi([0 1],S,log2(M));
encodedData = step(enc,bi2de(data));
modSignal = qammod(encodedData,M,'UnitAveragePower',true);
rxSignal = awgnChan(modSignal);
demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
rxBits = dec(demodSignal);
dataOut = de2bi(rxBits);

```
```

    errorStats = errorRate(data(:),data0ut(:));
    end
Display the error rate and number of errors.
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
errorStats(1), errorStats(2))
Error rate = 2.01e-02
Number of errors = 1509

```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

\section*{Introduced in R2012a}

\section*{step}

System object: comm. RSEncoder
Package: comm
Encode data using a Reed-Solomon encoder

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and \(y=o b j(x)\) perform equivalent operations.
\(Y=\operatorname{step}(H, X)\) encodes the numeric column input data vector, \(X\), and returns the encoded data, \(Y\). The value of the BitInput property determines whether \(X\) is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the step function equal the values listed in the table in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.Scrambler}

Package: comm
Scramble input signal

\section*{Description}

The comm.Scrambler object scrambles a scalar or column vector input signal.
This schematic shows the scrambler operation. The adders operate modulo \(N\), where \(N\) is the value specified by the Calculation base property.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the scrambler.

To scramble an input signal:
1 Create the comm. Scrambler object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
```

scrambler = comm.Scrambler
scrambler = comm.Scrambler(base,poly,cond)
scrambler = comm.Scrambler( ___ ,Name,Value)

```

\section*{Description}
scrambler = comm. Scrambler creates a scrambler System object. This object scrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.
scrambler \(=\) comm. Scrambler(base, poly, cond) creates the scrambler object with the CalculationBase property set to base, the Polynomial property set to poly, and the InitialConditions property set to cond.

Example: comm. Scrambler(8,'1 + \(z^{\wedge}-2+z^{\wedge}-3+z^{\wedge}-5+z^{\wedge}-7^{\prime},\left[\begin{array}{lllll}0 & 2 & 2 & 1 & 7\end{array}\right]\) ) sets the calculation base to 8 , and the scrambler polynomial and initial conditions as specified.
scrambler \(=\) comm. Scrambler( \(\qquad\) , Name, Value) sets properties using one or more namevalue pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: comm.Scrambler('CalculationBase', 2 )

\section*{Properties}

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

\section*{CalculationBase - Range of input data}

4 (default) | nonnegative integer
Range of input data used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from 0 to CalculationBase - 1 .

\section*{Data Types: double}

\section*{Polynomial - Connections for linear feedback shift registers}
\({ }^{\prime} 1+z^{\wedge}-1+z^{\wedge}-2+z^{\wedge}-4^{\prime}\) (default)| character vector | integer vector | binary vector
Connections for linear feedback shift registers in the scrambler, specified as a character vector, integer vector, or binary vector. The Polynomial property defines if each switch in the scrambler is on or off. Specify the polynomial as:
- A character vector, such as ' \(1+z^{\wedge}-6+z^{\wedge}-8\) '. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0-6-8], listing the scrambler coefficients in order of descending powers of \(z^{-1}\), where \(p\left(z^{-1}\right)=1+p_{1} z^{-1}+p_{2} z^{-2}+\ldots\)
- A binary vector, such as \(\left[\begin{array}{lllllll}1 & 0 & 0 & 0 & 0 & 1 & 1\end{array}\right]\), listing the powers of \(z\) that appear in the polynomial that have a coefficient of 1 . In this case, the order of the scramble polynomial is one less than the binary vector length.

Example: ' \(1+z^{\wedge}-6+z^{\wedge}-8^{\prime},\left[\begin{array}{ccc}0 & -6 & -8\end{array}\right]\), and \([10000010\) 1] all represent this polynomial:
\(p\left(z^{-1}\right)=1+z^{-6}+z^{-8}\)
Data Types: double | char

\section*{InitialConditionsSource - Initial conditions source}
'Property' (default)|'Input port'
- 'Property ' - Specify scrambler initial conditions by using the InitialConditions property.
- 'Input port' - Specify scrambler initial conditions by using an additional input argument, initcond, when calling the object.

\section*{Data Types: char}

\section*{InitialConditions - Initial conditions of scrambler registers}
\(\left[\begin{array}{llll}0 & 1 & 2 & 3\end{array}\right]\) (default)|nonnegative integer vector
Initial conditions of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of InitialConditions must equal the order of the Polynomial property. The vector element values must be integers from 0 to CalculationBase - 1 .

\section*{Dependencies}

This property is available when InitialConditionsSource is set to 'Property '.

\section*{ResetInputPort - Scrambler state reset port}
false (default) |true
Scrambler state reset port, specified as false or true. If ResetInputPort is true, you can reset the scrambler object by using an additional input argument, reset, when calling the object.

\section*{Dependencies}

This property is available when InitialConditionsSource is set to 'Property'.

\section*{Usage}

\section*{Syntax}
```

scrambledOut = scrambler(signal)
scrambledOut = scrambler(signal,initcond)
scrambledOut = scrambler(signal,reset)

```

\section*{Description}
scrambled0ut \(=\) scrambler(signal) scrambles the input signal. The output is the same data type and length as the input vector.
scrambledOut = scrambler(signal,initcond) provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to 'Input port'.
scrambledOut = scrambler(signal, reset) provides an additional input indicating whether to reset the state of the scrambler.

This syntax applies when you set InitialConditionsSource to 'Property ' and ResetInputPort to true.

\section*{Input Arguments}

\section*{signal - Input signal}
column vector
Input signal, specified as a column vector.

Example: scrambledOut = scrambler([00 11181\(])\)
Data Types: double | logical

\section*{initcond - Initial register conditions}
nonnegative integer column vector
Initial scrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of initcond must equal the order of the Polynomial property. The vector element values must be integers from 0 to CalculationBase - 1.

Example: scrambledOut \(=\) scrambler(signal, [0 11180\(]\) ) corresponds to possible initial register states for a scrambler with a polynomial order of 4 and a calculation base of 2 or higher.
Data Types: double
reset - Reset initial state of scrambler
scalar
Reset the initial state of the scrambler when the simulation starts, specified as a scalar. When the value of reset is nonzero, the object is reset before it is called.
Example: scrambled0ut \(=\) scrambler (signal, 0 ) scrambles the input signal without resetting the scrambler states.

Data Types: double

\section*{Output Arguments}

\section*{out - Scrambled output}
column vector
Scrambled output, returned as a column vector with the same data type and length as signal.

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Scramble and Descramble Data}

Scramble and descramble 8-ary data using comm. Scrambler and comm.Descrambler System objects \({ }^{\mathrm{TM}}\) having a calculation base of 8 .

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.
```

N = 8;
scrambler = comm.Scrambler(N,'1 + z^-2 + z^-3 + z^-5 + z^-7', ...
[0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
[0 3 2 2 5 1 7]);

```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.
```

data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
ans = 5*3

```
\begin{tabular}{lll}
6 & 7 & 6 \\
7 & 5 & 7 \\
1 & 7 & 1 \\
7 & 0 & 7 \\
5 & 3 & 5
\end{tabular}

Verify that the descrambled data matches the original data.
```

isequal(data,deScrData)
ans = logical
1

```

\section*{Scramble and Descramble Data with Changing Initial Conditions}

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the InitialConditionsSource property to 'Input port' so you can set the initial conditions as an argument to the object.
```

N = 4;
scrambler = comm.Scrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
descrambler = comm.Descrambler(N,'1 + z^-3','InitialConditionsSource','Input port');

```

Preallocate memory for the error vector which will be used to store errors output by the symerr function.
```

errVec = zeros(10,1);

```

Scramble and descramble random integers while changing the initial conditions, initCond, each time the loop executes. Use the symerr function to determine if the scrambling and descrambling operations result in symbol errors.
```

for k = 1:10
initCond = randperm(3)';
data = randi([0 N-1],5,1);
scrData = scrambler(data,initCond);
deScrData = descrambler(scrData,initCond);
errVec(k) = symerr(data,deScrData);
end

```

Examine errVec to verify that the output from the descrambler matches the original data.

Scrambler
Introduced in R2012a

\section*{comm.SphereDecoder}

Package: comm
Decode input using sphere decoder

\section*{Description}

The Sphere Decoder System object decodes the symbols sent over \(N_{\mathrm{T}}\) antennas using the sphere decoding algorithm.

To decode input symbols using a sphere decoder:
1 Define and set up your sphere decoder object. See "Construction" on page 3-1300.
2 Call step to decode input symbols according to the properties of comm. SphereDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((\mathrm{obj}, \mathrm{x})\) and \(\mathrm{y}=\mathrm{obj}(\mathrm{x})\) perform equivalent operations.

\section*{Construction}

H = comm.SphereDecoder creates a System object, H. This object uses the sphere decoding algorithm to find the maximum-likelihood solution for a set of received symbols over a MIMO channel with \(N_{\mathrm{T}}\) transmit antennas and \(N_{\mathrm{R}}\) receive antennas.

H = comm. SphereDecoder(Name, Value) creates a sphere decoder object, H, with the specified property name set to the specified value. Name must appear inside single quotes ('). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

H = comm.SphereDecoder(CONSTELLATION,BITTABLE) creates a sphere decoder object, H, with the Constellation property set to CONSTELLATION, and the BitTable property set to BITTABLE.

\section*{Properties}

\section*{Constellation}

Signal constellation per transmit antenna
Specify the constellation as a complex column vector containing the constellation points to which the transmitted bits are mapped. The default setting is a QPSK constellation with an average power of 1. The length of the vector must be a power of two. The object assumes that each transmit antenna uses the same constellation.

\section*{BitTable}

Bit mapping used for each constellation point.

Specify the bit mapping for the symbols that the Constellation property specifies as a numerical matrix. The default is [0 0; 01 ; 10 ; 11], which matches the default Constellation property value.

The matrix size must be [ConstellationLength bitsPerSymbol]. ConstellationLength represents the length of the Constellation property. bitsPerSymbol represents the number of bits that each symbol encodes.

\section*{InitialRadius}

Initial search radius of the decoding algorithm.
Specify the initial search radius for the decoding algorithm as either Infinity | ZF Solution. The default is Infinity.

When you set this property to Infinity, the object sets the initial search radius to Inf.
When you set this property to ZF Solution, the object sets the initial search radius to the zeroforcing solution. This calculation uses the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the ZF Solution will not provide a benefit.

\section*{DecisionType}

Specify the decoding decision method as either Soft | Hard. The default is Soft.
When you set this property to Soft, the decoder outputs log-likelihood ratios (LLRs), or soft bits.
When you set this property to Hard, the decoder converts the soft LLRs to bits. The hard-decision output logical array follows the mapping of a zero for a negative LLR and one for all other values.

\section*{Methods}
step Decode received symbols using sphere decoding algorithm

\section*{Common to All System Objects}
release Allow System object property value changes

\section*{Examples}

\section*{Decode Using a Sphere Decoder}

Modulate a set of bits using 16-QAM constellation. Transmit the signal as two parallel streams over a MIMO channel. Decode using a sphere decoder with perfect channel knowledge.

Specify the modulation order, the number of transmitted bits, the Eb/No ratio, and the symbol mapping.
```

bps = 4; % Bits per symbol
M = 2^bps; % Modulation order
nBits = 1e3*bps;

```
ebno = 10;
symMap \(=\left[\begin{array}{lllllllllllllll}11 & 10 & 14 & 15 & 9 & 12 & 13 & 1 & 0 & 4 & 3 & 2 & 6\end{array}\right] ;\)
Generate and display the symbol mapping of the 16-QAM modulator by using the qammod function and the custom symbol map.
sym = qammod(symMap(1:M)', M, symMap,'UnitAveragePower',true,'PlotConstellation',true);

Convert the decimal value of the symbol map to binary bits using the left bit as the most significant bit (msb). The M-by-bps matrix bitTable is used by the sphere decoder.
bitTable = de2bi(symMap,bps,'left-msb');
Create a 2 x 2 MIMO Channel System object with PathGainsOutputPort set to true to use the path gains as a channel estimate. To ensure the repeatability of results, set the object to use the global random number stream.
```

mimo = comm.MIMOChannel( ...
'PathGainsOutputPort',true, ...
'RandomStream','Global stream');

```

Create an AWGN Channel System object.
awgnChan = comm.AWGNChannel('EbNo',ebno,'BitsPerSymbol',bps);
Create a Sphere Decoder System object that processes bits using hard-decision decoding. Configure using the custom bit table and symbol map.
```

sphDec = comm.SphereDecoder('Constellation',sym, ...
'BitTable',bitTable,'DecisionType','Hard');

```

Create an error rate System object.
```

berRate = comm.ErrorRate;

```

Set the global random number generator seed.
```

rng(37)

```

Generate a random data stream.
```

data = randi([0 1],nBits,1);

```

Modulate the data and reshape it into two streams to be used with the 2x2 MIMO channel.
```

modData = qammod(data,M,symMap,'InputType','bit','UnitAveragePower',true);
modData = reshape(modData,[],2);

```

Pass the modulated data through the MIMO fading channel and add AWGN.
```

[fadedSig,pathGains] = mimo(modData);
rxSig = awgnChan(fadedSig);

```

Decode the received signal using pathGains as a perfect channel estimate.
```

decodedData = sphDec(rxSig,squeeze(pathGains));

```

Convert the decoded hard-decision data, which is a logical matrix, into a double column vector to enable the calculation of error statistics. Calculate and display the bit error rate and the number of errors.
```

dataOut = double(decodedData(:));
errorStats = berRate(data,dataOut);
errorStats(1:2)
ans = 2\times1
0.0380
152.0000

```

\section*{Algorithm}

This object implements a soft-output max-log a posteriori probability (APP) MIMO detector by means of a soft-output Schnorr-Euchner sphere decoder (SESD), implemented as single tree search (STS) tree traversal. The algorithm assumes the same constellation and bit table on all of the transmit antennas. Given as inputs, the received symbol vector and the estimated channel matrix, the algorithm outputs the log-likelihood ratios (LLRs) of the transmitted bits.

The algorithm assumes a MIMO system model with \(N_{\mathrm{T}}\) transmit antennas and \(N_{\mathrm{R}}\) receive antennas where \(N_{\mathrm{T}}\) symbols are simultaneously sent, expressed as:
\[
y=H s+n .
\]
where \(y\) is the received symbols, \(H\) is the MIMO channel matrix, \(s\) is the transmitted symbol vector, and \(n\) is the thermal noise.

The MIMO detector seeks the maximum-likelihood (ML) solution, \(\widehat{s}_{M L}\), such that:
\[
\widehat{S}_{M L}=\underset{S \in O}{\operatorname{argmin}} \| y-H s \mid
\]
where \(O\) is the complex-valued constellation from which the \(N_{\mathrm{T}}\) elements of \(s\) are chosen.
Soft detection also computes a log-likelihood ratio (LLR) for each bit that serves as a measure of the reliability of the estimate for each bit. The LLR is calculated as using the max-log approximation:
\[
L\left(x_{j, b}\right)=\min _{\substack{(0) \\ \square \\ j, b, b}}\|y-H s\|^{2}-\min _{\lambda^{M L}(1)} \| y-H
\]
where
- \(L\left(x_{j, b}\right)\) is the LLR estimate for each bit.
- \(x_{j, b}\) is each sent bit, the \(b\) th bit of the \(j\) th symbol.
- \(x_{j, b}^{(0)}\) and \(x_{j, b}^{(1)}\) are the disjoint sets of vector symbols that have the \(b\) th bit in the label of the \(j\) th scalar symbol equal to 0 and 1 , respectively. The two \(\lambda\) symbols denotes the distance calculated as norm squared., specifically:
- \(\lambda^{M L}\) is the distance \(\widehat{s}_{M L}\).
- \(\lambda_{j, b}^{\overline{M L}}\) is the distance to the counter-hypothesis, which denotes the binary complement of the \(b\) th bit in the binary label of the \(j\) th entry of \(\widehat{s}_{M L}\), specifically the minimum of the symbol set \(x_{j, b}\left(x_{j, b}^{\overline{M L}}\right)\), which contains all of the possible vectors for which the beth bit of the \(j\) th entry is flipped compared to the same entry of \(\widehat{s}_{M L}\).

Based on whether \(x_{j, b}^{\left(x_{j, b}^{M L}\right)}\) is 0 or 1 , the LLR estimate for bit \(x_{j, b}\) is computed as follows:
\[
L\left(x_{j, b}\right)= \begin{cases}\lambda^{M L}-\lambda_{j, b}^{\overline{M L}}, & x_{j, b}^{M L}= \\ \lambda_{j, b}^{\overline{M L}}-\lambda^{M L}, & x_{j, b}^{M L}=\end{cases}
\]

The design of a decoder strives to efficiently find \(\widehat{s}_{M L}, \lambda^{M L}\), and \(\lambda_{j, b}^{\overline{M L}}\).
This search can be converted into a tree search by means of the sphere decoding algorithms. To this end, the channel matrix is decomposed into \(H=Q R\) by means of a \(Q R\) decomposition. Leftmultiplying \(y\) by \(Q^{\mathrm{H}}\), the problem can be reformulated as:
\[
\lambda^{M L}=\underset{s_{\in}}{\arg \min } \| \bar{y}-R
\]

Using this reformulated problem statement, the triangular structure of \(R\) can be exploited to arrange a tree structure such that each of the leaf nodes corresponds to a possible \(s\) vector and the partial distances to the nodes in the tree can be calculated cumulatively adding to the partial distance of the parent node.

In the STS algorithm, the \(\lambda^{M L}\) and \(\lambda_{j, b}^{\overline{M L}}\) metrics are searched concurrently. The goal is to have a list containing the metric \(\lambda^{M L}\), along with the corresponding bit sequence \(x^{M L}\) and the metrics \(x_{j, b}^{\left(x_{j, b}^{M L}\right)}\) of all counter-hypotheses. The sub-tree originating from a given node is searched only if the result can lead to an update of either \(\lambda^{M L}\) or \(\lambda_{j, b}^{\overline{M L}}\).

The STS algorithm flow can be summarized as:
1 If when reaching a leaf node, a new ML hypothesis is found \(\left(d(x)<\lambda^{M L}\right)\), all \(\lambda_{j, b}^{\overline{M L}}\) for which \(x_{j, b}=x_{j, b}^{\overline{M L}}\) are set to \(\lambda^{M L}\) which now turns into a valued counter-hypothesis. Then, \(\lambda^{M L}\) is set to the current distance, \(d(x)\).
2 If \(d(x) \geq \lambda^{M L}\), only the counter-hypotheses have to be checked. For all \(j\) and \(b\) for which \(\left(d(x)<\lambda^{M L}\right)\) and \(x_{j, b}=x_{j, b}^{\overline{M L}}\), the decoder updates \(\lambda_{j, b}^{\overline{M L}}\) to be \(d(x)\).
3 A sub-tree is pruned if the partial distance of the node is bigger than the current \(\lambda_{j, b}^{\overline{M L}}\) which may be affected when traversing the subtree.
4 The STS concludes once all of the tree nodes have been visited once or pruned.

\section*{Limitations}
- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

Y = step(H, RXSYMBOLS, CHAN)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(Y=\) step( \(H\), RXSYMBOLS, CHAN) decodes the received symbols, RXSYMBOLS, using the sphere decoding algorithm. The algorithm can be employed to decode Ns channel realizations in one call, where in each channel realization, Nr symbols are received.

The inputs are:
RXSYMBOLS: a [Ns Nr] complex double matrix containing the received symbols.
CHAN: a [Ns Nt Nr] or [1 Nt Nr] complex double matrix representing the fading channel coefficients of the flat-fading MIMO channel. For the [ \(\mathrm{Ns} \mathrm{Nt} \mathrm{Nr]} \mathrm{case}\), each Nr symbol set. For the block fading case, i.e., when the size of CHAN is [1 Nt Nr], the same channel is applied to all of the received symbols.

The output Y , which depends on the setting of the DecisionType property, is a double matrix containing the Log-Likelihood Ratios (LLRs) of the decoded bits or the bits themselves. For both cases, the size of the output is [Ns*bitsPerSymbol Nt], where bitsPerSymbol represents the number of bits per transmitted symbol, as determined by the BitTable property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.SymbolSynchronizer}

Package: comm
Correct symbol timing clock skew

\section*{Description}

The comm. SymbolSynchronizer System object corrects symbol timing clock skew between a single-carrier transmitter and receiver for PAM, PSK, QAM, and OQPSK modulation schemes. For more information, see "Symbol Synchronization Overview" on page 3-1327.

Note The input signal operates on a sample-rate basis and the output signal operates on a symbolrate basis.

To correct symbol timing clock skew:
1 Create the comm. SymbolSynchronizer object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
symbolSync = comm.SymbolSynchronizer
symbolSync = comm.SymbolSynchronizer(Name, Value)

\section*{Description}
symbolSync = comm.SymbolSynchronizer creates a symbol synchronizer System objectfor correcting the clock skew between a single-carrier transmitter and receiver.
symbolSync = comm. SymbolSynchronizer(Name, Value) sets properties using one or more name-value pairs. For example, comm. SymbolSynchronizer('Modulation', 'OQPSK')
configures the symbol synchronizer System object for an OQPSK-modulated input signal. Enclose each property name in quotes.

Tunable DampingFactor, NormalizedLoopBandwidth, and DetectorGain properties enable you to optimize synchronizer performance in your simulation loop without releasing the object.

\section*{Properties}

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

\section*{Name-Value Pair Arguments}

\section*{Modulation - Modulation type}
'PAM/PSK/QAM' (default) | 'OQPSK'
Modulation type, specified as 'PAM/PSK/QAM' or 'OQPSK'.
Tunable: No
Data Types: char | string

\section*{TimingErrorDetector - Timing error detector method}

Zero-Crossing (decision-directed) (default)| Gardner (non-data-aided)|Early-Late (non-data-aided)| Mueller-Muller (decision-directed)

Timing error detector method, specified as Zero-Crossing (decision-directed), Gardner (non-data-aided), Early-Late (non-data-aided), or Mueller-Muller (decisiondirected). This property assigns the timing error detection scheme used in the synchronizer. For more information, see "Timing Error Detection (TED)" on page 3-1328.

Tunable: No
Data Types: char | string

\section*{SamplesPerSymbol - Samples per symbol}

2 (default) | integer greater than 1
Samples per symbol, specified as an integer greater than 1.
Tunable: No
Data Types: double

\section*{DampingFactor - Damping factor of loop filter}

1 (default) | positive scalar
Damping factor of the loop filter, specified as a positive scalar. For more information, see "Loop
Filter" on page 3-1331.
Tunable: Yes
Data Types: double | single

\section*{NormalizedLoopBandwidth - Normalized bandwidth of loop filter}
0.01 (default) | scalar in the range ( 0,1 )

Normalized bandwidth of the loop filter, specified as a scalar in the range ( 0,1 ). The loop bandwidth is normalized to the sample rate of the input signal. For more information, see "Loop Filter" on page 3-1331.

Note To ensure the symbol synchronizer locks, set the NormalizedLoopBandwidth property to a value less than 0.1.

Tunable: Yes
Data Types: double | single

\section*{DetectorGain - Phase detector gain}
2.7 (default) | positive scalar

Phase detector gain, specified as a positive scalar.
Tunable: Yes
Data Types: double | single

\section*{Usage}

Note For versions earlier than R2016b, use the step function to run the System object \({ }^{\mathrm{TM}}\) algorithm. The arguments to step are the object you created, followed by the arguments shown in this section.

For example, \(\mathrm{y}=\operatorname{step}(\mathrm{obj}, \mathrm{x})\) and \(\mathrm{y}=\mathrm{obj}(\mathrm{x})\) perform equivalent operations.

\section*{Syntax}
symbols = symbolSync(samples)

\section*{Description}
symbols = symbolSync(samples) corrects symbol timing clock skew between a single-carrier transmitter and receiver based on the input samples and outputs synchronized symbols.
- The input operates on a sample-rate basis and the output signal operates on a symbol-rate basis.
- You can tune the DampingFactor, NormalizedLoopBandwidth, and DetectorGain properties to improve the synchronizer performance.

\section*{Input Arguments}

\section*{samples - Input samples}
scalar (default) | column vector
Input samples, specified as a scalar or column vector of a PAM-, PSK-, QAM-, or OQPSK-modulated single-carrier signal.
Data Types: double | single
Complex Number Support: Yes

\section*{Output Arguments}
symbols - Synchronized symbols
column vector
Synchronized symbols, returned as a variable-sized column vector. The output symbols inherit the data type from the input samples. For an input with dimensions \(N_{\text {samp }}\)-by-1, this output has dimensions \(N_{\text {sym }}\)-by-1. \(N_{\text {sym }}\) is approximately equal to \(N_{\text {samp }}\) divided by \(N_{\text {sps }}\), where \(N_{\text {sps }}\) is equal to the

SamplesPerSymbol property value. If the output exceeds the maximum output size of \(\left\lceil\frac{N_{\text {samp }}}{N_{\text {sps }}} \times 1.1\right]\), it is truncated.

\section*{timingErr - Estimated timing error}
scalar in the range \([0,1] \mid\) column vector of elements in the range \([0,1]\)
Estimated timing error for each input sample, returned as a scalar in the range [0, 1] or column vector of elements in the range [ 0,1 ]. The estimated timing error is normalized to the input sample rate. timingErr has the same data type and size as input samples.

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
```

release(obj)

```

\section*{Specific to comm.SymbolSynchronizer}

\author{
clone Create duplicate System object
}
isLocked Determine if System object is in use

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Correct Symbol Timing Error of QPSK-Modulated Signal}

Correct a fixed symbol timing error on a noisy QPSK-modulated signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.
```

M = 4; % Modulation order for QPSK
nSym = 5000; % Number of symbols in a packet
sps = 4; % Samples per symbol
timingErr = 2; % Samples of timing error
snr = 15; % Signal-to-noise ratio (dB)

```

Create root raised cosine (RRC) transmit and receive filter System objects.
```

txfilter = comm.RaisedCosineTransmitFilter( ...
'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter( ...
'InputSamplesPerSymbol',sps,'DecimationFactor',2);

```

Create a symbol synchronizer System object to correct the timing error.
```

symbolSync = comm.SymbolSynchronizer;

```

Generate random M-ary symbols and apply QPSK modulation.
```

data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/4);

```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a \(1 / 4\) symbol through the fixed delay and channel.
```

fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols

```

Filter the modulated signal through a transmit RRC filter by using the txfilter object. Apply a signal timing error by using the fixedDelay object.
```

txSig = txfilter(modSig);
delaySig = fixedDelay(txSig);

```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.
```

rxSig = awgn(delaySig,snr,'measured');

```

Filter the modulated signal through a receive RRC filter by using the rxfilter object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected QPSK reference constellation.
```

rxSample = rxfilter(rxSig);
scatterplot(rxSample(1001:end),2)

```

Correct the symbol timing error by using the symbolSync object. Display the scatter plot. The synchronized signal now aligns with the expected QPSK constellation.
```

rxSync = symbolSync(rxSample);
scatterplot(rxSync(1001:end),2)

```

Demodulate the QPSK signal.
recData \(=\) pskdemod(rxSync, M, pi/4);
Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.
```

sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
rxfilter.FilterSpanInSymbols/2);

```

Compute the BER, taking into account the system delay.
```

[numErr,ber] = biterr(sysDelay(data),recData)
numErr = 12
ber = 0.0012

```

\section*{Correct Symbol Timing Error of BPSK-Modulated Signal}

Correct a fixed symbol timing error on a noisy BPSK transmission signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.
```

M = 2; % Modulation order for BPSK
nSym = 20000; % Number of symbols in a packet
sps = 4; % Samples per symbol
timingErr = 2; % Samples of timing error
snr = 15; % Signal-to-noise ratio (dB)

```

Create root raised cosine (RRC) transmit and receive filter System objects.
```

txfilter = comm.RaisedCosineTransmitFilter(...
'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter(...
'InputSamplesPerSymbol',sps,'DecimationFactor',1);

```

Create a symbol synchronizer System object \({ }^{T \mathrm{TM}}\) to correct the timing error.
symbolSync \(=\) comm.SymbolSynchronizer(...
    'SamplesPerSymbol',sps, ...
    'NormalizedLoopBandwidth',0.01, ...
    'DampingFactor',1.0, ...
    'TimingErrorDetector','Early-Late (non-data-aided)');

Generate random data symbols and apply BPSK modulation.
```

data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M);

```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a \(1 / 4\) symbol through the fixed delay and channel.
```

fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols

```

Filter the modulated signal through a transmit RRC filter by using the txfilter object. Apply a signal timing error by using the fixedDelay object.
```

txSig = txfilter(modSig);
delayedSig = fixedDelay(txSig);

```

Pass the delayed signal through an AWGN channel.
```

rxSig = awgn(delayedSig,snr,'measured');

```

Filter the modulated signal through a receive RRC filter by using the rxfilter object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected BPSK reference constellation.
```

rxSample = rxfilter(rxSig);
scatterplot(rxSample(10000:end),2)

```

Correct the symbol timing error by using the symbolSync object. Display the scatter plot. The synchronized signal now aligns with the expected BPSK constellation.
```

rxSync = symbolSync(rxSample);
scatterplot(rxSync(10000:end),2)

```

Demodulate the BPSK signal.
recData \(=\) pskdemod (rxSync, M) ;
Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.
```

sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
rxfilter.FilterSpanInSymbols/2);

```

Compute the BER, taking into account the system delay.
[numErr1,ber1] = biterr(sysDelay(data), recData)
numErrl \(=8\)
ber1 \(=4.0000 \mathrm{e}-04\)

\section*{Correct Symbol Timing and Doppler Offsets}

Correct symbol timing and frequency offset errors by using the comm. SymbolSynchronizer and comm. CarrierSynchronizer System objects.

\section*{Configuration}

Initialize simulation parameters.
```

M = 16; % Modulation order
nSym = 2000; % Number of symbols in a packet
sps = 2; % Samples per symbol
spsFilt = 8; % Samples per symbol for filters and channel
spsSync = 2; % Samples per symbol for synchronizers
lenFilt = 10; % RRC filter length

```

Create a matched pair of root raised cosine (RRC) filter System objects for transmitter and receiver.
```

txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',lenFilt, ...
'OutputSamplesPerSymbol',spsFilt,'Gain',sqrt(spsFilt));
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',lenFilt, ...
'InputSamplesPerSymbol',spsFilt,'DecimationFactor',spsFilt/2,'Gain',sqrt(1/spsFilt));

```

Create a phase-frequency offset System object to introduce a 100 Hz Doppler shift.
```

doppler = comm.PhaseFrequency0ffset('Frequency0ffset',100, ...
'PhaseOffset',45,'SampleRate',le6);

```

Create a variable delay System object to introduce timing offsets.
varDelay = dsp.VariableFractionalDelay;
Create carrier and symbol synchronizer System objects to correct for Doppler shift and timing offset, respectively.
```

carrierSync = comm.CarrierSynchronizer('SamplesPerSymbol',spsSync);
symbolSync = comm.SymbolSynchronizer( ...
'TimingErrorDetector','Early-Late (non-data-aided)', ...
'SamplesPerSymbol',spsSync);

```

Create constellation diagram System objects to view the results.
```

refConst = qammod(0:M-1,M,'UnitAveragePower',true);
cdReceive = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
'SamplesPerSymbol',spsFilt,'Title','Received Signal');
cdDoppler = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
'SamplesPerSymbol',spsSync,'Title','Frequency Corrected Signal');
cdTiming = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
'SamplesPerSymbol',spsSync,'Title','Frequency and Timing Synchronized Signal');

```

\section*{Main Processing Loop}

The main processing loop:
- Generates random symbols and apply QAM modulation.
- Filters the modulated signal.
- Applies frequency and timing offsets.
- Passes the transmitted signal through an AWGN channel.
- Filters the received signal.
- Corrects the Doppler shift.
- Corrects the timing offset.
```

for k = 1:15
data = randi([0 M-1],nSym,1);
modSig = qammod(data,M,'UnitAveragePower',true);

```
```

    txSig = txfilter(modSig);
    txDoppler = doppler(txSig);
    txDelay = varDelay(txDoppler,k/15);
    rxSig = awgn(txDelay,25);
    rxFiltSig = rxfilter(rxSig);
    rxCorr = carrierSync(rxFiltSig);
    rxData = symbolSync(rxCorr);
    end

```

\section*{Visualization}

Plot the constellation diagrams of the received signal, frequency corrected signal, and frequency and timing synchronized signal. Specific constellation points cannot be identified in the received signal and can be only partially identified in the frequency corrected signal. However, the timing and frequency synchronized signal aligns with the expected QAM constellation points.
```

cdReceive(rxSig)

```

cdDoppler(rxCorr)

cdTiming (rxData)

\section*{Timing Error for Noisy 8-PSK Signal}

Correct a monotonically increasing symbol timing error on a noisy 8-PSK signal. Display the normalized timing error.

Initialize simulation parameters.
```

M = 8; % Modulation order
nSym = 5000; % Number of symbol in a packet
sps = 2; % Samples per symbol
nSamp = sps*nSym; % Number of samples in a packet

```

Create root raised cosine (RRC) transmit and receive filter System objects.
txfilter = comm.RaisedCosineTransmitFilter( ...
'OutputSamplesPerSymbol',sps);
```

rxfilter = comm.RaisedCosineReceiveFilter( ...
'InputSamplesPerSymbol',sps, ...
'DecimationFactor',1);

```

Create a variable fractional delay System object \({ }^{\mathrm{TM}}\) to introduce a monotonically increasing timing error.
```

varDelay = dsp.VariableFractionalDelay;

```

Create a symbol synchronizer System object to correct the timing error.
```

symbolSync = comm.SymbolSynchronizer(...

```
    'TimingErrorDetector','Mueller-Muller (decision-directed)', ...
    'SamplesPerSymbol',sps);

Generate random 8-ary symbols and apply 8-PSK modulation.
```

data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/8);

```

Filter the modulated signal through a raised cosine transmit filter and apply a monotonically increasing timing delay.
```

vdelay = (0:1/nSamp:1-1/nSamp)';
txSig = txfilter(modSig);
delaySig = varDelay(txSig,vdelay);

```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.
```

rxSig = awgn(delaySig,15,'measured');

```

Filter the modulated signal through a receive RRC filter. Display the scatter plot. Due to the timing error, the received signal does not align with the expected 8 -PSK reference constellation.
```

rxSample = rxfilter(rxSig);
scatterplot(rxSample,sps)

```

Correct the symbol timing error by using the symbolSync object. Display the scatter plot. The synchronized signal now aligns with the expected 8-PSK constellation.
```

[rxSym,tError] = symbolSync(rxSample);
scatterplot(rxSym(1001:end))

```

Plot the timing error estimate. Over time, the normalized timing error increases to 1 sample.
figure
plot(vdelay,tError)

ylabel('Timing Error (samples)')

\section*{More About}

\section*{Symbol Synchronization Overview}

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:
- A timing error detector (TED)
- An interpolator
- An interpolation controller
- A loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on \(x(t)\), the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal, \(\chi\left(k T_{\mathrm{s}}+\widehat{\tau}\right)\), after correcting for the clock skew between the transmitter and receiver.

\section*{Timing Error Detection (TED)}

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.
\begin{tabular}{|c|c|}
\hline TED Method & Expression \\
\hline Zerocrossing (decisiondirected) & \(e(k)=x\left((k-1 / 2) T_{s}+\widehat{\tau}\right)\left[\widehat{a}_{0}(k-1)-\widehat{a}_{0}(k)\right]+y\left((k-1 / 2) T_{s}+\widehat{\tau}\right)\left[\widehat{a}_{1}(k-1)-\widehat{a}_{1}(k)\right]\) \\
\hline Gardner (non-dataaided) & \[
\begin{aligned}
& e(k)=x\left((k-1 / 2) T_{S}+\widehat{\tau}\right)\left[x\left((k-1) T_{S}+\widehat{\tau}\right)-x\left(k T_{S}+\widehat{\tau}\right)\right] \\
& +y\left((k-1 / 2) T_{S}+\widehat{\tau}\right)\left[y\left((k-1) T_{S}+\widehat{\tau}\right)-y\left(k T_{S}+\widehat{\tau}\right)\right]
\end{aligned}
\] \\
\hline Early-late (non-dataaided) & \[
\begin{aligned}
& e(k)=x\left(k T_{s}+\widehat{\tau}\right)\left[x\left((k+1 / 2) T_{s}+\widehat{\tau}\right)-\chi\left((k-1 / 2) T_{s}+\widehat{\tau}\right)\right]+y\left(k T_{s}+\widehat{\tau}\right. \\
& )\left[y\left((k+1 / 2) T_{s}+\widehat{\tau}\right)-y\left((k-1 / 2) T_{s}+\widehat{\tau}\right)\right]
\end{aligned}
\] \\
\hline MuellerMuller (decisiondirected) & \(e(k)=\widehat{a}_{0}(k-1) x\left(k T_{s}+\widehat{\tau}\right)-\widehat{a}_{0}(k) x\left((k-1) T_{s}+\widehat{\tau}\right)+\widehat{a}_{1}(k-1) y\left(k T_{s}+\widehat{\tau}\right)-\widehat{a}_{1}(k) y\left((k-1) T_{s}+\widehat{\tau}\right)\) \\
\hline
\end{tabular}

Non-data-aided TED uses received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at \(\{1+0 i, 0+1 i,-1+0 i, 0-1 i\}\) and BPSK-modulated signals with a zero phase offset.
- Gardner method - The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately \(40 \%\) and \(100 \%\). Examples include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1 . In the presence of noise, the
performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.
- Early-late method - The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

The early-late method is similar to the Gardner method. The Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

Decision-directed TED uses the sign function to estimate the in-phase and quadrature components of received samples, which result in lower computational complexity than non-data-aided TED.
- Zero-crossing method - The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6].
- Mueller-Muller method - The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component. \(x\left(k T_{\mathrm{s}}+\widehat{\tau}\right)\) and \(y\left(k T_{\mathrm{s}}+\widehat{\tau}\right)\) are the in-phase and quadrature components of the input signals to the timing error detector, where \(\widehat{\tau}\) is the estimated timing error. The Mueller-Muller method coefficients \(\widehat{a}_{0}(k)\) and \(\widehat{a}_{1}(k)\) are the estimates of \(x\left(k T_{\mathrm{s}}+\widehat{\tau}\right)\) and \(y\left(k T_{\mathrm{s}}+\widehat{\tau}\right)\). The timing estimates are made by applying the sign function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

\section*{Interpolator}

The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.

The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient \(\alpha\) set to \(1 / 2\) (see Rice, Michael, Digital Communications: A Discrete-Time Approach).

\section*{Interpolation Control}

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.

Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

\section*{Loop Filter}

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain, \(K_{1}\), and the integrator gain, \(K_{2}\), are calculated by
\[
K_{1}=\frac{-4 \zeta \theta}{\left(1+2 \zeta \theta+\theta^{2}\right) K_{p}}
\]
and
\[
K_{2}=\frac{-4 \theta^{2}}{\left(1+2 \zeta \theta+\theta^{2}\right) K_{p}} .
\]

The interim term, \(\theta\), is given by
\[
\theta=\frac{\frac{B_{n} T_{s}}{N}}{\zeta+\frac{1}{4 \zeta}},
\]
where:
- \(N\) is the number of samples per symbol.
- \(\zeta\) is the damping factor.
- \(B_{n} T_{\mathrm{s}}\) is the normalized loop bandwidth.
- \(K_{\mathrm{p}}\) is the detector gain.

\section*{Introduced in R2015a}

\section*{comm.ThermalNoise}

Package: comm
Add thermal noise to signal

\section*{Description}

The ThermalNoise object simulates the effects of thermal noise on a complex, baseband signal.
To add thermal noise to a complex, baseband signal:
1 Define and set up your thermal noise object. See "Construction" on page 3-1333.
2 Call step to add thermal noise according to the properties of comm. ThermalNoise.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
tn = comm. ThermalNoise creates a receiver thermal noise System object, H. This object adds thermal noise to the complex, baseband input signal.
tn = comm. ThermalNoise(Name, Value) creates a receiver thermal noise object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

\section*{NoiseMethod - Method used to set noise power}
'Noise temperature' (default)|'Noise figure'|'Noise factor'
Method used to set the noise power, specified as 'Noise temperature', 'Noise figure', or
'Noise factor'.
NoiseTemperature - Receiver noise temperature
290 (default) | nonnegative real scalar
Receiver noise temperature, specified in degrees K as a nonnegative real scalar. This property is available when NoiseMethod is equal to 'Noise temperature'. Noise temperature is typically used to characterize satellite receivers because the input noise temperature can vary and is often less than 290 K. Tunable.

\section*{NoiseFigure - Noise figure}
3.01 (default) | nonnegative real scalar

Noise figure, specified in dB as a nonnegative real scalar. This property is available when NoiseMethod is equal to 'Noise figure'. Noise figure describes the performance of a receiver
and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K . The noise figure is the dB equivalent of the noise factor. Tunable.

\section*{NoiseFactor - Noise factor}

2 (default) | real scalar \(\geq 1\)
Noise factor, specified as a real scalar greater than or equal to 1 . This property is available when NoiseMethod is equal to 'Noise factor'. Noise factor describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K . The noise factor is the linear equivalent of the noise figure. Tunable.

\section*{SampleRate - Sample rate \\ 1 (default) | positive real scalar}

Sample rate, specified as in Hz as a positive real scalar. The object computes the variance of the noise added to the input signal as \(k T \times\) SampleRate. The value \(k\) is Boltzmann's constant and \(T\) is the noise temperature specified explicitly or implicitly via one of the noise methods.

\section*{Add290KAntennaNoise - Add 290 K antenna noise}
false (default) |true
Add 290 K antenna noise to the input signal, specified as a logical scalar. To add 290 K antenna noise, set this property to true. This property is available when NoiseMethod is equal to ' Noise factor' or 'Noise figure'.

The total noise applied to the input signal is the sum of the circuit noise and the antenna noise.

\section*{Methods}
step \(\quad\) Add receiver thermal noise

\section*{Common to All System Objects}
release \(\quad\) Allow System object property value changes

\section*{Examples}

\section*{Add Thermal Noise to QPSK Signal}

Create a thermal noise object having a noise temperature of 290 K and a sample rate of 5 MHz .
```

thNoise = comm.ThermalNoise('NoiseTemperature',290,'SampleRate',5e6);

```

Generate QPSK-modulated data having an output power of 20 dBm .
```

data = randi([0 3],1000,1);
modData = 0.3162*pskmod(data,4,pi/4);

```

Attenuate the signal by the free space path loss assuming a 1000 m link distance and a carrier frequency of 2 GHz .
```

fsl = (4*pi*1000*2e9/3e8)^2;
rxData = modData/sqrt(fsl);

```

Add thermal noise to the signal. Plot the noisy constellation.
```

noisyData = thNoise(rxData);
scatterplot(noisyData)

```

\section*{Add Antenna and Receiver Thermal Noise to 16-QAM Signal}

Create a thermal noise object having a 5 dB noise figure and a 10 MHz sample rate. Specify that the 290 K antenna noise be included.
```

thermalNoise = comm.ThermalNoise('NoiseMethod','Noise figure', ...
'NoiseFigure',5, ...
'SampleRate',10e6, ...
'Add290KAntennaNoise',true);

```

Generate QPSK-modulated data having a 1 W output power.
```

data = randi([0 15],1000,1);
modSig = qammod(data,16,'UnitAveragePower',true);

```

Attenuate the signal by the free space path loss assuming a 1 km link distance and a 5 GHz carrier frequency.
```

fsl = (4*pi*1000*5e9/3e8)^2;
rxSig = modSig/sqrt(fsl);

```

Add thermal noise to the signal and plot its constellation.
```

noisySig = thermalNoise(rxSig);
scatterplot(noisySig)

```

Estimate the SNR.
```

mer = comm.MER;
snrEstl = mer(rxSig,noisySig)
snrEst1 = 22.6611

```

Decrease the noise figure to 0 dB , and plot the resultant received signal. Because antenna noise is included, the signal is not completely noiseless.
```

thermalNoise.NoiseFigure = 0;
noisySig = thermalNoise(rxSig);
scatterplot(noisySig)

```

Estimate the SNR. The SNR is 5 dB higher than in the first case, which is expected given the 5 dB decrease in the noise figure.
```

snrEst2 = mer(rxSig,noisySig)
snrEst2 = 27.8658
snrEst2 - snrEst1
ans = 5.2047

```

\section*{Algorithms}

Wireless receiver performance is often expressed as a noise factor or figure. The noise factor is defined as the ratio of the input signal-to-noise ratio, \(S_{i} / N_{i}\) to the output signal-to-noise ratio, \(S_{o} / N_{o}\), such that
\[
F=\frac{S_{i} / N_{i}}{S_{o} / N_{o}} .
\]

Given receiver gain \(G\) and receiver noise power \(N_{c k t}\), the noise factor can be expressed as
\[
\begin{aligned}
F= & \frac{S_{i} / N_{i}}{G S_{i} /\left(N_{c k t}+G N_{i}\right)} \\
& =\frac{N_{c k t}+G N_{i}}{G N_{i}} .
\end{aligned}
\]

The IEEE defines the noise factor assuming that noise temperature at the input is \(T_{0}\), where \(T_{0}=290\) K . The noise factor is then
\[
\begin{gathered}
F=\frac{N_{c k t}+G N_{i}}{G N_{i}} \\
=\frac{G k B T_{c k t}+G k B T_{0}}{G k B T_{0}} \\
=\frac{T_{c k t}+T_{0}}{T_{0}} .
\end{gathered}
\]
\(T_{c k t}\) is the equivalent input noise temperature of the receiver and is expressed as
\[
T_{c k t}=T_{0}(F-1)
\]

The overall noise temperature of an antenna and receiver, \(T_{\text {sys }}\), is
\[
T_{s y s}=T_{a n t}+T_{c k t},
\]
where \(T_{\text {ant }}\) is the antenna noise temperature.
The noise figure, \(N F\), is the dB equivalent of the noise factor and can be expressed as \(N F=10 \log _{10}(F)\).

\section*{step}

System object: comm. ThermalNoise
Package: comm
Add receiver thermal noise

\section*{Syntax}

Y = step( \(\mathrm{H}, \mathrm{X}\) )

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\) step \((\mathrm{H}, \mathrm{X})\) adds thermal noise to the complex, baseband input signal, X , and outputs the result in Y . The input signal X must be a complex, double or single precision data type column vector or scalar.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.TurboDecoder}

Package: comm
Decode input signal using parallel concatenated decoding scheme

\section*{Description}

The Turbo Decoder System object decodes the input signal using a parallel concatenated decoding scheme that employs the a-posteriori probability (APP) decoder as the constituent decoder. Both constituent decoders use the same trellis structure and algorithm.

To decode an input signal using a turbo decoding scheme:
1 Define and set up your turbo decoder object. See "Construction" on page 3-1340.
2 Call step to decode a binary signal according to the properties of comm. TurboDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((o b j, x)\) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm.TurboDecoder creates a System object, H. This object uses the a-posteriori probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.
\(\mathrm{H}=\) comm.TurboDecoder(Name, Value) creates a turbo decoder object, H , with the specified property name set to the specified value. Name must appear inside single quotes (' ' ' ). You can specify several name-value pair arguments in any order as Name1, Value1, ... ,NameN, ValueN.

H = comm.TurboDecoder(TRELLIS, INTERLVRINDICES, NUMITER) creates a turbo decoder object, H , with the TrellisStructure property set to TRELLIS, the InterleaverIndices property set to INTERLVRINDICES, and the NumIterations property set to NUMITER.

\section*{Properties}

\section*{TrellisStructure}

Trellis structure of constituent convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the result of poly2trellis(4, [13 15], 13).

\section*{InterleaverIndicesSource}

Source of interleaver indices

Specify the source of the interleaver indices as one of Property | Input port. When you set this property to Input port, the object uses the interleaver indices specified as an input to the step method. When you set this property to Property, the object uses the interleaver indices that you specify in the InterleaverIndices property. When you set this property to Input port, the object processes variable-size signals.

Default: Property

\section*{InterleaverIndices}

Interleaver indices
Specify the mapping used to permute the input bits at the encoder as a column vector of integers. This mapping is a vector with the number of elements equal to length, \(L\), of the output of the step method. Each element must be an integer between 1 and \(L\), with no repeated values.

Default: (64:-1:1).'.

\section*{Algorithm}

Decoding algorithm
Specify the decoding algorithm that the object uses for decoding as one of True APP | Max* | Max. When you set this property to True APP, the object implements true a-posteriori probability decoding. When you set this property to any other value, the object uses approximations to increase the speed of the computations.

Default: True APP

\section*{NumScalingBits}

Number of scaling bits
Specify the number of bits the constituent decoders use to scale the input data to avoid losing precision during the computations. The constituent decoders multiply the input by 2 NumScalingBits and divide the pre-output by the same factor. The NumScalingBits property must be a scalar integer between 0 and 8 . This property applies when you set the Algorithm property to Max*.

Default: 3

\section*{NumIterations}

Number of decoding iterations
Specify the number of decoding iterations used for each call to the step method. The object iterates and provide updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the step method is the hard-decision output of the final LLR update.

Default: 6

\section*{Transmit and Receive Turbo-Encoded Data over a BPSK-Modulated AWGN Channel}

Simulate the transmission and reception of BPSK data over an AWGN channel using turbo encoding and decoding.

Set the \(\mathrm{Eb} / \mathrm{No}(\mathrm{dB})\) and frame length parameters. Set the random number generator to its default state to ensure that the results are repeatable.
```

EbNo= -6;

```
frmLen = 256;
rng default

Calculate the noise variance from the Eb/No ratio. Generate random interleaver indices.
```

noiseVar = 10^(-EbNo/10);
intrlvrIndices = randperm(frmLen);

```

Create a turbo encoder and decoder pair using the trellis structure given by poly2trellis (4, [13 15 17],13) and intrlvrIndices.
hTEnc = comm.TurboEncoder('TrellisStructure', poly2trellis(4, ...
[13 15 17],13),'InterleaverIndices',intrlvrIndices);
hTDec \(=\) comm.TurboDecoder('TrellisStructure', poly2trellis(4, ...
[13 15 17],13),'InterleaverIndices',intrlvrIndices, ...
'NumIterations',4);
Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined by using a log-likelihood ratio method.
```

hMod = comm.BPSKModulator;
hDemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
'Variance',noiseVar);

```

Create an AWGN channel object and an error rate object.
```

hChan = comm.AWGNChannel('EbNo',EbNo);
hError = comm.ErrorRate;

```

The main processing loop performs the following steps:
- Generate binary data
- Turbo encode the data
- Modulate the encoded data
- Pass the modulated signal through an AWGN channel
- Demodulate the noisy signal using LLR to output soft bits
- Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite that expected by the turbo decoder, the decoder input must use the inverse of demodulated signal.
- Calculate the error statistics
```

for frmIdx = 1:100
data = randi([0 1],frmLen,1);
encodedData = step(hTEnc,data);
modSignal = step(hMod,encodedData);
receivedSignal = step(hChan,modSignal);
demodSignal = step(hDemod,receivedSignal);
receivedBits = step(hTDec,-demodSignal);
errorStats = step(hError,data,receivedBits);
end

```

Display the error data.
```

fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', ...
errorStats)
Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600

```

\section*{Turbo Coding with 16-QAM Modulation in an AWGN Channel}

Simulate an end-to-end communication link employing 16-QAM using turbo codes in an AWGN channel. The packet sizes are randomly selected from a set of \(\{500,1000,1500\}\). Because the packet size varies, provide the interleaver indices to the turbo encoder and decoder objects as an input to their associated object calls.

Set the modulation order and \(\mathrm{Eb} / \mathrm{No}(\mathrm{dB})\) parameters. Set the random number generator to its default state to be able to repeat the results.
\(M=16 ;\)
EbNo= -2;
rng default
Calculate the noise variance from the \(\mathrm{Eb} / \mathrm{No}\) ratio and the modulation order.
```

Turbo Decoder | comm.APPDecoder | comm. TurboEncoder
Introduced in R2012a

\section*{step}

System object: comm.TurboDecoder
Package: comm
Decode input signal using parallel concatenated decoding scheme

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)
Y = step(H, X, INTERLVRINDICES)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\) step \((\mathrm{H}, \mathrm{X})\) decodes the input data, X , using the parallel concatenated convolutional coding scheme that you specify using the TrellisStructure and InterleaverIndices properties. It returns the binary decoded data, Y . Both X and Y are column vectors of double precision data type. When the constituent convolutional code represents a rate \(1 / \mathrm{N}\) code, the step method sets the length of the output vector, Y , to ( \(\mathrm{M}-2^{*}\) numTails)/( \(2 * \mathrm{~N}-1\) ), where M represents the input vector length and numTails is given by \(\log 2(\) TrellisStructure.numStates)*N. The output length, L , is the same as the length of the interleaver indices.

Y = step( \(\mathrm{H}, \mathrm{X}\), INTERLVRINDICES) uses the INTERLVRINDICES specified as an input. INTERLVRINDICES is a column vector containing integer values from 1 to \(L\) with no repeated values. The lengths of the INTERLVRINDICES input and the \(Y\) output are the same.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.TurboEncoder}

Package: comm
Encode input signal using parallel concatenated encoding scheme

\section*{Description}

The Turbo Encoder System object encodes a binary input signal using a parallel concatenated coding scheme. This coding scheme uses two identical convolutional encoders and appends the termination bits at the end of the encoded data bits.

To encode an input signal using a turbo coding scheme:
1 Define and set up your turbo encoder object. See "Construction" on page 3-1347.
2 Call step to encode a binary signal according to the properties of comm. TurboEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((o b j, x)\) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. TurboEncoder creates a System object, H, that encodes binary data using a turbo encoder.

H = comm. TurboEncoder(Name, Value) creates a turbo encoder object, H , with the specified property name set to the specified value. Name must appear inside single quotes (' ' ' ) You can specify several name-value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

H = comm.TurboEncoder(TRELLIS, INTERLVRINDICES) creates a turbo encoder object, H. In this construction, the TrellisStructure property is set to TRELLIS, and the InterleaverIndices property is set to INTERLVRINDICES.

\section*{Properties}

\section*{TrellisStructure}

Trellis structure of constituent convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the result of poly2trellis(4, [13 15], 13).

\section*{InterleaverIndicesSource}

Source of interleaver indices
Specify the source of the interleaver indices as one of Property | Input port. When you set this property to Input port, the object uses the interleaver indices specified as an input to the step
method. When you set this property to Property, the object uses the interleaver indices that you specify in the InterleaverIndices property. When you set this property to Input port, the object processes variable-size signals.

Default: Property

\section*{InterleaverIndices}

Interleaver indices
Specify the mapping used to permute the input bits at the encoder as a column vector of integers. This mapping is a vector with the number of elements equal to the length of the input for the step method. Each element must be an integer between 1 and \(L\), with no repeated values.

Default: (64:-1:1).'.

Y = step(H, X, INTERLVRINDICES)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\) step \((\mathrm{H}, \mathrm{X})\) encodes the input data, X , using the parallel concatenated convolutional coding scheme that you specify using the TrellisStructure and InterleaverIndices properties. It returns the binary encoded data, Y . Both X and Y are column vectors of numeric, logical, or unsigned fixed point with word length 1 (fi object). When the constituent convolutional encoder represents a rate \(1 / \mathrm{N}\) code, the step method sets the length of the output vector, Y , to \(\mathrm{L}^{*}\left(2^{*} \mathrm{~N}-1\right)+2^{*}\) numTails where \(L\) represents the input vector length and numTails is given by
\(\log _{2}\) (TrellisStructure.numStates) \(*\) N. The tail bits, due to the termination, are appended at the end after the input bits are encoded.

Y = step(H, X, INTERLVRINDICES) uses the INTERLVRINDICES specified as an input. INTERLVRINDICES is a column vector containing integer values from 1 to \(L\) with no repeated values. The length of the data input X and the INTERLVRINDICES input must be the same.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.ViterbiDecoder}

Package: comm
Decode convolutionally encoded data using Viterbi algorithm

\section*{Description}

The ViterbiDecoder object decodes input symbols to produce binary output symbols. This object can process several symbols at a time for faster performance. This object processes variable-size signals; however, variable-size signals cannot be applied for erasure inputs.

To decode input symbols and produce binary output symbols:
1 Define and set up your Viterbi decoder object. See "Construction" on page 3-1353.
2 Call step to decode input symbols according to the properties of comm. ViterbiDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((o b j, x)\) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm.ViterbiDecoder creates a Viterbi decoder System object, H. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

H = comm.ViterbiDecoder(Name,Value) creates a Viterbi decoder object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.ViterbiDecoder(TRELLIS,Name,Value) creates a Viterbi decoder object, H. This object has the TrellisStructure property set to TRELLIS and the other specified properties set to the specified values.

\section*{Properties}

\section*{TrellisStructure}

Trellis structure of convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. The default is the result of poly2trellis(7, [171 133]). Use the istrellis function to verify whether a structure is a valid trellis.

\section*{InputFormat}

Input format

Specify the format of the input to the decoder as Unquantized | Hard | Soft. The default is Unquantized.

When you set this property to Unquantized, the input must be a real vector of double- or singleprecision soft values that are unquantized. The object considers negative numbers to be 1 s and positive numbers to be 0s.

When you set this property to Hard, the input must be a vector of hard decision values, which are 0s or 1 s . The data type of the inputs can be double-precision, single-precision, logical, 8-, 16-, and 32-bit signed integers. You can also use 8 -, 16 -, and 32 -bit unsigned integers.

When you set this property to Soft, the input requires a vector of quantized soft values represented
as integers between 0 and
\(2^{S o f i n g u t W o m L e c h}-1\). The data type of the inputs can be double-precision, single-precision, logical, 8-, 16-, and 32-bit signed integers. You can also use 8-, 16-, and 32-bit unsigned integers. Alternately, you can specify the data type as an unsigned and unscaled fixed point object (fi) with a word length equal to the word length that you specify in the SoftInputWordLength property. The object considers negative numbers to be 0 s and positive numbers to be 1s.

\section*{SoftInputWordLength}

Soft input word length
Specify the number of bits to represent each quantized soft input value as a positive, integer scalar value. The default is 4 bits. This property applies when you set the InputFormat on page 3-0 property to Soft.

\section*{InvalidQuantizedInputAction}

Action when input values are out of range
Specify the action the object takes when input values are out of range as Ignore | Error. The default is Ignore. Set this property to Error so that the object generates an error when the quantized input values are out of range. This property applies when you set the InputFormat on page 3-0 property to Hard or Soft.

\section*{TracebackDepth}

Traceback depth
Specify the number of trellis branches to construct each traceback path as a numeric, integer scalar value. The default is 34 . The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay.

When you set the TerminationMethod on page 3-0 property to Continuous, the decoding delay consists of TracebackDepth \(\times K\) zero bits for a rate \(K / N\) convolutional code.

When you set the TerminationMethod property to Truncated or Terminated, there is no output delay.

For more information, see "Traceback and Decoding Delay" on page 3-1358 and "Traceback Depth Estimates" on page 3-1359.

\section*{TerminationMethod}

Termination method of encoded frame
Specify the termination method as Continuous | Truncated | Terminated. The default is Continuous.

In Continuous mode, the object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently.

In Truncated mode, the object treats each frame independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. In Terminated mode, the object treats each frame independently, and the traceback path always starts and ends in the all-zeros state.

\section*{ResetInputPort}

Enable decoder reset input
Set this property to true to enable an additional step method input. The default is false. When the reset input is a nonzero value, the object resets the internal states of the decoder to initial conditions. This property applies when you set the TerminationMethod on page 3-0 property to
Continuous.

\section*{DelayedResetAction}

Reset on nonzero input via port
Set this property to true to delay resetting the object output. The default is false. When you set this property to true, the reset of the internal states of the decoder occurs after the object computes the decoded data. When you set this property to false, the reset of the internal states of the decoder occurs before the object computes the decoded data. This property applies when you set the ResetInputPort on page 3-0 property to true.

\section*{PuncturePatternSource}

Source of puncture pattern
Specify the source of the puncture pattern as None | Property. The default is None.
When you set this property to None, the object assumes no puncturing. Set this property to Property to decode punctured codewords based on a puncture pattern vector specified via the PuncturePattern on page 3-0 property.

\section*{PuncturePattern}

Puncture pattern vector
Specify puncture pattern to puncture the encoded data. The default is \([1 ; 1 ; 0 ; 1 ; 0 ; 1]\). The puncture pattern is a column vector of 1 s and 0 s . The 0 s indicate the position to insert dummy bits. The puncture pattern must match the puncture pattern used by the encoder. This property applies when you set the PuncturePatternSource on page 3-0 property to Property.

\section*{ErasuresInputPort}

Enable erasures input

Set this property to true to specify a vector of erasures as a step method input. The default is false. The erasures input must be a double-precision or logical, binary, column vector. This vector indicates which symbols of the input codewords to erase. Values of 1 indicate erased bits. The decoder does not update the branch metric for the erasures in the incoming data stream.

The lengths of the step method erasure input and the step method data input must be the same. When you set this property to false, the object assumes no erasures.

\section*{OutputDataType}

Data type of output
Specify the data type of the output as Full precision \(\mid\) Smallest unsigned integer|double | single | int8|uint8|int16|uint16|int32|uint32|logical. The default is Full precision.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

\section*{Fixed-Point Properties}

\section*{StateMetricDataType}

Data type of state metric
Specify the state metric data type as Full precision|Custom. The default is Full precision.
When you set this property to Full precision, the object sets the state metric fixed-point type to numerictype( [],16). This property applies when you set the InputFormat on page 3-0 property to Hard or Soft.

When you set the InputFormat property to Hard, the step method data input must be a column vector. This vector comprises unsigned, fixed point numbers (fi objects) of word length 1 to enable fixed-point Viterbi decoding. Based on this input (either a 0 or a 1), the object calculates the internal branch metrics using an unsigned integer of word length \(L\). In this case, \(L\) indicates the number of output bits as specified by the trellis structure.

When you set the InputFormat property to Soft, the step method data input must be a column vector. This vector comprises unsigned, fixed point numbers (fi objects) of word length N. N indicates the number of soft-decision bits specified in the SoftInputWordLength on page 3-0 property.

The step method data inputs must be integers in the range 0 to \(2^{N}-1\). The object calculates the internal branch metrics using an unsigned integer of word length \(L=(N+N o u t-1)\). In this case, Nout represents the number of output bits as specified by the trellis structure.

\section*{CustomStateMetricDataType}

Fixed-point data type of state metric
Specify the state metric fixed-point type as an unscaled, numerictype object with a signedness of Auto. The default is numerictype([],16). This property applies when you set the StateMetricDataType on page 3-0 property to Custom.

\section*{Methods}
reset Reset states of the Viterbi decoder object
step Decode convolutionally encoded data using Viterbi algorithm

\section*{Common to All System Objects}
```

release Allow System object property value changes

```

\section*{Examples}

\section*{Encode and Decode 8-DPSK Modulated Data}

Transmit a convolutionally encoded 8-DPSK modulated bit stream through an AWGN channel. Then, demodulate and decode using a Viterbi decoder.

Create the necessary System objects.
hConEnc = comm. ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.AWGNChannel('NoiseMethod', ...
'Signal to noise ratio (SNR)',...
'SNR',10);
hDemod = comm.DPSKDemodulator('Bit0utput',true);
hDec = comm.ViterbiDecoder('InputFormat','Hard');
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);
Process the data using the following steps:
1 Generate random bits
2 Convolutionally encode the data
3 Apply DPSK modulation
4 Pass the modulated signal through AWGN
5 Demodulate the noisy signal
6 Decode the data using a Viterbi algorithm
7 Collect error statistics
```

for counter = 1:20
data = randi([0 1],30,1);
encodedData = step(hConEnc, data);
modSignal = step(hMod, encodedData);
receivedSignal = step(hChan, modSignal);
demodSignal = step(hDemod, receivedSignal);
receivedBits = step(hDec, demodSignal);
errors = step(hError, data, receivedBits);
end

```

Display the number of errors.
errors(2)
ans \(=3\)

\section*{Convolutional Encoding and Viterbi Decoding with a Puncture Pattern Matrix}

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical

Define a puncture pattern matrix and reshape it into vector form for use with the Encoder and Decoder objects.
```

pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);

```

Create convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by pPatternVec.
```

ENC = comm.ConvolutionalEncoder(...
'PuncturePatternSource','Property', ...
'PuncturePattern',pPatternVec);
DEC = comm.ViterbiDecoder('InputFormat','Hard', ...
'PuncturePatternSource','Property',...
'PuncturePattern',pPatternVec);

```

Create an error rate counter with the appropriate receive delay.
```

ERR = comm.ErrorRate('ReceiveDelay',DEC.TracebackDepth);

```

Encode and decode a sequence of random bits.
```

dataIn = randi([0 1],600,1);
dataEncoded = step(ENC,dataIn);
dataOut = step(DEC,dataEncoded);

```

Verify that there are no errors in the output data.
```

errStats = step(ERR,dataIn,dataOut);
errStats(2)
ans = 0

```

\section*{More About}

\section*{Traceback and Decoding Delay}

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.
- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

\section*{Traceback Depth Estimates}

As a general estimate, a typical traceback depth value is approximately two to three times
(ConstraintLength -1) / ( 1 -coderate). The constraint length of the code, ConstraintLength, is equal to (log2(trellis.numStates) +1). The coderate is equal to ( \(K / N\) ) \(\times\) (length(PuncturePattern) / sum(PuncturePattern).
\(K\) is the number of input symbols, \(N\) is the number of output symbols, and PuncturePattern is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.
- A rate \(1 / 2\) code has a traceback depth of 5 (ConstraintLength - 1 ).
- A rate \(2 / 3\) code has a traceback depth of 7.5(ConstraintLength -1 ).
- A rate \(3 / 4\) code has a traceback depth of 10(ConstraintLength - 1).
- A rate \(5 / 6\) code has a traceback depth of 15 (ConstraintLength -1 ).

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the Viterbi Decoder block reference page. The object properties correspond to the block parameters, except:
- The Decision type parameter corresponds to the InputFormat on page 3-0 property.
- The Operation mode parameter corresponds to the TerminationMethod on page 3-0 property.

\section*{reset}

System object: comm.ViterbiDecoder
Package: comm
Reset states of the Viterbi decoder object

\section*{Syntax}
reset (H)

\section*{Description}
reset \((\mathrm{H})\) resets the states of the ViterbiDecoder object, H .

\section*{step}

System object: comm.ViterbiDecoder
Package: comm
Decode convolutionally encoded data using Viterbi algorithm

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)
\(Y=\operatorname{step}(H, X, E R A S U R E S)\)
\(Y=\operatorname{step}(H, X, R)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

Y = step ( \(\mathrm{H}, \mathrm{X}\) ) decodes encoded data, X , using the Viterbi algorithm and returns \(\mathrm{Y} . \mathrm{X}\), must be a column vector with data type and values that depend on how you set the InputFormat property. If the convolutional code uses an alphabet of \(2^{N}\) possible symbols, the length of the input vector, X , must be \(L \times N\) for some positive integer \(L\). Similarly, if the decoded data uses an alphabet of \(2^{K}\) possible output symbols, the length of the output vector, Y , is \(L \times K\).

Y = step( \(\mathrm{H}, \mathrm{X}\), ERASURES) uses the binary column input vector, ERASURES, to erase the symbols of the input codewords. The elements in ERASURES must be of data type double or logical. Values of 1 in the ERASURES vector correspond to erased symbols, and values of 0 correspond to non-erased symbols. The lengths of the \(X\) and ERASURES inputs must be the same. This syntax applies when you set the ErasuresInputPort property to true.
\(Y=\operatorname{step}(H, X, R)\) resets the internal states of the decoder when you input a non-zero reset signal, R. R must be a double precision or logical scalar. This syntax applies when you set the TerminationMethod property to Continuous and the ResetInputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.WalshCode}

Package: comm
Generate Walsh code from orthogonal set of codes

\section*{Description}

The WalshCode object generates a Walsh code from an orthogonal set of codes.
To generate a Walsh code:
1 Define and set up your Walsh code object. See "Construction" on page 3-1362.
2 Call step to encode the input signal according to the properties of comm. Wal shCode. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and \(y=o b j()\) perform equivalent operations.

\section*{Construction}

H = comm. WalshCode creates a Walsh code generator System object, H. This object generates a Walsh code from a set of orthogonal codes.

H = comm. WalshCode(Name, Value) creates a Walsh code generator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

\section*{Length}

Length of generated code
Specify the length of the generated code as a numeric, integer scalar value that is a power of two. The default is 64 .

\section*{Index}

Index of code of interest
Specify the index of the desired code from the available set of codes as a numeric, integer scalar value in the range \([0,1, \ldots, N-1] . N\) is the value of the Length on page 3-0 property. The default is 60 . The number of zero crossings in the generated code equals the value of the specified index.

\section*{SamplesPerFrame}

Number of output samples per frame

Specify the number of Walsh code samples that the step method outputs as a numeric, positive, integer scalar value. The default is 1 . If you set this property to a value of \(M\), then the step method outputs \(M\) samples of a Walsh code of length \(N . N\) is the length of the code that you specify in the Length on page 3-0 property.

\section*{OutputDataType}

Data type of output
Specify the output data type as double | int8. The default is double.

\section*{Syntax}

Y = step(H)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj) and y = obj() perform equivalent operations.
\(\mathrm{Y}=\operatorname{step}(\mathrm{H})\) outputs a frame of the Walsh code in column vector Y . Specify the frame length with the SamplesPerFrame property. The Walsh code corresponds to a row of an NxN Hadamard matrix, where \(N\) is a nonnegative power of 2 that you specify in the Length property. Use the Index property to choose the row of the Hadamard matrix. The output code is in a bi-polar format with 0 and 1 mapped to 1 and -1 respectively.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.WINNER2Channel}

Package: comm
Filter input signal through WINNER II fading channel

\section*{Download Required}

To use comm.WINNER2Channel, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see "Get and Manage Add-Ons" (MATLAB).

\section*{Description}

The comm. WINNER2Channel System object filters an input signal through a WINNER II fading channel. The object utilizes the basic model defined and provided by the WINNER II Channel Models [1].

To filter an input signal using a WINNER II fading channel:
1 Define and set up your WINNER II channel object. See "Construction" on page 3-1367.
2 Call step to filter the input signal through a WINNER II fading channel according to the properties of comm. WINNER2Channel.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((\mathrm{obj}, \mathrm{x})\) and \(\mathrm{y}=\mathrm{obj}(\mathrm{x})\) perform equivalent operations.

\section*{Construction}
chan = comm.WINNER2Channel creates a WINNER II fading channel System object to model single or multiple links. chan generates channel coefficients using the WINNER II spatial channel model (SCM). It also filters a real or complex input signal through the fading channel for each link.
chan = comm.WINNER2Channel (Name, Value) creates a WINNER II fading channel object, chan, that overrides default values using one or more Name, Value pair arguments. You can specify additional name-value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
chan = comm.WINNER2Channel (cfgModel) creates a WINNER II fading channel object with the ModelConfig property set to cfgModel.
chan = comm.WINNER2Channel(cfgModel,cfgLayout) creates a WINNER II fading channel object with the ModelConfig property set to cfgModel and the LayoutConfig property set to cfgLayout.

\section*{Properties}

\section*{ModelConfig}

WINNER II model parameter configuration
WINNER II model parameter configuration, specified as a structure containing these fields:

\section*{NumTimeSamples}

Number of time samples. The default value is 100 .

Note If the number of samples in the input signal \(\left(N_{\mathrm{S}}\right)\) does not match NumTimeSamples, NumTimeSamples is updated to match \(N_{\text {S }}\).

\section*{FixedPdpUsed}

Set to 'yes ' to use predefined path delays and powers for specific scenarios. The default value is 'no'.

\section*{FixedAnglesUsed}

Set to ' yes ' to use predefined angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios. The default value is ' \(n o\) '.

\section*{IntraClusterDsUsed}

Set to 'yes ' to divide each of the two strongest clusters per link into three subclusters. The default value is 'yes'.

\section*{PolarisedArrays}

Set to 'yes' to use dual polarized arrays. The default value is 'yes '.

\section*{UseManualPropCondition}

Set to 'yes ' to use the manually defined propagation conditions (LOS or NLOS) in the LayoutConfig.PropagConditionVector field. Set to ' no ' to draw propagation conditions from predefined LOS probabilities. The default value is 'yes '.

\section*{UniformTimeSampling}

Set to 'yes' to sample all links at the same time instants. The default value is 'no '.

\section*{SampleDensity}

Number of time samples per half wavelength. The default value is 2 e 6 .

\section*{CenterFrequency}

Center frequency of carrier. The default value 5.25 e 9 Hz .

\section*{DelaySamplingInterval}

Sampling grid to which the path delays are rounded. The default value of 0 seconds indicates no rounding on path delays.
- DelaySamplingInterval specifies the input signal sample time.
- When performing channel filtering, the object uses DelaySamplingInterval = 0 to obtain the original path delays. Any non-zero value of DelaySamplingInterval is ignored, specifically the path delays used are not rounded to be multiples of DelaySamplingInterval values that are non-zero.

\section*{ShadowingModelUsed}

Set to 'yes ' to include shadow fading in the model. The default value is ' no '.

\section*{PathLossModelUsed}

Set to 'yes ' to include path loss in the model. The default value is ' no '.

\section*{PathLossModel}

Path loss model function name, specified as 'pathloss', which uses the internal pathloss function from the "WINNER II Channel" Add-On to model the path loss. The PathLossModel property is applicable only when PathLossModelUsed is 'yes'. The default value is 'pathloss'.

\section*{PathLossOption}

Path loss option indicating the wall material for the NLOS path loss calculation of scenario A1, specified as one of \{'CR light', 'CR heavy', 'RR light', 'RR heavy'\}. The default value is 'CR_light'. The PathLossOption property is applicable only when PathLossModelUsed is 'yes'.

See LayoutConfig.ScenarioVector for the scenario number mapping.

\section*{RandomSeed}

Seed for random number generators. To use the global random stream, set RandomSeed to empty, []. The default is [].

\section*{LayoutConfig}

WINNER II layout parameter configuration
WINNER II layout parameter configuration, specified as a structure containing these fields:

\section*{Stations}

Row vector of structures to describe antenna arrays for active stations. The row ordering specifies BS sectors first, followed by the MS. The default assigns two structures, one for BS and one for MS.

\section*{NofSect}

Vector of number of sectors in each BS. The default is 1.

\section*{Pairing}

A 2-by- \(N_{\mathrm{L}}\) matrix, where \(N_{\mathrm{L}}\) specifies the number links to be modeled. The default is [1;2].

\section*{ScenarioVector}

A 1-by- \(N_{\mathrm{L}}\) vector of scenario numbers. The default is 1 , which specifies scenario A1.
The scenarios numbers map as \(\{1=\mathrm{A} 1,2=\mathrm{A} 2,3=\mathrm{B} 1,4=\mathrm{B} 2,5=\mathrm{B} 3,6=\mathrm{B} 4,10=\mathrm{C} 1,11=\mathrm{C} 2,12=\mathrm{C} 3\), \(13=\mathrm{C} 4,14=\mathrm{D} 1,15=\mathrm{D} 2 \mathrm{a}\}\).

For more information, see WINNER II Channel Models [1], Section 2.3.

\section*{PropagConditionVector}

A 1-by- \(N_{\mathrm{L}}\) vector of propagation conditions ( \(\mathrm{LOS}=1\) and \(\mathrm{NLOS}=0\) ) for each link. The default is 1.

\section*{StreetWidth}

A 1-by- \(N_{\mathrm{L}}\) vector of identical values that specify the average width (in meters) of the streets. StreetWidth is used for the path loss model of the B1 and B2 scenarios. The default is 20 . See ScenarioVector for the scenario number mapping. All elements must have the same value. The StreetWidth property is applicable only when the ModelConfig.PathLossModelUsed property is 'yes'.

\section*{Dist1}

A 1-by- \(N_{\mathrm{L}}\) vector of distances from BS to the last LOS point. Dist1 is used for the path loss model of the B1 and B2 scenarios. The default value is NaN, which means the distance is randomly determined in path loss function. See ScenarioVector for the scenario number mapping. Dist1 is applicable only when the ModelConfig.PathLossModelUsed property is 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

\section*{NumFloors}

A 1-by- \(N_{\mathrm{L}}\) vector indicating the floor number where the indoor BS or MS is located. The default value is 1 . The NumFloors property is used for the path loss model of the A2 and B4 scenarios only. See ScenarioVector for the scenario number mapping. The NumFloors property is applicable only when ModelConfig.PathLossModelUsed is 'yes'.

\section*{NumPenetratedFloors}

A 1-by- \(N_{\mathrm{L}}\) vector indicating the number of penetrated floors between BS and MS. The default value is 0 . The NumPenetratedFloors is used for the NLOS path loss model of the A1 scenario. See ScenarioVector for the scenario number mapping. The NumPenetratedFloors property is applicable only when PathLossModelUsed is 'yes'.

For more information, see WINNER II Channel Models [1], Table 4-4.

\section*{NormalizeChannelOutputs}

Normalize channel outputs, specified as true or false. Set this property to true to normalize the channel outputs by the number of receive antennas at the mobile station (MS) for each link. The default value is true.

For more information, see "Channel Power" on page 3-1374.

\section*{Methods}
\begin{tabular}{ll} 
info & Display information about WINNER2Channel object \\
reset & Reset states of WINNER2Channel object \\
step & Filter input signal through WINNER II fading channel
\end{tabular}

Common to All System Objects
release Allow System object property value changes

\section*{Examples}

\section*{WINNER II Channel with Two Mobile Stations}

Simulate a system that has two MS connected to one BS. One MS is 8 meters away from the BS; the other is 20 meters away from the BS. Impulse signals are sent through the two links. The spectrum of the received signals at MS shows frequency selectivity. It also shows the MS that is closer the BS has a larger average received power than the other MS.

Specify random number generator seed for repeatability.
rng(100) ;
Initial frame length and sample rate.
```

frmLen = 1024;

```

Configure layout parameters.
```

BSAA = winner2.AntennaArray('UCA', 8, 0.02); % UCA-8 antenna array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01); % ULA-2 antenna array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 antenna array for MS
MSIdx = [2 3]; BSIdx = {1}; NL = 2; maxRange = 100; rndSeed = 101;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL, ...
[BSAA,MSAA1,MSAA2],maxRange,rndSeed);

```

Adjust BS and MS positions.
```

cfgLayout.Stations(1).Pos(1:2) = [10, 10];
cfgLayout.Stations(2).Pos(1:2) = [18, 10]; % 8 meters away from BS
cfgLayout.Stations(3).Pos(1:2) = [22, 26]; % 20 meters away from BS

```

NLOS for both links
```

cfgLayout.Pairing = [1 1; 2 3];
cfgLayout.PropagConditionVector = [0 0];
Configure model parameters

```
```

cfgModel = winner2.wimparset;

```
cfgModel = winner2.wimparset;
cfgModel.NumTimeSamples = frmLen; % Frame length
cfgModel.NumTimeSamples = frmLen; % Frame length
cfgModel.IntraClusterDsUsed = 'no'; % No cluster splitting
```

cfgModel.IntraClusterDsUsed = 'no'; % No cluster splitting

```
```

cfgModel.SampleDensity = 2e5; % For lower sample rate
cfgModel.PathLossModelUsed = 'yes'; % Turn on path loss
cfgModel.ShadowingModelUsed = 'yes'; % Turn on shadowing

```

Create a WINNER II channel System object.
```

wimChan = comm.WINNER2Channel(cfgModel, cfgLayout);

```

Call the info method of the object to get some system information
```

chanInfo = info(wimChan)
chanInfo = struct with fields:
NumLinks: 2
NumBSElements: [8 8]
NumMSElements: [2 4]
NumPaths: [16 16]
SampleRate: [1.0000e+07 1.0000e+07]
ChannelFilterDelay: [7 7]
NumSamplesProcessed: 0
numTx = chanInfo.NumBSElements(1);
Rs = chanInfo.SampleRate(1);

```

Create a Spectrum Analyzer System object.
```

SA = dsp.SpectrumAnalyzer('SampleRate', Rs, ...
'YLimits', [-170, -100], 'ShowLegend', true, ...
'ChannelNames', {'MS 1 (8 meters away)','MS 2 (20 meters away)'});

```

Pass impulse signals through the two links and show spectra of the received signals at the two MS.
```

for i = 1:10
x = [ones(1,numTx); zeros(frmLen-1, numTx)];
y = wimChan(x);
SA([y{1}(:,1), y{2}(:,1)]);
end

```

\section*{More About}

\section*{WINNER II Sampling Rate}

The signal sample rate \(\left(R_{S}\right)\) for generating channel coefficients and performing channel filtering is calculated per link using the mobile station speed ( \(V_{\mathrm{MS}}\) ), half wavelength distance, and sample density. The sample rate for each link is available as a field in the info method return.
\(R_{\mathrm{S}}=V_{\mathrm{MS}} /\left(C / F_{\text {center }} / 2 / N_{\mathrm{SD}}\right)\),
- For the MS speed, \(V_{\mathrm{MS}}\),
- When ModelConfig.UniformTimeSampling is set to 'no', \(V_{\mathrm{MS}}\) is the speed of the MS for the corresponding link, derived from the LayoutConfig.Stations(i).Velocity field.
- When ModelConfig.UniformTimeSampling is set to 'yes', \(V_{\mathrm{MS}}\) is the maximum speed of the MS for all links.
- \(C\) is the speed of light ( \(2.99792458 \mathrm{e} 8 \mathrm{~m} / \mathrm{s}\) ).
- \(F_{\text {center }}\) is ModelConfig.CenterFrequency.
- \(N_{\text {SD }}\) is ModelConfig.SampleDensity.

\section*{Channel Power}

These conditions apply to the channel power of the comm.WINNER2Channel object:
- When path loss and shadowing are off, path gains are normalized. Specifically, path gains are normalized when the ModelConfig.ShadowingModelUsed and
ModelConfig.PathLossModelUsed parameters are set to 'no'.
- When the NormalizeChannelOutputs property is true, the average gain of the channel is 0 dB .

\section*{info}

System object: comm.WINNER2Channel
Package: comm
Display information about WINNER2Channel object

\section*{Syntax}
s = info(obj)

\section*{Description}
\(\mathrm{s}=\) info(obj) returns a structure containing information about the Winner2Channel System object characteristics. The information structure contains:
- Numlinks - Number of links in the system
- NumBSElements - Number of transmit antennas at the BS for each link
- NumMSElements - Number of receive antennas at the MS for each link
- NumPaths - Number of delay paths for each link
- SampleRate - Sample rate for each link
- ChannelFilterDelay - Channel filter delay per link, measured in samples
- NumSamplesProcessed - Number of samples the channel has processed since the last reset

\section*{Introduced in R2016b}

\section*{reset}

System object: comm.WINNER2Channel
Package: comm
Reset states of WINNER2Channel object

\section*{Syntax}
reset(obj)

\section*{Description}
reset (obj) resets the states of the Winner2Channel System object.
If the ModelConfig.RandomSeed property of obj is empty, the reset method resets the filters only. Otherwise, the reset method resets the filters and also reinitializes the random number stream to the value of the ModelConfig.RandomSeed property.

Introduced in R2016b

\section*{step}

System object: comm.WINNER2Channel
Package: comm
Filter input signal through WINNER II fading channel

\section*{Syntax}
```

y = step(obj,x)
[y,pathGains] = step(obj,x)

```

\section*{Description}

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(y=s t e p(o b j, x)\) filters input signal \(x\) through a WINNER II fading channel and returns the result in y . Both x and y are \(N_{\mathrm{L}}\)-by- 1 cell arrays, where \(N_{\mathrm{L}}\) represents the number of links, as determined by the LayoutConfig property of obj. The ith element of x must be an \(N_{\mathrm{S}}\)-by- \(N_{\mathrm{T}}(\mathrm{i})\) matrix of doubles.
- \(N_{\mathrm{S}}\) represents the number of samples to be generated and must be the same for all elements of x .
- \(N_{T}(i)\) is the number of transmit antennas at the base station (BS) for the ith link, determined by the LayoutConfig property of obj.

If the channel has only one link or if all links have the same number of transmit antennas, x can also be an \(N_{\mathrm{S}}\)-by- \(N_{\mathrm{T}}\) matrix of doubles. In this case, the same input signal is filtered through all the links. The ith element of y is an \(N_{\mathrm{S}}\)-by- \(N_{\mathrm{R}}(\mathrm{i})\) matrix of doubles. \(N_{\mathrm{R}}(\mathrm{i})\) is the number of receive antennas at the mobile station (MS) for the ith link, as determined by the LayoutConfig property of obj.
[ \(y\), pathGains] = step(obj,x) also returns the channel coefficients of the underlying WINNER II fading process. pathGains is an \(N_{\mathrm{L}}\)-by- 1 cell array. The ith element of pathGains is an \(N_{\mathrm{R}}\) (i)-by-\(N_{T}(i)\)-by- \(N_{P}(i)\)-by- \(N_{S}\) array of complex doubles. \(N_{P}(i)\) is the number of paths for the ith link, as determined by the LayoutConfig property of obj.
\(N_{\mathrm{R}}, N_{\mathrm{T}}\), and \(N_{\mathrm{P}}\) are link specific. \(N_{\mathrm{S}}\) is the same for all the links.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{Introduced in R2016b}

\section*{rxsite}

Create radio frequency receiver site

\section*{Description}

Use the rxsite object to create a radio frequency receiver site.

\section*{Creation}

\section*{Syntax}
rx = rxsite
rx = rxsite(Name,Value)

\section*{Description}
\(r x=r x s i t e ~ c r e a t e s ~ a ~ r a d i o ~ f r e q u e n c y ~ r e c e i v e r ~ s i t e . ~ . ~\)
\(r x=r x s i t e(N a m e, V a l u e)\) sets properties using one or more name-value pairs. For example, rx = rxsite('Name','RX Site') creates a receiver site with name RX Site. Enclose each property name in quotes.

\section*{Properties}

\section*{Name - Site name}
character vector | string | row or column vector
Site name, specified as a character vector or as a row or column vector or as a string.
Example: 'Name','Site 3'
Example: RX.Name = 'Site 3'
Example: If you want to assign multiple values then - names = ["Fenway Park", "Faneuil
Hall","Bunker Hill Monument"]; RX = rxsite('Name',names)
Data Types: char | string

\section*{Latitude - Site latitude coordinates}
42.3021 (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar or a row or column vector in the range of range -90 to 90. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/ south angle.
Example: 'Latitude',45.098
Example: RX \(=45.098\)
Example: If you want to assign multiple values then - latitude \(=[42.3467,42.3598,42.3763]\);
RX = rxsite('Latitude',latitude)

\section*{Longitude - Site longitude coordinates}
- 71.3764 (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or a row or column vector. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.

Example: 'Longitude',-68.890
Example: RX.Longitude \(=-68.890\)
Example: If you want to assign multiple values then - longitude = [-71.0972,-71.0545,-71.0611]; RX = rxsite('Longitude',longitude)

\section*{Antenna - Antenna element or array}
'isotropic' (default)| object | row vector
Antenna element or array specified as an object or 'isotropic'. By default, the antenna is 'isotropic', which defines an antenna that radiates uniformly in all directions.

\section*{AntennaAngle - Antenna x-axis angle}

0 (default) | numeric scalar | 2 -by-1 vector | 2 -by- \(N\) matrix
Antenna \(x\)-axis angle, specified as a numeric scalar, a 2 -by- 1 vector, or a 2 -by- \(N\) matrix in degrees.
The numeric scalar is the azimuth angle measured counterclockwise from the east to the antenna \(x\) axis.

In the 2-by-1 vector, the first element is the azimuth angle and the second element elevation angle. The elevation angle measures from the horizontal plane to antenna \(x\)-axis from -90 to 90 degrees.
Example: 'AntennaAngle',25
Example: RX.AntennaAngle = [25,-80]
Data Types: double

\section*{AntennaHeight - Antenna height above surface}

1 (default) | non-negative numeric scalar | row vector
Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is \(6,371,000 \mathrm{~m}\).

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise, the height is measured from ground elevation to the center of the antenna.
Example: 'AntennaHeight', 25
Example: RX.AntennaHeight \(=15\)
Data Types:

\section*{SystemLoss - System loss}

0 (default) | nonnegative numeric scalar | row vector
System loss, specified as a non-negative numeric scalar or a row vector in dB .
System loss includes transmission line loss and any other miscellaneous system losses.
Example: 'SystemLoss',10

Example: RX.SystemLoss \(=10\)
Data Types:

\section*{ReceiverSensitivity - Minimum received power to detect signal}
- 100 (default) | numeric scalar | row vector

Minimum received power to detect the signal, specified as a numeric scalar or a row vector in dBm .
Example: 'ReceiverSensitivity',-80
Example: RX.ReceiverSensitivity \(=-80\)
Data Types: double

\section*{Object Functions}
\begin{tabular}{ll} 
show & Show site location on map \\
hide & Hide site location on map \\
distance & Distance between sites \\
angle & Angle between sites \\
elevation & Elevation of site \\
location & Location coordinates at a given distance and angle from site \\
sigstrength & Signal strength due to transmitter \\
los & Plot or compute the line-of-sight (LOS) visibility between sites on a map \\
link & Display communication link on map \\
pattern & Plot antenna radiation pattern on map
\end{tabular}

\section*{Examples}

\section*{Default Receiver Site}

Create and show the default receiver site.
```

rx = rxsite
rx =
rxsite with properties:
Name: 'Site 2'
Latitude: 42.3021
Longitude: -71.3764
Antenna: 'isotropic'
AntennaAngle: 0
AntennaHeight: 1
SystemLoss: 0
ReceiverSensitivity: -100

```
show(rx)

\section*{See Also}
siteviewer|txsite
Introduced in R2019b

\section*{siteviewer}

Create Site Viewer map display for visualizing sites

\section*{Description}

Use the siteviewer object to create a map viewer for visualizing transmitter and receiver sites.

Note Site Viewer is a 3-D map display and requires hardware graphics support for WebGL \({ }^{\mathrm{Tm}}\).

\section*{Creation}

\section*{Syntax}
```

viewer = siteviewer
viewer = siteviewer(Name,Value)

```

\section*{Description}
viewer = siteviewer creates a "Site Viewer" map display for visualizing transmitter or receiver sites.
viewer = siteviewer(Name,Value) creates a Site Viewer map display with properties specified by one or more name-value pairs. Properties you do not specify retain their default values.

\section*{Properties}

\section*{Name - Caption to display on map viewer window}
'Site Viewer' (default)| character vector | string scalar
Caption to display on map viewer window, specified as a character vector or a string scalar.
Data Types: char | string

\section*{Position - Size and location of map viewer window in pixels}
four-element integer-valued vector
Size and location of map viewer window in pixels, specified as a four-element integer-valued vector in the form [left bottom width height]. The default value depends on the screen resolution such that the window lies in the center of the screen with a width of 800 pixels and a height of 600 pixels.

\section*{Data Types: double}

\section*{Basemap - Map imagery used to visualize sites}
'satellite' (default)|'streets'|'openstreetmap'|'darkwater'|'grayland'|
'bluegreen'|'colorterrain'|'grayterrain'|'landcover'
Map imagery used to visualize sites, specified as a one of the following:
- 'satellite' - Satellite imagery provided by ESRI
- 'streets' - Street maps provided by ESRI.
- 'openstreetmap' - Street maps provided by OpenStreetMap.
- 'darkwater' - Two-tone map with light gray for land and dark gray for water.
- 'grayland ' - Two-tone map with gray for land and white for water.
- 'bluegreen ' - Two-tone map with green for land and blue for water.
- 'colorterrain' - Shaded relief map derived from elevation and climate.
- 'grayterrain' - Shaded relief map in shades of gray.
- ' landcover' - Shaded relief map derived from satellite data.

Data Types: char | string
Terrain - Data on which to visualize sites and perform terrain calculations
'gmted2010' (default) | ' none' | character vector | scalar
Data on which to visualize sites and perform terrain calculations, specified as a character vector or a scalar previously added using addCustomTerrain or one of the following options:
- 'none' - Terrain elevation is 0 everywhere.
- 'gmted2010' - USGS GMTED2010 terrain data. This option requires an internet connection.

This property is read-only once the Site Viewer is created.
For limitations, see "Limitations" (Antenna Toolbox).
Data Types: char | string

\section*{Buildings - Name of OpenStreetMap (.osm) file to use as buildings data} string scalar | character vector

Name of the OpenStreetMap (.osm) file to use as buildings data, specified as a string scalar or a character vector. The file must be in the current directory, in a directory on the MATLAB path. You can also use a full or relative path to the file to specify the data. By default, this value is empty.

This property is read-only once the Site Viewer is created.
For limitations, see "Limitations" (Antenna Toolbox).
Data Types: char | string

\section*{Object Functions}
clearMap Clear map visualizations
close Close map viewer window

\section*{Examples}

\section*{Default Site Viewer Map Display}

Create a default Site Viewer map display.
viewer = siteviewer;

\section*{View Transmitter Site On Site Viewer}

Launch a Site Viewer with streets basemap.
viewer = siteviewer("Basemap","streets");

View a transmitter site on this map.
tx = txsite;
show(tx)

\section*{Compare Coverage Maps}

Launch two Site Viewer windows.

One Site Viewer window uses the terrain model.
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");

The second Site Viewer window does not use the terrain model.
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");

Create a transmitter site.
tx = txsite;

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.
coverage(tx, "Map", viewer1)

The map without terrain uses the free-space model by default.
```

coverage(tx,"Map",viewer2)

```

Close the maps.
close(viewer1) close(viewer2)

\section*{Site Viewer with Buildings}

Launch siteviewer map window with basemap and buildings file.
viewer = siteviewer("Basemap", "openstreetmap", ...
"Buildings", "manhattan.osm");

Show a transmitter site on a building.
```

tx = txsite("Latitude",40.7107,...
"Longitude",-74.0114,...
"AntennaHeight",50);
show(tx)

```

\section*{Add and Remove a Custom Basemap}

Add a custom basemap to view locations on an OpenTopoMap \({ }^{\circledR}\) basemap, then remove the custom basemap from siteviewer.

Initialize simulation variables to:
- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: \(\mathrm{a}, \mathrm{b}\), or c .
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.
```

name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';

```

Use addCustomBasemap to load the custom basemap, and then create a siteviewer object that loads the custom basemap.
addCustomBasemap(name, url,'Attribution', attribution', 'DisplayName',displayName) viewer = siteviewer('Basemap',name);

After a custom basemap is added to siteviewer, the custom map is available for future calls to siteviewer. Note the 'Open Topo Map' icon in the Imagery tab.
siteviewer;

Use removeCustomBasemap to remove the custom basemap from future calls to siteviewer. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.
removeCustomBasemap(name)
siteviewer;

\section*{Limitations}

\section*{Terrain}
- Default terrain access requires Internet connection. If no internet connection exists, then Site Viewer automatically uses ' none' in the property Terrain.
- Custom DTED terrain files for use with addCustomTerrain must be acquired outside of MATLAB for example by using USGS EarthExplorer.
- When using custom terrain, analysis is restricted to the terrain region. For example, an error occurs if trying to show a txsite or rxsite outside of the region.

\section*{Buildings}
- OpenStreetMap files obtained from https://www.openstreetmap.org represent crowd-sourced map data, and the completeness and accuracy of the buildings data may vary depending on the map location.
- When downloading data from https://www.openstreetmap.org, select an export area larger than the desired area to ensure that all expected building features are fully captured. Building features at the edge of the selected export area may be missing.
- Building geometry and features are interpreted from the file according to the recommendations of OpenStreetMap for 3D buildings.

\section*{See Also}

Topics
"Site Viewer"

Introduced in R2019b

\section*{txsite}

Create radio frequency transmitter site

\section*{Description}

Use txsite object to create a radio frequency transmitter site.

\section*{Creation}

\section*{Syntax}
tx = txsite
tx = txsite(Name, Value)

\section*{Description}
\(\mathrm{tx}=\mathrm{txsite}\) creates a radio frequency transmitter site.
tx = txsite(Name,Value) sets properties using one or more name-value pairs. For example, tx = txsite('Name','TX Site') creates a transmitter site with name TX Site. Enclose each property name in quotes.

\section*{Properties}

\section*{Name - Site name}
character vector | string | row or column vector
Site name, specified as a character vector or string, or row or column vector of \(N\) elements.
Example: 'Name','Site 2'
Example: TX.Name = 'Fenway Park'
Example: If you want to assign multiple values then - names = ["Fenway Park", "Faneuil Hall","Bunker Hill Monument"]; TX = txsite('Name',names)

Data Types: char | string

\section*{Latitude - Site latitude coordinates}
42.3001 (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar in the range of -90 to 90, or as a row or column vector of \(N\) elements. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/south angle.
```

Example: 'Latitude',45.098
Example: TX.Latitude = 45.098
Example: If you want to assign multiple values then - latitude = [42.3467,42.3598,42.3763];
TX = txsite('Latitude',latitude)

```

\section*{Longitude - Site longitude coordinates}
- 71.3504 (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or as a row or column vector of \(N\) elements. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.
Example: 'Longitude',-68.890
Example: TX.Longitude \(=-71.0972\)
Example: If you want to assign multiple values then - longitude \(=\)
[-71.0972,-71.0545,-71.0611]; TX = txsite('Longitude',longitude)

\section*{Antenna - Antenna element or array}
'isotropic' (default)| object | row vector
Antenna element or array specified as an object or 'isotropic'. By default, the antenna is 'isotropic', which defines an antenna that radiates uniformly in all directions.

\section*{AntennaAngle - Antenna x-axis angle}

0 (default) | numeric scalar | 2 -by-1 vector | 2 -by- \(N\) matrix
Antenna x-axis angle, specified as a numeric scalar or a 2 -by- 1 vector or a 2 -by- \(N\) matrix in degrees.
The azimuth angle measured counterclockwise from the east to the antenna x-axis.
The elevation angle measures from the horizontal plane to antenna x-axis from -90 to 90 degrees.
Example: 'AntennaAngle',25
Example: TX.AntennaAngle \(=[25,-80]\)

\section*{AntennaHeight - Antenna height above surface}

10 (default) | non-negative numeric scalar | row vector
Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is \(6,371,000 \mathrm{~m}\).

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise, the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight ',25
Example: TX.AntennaHeight \(=15\)
Data Types:

\section*{SystemLoss - System loss}

0 (default) | nonnegative numeric scalar | row vector
System loss, specified as a non-negative numeric scalar in dB .
System loss includes transmission line loss and any other miscellaneous system losses.
```

Example: 'SystemLoss',10
Example: txsite.SystemLoss = 10
Data Types:

```

\section*{TransmitterFrequency - Transmitter operating frequency}

\section*{\(1.9000 \mathrm{e}+09\) (default) | numeric scalar | row vector}

Transmitter operating frequency, specified as a numeric scalar in Hz . The range is from 1 e 3 to 200e9.

Example: 'TransmitterFrequency',30e9
Example: txsite.TransmitterFrequency = 30e9
Data Types: double

\section*{TransmitterPower - Signal power at transmitter output}

10 (default) | positive numeric scalar
Signal power at transmitter output, specified as a positive numeric scalar in watts. The transmitter out is connected to the antenna.
Example: 'TransmitterPower',30
Example: txsite.TransmitterPower = 30
Data Types: double

\section*{Object Functions}
\begin{tabular}{ll} 
show & Show site location on map \\
hide & Hide site location on map \\
distance & Distance between sites \\
angle & Angle between sites \\
elevation & Elevation of site \\
location & Location coordinates at a given distance and angle from site \\
los & Plot or compute the line-of-sight (LOS) visibility between sites on a map \\
coverage & Display coverage map \\
sinr & Display signal-to-interference-plus-noise ratio (SINR) map \\
pattern & Plot antenna radiation pattern on map
\end{tabular}

\section*{Examples}

\section*{Default Transmitter Site}

Create and view a transmitter site at a latitude of 42.3001 and a longitude of -71.3504 .
```

tx = txsite('Name','MathWorks Apple Hill','Latitude',42.3001,...
'Longitude',-71.3504)
tx =
txsite with properties:
Name: 'MathWorks Apple Hill'
Latitude: 42.3001
Longitude: -71.3504
Antenna: 'isotropic'
AntennaAngle: 0
AntennaHeight: 10
SystemLoss: 0
TransmitterFrequency: 1.9000e+09

```
show(tx)

View the coverage of the antenna.
pattern(tx)

\section*{propagationData}

Create RF propagation data container

\section*{Description}

Use the propagationData object to import and visualize geolocated propagation data. The measurement data can be path loss data, signal strength measurements, signal-to-noise-ratio (SNR) data, or cellular information.

\section*{Creation}

\section*{Syntax}
```

pd = propagationData(filename)
pd = propagationData(table)
pd = propagationData(latitude,longitude,varname,varvalue)
pd = propagationData(

```
\(\qquad\)
``` ,Name, Value)
```

## Description

pd = propagationData(filename) creates a propagation data container object by reading data from a file specified by filename.
pd = propagationData(table) creates a propagation data container object from a table object specified by table.
pd = propagationData(latitude,longitude,varname,varvalue) creates a propagation data container object using latitude and longitude coordinates with data specified using varname and varvalue.
pd = propagationData( $\qquad$ ,Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes.

## Input Arguments

## filename - Name of file containing propagation data

character vector | string scalar
Name of the file containing propagation data, specified as a character vector or a string scalar. The file must be in the current directory, in a directory on the MATLAB path, or be specified using a full or relative path. The file must be compatible with the readtable function. Call the readtable function if customized parameters are required to import the file and then pass the table object to the propagationData object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: string|char

## table - Table containing propagation data

table object
Table containing propagation data, specified as a table object.
Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.
Data Types: table

## latitude - Latitude coordinate values

vector
Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid model WGS-84. The latitude coordinates must be in the range [-90 90].
Data Types: double

## longitude - Longitude coordinate values

vector
Longitude coordinate values, specified as a vector in decimal degrees with reference to earth's ellipsoid. model WGS-84.
Data Types: double

## varname - Variable name

character vector | string scalar
Variable name, specified as a character vector or a string scalar. This variable name must correspond to the variable with numeric data other than latitude or longitude. The variable name and the corresponding values are stored as a column in the Data property table object.

## Data Types: string | char

## varvalue - Variable values

numeric vector
Variable values, specified as a numeric vector. The numeric vectors must be the same size as latitude and longitude. The variable name and corresponding values are stored as a column in the Data property table object.
Data Types: double

## Output Arguments

## pd - Propagation data

propagationData object
Propagation data, returned as a propagationData object.

## Properties

## Name - Propagation data name

'Propagation Data' (default)|character vector | string scalar
Propagation data name, specified as a character vector or string scalar.

Example: 'Name','propdata'
Example: pd.Name = 'propdata'
Data Types: char \| string

## Data - Propagation data table

scalar table object
This property is read-only.
Propagation data table, specified as a scalar table object containing a column corresponding to latitude coordinates, a column corresponding to longitude coordinates, and one or more columns corresponding to associated propagation data.
Data Types: table

## DataVariableName - Name of data variable to plot <br> character vector | string scalar

Name of the data variable to plot, specified as a character vector or string scalar corresponding to a variable name in the Data table used to create propagation data container object. The variable name must correspond to a variable with numeric data and cannot correspond to the latitude or longitude variables. The default value for this property is the name of the first numeric data variable name in the Data table that is not a latitude or longitude variable.
Data Types: char | string

## Object Functions

| plot | Plot propagation data on map |
| :--- | :--- |
| contour | Display contour map |
| location | Data location coordinates |
| getDataVariable | Get data variable values of data points in propagation data object |
| interp | Geographic data interpolation |

## Examples

## Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files.

```
viewer = siteviewer("Basemap","streets dark",...
    "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...
    "Longitude",-74.0114,...
    "AntennaHeight",80);
show(tx)
```

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
    linspace(40.71416, 40.715505, 25), ...
    linspace(40.715505, 40.7133, 25),
    linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
    linspace(-74.00627,-74.0092, 25), ...
    linspace(-74.0092, -74.0110, 25), ...
    linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a propagationData object to hold computed signal strength data.
$\mathrm{tbl}=$ table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

## Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

```
txs = txsite("Name",names,...
    "Latitude",lats,...
    "Longitude",lons, ...
    "TransmitterFrequency",2.5e9);
```

show(txs)

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.
sv1 = siteviewer("Name","SINR map");
sinr(txs,"MaxRange",5000)

Return SINR propagation data.
pd = sinr(txs,"MaxRange", 5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
Compute capacity using the Shannon-Hartley theorem.
bw = 1e6; \% Bandwidth is 1 MHz
sinrRatio $=10 . \wedge(s i n r D b . / 10) ; \%$ Convert from dB to power ratio
capacity $=b w^{*} \log 2(1+s i n r R a t i o) / l e 6 ; ~ \% ~ U n i t: ~ M b p s$
Create new propagation data for capacity and display the contour plot.
pdCapacity $=$ propagationData(lats,lons,"Capacity", capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)"; contour(pdCapacity,"LegendTitle", legendTitle);

## comm.Ray

Propagation ray container object

## Description

The comm. Ray object is a container object for the properties of a propagation ray. The object contains the geometric and electromagnetic information of a radio wave propagating from one point to another point in the space.

## Creation

Typically you create comm. Ray objects by using the raytrace function.

## Syntax

ray = comm.Ray
ray = comm.Ray(Name,Value)

## Description

ray $=$ comm. Ray creates a container object that initializes properties for a propagation ray.
ray = comm.Ray(Name, Value) sets properties using one or more name-value pair arguments.
Enclose each property name in quotes. For example,
comm.Ray('CoordinateSystem','Geographic','TransmitterLocation',
[40.730610, $-73.935242,0]$ ) specifies the geographic coordinate system and a transmitter located in New York City.

## Properties

## PathSpecification - Propagation path specification method <br> 'Locations' (default)|'Delay and angles'

Propagation path specification method, specified as one of these values.

- 'Locations ' - The ray object path between waypoints are conveyed as $(x, y, z)$ coordinate points by the TransmitterLocation, ReceiverLocation, and, if applicable, ReflectorLocations properties.
- 'Delay and angles' - The ray object path between waypoints are conveyed by the PropagationDelay, AngleOfDeparture, and AngleOfArrival properties.

Data Types: char | string

## CoordinateSystem - Coordinate system

'Cartesian' (default)|'Geographic'
Coordinate system, specified as 'Cartesian' or 'Geographic'. When you set the CoordinateSystem property to 'Geographic', the coordinate system is defined relative to the

WGS-84 Earth ellipsoid model and the object defines angles relative to the local East-North-Up (ENU) coordinate system at the transmitter and receiver.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations'.
Data Types: char|string

## SystemScale - Cartesian coordinate system scale <br> 1 (default) | positive scalar

Cartesian coordinate system scale in meters, specified as a positive scalar.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations' and the CoordinateSystem property to 'Cartesian'.
Data Types: double

## TransmitterLocation - Transmitter location

[0;0;0] (default)| three-element numeric column vector
Transmitter location, specified as a three-element numeric column vector of coordinates in one of these forms.

- $[x ; y ; z]$ - This form applies when you set the CoordinateSystem property to 'Cartesian'. The object does not perform range validation for $x, y$, and $z$.
- [latitude; longitude; height] - This form applies when you set the CoordinateSystem property to 'Geographic' . latitude must be in the range [-90, 90], and height must be nonnegative. The object does not perform range validation for longitude.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations'.
Data Types: double

## ReceiverLocation - Receiver location

[10;10;10] (default) | three-element numeric column vector
Receiver location, specified as a three-element numeric column vector of coordinates in one of these forms.

- $[x ; y ; z]$ - This form applies when you set the CoordinateSystem property to 'Cartesian'. The object does not perform range validation for $x, y$, and $z$.
- [latitude; longitude; height] - This form applies when you set the CoordinateSystem property to 'Geographic ' . latitude must be in the range [-90, 90], and height must be nonnegative. The object does not perform range validation for longitude.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations '.
Data Types: double

## LineOfSight - Line of sight

true or 1 (default) | false or 0
Line of sight, specified as a logical value of 1 (true) or 0 (false) to indicate whether the ray is a line-of-sight ray.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations'.

## Data Types: logical

## ReflectorLocations - Reflector locations

[10;10;0] (default) | 3 -by- $N$ numeric matrix
Reflector locations, specified as a 3-by- $N$ numeric matrix containing the coordinates of the reflection points for the ray. $N$ is the number of reflection points for the ray and is set by the NumReflections property. Each column represents the coordinate location of one reflection point along the propagation path from transmitter to receiver. The order of the columns is the same as the order of the points along the path. Columns (reflection point coordinates) are of one of these forms.

- $[x ; y ; z]$ - when the CoordinateSystem property is set to 'Cartesian'. The object does not perform range validation for $x, y$, and $z$.
- [latitude; longitude; height] - when the CoordinateSystem property is set to 'Geographic'. latitude must be in the range [-90, 90], and height must be nonnegative. The object does not perform range validation for longitude.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations' and the LineOfSight property to 0 (false).

## Data Types: double

## PropagationDelay - Propagation delay

### 5.7775e-08 | nonnegative scalar

Propagation delay in seconds, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-ofsight ray.

- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When you set the PathSpecification property to 'Delay and angles', this property is configurable.

## Data Types: double

## PropagationDistance - Propagation distance

17.3205 | nonnegative scalar

This property is read-only.

Propagation distance in meters, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Locations', the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When you set the PathSpecification property to 'Delay and angles', the value is derived from PropagationDelay.

## Data Types: double

## AngleOfDeparture - Angle of departure

[45; 35.2644] | numeric vector of the form [az; el]
Angle of departure in degrees of the ray at the transmitter, specified as a numeric vector of the form [az; el]. The azimuth angle, $a z$, is measured from the positive x -axis counterclockwise and must be in the range $(-180,180]$. The elevation angle, el, is measured from the $x-y$ plane and must be in the range $[-90,90]$. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Delay and angles', this property is configurable.
- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When CoordinateSystem is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at transmitter.

## Data Types: double

## AngleOfArrival - Angle of arrival

[-135; -35.2644] | numeric vector of the form [az; el]
Angle of arrival in degrees of the ray at the receiver, specified as a numeric vector of the form [az; el]. The azimuth angle, $a z$, is measured from the positive x -axis counterclockwise and must be in the range ( $-180,180$ ]. The elevation angle, el, is measured from the $x-y$ plane and must be in the range [$90,90]$. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Delay and angles', this property is configurable.
- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the ReflectionLocations.
- When CoordinateSystem is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at receiver.

Data Types: double

## NumReflections - Number of reflection points

0 (default) | nonnegative integer
This property is read-only.

Number of reflection points for the ray object from the transmitter to the receiver, specified as a nonnegative integer. The value is derived from LineOfSight and, if applicable, the ReflectionLocations.

## Dependencies

To enable this property, set the PathSpecification property to 'Locations'.
Data Types: double

## Frequency - Signal frequency

$1.9 \mathrm{e}+09$ (default) | positive scalar
Signal frequency in Hz , specified as a positive scalar.
Data Types: double

## PathLossSource - Path loss source

'Free space model' (default)|'Custom'
Path loss source, specified as 'Free space model' or 'Custom'.

## Data Types: char | string

## PathLoss - Path loss

62.7941 | nonnegative scalar

Path loss in dB, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathLossSource property to 'Free space model', the PathLoss property is read-only and derived from the PropagationDistance and Frequency properties by using the free space propagation model.
- When you set the PathLossSource property to 'Custom' , you can set the PathLoss property, independent of the geometric properties.
Data Types: double

## PhaseShift - Phase shift

4.8537 | numeric scalar

Phase shift in radians, specified as a numeric scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathLossSource property to 'Free space model', the PhaseShift property is read-only and derived from the PropagationDistance and Frequency properties by using the free space propagation model.
- When you set the PathLossSource property to 'Custom' , you can set the PhaseShift property, independent of the geometric properties.

## Data Types: double

## Object Functions

plot (rays) Plot rays in Site Viewer map

## Examples

## Perform Ray Tracing Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, generating a cell array containing comm. Ray objects. The comm. Ray objects contain the geometric and electromagnetic information for the radio wave propagation paths from the transmitter site to the receiver site.

Create a Site Viewer map, loading building data for Hong Kong.
viewer = siteviewer('Buildings','hongkong.osm');
Specify transmitter and receiver sites.

```
tx = txsite('Latitude',22.2789,'Longitude',114.1625, ...
    'AntennaHeight',10,'TransmitterPower',5, ...
    'TransmitterFrequency',28e9);
rx = rxsite('Latitude',22.2799,'Longitude',114.1617, ...
    'AntennaHeight',1);
```

Perform ray tracing between the sites, generating comm. Ray objects in a cell array. For the specified transmitter and receiver sites, performing ray tracing results in a 1 -by- 1 cell array containing three ray objects in a row vector.

```
rays = raytrace(tx,rx,'Type','pathloss','ColorLimits',[100 250])
rays = l×1 cell array
    {1\times3 comm.Ray}
```

Display the properties of the first comm. Ray object. The LineOfSight property value is 1 , and the NumReflections property value is 0 . This combination indicates that the ray defines a line-of-sight path.

```
rays{1}(1)
```

```
ans =
    Ray with properties:
        PathSpecification:
            CoordinateSystem: 'Geographic'
        TransmitterLocation: [ }3\times1\mathrm{ double]
            ReceiverLocation: [ 3×1 double]
            LineOfSight: 1
                            Frequency: 2.8000e+10
                PathLossSource: 'Custom'
                    PathLoss: 104.2656
                    PhaseShift: 4.6390
        Read-only properties:
            PropagationDelay: 4.6442e-07
        PropagationDistance: 139.2294
            AngleOfDeparture: [2\times1 double]
                AngleOfArrival: [2×1 double]
                NumReflections: 0
```

Display the properties of the second and third comm. Ray objects. The LineOfSight property values are 0, and the NumReflections property values are greater than 0 . This combination indicates that the rays define reflected paths.

```
rays{1}(2)
ans =
    Ray with properties:
                PathSpecification: 'Locations'
                CoordinateSystem: 'Geographic'
        TransmitterLocation: [ 3\times1 double]
            ReceiverLocation: [3\times1 double]
                    LineOfSight: 0
        ReflectionLocations: [ 3\times1 double]
                            Frequency: 2.8000e+10
                PathLossSource: 'Custom'
                    PathLoss: 106.1296
                PhaseShift: 3.5385
        Read-only properties:
            PropagationDelay: 4.6490e-07
        PropagationDistance: 139.3720
            AngleOfDeparture: [2×1 double]
                AngleOfArrival: [2×1 double]
                NumReflections: 1
rays{1}(3)
ans =
    Ray with properties:
            PathSpecification: 'Locations'
            CoordinateSystem: 'Geographic'
        TransmitterLocation: [ }3\times1\mathrm{ double]
            ReceiverLocation: [ }3\times1\mathrm{ double]
                    LineOfSight: 0
        ReflectionLocations: [ 3\times1 double]
                            Frequency: 2.8000e+10
                PathLossSource: 'Custom'
                    PathLoss: 146.9796
                    PhaseShift: 3.5367
        Read-only properties:
            PropagationDelay: 1.1327e-06
        PropagationDistance: 339.5692
            AngleOfDeparture: [2\times1 double]
                AngleOfArrival: [2×1 double]
                NumReflections: 1
```

Visualize ray tracing results.

```
plot(rays{1});
```

## Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in comm. Ray objects and plot the ray propagation path after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago.
viewer = siteviewer('Buildings','chicago.osm');
Create and show a transmitter site on one building and a receiver site on another building.

```
tx = txsite('Latitude',41.8800,'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
show(tx);
rx = rxsite('Latitude',41.881352,'Longitude',-87.629771, ...
    'AntennaHeight',30);
show(rx);
```

Perform ray tracing, returning the ray object results. For the configuration defined, ray tracing returns a cell array containing one ray object. Display the ray object properties. Then, close the Site Viewer map.

```
rays = raytrace(tx,rx)
rays = l×1 cell array
    {1\times1 comm.Ray}
rays{1}
ans =
    Ray with properties:
            PathSpecification: 'Locations'
                CoordinateSystem: 'Geographic'
        TransmitterLocation: [3\times1 double]
            ReceiverLocation: [3×1 double]
                    LineOfSight: 0
        ReflectionLocations: [3\times1 double]
                            Frequency: 2.5000e+09
            PathLossSource: 'Custom'
                        PathLoss: 95.4412
                            PhaseShift: 4.4413
        Read-only properties:
        PropagationDelay: 5.7088e-07
        PropagationDistance: 171.1462
        AngleOfDeparture: [2×1 double]
                AngleOfArrival: [2×1 double]
                NumReflections: 1
```

close(viewer);

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for one ray object at a time.

```
siteviewer('Buildings','chicago.osm');
show(tx);
show(rx);
plot(rays{1},'Type','power', ...
    'TransmitterSite',tx,'ReceiverSite',rx);
```

## hide

Package: comm
Hide scope window

## Syntax

hide(scope)

## Description

hide(scope) hides the window of the System object scope.

## Examples

## Hide and Show Scope

Create a comm.ConstellationDiagram object.
scope = comm.ConstellationDiagram;
Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

## Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

```
M = 16
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object ${ }^{\text {TM }}$, specifying the constellation reference points and axes limits using name-value pairs.
scope $=$ comm.ConstellationDiagram('ReferenceConstellation',refConst, ... 'XLimits',[-4 4],'YLimits',[-4 4]);

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Clear the workspace variables.
clear scope sym rcv M refConst signal xRef

## Hide and Show Eye Diagram

Create a signal to display in an eye diagram. Use the isVisible, hide, and show object functions to check the visibility of the window, and to hide and show the window.

Specify the modulation order, sample rate, and the number of output samples per symbol parameters.

```
M = 4;
fs = 1000;
sps = 4;
```

Create transmit filter and eye diagram System objects specifying the name-value pairs for input properties.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
eyediag = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols, apply modulation, and filter the modulated signal. Display the eye diagram.

```
data = randi([0 M-1],1000,1);
modSig = pskmod(data,M,pi/4);
txSig = txfilter(modSig);
eyediag(txSig)
```

Hide the scope window.

```
if(isVisible(eyediag))
    hide(eyediag)
end
```

Show the scope window.

```
if(~isVisible(eyediag))
    show(eyediag)
end
```

Clean up workspace variables.

```
clear data eyediag fs M modSig sps txfilter txSig
```

## Input Arguments

## scope - Scope System object

scope System object
Scope System object, specified as a comm. ConstellationDiagram or comm. EyeDiagram System object.

```
Example: scope = comm.EyeDiagram;
```

## isVisible

Package: comm
Determine visibility of scope window

## Syntax

visibility = isVisible(scope)

## Description

visibility = isVisible(scope) returns a logical to verify in the System object scope is open. visibility is 1 if the scope window is open and 0 otherwise.

## Examples

## Hide and Show Scope

Create a comm.ConstellationDiagram object.
scope $=$ comm. ConstellationDiagram;
Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

## Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

```
M = 16
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object ${ }^{\text {TM }}$, specifying the constellation reference points and axes limits using name-value pairs.
scope $=$ comm.ConstellationDiagram('ReferenceConstellation',refConst, ... 'XLimits',[-4 4],'YLimits',[-4 4]);

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Processing
Frame=1

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## Input Arguments

## scope - Scope System object

scope System object
Scope System object, specified as a comm. ConstellationDiagram or comm.EyeDiagram System object.

Example: scope = comm.ConstellationDiagram;

## See Also

## Functions

hide \| show
Objects

Introduced in R2013a

## show

## Package: comm

Show scope window

## Syntax

show(scope)

## Description

show(scope) shows the window of the System object scope.

## Examples

## Hide and Show Scope

Create a comm. ConstellationDiagram object.
scope = comm.ConstellationDiagram;
Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))
    hide(scope)
end
```

## Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

```
M = 16;
xRef = (0:M-1)';
refConst = qammod(xRef,M);
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object ${ }^{\text {TM }}$, specifying the constellation reference points and axes limits using name-value pairs.
scope $=$ comm.ConstellationDiagram('ReferenceConstellation',refConst, ... 'XLimits',[-4 4],'YLimits',[-4 4]);

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Clear the workspace variables.
clear scope sym rcv M refConst signal xRef

## Hide and Show Eye Diagram

Create a signal to display in an eye diagram. Use the isVisible, hide, and show object functions to check the visibility of the window, and to hide and show the window.

Specify the modulation order, sample rate, and the number of output samples per symbol parameters.

```
M = 4;
fs = 1000;
sps = 4;
```

Create transmit filter and eye diagram System objects specifying the name-value pairs for input properties.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
eyediag = comm.EyeDiagram('SampleRate',fs*sps,'SamplesPerSymbol',sps);
```

Generate random symbols, apply modulation, and filter the modulated signal. Display the eye diagram.

```
data = randi([0 M-1],1000,1);
modSig = pskmod(data,M,pi/4);
txSig = txfilter(modSig);
eyediag(txSig)
```

Hide the scope window.

```
if(isVisible(eyediag))
    hide(eyediag)
end
```

Show the scope window.

```
if(~isVisible(eyediag))
    show(eyediag)
end
```

Clean up workspace variables.

```
clear data eyediag fs M modSig sps txfilter txSig
```

## Input Arguments

## scope - Scope System object

## info

Package: comm
Characteristic information about fading channel object

## Syntax

infostruct = info(obj)

## Description

infostruct = info(obj) returns a structure containing characteristic information about the fading channel System object.

## Examples

## Get comm.RayleighChannel Info

Use the info object function to get information from a comm. RayleighChannel object.
Create a Rayleigh channel object and some data to pass through the channel.

```
rayleighchan = comm.RayleighChannel('SampleRate',1000,'PathDelays',[0 0],'AveragePathGains',[0 0
rayleighchan =
    comm.RayleighChannel with properties:
                                    SampleRate: 1000
                    PathDelays: [0 0]
            AveragePathGains: [0 0]
            NormalizePathGains: true
        MaximumDopplerShift: 1.0000e-03
            DopplerSpectrum: [1x1 struct]
    Show all properties
```

data $=$ randi([0 1],600,1);

Check the Rayleigh channel object information
info(rayleighchan)
ans = struct with fields:
ChannelFilterDelay: 0
ChannelFilterCoefficients: [2x1 double]
NumSamplesProcessed: 0

Pass data through the channel and check the object information again.

```
rayleighchan(data);
info(rayleighchan)
ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x1 double]
        NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a $1.5 \mathrm{e}-3$ second path delay to the second delay path.

```
release(rayleighchan)
rayleighchan.PathDelays = [0 1.5e-3]
```

rayleighchan =
comm.RayleighChannel with properties:
SampleRate: 1000
PathDelays: [0 0.0015]
AveragePathGains: [0 0]
NormalizePathGains: true
MaximumDopplerShift: 1.0000e-03
DopplerSpectrum: [1x1 struct]
Show all properties

Pass data through the channel and check the object information again.

```
rayleighchan(data);
info(rayleighchan)
ans = struct with fields:
    ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
            NumSamplesProcessed: 600
```

## Get comm.RicianChannel Info

Use the info object function to get information from a comm. RicianChannel object.
Create a Rician channel object and some data to pass through the channel.

```
ricianchan = comm.RicianChannel('SampleRate',500)
ricianchan =
    comm.RicianChannel with properties:
            SampleRate: 500
            PathDelays: 0
            AveragePathGains: 0
            NormalizePathGains: true
                KFactor: 3
        DirectPathDopplerShift: 0
```

```
    DirectPathInitialPhase: 0
    MaximumDopplerShift: 1.0000e-03
    DopplerSpectrum: [1x1 struct]
Show all properties
data = randi([0 1],600,1);
```

Check the Rician channel object information

```
info(ricianchan)
ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
        NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)
ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
        NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a second path delay with a delay of 3.1e-3 second and an average path gain of -3 dB .

```
release(ricianchan)
ricianchan.PathDelays = [0 3.1e-3];
ricianchan.AveragePathGains = [0 -3]
ricianchan =
    comm.RicianChannel with properties:
                    SampleRate: 500
                    PathDelays: [0 0.0031]
            AveragePathGains: [0 -3]
            NormalizePathGains: true
                KFactor: 3
        DirectPathDopplerShift: 0
        DirectPathInitialPhase: 0
            MaximumDopplerShift: 1.0000e-03
                        DopplerSpectrum: [1x1 struct]
    Show all properties
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)
ans = struct with fields:
    ChannelFilterDelay: 6
```

```
ChannelFilterCoefficients: [2x16 double]
```

    NumSamplesProcessed: 600
    
## Get comm.MIMOChannel Info

Use the info object function to get information from a comm. MIMOChannel object.
Create a MIMO channel object and some data to pass through the channel.

```
mimo = comm.MIMOChannel('SampleRate',1000);
data = randi([0 1],600,2);
```

Check the MIMO channel object information

```
info(mimo)
ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
        NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
mimo(data);
info(mimo)
ans = struct with fields:
        ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
        NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a 2.5e-3 second path delay. Recheck the object information.

```
release(mimo)
mimo.PathDelays = 2.5e-3;
info(mimo)
ans = struct with fields:
    ChannelFilterDelay: 5
    ChannelFilterCoefficients: [1x16 double]
            NumSamplesProcessed: 0
```

## Model MIMO Channel Using Sum-of-Sinusoids Technique

Create a MIMO channel object and pass data through it using the sum-of-sinusoids technique. The example demonstrates how the channel state is maintained in cases in which data is discontinuously transmitted.

Define the overall simulation time and three time segments for which data will be transmitted. In this case, the channel is simulated for 1 s with a 1000 Hz sampling rate. One $1000-\mathrm{sample}$, continuous data sequence is transmitted at time 0 . Three 100 -sample data packets are transmitted at time 0.1 s , 0.4 s , and 0.7 s .

```
t0 = 0:0.001:0.999; % Transmission 0
t1 = 0.1:0.001:0.199; % Transmission 1
t2 = 0.4:0.001:0.499; % Transmission 2
t3 = 0.7:0.001:0.799; % Transmission 3
```

Generate random binary data corresponding to the previously defined time intervals.

```
d0 = randi([0 1],1000,2); % 1000 samples
d1 = randi([0 1],100,2); % 100 samples
d2 = randi([0 1],100,2); % 100 samples
d3 = randi([0 1],100,2); % 100 samples
```

Create a flat fading 2 x 2 MIMO channel System object with the Sum of sinusoids fading technique. So that results can be repeated, specify a seed using a name-value pair. As the InitialTime property is not specified, the fading channel will be simulated from time 0 . Enable the path gains output port.

```
mimoChan1 = comm.MIMOChannel('SampleRate',1000, ...
    'MaximumDopplerShift',5, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'PathGainsOutputPort',true);
```

Create a clone of the MIMO channel System object. Set the InitialTimeSource property to Input port so that the fading channel offset time can be specified as an input argument to the mimoChan function.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
```

Pass random binary data through the first channel object, mimoChan1. Data is transmitted over all 1000 time samples. For this example, only the complex path gain is needed.
[~,pg0] = mimoChan1(d0);
Pass random data through the second channel object, mimoChan2, where the initial time offsets are provided as input arguments.

```
[~,pg1] = mimoChan2(d1,0.1);
[~,pg2] = mimoChan2(d2,0.4);
[~,pg3] = mimoChan2(d3,0.7);
```

Compare the number of samples processed by the two channels using the info method. You can see that 1000 samples were processed by mimoChan1 while only 300 were processed by mimoChan2.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
ans = 1\times2
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. Observe that the gains for the three segments perfectly match the gain for the continuous case. The alignment of the two highlights that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data as the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```

## Input Arguments

## obj - System object to get information from

System object
System object to get information from, specified as a comm.MIMOChannel, comm. RayleighChannel, or comm.RicianChannel System object.

## Output Arguments

## infostruct - Structure containing object information

structure
Structure containing these fields with information about the System object.

## ChannelFilterDelay - Channel filter delay positive integer

Channel filter delay in samples, returned as a positive integer.
ChannelFilterCoefficients - Channel filter coefficients
matrix
Channel filter coefficients, returned as a matrix. The coefficient matrix is used to convert path gains to channel filter tap gains for each sample and each pair of transmit and receive antennas.

## NumSamplesProcessed - Number of samples processed by the channel object <br> positive integer

Number of samples processed by the channel object since the last reset, returned as a positive integer.

## LastFrameTime - Last frame ending time <br> positive scalar

Last frame ending time in seconds, returned as a positive scalar. Use this value to confirm the simulation time.

## Dependencies

This property applies when the FadingTechnique property is 'Sum of sinusoids' and the InitialTimeSource property is 'Input port'.

## constellation

Package: comm
Calculate or plot ideal signal constellation

## Syntax

symbols = constellation(obj)
constellation(obj)

## Description

symbols = constellation(obj) returns the numerical values of the constellation. constellation(obj) generates a constellation plot for the object.

## Examples

## Plot QPSK Reference Constellation

Create a QPSK modulator.
$\bmod =$ comm.QPSKModulator;
Determine the reference constellation points.

```
refC = constellation(mod)
refC = 4×1 complex
    0.7071 + 0.7071i
    -0.7071 + 0.7071i
    -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Constellation: QPSK,Gray Mapping,PhaseOffset=0.7854rad

Create a PSK demodulator having 0 phase offset.
demod = comm.QPSKDemodulator('PhaseOffset',0);
Plot its reference constellation. The constellation method works for both modulator and demodulator objects.

```
constellation(demod)
```

## Input Arguments

obj - System object to return constellation for
System object
System object to return constellation for, specified as a comm. QPSKModulator System object.
Data Types: object

## See Also

## Objects

comm.QPSKModulator
Introduced in R2012a

## info

Package: comm
Provide dimensioning information for OFDM modulator

## Syntax

infostruct $=$ info(ofdmmod)

## Description

infostruct = info(ofdmmod) returns the input, pilot, and output data dimensions for the specified OFDM modulator System object.

## Examples

## Info Method to Determine OFDM Modulator Data Dimensions

Determine the OFDM modulator data dimensions by using the info method.
Construct an OFDM modulator System object ${ }^{\mathrm{TM}}$ with user-specified pilot indices, insert a DC null, and specify two transmit antennas.

```
hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
    [11; 25; 39; 53]), ...
    'InsertDCNull',true, ...
    'NumTransmitAntennas',2);
```

Use the info method to find the modulator input data, pilot input data, and output data sizes.

```
info(hMod)
```

ans = struct with fields:
DataInputSize: [48 1 2]

OutputSize: [80 2]

## Input Arguments

ofdmmod - OFDM modulator
System object
OFDM modulator, specified as a comm. OFDMModulator System object.

## Output Arguments

## infostruct - Dimensions of structure for OFDM modulator struct

Dimensions of structure for OFDM modulator, returned as a structure containing these fields.
System object.

## DataInputSize - Dimensions of input data

3-D array
Dimensions of input data, returned as a 3-D array of numeric values. The dimensions of this field are $N_{\text {data }}$-by- $N_{\text {sym, }}$, where $N_{\text {data }}$ is the number of data subcarriers such that $N_{\text {data }}=N_{\text {FFT }}-N_{\text {leftG }}-N_{\text {rightG }}-$ $N_{\text {DCNull }}-N_{\text {pilot }}-N_{\text {custNull }}$.

For variable definitions, see Variable Definitions.

## PilotInputSize - Dimensions of the pilot input data

3-D array
Dimensions of the pilot input array, returned as a 3-D array of numeric values. The output dimensions of this field are $N_{\text {pilot }}-$ by- $N_{\text {sym }}$-by- $N_{\mathrm{t}}$.

## OutputSize - Dimensions of modulator output data

3-D array
Dimensions of the modulator output data, returned as a 3-D array of numeric values. The dimensions of this field are $\left(\left(N_{\mathrm{FFT}}+N_{\mathrm{CP}}\right) \times N_{\mathrm{sym}}\right)$-by- $N_{\mathrm{t}}$.

For variable definitions, see Variable Definitions.
Data Types: struct

## More About

## List of Variables

The variables mentioned in this table are defined in this table:

Variable Definitions

| Variable | Description |
| :--- | :--- |
| $N_{\text {FFT }}$ | Number of subcarriers |
| $N_{\text {leftG }}$ | Number of subcarriers in the left guard band |
| $N_{\text {rightG }}$ | Number of subcarriers in the right guard band |
| $N_{\text {DCNull }}$ | Number of subcarriers in the DC null (either 0 or 1) |
| $N_{\text {pilot }}$ | Number of pilot subcarriers |
| $N_{\text {custNull }}$ | Number of subcarriers used for custom nulls (applies only when the <br> PilotCarrierIndices property of input ofdmmod is a 3-D array) |
| $N_{\mathrm{t}}$ | Number of transmit antennas |
| $N_{\mathrm{CP}}$ | Length of cyclic prefix. |

## showResourceMapping

Package: comm
Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object

## Syntax

showResourceMapping(ofdmmod)
showResourceMapping(ofdmmod,ci)

## Description

showResourceMapping (ofdmmod) shows a visualization of the subcarrier mapping for the OFDM symbols created by the OFDM modulator System object. The subcarrier indices are numbered from 1 to ci $N_{\mathrm{FFT}}$, where $N_{\mathrm{FFT}}$ is the number of FFT points.
showResourceMapping(ofdmmod, ci) uses the values in input ci to number the subcarrier indices that the function displays.

## Examples

## Construct and Modify OFDM Modulator

An OFDM modulator System object ${ }^{\mathrm{TM}}$ can be constructed using default properties. Once constructed, these properties can be modified.

Construct an OFDM modulator.
ofdmMod = comm. OFDMModulator;
Display the properties of the modulator.

```
disp(ofdmMod)
    comm.OFDMModulator with properties:
                            FFTLength: 64
        NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
            PilotInputPort: false
        CyclicPrefixLength: 16
            Windowing: false
                NumSymbols: 1
        NumTransmitAntennas: 1
```

Modify the number of subcarriers and symbols.
ofdmMod.FFTLength = 128;
ofdmMod.NumSymbols = 2;
Verify that the number of subcarriers and the number of symbols changed.

```
disp(ofdmMod)
    comm.OFDMModulator with properties:
    FFTLength: 128
        NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
            PilotInputPort: false
        CyclicPrefixLength: 16
                            Windowing: false
                            NumSymbols: 2
        NumTransmitAntennas: 1
```

The showResourceMapping method shows the mapping of data, pilot, and null subcarriers in the time-frequency space. Apply the showResourceMapping method.
showResourceMapping(ofdmMod)

OFDM Subcarrier Mapping for All Tx Antennas

## Input Arguments

ofdmmod - System object to visualize
comm. OFDMModulatorSystem object
OFDM modulator, specified as a comm. OFDMModulatorSystem object.

## ci - Subcarrier indices to visualize

[1,..., $N_{\text {FFT }}$ ] (default)|1-by-2 integer row vector
Subcarrier indices to visualize, specified as a two-element row vector of integers. ci should satisfy $\operatorname{diff}(\mathrm{ci})=N_{\text {FFT }}-1$.

## info

Package: comm
Characteristic information about carrier synchronizer

## Syntax

infostruct = info(carrSynch)

## Description

infostruct = info(carrSynch) returns a structure containing characteristic information for the CarrierSynchronizer System object.

## Examples

## Determine Carrier Synchronizer Loop Parameters

Create a carrier synchronizer object.

```
csync = comm.CarrierSynchronizer;
```

Determine the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay by using the info method.

```
syncInfo = info(csync)
syncInfo = struct with fields:
    NormalizedPullInRange: 0.0628
    MaxFrequencyLockDelay: 1.5787e+04
        MaxPhaseLockDelay: 130
```

The normalized pull-in range is $0.0628 \mathrm{rad} / \mathrm{sec}$. Convert the pull-in range to Hz. This represents the maximum normalized frequency offset that can be corrected by the carrier synchronizer.

```
foffsetmax = syncInfo.NormalizedPullInRange/(2*pi)
foffsetmax = 0.0100
```

The time to acquire a frequency lock is 15787 s , and the time to acquire a phase lock is 130 s .
The overall acquisition time, Tlock, is well approximated by the sum of the frequency and phase lock terms.

```
Tlock = syncInfo.MaxFrequencyLockDelay + syncInfo.MaxPhaseLockDelay
Tlock = 1.5917e+04
```

## Input Arguments

## carrSynch - System object to get information from

System object
System object to get information from.

## Output Arguments

## infostruct - Structure containing object information struct

Structure containing these fields with information about the System object.

## NormalizedPullInRange - Normalized pull in range scalar

Normalized pull in range in radians, returned as a scalar. NormalizedPullInRange is the largest frequency offset (rad), normalized by the loop bandwidth, for which the synchronizer can acquire lock.

## MaxFrequencyLockDelay - Maximum frequency lock delay

 positive integerMaximum frequency lock delay, returned as a positive integer. MaxFrequencyLockDelay is the number of samples required for the synchronizer to acquire frequency lock.

## MaxPhaseLockDelay - Maximum phase lock delay

 positive integerMaximum phase lock delay, returned as a positive integer. MaxPhaseLockDelay is the number of samples required for the synchronizer to acquire phase lock.

## maxstep

Package: comm
Maximum step size for LMS equalizer convergence

## Syntax

mumax $=$ maxstep(eq, $x$ )

## Description

mumax $=$ maxstep $(e q, x)$ predicts a bound on the step size to provide convergence of the mean values of the coefficients of the equalizer defined by the eq System object. The set input signal sequences in x are assumed to have zero mean or nearly so.

## Examples

## Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object ${ }^{\text {TM }}$, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03 .

```
bpsk = comm.BPSKModulator;
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.
eqdfe_lms.ReferenceTap $=4$;
Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use maxstep to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

## Input Arguments

## eq - Equalizer object

System object

Equalizer object, specified as a comm.LinearEqualizer or comm.DecisionFeedbackFEqualizer System object.

## x - Input signal

column vector
Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property. For more information, see "Symbol Tap Spacing" on page 3-513.
Data Types: double
Complex Number Support: Yes

## Output Arguments

mumax - Prediction of maximum step size for LMS equalizer convergence
scalar
Prediction of maximum step size for LMS equalizer convergence, returned as a scalar.

## mmseweights

Package: comm
Linear equalizer MMSE tap weights

## Syntax

weights = mmse(eq,chTaps,EbN0)

## Description

weights = mmse(eq,chTaps,EbN0) calculated minimum mean squared error (MMSE) solution for the linear equalizer, eq System object given the channel delay taps, chTaps, and signal to noise ratio, EbN0.

## Examples

## Calculate MMSE Weights for Linear Equalizer

Calculate the minimum mean squared error (MMSE) solution and use the weights for the linear equalizer taps weights.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm and input the taps weights. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm','CMA','AdaptWeights',false,'InitialWeightsSource','Propert
eq =
    comm.LinearEqualizer with properties:
                            Algorithm: 'CMA'
                        NumTaps: 5
                            StepSize: 0.0100
                Constellation: [1x4 double]
        InputSamplesPerSymbol: 1
```

```
            AdaptWeightsSource: 'Property'
            AdaptWeights: false
    InitialWeightsSource: 'Property'
        InitialWeights: [5x1 double]
        WeightUpdatePeriod: 1
wgts = mmseweights(eq,chtaps,EbN0)
wgts = 5x1 complex
    0.0005 - 0.0068i
    0.0103 + 0.0117i
    0.9694 - 0.0019i
    0.3987 + 0.2186i
    0.0389 - 0.1756i
eq.InitialWeights = wgts;
[y,err,weights] = eq(rx);
```

Plot constellation of impaired and equalized symbols.
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')

errevm = comm.EVM;
evm $=$ errevm(tx,y)
evm $=140.6177$
Plot equalizer tap weights.
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8 line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1) title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8 line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1) subplot (3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 - 0 line([eq. NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)

## Input Arguments

## eq - Equalizer object

System object
Equalizer object, specified as a comm. LinearEqualizer System object.

## chTaps - Channel delay taps

vector
Channel delay taps, specified as a vector.
Data Types: double
Complex Number Support: Yes

## EbN0 - Signal to noise ratio

scalar
Signal to noise ratio of the channel, specified as a scalar.
Data Types: double

## Output Arguments

weights - Weights for linear equalizer
vector
Weights for linear equalizer, returned as a vector.

## visualize

Package: comm
Visualize spectrum mask of phase noise

## Syntax

visualize(phznoise)

## Description

visualize(phznoise) displays the magnitude response of the filter defined by the comm. PhaseNoise System object. The function uses the fvtool function to display the magnitude response.

## Examples

## Visualize Spectrum Mask of Phase Noise

Create a phase noise object and display the spectral mask.

```
pnoise = comm.PhaseNoise('Level',[-40 -70],'Frequency0ffset',[100 200], ...
    'SampleRate',1000);
visualize(pnoise)
```

## Input Arguments

phznoise - Phase noise
comm.PhaseNoise System object
Phase noise that defines the spectrum mask that is displayed, specified as a comm.PhaseNoise System object.

## See Also

## Functions

fvtool
Objects
comm. PhaseNoise

## Introduced in R2012a

## addCustomTerrain

Add custom terrain data

## Syntax

addCustomTerrain(terrainName,files)
addCustomTerrain( __ ,Name, Value)

## Description

addCustomTerrain(terrainName,files) adds the terrain data specified with a user-defined terrainName and files. You can use this function to add custom terrain data in Site Viewer and other RF propagation functions. You can access the custom terrain data in the current and future sessions of MATLAB until you call removeCustomTerrain.

Note In Antenna Toolbox ${ }^{\text {rM }}$, addCustomTerrain function converts terrain elevation data from orthometric to ellipsoidal for visualization and when performing Euclidean distance or angle calculations between locations for example for free space path loss.
addCustomTerrain( $\qquad$ ,Name, Value) adds custom terrain data with additional options specified by one or more name-value pairs.

## Examples

## Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";
attribution = "SRTM 3 arc-second resolution. Data available " + ...
    "from the U.S. Geological Survey.";
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer("Terrain","southboulder");
```

Create a site with the terrain region.
mtzion = txsite("Name","Mount Zion", ...
"Latitude", 39.74356, ...
"Longitude",-105.24193, ...
"AntennaHeight", 30);
show(mtzion)

Create a coverage map of the area within 20 km of the transmitter site.
coverage(mtzion, ...
"MaxRange", 20000, ...
"SignalStrengths",-100:-5)

Remove the custom terrain.
close(viewer)
removeCustomTerrain("southboulder")

## Input Arguments

## terrainName - User-defined identifier for terrain data

string scalar | character vector
User-defined identifier for terrain data, specified as a string scalar or a character vector.
Data Types: char | string

## files - List of DTED files

string scalar | character vector | cell array of character vectors
List of DTED files, specified as a string scalar, a character vector or a cell array of character vectors.

Note If you specify multiple files, they must combine to define a complete rectangular geographic region. If not, you must set the name-value pair 'FillMissing' to 'true'.

Data Types: char|string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'FillMissing', true

## Attribution - Attribution of custom terrain data

character vector | string scalar
Attribution of custom terrain data, specified as a character vector or a string scalar. The attribution is displayed on the Site Viewer map. By default, the value is empty.
Data Types: char | string
FillMissing - Fill data of missing files with value 0
false (default)| true
Fill data of missing files with value 0 , specified as true or false. Missing file values are required to complete a rectangular geographic region with the input files.
Data Types: logical

## WriteLocation - Name of folder to write extracted terrain files to <br> character vector | string scalar

Name of folder to write extracted terrain files to, specified as a character vector or a string scalar. The folder must exist and have write permissions. By default, addCustomTerrain writes extracted terrain files to a temporary folder that it generates using the tempname function.

Data Types: char | string

## See Also

removeCustomTerrain|siteviewer
Introduced in R2019b

## angle

Angle between sites

## Syntax

[az,el] = angle(site1,site2)
[az,el] = angle(site1,site2,path)
[az,el] = angle( $\qquad$ ,Name, Value)

## Description

[az,el] = angle(site1,site2) returns the azimuth and elevation angles between site 1 and site
[az,el] = angle(site1,site2,path) returns the angles using a specified path type, either Euclidean or great circle path.
[az,el] = angle( $\qquad$ ,Name, Value) returns the azimuth and elevation angles with additional options specified by name-value pairs.

## Examples

## Angle Between Sites

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx)
az = 14.0142
el = -0.2816
```

Get the azimuth angle between sites in degrees clockwise from north.

```
azFromEast = angle(tx,rx); % Unit: degrees counter-clockwise from east
azFromNorth = -azFromEast + 90 % Convert angle to clockwise from north
azFromNorth = 75.9858
```

## Angle Between Sites When Path is Great Circle

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx,'greatcircle')
az = 14.0635
el = 0
```

## Input Arguments

## site1, site2 - Transmitter or receiver site

txsite or rxsite object
Transmitter or receiver site, specified as a txsite or rxsite object. You can use array inputs to specify multiple sites.

## path - Measurement path type

'euclidean' or 'greatcircle'
Measurement path type, specified as one of the following:

- 'euclidean ': Uses the shortest path through space connecting the antenna center positions of the site 1 and site 2.
- 'greatcircle': Uses the shortest path on the surface of the earth connecting the latitude and longitude locations of site 1 and site 2. This path uses a spherical Earth model.

## Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.
Example: 'Map', 'siteviewerl'

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.

## Data Types: char | string

## Output Arguments

## az - Azimuth angle between site 1 and site 2

$M$-by- $N$ arrays
Azimuth angle between site 1 and site 2 , returned as $M$-by- $N$ arrays in degrees. $M$ is the number of sites in sites 2 and $N$ is the number of sites in sites 1 . The values range from - 180 to 180.

## el - Elevation angle between site 1 and site 2

$M$-by- $N$ arrays
Elevation angle between site 1 and site 2, returned as $M$-by- $N$ arrays in degrees. $M$ is the number of sites in sites 2 and $N$ is the number of sites in sites 1 The values range from -90 to 90 .

When the path type specified is 'greatcircle', elevation angle is always zero.

distance
Introduced in R2019b

## clearMap

Clear map visualizations

## Syntax

clearMap(viewer)

## Description

clearMap(viewer) removes all visualizations from the map.

## Examples

View Transmitter Site On Site Viewer
Launch a Site Viewer with streets basemap.
viewer = siteviewer("Basemap","streets");

View a transmitter site on this map.
tx = txsite; show(tx)

Clear the map.
t = timer('TimerFcn',@(~,~)disp('Fired.'),'StartDelay', 3);
start(t)
wait(t)
clearMap(viewer)

## Input Arguments

viewer - Map viewer for visualizing transmitter or receiver sites siteviewer object

Map viewer for visualizing transmitter or receiver sites, specified as a siteviewer object.

## See Also

close|siteviewer

## Introduced in R2019b

## close

Close map viewer window

## Syntax

close(viewer)

## Description

close(viewer) closes the map viewer window and deletes the handle

## Examples

## Compare Coverage Maps

Launch two Site Viewer windows.
One Site Viewer window uses the terrain model.

```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");
```

The second Site Viewer window does not use the terrain model.

```
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```

Create a transmitter site.
tx = txsite;
Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.
coverage(tx,"Map", viewer1)

The map without terrain uses the free-space model by default.
coverage(tx, "Map", viewer2)

Close the maps.
close(viewer1)
close(viewer2)

## Input Arguments

viewer - Map viewer for visualizing transmitter or receiver sites
siteviewer object
Map viewer for visualizing transmitter or receiver sites, specified as a siteviewer object.

## See Also

clearMap|siteviewer
Introduced in R2019b

## contour

Display contour map

## Syntax

```
contour(pd)
contour(
,Name,Value)
```

## Description

contour ( pd ) creates a filled contour plot on a map. Contours are colored according to data values of corresponding locations.
contour ( $\qquad$ ,Name, Value) creates a filled contour map with additional options specified by name-value pair arguments.

## Examples

## Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
Create an array of transmitter sites.
txs = txsite("Name",names,...
    "Latitude",lats,...
    "Longitude",lons, ...
    "TransmitterFrequency",2.5e9);
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.
sv1 = siteviewer("Name","SINR map");
sinr(txs,"MaxRange",5000)

Return SINR propagation data.
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
Compute capacity using the Shannon-Hartley theorem.
bw = 1e6; \% Bandwidth is 1 MHz
sinrRatio $=10 . \wedge(s i n r D b . / 10) ;$ Convert from dB to power ratio
capacity $=b^{*} \log 2(1+s i n r R a t i o) / 1 e 6 ; ~ \% ~ U n i t: ~ M b p s$
Create new propagation data for capacity and display the contour plot.
pdCapacity = propagationData(lats,lons,"Capacity", capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)"; contour(pdCapacity,"LegendTitle", legendTitle);

## Input Arguments

pd - Propagation data
propagationData object (default)
Propagation data, specified as a propagationData object.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'Type','power'

## DataVariableName - Data variable to contour map

DataVariableName (default) | character vector | string scalar
Data variable to contour map, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or a string scalar corresponding to a variable name in the data table used to create the propagation data container object pd.

## Data Types: char | string

## Type - Type of value to plot

'custom' (default)| 'power'| 'efield'|'sinr'|'pathloss'
Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the 'Type' column:

| Type | ColorLimits | LegendTitle |
| :--- | :--- | :--- |
| 'custom' | $[\min ($ Data $) \max ($ Data) $]$ | $'^{\prime}$ |
| 'power' | $\left[\begin{array}{ll}-120-5\end{array}\right]$ | 'Power (dBm)' |
| 'efield' | $\left[\begin{array}{ll}20 & 135\end{array}\right]$ | 'E-field (dBuV/m)' |
| 'sinr' | $\left[\begin{array}{ll}-5 & 20\end{array}\right]$ | 'SINR (dB)' |
| 'pathloss' | $\left[\begin{array}{ll}45 & 160\end{array}\right]$ | 'Path loss (dB)' |

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

## Data Types: char|string

## Levels - Data value levels to plot

numeric vector
Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and numeric vector. Each level is displayed as a different colored, filled contour on the map. The colors are selected using Colors if specified, or else Colormap and ColorLimits. Data points with values below the minimum level are not included in the plot.

The default value for Levels is a linearly spaced vector bounded by ColorLimits.
Data Types: double

## Colors - Colors of data points

$M$-by-3 array of RGB | array of strings | cell array of character vectors
Colors of the filled contours, specified as the comma-separated pair consisting of 'Colors ' and an M-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in Levels for coloring the corresponding points. Colors cannot be used with Colormap and ColorLimits.

Data Types: double |char|string

## Colormap - Color map for coloring points

' jet (256) ' (default) | predefined colormap name | M-by-3 array of RGB triplets
Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormpa' and a predefined colormap name or an $M$-by-3 array of RGB (red, blue, green) triplets that define $M$ individual colors. Colormap cannot be used with Colors.
Data Types: double | char \| string

## ColorLimits - Color limits for color map

two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. ColorLimits cannot be used with Colors.
Data Types: double

## Transparency - Transparency of contour map

0.4 (default) | numeric scalar in the range of [0,1]

Transparency of the contour plot, specified as a numeric scalar in the range [0,1], where 0 is completely transparent and 1 is completely opaque.
Data Types: double
ShowLegend - Show color legend on map
true (default) | false
Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend ' and true or false.

Data Types: logical

## LegendTitle - Title of color legend

character vector | string scalar
Title of color legend, specified as the comma-separated pair consisting of 'LegendTitle' and a character vector or a string scalar.

Data Types: string | char

## Map - Map for surface data

siteviewer object
Map for surface data, specified as the comma-separated pair consisting of 'Map' and a siteviewer object. The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: char|string

## See Also

Introduced in R2020a

## coverage

Display coverage map

## Syntax

```
coverage(tx)
coverage(tx,propmodel)
coverage(tx,rx)
coverage(tx,rx,propmodel)
coverage( ___,Name,Value,
```

$\qquad$
pd = coverage(tx,
$\qquad$ )

## Description

coverage (tx) displays the coverage map for the transmitter site. Each colored contour of the map defines an area where the corresponding signal strength is transmitted to the mobile receiver.
coverage(tx, propmodel) displays the coverage map based on the specified propagation model.
coverage ( $t x, r x$ ) displays the coverage map based on the receiver site properties.
coverage(tx,rx, propmodel) displays the coverage map based on the receiver site properties and specified propagation model.
coverage (__, Name, Value, ___ ) displays the coverage map using additional options specified by the Name, Value pairs.
$\mathrm{pd}=$ coverage(tx,__ ) returns computed coverage data in the propagation data object, pd. No plot is displayed and any graphical only name-value pairs are ignored.

## Examples

## Coverage Map of Transmitter

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
    'Latitude', 42.3001, ...
    'Longitude', -71.3503);
```

Show the coverage map.
coverage(tx)

## Coverage Map Using Transmitter and Receiver

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
    'Latitude', 42.3001, ...
    'Longitude', -71.3503);
```

Create a receiver site at Fenway Park with an antenna height of 1.2 m and system loss of 10 dB .

```
rx = rxsite('Name','Fenway Park', ...
```

    'Latitude',42.3467, ...
    'Longitude',-71.0972,'AntennaHeight',1.2,'SystemLoss',10);
    Calculate the coverage area of the transmitter using a close-in propagation model.

```
coverage(tx,rx,'PropagationModel','closein')
```

## Coverage Map for Strong and Weak Signals

Define strong and weak signal strengths with corresponding colors.

```
strongSignal = -75;
strongSignalColor = "green";
weakSignal = -90;
weakSignalColor = "cyan";
```

Create a transmitter site and display the coverage map.
tx = txsite('Name','MathWorks','Latitude', 42.3001,'Longitude', -71.3503);
coverage(tx,'SignalStrengths',[strongSignal,weakSignal], ...
'Colors', [strongSignalColor,weakSignalColor])

## Combined Coverage Map of Multiple Transmitters

Define the names and the locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create the transmitter site array.
txs = txsite('Name', names,...
'Latitude',lats,...
'Longitude',lons, ...
'TransmitterFrequency',2.5e9) ;
Display the combined coverage map for multiple signal strengths, using close-in propagation model. coverage(txs,'close-in','SignalStrengths',-100:5:-60)

## Coverage Map Using Longley-Rice and Ray Tracing Method

Launch Site Viewer using buildings in Chicago.
viewer = siteviewer("Buildings","chicago.osm");

Create a transmitter site on the building.

```
tx = txsite('Latitude',41.8800, ...
    'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
show(tx)
```

## Coverage Map Using Longley-Rice Propagation Model

Create a coverage map of the city using the Longley-Rice propagation model. coverage(tx,"SignalStrengths",-100:-5,"MaxRange",250,"Resolution",1)

Longley-Rice models over-the-rooftops propagation along vertical slices and obstructions tend to dominate the coverage region.

## Coverage Map Using Ray Tracing Propagation Model

Create a coverage map of the city using the ray tracing image method propagation model.

```
coverage(tx,"raytracing-image-method","SignalStrengths",-100:-5,"MaxRange", 250, "Resolution",2)
```

This coverage map shows new regions that are in service due to reflected propagation paths.

## Input Arguments

## tx - Transmitter site

txsite object|array of txsite objects
Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

## rx - Receiver site

rxsite object
Receiver site, specified as an rxsite object. You can also use the name-value pairs
'ReceiverGain' and 'ReceiverAntennaHeight' to specify the receiver values.

## propmodel - Propagation model

character vector | string
Propagation model, specified as a character vector or string. You can also use the name-value pair ' PropagationModel' to specify this parameter. You can also use the propagationModel function to define this input. The default propagation model is 'longeley-rice' when terrain is enabled and ' freespace' when terrain is disabled.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Type','power'

## Type - Type of signal strength to compute

'power' (default)|'efield'
Type of signal strength to compute, specified as the comma-separated pair consisting of 'Type ' and 'power' or 'efield'.

When type is 'power', SignalStrengths is expressed in power units ( dBm ) of the signal at the mobile receiver input. When type is 'efield', SignalStrengths is expressed in electric field strength units ( $\mathrm{dB} \mu \mathrm{V} / \mathrm{m}$ ) of signal wave incident on the antenna.

Data Types: char

## SignalStrengths - Signal strengths to display on coverage map <br> numeric vector

Signal strengths to display on coverage map, specified as the comma-separated pair consisting of 'SignalStrengths' and a numeric vector.

Each strength uses different colored filled contour on the map. The default value is -100 dBm if the 'Type' name-value pair is 'power' and $40 \mathrm{~dB} \mathrm{\mu V} / \mathrm{m}$ if 'Type' is 'efield'.
Data Types: double

## PropagationModel - Propagation model to use for path loss calculations <br> 'longley-rice' (default)|'freespace'|'close-in'|'rain'|'gas'|'fog'| <br> 'raytracing-image-method' | propagation model object

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and 'freespace', close-in', 'rain', 'gas','fog', 'longley-rice', 'raytracing-image-method', or as an object created using the propagationModel function. The default propagation model is 'longeley-rice' when terrain is enabled and 'freespace' when terrain is disabled. If 'raytracing-image-method ' is specified, the value of 'MaxNumReflections ' property must be lesser than 1.

## Data Types: char

## MaxRange - Maximum range of coverage map from each transmitter site

numeric scalar
Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the propagation model type as shown:

| Propagation Model | MaxRange |
| :--- | :--- |
| Basic or urban | Range of minimum value in SignalStrengths. |
| Terrain | 30 km or distance to the furthest building. |

| Propagation Model | MaxRange |
| :--- | :--- |
| Multipath | 500 m |

## Data Types: double

## Resolution - Resolution of coverage map

'auto' (default) | numeric scalar
Resolution of coverage map, specified as the comma-separated pair consisting of 'Resolution' and a numeric scalar in meters.

The resolution of 'auto' computes the maximum value scaled to 'MaxRange'. Decreasing the resolution increases the quality of the coverage map and the time required to create it.
Data Types: char | double

## ReceiverGain - Mobile receiver gain

2.1 (default) | numeric scalar

Mobile receiver gain, specified as the comma-separated pair consisting of 'ReceiverGain' and a numeric scalar in dB . The receiver gain value includes the mobile receiver antenna gain and system loss.

The receiver gain computes received signal strength when the 'Type' is 'power'.
If receiver site argument $r x$ is passed to coverage, the default value is the maximum gain of the receiver antenna with the system loss subtracted. Otherwise the default value is 2.1 .
Data Types: char | double

## ReceiverAntennaHeight - Mobile receiver antenna height above ground elevation

1 (default) | numeric scalar
Mobile receiver antenna height above ground elevation, specified as the comma-separated pair consisting of 'ReceiverAntennaHeight' and a numeric scalar in meters.

If receiver site argument $r x$ is passed to coverage, the default value is the AntennaHeight of the receiver. Otherwise the default value is 1 .
Data Types: double

## Colors - Colors of filled contours on coverage map

M-by-3 array of RGB triplets | array of strings | cell array of character vectors
Filled contours color of coverage map, specified as the comma-separated pair consisting of 'Colors ' and an $M$-by- 3 array of RGB triplets, an array of strings, or a cell array of character vectors.

Colors are assigned element-wise to 'SignalStrengths ' values for coloring the corresponding filled contours.
'Colors' cannot be used with 'ColorLimits' or 'ColorMap'.
For more information, see ColorSpec (Color Specification).
Data Types: char | string | double

## ColorLimits - Color limits for colormap

two-element vector
Color limits for colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of type [min max].

The color limits indicate the signal level values that map to the first and last colors on the colormap.
The default value is [-120-5] if the 'Type' name-value pair is 'power' and [20 135] if 'Type' is 'efields'.
'ColorLimits ' cannot be used with 'Color'.
Data Types: double

## ColorMap - Colormap filled contours for coverage map

' jet ' (default) | predefined color map | M-by-3 array of RGB triplets
Colormap filled contours on coverage map, specified as the comma-separated pair consisting of
' ColorMap ' and a predefined colormap or $M$-by-3 array of RGB triplets, where $M$ defines individual colors.
'ColorMap' cannot be used with 'Colors'.
Data Types: char | double

## ShowLegend - Show signal strength color legend on map

true (default) | false
Show signal strength color legend on map, specified as the comma-separated pair consisting of 'ShowLegend ' and true or false.
Data Types: logical

## Transparency - Transparency of coverage map

0.4 (default) | numeric scalar

Transparency of coverage map, specified as the comma-separated pair consisting of 'Transparency ' and a numeric scalar in the range 0 to 1.0 is transparent and 1 is opaque.

## Data Types: double

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.

Data Types: char|string

## Output Arguments

## pd - Coverage data

propagationData object
Coverage data, returned as a propagationData object consisting of Latitude and Longitude, and a signal strength variable corresponding to the plot type. Name of the propagationData is "Coverage Data".

## distance

Distance between sites

## Syntax

d = distance(site1,site2)
d = distance(site1,site2,path)
d = distance( $\qquad$ , Name, Value)

## Description

$\mathrm{d}=$ distance(site1, site2) returns the distance in meters between site1 and site 2 .
d = distance(site1, site2, path) returns the distance using a specified path type, either Euclidean or great circle path.
d = distance( $\qquad$ , Name, Value) returns the distance with additional options specified by namevalue pairs.

## Examples

## Distance Between Transmitter and Receiver Site

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the Euclidean distance in km between the sites.

```
dme = distance(tx,rx)
dme = 2.1504e+04
dkm = dme / 1000
dkm = 21.5037
```

Get the great circle distance between the two sites.

```
dmg = distance(tx,rx,'greatcircle')
dmg = 2.1451e+04
```

## Input Arguments

## sitel, site2 - Transmitter or receiver site

txsite or rxsite object

Transmitter or receiver site, specified as a txsite or rxsite. You can use array inputs to specify multiple sites.

## path - Measurement path type <br> 'euclidean'|'greatcircle'

Measurement path type, specified as one of the following:

- 'euclidean ': Uses the shortest path through space that connects the antenna center positions of the site 1 and site 2 .
- 'greatcircle': Uses the shortest path on the surface of the earth that connects the latitude and longitude locations of site 1 and site 2. This path uses a spherical Earth model.

## Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## Example: 'Map','siteviewerl'

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none ', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.
Data Types: char | string

## Output Arguments

## d - Distance between sites

$M$-by- $N$ numeric array
Distance between sites, returned as $M$-by- $N$ arrays in degrees. $M$ is the number of sites in site 2 and $N$ is the number of sites in site 1.

See Also<br>angle<br>\section*{Introduced in R2019b}

## elevation

Elevation of site

## Syntax

z = elevation(site)
z = elevation( $\qquad$ ,Name, Value)

## Description

$z=$ elevation(site) returns the ground or building surface elevation of antenna site in meters. Elevation is measured relative to mean sea level using earth gravitational model, EGM-96. If the site coincides with a building, elevation is measured at the top of the building. Otherwise, elevation is measured at the ground.
z = elevation( $\qquad$ ,Name, Value) returns the ground elevation of the antenna in meters with additional options specified by name-value pairs.

## Examples

## Elevation at Mount Washington

Compute and display the elevation at Mount Washington in meters.

```
mtwash = txsite('Name','Mt Washington','Latitude',44.2706, ...
    'Longitude',-71.3033);
z = elevation(mtwash)
z = 1.8675e+03
```

## Input Arguments

site - Transmitter or receiver site
txsite or rxsite object | array of txsite or rxsite objects
Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'Map','siteviewer1'

## Map - Map for visualization or surface data

siteviewer object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.
Data Types: char | string

## Output Arguments

## z - Ground or building surface elevation of antenna site <br> M-by-1 matrix

Ground or building surface elevation of the antenna site, returned as an $M$-by-1 matrix with each element unit in meters. $M$ is the number of sites in site.

## See Also

## Introduced in R2019b

## getDataVariable

Get data variable values of data points in propagation data object

## Syntax

```
datavariable = getDataVariable(pd)
[datavariable,lat,lon] = getDataVariable(pd)
[___] = getDataVariable(pd,varname)
```

## Description

datavariable $=$ getDataVariable(pd) returns the values of the data points in the propagation data object. The data is processed such that the missing values are removed and duplicate location data are replaced with mean values.
[datavariable,lat,lon] = getDataVariable(pd) returns the location coordinates of the data points in the propagation data object.
[___] = getDataVariable(pd, varname) returns the values of the data points corresponding to the varname variable.

## Examples

## Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
Create an array of transmitter sites.
```

```
txs = txsite("Name",names,...
```

txs = txsite("Name",names,...
"Latitude",lats,...
"Latitude",lats,...
"Longitude",lons, ...
"Longitude",lons, ...
"TransmitterFrequency",2.5e9);
"TransmitterFrequency",2.5e9);
show(txs)

```
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.
sv1 = siteviewer("Name","SINR map");
sinr(txs,"MaxRange",5000)

Return SINR propagation data.
pd = sinr(txs,"MaxRange", 5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
Compute capacity using the Shannon-Hartley theorem.
bw = 1e6; \% Bandwidth is 1 MHz
sinrRatio $=10 . \wedge(s i n r D b . / 10)$; $\%$ Convert from $d B$ to power ratio
capacity $=b^{*} \log 2(1+s i n r R a t i o) / 1 e 6 ; ~ \% ~ U n i t: ~ M b p s$
Create new propagation data for capacity and display the contour plot.
pdCapacity $=$ propagationData(lats,lons,"Capacity", capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)"; contour(pdCapacity,"LegendTitle", legendTitle);

## Input Arguments

pd - Propagation data
propagationData object (default)
Propagation data, specified as a propagationData object.
varname - Variable name in data table
character vector | string scalar
Variable name in the data table, specified as a character vector or a string scalar. This variable name must correspond to a variable with numeric data other than the latitude or longitude data.

## Output Arguments

## datavariable - Values of data points

column vector
Values of data points in the propagation data object, returned as a column vector.

## lat - Latitude of data points

M-by-1 vector
Latitude of data points, returned as an $M$-by-1 vector with each element unit in degrees.

## lon - Longitude of data points

$M$-by-1 vector
Longitude of data points, returned as an $M$-by-1 matrix with each element unit in degrees. The output is wrapped so that the values are in the range [-180 180].

## See Also

Introduced in R2020a

## hide

Hide site location on map

## Syntax

hide(site)
hide( ___ ,Name, Value)

## Description

hide(site) hides the site location of the antenna site on a map.
hide (__ , Name, Value) hides the site location with additional options specified by one or more name-value pairs.

## Examples

## Show and Hide Transmitter Site

Create a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504);
```

Show the transmitter site.

```
show(tx)
```

Hide the transmitter site.
hide(tx)

## Input Arguments

## site - Transmitter or receiver site

txsite or rxsite object|array of txsite or rxsite objects
Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Map','siteviewer1'

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.

Data Types: char \| string

## See Also

show

Introduced in R2019b

## interp

Geographic data interpolation

## Syntax

```
interpvalue = interp(pd,lat,lon)
interpvalue = interp(pd,Name,Value)
```

## Description

interpvalue $=$ interp(pd,lat,lon) returns interpolated values from the propagation data for each query point specified in latitude and longitude vectors. The interpolation is performed using a scattered data interpolation method. Values corresponding to query points outside the data region are assigned a NaN.
interpvalue $=$ interp(pd,Name,Value) returns interpolated values with additional options specified by name-value pair arguments.

## Examples

## Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
    "Latitude",lats,...
    "Longitude",lons, ...
    "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1),"MaxRange",maxr);
pd2 = coverage(txs(2),"MaxRange",maxr);
pd3 = coverage(txs(3),"MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
Create grid of locations over rectangle.
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
```

```
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

```
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
Plot minimum received power, which shows the weakest signal received from any transmitter site.
The area shown may correspond to the service area of triangulation using the three transmitter sites.

## Input Arguments

```
pd - Propagation data
propagationData object (default)
```

Propagation data, specified as a propagationData object.

## lat - Latitude coordinate values

vector
Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84. The latitude coordinates must be in the range [-90 90].

## lon - Longitude coordinate values

vector
Longitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'Method','linear'

## DataVariableName - Data variable to interpolate

character vector | string scalar
Data variable to interpolate, specified as the comma-separated pair consisting of
'DataVariableName' and a character vector or string scalar corresponding to a variable name in the data table used to create the propagationData container object. The default value is the DataVariableName property in the propagationData.
Data Types: char|string

## Method - Method used to interpolate data

'natural' (default)|'nearest'|'linear'
Method used to interpolate data, specified as the comma separated-pair consisting 'Method ' and one of the following:

- 'natural' - Natural neighbor interpolation
- 'linear' - Linear interpolation
- 'nearest' - Nearest neighbor interpolation

Data Types: char|string

## Output Arguments

## interpvalue - Interpolated values from propagation data numeric vector

Interpolated values from the propagation data for each query point specified in latitude and longitude vectors, returned as a numeric vector.

## See Also

Introduced in R2020a

## link

Display communication link on map

## Syntax

link(rx,tx)
link(rx,tx, propmodel)
link( _, Name,Value)
status = link( $\qquad$ )

## Description

link( $r x, t x$ ) plots a one-way point-to-point communication link between a receiver site and transmitter site. The plot is color coded to identify the link success status.
link(rx,tx, propmodel) plots the communication link based on the specified propagation model.
link( ,Name, Value) plots a communication link using additional options specified by Name, Value pairs.
status = link( $\qquad$ ) returns the success status of the communication link as true or false.

## Examples

## Communication Link Between Transmitter and Receiver

Create a transmitter site.

```
tx = txsite('Name','MathWorks', ...
    'Latitude', 42.3001, ...
    'Longitude', -71.3503);
```

Create a receiver site with sensitivity defined in dBm .

```
rx = rxsite('Name','Boston', ...
    'Latitude', 42.3601, ...
    'Longitude', -71.0589, ...
    'ReceiverSensitivity', -90);
```

Plot the communication link between the transmitter and the receiver.
link(rx,tx)

## Input Arguments

rx - Receiver site
rxsite object | array of rxsite objects
Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

## tx - Transmitter site

txsite object | array of txsite objects
Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

## propmodel - Propagation model

character vector | string
Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel' to specify this parameter.
Data Types: char|string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'Type', 'power'

## PropagationModel - Propagation model to use for path loss calculations

'longley-rice' (default)|'freespace'|'close-in'|'rain'|'gas'|'fog'|
'raytracing-image-method ' | propagation model object
Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and 'freespace', close-in', 'rain', 'gas', 'fog', 'longley-rice', 'raytracing-image-method', or as an object created using the propagationModel function. The default propagation model is 'longeley-rice' when terrain is enabled and 'freespace' when terrain is disabled. If 'raytracing-image-method ' is specified, the value of 'MaxNumReflections ' property must be lesser than 1.

## Data Types: char

## SuccessColor - Color of successful links <br> 'green' (default) | RGB triplet | character vector

Color of successful links, specified as the comma-separated pair consisting of 'SuccessColor and an RGB triplet or character vector. For more information, see ColorSpec (Color Specification).
Data Types: char | double

## FailColor - Color of unsuccessful links

## ' red ' (default) | RGB triplet | character vector

Color of unsuccessful links, specified as the comma-separated pair consisting of 'FailColor and RGB triplet or character vector. For more information, see ColorSpec (Color Specification).

## Data Types: char | double

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.
Data Types: char | string

## Output Arguments

## status - Success status of communication link

M-by- $N$ array
Success status of communication links, returned as an $M$-by- $N$ arrays. $M$ is the number of transmitter sites and $N$ is the number of receiver sites.

## See Also

coverage | los | propagationModel | sigstrength | sinr

## Topics

ColorSpec (Color Specification)

Introduced in R2019b

## location

Location coordinates at a given distance and angle from site

## Syntax

```
sitelocation = location(site)
[lat,lon] = location(site)
[___] = location(site,distance,azimuth)
```

## Description

sitelocation $=$ location(site) returns the site location of the antenna.
[lat,lon] = location(site) returns the latitude and longitude of the antenna site.
[ ___ ] = location(site,distance, azimuth) returns the new location achieved by moving the antenna site by the distance specified in the direction of the azimuth angle. The location is calculated by moving along a great circle path using a spherical Earth model.

## Examples

## Location of Antenna Site

Create a site 1 km north of a given site.
Create the first transmitter site.

```
tx = txsite('Name','MathWorks',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504);
```

Calculate the location 1 km north of the first site.
[lat,lon] = location(tx,1000,90)
lat $=42.3091$
lon $=-71.3504$
Create a second transmitter site at the location specified by lat and lon.

```
tx2 = txsite('Name','Second transmitter', ...
    'Latitude',lat, ...
    'Longitude',lon);
```

Show the two transmitter sites.

```
show([tx,tx2])
```

## Input Arguments

## site - Antenna site

scalar | array
Antenna site, specified as a scalar or an array. It is either a txsite or a rxsite object. For more information, see txsite, and rxsite

Note If distance or azimuth is a vector, then site must be a scalar.

## distance - Distance to move antenna site

scalar | vector
Distance to move antenna site, specified as a scalar or vector in meters.
azimuth - Azimuth angle
scalar | vector
Azimuth angle, specified as a scalar or vector in degrees. Azimuth angle is measured counterclockwise from due east.

## Output Arguments

## sitelocation - Location of antenna site

M-by-2 matrix
Location of antenna site, returned as an $M$-by-2 matrix with each element unit in degrees. $M$ is the number of sites in sites. The location value includes the latitude and longitude of the antenna site.

## lat - Latitude of one or more antenna sites

M-by-1 vector
Latitude of one or more antenna sites, returned as an $M$-by- 1 vector with each element unit in degrees. $M$ is the number of sites in site.

## Lon - Longitude of one or more antenna sites

M-by-1 matrix
Longitude of one or more antenna sites, returned as an $M$-by- 1 matrix with each element unit in degrees. $M$ is the number of sites in site. The output is wrapped so that the values are in the range [-180 180].

See Also<br>angle|distance|rxsite|txsite

## Introduced in R2019b

## los

Plot or compute the line-of-sight (LOS) visibility between sites on a map

## Syntax

los(site1,site2)
los(site1, site2, Name, Value)
vis $=$ los(sitel,site 2, Name,Value)

## Description

los(site1, site2) plots the LOS from site 1 to site 2 . The plot is color coded to identify the visibility of the points along the LOS.
los(site1, site2,Name, Value) sets properties using one or more name-value pairs. For example, los(site1,site2,'ObstructedColor','red') plots the LOS using red to show blocked visibility.
vis $=$ los(site1, site2,Name, Value) returns the status of the LOS visibility.

## Examples

## LOS from a Transmitter Site to a Receiver Site

Plot the LOS from the MathWorks Apple Hill campus to the MathWorks Lakeside campus.
Create a transmitter site with an antenna of height 30 m .

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001,'Longitude',-71.3504,'AntennaHeight' ,30);
```

Create a receiver site with an antenna at ground level.

```
rx = rxsite('Name','MathWorks Lakeside', ...
    'Latitude',42.3021,'Longitude',-71.3764);
```

Plot the LOS between the two sites.

```
los(tx,rx);
```

## LOS from a Transmitter Site to Two Receiver Sites

Create a transmitter site with an antenna of height 30 m .
tx = txsite('Name','MathWorks Apple Hill',...
'Latitude',42.3001,'Longitude',-71.3504,'AntennaHeight' , 30);
Create two receiver sites with antennas at ground level.
names = ["Fenway Park","Bunker Hill Monument"];
lats $=$ [42.3467,42.3763];
lons $=[-71.0972,-71.0611] ;$
Create the receiver site array.
rxs = rxsite('Name', names,...
'Latitude',lats,...
'Longitude', lons) ;

Plot the lines of sight to the receiver sites. The red portion of the LOS represents obstructed visibility.
los(tx,rxs);

## Input Arguments

## sitel - Source antenna site

txsite object | rxsite object
Source antenna site, specified as a txsite object or a rxsite object. Site 1 must be a single site object.

## site2 - Target antenna site

txsite object | rxsite object | vector of txsite or rxsite objects
Target antenna site, specified as a txsite object or a rxsite object. Site 2 can be a single site object or a vector of multiple site objects.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.
Example: 'ObstructedColor','blue'

## VisibleColor - Plot color for successful visibility

'green' (default)| RGB triplet | character vector | color name string
Plot color for successful visibility, specified as an RGB triplet, a character vector, or a color name specified as a string. For more information, see ColorSpec (Color Specification).

## ObstructedColor - Plot color for blocked visibility

' red ' (default) | RGB triplet | character vector | color name string
Plot color for blocked visibility, specified as an RGB triplet, a character vector, or a color name specified as a string. For more information, see ColorSpec (Color Specification).

## Resolution - Sampling distance between two sites

'auto ' (default) | numeric scalar
Resolution of sample locations used to compute line-of-sight visibility, specified as 'auto ' or a numeric scalar expressed in meters. Resolution defines the distance between samples on the great circle path using a spherical Earth model. If Resolution is 'auto', the function computes a value based on the distance between the sites.

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.
Data Types: char | string

## Output Arguments

## vis - Status of LOS visibility

'true'|'false'|n-by 1 logical array
Status of LOS visibility, returned as 'true' or 'false'. If there are multiple target sites, the function returns a logical array of $n$-by- 1 .

## Topics

ColorSpec (Color Specification)

## Introduced in R2019b

## pathloss

Path loss of radio wave propagation

## Syntax

```
pl = pathloss(propmodel,rx,tx)
pl = pathloss(
```

$\qquad$

``` ,Name, Value) [pl,info] = pathloss(
``` \(\qquad\)
``` )
```

## Description

$\mathrm{pl}=$ pathloss(propmodel, $\mathrm{rx}, \mathrm{tx}$ ) returns the path loss of radio wave propagation at the receiver site from the transmitter site.
pl = pathloss( $\qquad$ , Name, Value) returns the path loss using additional options specified by Name, Value pairs.
[pl,info] = pathloss( $\qquad$ ) returns the path loss and the information about the propagation paths.

## Examples

## Path Loss of Receiver In Heavy Rain

Specify the transmitter and the receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504, ...
    'TransmitterFrequency', 2.5e9);
rx = rxsite('Name','Fenway Park',...
    'Latitude',42.3467, ...
    'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
pm =
    Rain with properties:
        RainRate: 50
            Tilt: 0
```

Calculate the pathloss at the receiver using the rain propagation model.

```
pl = pathloss(pm,rx,tx)
pl = 127.1559
```

## Input Arguments

## propmodel - Propagation model

character vector or string
Propagation model, specified as a character vector or string.
Data Types: char
rx - Receiver site
rxsite object
Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.
Data Types: char

## tx - Transmitter site <br> txsite object

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.
Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Map', 'none'

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.
Data Types: char \| string

## Output Arguments

## pl - Path loss

scalar | $M$-by- $N$ arrays
Path loss, returned as a scalar or $M$-by- $N$ arrays with each element in decibels. $M$ is the number of TX sites and $N$ is the number of RX sites.

Path loss is computed along the shortest path shortest path through space connecting the transmitter and receiver antenna centers.

For terrain propagation models, path loss is computed using terrain elevation profile that is computed at sample locations on the great circle path between the transmitter and the receiver. If Map is a
siteviewer object with buildings specified, the terrain elevation is adjusted to include the height of the buildings.

## info - Information corresponding to each propagation path

$M$-by- $N$ struct array | $M$-by- $N$ cell array containing vector of structs in each cell
Information corresponding to each propagation path, returned as a $M$-by- $N$ cell array containing vector of structs in each cell for ray-tracing-image-method propagation model and $M$-by- $N$ struct array fro all other propagation models. The field and values for the structures are:

- PropagationDistance - Total distance of propagation path returned as a double scalar in meters.
- AngleOfDeparture - Angle of departure of signal from transmitter site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- AngleOfArrival - Angle of arrival of signal at receiver site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- NumReflections - Number of reflections undergone by signal along propagation path, returned specified as 0,1 , or 2 . This field and value is only for raytrtacing-image-method.

Angle values are defined using the antenna's local East-North-Up coordinate system. Azimuth angle is measured counter-clockwise from east in the range 0 to 360, and elevation angle is measured from the horizontal plane in the range -90 to 90 .

See Also<br>propagationModel|range<br>\section*{Introduced in R2019b}

## plot

Plot propagation data on map

## Syntax

plot(pd)
plot( $\qquad$ ,Name, Value)

## Description

plot (pd) plots the propagation data on a map. Each data point is displayed as a circular marker that is colored according to the corresponding value.
plot( $\qquad$ , Name, Value) plots the propagation data with additional options specified by namevalue pair arguments.

## Examples

## Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files.

```
viewer = siteviewer("Basemap","streets_dark",...
    "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...
    "Longitude",-74.0114,...
    "AntennaHeight",80);
show(tx)
```

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
    linspace(40.71416, 40.715505, 25), ...
    linspace(40.715505, 40.7133, 25),
    linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
    linspace(-74.00627 ,-74.0092, 25), ...
    linspace(-74.0092, -74.0110, 25), ...
    linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a propagationData object to hold computed signal strength data.
$\mathrm{tbl}=$ table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

## Input Arguments

## pd - Propagation data

propagationData object (default)
Propagation data, specified as a propagationData object.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Type', 'power'

## DataVariableName - Data variable to plot

pd. DataVariableName (default) | character vector | string scalar
Data variable to plot, specified as the comma-separated pair consisting of 'DataVariableName ' and a character vector or a string scalar corresponding to a variable name in the data table used to create the propagation data container object pd. The default value is dynamic and corresponds to the DataVariableName property of the propagationData object.

## Data Types: char|string

## Type - Type of value to plot

'custom' (default)|'power'|'efield'|'sinr'|'pathloss'
Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the Type column:

| Type | ColorLimits | LegendTitle |
| :--- | :--- | :--- |
| 'custom' | $[$ min(Data) max(Data) $]$ | '' |
| 'power' | $\left[\begin{array}{ll}-120-5\end{array}\right]$ | 'Power (dBm)' |
| 'efield' | $\left[\begin{array}{ll}20 & 135\end{array}\right]$ | 'E-field (dBuV/m)' |
| 'sinr' | $\left[\begin{array}{ll}-5 & 20\end{array}\right]$ | 'SINR (dB) ' |
| 'pathloss' | $\left[\begin{array}{ll}45 & 160\end{array}\right]$ | 'Path loss (dB)' |

The default value for Levels is a linearly spaced vector bounded by ColorLimits.
Data Types: char | string

## Levels - Data value levels to plot

numeric vector
Data value levels to plot, specified as the comma-separated pair consisting of 'Levels ' and a numeric vector. The propagation data is binned according to Levels. The data in each bin is color coded according to the corresponding level. The colors are selected using Colors if specified, or else Colormap and ColorLimits. Data points with values below the minimum level are not included in the plot.

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

## Data Types: double

## Colors - Colors of data points

M-by-3 array of RGB | array of strings | cell array of character vectors
Colors of the data points, specified as the comma-separated pair consisting of 'Colors' and an M-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in Levels for coloring the corresponding points. Colors cannot be used with Colormap and ColorLimits.

## Data Types: double | char|string

## Colormap - Color map for coloring points <br> ' jet (256) ' (default) | predefined colormap name | M-by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormap ' and a predefined colormap name or an $M$-by-3 array of RGB (red, blue, green) triplets that define $M$ individual colors. Colormap cannot be used with Colors.
Data Types: double \| char \| string

Color limits for the colormap, specified as the comma-separated pair consisting of 'ColorLimits ' and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. ColorLimits cannot be used with Colors.
Data Types: double

## MarkerSize - Size of data markers

10 (default) | positive numeric scalar
Size of data markers plotted on the map, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric scalar in pixels.
Data Types: double
ShowLegend - Show color legend on map
true (default) | false
Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend ' and true or false.

Data Types: logical

## LegendTitle - Title of color legend

character vector | string scalar
Title of color legend, specified as the comma-separated pair consisting of 'LegendTitle' and a character vector or a string scalar.

Data Types: string | char

## Map - Map for surface data

siteviewer object
Map for surface data, specified as the comma-separated pair consisting of 'Map' and a siteviewer object. The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: char|string

## See Also

Introduced in R2020a

## location

Data location coordinates

## Syntax

```
datalocation = location(pd)
[lat,lon] = location(pd)
```

## Description

datalocation $=$ location( pd ) returns the location coordinates of the data points in the propagation data object.
[lat,lon] = location(pd) returns the latitude and longitude of the propagation data object

## Examples

## Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
    "Latitude",lats,...
    "Longitude",lons, ...
    "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1),"MaxRange",maxr);
pd2 = coverage(txs(2),"MaxRange",maxr);
pd3 = coverage(txs(3),"MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
Create grid of locations over rectangle.
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
Create propagation data containing minimum received power values.
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.
sensitivity = -110;
contour(pd,"Levels", sensitivity:-5,"Type", "power")

## Input Arguments

## pd - Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

## Output Arguments

## datalocation - Location coordinates of data points <br> M-by-2 matrix

Location of antenna site, returned as an $M$-by-2 matrix with each element unit in degrees. $M$ is the number of rows in the data table with valid latitude and longitude values. Duplicate locations are not removed.

## lat - Latitude of data points

$M$-by-1 vector
Latitude of data points, returned as an $M$-by-1 vector with each element unit in degrees.

## Lon - Longitude of data points

$M$-by-1 vector
Longitude of data points, returned as an $M$-by-1 matrix with each element unit in degrees. The output is wrapped so that the values are in the range [-180 180].

## See Also

Introduced in R2020a

## propagationModel

Create RF propagation model

## Syntax

```
pm = propagationModel(modelname)
pm = propagationModel(
```

$\qquad$

``` ,Name, Value)
```

## Description

pm = propagationModel(modelname) creates an RF propagation model for the specified model.
pm = propagationModel $\qquad$ ,Name, Value) sets properties using one or more name-value pairs. For example, pm = propagationModel('rain','RainRate',96) creates a rain propagation model with a rain rate of $96 \mathrm{~mm} / \mathrm{h}$. Enclose each property name in quotes.

## Examples

## Signal Strength of Receiver in Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504, ..
    'TransmitterFrequency', 2.5e9);
rx = rxsite('Name','Fenway Park',...
    'Latitude',42.3467, ...
    'Longitude',-71.0972);
```

Create the propagation model for a heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
pm =
    Rain with properties:
        RainRate: 50
            Tilt: 0
```

Calculate the signal strength at the receiver using the rain propagation model.

```
ss = sigstrength(rx,tx,pm)
ss = -87.1559
```

## Longley-Rice Propagation Model

Create a transmitter site.

```
tx = txsite
tx =
    txsite with properties:
                    Name: 'Site 1'
                Latitude: 42.3001
            Longitude: -71.3504
                        Antenna: 'isotropic'
            AntennaAngle: 0
            AntennaHeight: 10
                    SystemLoss: 0
        TransmitterFrequency: 1.9000e+09
            TransmitterPower: 10
```

Create a Longley-Rice propagation model using the propagationModel function.

```
pm = propagationModel('longley-rice','TimeVariabilityTolerance',0.7)
pm =
    LongleyRice with properties:
            AntennaPolarization: 'horizontal'
                GroundConductivity: 0.0050
                    GroundPermittivity: 15
            AtmosphericRefractivity: 301
                    ClimateZone: 'continental-temperate'
            TimeVariabilityTolerance: 0.7000
                SituationVariabilityTolerance: 0.5000
```

Find the coverage of the transmitter site using the defined propagation model.

```
coverage(tx,'PropagationModel',pm)
```

## Input Arguments

modelname - Type of propagation model
'freespace'|'rain'|'gas'|'fog'|'close-in'|'longley-rice'
Type of propagation model:

- 'freespace ' - Free space propagation model
- 'rain' - Rain propagation model. For more information, see [3].
- 'gas' - Gas propagation model
- ' fog ' - Fog propagation model. For more information, see [2] (Antenna Toolbox).
- 'close-in' - Close-in propagation model typically used in urban macro cell scenarios. For more information, see [1].

Note The close-in model implements a statistical path loss model and can be configured for different scenarios. The default values correspond to an urban macro-cell scenario in a non-line-ofsight (NLOS) environment.

- ' longley-rice' - Longley-Rice propagation model. This model is also known as Irregular Terrain Model (ITM). You can use this model to calculate point-to-point path loss between sites over irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. For more information and list of limitations, see [4].

Note The Longley-Rice model implements the point-to-point mode of the model, which uses terrain data to predict the loss between two points.

- 'tirem' -- Terrain Integrated Rough Earth Model ${ }^{\mathrm{TM}}\left(\right.$ TIREM $^{\mathrm{TM}}$ ). You can use this model to calculate point-to-point path loss between sites over irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. The model needs access to an external TIREM library. The actual model is valid from 1 MHZ to 1000 GHz . But with Antenna Toolbox elements and arrays the frequency range is limited at 200 GHz .
- 'raytracing-image-method' - The ray tracing propagation model is a multipath propagation model that uses ray tracing analysis to compute propagation paths and their corresponding path losses. Path loss is calculated from free-space loss, reflection loss due to material, and antenna polarization loss. The ray tracing analysis uses the method of images, which includes surface reflections but does not include effects from refraction, diffraction, or scattering. This model is valid from 100 MHz to 100 GHz .

You can use the following functions on RF propagation models:

- range - Calculate the range of the radio wave under different propagation scenarios. range function does not support Longley-Rice or TIREM propagation models. This function does not support the TIREM or 'raytracing-image-method ' propagation models.
- pathloss - Calculate the path loss of radio wave propagation between the transmitter and receiver sites under different propagation scenarios.
- add - Add propagation models.

## Dependencies

To specify 'tirem ' , requires the Antenna Toolbox.

## Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

## Example: 'RainRate',50

## Rain

## RainRate - Rain rate

16 (default) | positive scalar
Rain rate, specified as a positive scalar in millimeters per hour ( $\mathrm{mm} / \mathrm{h}$ ).

## Dependencies

To specify 'RainRate', you must specify 'rain' propagation model.

## Data Types: double

## Tilt - Polarization tilt angle of the signal

0 (default) | scalar
Polarization tilt angle of the signal, specified as scalar in degrees.

## Dependencies

To specify 'Tilt', you must specify 'rain' propagation model.
Data Types: double
Gas
Temperature - Air temperature
15 (default) | scalar
Air temperature, specified as a scalar in Celsius (C).

## Dependencies

To specify 'Temperature', you must specify 'gas ' propagation model.
Data Types: double

## AirPressure - Dry air pressure

101300 (default) | scalar
Dry air pressure, specified as a scalar in pascals (Pa).
Dependencies
To specify 'AirPressure', you must specify 'gas ' propagation model.
Data Types: double
WaterDensity - Water vapor density
7.5 (default) | scalar

Water vapor density, specified as a scalar in grams per cubic meter $\left(\mathrm{g} / \mathrm{m}^{3}\right)$.

## Dependencies

To specify 'WaterDensity', you must specify 'gas ' propagation model.
Data Types: double
Fog
Temperature - Air temperature
15 (default) | scalar
Air temperature, specified as a scalar in Celsius (C).
Dependencies
To specify 'Temperature', you must specify ' fog ' propagation model.
Data Types: double
WaterDensity - Liquid water density
0.5 (default) | scalar

Liquid water density, specified as a scalar in grams per cubic meter $\left(\mathrm{g} / \mathrm{m}^{3}\right)$.

## Dependencies

To specify 'WaterDensity', you must specify 'fog' propagation model.
Data Types: double

## Close-In

## ReferenceDistance - Free-space reference distance

1 (default) | scalar
Free-space reference distance, specified as a scalar in meters.

## Dependencies

To specify 'ReferenceDistance', you must specify the 'close-in' propagation model.
Data Types: double

## PathLossExponent - Path loss exponent

## 2.9 (default) | scalar

Path loss exponent, specified as a scalar.

## Dependencies

To specify 'PathLossExponent', you must specify 'close-in' propagation model.
Data Types: double

## Sigma - Standard deviation

5.7 (default) | scalar

Standard deviation of the zero-mean Gaussian random variable, specified as a scalar in decibels (dB).

## Dependencies

To specify 'Sigma', you must specify 'close-in' propagation model.

## Data Types: double

## NumDataPoints - Number of data points

1869 (default) | integer
Number of data points of zero-mean Gaussian random variable, specified as an integer.

## Dependencies

To specify 'NumPoints', you must specify 'close-in' propagation model.

## Data Types: double

Note The close-in model is valid for distances greater than or equal to the 'ReferenceDistance' property. If a distance less than the 'ReferenceDistance' is used, path loss is 0.

## Longley-Rice

AntennaPolarization - Polarization of transmitter and receiver antennas
'horizontal' (default)|'vertical'

Polarization of transmitter and receiver antennas, specified as 'horizontal' or 'vertical'. Both antennas are assumed to have the same polarization. This value is used to calculate path loss due to ground reflection.

## Dependencies

To specify 'AntennaPolarization', you must specify ' longley-rice' propagation model.
Data Types: char|string

## GroundConductivity - Conductivity of ground

0.005 (default) | scalar

Conductivity of the ground, specified as a scalar in Siemens per meter ( $\mathrm{S} / \mathrm{m}$ ). This value is used to calculate path loss due to ground reflection. The default value corresponds to average ground.

## Dependencies

To specify 'GroundConductivity', you must specify 'longley-rice' propagation model.

## Data Types: double

## GroundPermittivity - Relative permittivity of ground <br> 15 (default) | scalar

Relative permittivity of the ground, specified as a scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to average ground.

## Dependencies

To specify 'GroundPermittivity', you must specify 'longley-rice' propagation model.

## Data Types: double

## AtmosphericRefractivity - Atmospheric refractivity near ground

301 (default) | scalar
Atmospheric refractivity near the ground, specified as a scalar in N -units. This value is used to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

## Dependencies

To specify 'AtmosphericRefractivity', you must specify ' longley-rice' propagation model.
Data Types: double

## ClimateZone - Radio climate zone

'continental-temperate' (default)|'equatorial' |'continental-subtropical'| 'maritime-subtropical'|'desert'|maritime-over-land'|'maritime-over-sea'

Radio climate zone. This value is used to calculate the variability due to changing atmospheric conditions. The default value corresponds to average atmospheric conditions in a particular climate zone.

## Dependencies

To specify 'ClimateZone', you must specify ' longley-rice' propagation model.

Data Types: char | string

## TimeVariabilityTolerance - Time variability tolerance level

0.5 (default) | scalar

Time variability tolerance level of the path loss, specified as a scalar between [0.001, 0.999]. Time variability occurs due to changing atmospheric conditions. This value gives the required system reliability or the fraction of time during which the actual path loss is expected to be less than or equal to model prediction. For more information, see [5].

## Dependencies

To specify 'TimeVariabilityTolerance', you must specify 'longley-rice' propagation model.

## Data Types: double

## SituationVariabilityTolerance - Situation variability tolerance level <br> 0.5 (default) | scalar

Situation variability tolerance level of the path loss, specified as a scalar in between [0.001, 0.999]. Situation variability occurs due to uncontrolled or hidden random variables. This value gives the required system confidence or the fraction of similar situations for which the actual path loss is expected to be less than or equal to the model prediction. For more information, see [5].

## Dependencies

To specify 'SituationVariabilityTolerance', you must specify 'longley-rice' propagation model.
Data Types: double

## TIREM

## AntennaPolarization - Polarization of transmitter and receiver antennas

'horizontal' (default) | 'vertical'
Polarization of transmitter and receiver antennas, specified as 'horizontal' or 'vertical '. Both antennas are assumed to have the same polarization. This value is used to calculate path loss due to ground reflection.

## Dependencies

To specify 'AntennaPolarization', you must specify 'tirem' propagation model.

```
Data Types: char | string
```

## GroundConductivity - Conductivity of ground

0.005 (default) | numeric scalar

Conductivity of the ground, specified as a numeric scalar in Siemens per meter ( $\mathrm{S} / \mathrm{m}$ ) in the range of 0.0005 to 100 . This value is used to calculate path loss due to ground reflection. The default value corresponds to average ground.

## Dependencies

To specify 'GroundConductivity', you must specify 'tirem' propagation model.
Data Types: double

## GroundPermittivity - Relative permittivity of ground <br> 15 (default) | numeric scalar

Relative permittivity of the ground, specified as a numeric scalar in the range of 1 to 100 . Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate the path loss due to ground reflection. The default value corresponds to average ground.

## Dependencies

To specify 'GroundPermittivity', you must specify 'tirem' propagation model.

## Data Types: double

## AtmosphericRefractivity - Atmospheric refractivity near ground <br> 301 (default) | scalar

Atmospheric refractivity near the ground, specified as a numeric scalar in N-units in the range of 250 to 400 . This value is used to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

## Dependencies

To specify 'AtmosphericRefractivity', you must specify 'tirem' propagation model.
Data Types: double
Humidity - Absolute air humidity near ground
' 9 ' (default) | numeric scalar
Absolute air humidity near ground,specified as a numeric scalar in $\mathrm{g} / \mathrm{m}^{\wedge} 3$ units in the range of 0 to 110. You can use this value to calculate path loss due to atmospheric absorption. The default value corresponds to the absolute humidity of air at 15 degrees Celsius and 70 percent relative humidity.

## Dependencies

To specify 'Humidity', you must specify 'tirem' propagation model.

## Data Types: double

raytracing-image-method
MaxNumReflections - Maximum number of path reflections
1 (default) | 0 | 2
Maximum number of reflections in the propagation paths to search for using ray tracing, specified as 0,1 , or 2 . The default value results in a search for a line-of-sight propagation path along with propagation paths that each contain a single reflection.

## Dependencies

To specify 'MaxNumReflections', you must specify ' raytracing-image-method' propagation model.

Data Types: double

## BuildingsMaterial - Surface material of buildings

```
'concrete' (default)|'perfect-reflector'|'brick'|'wood'|'glass'|'metal' |
'custom'
```

Surface material of buildings, specified as one of the following: 'perfect-reflector',
'concrete', 'brick', 'wood', 'glass','metal', or 'custom'. The material type is used to calculate reflection loss where propagation paths reflect off of building surfaces. When
'BuildingsMaterial' is set to 'custom', the material permittivity and conductivity are specified in the BuildingsMaterialPermittivity and BuildingsMaterialConductivity properties.

## Dependencies

To specify 'BuildingsMaterial', you must specify 'raytracing-image-method' propagation model.

Data Types: char|string

## BuildingsMaterialPermittivity - Relative permittivity of buildings surface materials

 5.31 (default) | non-negative numeric scalarRelative permittivity of the buildings surface material, specified as a non-negative numeric scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz .

## Dependencies

To specify 'BuildingsMaterialPermittivity', you must specify 'raytracing-imagemethod' propagation model and set 'BuildingsMaterial' to 'custom'.
Data Types: double

## BuildingsMaterialConductivity - Conductivity of buildings surface materials <br> 0.0548 (default) | non-negative numeric scalar

Conductivity of the buildings surface material, specified as a non-negative numeric scalar in Siemens per meter ( $\mathrm{S} / \mathrm{m}$ ). This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz .

## Dependencies

To specify ' BuildingsMaterialConductivity ', you must specify 'raytracing-imagemethod' propagation model and set 'BuildingsMaterial' to 'custom'.
Data Types: double

## TerrainMaterial - Surface material of terrain

'concrete' (default)|'perfect-reflector'|'brick'|'water'|'vegetation'|'loam'| 'custom'

Surface material of terrain, specified as one of the following: 'perfect-reflector', 'concrete', 'brick', 'water', 'vegetation', 'loam', or 'custom'. The material type is used to calculate reflection loss where propagation paths reflect off of terrain surfaces. When 'TerrainMaterial' is set to 'custom', the material permittivity and conductivity are specified in the
'TerrainMaterialPermittivity' and 'TerrainMaterialConductivity' properties.

## Dependencies

To specify 'TerrainMaterial', you must specify 'raytracing-image-method ' propagation model.

Data Types: char | string

## TerrainMaterialPermittivity - Relative permittivity of terrain materials

5.31 (default) | non-negative numeric scalar

Relative permittivity of the terrain material, specified as a non-negative numeric scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz .

## Dependencies

To specify 'TerrainMaterialPermittivity', you must specify 'raytracing-image-method' propagation model and set 'TerrainMaterial' to 'custom'.
Data Types: double

## TerrainMaterialConductivity - Conductivity of terrain materials

0.0548 (default) | non-negative numeric scalar

Conductivity of the terrain material, specified as a non-negative numeric scalar in Siemens per meter $(\mathrm{S} / \mathrm{m})$. This value is used to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz .

## Dependencies

To specify 'TerrainMaterialConductivity ', you must specify 'raytracing-image-method' propagation model and set 'TerrainMaterial' to 'custom'.

Data Types: double

## More About

## Propagation models

Basic propagation models predict path loss as a function of distance between sites and assume line-of-sight (LOS) conditions, disregarding the curvature of the Earth, terrain, or other obstacles. Urban propagation models also predict path loss as a function of distance but use empirical models that are derived from measurements in non-line-of-sight (NLOS) conditions. Terrain propagation models predict path loss as a function of the terrain elevation profile between sites including buildings, which may be used to compute whether LOS or NLOS conditions apply.

## N -Units

The refractive index of air $n$ is related to the dielectric constants of the gas constituents of an air mixture. The numerical value of $n$ is only slightly larger than one. To make the calculation more convenient, you can use $N$ units which are given by the formula: $N=(n-1) \times 10^{6}$

## range

Range of radio wave propagation

## Syntax

$r=$ range(propmodel,tx, pl)

## Description

$r=r a n g e(p r o p m o d e l, t x, p l)$ returns the range of radio wave propagation from the transmitter site.

## Examples

## Range of Transmitter In Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504, ...
    'TransmitterFrequency', 2.5e9);
rx = rxsite('Name','Fenway Park',...
    'Latitude',42.3467, ...
    'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
pm =
    Rain with properties:
        RainRate: 50
            Tilt: 0
```

Calculate the range of transmitter using the rain propagation model and a path loss of 127 dB .
$r=r a n g e(p m, t x, 127)$
$r=2.0747 \mathrm{e}+04$

## Input Arguments

propmodel - Propagation model
character vector or string
Propagation model, specified as a character vector or string.

Data Types: char
tx - Transmitter site
txsite object
Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.
Data Types: char
pl - Path loss
scalar
Path loss, specified as a scalar in decibels.
Data Types: double

## Output Arguments

r-range
scalar | M-by-1 arrays
Range, returned as a scalar or $M$-by-1 array with each element in meters. $M$ is the number of TX sites.

Range is the maximum distance for which the path loss does not exceed the value of specified pl .

See Also<br>pathloss | propagationModel<br>Introduced in R2019b

## raytrace

Plot propagation paths between sites

## Syntax

```
raytrace(tx,rx)
raytrace(tx,rx,propmodel)
raytrace(
```

$\qquad$

``` ,Name, Value)
rays = raytrace(
``` \(\qquad\)
``` )
```

## Description

raytrace ( $t x, r x$ ) plots the propagation paths from the transmitter site ( $t x$ ) to the receiver site ( $r x$ ). The propagation paths are found using ray tracing with the terrain and buildings data defined in the Site Viewer map. Each propagation path is color-coded according to the received power (dBm) or path loss $(\mathrm{dB})$ along the path.

Note The ray tracing analysis includes surface reflections but does not include effects from refraction, diffraction, or scattering.
raytrace(tx, rx, propmodel) plots the propagation paths from the transmitter site ( tx ) to the receiver site ( $r x$ ) based on the specified propagation model. To input building and terrain materials to calculate path loss, please use the ' raytracing-image-method' propagation model and set the properties to specify building materials.
raytrace( $\qquad$ , Name, Value) plots propagation paths with additional options specified by one or more name-value pairs.
rays $=$ raytrace (__ ) returns the propagation paths in rays.

## Examples

## Signal Strength Using Ray Tracing Image Method Propagation Model

Launch Site Viewer with buildings in Chicago.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...
```

    'Longitude',-87.6295, ...
    'TransmitterFrequency' ,2.5e9) ;
Create receiver site near another building.

```
rx = rxsite('Latitude',41.881352, ...
    'Longitude',-87.629771, ...
    'AntennaHeight',30);
```

Compute signal strength using ray tracing propagation model and default single-reflection analysis.
pm = propagationModel("raytracing-image-method");
ssOneReflection = sigstrength (rx,tx, pm)
ssOneReflection = -55.2839
Compute signal strength with analysis up to two reflections, where total received power is the cumulative power of all propagation paths
pm.MaxNumReflections = 2;
ssTwoReflections = sigstrength(rx,tx, pm)

```
ssTwoReflections = -53.1827
```

Observe effect of material by replacing default concrete material with perfect reflector.

```
pm.BuildingsMaterial = 'perfect-reflector';
ssPerfect = sigstrength(rx,tx,pm)
ssPerfect = -42.0872
```

Plot propagation paths.
raytrace(tx, rx, pm)

## Path Loss Due to Material Reflection and Atmosphere

Launch Site Viewer with buildings in Hong Kong.
viewer = siteviewer("Buildings","hongkong.osm");

Define transmitter and receiver sites to model a small cell scenario in a dense urban environment.

```
tx = txsite("Name","Small cell transmitter", ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaHeight",10, ...
    "TransmitterPower",5, ...
    "TransmitterFrequency",28e9);
rx = rxsite("Name","Small cell receiver", ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaHeight",1);
```

Create ray tracing propagation model for perfect reflection.

```
pm = propagationModel("raytracing-image-method", ...
    "BuildingsMaterial","perfect-reflector", ...
    "TerrainMaterial","perfect-reflector");
```

Visualize propagation paths and compute corresponding path losses.

```
raytrace(tx,rx,pm,"Type","pathloss")
raysPerfect = raytrace(tx,rx,pm,"Type","pathloss");
plPerfect = [raysPerfect{1}.PathLoss]
```

```
plPerfect = 1×3
    104.2656 104.2745 112.0095
```

Re-compute with material reflection loss by setting material type on the propagation model. The first value is unchanged because it corresponds to the line-of-sight propagation path.

```
pm.BuildingsMaterial = "glass";
pm.TerrainMaterial = "concrete";
raytrace(tx,rx,pm,"Type","pathloss")
raysMtrls = raytrace(tx,rx, pm,"Type","pathloss");
plMtrls = [raysMtrls{1}.PathLoss]
plMtrls = 1\times3
104.2656 106.2547 146.5527
```

## Input Arguments

## rx - Receiver site

rxsite object| array of rxsite objects
Receiver site, specified as a rxsite object or an array of rxsite objects. If the transmitter sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

## tx - Transmitter site

txsite object|array of txsite objects
Transmitter site, specified as a txsite object or an array of txsite objects. If the receiver sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

## propmodel - Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel ' to specify this parameter. You can also use the propagationModel function to define this input. The default propagation model is 'raytracing-image-method '.

## Data Types: char | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'Type', 'power'

## Type - Type of quantity to plot

'power' (default)|'pathloss'
Type of quantity to plot, specified as the comma-separated pair consisting of 'Type' and 'power' in dBm or 'pathloss' in dB.

When you specify ' power', each path is color-coded according to the received power along the path. When you specify 'pathloss', each path is color-coded according to the path loss along the path.

Friis equation is used to calculate the received power:

$$
P_{r \chi}=P_{t \chi}+G_{t \chi}+G_{r x}-L-L_{t x}-L_{r x}
$$

where:

- $P_{r x}$ is the received power along the path.
- $P_{t x}$ is the transmit power defined in tx.TransmitterPower.
- $G_{t x}$ is the antenna gain of $t x$ in the direction of the angle-of-departure (AoD).
- $G_{r x}$ is the antenna gain of $r x$ in the direction of the angle-of-arrival (AoA).
- $L$ is the path loss calculated along the path.
- $L_{t x}$ is the system loss of the transmitter defined in tx.SystemLoss.
- $L_{r x}$ is the system loss of the receiver defined in rx.SystemLoss.

## Data Types: char

## PropagationModel - Type of propagation model for ray tracing analysis

' raytracing-image-method ' (default) | ray tracing propagation model object
Type of propagation model for ray tracing analysis, specified as the comma-separated pair consisting of 'PropagationModel' and 'raytracing-image-method' or a ray tracing propagation model object created using propagationModel.
Data Types: char
NumReflections - Number of reflections to search for in propagation paths
[0 1] (default) | numeric row vector
Number of reflections to search for in propagation paths using ray tracing, specified as the commaseparated pair consisting of 'NumReflections' and a numeric row vector whose elements are 0,1 , or 2.

The default value results in the search for a line-of-sight propagation path along with propagation paths that each contain a single reflection.
Data Types: double

## Colormap - Color map for coloring propagation paths

' jet ' (default) | predefined color map name | $M$-by-3 array of RGB
Color map for coloring propagation paths, specified as the comma-separated pair consisting of 'Colormap ' and a predefined color map name or an M-by-3 array of RGB (red, blue, green) triplets that define $M$ individual colors.
Data Types: char | double

## ColorLimits - Color limits for colormap

two-element numeric row vector
Color limits for colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element numeric row vector of the form [min max]. The units and default values of the color limits depend on the value of the 'Type' parameter:

- 'power'- Units are in dBm , and the default value is [-120-5].
- 'pathloss' - Units are in dB , and the default value is [45 160].

The color limits indicate the values that map to the first and last colors in the colormap. Propagation paths with values below the minimum color limit are not plotted.
Data Types: double

## ShowLegend - Show color legend on map

true (default) | false
Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend ' and true or false.

Data Types: logical

## Map - Map for visualization and surface data

siteviewer object
Map for visualization and surface data, specified as a siteviewer object. The default value is the current Site Viewer.

Data Types: char | string

## Output Arguments

## rays - Ray configuration object

$M$-by- $N$ cell array
Ray configuration, returned as a $M$-by- $N$ cell array where $M$ is the number of transmitter sites and $N$ is the number of receiver sites. Each cell element is a row vector of objects representing all the rays found between the corresponding transmitter site and receiver site. array. Within each row vector, the comm. Ray objects are ordered by increasing number of reflections, and where number of reflections are equal they are ordered by increasing propagation distance.

## removeCustomTerrain

Remove custom terrain data

## Syntax

removeCustomTerrain(terrainName)

## Description

removeCustomTerrain(terrainName) removes the custom terrain data specified by the userdefined terrainName. You can use this function to remove terrain data that is no longer needed. The terrain data to be removed must have been previously added using addCustomTerrain.

## Examples

## Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";
attribution = "SRTM 3 arc-second resolution. Data available " + ...
    "from the U.S. Geological Survey.";
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer("Terrain","southboulder");
```

Create a site with the terrain region.
mtzion = txsite("Name","Mount Zion", ...
"Latitude", 39.74356, ...
"Longitude",-105.24193, ...
"AntennaHeight", 30);
show(mtzion)

Create a coverage map of the area within 20 km of the transmitter site.
coverage(mtzion, ...
"MaxRange", 20000, ...
"SignalStrengths", -100:-5)

Remove the custom terrain.
close(viewer)
removeCustomTerrain("southboulder")

## Input Arguments

## terrainName - User-defined identifier for terrain data

string scalar | character vector
User-defined identifier for terrain data previously added using addCustomTerrain, specified as a string scalar or a character vector.
Data Types: char \| string

## See Also

addCustomTerrain|siteviewer

## Introduced in R2019b

## pattern

Plot antenna radiation pattern on map

## Syntax

pattern(tx)
pattern(rx,frequency)
pattern( $\qquad$ , Name, Value)

## Description

pattern(tx) plots the 3-D antenna radiation pattern for the transmitter site, txsite. Signal gain value ( dBi ) in a particular direction determines the color of the pattern.
pattern (rx,frequency) plots the 3-D radiation pattern for the receiver site, rxsite for the specified frequency.
pattern( $\qquad$ , Name, Value) plots the 3-D radiation pattern with additional options specified by name-value pair arguments.

## Examples

## Single Transmitter Site Pattern

Define and visualize the radiation pattern of a single transmitter site.

```
tx = txsite;
pattern(tx)
```

## Input Arguments

## tx - Transmitter site

txsite object
Transmitter site, specified as a txsite object.

## rx - Receiver site

rxsite object
Receiver site, specified as a rxsite object.

## frequency - Frequency to calculate radiation pattern

positive scalar
Frequency to calculate radiation pattern, specified as a positive scalar.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Size',2

## Size - Size of pattern plot

50 (default) | numerical scalar

Size of the pattern plot, specified as a numerical scalar in meters. This parameter represents the distance between the antenna position and the point on the plot with the highest gain.
Data Types: double

## Transparency - Transparency of pattern plot

0.4 (default) | real number in the range of $[0,1]$

Transparency of the pattern plot, specified as a real number in the range of [0,1], where 0 is completely transparent and 1 is completely opaque.

## Data Types: double

## Colormap - Colormap for coloring of pattern plot

' jet (256) ' (default) | predefined colormap name | M-by-3 array of RGB triplets
Colormap for coloring of the pattern plot, specified as a predefined colormap name or an $M$-by-3 array of RGB (red, blue, green) triplets that define $M$ individual colors.
Data Types: double

## Map - Map for visualization or surface data <br> siteviewer object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none ', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.
Data Types: char|string

## See Also

## Introduced in R2019b

## show

Show site location on map

## Syntax

show(site)
show(site, Name, Value)

## Description

show(site) displays the location of transmitter or receiver site on a map using a marker.
show (site, Name, Value) uses icon displays the site map using additional options specified by the Name, Value pairs.

## Examples

## Default Receiver Site

Create and show the default receiver site.

```
rx = rxsite
rx =
    rxsite with properties:
                                    Name: 'Site 2'
                Latitude: 42.3021
                Longitude: -71.3764
                    Antenna: 'isotropic'
            AntennaAngle: 0
            AntennaHeight: 1
                SystemLoss: 0
        ReceiverSensitivity: -100
```

show(rx)

## Show and Hide Transmitter Site

Create a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504);
```

Show the transmitter site.

```
show(tx)
```

Hide the transmitter site.
hide(tx)

## Input Arguments

## site - Transmitter or receiver site

txsite or rxsite object| array of txsite or rxsite objects
Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'ClusterMarkers',true

## Icon - Image file

character vector
Image file, specified as a character vector.
Data Types: char

## IconSize - Width and height of icon

36-by-36 (default) | 1-by-2 vector of positive numeric values
Width and height of the icon, specified as a 1-by-2 vector of positive numeric values in pixels.

## IconAlignment - Vertical position of icon relative to site <br> 'top' (default) | 'center' | 'bottom'

Vertical position of icon relative to site, specified as:

- ' bottom - Aligns the icon below the site antenna position.
- 'center' - Aligns the center of the icon to the site antenna position.
- 'top ' - Aligns the icon above the site antenna position.

## ClusterMarkers - Combine nearby markers into groups or clusters

true | false
Combine nearby markers into groups or clusters, specified as true or false.
Data Types: char

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none ', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.

Data Types: char | string

## See Also

## Introduced in R2019b

## sigstrength

Signal strength due to transmitter

## Syntax

```
ss = sigstrength(rx,tx)
ss = sigstrength(rx,tx,propmodel)
ss = sigstrength(
```

$\qquad$

``` , Name, Value)
```

## Description

ss = sigstrength(rx,tx) returns the signal strength at the receiver site due to the transmitter site.
ss $=$ sigstrength (rx,tx, propmodel) returns the signal strength at the receiver site using the specified propagation model. Specifying propagation model is same as specifying the
'PropagationModel ' name-value pair.
ss = sigstrength( $\qquad$ ,Name, Value) returns the signal strength using additional options specified by Name, Value pairs and either of the previous syntaxes.

## Examples

## Received Power and Link Margin at Receiver

Create a transmitter site.

```
tx = txsite('Name','Fenway Park', ...
    'Latitude', 42.3467, ...
    'Longitude', -71.0972);
```

Create a receiver site with sensitivity defined (in dBm).

```
rx = rxsite('Name','Bunker Hill Monument', ...
    'Latitude', 42.3763, ...
    'Longitude', -71.0611, ...
    'ReceiverSensitivity', -90);
```

Calculate the received power and link margin. Link margin is the difference between the receiver's sensitivity and the received power.

```
ss = sigstrength(rx,tx)
ss = -71.1414
margin = abs(rx.ReceiverSensitivity - ss)
margin = 18.8586
```

Signal Strength Using Ray Tracing Image Method Propagation Model
Launch Site Viewer with buildings in Chicago.
viewer = siteviewer("Buildings","chicago.osm");

Create transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...
    'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
```

Create receiver site near another building.

```
rx = rxsite('Latitude',41.881352, ...
    'Longitude',-87.629771, ...
    'AntennaHeight',30);
```

Compute signal strength using ray tracing propagation model and default single-reflection analysis.

```
pm = propagationModel("raytracing-image-method");
ssOneReflection = sigstrength(rx,tx,pm)
ssOneReflection = -55.2839
```

Compute signal strength with analysis up to two reflections, where total received power is the cumulative power of all propagation paths

```
pm.MaxNumReflections = 2;
ssTwoReflections = sigstrength(rx,tx,pm)
ssTwoReflections = -53.1827
```

Observe effect of material by replacing default concrete material with perfect reflector.

```
pm.BuildingsMaterial = 'perfect-reflector';
ssPerfect = sigstrength(rx,tx,pm)
ssPerfect = -42.0872
```

Plot propagation paths.
raytrace(tx, rx, pm)

## Input Arguments

## rx - Receiver site

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

## tx - Transmitter site <br> txsite object | array of txsite objects

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

## propmodel - Propagation model

character vector | string
Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel ' to specify this parameter. You can also use the propagationModel function to define this input.
Data Types: char|string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## Example: 'Type','power'

## Type - Type of signal strength to compute <br> 'power' (default)|'efield'

Type of signal strength to compute, specified as the comma-separated pair consisting of 'Type and 'power' or 'efield'.

When type is 'power', signal strength is expressed in power units ( dBm ) of the signal at the mobile receiver input. When type is 'efield', signal strength is expressed in electric field strength units $(\mathrm{dB} \mu \mathrm{V} / \mathrm{m})$ of signal wave incident on the antenna.

## Data Types: char | string

PropagationModel - Propagation model to use for path loss calculations
'longley-rice' (default)|'freespace'|'close-in'|'rain'|'gas'|'fog'|
'raytracing-image-method' | propagation model object
Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and 'freespace', 'close-in', 'rain', 'gas', 'fog', 'longley-rice', 'raytracing-image-method', or as an object created using the propagationModel function. The default propagation model is 'longeley-rice' when terrain is enabled and 'freespace' when terrain is disabled.

## Data Types: char

## Map - Map for visualization or surface data

## siteviewer object | terrain name

Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none ', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.

Data Types: char|string

## Output Arguments

## ss - Signal strength

$M$-by- $N$ array
Signal strength, returned as $M$-by- $N$ array in dBm. $M$ is the number of TX sites and $N$ is the number of RX sites.

## See Also

link|propagationModel|sinr
Introduced in R2019b

## sinr

Display signal-to-interference-plus-noise ratio (SINR) map

## Syntax

```
sinr(txs)
sinr(txs,propmodel)
sinr(__, Name,Value)
pd = sinr(txs,
```

$\qquad$

``` )
r = sinr(rxs,txs,__)
```

## Description

$\operatorname{sinr}(\mathrm{txs})$ displays the signal-to-interference-plus-noise ratio (SINR) for transmitter sites, txs. Each colored contour of the map defines the areas where the corresponding SINR is available to a mobile receiver. For each location, the signal source is the transmitter site in txs with the greatest signal strength. The remaining transmitter sites in txs act as interference. If $t x s$ is scalar, or there are no sources of interference, the resultant map displays signal-to-noise ratio (SNR).
sinr(txs, propmodel) displays the SINR map with the propagation model set to the value in propmodel.
sinr (__ , Name, Value) sets properties using one or more name-value pairs, in addition to the input arguments in previous syntaxes. For example, sinr(txs,'MaxRange',8000) sets the range from the site location at 8000 meters to include in the SINR map region.
$\mathrm{pd}=\operatorname{sinr}(\mathrm{txs}, \quad \ldots \quad$ ) returns computed SINR data in the propagation data object, pd. No plot is displayed and any graphical only name-value pairs are ignored.
$r=\sin r(r x s, t x s, \ldots \quad)$ returns the sinr in dB computed at the receiver sites due to the transmitter sites.

## Examples

## SINR Map for Multiple Transmitters

Define names and location of sites in Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
Create a transmitter site array.
```

```
txs = txsite('Name', names,...
```

txs = txsite('Name', names,...
'Latitude',lats,...
'Latitude',lats,...
'Longitude',lons, ...
'Longitude',lons, ...
'TransmitterFrequency',2.5e9);

```
    'TransmitterFrequency',2.5e9);
```

Display the SINR map, where signal source for each location is selected as the transmitter site with the strongest signal.
sinr(txs)

## Input Arguments

## txs - Transmitter sites

txsite object|array of txsite objects
Transmitter site, specified as a txsite object. Use array inputs to specify multiple sites.

## rxs - Receiver sites

rxsite object | array of rxsite objects
Receiver site, specified as a rxsite object. Use array inputs to specify multiple sites.

## propmodel - Propagation model

character vector | string
Propagation model, specified as a character vector or string. You can use the propagationModel function to define this input.

You can also use the name-value pair 'PropagationModel ' to specify this parameter.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.
Example: 'MaxRange',8000

## General

## SignalSource - Signal source of interest

'strongest' (default)| transmitter site object
Signal source of interest, specified as the comma-separated pair consisting of SignalSource and 'strongest' or as a transmitter site object. When the signal source of interest is 'strongest', the transmitter with the greatest signal strength is chosen as the signal source of interest for that location. When computing sinr, SignalSource can be a txsite array with equal number of elements rxs where each transmitter site element defines the signal source for the corresponding receiver site.

## PropagationModel - Propagation model to use for path loss calculations

'longley-rice' (default)|'freespace'|'close-in'|'rain'|'gas'|'fog'|
'raytracing-image-method ' | propagation model object
Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and 'freespace', 'close-in', 'rain', 'gas', 'fog' 'longley-rice', 'raytracing-image-method', or as an object created using the propagationModel function. The default propagation model is 'longeley-rice' when terrain is enabled and 'freespace' when terrain is disabled. If 'raytracing-image-method ' is specified, the value of 'MaxNumReflections' property must be lesser than 1.

## Data Types: char

## ReceiverNoisePower - Total noise power at receiver

- 107 (default) | scalar

Total noise power at receiver, specified as the comma-separated pair consisting of 'ReceiverNoisePower' and a scalar in dBm. The default value assumes that the receiver bandwidth is 1 MHz and receiver noise figure is 7 dB .

$$
N=-174+10 * \log (B)+F
$$

where,

- $N=$ Receiver noise in dBm
- $B=$ Receiver bandwidth in Hz
- $F=$ Noise figure in dB

## ReceiverGain - Receiver gain

2.1 (default) | scalar

Mobile receiver gain, specified as the comma-separated pair consisting of 'ReceiverGain' and a scalar in dB . The receiver gain values include the antenna gain and the system loss. If you call the function using an output argument, the default value is computed using rxs.

## ReceiverAntennaHeight - Receiver antenna height

## 1 (default) | scalar

Receiver antenna height above the ground, specified as the comma-separated pair consisting of 'ReceiverAntennaHeight' and a scalar in meters. If you call the function using an output argument, the default value is computed using rxs.

## Map - Map for visualization or surface data

siteviewer object | terrain name
Map for visualization or surface data, specified as the comma-separated pair consisting of 'Map and a siteviewer object or a terrain name. A terrain name may be specified if the function is called with an output argument. Valid terrain names are ' none ', 'gmted2010' , or the name of the custom terrain data added using addCustomTerrain. The default value is the current Site Viewer. If no Site Viewer is open, the default value is a new Site Viewer or else 'gmted2010' if the function is called with an output argument.

Data Types: char|string
For Plotting SINR

## Values - Values of SINR for display

[-5:20] (default)| numeric vector
Values of SINR for display, specified as the comma-separated pair consisting of 'Values ' and a numeric vector. Each value is displayed as a different colored, filled on the contour map. The contour colors are derived using Colormap and ColorLimits.

## MaxRange - Maximum range of coverage map from each transmitter site

numeric scalar
Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the propagation model type as shown:

| Propagation Model | MaxRange |
| :--- | :--- |
| Basic or urban | 30 km |
| Terrain | 30 km or distance to the furthest building. |
| Multipath | 500 m |

## Data Types: double

## Resolution - Resolution of receiver site locations used to compute SINR values

'auto ' (default) | numeric scalar
Resolution of receiver site locations used to compute SINR values, specified as the comma-separated pair consisting of 'Resolution' and 'auto' or a numeric scalar in meters. The resolution defines the maximum distance between the locations. If the resolution is 'auto', sinr computes a value scaled to MaxRange. Decreasing the resolution increases the quality of the SINR map and the time required to create it.

## Colormap - Colormap for coloring filled contours

' jet ' (default) | M-by-3 array of RGB triplets

Colormap for coloring filled contours, specified as the comma-separated pair consisting of 'ColorMap ' and an $M$-by- 3 array of RGB triplets, where $M$ is the number of individual colors.

## ColorLimits - Color limits for color maps

[-5 20] (default)|two-element vector
Color limits for color maps, specified as the comma-separated pair consisting of 'ColorLimits ' and a two-element vector of the form [min max]. The color limits indicate the SINR values that map to the first and last colors in the colormap.

## ShowLegend - Show signal strength color legend on map <br> 'true' (default)|'false'

Show signal strength color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and 'true' or 'false'.

## Transparency - Transparency of SINR map

## 0.4 (default) | numeric scalar

Transparency of SINR map, specified as the comma-separated pair consisting of 'Transparency ' and a numeric scalar in the range $0-1$. If the value is zero, the map is completely transparent. If the value is one, the map is completely opaque.

## Output Arguments

## $r$ - Signal to interference plus noise ratio at the receiver <br> numeric vector (default)

Signal to interference plus noise ratio at the receiver due to the transmitter sites, returned as a numeric vector. The vector length is equal to the number of receiver sites.

Data Types: double
pd - SINR data
propagationData object
SINR data, returned as a propagationData object consisting of Latitude and Longitude, and a signal strength variable corresponding to the plot type. Name of the propagationData is "SINR Data".

coverage | propagationModel
Introduced in R2019b

## plot (rays)

Package: comm
Plot rays in Site Viewer map

## Syntax

plot(rays)
plot(rays,Name,Value)

## Description

plot (rays) plots the propagation paths for ray objects in the Site Viewer map.
plot (rays, Name, Value) plots the propagation paths for ray objects in the Site Viewer map with additional options specified by one or more name-value pair arguments.

## Examples

## Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in comm. Ray objects and plot the ray propagation path after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago.
viewer = siteviewer('Buildings','chicago.osm');
Create and show a transmitter site on one building and a receiver site on another building.

```
tx = txsite('Latitude',41.8800,'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
show(tx);
rx = rxsite('Latitude',41.881352,'Longitude',-87.629771, ...
    'AntennaHeight',30);
show(rx);
```

Perform ray tracing, returning the ray object results. For the configuration defined, ray tracing returns a cell array containing one ray object. Display the ray object properties. Then, close the Site Viewer map.

```
rays = raytrace(tx,rx)
rays = l×1 cell array
    {1×1 comm.Ray}
rays{1}
ans =
    Ray with properties:
```

```
    PathSpecification: 'Locations'
    CoordinateSystem: 'Geographic'
TransmitterLocation: [ 3\times1 double]
    ReceiverLocation: [3×1 double]
            LineOfSight: 0
ReflectionLocations: [ }3\times1\mathrm{ double]
            Frequency: 2.5000e+09
        PathLossSource: 'Custom'
                    PathLoss: 95.4412
            PhaseShift: 4.4413
Read-only properties:
    PropagationDelay: 5.7088e-07
PropagationDistance: 171.1462
    AngleOfDeparture: [2×1 double]
        AngleOfArrival: [2×1 double]
        NumReflections: 1
close(viewer);
```

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for one ray object at a time.

```
siteviewer('Buildings','chicago.osm');
show(tx);
show(rx);
plot(rays{1},'Type','power', ...
    'TransmitterSite',tx,'ReceiverSite',rx);
```

## Input Arguments

## rays - Ray configuration object

comm. Ray object
Ray configuration, specified as one comm. Ray object or a vector of comm. Ray objects. Each object must have the PathSpecification property set to "Locations" and the CoordinateSystem property set to "Geographic".
Data Types: comm. Ray

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: plot(rays,"Type","pathloss","ColorLimits", [-100 0]) adds the propagation path specified in rays to the current Site Viewer and adjusts the default color limits.

## Type - Quantity type to plot <br> "pathloss" (default) | "power"

Quantity type to plot, specified as "pathloss" or "power". Based on the value specified for Type, the color applied along the path maps to the path loss in dB or the power in dBm of the signal along the path.

## Data Types: char \| string

## TransmitterSite - Transmitter site <br> txsite object

Transmitter site, specified as a txsite object.

## Dependencies

Applies only when Type is set to "power".

## Data Types: char

## ReceiverSite - Receiver site

## rxsite object

Receiver site, specified as an rxsite object.

## Dependencies

Applies only when Type is set to "power".
Data Types: char

## ColorLimits - Colormap color limits

[-120 -5] or [45 160] (default) | 1-by-2 numeric vector
Color limits for colormap, specified as a 1-by-2 numeric vector, [min, max], where min represents the lower saturation limit and max represents the upper saturation limit. The default is [-120-5] when Type is set to ' power' and [45 160] when Type is set to 'pathloss'.

## Data Types: double

## Colormap - Colormap applied to propagation path

' jet ' (default)| M-by-3 numeric array
Colormap applied to propagation path, specified as an M-by-3 numeric array of RGB (red,green,blue) triplets that define $M$ individual colors.
Data Types: double | char \| string

## ShowLegend - Show color legend on map <br> true (default) | false

Show color legend on map, specified as true or false.
Data Types: logical

## Map - Map for visualization and surface data

siteviewer object
Map for visualization and surface data, specified as a siteviewer object. The default is the current siteviewer object, or if no Site Viewer is open a new siteviewer object opens.
Data Types: siteviewer object

## A-Law Compressor

Implement A-law compressor for source coding

```
A-Lam
Compressor
```

## Library

## Source Coding

## Description

The A-Law Compressor block implements an A-law compressor for the input signal. The formula for the A-law compressor is

$$
y= \begin{cases}\frac{A|x|}{1+\log A} \operatorname{sgn}(x) & \text { for } 0 \leq|x| \leq \frac{V}{A} \\ \frac{V(1+\log (A|x| / V))}{1+\log A} \operatorname{sgn}(x) & \text { for } \frac{V}{A}<|x| \leq V\end{cases}
$$

where $A$ is the A-law parameter of the compressor, $V$ is the peak signal magnitude for $x, \log$ is the natural logarithm, and sgn is the sign function.

The most commonly used $A$ value is 87.6 .
The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

## A value

The A-law parameter of the compressor.

## Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

## Supported Data Type

| Port | Supported Data Types |
| :--- | :--- |
| In | $\bullet$ double |
| Out | $\bullet$ double |

Expander
```

## Library

Source Coding

## Description

The A-Law Expander block recovers data that the A-Law Compressor block compressed. The formula for the A-law expander, shown below, is the inverse of the compressor function.

$$
x= \begin{cases}\frac{y(1+\log A)}{\mathrm{A}} & \text { for } 0 \leq|y| \leq \frac{\mathrm{V}}{1+\log \mathrm{A}} \\ \exp (|\mathrm{y}|(1+\log A) / V-1) \frac{V}{A} \operatorname{sgn}(y) & \text { for } \frac{\mathrm{V}}{1+\log \mathrm{A}}<|y| \leq V\end{cases}
$$

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

## A value

The A-law parameter of the compressor.

## Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.
Match these parameters to the ones in the corresponding A-Law Compressor block.

## Algebraic Deinterleaver

Restore ordering of input symbols using algebraically derived permutation

## Library

Block sublibrary of Interleaving

## Description

The Algebraic Deinterleaver block restores the original ordering of a sequence that was interleaved using the Algebraic Interleaver block. In typical usage, the parameters in the two blocks have the same values.

The Number of elements parameter, $N$, indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

The Type parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are Takeshita-Costello and Welch-Costas. Each of these methods has parameters and restrictions that are specific to it; these are described on the reference page for the Algebraic Interleaver block.

## Parameters

## Type

The type of permutation table that the block uses for deinterleaving. Choices are TakeshitaCostello and Welch-Costas.

## Number of elements

The number of elements, $N$, in the input vector.

## Multiplicative factor

The factor the block uses to compute the corresponding interleaver's cycle vector. This field appears only when you set Type to Takeshita-Costello.

## Cyclic shift

The amount by which the block shifts indices when creating the corresponding interleaver's permutation table. This field appears only when you set Type to Takeshita-Costello.

## Primitive element

An element of order $N$ in the finite field $\mathrm{GF}(\mathrm{N}+1)$. This field appears only if Type is set to WelchCostas.

## Pair Block

Algebraic Interleaver

Blocks
Algebraic Interleaver | General Block Deinterleaver
Introduced before R2006a

## Algebraic Interleaver

Reorder input symbols using algebraically derived permutation table

## Library

Block sublibrary of Interleaving

## Description

The Algebraic Interleaver block rearranges the elements of its input vector using a permutation that is algebraically derived. The Number of elements parameter, $N$, indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

The Type parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are Takeshita-Costello and Welch-Costas. Each of these methods has parameters and restrictions that are specific to it:

- If you set Type to Welch-Costas, then $N+1$ must be prime. The Primitive element parameter is an integer, $A$, between 1 and $N$ that represents a primitive element of the finite field $\mathrm{GF}(N+1)$. This means that every nonzero element of $\mathrm{GF}(N+1)$ can be expressed as $A$ raised to some integer power.

In a Welch-Costas interleaver, the permutation maps the integer $k$ to $\bmod \left(A^{k}, N+1\right)-1$.

- If you set Type to Takeshita-Costello, then $N$ must be $2^{m}$ for some integer $m$. The Multiplicative factor parameter, $k$, must be an odd integer less than $N$. The Cyclic shift parameter, $h$, must be a nonnegative integer less than $N$.

A Takeshita-Costello interleaver uses a length- $N$ cycle vector whose $n$th element is

$$
c(n)=\bmod \left(k \cdot \frac{n \cdot(n-1)}{2}, N\right)+1, n
$$

for integers n between 1 and N . The intermediate permutation function is obtained by using the following relationship:

$$
\Pi(c(n))=c(n+1)
$$

where

$$
n=1: N
$$

The interleaver's actual permutation vector is the result of cyclically shifting the elements of the permutation vector, $\pi$, by the Cyclic shift parameter, $h$.

## Parameters

## Type

The type of permutation table that the block uses for interleaving.

## Number of elements

The number of elements, $N$, in the input vector.

## Multiplicative factor

The factor used to compute the interleaver's cycle vector. This field appears only if Type is set to Takeshita-Costello.

## Cyclic shift

The amount by which the block shifts indices when creating the permutation table. This field appears only if Type is set to Takeshita-Costello.

## Primitive element

An element of order $N$ in the finite field $\mathrm{GF}(\mathrm{N}+1)$. This field appears only if Type is set to WelchCostas.

## Align Signals

(To be removed) Align two signals by finding delay between them

## Compatibility

Align Signals Block will be removed in a future release. Use the Find Delay block to find delays and the Delay block to apply delays instead. For more information, see "Compatibility Considerations" on page 5-11.

## Library

Utility Blocks

## Description

The Align Signals block aligns two signals by finding the delay between them. This is useful when you want to compare a transmitted and received signal to determine the bit error rate, but do not know the delay in the received signal. This block accepts a column vector or matrix input signal. For a matrix input, the block aligns each channel independently.

The $s 1$ input port receives the original signal, while the $s 2$ input port receives a delayed version. The two input signals must have the same dimensions and sample times. The block calculates the delay between the two signals, and then

- Delays the first signal, s1, by the calculated value, and outputs it through the port labeled s1 del.
- Outputs the second signal s2 without change through the port labeled s2.
- Outputs the delay value through the port labeled delay.

See "Delays" for more information about signal delays.
The block's Correlation window length parameter specifies how many samples of the signals the block uses to calculate the cross-correlation. The delay output is a nonnegative integer less than the Correlation window length.

As the Correlation window length is increased, the reliability of the computed delay also increases. However, the processing time to compute the delay increases as well.

You can make the Align Signals block stop updating the delay after it computes the same delay value for a specified number of samples. To do so, select Disable recurring updates, and enter a positive integer in the Number of constant delay outputs to disable updates field. For example, if you set Number of constant delay outputs to disable updates to 20, the block will stop recalculating and updating the delay after it calculates the same value 20 times in succession. Disabling recurring updates causes the simulation to run faster after the target number of constant delays occurs.

## Tips for Using the Block Effectively

- Set the Correlation window length parameter sufficiently large so that the computed delay eventually stabilizes at a constant value. If the computed delay is not constant, you should increase Correlation window length. If the increased value of Correlation window length exceeds the duration of the simulation, then you should also increase the duration of the simulation accordingly.
- If the cross-correlation between the two signals is broad, then Correlation window length should be much larger than the expected delay, or else the algorithm might stabilize at an incorrect value. For example, a CPM signal has a broad autocorrelation, so it has a broad crosscorrelation with a delayed version of itself. In this case, the Correlation window length value should be much larger than the expected delay.
- If the block calculates a delay that is greater than 75 percent of Correlation window length, the signal s1 is probably delayed relative to the signal s2. In this case, you should switch the signal lines leading into the two input ports.
- If you use the Align Signals block with the Error Rate Calculation block, you should set the Receive delay parameter of the Error Rate Calculation block to 0 because the Align Signals block compensates for the delay. Also, you might want to set the Error Rate Calculation block's Computation delay parameter to a nonzero value to account for the possibility that the Align Signals block takes a nonzero amount of time to stabilize on the correct amount by which to delay one of the signals.

## Parameters

## Correlation window length

The number of samples the block uses to calculate the cross-correlations of the two signals.

## Disable recurring updates

Selecting this option causes the block to stop computing the delay after it computes the same delay value for a specified number of samples.

## Number of constant delay outputs to disable updates

A positive integer specifying how many times the block must compute the same delay before ceasing to update. This field appears only if Disable recurring updates is selected.

## Algorithm

The Align Signals block finds the delay by calculating the cross-correlations of the first signal with time-shifted versions of the second signal, and then finding the index at which the cross-correlation is maximized.

## Compatibility Considerations

## Align Signals Block will be removed

Warns starting in R2019b
Align Signals Block will be removed in a future release. Use the Find Delay block to find delays and the Delay block to apply delays instead.

See "Delays" for an example that uses the Find Delay block in conjunction with the Error Rate Calculation block.

For an example that illustrates how to set the correlation window length properly, see the section Setting the Correlation Window Length on the Find Delay block reference page.

## APP Decoder

Decode convolutional code using a posteriori probability (APP) method

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The APP Decoder block performs a posteriori probability (APP) decoding of a convolutional code.

## Input Signals and Output Signals

The input $L(u)$ represents the sequence of log-likelihoods of encoder input bits, while the input $L(c)$ represents the sequence of log-likelihoods of code bits. The outputs $L(u)$ and $L(c)$ are updated versions of these sequences, based on information about the encoder.

If the convolutional code uses an alphabet of $2^{n}$ possible symbols, this block's $L(c)$ vectors have length $Q^{*} n$ for some positive integer $Q$. Similarly, if the decoded data uses an alphabet of $2^{k}$ possible output symbols, then this block's $L(u)$ vectors have length $Q^{*} k$.

This block accepts a column vector input signal with any positive integer for $Q$.
If you only need the input $L(c)$ and output $L(u)$, you can attach a Simulink Ground block to the input $L(u)$ and a Simulink Terminator block to the output $L(c)$.

This block accepts single and double data types. Both inputs, however, must be of the same type. The output data type is the same as the input data type.

## Specifying the Encoder

To define the convolutional encoder that produced the coded input, use the Trellis structure parameter. This parameter is a MATLAB structure whose format is described in "Trellis Description of a Convolutional Code". You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name as the Trellis structure parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a poly2trellis command within the Trellis structure field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the Trellis structure parameter to
poly2trellis(7,[171 133],171)

To indicate how the encoder treats the trellis at the beginning and end of each frame, set the Termination method parameter to either Truncated or Terminated. The Truncated option indicates that the encoder resets to the all-zeros state at the beginning of each frame. The Terminated option indicates that the encoder forces the trellis to end each frame in the all-zeros state. If you use the Convolutional Encoder block with the Operation mode parameter set to Truncated (reset every frame), use the Truncated option in this block. If you use the Convolutional Encoder block with the Operation mode parameter set to Terminate trellis by appending bits, use the Terminated option in this block.

## Specifying Details of the Algorithm

You can control part of the decoding algorithm using the Algorithm parameter. The True APP option implements a posteriori probability decoding as per equations 20-23 in section V of [1]. To gain speed, both the Max* and Max options approximate expressions like

$$
\log \sum_{i} \exp \left(a_{i}\right)
$$

by other quantities. The Max option uses $\max \left(a_{\mathrm{i}}\right)$ as the approximation, while the Max* option uses $\max \left(a_{\mathrm{i}}\right)$ plus a correction term given by $\ln \left(1+\exp \left(-\left|a_{i-1}-a_{i}\right|\right)\right)$ [3].

The Max* option enables the Scaling bits parameter in the dialog box. This parameter is the number of bits by which the block scales the data it processes internally (multiplies the input by ( $2^{\wedge}$ numScalingBits) and divides the pre-output by the same factor). Use this parameter to avoid losing precision during the computations.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## Termination method

Either Truncated or Terminated. This parameter indicates how the convolutional encoder treats the trellis at the beginning and end of frames.

## Algorithm

Either True APP, Max*, or Max.

## Number of scaling bits

An integer between 0 and 8 that indicates by how many bits the decoder scales data in order to avoid losing precision. This field is active only when Algorithm is set to Max*.

## Disable L(c) output port

Select this check box to disable the secondary block output, L(c).

## Examples

For an example using this block, see the "Iterative Decoding of a Serially Concatenated Convolutional Code" example.

## AGC Block

Adaptively adjust gain for constant signal-level output

## Library

RF Impairments Correction

## Description

The automatic gain controller (AGC) block adaptively adjusts its gain to achieve a constant signal level at the output.

## Parameters

## Step size

Specify the step size for gain updates as a double-precision or single-precision real positive scalar. The default is 0.01 .

If you increase Step size, the AGC responds faster to changes in the input signal level. However, gain pumping also increases.

## Desired output power (W)

Specify the desired output power level as a real positive scalar. The power level is specified in Watts referenced to 1 ohm . The default is 1 .

## Averaging length

Specify the length of the averaging window in samples as a positive integer scalar. The default is 100.

Note If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC and increase the averaging length as needed. An increase in Averaging length reduces execution speed.

## Maximum power gain (dB)

Specify the maximum gain of the AGC in decibels as a positive scalar. The default is 60 .
If the AGC input signal power is very small, the AGC gain will be very large. This can cause problems when the input signal power suddenly increases. Use Maximum power gain (dB) to avoid this by limiting the gain that the AGC applies to the input signal.

## Enable output of estimated input power

Select this check box to provide an input signal power estimate to an output port. By default, the check box is not selected.

## Simulate using

Select the simulation mode.

## Code generation

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects corresponding to the blocks accept a maximum of nine inputs.
Interpreted execution
Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the comm. AGC reference page. The object properties correspond to the block parameters.

## Examples

To open these examples, enter the example names at the MATLAB command prompt:

- doc_agc_received_signal_amplitude - Adaptively adjusts the received signal power to approximately 1 Watt.
- doc_agc_plot_step_size - Plots the effect of step size on AGC performance.
- doc_agc_plot_max_gain - Shows how the maximum gain affects the ability of the AGC to reach its target output power.

## AWGN Channel

Add white Gaussian noise to input signal

## Library: Communications Toolbox / Channels

## Description

The AWGN Channel block adds white Gaussian noise to the input signal. It inherits the sample time from the input signal.

## Ports

Input

## In - Input data signal

vector | matrix
Input data signal, specified as an $N_{\mathrm{S}}$-by- 1 vector or an $N_{\mathrm{S}}$-by- $N_{\mathrm{C}}$ matrix.
$N_{\mathrm{S}}$ represents the number of samples in the input signal. $N_{\mathrm{C}}$ represents the number of channels, as determined by the number of columns in the input signal matrix. Both $N_{\mathrm{S}}$ and $N_{\mathrm{C}}$ can be equal to 1 .

The block adds frames of length- $N_{\mathrm{S}}$ Gaussian noise to each of the $N_{\mathrm{C}}$ channels, using a distinct random distribution per channel.
Data Types: double | single
Complex Number Support: Yes

## Var - Variance of additive white Gaussian noise <br> positive scalar | vector

Variance of additive white Gaussian noise, specified as a positive scalar or a 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ represents the number of channels, as determined by the number of columns in the input signal matrix. For more information, see "Specifying the Variance Directly or Indirectly" on page 5-22.

## Dependencies

To enable this port, set Mode to Variance from port.
Data Types: double

## Output

Out - Output data signal
vector | matrix
Output data signal for the AWGN channel, returned as a vector or matrix. The datatype and dimensions of Out match those of the input signal, In.

## Parameters

## Initial seed - Noise generator initial seed

67 (default) | positive scalar | vector
Noise generator initial seed, specified as a positive scalar or a 1 -by- $N_{\mathrm{C}}$ vector.
This block uses the Random Source block to generate noise. Random numbers are generated using the Ziggurat method (V5 RANDN algorithm). The block reuses the same initial seeds every time you rerun the simulation, so that this block outputs the same signal each time you run a simulation.

When the input signal is complex, the block creates random data as:

```
randData \(=\) randn \(\left(2 * N_{S}, N_{C}\right)\)
noise \(=\) randData(1:2:end) \(+1 i(r a n d D a t a(2: 2: e n d))\)
```

$N_{\mathrm{S}}$ is the number of samples and $N_{\mathrm{C}}$ is the number of channels.
You can specify different seed values for each DLL build.
Tunable: Yes

## Mode - Variance mode

Signal to noise ratio (Eb/No) (default)|Signal to noise ratio (Es/No)|Signal to noise ratio (SNR)|Variance from mask|Variance from port

Variance mode, specified as Signal to noise ratio (Eb/No), Signal to noise ratio (Es/ No), Signal to noise ratio (SNR), Variance from mask, or Variance from port. For more information, see "Relationship Among Eb/No, Es/No, and SNR Modes" on page 5-21 and "Specifying the Variance Directly or Indirectly" on page 5-22.

## $\mathrm{Eb} / \mathrm{No}$ (dB) - Ratio of information bit energy per symbol to noise power spectral density 10 (default) | scalar | vector

Ratio of information bit energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

Tunable: Yes

## Dependencies

To enable this parameter, set Mode to Eb/No.

## Es/No (dB) - Ratio of information symbol energy per symbol to noise power spectral density <br> 10 (default) | scalar | vector

Ratio of information symbol energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

Tunable: Yes
Dependencies
To enable this parameter, set Mode to Es/No.

SNR (dB) - Ratio of signal power to noise power
10 (default) | scalar | vector
Ratio of signal power to noise power in decibels, specified as a scalar or vector.
Tunable: Yes

## Dependencies

To enable this parameter, set Mode to SNR.

## Number of bits per symbol - Number of bits in each input symbol <br> 1 (default) | scalar | vector

Number of bits in each input symbol, specified as a scalar or vector.

## Dependencies

To enable this parameter, set Mode to Eb/No.

## Input signal power, referenced to 1 ohm (watts) - Mean square power of input 1 (default) | scalar | vector

Mean square power of the input in watts, specified as a scalar or vector.

- When Mode is Eb/No or Es/No, the parameter is the mean square power of the input symbols.
- When Mode is SNR, this parameter is the mean square power of the input samples.

Tunable: Yes
Dependencies
To enable this parameter, set Mode to Eb/No, Es/No, or SNR.

## Symbol period (s) - Duration of an information channel

1 (default) | positive scalar | vector
Duration of an information channel symbol in seconds, specified as a positive scalar or vector. The duration of the information channel is measured without channel coding.

## Dependencies

To enable this parameter, set Mode to Eb/No or Es/No.

## Variance - Variance of white Gaussian noise

1 (default) | scalar | vector
Variance of the white Gaussian noise, specified as a scalar or vector. For more information, see "Specifying the Variance Directly or Indirectly" on page 5-22.

Tunable: Yes
Dependencies
To enable this parameter, set Mode to Variance from mask.

## Block Characteristics

| Data Types | double \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## Tips

- You can tune parameters in normal mode, accelerator mode, or rapid accelerator mode.
- Unless otherwise indicated, parameters are nontunable.
- For nontunable parameters, when you use the Simulink Coder ${ }^{\mathrm{TM}}$ rapid simulation (RSIM) target to build an RSIM executable, you cannot change their values without recompiling the model.
- If a parameter is tunable, you can change its value at any time. This is useful for Monte Carlo simulations in which you run the simulation multiple times (such as on multiple computers) with different amounts of noise.

## Algorithms

## Relationship Among Eb/No, Es/No, and SNR Modes

For uncoded complex input signals, the AWGN Channel block relates $E_{b} / N_{0}, E_{s} / N_{0}$, and SNR according to these equations:

$$
\begin{aligned}
& E_{\mathrm{s}} / N_{0}=\left(T_{\text {sym }} / T_{\text {samp }}\right) \cdot S N R \\
& E_{\mathrm{s}} / N_{0}=E_{\mathrm{b}} / N_{0}+10 \log _{10}(k) \text { in } \mathrm{dB}
\end{aligned}
$$

- $E_{\mathrm{s}}$ represents the signal energy in joules.
- $E_{\mathrm{b}}$ represents the bit energy in joules.
- $N_{0}$ represents the noise power spectral density in watts/Hz.
- $T_{\text {sym }}$ represents the Symbol period (s) parameter of the block in Es/No mode.
- $k$ represents the number of information bits per input symbol, Number of bits per symbol.
- $T_{\text {samp }}$ represents the inherited sample time of the block, in seconds.

For real signal inputs, the AWGN Channel block relates $E_{\mathrm{s}} / N_{0}$ and $\operatorname{SNR}$ according to this equation:

$$
E_{\mathrm{s}} / N_{0}=0.5\left(T_{\text {sym }} / T_{\text {samp }}\right) \cdot S N R
$$

## Note

- All values of power assume a nominal impedance of 1 ohm.
- The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of $N_{0} / 2$ watts/Hz for real input signals, versus $N_{0}$ watts/Hz for complex signals.

For more information, see "AWGN Channel Noise Level".

## Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by AWGN Channel, specify the Mode as:

- Variance from mask, where you specify the variance in the dialog box. The value must be positive.
- Variance from port, where you provide the variance as an input to the block. The variance input must be positive, and its sampling rate must equal that of the input signal.

For Variance from mask and Variance from port mode:

- If the variance is a scalar, then all signal channels are uncorrelated but share the same variance.
- If the variance is a vector whose length is the number of channels in the input signal, then each element represents the variance of the corresponding signal channel.

Note If you apply complex input signals to the AWGN Channel block, then it adds complex zeromean Gaussian noise with the calculated or specified variance. The variance for each quadrature component of the complex noise is half of the calculated or specified value.

To specify the variance indirectly, that is, to have the block calculate the variance, specify the Mode as:

- Signal to noise ratio (Eb/No), where the block calculates the variance from these quantities that you specify in the dialog box:
- $\mathrm{Eb} / \mathrm{No}(\mathrm{dB})$, the ratio of bit energy to noise power spectral density
- Number of bits per symbol
- Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
- Symbol period (s)
- Signal to noise ratio (Es/No), where the block calculates the variance from these quantities that you specify in the dialog box:
- Es/No (dB), the ratio of signal energy to noise power spectral density
- Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
- Symbol period (s)
- Signal to noise ratio (SNR), where the block calculates the variance from these quantities that you specify in the dialog box:
- SNR (dB), the ratio of signal power to noise power
- Input signal power, referenced to 1 ohm (watts), the actual power of the samples at the input of the block

Changing the symbol period in the AWGN Channel block affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$
\text { NoiseVariance }=\frac{\text { SignalPower } \times \text { SymbolPeriod }}{\text { SampleTime } \times 10 \frac{\text { Es/No }}{10}}
$$

Tip Select the symbol period equal to the symbol period of the model. The value depends on what constitutes a symbol and what the oversampling applied to it is. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see "AWGN Channel Noise Level".

## Barker Code Generator

Generate bipolar Barker Code
$\begin{array}{ll}\text { Library: } & \text { Communications Toolbox } \\ & \text { Communications Toolbox / Comm Sources / Sequence }\end{array}$

Barker Code Generator

## Description

The Barker Code Generator block generates a bipolar Barker code. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see "Barker Codes" on page 5-25.

## Ports

Output
output - Barker code frame
column vector
Barker code frame, returned as a column vector. If the frame length exceeds the Barker code length, the block fills the frame by repeating the Barker code.

## Dependencies

Set the data type of the output with the Output data type parameter.

## Parameters

Code length - Length of generated code
7 (default) | 1 | 2 | 3 | 4 | 5 | 11 | 13
Length of the generated code, specified as $1,2,3,4,5,7,11$, or 13 . For more information, see "Barker Codes" on page 3-70.

Example: 2 outputs the Barker code [-1;1].
Data Types: double
Sample time - Output sample time
1 (default) |-1 | positive scalar
Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1, the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-26.

## Samples per frame - Samples per output frame

1 (default) | positive integer
Samples per output frame, specified as a positive integer. If Samples per frame is $M$, the block outputs a frame containing $M$ samples comprised of length $N$ Barker code sequences. $N$ is the length
of the generated code, which is set by the Code length parameter. When $M$ is not an integer multiple of $N$, consecutive frames maintain continuity of the Barker code across frame boundaries.

For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-26.

Data Types: double

## Output data type - Output data type

double (default) | int8
Output data type, specified as double or int8.

## Data Types: char \| string

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double \\| integer |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe, $C_{k}$, for a $k$-symbol shift of an $N$-bit code sequence, $\left\{X_{j}\right\}$, is

$$
C_{k}=\sum_{j=1}^{N-k} X_{j} X_{j+k}
$$

For $j=1,2,3, \ldots, N, X_{j}$ is an individual code symbol that is equal to +1 or -1 . The adjacent symbols are assumed to be 0 .

The output code is in a bipolar format with 0 and 1 mapped to 1 and -1 . The maximum known Barker code length is 13 . The short length and low correlation sidelobes make Barker codes useful for frame
synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

| Barker <br> Code <br> Length | Barker Code | Sidelobe Level |
| :--- | :--- | :--- |
| 1 | $[-1]$ | 0 dB |
| 2 | $[-1 ; 1]$ | -6 dB |
| 3 | $[-1 ;-1 ; 1]$ | -9.5 dB |
| 4 | $[-1 ;-1 ; 1 ;-1]$ | -12 dB |
| 5 | $[-1 ;-1 ;-1 ; 1 ;-1]$ | -14 dB |
| 7 | $[-1 ;-1 ;-1 ; 1 ; 1 ;-1 ; 1]$ | -16.9 dB |
| 11 | $[-1 ;-1 ;-1 ; 1 ; 1 ; 1 ;-1 ; 1 ; 1 ;-1 ; 1]$ | -20.8 dB |
| 13 | $[-1 ;-1 ;-1 ;-1 ;-1 ; 1 ; 1 ;-1 ;-1 ; 1 ;-1 ; 1 ;-1]$ | -22.3 dB |

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10 , then a 10 -by- 1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

## Existing models automatically update this block to current version <br> Behavior changed in R2020a

Starting in R2020a, Simulink no longer allows you to use the Barker Code Generator block version available before R2015b.

Existing models automatically update to load the Barker Code Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes. For more information on block forwarding, see "Forwarding Tables" (Simulink).

# Baseband File Reader 

Read baseband signals from file
Library: Communications Toolbox / Comm Sources

```
Baseband
File Reader
```

## Description

The Baseband File Reader block reads a signal from a baseband file. A baseband file is a specific type of binary file written by the Baseband File Writer block. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz . The block automatically reads the sample rate, center frequency, number of channels, and any descriptive data.

## Input/Output Ports

## Output

## Data - Baseband signal

scalar | vector | matrix
Baseband signal, returned as a scalar, vector, or matrix. The signal is read from the file specified by the Baseband file name parameter. The sample time is either inherited from the file or can be set by the Sample Time (s) parameter.
Data Types: double

## EOF - End-of-file indicator

logical scalar
End-of-file indicator, returned as a logical scalar. The output is true when the Repeatedly read the file parameter is false and the entire file has been read. To enable this port, select the Output end-of-file indicator parameter.

## Parameters

## Baseband file name - Name of file from which data is read example.bb (default) | character vector

Specify the name of the baseband file as a character vector.
Click Browse to locate the baseband file you want to read. Click File Info to display this information:

- File name
- Sample rate
- Center frequency
- Number of samples
- Number of channels
- Data type
- Any metadata fields

Data Types: char
Inherit sample time from file - Select source of sample time
on (default) |off
Select this check box to inherit the sample time from the file specified by Baseband file name.

## Sample time (s) - Block sample time

1 (default) | positive scalar
Specify the block sample time in seconds as a positive scalar. To enable this parameter, clear the Inherit sample time from file check box.

## Samples per frame - Number of samples in one frame 100 (default) | positive integer scalar

Specify the samples per frame as a positive integer scalar.

## Repeatedly read the file - Continuously loop data from file off (default) | on

Select this check box to repeatedly read the contents of the baseband file. When the end of the file is reached:

- The block outputs zeros, if the Repeatedly read the file parameter is not selected (off).
- The block outputs samples from the beginning of the file, if the Repeatedly read the file parameter is selected (on).

## Simulate using - Type of simulation to run

Code generation (default) | Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated $C$ code. The first time you run a simulation, Simulink generates $C$ code for the block. The $C$ code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double \| integer $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

Baseband File Writer

Introduced in R2016b

## Baseband File Writer

Write baseband signals to file
Library: Communications Toolbox / Comm Sinks

Baseband
File
Writer

## Description

The Baseband File Writer block writes a baseband signal to a specific type of binary file. Baseband signals are typically down-converted from a nonzero center frequency to 0 Hz . Sample rate, which is determined by the input signal sample time and frame size, and center frequency are saved when the signal is written to a file.

## Input/Output Ports

Input
Port_1 - Baseband signal
scalar | vector | matrix
This port accepts a baseband signal to be saved under the filename specified by the Baseband file name parameter. The saved signal is always complex.

Data Types: single | double

## Parameters

## Baseband file name - Name of file in which data is saved untitled.bb (default) | character vector

Specify the name of the baseband file as a character vector.
To specify the location where the file is saved, click Browse.

## Center frequency ( Hz ) - Center frequency of the baseband signal le8 (default) | nonnegative scalar

Specify the center frequency in Hz as a nonnegative scalar.
Metadata in a structure - Data describing the baseband signal
struct() (default)| structure
Specify data describing the baseband signal as a structure. If the signal has no descriptive data, this parameter is an empty structure. The structure can contain any number of fields. Field names have no restrictions, but the field values must be numeric, logical, or character data types having any dimension.

[^2]Specify the number to write. If this parameter is inf, all samples are saved. Otherwise, only the last $N$ samples are saved, where $N$ is specified by this parameter.

## Simulate using - Select simulation mode

Code generation (default)| Interpreted execution
Code generation
On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.
Interpreted execution
Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

## Block Characteristics

| Data Types | double $\mid$ integer $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## Tips

- The Baseband File Writer block writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the zip function. For more information, see "Create and Extract from Zip Archives" (MATLAB).

## Extended Capabilities

## Baseband PLL

Implement baseband phase-locked loop

```
Baseband Filt F
    PLL vCO
```

## Library

Components sublibrary of Synchronization

## Description

The Baseband PLL (phase-locked loop) block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. Unlike the PhaseLocked Loop block, this block uses a baseband method and does not depend on a carrier frequency.

This PLL has these three components:

- An integrator used as a phase detector.
- A filter. You specify the filter's transfer function using the Lowpass filter numerator and Lowpass filter denominator parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of $s$.

To design a filter, you can use the Signal Processing Toolbox ${ }^{\mathrm{TM}}$ functions cheby1, and cheby2. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.
[num, den] = cheby2(3,40,100,'s')

- A voltage-controlled oscillator (VCO). You specify the sensitivity of the VCO signal to its input using the VCO input sensitivity parameter. This parameter, measured in Hertz per volt, is a scale factor that determines how much the VCO shifts from its quiescent frequency.

This block accepts a sample-based scalar signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

This model is nonlinear; for a linearized version, use the Linearized Baseband PLL block.

## Parameters

## Lowpass filter numerator

The numerator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## Lowpass filter denominator

The denominator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO's quiescent frequency.

## BCH Decoder

Decode BCH code to recover binary vector data
Library:
Communications Toolbox / Error Detection and Correction / Block

## Description

The BCH Decoder block recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the Codeword length, $\mathbf{N}$ and Message length, $\mathbf{K}$ parameter values in this block must match the parameters in the corresponding BCH Encoder block. The full-length values of $N$ and $K$ must produce a valid narrow-sense BCH code.

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in "Input and Output Signal Length in BCH Blocks" on page 5-38.

See "Tips" on page 5-40 for information about valid $N$ values, valid ( $N, K$ ) pairs, and error-correcting capabilities for a given BCH code.

If decoding fails, the message portion of the decoder input is returned unchanged as the decoder output.

The sample times of all input and output signals are equal.

This icon shows optional ports.

## Ports

## Input

## In - Encoded message

binary column vector
Encoded message, specified as a binary column vector. The encoded message is a BCH code with message length $K$ and codeword length ( $N$ - number of punctures).
Data Types: single | double | int8|int16| int32 | uint8|uint16|uint32|Boolean
Era - Erasure vector
binary column vector
Erasure vector, specified as a binary column vector that is the same length as In. Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased.

## Dependencies

To enable this port, select Enable erasures input port.
Data Types: double | Boolean

## Output

## Out - Decoded message

binary column vector
Decoded message, returned as a binary column vector input signal with an integer multiple of Message length, K elements or Shortened message length, $\mathbf{S}$ elements if the code is shortened. Each group of input elements represents one codeword to decode. The input and output signal lengths are listed in the "Input and Output Signal Length in BCH Blocks" on page 5-38 table.

## Data Types: single | double | int8 | int16|int32 |uint8 | uint16 | uint32 | Boolean

## Err - Decoding errors

integer vector
Decoding errors, returned as an integer vector that indicates the number of errors detected during decoding of the codeword. A negative integer indicates that the block detected more errors than it could correct by using the coding scheme.

## Dependencies

To enable this port, select Output number of corrected errors.

## Data Types: single | double | int8 | int16| int32 |uint8|uint16|uint32 | Boolean

For more information, see "Supported Data Types" on page 5-40.

## Parameters

## Codeword length, N - Codeword length

15 (default) | integer
Codeword length, specified as an integer of the form $N=2^{M}-1$, where $M$ is an integer from 3 through 16. For more information, see "Tips" on page 5-40.

## Message length, K - Message length

5 (default) | integer
Message length, specified as an integer. The ( $\mathrm{N}, \mathrm{K}$ ) pair must produce a narrow-sense BCH code.

## Shortened message length, S - Shortened message length

5 (default) | integer
Shortened message length, specified as an integer. When you specify this parameter, provide fulllength $N$ and $K$ values to specify the ( $N, K$ ) code that is shortened to an $(N-K+S, S)$ code.

## Dependencies

To enable this parameter, select Specify shortened message length.

## Generator polynomial - Generator polynomial

${ }^{\prime} X^{\wedge} 10+X^{\wedge} 8+X^{\wedge} 5+X^{\wedge} 4+X^{\wedge} 2+X+1^{\prime}$ (default)| polynomial character vector $\mid$ binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector - For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

```
Example: ' X^10 + X^8 + X^5 + X^4 + X^2 + X + 1', which is equivalent to
bchgenpoly(15,5)
```

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Primitive polynomial - Primitive polynomial

```
'X^4 + X + 1' (default)| polynomial character vector | binary row vector
```

Primitive polynomial in order of descending power. It is a polynomial of order $M$ that defines the finite Galois field $\mathrm{GF}(2)$, specified as one of the following:

- A polynomial character vector - For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: ' $X^{\wedge} 4+X+1$ ', which is the primitive polynomial used for a $(15,5)$ code, de2bi(primpoly(4,'nodisplay'),'left-msb')

## Dependencies

To enable this parameter, select Specify primitive polynomial.

## Disable generator polynomial checking - Option to disable generator polynomial checking

on (default) | off
Select this parameter to disable generator polynomial check.
Each time a model initializes, the block performs a polynomial check. This check verifies that $X^{N}+1$ is divisible by the specified generator polynomial, where $N$ represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

Tip Always run the check at least once before disabling this feature.

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Puncture vector - Puncture vector

[ones (8,1); zeros(2,1)] (default)| column vector
Puncture vector, specified as a binary column vector of length $N-K$. Element indices with 1 s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see "Puncturing and Erasures" on page 5-39.

## Dependencies

To enable this parameter, select Puncture code.
Enable erasures input port - Option to enable erasures input port
off (default) | on
Selecting this check box enables the erasures port, Era.
Through the port, you can input a binary column vector that is $1 / M$ times as long as the codeword input.

Erasure values of 1 correspond to erased symbols in the same position in the bit-packed codeword. Values of 0 correspond to nonerased symbols. For more information, see "Puncturing and Erasures" on page 5-39.

Output number of corrected errors - Option to enable port to output number of corrected errors
off (default) | on
Selecting this check box enables an additional output port, Err, which indicates the number of errors the block corrected in the input codeword.

## Block Characteristics

| Data Types | Boolean $\mid$ double $\mid$ integer $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Input and Output Signal Length in BCH Blocks

This table shows how to compute the input and output signal lengths for the BCH encoder and decoder blocks.

The notation $\mathrm{y}=\mathrm{c} * \mathrm{x}$ denotes that y is an integer multiple of x .

| Specify Shortened Message Length, S | BCH Encoder | BCH Decoder |
| :---: | :---: | :---: |
| off | Input Length: $c * K$ <br> Output Length: $c^{*}(N-P)$ | Input Length: $c^{*}(N-P)$ <br> Output Length: $c * K$ <br> Erasures Length: $c^{*}(N-P)$ |
| on | Input Length: $c * S$ <br> Output Length: $c^{*}(N-K+S-P)$ | Input Length: $c^{*}(N-K+S-P)$ <br> Output Length: $c * S$ <br> Erasures Length: $c *(N-K+S-P)$ |

- $N$ is the codeword length
- $K$ is the message length
- $S$ is the shortened message length
- $P$ is the number of punctures value, and is equal to the number of zeros in the puncture vector.

## Puncturing and Erasures

1 s and 0 s have precisely opposite meanings for the puncture and erasure vectors.
In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see "Shortening, Puncturing, and Erasures".

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Boolean <br> - $8-, 16$-, and 32 -bit signed integers <br> - $8-16$-, and 32 -bit unsigned integers |
| Out | - Double-precision floating point <br> - Boolean <br> - 8-, 16-, and 32 -bit signed integers <br> - $8-16$-, and 32 -bit unsigned integers |
| Era | - Double-precision floating point <br> - Boolean |
| Err | - Double-precision floating point <br> - Boolean <br> - $8-, 16$-, and 32 -bit signed integers <br> - $8-16$-, and 32 -bit unsigned integers |

## Pair Block

BCH Encoder - Encodes data using BCH algorithm.

## Tips

- To generate the list of valid ( $\mathrm{N}, \mathrm{K}$ ) pairs along with the corresponding values of the error-correction capability, run bchnumerr(N).
- Valid values for $N=2^{M}-1$, where $M$ is an integer from 3 through 16 . The maximum allowable value of $N$ is 65,535 .

## Algorithms

This block implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

## BCH Encoder

Create BCH code from binary vector data
Library:
Communications Toolbox / Error Detection and Correction / Block

## Description

The BCH Encoder block creates a BCH code with message length $K$ and codeword length ( $N$ number of punctures).

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in "Input and Output Signal Length in BCH Blocks" on page 5-44.

See "Tips" on page 5-45 for information about valid $N$ values, valid ( $N, K$ ) pairs, and error-correcting capabilities for a given BCH code.

## Ports

## Input

## In - Message to encode

binary column vector
Message to encode, specified as a binary column vector input signal with an integer multiple of Message length, K elements or Shortened message length, S elements if the code is shortened. Each group of input elements represents one message word to encode. The input and output signal lengths are listed in "Input and Output Signal Length in BCH Blocks" on page 5-44.
Data Types: single | double | int8|int16| int32 | uint8|uint16|uint32|Boolean

## Output

## Out - Encoded message

binary column vector
Encoded message, returned as a binary column vector. The encoded message is a BCH code with message length $K$ and codeword length ( $N$ - number of punctures).
Data Types: single | double | int8 | int16|int32 | uint8|uint16|uint32 | Boolean
For more information, see "Supported Data Types" on page 5-45.

## Parameters

## Codeword length, N - Codeword length

15 (default) | integer

Codeword length, specified as an integer of the form $N=2^{M}-1$, where $M$ is an integer from 3 through 16. For more information, see "Tips" on page 5-45.

## Message length, K - Message length

5 (default) | integer
Message length, specified as an integer. The ( $\mathrm{N}, \mathrm{K}$ ) pair must produce a narrow-sense BCH code.

## Shortened message length, S - Shortened message length

5 (default) | integer
Shortened message length, specified as an integer. When you specify this parameter, provide fulllength $N$ and $K$ values to specify the ( $N, K$ ) code that is shortened to an $(N-K+S, S)$ code.

## Dependencies

To enable this parameter, select Specify shortened message length.

## Generator polynomial - Generator polynomial

' $\mathrm{X}^{\wedge 10 ~+~ X \wedge 8 ~+~ X \wedge 5 ~+~ X \wedge 4 ~+~ X \wedge 2 ~+~ X ~+~ 1 ' ~(d e f a u l t)|~ p o l y n o m i a l ~ c h a r a c t e r ~ v e c t o r| ~ b i n a r y ~ r o w ~}$ vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector - For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: ' $X^{\wedge} 10+X^{\wedge} 8+X^{\wedge} 5+X^{\wedge} 4+X^{\wedge} 2+X+1$ ', which is equivalent to bchgenpoly (15,5)

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Primitive polynomial - Primitive polynomial

' $\mathrm{X}^{\wedge} 4+X+1$ ' (default) | polynomial character vector | binary row vector
Primitive polynomial in order of descending power. It is a polynomial of order $M$ that defines the finite Galois field $\mathrm{GF}(2)$, specified as one of the following:

- A polynomial character vector - For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: ' $\mathrm{X}^{\wedge} 4+\mathrm{X}+1$ ', which is the primitive polynomial used for a $(15,5)$ code, de2bi(primpoly(4,'nodisplay'),'left-msb')

## Dependencies

To enable this parameter, select Specify primitive polynomial.

## Disable generator polynomial checking - Option to disable generator polynomial checking

on (default) | off
Select this parameter to disable generator polynomial check.
Each time a model initializes, the block performs a polynomial check. This check verifies that $X^{N}+1$ is divisible by the specified generator polynomial, where $N$ represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

Tip Always run the check at least once before disabling this feature.

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Puncture vector - Puncture vector

[ones $(8,1)$; zeros $(2,1)]$ (default) | binary column vector
Puncture vector, specified as a binary column vector of length $N-K$. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see "Shortening, Puncturing, and Erasures".

Note 1 s and 0 s have precisely opposite meanings for the puncture and erasure vectors. For an erasure vector, 1 means that the data symbol is to be replaced with an erasure symbol, and 0 means that the data symbol is passed through the block unaltered. This convention applies to both the encoder and the decoder.

## Dependencies

To enable this parameter, select Puncture code.

## Bernoulli Binary Generator

Generate Bernoulli-distributed random binary numbers
Library: Communications Toolbox / Comm Sources / Random Data

## Description

The Bernoulli Binary Generator block generates random binary numbers using a Bernoulli distribution. Use this block to generate random data bits to simulate digital communication systems and obtain performance metrics such as bit error rate. The Bernoulli distribution with parameter $p$ produces zero with probability $p$ and one with probability 1-p. The Bernoulli distribution has mean value 1-p and variance $p(1-p)$. The Probability of zero parameter specifies $p$ and can be any real number in range [ 0,1 .

The output signal can be a column or row vector, two-dimensional matrix, or scalar. The number of rows in the output signal corresponds to the number of samples in one frame and is set by the Samples per frame parameter. The number of columns in the output signal corresponds to the number of channels and is set by the number of elements in the Probability of zero parameter. For more details, see "Sources and Sinks" in Communications Toolbox User's Guide

## Ports

Output
Out - Output data signal
numeric scalar | numeric vector | numeric matrix
Output data signal, returned as a numeric scalar, vector, or matrix.
Data Types: double

## Parameters

## Probability of zero - Probability of generating zero at output

0.5 (default) | integer in the range [0, 1] | vector of integers in the range [0, 1]

Probability of zero must be in the range of [0,1]. The number of elements in the Probability of zero parameter corresponds to the number of independent channels output from the block. The Bernoulli distribution with parameter $p$ produces zero with probability $p$ and one with probability $1-p$.

## Source of initial seed - Source of initial seed for random number generator Auto (default)| Parameter <br> Select Parameter to use the Initial seed parameter to specify the initial seed for the random number generator.

Note When the Source of initial seed parameter is set to Auto and the Simulate using parameter is set to Code generation, the random number generator uses an initial seed of zero. In this case,
the block generates the same random numbers each time it is started. To ensure that the model uses different initial seeds, set Simulate using parameter to Interpreted execution. If you run Interpreted execution in Rapid accelerator mode, then the model behaves the same as Code generation mode.

## Dependencies

Select Auto for the block to use the global random number stream as the initial seed. For more information, see "Managing the Global Stream" (MATLAB) and "Random Number Generators" (MATLAB).

## Initial seed - Initial seed for random number generator <br> nonnegative numeric scalar

If you set the Initial seed parameter to a constant value, then the resulting sequence is repeatable.

## Dependencies

To enable this parameter, set the Source of initial seed to Parameter.

## Sample time - Sample time of output signal

1 (default) |-1 | positive scalar
Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to - 1 , the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-49.

## Samples per frame - Samples per frame of output signal

1 (default) | positive scalar
Samples per frame in one channel of the output signal, specified as a positive integer. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 549.

## Output data type - Data type of output signal <br> double (default) | boolean

Select the data type for the output signal.

## Simulate using - Type of simulation to run

Code generation (default) | Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

## Bernoulli Binary Generator block update supported in Upgrade Advisor

Behavior changed in R2020a
Starting in R2020a, Bernoulli Binary Generator block allows you to use the Upgrade Advisor. You can update to the block version announced in R2015b or keep the block version available before R2015b.

- Use the Upgrade Advisor to update existing models that include the Bernoulli Binary Generator block.
- Behavior of the random number generator is changed. The statistics are improved. For more information, see "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes.

## Binary Cyclic Decoder

Decode systematic cyclic code to recover binary vector data
$\underbrace{\text { 日 }} \begin{array}{l}\text { Cyclic Decoder }\end{array}\}$

## Library

Block sublibrary of Error Detection and Correction

## Description

The Binary Cyclic Decoder block recovers a message vector from a codeword vector of a binary systematic cyclic code. For proper decoding, the parameter values in this block should match those in the corresponding Binary Cyclic Encoder block.

This block accepts a column vector input signal containing $N$ elements, where $N$ is the codeword length. The output signal is a column vector containing $K$ elements, where $K$ is the message length of the cyclic code.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an $[\mathrm{N}, \mathrm{K}]$ code, enter $N$ and $K$ as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, cyclpoly (N,K,'min').
- To create a code with codeword length N and a particular degree-( $\mathrm{N}-\mathrm{K}$ ) binary generator polynomial, enter $N$ as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox cyclpoly function.

For information about the data types each block port supports, see the "Supported Data Type" on page 5-51 table on this page.

## Parameters

## Codeword length $\mathbf{N}$

The codeword length $N$, which is also the input vector length.

## Message length $K$, or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

## Supported Data Type

## Binary-Input RS Encoder

Create Reed-Solomon code from binary vector data
Library: Communications Toolbox / Error Detection and Correction / Block

## Description

The Binary-Input RS Encoder block creates a Reed-Solomon code.
The symbols for the code are binary sequences of length $M$, corresponding to elements of the Galois field $G F\left(2^{M}\right)$. The first bit in each symbol is the most significant bit.

Suppose $\mathrm{M}=3, \mathrm{~N}=2^{3}-1=7$, and $\mathrm{K}=2$. Then a message is a vector of length 2 whose entries are integers between 0 and 7. A corresponding codeword is a vector of length 7 whose entries are integers between 0 and 7. The following figure illustrates possible input and output signals to this block when codeword length $N=7$ and message word length $K=2$. Since $N=2^{M}-1$, when $N=7$, the symbol length, $M=3$.

Codewords, output as a binary column vector

Each input message word is a binary vector of length 6, that represents 2 three-bit integers. Each corresponding output codeword is a binary vector of length 21 that represents 7 three-bit integers. For more information, see "Input and Output Signal Length in RS Blocks" on page 5-57.

## Ports

Input

## In - Message

binary column vector
Message in bits, specified as one of the following:

- When there is no message shortening, a ( $N_{\mathrm{C}} \times K \times M$ )-by-1 binary column vector.
- When there is message shortening, a ( $N_{\mathrm{C}} \times S \times M$ )-by-1 binary column vector.
$N_{\mathrm{C}}$ is the number of message words, $K$ is the Message length $\mathbf{K}$ (symbols), $M$ is the number of bits per symbol, and $S$ is the Shortened message length $\mathbf{S}$ (symbols).

Note The number of decoded message words equals the number of codewords.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-57.
Data Types: single|double|int8|int16|int32|uint8|uint16|uint32|Boolean | ufix(1)

## Output

## Out - Reed-Solomon codeword

binary column vector
Reed-Solomon codeword in bits, returned as an $\left(N_{\mathrm{C}} \times(N-K+S-P) \times M\right)$-by-1 binary column vector. $N_{\mathrm{C}}$ is the number of codewords, $N$ is the Codeword length $\mathbf{N}$ (symbols), $K$ is the Message length $\mathbf{K}$ (symbols), $S$ is the Shortened message length $\mathbf{S}$ (symbols), $P$ is the number of punctures per codeword, and $M$ is the number of bits per symbol.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-57.
Data Types: single|double|int8|int16|int32|uint8|uint16|uint32|Boolean| ufix(1)

For more information, see "Supported Data Types" on page 5-59.

## Parameters

Codeword length N (symbols) - Codeword length
7 (default) | integer
Codeword length in symbols, specified as an integer.
For more information, see "Restrictions on the M and the Codeword Length N" on page 5-58 and "Input and Output Signal Length in RS Blocks" on page 5-57.

## Message length K (symbols) - Message word length

3 (default) | integer
Message word length in symbols, specified as an integer in the range [1, $N-2$ ], where $N$ is the codeword length.

## Shortened message length S (symbols) - Shortened message word length 3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that $S \leq K$. When
Shortened message length S (symbols) < Message length K (symbols), the Reed-Solomon code is shortened.

You still specify $N$ and $K$ values for the full-length $(N, K)$ code but the decoding is shortened to an ( $N-$ $K+S, S$ ) code.

## Dependencies

To enable this parameter, select Specify shortened message length.

## Generator polynomial - Generator polynomial

rsgenpoly(7, 3, [], [], 'double') (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values from 0 to $2^{M}-1$, in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see "Specify the Generator Polynomial" on page 5-58.
Example: $\left.\begin{array}{lllll}1 & 3 & 1 & 2 & 3\end{array}\right]$, which is equivalent to rsgenpoly (7,3)

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Primitive polynomial - Primitive polynomial

' $X^{\wedge} 3+X+1$ ' (default) | polynomial character vector $\mid$ binary row vector
Primitive polynomial in order of descending power. This polynomial is of order $M$ and defines the finite Galois field $\mathrm{GF}\left(2^{\mathrm{M}}\right)$ corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see "Restrictions on the M and the Codeword Length N " on page 5-58.
Example: ' $X^{\wedge} 3+X+1$ ', which is the primitive polynomial used for a $(7,3)$ code, de2bi(primpoly(3,'nodisplay'), 'left-msb')

## Dependencies

To enable this parameter, select Specify primitive polynomial.

## Puncture vector - Puncture vector

## [ones(2,1); zeros(2,1)] (default) | binary column vector

Puncture vector, specified as an ( $N-K$ )-by-1 binary column vector. Element indices with 1 s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see "Puncturing and Erasures" on page 5-59.

## Dependencies

To enable this parameter, select Puncture code.

## Output data type - Output type of the block

Same as input (default)| boolean|double
Output type of the block, specified as Same as input, boolean, or double.

## Block Characteristics

| Data Types | Boolean \| double | fixed pointa | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

ufix(1) only.

## More About

## Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length, $K$, or shortened message word length, $S$. The codeword length is $N-K+S-P$, where $N$ is the full codeword length and $P$ is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N-P$, because $K=S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y=N_{\mathrm{C}} \times x$ denotes that $y$ is an integer multiple of $x$.

|  | Input, Erasure, and Output Vector Lengths |  |
| :--- | :--- | :--- |
| RS Block Coder | No Message Shortening Used | Message Shortening Used |
| Binary-Input RS Encoder | Input Length (bits): | Input Length (bits): |
|  | $N_{\mathrm{C}} \times K \times M$ | $N_{\mathrm{C}} \times S \times M$ |
|  | Output Length (bits): | Output Length (bits): |
|  | $N_{\mathrm{C}} \times(N-P) \times M$ | $N_{\mathrm{C}} \times(N-K+S-P) \times M$ |

|  | Input, Erasure, and Output Vector Lengths |  |
| :--- | :--- | :--- |
| RS Block Coder | No Message Shortening Used | Message Shortening Used |
| Binary-Output RS Decoder | Input Length (bits): | Input Length (bits): |
|  | $N_{\mathrm{C}} \times(N-P) \times M$ | $N_{\mathrm{C}} \times(N-K+S-P) \times M$ |
|  | Erasures Length (symbols): | Erasures Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
|  | Output Length (bits): | Output Length (bits): |
|  | $N_{\mathrm{C}} \times K \times M$ | $N_{\mathrm{C}} \times S \times M$ |

- $N$ is the codeword length.
- $K$ is the message word length.
- $S$ is the shortened message word length.
- $N_{\mathrm{C}}$ is the number of codewords (and message words).
- $P$ is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- $M$ is the degree of the primitive polynomial. Each group of $M$ bits represents an integer between 0 and $2^{M}-1$ that belongs to the finite Galois field $\mathrm{GF}\left(2^{M}\right)$.

For more information on representing data for Reed-Solomon codes, see "Integer Format (ReedSolomon Only)".

Also, see "Restrictions on the M and the Codeword Length N " on page 5-58.

## Restrictions on the $\mathbf{M}$ and the Codeword Length $\mathbf{N}$

- If you do not select Specify primitive polynomial, valid values for the codeword length, $N$, are from 7 to 65535 . In this case, the block uses the default primitive polynomial of degree $\mathrm{M}=$ ceil ( $\log 2(N+1))$. You can display the default primitive polynomial by running primpoly(ceil(log2(N+1))).
- If you select Specify primitive polynomial, valid values for the primitive polynomial degree, $M$, are from 3 to 16 . The valid values for $N$ in this case are from 7 to $2^{M}-1$. Selecting Specify primitive polynomial enables you to specify the primitive polynomial that defines the finite field $G F\left(2^{M}\right)$, which corresponds to the values that form message words and codewords.

## Specify the Generator Polynomial

Select Specify generator polynomial to enable the Generator polynomial parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to $2^{M}-1$. The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $G F\left(2^{M}\right)$ represented in integer format. For more information about integer and binary format, see "Integer Format (Reed-Solomon Only)". The generator polynomial must be equal to a polynomial with this factored form:
g(x)

$$
=\quad\left(x+\alpha^{b}\right)\left(x+\alpha^{b+1}\right)\left(x+\alpha^{b+2}\right) \ldots\left(x+\alpha^{b+N-K-1}\right)
$$

$\alpha$ is the primitive element of the Galois field over which the input message is defined, and $b$ is an integer.

If you do not select Specify generator polynomial, the block uses the default generator polynomial, corresponding to $b=1$, for Reed-Solomon encoding. You can display the default generator polynomial by running rsgenpoly.

- If you are using the default primitive polynomial (Specify primitive polynomial is not selected), the default generator polynomial is rsgenpoly $(\mathrm{N}, \mathrm{K})$, where $\mathrm{N}=2^{\mathrm{M}}-1$.
- If you are not using the default primitive polynomial (Specify primitive polynomial is selected) and you specify the primitive polynomial as poly, the generator polynomial is rsgenpoly(N,K, poly).

Note The degree of the generator polynomial is $N-K$, where $N$ is the codeword length and $K$ is the message word length.

## Puncturing and Erasures

1 s and 0 s have precisely opposite meanings for the puncture and erasure vectors.
In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see "Shortening, Puncturing, and Erasures".

## Supported Data Types

## Binary Linear Decoder

Decode linear block code to recover binary vector data

## Library

Block sublibrary of Error Detection and Correction

## Description

The Binary Linear Decoder block recovers a binary message vector from a binary codeword vector of a linear block code.

The Generator matrix parameter is the generator matrix for the block code. For proper decoding, this should match the Generator matrix parameter in the corresponding Binary Linear Encoder block. If $N$ is the codeword length of the code, then Generator matrix must have $N$ columns. If $K$ is the message length of the code, then the Generator matrix parameter must have $K$ rows.

This block accepts a column vector input signal containing $N$ elements. This block outputs a column vector with a length of $K$ elements.

The decoder tries to correct errors, using the Decoding table parameter. If Decoding table is the scalar 0 , then the block defaults to the table produced by the Communications Toolbox function syndtable. Otherwise, Decoding table must be a $2^{\mathrm{N}-\mathrm{K}-\mathrm{by}-\mathrm{N}}$ binary matrix. The $r$ th row of this matrix is the correction vector for a received binary codeword whose syndrome has decimal integer value $r$-1. The syndrome of a received codeword is its product with the transpose of the parity-check matrix.

For information about the data types each block port supports, see the "Supported Data Type" on page $5-62$ table on this page.

## Parameters

## Generator matrix

Generator matrix for the code; same as in Binary Linear Encoder block.

## Decoding table

Either a $2^{\mathrm{N}-\mathrm{K}}$-by-N matrix that lists correction vectors for each codeword's syndrome; or the scalar 0 , in which case the block defaults to the table corresponding to the Generator matrix parameter.

## Binary-Output RS Decoder

Decode Reed-Solomon code to recover binary vector data
Library: Communications Toolbox / Error Detection and Correction /

## Description

The Binary-Output RS Decoder block recovers a binary message vector from a binary Reed-Solomon codeword vector. For proper decoding, the parameter values in this block must match parameter values in the corresponding Binary-Input RS Encoder block.

The symbols for the code are binary sequences of length $M$, corresponding to elements of the Galois field $G F\left(2^{M}\right)$. The first bit in each symbol is the most significant bit.

This figure shows the decoder input-output word length for codeword length $N=7$ and message word length $K=2$. Since $N=2^{M}-1$, when $N=7$, the symbol length, $M=3$.

Each input codeword is a binary vector of length 21 that represents 7 three-bit integers. Each corresponding output message word is a binary vector of length 6 , that represents 2 three-bit integers. For more information, see "Input and Output Signal Length in RS Blocks" on page 5-69.

This icon shows all ports, including optional ones:

## Ports

## Input

## In - Reed-Solomon codeword

binary column vector
Reed-Solomon codeword in bits, specified as an $\left(N_{\mathrm{C}} \times(N-K+S-P) \times M\right)$-by-1 binary column vector. $N_{\mathrm{C}}$ is the number of codewords, $N$ is the Codeword length $\mathbf{N}$ (symbols), $K$ is the Message length $\mathbf{K}$ (symbols), $S$ is the Shortened message length $\mathbf{S}$ (symbols), $P$ is the number of punctures per codeword, and $M$ is the number of bits per symbol.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-69.
Data Types: single | double | int8| int16|int32|uint8|uint16|uint32|Boolean | ufix(1)

## Era - Erasure vector

binary column vector
Erasure vector in symbols, specified as an $\left(N_{\mathrm{C}} \times(N-K+S-P)\right.$ )-by-1 binary column vector. $N_{\mathrm{C}}$ is the number of codewords, $N$ is the Codeword length $\mathbf{N}$ (symbols), $K$ is the Message length $K$ (symbols), $S$ is the Shortened message length $\mathbf{S}$ (symbols), $P$ is the number of punctures per codeword, and $M$ is the number of bits per symbol.

Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased. For more information, see "Puncturing and Erasures" on page 5-71.

## Dependencies

To enable this port, select Enable erasures input port.
Data Types: double | Boolean

## Output

## Out - Decoded message

binary column vector
Decoded message in bits, returned as one of the following:

- When there is no message shortening, a ( $N_{\mathrm{C}} \times K \times M$ )-by- 1 binary column vector.
- When there is message shortening, a $\left(N_{\mathrm{C}} \times S \times M\right)$-by-1 binary column vector.
$N_{\mathrm{C}}$ is the number of message words, $K$ is the Message length K (symbols), $M$ is the number of bits per symbol, and $S$ is the Shortened message length $\mathbf{S}$ (symbols).

Note The number of decoded message words equals the number of codewords.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-69.
Data Types: single | double | int8 | int16 | int32 | uint8 | uint16|uint32 | Boolean | ufix(1)

## Err - Decoding errors

integer vector
Symbol decoding errors, returned as an integer vector with $N_{\mathrm{C}}$ elements, where $N_{\mathrm{C}}$ is the number of codewords. This port indicates the number of symbol errors detected during decoding of each codeword. A negative integer indicates that the block detected more errors than it could correct by using the specified coding scheme.

Note An ( $N, K$ ) Reed-Solomon code can correct up to floor ( $(N-K) / 2$ ) symbol errors (not bit errors) in each codeword. When a received codeword contains more than $(N-K) / 2$ symbol errors, a decoding failure occurs.

## Dependencies

To enable this port, select Output number of corrected symbol errors.

## Data Types: double

For more information, see "Supported Data Types" on page 5-71.

## Parameters

Codeword length N (symbols) - Codeword length
7 (default) | integer
Codeword length in symbols, specified as an integer.
For more information, see "Restrictions on M and Codeword Length N" on page 5-70 and "Input and Output Signal Length in RS Blocks" on page 5-69.

## Message length K (symbols) - Message word length

3 (default) | integer
Message word length in symbols, specified as an integer in the range [1, $N-2$ ], where $N$ is the codeword length.

Shortened message length S (symbols) - Shortened message word length
3 (default) | integer
Shortened message word length in symbols, specified as an integer, such that $S \leq K$. When
Shortened message length S (symbols) < Message length K (symbols), the Reed-Solomon code is shortened.

You still specify $N$ and $K$ values for the full-length ( $N, K$ ) code but the decoding is shortened to an ( $N$ $K+S, S$ ) code.

## Dependencies

To enable this parameter, select Specify shortened message length.

## Generator polynomial - Generator polynomial

rsgenpoly(7, 3, [], [], 'double') (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values from 0 to $2^{M}-1$, in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see "Specify the Generator Polynomial" on page 5-70.

Example: [ $\left.\begin{array}{lllll}1 & 3 & 1 & 2 & 3\end{array}\right]$, which is equivalent to $\operatorname{rsgenpoly}(7,3)$

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Primitive polynomial - Primitive polynomial

' X^3 + X + 1' (default) | polynomial character vector | binary row vector
Primitive polynomial in order of descending power. This polynomial is of order $M$ and defines the finite Galois field GF $\left(2^{\mathrm{M}}\right)$ corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see "Restrictions on M and Codeword Length N " on page 5-70.
Example: ' $X^{\wedge} 3+X+1$ ', which is the primitive polynomial used for a $(7,3)$ code, de2bi(primpoly(3,'nodisplay'),'left-msb')

## Dependencies

To enable this parameter, select Specify primitive polynomial.

## Puncture vector - Puncture vector

[ones $(2,1)$; zeros $(2,1)$ ] (default) | binary column vector
Puncture vector, specified as an ( $N-K$ )-by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see "Puncturing and Erasures" on page 5-71.

## Dependencies

To enable this parameter, select Punctured code.

## Enable erasures input port - Enable erasures input port <br> off (default) | on

Selecting this check box enables the erasures port, Era. For more information, see "Puncturing and Erasures" on page 5-71.

## Output number of corrected symbol errors - Enable port to output number of corrected symbol errors

off (default) | on
Selecting this check box enables an additional output port, Err, which indicates the number of symbol errors the block corrected in the input codeword.

## Output data type - Output type of the block

Same as input (default)| boolean| double
Output type of the block, specified as Same as input, boolean, or double.

## Block Characteristics

| Data Types | Boolean \| double \| fixed point ${ }^{\text {\| }}$ integer \\| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

a. ufix(1) only.

## More About

## Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length, $K$, or shortened message word length, $S$. The codeword length is $N-K+S-P$, where $N$ is the full codeword length and $P$ is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N-P$, because $K=S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y=N_{\mathrm{C}} \times x$ denotes that $y$ is an integer multiple of $x$.

|  | Input, Erasure, and Output Vector Lengths |  |
| :--- | :--- | :--- |
| RS Block Coder | No Message Shortening Used | Message Shortening Used |
| Binary-Input RS Encoder | Input Length (bits): | Input Length (bits): |
|  | $N_{\mathrm{C}} \times K \times M$ | $N_{\mathrm{C}} \times S \times M$ |
|  | Output Length (bits): | Output Length (bits): |
|  | $N_{\mathrm{C}} \times(N-P) \times M$ | $N_{\mathrm{C}} \times(N-K+S-P) \times M$ |

|  | Input, Erasure, and Output Vector Lengths |  |
| :--- | :--- | :--- |
| RS Block Coder | No Message Shortening Used | Message Shortening Used |
| Binary-Output RS Decoder | Input Length (bits): | Input Length (bits): |
|  | $N_{\mathrm{C}} \times(N-P) \times M$ | $N_{\mathrm{C}} \times(N-K+S-P) \times M$ |
|  | Erasures Length (symbols): | Erasures Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
|  | Output Length (bits): | Output Length (bits): |
|  | $N_{\mathrm{C}} \times K \times M$ | $N_{\mathrm{C}} \times S \times M$ |

- $N$ is the codeword length.
- $K$ is the message word length.
- $S$ is the shortened message word length.
- $N_{\mathrm{C}}$ is the number of codewords (and message words).
- $P$ is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- $M$ is the degree of the primitive polynomial. Each group of $M$ bits represents an integer between 0 and $2^{M}-1$ that belongs to the finite Galois field $\mathrm{GF}\left(2^{M}\right)$.

For more information on representing data for Reed-Solomon codes, see "Integer Format (ReedSolomon Only)".

Also, see "Restrictions on M and Codeword Length N " on page 5-70.

## Restrictions on M and Codeword Length N

- If you do not select Specify primitive polynomial, valid values for the codeword length, $N$, are from 7 to 65535 . In this case, the block uses the default primitive polynomial of degree $\mathrm{M}=$ ceil( $\log 2(N+1))$. You can display the default primitive polynomial by running primpoly(ceil(log2(N+1))).
- If you select Specify primitive polynomial, valid values for the primitive polynomial degree, $M$, are from 3 to 16 . The valid values for $N$ in this case are from 7 to $2^{M}-1$. Selecting Specify primitive polynomial enables you to specify the primitive polynomial that defines the finite field $G F\left(2^{M}\right)$, which corresponds to the values that form message words and codewords.

## Specify the Generator Polynomial

Select Specify generator polynomial to enable the Generator polynomial parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to $2^{M}-1$. The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $G F\left(2^{M}\right)$ represented in integer format. For more information about integer and binary format, see "Integer Format (Reed-Solomon Only)". The generator polynomial must be equal to a polynomial with this factored form:
g(x)

$$
=\quad\left(x+\alpha^{b}\right)\left(x+\alpha^{b+1}\right)\left(x+\alpha^{b+2}\right) \ldots\left(x+\alpha^{b+N-K-1}\right)
$$

$\alpha$ is the primitive element of the Galois field over which the input message is defined, and $b$ is an integer.

If you do not select Specify generator polynomial, the block uses the default generator polynomial, corresponding to $b=1$, for Reed-Solomon encoding. You can display the default generator polynomial by running rsgenpoly.

- If you are using the default primitive polynomial (Specify primitive polynomial is not selected), the default generator polynomial is rsgenpoly $(\mathrm{N}, \mathrm{K})$, where $\mathrm{N}=2^{\mathrm{M}}-1$.
- If you are not using the default primitive polynomial (Specify primitive polynomial is selected) and you specify the primitive polynomial as poly, the generator polynomial is rsgenpoly(N,K, poly).

Note The degree of the generator polynomial is $N-K$, where $N$ is the codeword length and $K$ is the message word length.

## Puncturing and Erasures

1 s and 0 s have precisely opposite meanings for the puncture and erasure vectors.
In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see "Shortening, Puncturing, and Erasures".

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean <br> - 8 -, 16 -, and 32 -bit signed integers <br> - 8 -, 16-, and 32 -bit unsigned integers <br> - 1-bit unsigned integer (ufix(1)) |
| Out | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean <br> - 8 -, 16 -, and 32 -bit signed integers <br> - $8-16$-, and 32 -bit unsigned integers <br> - 1-bit unsigned integer (ufix(1)) |

| Port | Supported Data Types |
| :--- | :--- |
| Era | $\bullet$ <br>  |
| Err | Double-precision floating point |

## Pair Block

Binary-Input RS Encoder

## Algorithms

This block uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see "Algorithms for BCH and RS Errors-only Decoding".

Objects
comm.RSDecoder
Functions
primpoly|rsdec|rsgenpoly

Introduced before R2006a

## Binary Symmetric Channel

Introduce binary errors
Library: Communications Toolbox / Channels

## Description

The Binary Symmetric Channel block introduces errors to the input signal transmitted through a binary symmetric channel. The errors are introduced based on the specified Error probability. For more information, see "Tips" on page 5-74.

## Ports

## Input

## Input - Input signal

column vector | matrix
Input signal, specified as a column vector or an $N_{\mathrm{S}}$-by- $N_{\mathrm{C}}$ matrix of Boolean values. $N_{\mathrm{S}}$ is the number of samples per channel. $N_{\mathrm{C}}$ is the number of independent data channels. For more information, see "Tips" on page 5-74.

## Output

## Output - Binary output signal

column vector | matrix
Binary output signal, returned as a column vector or matrix with the same dimensions as Input. The output signal is a version of the input signal that has been modified by introducing random errors based on the specified Error probability. To set the output data type, use Output data type.

## Err - Error locations

column vector | matrix
Error locations, returned as a column vector or matrix with the same dimensions as Input. Element values in Err are 1 or 0, where:

- 1 indicates that the corresponding element in Output has an error.
- 0 indicates that the corresponding element in Output does not have an error.

The data type of Err is the same as Output, as set by Output data type.

## Dependencies

To enable this port, select Output error vector.

## Parameters

## Error probability - Probability of error occurrence <br> 0.05 (default) | scalar

Probability of error occurrence for the input signal elements, specified as a scalar in the range $[0,1]$. The probability of error applies independently for each element.

## Output error vector - Option to output error locations on (default) | off

To enable the Err output port to the block, select this parameter.
Output data type - Output data type
double (default) | single | boolean
Select the output data type as double, single, or boolean. This parameter sets the output data type for both the Output and Err ports.

## Initial seed - Initial seed

71 (default) | integer
Initial seed value for the random number generator used by the block, specified as an integer. The block uses the mt19937ar algorithm to generate uniformly distributed random numbers. For details about the mt19937ar algorithm, see "Choosing a Random Number Generator" (MATLAB).

## Simulate using - Type of simulation to run

Code generation (default)|Interpreted execution
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | Boolean \\| double \| fixed point \| integer \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## Tips

- When the input consists of not Boolean values, Binary Symmetric Channel converts zero-valued elements to 0 and converts nonzero-valued elements to 1.
- The Binary Symmetric Channel block creates and uses an independent RandStream to provide a random number stream for probability determination.
- To generate repeatable results, use the same Initial seed value.
- To generate independent probability statistics, set different Initial seed values for multichannel signals, multiple processing chains, or simulation runs.

## Compatibility Considerations

Random Number Generation
Behavior changed in R2018b
To improve statistical properties, the Binary Symmetric Channel block uses the mt19937ar algorithm with RandStream. The Binary Symmetric Channel block accepts a single scalar value for the Initial seed parameter.

# Bipolar to Unipolar Converter 

Map bipolar signal into unipolar signal in range [0, M-1]

| Bipolar to |
| :---: |
| Unipolar |
| Converter |

## Library

Utility Blocks

## Description

The Bipolar to Unipolar Converter block maps the bipolar input signal to a unipolar output signal. If the input consists of integers in the set $\{-M+1,-M+3,-M+5, \ldots, M-1\}$, where $M$ is the $\mathbf{M}$-ary number parameter, then the output consists of integers between 0 and $\mathrm{M}-1$. This block is only designed to work when the input value is within the set $\{-M+1,-M+3,-M+5, \ldots, M-1\}$, where $M$ is the $\mathbf{M}$-ary number parameter. If the input value is outside of this set of integers the output may not be valid.

The table below shows how the block's mapping depends on the Polarity parameter.

| Polarity Parameter Value | Output Corresponding to Input Value of $\mathbf{k}$ |
| :--- | :--- |
| Positive | $(\mathrm{M}-1+\mathrm{k}) / 2$ |
| Negative | $(\mathrm{M}-1-\mathrm{k}) / 2$ |

## Parameters

## M-ary number

The number of symbols in the bipolar or unipolar alphabet.

## Polarity

A value of Positive causes the block to maintain the relative ordering of symbols in the alphabets. A value of Negative causes the block to reverse the relative ordering of symbols in the alphabets.

## Output Data Type

The type of bipolar signal produced at the block's output.
The block supports the following output data types:

- Inherit via internal rule
- Same as input
- double
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

When the parameter is set to its default setting, Inherit via internal rule, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either single or double), the output data type is the same as the input data type.
- If the input data type is not floating-point:
- Based on the $\mathbf{M}$-ary number parameter, the output data type is the ideal unsigned integer output word length required to contain the range [ $0 \mathrm{M}-1$ ] and is computed as follows:
ideal word length $=\operatorname{ceil}(\log 2(M))$
- The block sets the output data type to be an unsigned integer, based on the smallest word length (in bits) that can fit best the computed ideal word length.

Note The selections in the "Hardware Implementation Pane" (Simulink) pane pertaining to word length constraints do not affect how this block determines output data types.

## Examples

If the input is $[-3 ;-1 ; 1 ; 3]$, the $\mathbf{M}$-ary number parameter is 4 , and the Polarity parameter is Positive, then the output is $[0 ; 1 ; 2 ; 3]$. Changing the Polarity parameter to Negative changes the output to $[3 ; 2 ; 1 ; 0]$.

If the value for the $\mathbf{M}$-ary number is $2^{8}$ the block gives an output of uint8.
If the value for the $\mathbf{M}$-ary number is $2^{8}+1$ the block gives an output of uint16.

## Pair Block

Unipolar to Bipolar Converter

## Extended Capabilities

## Introduced before R2006a

## Bit to Integer Converter

Map vector of bits to corresponding vector of integers
Library: Communications Toolbox / Utility Blocks

Bit to Integer Converter

## Description

The Bit to Integer Converter block maps groups of bits in the input vector to integers in the output vector.

If $M$ is specified by the Number of bits per integer(M) parameter:

- For unsigned integers, the block maps each group of $M$ bits to an integer in the range [0, $\left.\left(2^{M}-1\right)\right]$. As a result, the output vector length is $1 / M$ times the input vector length.
- For signed integers, the block maps each group of $M$ bits to an integer in the range $\left[\left(-2^{M-1}\right),\left(2^{M-1}\right.\right.$ -1)].

## Ports

Input

## In - Input signal

bit scalar | column vector of bits
Input signal, specified as a scalar or column vector of bits with a length that is a multiple of the value specified in the Number of bits per integer(M) parameter. The input must be bits with values of 0 or 1 .
Data Types: double

## Output

## Out - Output signal

integer | integer column vector of integers
Output signal, returned as an integer or column vector of integers. The After bit packing, treat resulting integer values as parameter specifies whether input bits are treated as unsigned or signed.

- When the input bits are treated as unsigned, each integer output is in the range $\left[0,\left(2^{M}-1\right)\right]$.
- When the input bits are treated as signed, each integer output is in the range $\left[\left(-2^{M-1}\right),\left(2^{M-1}-1\right)\right]$.

## Parameters

## Number of bits per integer(M) - Number of bits per integer

3 (default) | integer in the range [1, 32]

Number of input bits mapped to each integer in the output, specified as an integer in the range [1, 32].

## Input bit order - Input bit order

MSB first (default)|LSB first
Input bit order, specified as 'MSB first' or 'LSB first'.

- 'MSB first' -- First bit of the input signal is the most significant bit (MSB).
- 'LSB first' -- First bit of the input signal is the least significant bit (LSB).

After bit packing, treat resulting integer values as - Flag for signed integer values after bit packing
Unsigned (default)|Signed
Specify whether the resulting integer values are treated as signed or unsigned after bit packing. This parameter setting determines which Output data type selections are available.

## Output data type - Output data type

Inherit via internal rule (default) | Smallest integer | Same as input|double |
single |int8|uint8|int16|uint16|int32|uint32
The Output data type options change depending on the desired signedness of the output.
If the output integers are Signed, you can choose from the following Output data type options:

- Inherit via internal rule
- Smallest integer
- double
- single
- int8
- int16
- int32

If the output integers are Unsigned, you can choose from the following options in addition to the Signed options:

- Same as input
- uint8
- uint16
- uint32

When you set the parameter to Inherit via internal rule, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either double or single), the output data type is the same as the input data type.
- If the input data type is not floating-point, the output data type is determined as if the parameter is set to Smallest integer.

When you set the parameter to Smallest integer, the block selects the output data type based on the settings used in the "Hardware Implementation Pane" (Simulink) of the Configuration Parameters dialog box.

- If you select ASIC/FPGA for the device vendor, the output data type is the smallest ideal integer or fixed-point data type, based on the setting for the Number of bits per integer(M) parameter.
- For all other device vendor selections, the output data type is the smallest available (signed or unsigned) integer word length that is large enough to fit the ideal minimum bit size.

## Block Characteristics

| Data Types | Boolean \\| double \| fixed point ${ }^{\text {ab } \mid \text { integer \\| single }}$ |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

a. Fixed-point inputs must be ufix(1).
b. ufix( N ) or sfix $(\mathrm{N})$ when ASIC/FPGA is selected in the Hardware Implementation Pane and output data-type is set to either (a) Smallest integer or, (b) Inherit via internal rule and at the same time input is non floating-point.

## BPSK Demodulator Baseband

Demodulate BPSK-modulated data

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The BPSK Demodulator Baseband block demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal. The input signal must be a discrete-time complex signal. The block maps the points $\exp (j \theta)$ and $-\exp (j \theta)$ to 0 and 1 , respectively, where $\theta$ is the Phase offset parameter.

For information about the data types each block port supports, see "Supported Data Types" on page 5-86.

Algorithm

Hard-Decision BPSK Demodulator Signal Diagram for Trivial Phase Offset (multiple of $\boldsymbol{\pi} / \mathbf{2}$ )

Hard-Decision BPSK Demodulator Floating-Point Signal Diagram for Nontrivial Phase Offset

Hard-Decision BPSK Demodulator Fixed-Point Signal Diagram for Nontrivial Phase Offset
The exact LLR and approximate LLR cases (soft-decision) are described in "Exact LLR Algorithm" and "Approximate LLR Algorithm" in the Communications Toolbox User's Guide.

## Dialog Box

## Phase offset (rad)

The phase of the zeroth point of the signal constellation.

## Decision type

Specifies the use of hard decision, LLR, or approximate LLR during demodulation. The output values for Log-likelihood ratio and Approximate log-likelihood ratio are of the same data type as the input values. See "Exact LLR Algorithm" and "Approximate LLR Algorithm" in the Communications Toolbox User's Guide for algorithm details.

## Noise variance source

This field appears when Approximate log-likelihood ratio or Log-likelihood ratio is selected for Decision type.

When set to Dialog, the noise variance can be specified in the Noise variance field. When set to Port, a port appears on the block through which the noise variance can be input.

## Noise variance

This parameter appears when the Noise variance source is set to Dialog and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo
simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- Inf to - Inf if Noise variance is very high
- NaN if Noise variance and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Data Types Pane for Hard-Decision

## Output

When Decision type is set to Hard decision, the output data type can be set to 'Inherit via internal rule','Smallest unsigned integer', double, single, int8, uint8, int16, uint16, int32, uint32, or boolean.

When this parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is a floating-point type (single or double). If the input data type is fixed-point, the output data type will work as if this parameter is set to 'Smallest unsigned integer'.

When this parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is the ideal minimum one-bit size, i.e., ufix(1). For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (e.g., uint8).

## Derotate factor

This parameter only applies when the input is fixed-point and Phase offset is not a multiple of п/2.

This can be set to Same word length as input or Specify word length, in which case a field is enabled for user input.

## Data Types Pane for Soft-Decision

When Decision type is set to Log-likelihood ratio or Approximate log-likelihood ratio, the output data type is inherited from the input (e.g., if the input is of data type double, the output is also of data type double).

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed point (only for Hard decision mode) |
| Var | - Double-precision floating point <br> - Single-precision floating point |
| Output | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean <br> - 8 -, 16-, and 32 -bit signed integers <br> - 8 -, 16-, and 32 -bit unsigned integers <br> - ufix(1) in ASIC/FPGA and when Decision type is Hard decision modes |

## Introduced before R2006a

## BPSK Modulator Baseband

Modulate using binary phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The BPSK Modulator Baseband block modulates using the binary phase shift keying method. The output is a baseband representation of the modulated signal.

This block accepts a column vector input signal. The input must be a discrete-time binary-valued signal. If the input bit is 0 or 1 , respectively, then the modulated symbol is $\exp (j \theta)$ or $-\exp (j \theta)$, respectively, where $\theta$ represents the Phase offset parameter.

For information about the data types each block port supports, see the "Supported Data Types" on page 5-90 table on this page.

## Constellation Visualization

The BPSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the "Constellation Visualization" section of the Communications Toolbox User's Guide.

## Dialog Box

## Phase offset (rad)

The phase of the zeroth point of the signal constellation.

## Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this parameter to Fixed-point or User-defined enables fields in which you can further specify details. Setting this parameter to Inherit via back propagation, sets the output data type and scaling to match the following block.

## Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select Fixed-point for the Output data type parameter.

## Set output fraction length to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose Best precision to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose User-defined to specify the output scaling in the Output fraction length parameter.

This parameter is only visible when you select Fixed - point for the Output data type parameter or when you select User-defined and the specified output data type is a fixed-point data type.

## User-defined data type

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the sfix, sint, sfrac, and fixdt functions from Fixed-Point Designer. This parameter is only visible when you select User-defined for the Output data type parameter.

## Output fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select Fixed-point or User-defined for the Output data type parameter and User-defined for the Set output fraction length to parameter.

## Supported Data Types

## Introduced before R2006a

## Carrier Synchronizer

Compensate for carrier frequency offset

## Library

## Synchronization

## Description

The Carrier Synchronizer block compensates for carrier frequency and phase offsets using a closedloop approach for BPSK, QPSK, OQPSK, 8-PSK, QAM, and PAM modulation schemes. The block accepts a single input port. To obtain an estimate of the phase error in radians, select the Estimated phase error output port check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a an real phase estimate. The block outputs have the same dimensions as the input.

## Note

- This block does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

| Modulation | Phase Ambiguity (degrees) |
| :--- | :--- |
| 'BPSK' or 'PAM' | 0,180 |
| ' $O Q P S K$ ' , 'QPSK' , or ' QAM' ' | $0,90,180,270$ |
| ' 8 PSK' | $0,45,90,135,180,225,270,315$ |

- For best results, apply carrier synchronization to non-oversampled signals.

## Parameters

## Modulation

Specify the modulation type as BPSK, QPSK, OQPSK, 8PSK, QAM, or PAM.

## Modulation phase offset

Specify the method used to calculate the modulation phase offset as either Auto or Custom.

- Auto applies the traditional offset for the specified modulation type.

| Modulation | Phase Offset (radians) |
| :--- | :--- |
| BPSK, QAM, or PAM | 0 |
| QPSK or OQPSK | $\Pi / 4$ |
| 8PSK | $\Pi / 8$ |

- Custom enables the Custom phase offset (radians) parameter.

## Custom phase offset (radians)

Specify the phase offset in radians as a real scalar. This parameter is available only when Modulation phase offset is set to Custom.

## Samples per symbol

Specify the number of samples per symbol as a positive integer scalar.

## Damping factor

Specify the damping factor of the loop as a positive real finite scalar.

## Normalized loop bandwidth

Specify the normalized loop bandwidth as a real scalar between 0 and 1 . The bandwidth is normalized by the sample rate of the carrier synchronizer block.

## Estimated phase error output port

Select this check box to provide the estimated phase error to an output port.

## Simulate using

Select the simulation mode.

## Code generation

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

## Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the comm. CarrierSynchronizer reference page. The object properties correspond to the block parameters.

## Examples

## Correct for Frequency and Phase Offset

Correct for a phase and frequency offset imposed on a noisy 16-QAM channel using the Carrier Synchronizer block.

Open the doc_qamcarriersync model.

Run the model. The Constellation Diagram Without Sync block shows a spiral pattern that indicates a phase and frequency offset. After the carrier synchronizer converges to a solution, the data displayed on the Constellation Diagram With Sync block are grouped around the reference constellation.

Experiment with the parameters in the Phase/Frequency Offset and Carrier Synchronizer blocks. By varying these parameters, you can change how quickly the output conforms to an ideal 16-QAM constellation.

If the signal does not converge to the expected constellation, additional measures can be taken to achieve successful recovery. For more information, see the "Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization" on page 3-250 example.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Signal Input | - Double-precision floating point <br> - Single-precision floating point |
| Signal Output | - Double-precision floating point <br> - Single-precision floating point |
| Phase Error Estimate | - Double-precision floating point <br> - Single-precision floating point |

## Charge Pump PLL

Implement charge pump phase-locked loop using digital phase detector

```
Charge Filt,
    Pump PD
    PLL VCO
```

## Library

Components sublibrary of Synchronization

## Description

The Charge Pump PLL (phase-locked loop) block automatically adjusts the phase of a locally generated signal to match the phase of an input signal. It is suitable for use with digital signals.

This PLL has these three components:

- A sequential logic phase detector, also called a digital phase detector or a phase/frequency detector.
- A filter. You specify the filter transfer function using the Lowpass filter numerator and Lowpass filter denominator parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of $s$.

To design a filter, use functions such as butter, cheby1, and cheby 2 in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify characteristics of the VCO using the VCO input sensitivity, VCO quiescent frequency, VCO initial phase, and VCO output amplitude parameters.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

A sequential logic phase detector operates on the zero crossings of the signal waveform. The equilibrium point of the phase difference between the input signal and the VCO signal equals $\pi$. The sequential logic detector can compensate for any frequency difference that might exist between a VCO and an incoming signal frequency. Hence, the sequential logic phase detector acts as a frequency detector.

## Parameters

## Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO quiescent frequency value. The units of VCO input sensitivity are Hertz per volt.

## VCO quiescent frequency (Hz)

The frequency of the VCO signal when the voltage applied to it is zero. This should match the frequency of the input signal.

## VCO initial phase (rad)

The initial phase of the VCO signal.

## VCO output amplitude

The amplitude of the VCO signal.

## CMA Equalizer

(To be removed) Equalize using constant modulus algorithm

Note will be removed in a future release. Use Linear Equalizer instead.

## Library

## Equalizers

## Description

The CMA Equalizer block uses a linear equalizer and the constant modulus algorithm (CMA) to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the CMA to update the weights, once per symbol. If the Number of samples per symbol parameter is 1 , then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

When using this block, you should initialize the equalizer weights with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and zeros elsewhere.

## Input and Output Signals

The Input port accepts a scalar-valued or column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal.

You can configure the block to have one or more of the extra ports listed in the table below.

| Port | Meaning | How to Enable |
| :--- | :--- | :--- |
| Err output | $\mathrm{y}\left(\mathrm{R}-\|\mathrm{y}\|^{2}\right)$, where y is the <br> equalized signal and R is a <br> constant related to the signal <br> constellation | Select Output error. |
| Wts output | A vector listing the weights <br> after the block has processed <br> either the current input frame <br> or sample. | Select Output weights. |

## Algorithms

Referring to the schematics in "Adaptive Equalizers", define $w$ as the vector of all weights $w_{\mathrm{a}}$ and define $u$ as the vector of all inputs $u_{i}$. Based on the current set of weights, $w$, this adaptive algorithm creates the new set of weights given by

## (LeakageFactor) w + (StepSize) u*e

where the * operator denotes the complex conjugate.

## Equalizer Delay

The delay between the transmitter's modulator output and the CMA equalizer output is typically unknown (unlike the delay for other adaptive equalizers in this product). If you need to determine the delay, you can use the Find Delay block.

## Parameters

## Number of taps

The number of taps in the filter of the equalizer.

## Number of samples per symbol

The number of input samples for each symbol.
When you set this parameter to 1 , the filter weights are updated once for each symbol, for a symbol spaced (i.e. T-spaced) equalizer. When you set this parameter to a value greater than one, the weights are updated once every $N^{\text {th }}$ sample, for a fractionally spaced (i.e. T/N-spaced) equalizer.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Step size

The step size of the CMA.

## Leakage factor

The leakage factor of the CMA, a number between 0 and 1 . A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Initial weights

A vector that lists the initial weights for the taps.

## Output error

If you check this box, the block outputs the error signal described in the table above.

## Output weights

If you check this box, the block outputs the current weights.

## Compatibility Considerations

## CMA Equalizer will be removed

Warns starting in R2020a

- CMA Equalizer will be removed in a future release. Use Linear Equalizer instead with the adaptive algorithm set to CMA.
- The Linear Equalizer block does not have a leakage factor parameter. This is equivalent to setting the Leakage factor parameter to 1 in the CMA Equalizer block.

## Coarse Frequency Compensator

Compensate for carrier frequency offset for PAM, PSK, or QAM

## Library

Synchronization

## Description

The Coarse Frequency Compensator block compensates for a carrier frequency offset for BPSK, QPSK, OQPSK, 8-PSK, PAM, and QAM modulation schemes. The block accepts a single input signal. To obtain an estimate of the frequency offset in Hz , select the Estimated frequency offset output port check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a real frequency offset estimate. The output signal has the same dimensions as the input signal. The frequency offset estimate is a scalar.

## Parameters

## Modulation type of input signal

Specify the modulation type as BPSK, QPSK, OQPSK, 8PSK, PAM, or QAM.
The default setting is QAM.

## Estimation algorithm

Specify the frequency offset estimation algorithm as FFT-based or Correlation-based. This parameter appears when Modulation type of input signal is BPSK, QPSK, 8PSK, or PAM.

The table shows the allowable combinations of the modulation type and the estimation algorithm.

| Modulation | FFT-Based Algorithm | Correlation-Based <br> Algorithm |
| :--- | :--- | :--- |
| BPSK, QPSK, 8PSK, PAM | $\checkmark$ | $\checkmark$ |
| OQPSK, QAM | $\checkmark$ |  |

## Frequency resolution (Hz)

Specify the frequency resolution in Hz as a positive real scalar. This option is available when the FFT-based algorithm is used. The default setting is 0.001 Hz .

## Samples per symbol

Specify the number of samples per symbol as a positive integer scalar greater than or equal to 4 . The default setting is 4 .

## Maximum frequency offset (Hz)

Specify the maximum frequency offset in Hz as a positive real scalar. This option is appears when you set Estimation algorithm to Correlation-based. The default setting is 0.05 Hz .

## Estimated frequency offset output port

Select this check box to provide the estimated frequency offset to an output port. The default for this parameter is selected.

## Simulate using

Select the simulation mode.

## Code generation

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects accept a maximum of nine inputs.
Interpreted execution
Simulate your model using all supported MATLAB functions. Choosing this option can slow simulation performance.

The default setting is Code generation.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the comm. CoarseFrequencyCompensator reference page. The object properties correspond to the block parameters.

## Examples

## Correct for Frequency and Phase Offset

Correct for a frequency offset imposed on a noisy 8-PSK channel by using the Coarse Frequency Compensator block.

Open the doc_coarsefreqcomp model.
Open the dialog boxes to verify these parameter values:

- Random Integer Generator - Sample time is $1 \mathrm{e}-4$, which is equivalent to a $10 \mathrm{ksym} / \mathrm{sec}$ symbol rate.
- Raised Cosine Transmit Filter - Output samples per symbol is 4.
- AWGN Channel - Mode is Signal to noise ratio (SNR) and SNR (dB) is 20.
- Phase/Frequency Offset - Frequency offset (Hz) is 2000.
- Coarse Frequency Compensator - Estimation algorithm is FFT-based and Frequency resolution $(\mathrm{Hz})$ is 1 .

Run the model. The Spectrum Analyzer block shows both the frequency offset signal and the compensated signal. In addition, the Display block shows the estimate of the frequency offset. Observe that the spectrum plot shows that the Coarse Frequency Compensator correctly centers the signal around 0 Hz . Additionally, the display shows that the estimated frequency offset is 2000 Hz .

Adjust the parameters in the Phase/Frequency Offset and Coarse Frequency Compensator blocks and see their effect on frequency compensation performance.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Signal Input | - Double-precision floating point <br> - Single-precision floating point |
| Signal Output | - Double-precision floating point <br> - Single-precision floating point |
| Frequency Estimate | - Double-precision floating point <br> - Single-precision floating point |

## Complex Phase Difference

Output phase difference between two complex input signals

## Library

Utility Blocks

## Description

The Complex Phase Difference block accepts two complex input signals that have the same size and frame status. The output is the phase difference from the second to the first, measured in radians. The elements of the output are between $-п$ and $п$.

The input signals can have any size or frame status. This block processes each pair of elements independently.

## Examples

## Calculate Complex Phase Difference

Open the complex phase difference model. The model generates random integers and applies QPSK modulation. The first QPSK modulator has a phase offset of 0 , while the second has a pi/4 phase offset. The Complex Phase Difference block determines the phase difference. The data is passed to the workspace from the To Workspace block.

Run the model.
Display the phase difference.
phDiff =
$-0.7854$

The phase difference is equal to -pi/4 as expected.

## Complex Phase Shift

Shift phase of complex input signal by second input value

## Library

Utility Blocks

## Description

The Complex Phase Shift block accepts a complex signal at the port labeled In. The output is the result of shifting this signal's phase by an amount specified by the real signal at the input port labeled Ph . The Ph input is measured in radians, and must have the same size and frame status as the In input.

The input signals can have any size or frame status. This block processes each pair of corresponding elements independently.

## Constellation Diagram

Display constellation diagram for input signals
$\begin{array}{ll}\text { Library: } & \text { Communications Toolbox / Comm Sinks } \\ & \text { Communications Toolbox HDL Support / Comm Sinks }\end{array}$

## Description

The Constellation Diagram block displays real and complex-valued floating and fixed-point signals in the I/Q plane. Use this block to perform qualitative and quantitative analysis on modulated singlecarrier signals.

In the constellation diagram window you can:

- Input and plot multiple signals on a single constellation diagram. You can define one reference constellation for each input signal. For more information, see Reference constellation.
- Choose which channels are displayed by selecting signals in the legend. Use the Show legend parameter to display the legend.
- Display the "EVM / MER Measurements" on page 5-119 panel, which displays calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements. When a multichannel signal is input, use Trace Selection to choose the signal being measured.

## Ports

## Input

## Port_1 - Signal or signals to visualize

column vector | matrix
Connect to the signal or signals you want to visualize as an $N_{\text {sym }}$-by-1 column vector or $N_{\text {sym }}$-by- $N_{\text {sig }}$ matrix. $N_{\text {sym }}$ is the number of symbols and $N_{\text {sig }}$ is the number of input signals.

You can specify up to 20 input signals. Specifically, the maximum number of channels through all the ports is 20 . For example, if you create a two-channel signal for every input port, then you can define up 10 number of input ports.
Example: [-1 + 1i; -1 - 1i; 1 + 1i; 1 - 1i] specifies a 4 -symbol input signal.

## Parameters

## File

From the Constellation Diagram window, select File to view the options available.
Open at Start of Simulation - Open constellation diagram at start of simulation on (default) | off

Select to open constellation diagram window at start of simulation. Deselect to prevent constellation diagram window from opening at start of simulation.

## Number of input ports - Number of input ports on scope block

1 (default) | positive integer in the range [1, 20]
Specify the number of input ports on the Scope block, specified as an integer in the range [1, 20].
When multichannel input signals are specified, the maximum number of input ports is limited by the total number of input signals defined. The total number of input signal cannot exceed 20.

## Tools > Axes Scaling Properties

From the Constellation Diagram window, under Tools, select Axes Scaling Properties to open the Axes Scaling Properties: Constellation Diagram dialog box. In this dialog box, you can customize the graphical properties of the axes.

## Properties

## Axes scaling - Axes scaling options

Manual (default)|Auto|After N Updates
Axes scaling options, specified as:

- Manual - Applies the $x$ and $y$ axes limits specified in the Visuals - Constellation Properties: Constellation Diagram dialog box.
- Auto - Scales the axes limits as needed during and after simulation.
- After $N$ Updates - Scales the axes limits after the specified Number of updates.

Tunable: Yes
Number of updates - Number of updates after which to scale the axes
10 (default) | positive integer
Number of updates after which to scale the axes, specified as a positive integer.
Tunable: Yes
Dependencies
This parameter appears when Axes scaling is set to After N Updates.
Scale axes limits at stop - Option to scale axes at end of simulation
off (default) | on
Select to scale axes at end of the simulation to the data range percentage limits specified by $\mathbf{X}$-axis Data range (\%) and $\mathbf{Y}$-axis Data range (\%).

## X-axis Data range (\%) - Percentage of $\boldsymbol{x}$-axis used to display data

80 (default) | scalar from 1 to 100
Percentage of $x$-axis used to display data.
Example: 100 scales the x -axis range to the maximum value of the in-phase amplitude component of the input signal.

Tunable: Yes

## X -axis Align - Align data along x -axis

Center (default) | Left | Right
Align data along $x$-axis, specified as Center, Left, or Right.
Example: Right aligns the maximum value of the in-phase amplitude component of the input signal toward the upper x -axis limit.

Tunable: Yes
Y -axis Data range (\%) - Percentage of $\boldsymbol{y}$-axis used to display data
80 (default) | scalar from 1 to 100
Percentage of $y$-axis used to display data.
Example: 30 scales the $y$-axis range so that the maximum value of the quadrature amplitude component of the signal occupies $30 \%$ of the $y$-axis range.

Tunable: Yes
Y -axis Align - Align data along $\boldsymbol{y}$-axis
Center (default) | Top | Bottom
Align data along $y$-axis, specified as Center, Top, or Bottom.
Example: Bottom aligns the maximum value of the quadrature amplitude component of the signal toward the lower y-axis limit.

Tunable: Yes

## Tools > Measurements

From the Constellation Diagram window, under Tools, select Measurements for options to display the Trace Selection and Signal Quality panes. By default these panes are docked in the Constellation Diagram window when displayed.

The Signal Quality pane contains the Settings and EVM / MER subpanes. Both subpanes can be independently expanded or collapsed.

For more information about the signal quality measurements, see "EVM / MER Measurements" on page 5-119.

## Trace Selection - Signal trace used to compute measurements <br> list of signals

Select the signal trace used to compute measurements from the list of available signals. This parameter lists the signals input to the block.

Tunable: Yes
Dependencies
To set this parameter, the Trace Selection pane must be visible. The Trace Selection pane automatically appears when you plot multiple signals on the Constellation Diagram window. To hide or display the Trace Selection pane from the Constellation Diagram window, under Tools, select Measurements > Trace Selection to toggle the visibility of the traceback selection measurement.

## EVM / MER Settings Pane

## Measurement interval - Duration of EVM or MER measurement

Current Display (default)|All displays | positive integer
Duration of the EVM or MER measurement in symbols, specified as Current Display, All displays, or a positive integer. To specify a positive integer, select and then replace <userdefined> with your desired value. The value must be positive and less than or equal to Symbols to display. The measurement is computed after the number of input data samples exceeds the measurement interval.

Tunable: Yes
EVM normalization - Normalization method used for EVM calculation
Average constellation power (default)|Peak constellation power
Normalization method used for EVM calculation, specified as Average constellation power or Peak constellation power. The comm.EVM System object computes the EVM.

Tunable: Yes

## Reference constellation - Reference constellation

QPSK (default) | BPSK | 8-PSK | 16-QAM | 64-QAM | 256-QAM | vector
Reference constellation, specified as BPSK, QPSK, 8-PSK, 16-QAM, 64-QAM, 256-QAM, or a <userdefined> vector. To specify a custom value, select <user-defined>, then in the Custom value property replace the entry with your desired value.

Each input port can have its own reference constellation. For a multichannel input signal, a single reference constellation is applied for all signals in that input port.

To obtain the EVM/MER measurements, you must set Reference constellation to a valid value corresponding to the modulation of the input signal.

Tunable: Yes

## Custom value - Input reference constellation

 vectorInput the reference constellation, specified as a vector.

## Dependencies

To enable this parameter, set Reference constellation to <user-defined>.

## Data Types: double

Complex Number Support: Yes
Average reference power - Average power of reference constellation
1 (default) | positive scalar
Average power of the reference constellation in watts, specified as a positive scalar and referenced to a one-ohm load.

Tunable: Yes
Reference phase offset (rad) - Phase offset of reference constellation
pi/4 (default) | scalar
Phase offset of the reference constellation in radians, specified as a scalar.
Tunable: Yes

## View > Configuration Properties

From the Constellation Diagram window, select View > Configuration Properties to open the Visuals - Constellation Properties: Constellation Diagram dialog box. In this dialog box, you can customize the graphical properties of the plotted signals.

Main
Number of input ports - Number of input ports on scope block
1 (default) | positive integer in the range [1, 20]
Specify the number of input ports on the Scope block, specified as an integer in the range [1, 20].

## Samples per symbol - Number of samples used to represent each symbol

1 (default) | positive integer
Number of samples used to represent each symbol, specified as a positive integer. When Samples per symbol is greater than 1 , the signal is downsampled before it is plotted.

Tunable: Yes

## Offset (samples) - Number of samples to skip before plotting points <br> 0 (default) | nonnegative integer

Number of samples to skip before plotting points, specified as a nonnegative integer less than Samples per symbol. This parameter specifies the number of samples to skip when downsampling the input signal.

Tunable: Yes

## Symbols to display - Maximum number of symbols to display <br> Input frame length (default)| positive integer

Maximum number of symbols to display, specified as Input frame length or a positive integer. To specify a positive integer, select and then replace <user-defined> with your desired value.

Use Symbols to display to limit the maximum number of symbols displayed when long signals are input. Symbols plotted are the most recent symbols received.

Tunable: Yes
Display
Show grid - Display plot grid lines
on (default) | off
Select to display plot grid lines.
Tunable: Yes

## Show legend - Display plot legend

off (default) | on
Select to display plot legend. The names listed in the legend are the signal names from the model.
From the legend, you can control which signals are plotted. This control is equivalent to changing the visibility in the View > Style dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal and hide all other signals, right-click the signal name. To show all signals, press Esc.

Tunable: Yes
Show signal trajectory - Display signal trajectory
off (default) | on
Select to display the trajectory between constellation points for the plotted signals.
Tunable: Yes

## Color fading - Option to add color fading effect off (default) | on

When you select Color fading, the points in the display fade as the interval of time after they are first plotted increases. Color fading is for animation that resembles an oscilloscope.

Tunable: Yes
X-limits (Minimum) - Minimum x-axis value
-1. 375 (default) | scalar
Minimum $x$-axis value, specified as a scalar.
Tunable: Yes
X-limits (Maximum) - Maximum $x$-axis value
1.375 (default) | scalar

Maximum $x$-axis value, specified as a scalar.
Tunable: Yes
Y-limits (Minimum) - Minimum $\boldsymbol{y}$-axis value
-1. 375 (default) | scalar

Minimum $y$-axis value, specified as a scalar.
Tunable: Yes

## Y-limits (Maximum) - Maximum $\boldsymbol{y}$-axis value <br> 1.375 (default) | scalar

Maximum $y$-axis value, specified as a scalar.
Tunable: Yes

## Title - Title on plot

blank (default) | character vector | string
Title on plot, specified as a character vector or string.
Tunable: Yes

## X-axis label - x-axis label

'In-phase Amplitude' (default) | character vector \| string
$x$-axis label, specified as a character vector or string.
Tunable: Yes

## $\mathbf{Y}$-axis label - $\boldsymbol{y}$-axis label

'Quadrature Amplitude' (default)| character vector | string
$y$-axis label, specified as a character vector or string.
Tunable: Yes

## Reference constellation

## Show reference constellation - Select to display reference constellation

 on (default) | offSelect to display the reference constellation.
Tunable: Yes

## Input - Input port number

1 (default) | integer
Select the input port number for which you want to view/change the reference constellation and the associated attributes.

## Dependencies

To enable this parameter, set the Number of input ports parameter to a value greater than 1.

## Reference constellation - Reference constellation

QPSK (default) | BPSK | 8-PSK | 16- QAM | 64-QAM | 256-QAM | vector
Reference constellation, specified as BPSK, QPSK, 8-PSK, 16-QAM, 64-QAM, 256-QAM, or a <userdefined> vector. To specify the value, select and then replace <user-defined> with your desired value. When defined by the user, the reference constellation values can be specified as a vector.

Each input port can have its own reference constellation. For a multichannel input signal, a single reference constellation is applied for all signals in that input port.

To obtain the EVM/MER measurements, you must set Reference constellation to a valid value corresponding to the modulation of the input signal.

Tunable: Yes
Data Types: double
Complex Number Support: Yes
Average reference power - Average power of reference constellation
1 (default) | positive scalar
Average power of the reference constellation in watts, specified as a positive scalar and referenced to a one-ohm load.

Tunable: Yes
Reference phase offset (rad) - Phase offset of reference constellation pi/4 (default) | scalar

Phase offset of the reference constellation in radians, specified as a scalar.
Tunable: Yes

## View > Style

From the Constellation Diagram window, select View > Style to open the Constellation Diagram Style dialog box. In this dialog box, you can customize the graphical properties of the components in the Constellation Diagram window.

## Figure color - Select background color

gray (default)
Select the background color within the Constellation Diagram window and outside the scope axes.

## Axes colors - Select colors of plot and measurement panes

## black (default for background) | gray (default for axes)

Select colors of plot and measurement panes. The first color option specifies the background color of the plot figure and the measurement panes. The second option specifies the color of the plot figure axes (ticks, labels, and grid lines) and the text. For more a description of the measurement panes, see in the "Tools > Measurements" on page 5-112.

Tunable: Yes
Properties for channel - View or change graphical properties of each channel Channel 1 (default)

Select a channel to view or change its graphical properties.

## Bring To Front - Bring channel to front <br> button

Bring the active channel, as indicated by Properties for channel, to the front.

## Show signal and reference constellation - Option to hide channel on (default) | off

Clear to hide the active channel and its associated reference constellation. Use Properties for channel to select the active channel. The setting is synchronized with actions in the interactive legend, see Show legend.

## Symbols - Set properties of symbols

symbol properties
Set graphical properties of the symbols for the active channel. Adjust style, size, line width, and color of the marker. Use Properties for channel to select the active channel.

## Dependencies

To set marker shape to none, Show signal trajectory must be selected.

## Signal trajectory - Select properties of signal trajectory

no line (default) | trajectory properties
Set graphical properties for the signal trajectory of the active channel. Adjust style, width, and color of the line. Use Properties for channel to select the active channel.

## Dependencies

To adjust signal trajectory properties, Show signal trajectory must be selected. When Show signal trajectory is selected, the Signal trajectory line style cannot be set to no line.

## Reference Constellation

## Input - Input port number

1 (default) | integer
View or change the graphical properties for the symbol of the reference constellation for each port individually.

If none of the input are multichannel signals, then the graphical properties of the reference constellation can be adjusted by selecting the channel from the Properties for channel parameter.

## Dependencies

To enable this parameter, set the Number of input ports parameter to a value greater than 1 and specify at least one multichannel input signal.

## Properties - Select properties of reference constellation symbols <br> symbol properties

Select the graphical properties for the symbols of the reference constellation. Adjust the style, size, line width, and color of the marker.

## Dependencies

To adjust reference constellation graphical properties, Show reference constellation must be selected.

## Block Characteristics

| Data Types | Boolean \| double | enumerated | fixed point | integer | single |
| :--- | :--- |
| Direct Feedthrough | no |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |
| Zero-Crossing <br> Detection | no |

## More About

## EVM / MER Measurements

The EVM / MER signal quality pane displays the measurement settings, and error vector magnitude (EVM) and modulation error ratio (MER) measurement calculation results for the specified trace selection.

- EVM - An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The root mean square error vector magnitude, $E V M_{\mathrm{RMS}}$, is measured for the average and peak constellation power.

On the constellation diagram, you can display the $E V M_{\text {RMS }}$ measurements normalized by either the Average constellation power or Peak constellation power method as computed using these algorithms.

| EVM Normalization Method | Algorithm |
| :---: | :---: |
| Average constellation power | Average constellation power normalization: |
|  | $\mathrm{EVM}_{k}=100 \sqrt{\frac{e_{k}}{P_{\mathrm{avg}}}}$ <br> $\mathrm{EVM}_{\mathrm{RMS}}$, in percent, for average constellation power normalization: |
|  | $\operatorname{EVM}_{\mathrm{RMS}}(\%)=100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{P_{\mathrm{avg}}}}$ |
| Peak constellation power | Peak constellation power normalization |
|  | $\mathrm{EVM}_{k}=100 \sqrt{\frac{\mathrm{c}_{k}}{P_{\max }}}$ <br> $E V M_{\text {RMS }}$, in percent, for peak constellation power normalization |
|  | $\operatorname{EVM}_{\operatorname{RMS}}(\%)=100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{P_{\max }}}$ |

The EVM / MER pane shows the average and peak EVM $_{\text {RMS }}$ in both percent and decibels for the selected trace. The EVM reported in decibels is computed as EVM (dB) $=10-\log 10\left(\mathrm{EVM}_{\text {MS }}\right)=$ $20-\log 10\left(\mathrm{EVM}_{\mathrm{RMS}}\right)$, where:

- $e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}$
- $I_{k}$ is the in-phase value of the $k$ th symbol in the input vector.
- $Q_{k}$ is the quadrature phase value of the $k$ th symbol in the input vector.
- $I_{k}$ and $Q_{k}$ represent ideal (reference) symbol values. $\tilde{I}_{k}$ and $\widetilde{Q}_{k}$ represent measured (received) symbol values.
- $N$ is the input vector length.
- $P_{\text {avg }}$ is the value for Average constellation power.
- $P_{\max }$ is the value for Peak constellation power.
- $\mathrm{EVM}_{\mathrm{RMS}}=\sqrt{\mathrm{EVM}_{\mathrm{MS}}}$

The maximum EVM value in a vector is $\mathrm{EVM}_{\max }=\max _{k \in[1, \ldots, N]}\left\{\mathrm{EVM}_{k}\right\}$, where $k$ is the $k$ th symbol in a vector of length $N$.

For more information, see comm. EVM.

- MER - MER is the ratio of the average power of the transmitted signal to the average power of the error vector. The EVM / MER pane indicates average MER measurement result in decibels for the selected trace.

MER is a measure of the SNR in a modulated signal, calculated in dB. The MER over $N$ symbols is

where:

- $e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}$
- $I_{k}$ is the in-phase value of the $k$ th symbol in the input vector.
- $Q_{k}$ is the quadrature phase value of the $k$ th symbol in the input vector.
- $I_{k}$ and $Q_{k}$ represent ideal (reference) values. $\tilde{I}_{k}$ and $\widetilde{Q}_{k}$ represent measured (received) symbols.

For more information, see comm.MER.

## Programmatic Configuration

You can programmatically configure the scope properties with callbacks or within scripts using a scope configuration object as, described in "Control Scope Blocks Programmatically" (Simulink).

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.
This block is excluded from the generated code when code generation is performed on a system containing this block.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\mathrm{TM}}$.
This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

## Continuous-Time VCO

Implement voltage-controlled oscillator

```
Continuous-Time
    VCO
```

## Library

Components sublibrary of Synchronization

## Description

The Continuous-Time VCO (voltage-controlled oscillator) block generates a signal with a frequency shift from the Quiescent frequency parameter that is proportional to the input signal. The input signal is interpreted as a voltage. If the input signal is $u(t)$, then the output signal is

$$
y(t)=A_{C} \cos \left(2 \pi f_{C} t+2 \pi k_{C} \int_{0}^{t} u(\tau) d \tau+\varphi\right)
$$

where $A_{\mathrm{c}}$ is the Output amplitude parameter, $f_{\mathrm{c}}$ is the Quiescent frequency parameter, $k_{\mathrm{c}}$ is the Input sensitivity parameter, and $\varphi$ is the Initial phase parameter.

This block uses a continuous-time integrator to interpret the equation above.
The input and output are both sample-based scalar signals.

## Parameters

## Output amplitude

The amplitude of the output.

## Quiescent frequency

The frequency of the oscillator output when the input signal is zero.

## Input sensitivity

This value scales the input voltage and, consequently, the shift from the Quiescent frequency value. The units of Input sensitivity are Hertz per volt.

## Initial phase

The initial phase of the oscillator in radians.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.
Not recommended for production code.

## Convolutional Deinterleaver

Restore ordering of symbols that were permuted using shift registers

```
Convolutional
Deinterleaver
```

## Library

Convolutional sublibrary of Interleaving

## Description

The Convolutional Deinterleaver block recovers a signal that was interleaved using the Convolutional Interleaver block. Internally, this block uses a set of shift registers. The delay value of the $k^{\text {th }}$ shift register is ( $N-k$ ) times the Register length step parameter. The number of shift registers, $N$, is the value of the Rows of shift registers parameter. The parameters in the two blocks must have the same values.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

This block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point.

## Parameters

## Rows of shift registers

The number of shift registers that the block uses internally.

## Register length step

The difference in symbol capacity of each successive shift register, where the last register holds zero symbols.

## Initial conditions

Indicates the values that fill each shift register at the beginning of the simulation (except for the last shift register, which has zero delay).

- When you select a scalar value for Initial conditions, the value fills all shift registers (except for the last one)
- When you select a column vector with a length equal to the Rows of shift registers parameter, each entry fills the corresponding shift register.

The value of the first element of the Initial conditions parameter is unimportant, since the last shift register has zero delay.

## Examples

For an example that uses this block, see "Convolutional Interleaving".

## Pair Block

Convolutional Interleaver

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\mathrm{TM}}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

You can generate HDL code for the Convolutional Deinterleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Deinterleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter ResetType to ' none '. When you set ResetType to ' none ' , reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the Ignore output data checking
(number of samples) option accordingly. (If you are using the command-line interface, you can use the IgnoreDataChecking property for this purpose.)

When you select the RAM implementation for a Convolutional Deinterleaver block, HDL Coder uses RAM resources instead of shift registers.

HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |
| ResetType | Suppress reset logic generation. The default is default, which generates <br> reset logic. See also "ResetType" (HDL Coder). |

## Restrictions

When you select the RAM implementation:

- Double or single data types are not supported for either input or output signals.
- You must set Initial conditions for the block to zero.
- At least two rows of interleaving are required.

## Introduced before R2006a

## Convolutional Encoder

Create convolutional code from binary data

```
Convolutional
```

Encoder

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Convolutional Encoder block encodes a sequence of binary input vectors to produce a sequence of binary output vectors. This block can process multiple symbols at a time.

This block can accept inputs that vary in length during simulation. For more information about variable-size signals, see "Variable-Size Signal Basics" (Simulink).

## Input and Output Sizes

If the encoder takes $k$ input bit streams (that is, it can receive $2^{k}$ possible input symbols), the block input vector length is $\mathrm{L}^{*} k$ for some positive integer L. Similarly, if the encoder produces $n$ output bit streams (that is, it can produce $2^{n}$ possible output symbols), the block output vector length is $L^{*} n$.

This block accepts a column vector input signal with any positive integer for L. For variable-size inputs, the L can vary during simulation. The operation of the block is governed by the Operation mode parameter.

For both its inputs and outputs for the data ports, the block supports double, single, boolean, int8, uint8, int16, uint16, int32, uint32, and ufix1. The port data types are inherited from the signals that drive the block. The input reset port supports double and boolean typed signals.

## Specifying the Encoder

To define the convolutional encoder, use the Trellis structure parameter. This parameter is a MATLAB structure whose format is described in "Trellis Description of a Convolutional Code". You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name in the Trellis structure parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a poly2trellis command in the Trellis structure parameter. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the Trellis structure parameter to

```
poly2trellis(7,[171 133],171)
```

The encoder registers begin in the all-zeros state. Set the Operation mode parameter to Reset on nonzero input via port to reset all encoder registers to the all-zeros state during the simulation. This selection opens a second input port, labeled Rst, which accepts a scalar-valued input signal. When the input signal is nonzero, the block resets before processing the data at the first input port. To reset the block after it processes the data at the first input port, select Delay reset action to next time step.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## Operation mode

In Continuous mode, the block retains the encoder states at the end of each input, for use with the next frame.

In Truncated (reset every frame) mode, the block treats each input independently. The encoder states are reset to all-zeros state at the start of each input.

Note When this block outputs sequences that vary in length during simulation and you set the Operation mode to Truncated (reset every frame) or Terminate trellis by appending bits, the block's state resets at every input time step.

In Terminate trellis by appending bits mode, the block treats each input independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by $y=n \cdot(x+s) / k$, where $x$ is the number of input bits, and $s=$ constraint length -1 (or, in the case of multiple constraint lengths, $s$
$=\operatorname{sum}($ ConstraintLength(i)-1)).

Note This block works for cases $k \geq 1$, where it has the same values for constraint lengths in each input stream (e.g., constraint lengths of [2 2] or [7 7] will work, but [5 4] will not).

In Reset on nonzero input via port mode, the block has an additional input port, labeled Rst. When the Rst input is nonzero, the encoder resets to the all-zeros state.

## Delay reset action to next time step

When you select Delay reset action to next time step, the Convolutional Encoder block resets after computing the encoded data. This check box only appears when you set the Operation mode parameter to Reset on nonzero input via port.

The delay in the reset action allows the block to support HDL code generation. In order to generate HDL code, you must have an HDL Coder license.

## Output final state

When you select Output final state, the second output port signal specifies the output state for the block. The output signal is a scalar, integer value. You can select Output final state for all operation modes except Terminate trellis by appending bits.

## Specify initial state via input port

When you select Specify initial state via input port the second input port signal specifies the starting state for every frame in the block. The input signal must be a scalar, integer value. Specify initial state via input port appears only in Truncated operation mode.

## Puncture code

Selecting this option opens the field Puncture vector.

## Puncture vector

Vector used to puncture the encoded data. The puncture vector is a pattern of 1 s and 0 s where the 0s indicate the punctured bits. This field appears when you select Punctured code.

## Puncture Pattern Examples

For some commonly used puncture patterns for specific rates and polynomials, see the last three references listed on this page.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink $\circledR^{\circledR}$ Coder ${ }^{\text {TM }}$.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\text {TM }}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |

## Restrictions

- Input data requirements:
- Must be sample-based,
- Must have a boolean or ufix1 data type.
- HDL Coder supports only the following coding rates:
- $1 / 2$ to $1 / 7$
- $2 / 3$
- The coder supports only constraint lengths for 3 to 9 .
- Specify Trellis structure by the poly2trellis function.
- The coder supports the following Operation mode settings:
- Continuous
- Reset on nonzero input via port

If you select this mode, you must select the Delay reset action to next time step option. When you select this option, the Convolutional Encoder block finishes its current computation before executing a reset.

- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

## Introduced before R2006a

## Convolutional Interleaver

Permute input symbols using set of shift registers

## Library

Convolutional sublibrary of Interleaving

## Description

The Convolutional Interleaver block permutes the symbols in the input signal. Internally, it uses a set of shift registers. The delay value of the kth shift register is ( $\mathrm{k}-1$ ) times the Register length step parameter. The number of shift registers is the value of the Rows of shift registers parameter.

The Initial conditions parameter indicates the values that fill each shift register at the beginning of the simulation (except for the first shift register, which has zero delay). If Initial conditions is a scalar, then its value fills all shift registers except the first; if Initial conditions is a column vector whose length is the Rows of shift registers parameter, then each entry fills the corresponding shift register. The value of the first element of the Initial conditions parameter is unimportant, since the first shift register has zero delay.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

The block can accept the data types int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The data type of this output will be the same as that of the input signal.

## Parameters

## Rows of shift registers

The number of shift registers that the block uses internally.

## Register length step

The number of additional symbols that fit in each successive shift register, where the first register holds zero symbols.

## Initial conditions

The values that fill each shift register when the simulation begins.

## Examples

For an example that uses this block, see "Convolutional Interleaving".

## Pair Block

Convolutional Deinterleaver

## Restrictions

When you select the RAM implementation:

- Double or single data types are not supported for either input or output signals.
- You must set Initial conditions for the block to zero.
- At least two rows of interleaving are required.

## Introduced before R2006a

## CPFSK Demodulator Baseband

Demodulate CPFSK-modulated data

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The CPFSK Demodulator Baseband block demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input to this block is a baseband representation of the modulated signal. The M-ary number parameter, $M$, is the size of the input alphabet. $M$ must have the form $2^{K}$ for some positive integer $K$.

This block supports multi-h Modulation index. See CPM Modulator Baseband for details.

## Integer-Valued Signals and Binary-Valued Signals

When you set the Output type parameter to Integer, then the block produces odd integers between -(M-1) and M-1.

When you set the Output type parameter to Bit, then the block produces groupings of $K$ bits. Each grouping is called a binary word.

In binary output mode, the block first maps each input symbol to an intermediate value as in the integer output mode. The block then maps the odd integer $k$ to the nonnegative integer $(\mathrm{k}+\mathrm{M}-1) / 2$. Finally, the block maps each nonnegative integer to a binary word, using a mapping that depends on whether the Symbol set ordering parameter is set to Binary or Gray.

This block accepts a scalar-valued or column vector input signal with a data type of single or double.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the Samples per symbol parameter value, and the input can be a column vector.

- When you set Output type to Bit, the output width is $K$ times the number of input symbols.
- When you set Output type to Integer, the output width is the number of input symbols.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the Samples per symbol parameter value.

- When you set Output type to Bit, the output width equals the number of bits per symbol.
- When you set Output type to Integer, the output is a scalar.

## Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The Traceback depth parameter, $D$, in this block is the number of trellis branches that the algorithm uses to construct each traceback path. $D$ influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the Rate options parameter to Allow multirate processing, and the model uses a variable-step solver or a fixed-step solver with the Tasking Mode parameter set to SingleTasking, then the delay consists of $\mathrm{D}+1$ zero symbols.
- When you set the Rate options parameter to Enforce single-rate processing, then the delay consists of $D$ zero symbols.

The optimal Traceback depth parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the "five-times-the-constraint-length" rule, which corresponds to $5 \cdot \log 2$ (numStates).

For the definition of the number of states, see CPM Demodulator Baseband Help page.

## Parameters

## M-ary number

The size of the alphabet.

## Output type

Determines whether the output consists of integers or groups of bits.

## Symbol set ordering

Determines how the block maps each integer to a group of output bits. This field is active only when Output type is set to Bit.

## Modulation index

Specify the modulation index $\left\{h_{i}\right\}$. The default is 0.5 . The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h Modulation index. See CPM Modulator Baseband for details.

## Phase offset (rad)

The initial phase of the modulated waveform.

## Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see "Upsample Signals and Rate Changes" in Communications Toolbox User's Guide.

## Rate options

Select the rate processing method for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the Samples per symbol parameter value when the Output type parameter is set to Integer).
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the Samples per symbol parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

## Traceback depth

The number of trellis branches that the CPFSK Demodulator Baseband block uses to construct each traceback path.

## Output datatype

The output data type can be boolean, int8, int16, int32, or double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point |
| Output | - Double-precision floating point <br> - Boolean (When Output type set to Bit) <br> - 8-, 16-, and 32 -bit signed integers (When Output type set to Integer) |

## CPFSK Modulator Baseband

Modulate using continuous phase frequency shift keying method

```
\square-1NMM
CPFSK
```

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The CPFSK Modulator Baseband block modulates a signal using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal. The $\mathbf{M}$-ary number parameter, $M$, represents the size of the input alphabet. $M$ must have the form $2^{K}$ for some positive integer $K$.

This block supports multi-h Modulation index. See CPM Modulator Baseband for details.

## Integer-Valued Signals and Binary-Valued Signals

When you set the Input type parameter to Integer, the block accepts odd integers between -(M-1) and M-1.

When you set the Input type parameter to Bit, the block accepts groupings of $K$ bits. Each grouping is called a binary word. The input vector length must be an integer multiple of $K$.

In binary input mode, the block maps each binary word to an integer between 0 and $\mathrm{M}-1$, using a mapping scheme that depends on whether you set the Symbol set ordering parameter to Binary or Gray. The block then maps the integer $k$ to the intermediate value $2 \mathrm{k}-(\mathrm{M}-1)$ and proceeds as if it operates in the integer input mode. For more information, see "Integer-Valued Signals and BinaryValued Signals".

This block accepts a scalar-valued or column vector input signal. If you set Input type to Bit, then the input signal can also be a vector of length $K$.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set Input type to Integer, the input can be a column vector, the length of which is the number of input symbols.
- When you set Input type to Bit, the input must be a column vector with a width that is an integer multiple of $K$, the number of bits per symbol.

The output width equals the product of the number of input symbols and the Samples per symbol parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set Input type to Integer, the input must be a scalar.
- When you set Input type to Bit, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Parameters

## M-ary number

The size of the alphabet.

## Input type

Indicates whether the input consists of integers or groups of bits.

## Symbol set ordering

Determines how the block maps each group of input bits to a corresponding integer. This field is active only when Input type is set to Bit.

## Modulation index

Specify the modulation index $\left\{h_{i}\right\}$. The default is 0.5 . The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h Modulation index. See CPM Modulator Baseband for details.
Phase offset (rad)
The initial phase of the output waveform, measured in radians.

## Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1 .

For more information, see "Upsample Signals and Rate Changes".

## Rate options

Select the rate processing option for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the Samples per symbol parameter value.
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Output data type

Select the data type of the output signal. The output data type can be single or double.

## Supported Data Types

| Port | Supported Data Types |
| :--- | :--- |
| Input | - $\quad$ Double-precision floating point |
|  | $-\quad$ Boolean (When Input type set to Bit) |
|  | $-8-, 16-$ and 32-bit signed integers (When Input type set to Integer) |
| Output | -Double-precision floating point |

# CPM Demodulator Baseband 

Demodulate CPM-modulated data

Library: Communications Toolbox / Modulation / Digital Baseband Modulation / CPM

## Description

The CPM Demodulator Baseband block demodulates a signal that was modulated using continuous phase modulation (CPM).

CPM is a modulation method with memory. The block processing includes a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. The block uses the Viterbi algorithm to perform MLSD.

For more information about this demodulation and the filtering applied, see "CPM Demodulation" on page 5-145 and "Pulse Shape Filtering" on page 5-146.

## Ports

Input

## In - Input signal

scalar | column vector
Input signal, specified as a scalar or column vector. The length of the input signal must be an integer multiple of the number of samples per symbol specified in the Samples per symbol parameter. For more information, see "Integer-Valued and Binary-Valued Output Signals" on page 5-147.
Data Types: double | single

## Output

## Out - Output signal

scalar | column vector
Output signal, returned as a scalar or column vector. For more information, see "Integer-Valued and Binary-Valued Output Signals" on page 5-147.

## Supported Data Types

- Double-precision floating point
- Boolean (when Output type is set to Bit)
- 8-, 16-, and 32-bit signed integers (when Output type is set to Integer)

Data Types: double | Boolean | int8 | int16 | int32
For more information on the processing rates, see "Single-Rate Processing" on page 5-147, and "Multirate Processing" on page 5-147.

## Parameters

## M-ary number - Modulation order <br> 4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two. $M$ must have the form $2^{K}$ for some positive integer $K$, where $K$ is the number of bits per symbol.

Output type - Determines whether output consists of integers or groups of bits Integer (default)|Bit

Determines whether the output consists of integers or groups of bits, specified as Integer or Bit.

## Symbol set ordering - Bit mapping

Binary (default) |Gray
Bit mapping, specified as Binary or Gray.
This parameter determines how the block maps each integer to a group of output bits. For more information, see "Integer-Valued and Binary-Valued Output Signals" on page 5-147.

## Dependencies

To enable this parameter, set Output type to Bit.
Modulation index - Modulation index $\left\{h_{i}\right\}$
0.5 (default) | nonnegative scalar | column vector

Modulation index $\left\{h_{\mathrm{i}}\right\}$, specified as a nonnegative scalar or column vector.
$\{h\}$ represents a sequence of modulation indices. For more information, see "CPM Demodulation" on page 5-145.

Frequency pulse shape - Type of pulse shaping
Rectangular (default)|Raised Cosine|Spectral Raised Cosine|Gaussian|Tamed FM
Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as Rectangular, Raised Cosine, Spectral Raised Cosine, Gaussian, or Tamed FM. For more information on the filtering options, see "Pulse Shape Filtering" on page 5-146.

## Main lobe pulse duration (symbol intervals) - Number of symbol intervals of largest

 lobe of the spectral raised cosine pulse1 (default) | positive scalar
Number of symbol intervals of the largest lobe of the spectral raised cosine pulse, specified as a positive scalar.

Dependencies
To enable this parameter, set Frequency pulse shape to Spectral Raised Cosine.
Rolloff - Rolloff factor of spectral raised cosine pulse shape
0.2 (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse shape, specified as a scalar from 0 to 1 .

## Dependencies

To enable this parameter, set Frequency pulse shape to Spectral Raised Cosine.

## BT product - Product of bandwidth and time

0.3 (default) | nonnegative scalar

Product of bandwidth and time, specified as a nonnegative scalar. Use BT product to reduce the bandwidth, at the expense of increased intersymbol interference.

## Dependencies

To enable this parameter, set Frequency pulse shape to Gaussian.

## Pulse length (symbol intervals) - Frequency pulse length

1 (default) | positive scalar
Frequency pulse shape length, specified as a positive scalar. Refer to $L T$ in "Pulse Shape Filtering" on page 5-146 for more information on the frequency pulse length.

## Symbol prehistory - Data symbols used before the start of simulation

1 (default) | scalar | vector
Data symbols used before the start of simulation in reverse chronological order. If Symbol prehistory is a vector, then its length must be one less than the Pulse length parameter value.

## Phase offset (rad) - Initial phase offset

0 (default) | scalar
Initial phase offset of output in radians, specified as a scalar.

## Samples per symbol - Symbol sampling rate

8 (default) | positive scalar
Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see "Upsample Signals and Rate Changes".

## Rate options - Block processing rate

Enforce single-rate processing (default)|Allow multirate processing
Block processing rate, specified as one of these options:

- Enforce single-rate processing - The input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the Samples per symbol parameter value when the Output type parameter is set to Integer).
- Allow multirate processing - The input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the Samples per symbol parameter value.

## Traceback depth - Number of trellis branches <br> 16 (default) | positive integer

Number of trellis branches used to construct each traceback path, specified as a positive integer. For more information, see "Traceback Depth and Output Delays" on page 5-148.

## Output data type - Output data type

double (default) | boolean | int8 | int16 | int32
Output data type, specified as double, boolean, int8, int16, or int32. For more information, see Supported Data Types in Out.

## Block Characteristics

| Data Types | Boolean \| double \| integer \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## CPM Demodulation

The CPM demodulation processing consists of a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. When the modulation index is rational ( $h=m / p$ ), there are a finite number of phase states in the symbol. The block uses the Viterbi algorithm to perform MLSD.
$\left\{h_{\mathrm{i}}\right\}$ represents a sequence of modulation indices that moves cyclically through a set of indices $\left\{h_{0}\right.$, $\left.h_{1}, h_{2}, \ldots, h_{H-1}\right\}$.

- $h_{\mathrm{i}}=m_{\mathrm{i}} / p_{\mathrm{i}}$ represents the modulation index in proper rational form.
- $m_{\mathrm{i}}$ represents the numerator of the modulation index.
- $p_{\mathrm{i}}$ represents the denominator of the modulation index.
- $m_{\mathrm{i}}$ and $p_{\mathrm{i}}$ are relatively prime positive numbers.
- The least common multiple (LCM) of $\left\{p_{0}, p_{1}, p_{2}, \ldots, p_{H-1}\right\}$ is denoted as $p$.
- $h_{\mathrm{i}}=m_{\mathrm{i}} \mathrm{I}^{2} p$
$\left\{h_{\mathrm{i}}\right\}$ determines the number of phase states:

$$
\text { numPhaseStates }=\left\{\begin{array}{l}
p, \text { for all even } m_{i}^{\prime} \\
2 p, \text { for any odd } m_{i}^{\prime}
\end{array}\right\}
$$

and affects the number of trellis states:
numStates $=$ numPhaseStates $* M^{(L-1)}$

- $L$ represents the Pulse length.
- $M$ represents the $\mathbf{M}$-ary number.

## CPM Modulation

The input to the demodulator is a baseband representation of the modulated signal:

$$
\begin{aligned}
& s(t)=\exp \left[j 2 \pi \sum_{i=0}^{n} \alpha_{i} h_{i} q(t-i T)\right], \\
& n T<t<(n+1) T
\end{aligned}
$$

where:

- $\left\{\alpha_{\mathrm{i}}\right\}$ represents a sequence of $M$-ary data symbols selected from the alphabet $\pm 1, \pm 3, \pm(M-1)$.
- $M$ must have the form $2^{K}$ for some positive integer $K$, where $M$ is the modulation order and specifies the size of the symbol alphabet.
- $\left\{h_{\mathrm{i}}\right\}$ represents a sequence of modulation indices and $h_{\mathrm{i}}$ moves cyclically through a set of indices $\left\{h_{0}, h_{1}, h_{2}, \ldots, h_{H-1}\right\}$. When $H=1$, there is only one modulation index, $h_{0}$, which is denoted as $h$.

## Pulse Shape Filtering

Continuous phase modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation:

$$
q(t)=\int_{-\infty}^{t} g(t) d t
$$

The specified frequency pulse shape corresponds to these pulse shape expressions, $g(t)$.

| Pulse Shape | Expression |
| :---: | :---: |
| Rectangular | $g(t)=\left\{\begin{array}{cc}\frac{1}{2 L T}, & 0 \leq t \leq L T \\ 0 & \text { otherwise }\end{array}\right.$ |
| Raised Cosine | $g(t)=\left\{\begin{array}{cc} \frac{1}{2 L T}\left[1-\cos \left(\frac{2 \pi t}{L T}\right)\right], & 0 \leq t \leq L T \\ 0 & \text { otherwise } \end{array}\right.$ |
| Spectral Raised Cosine | $g(t)=\frac{1}{L_{\text {main }} T} \frac{\sin \left(\frac{2 \pi t}{L_{\text {main }} T}\right)}{\frac{2 \pi t}{L_{\text {main }} T}} \frac{\cos \left(\beta \frac{2 \pi t}{L_{\text {main }} T}\right)}{1-\left(\frac{4 \beta}{L_{\text {main }} T} t\right)^{2}}, \quad 0 \leq \beta \leq 1$ |
| Gaussian | $\begin{aligned} & g(t)=\frac{1}{2 T}\left\{Q\left[2 \pi B_{b} \frac{t-\frac{T}{2}}{\sqrt{\ln 2}}\right]-Q\left[2 \pi B_{b} \frac{t+\frac{T}{2}}{\sqrt{\ln 2}}\right]\right\}, \text { where } \\ & Q(t)=\int_{t}^{\infty} \frac{1}{\sqrt{2 \pi}} e^{-t^{2} / 2} d \tau \end{aligned}$ |

| Pulse Shape |
| :--- |
| Tamed FM (tamed frequency modulation) |
|  |
|  |

## Expression

$$
\begin{aligned}
& g(t)=\frac{1}{8}\left[g_{0}(t-T)+2 g_{0}(t)+g_{0}(t+T)\right], \text { where } \\
& g_{0}(t) \approx \frac{1}{T}\left[\frac{\sin \left(\frac{\pi t}{T}\right)}{\frac{\pi t}{T}}-\frac{\pi^{2}}{24} \frac{2 \sin \left(\frac{\pi t}{T}\right)-\frac{2 \pi t}{T} \cos \left(\frac{\pi t}{T}\right)-\left(\frac{\pi t}{T}\right)^{2} \sin \left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^{3}}\right.
\end{aligned}
$$

- $L_{\text {main }}$ is the main lobe pulse duration in symbol intervals.
- $\quad \beta$ is the rolloff factor of the spectral raised cosine.
- $B_{b}$ is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, $L T$, is the pulse length in symbol intervals. As defined by the expressions, the Spectral Raised Cosine, Gaussian, and Tamed FM pulse shapes have infinite length. For all practical purposes, $L T$ specifies the truncated finite length.

For more information on pulse shape filtering, see [1]

## Integer-Valued and Binary-Valued Output Signals

When the Output type parameter is set to Integer:

- The block produces odd integers between -(M-1) and $M-1$. The modulation order, $M$, is specified by the $\mathbf{M}$-ary number parameter.
- The Output datatype parameter cannot be set to boolean.

When the Output type parameter is set to Bit:

- The block produces groupings of $K$ bits. Each grouping is called a binary word.
- The Output datatype can only be double or boolean.
- In binary output mode, the block processing follows this procedure:

1 Maps each input symbol to an intermediate value, as in the integer output mode.
2 Maps the odd integer $k$ to the nonnegative integer $(k+M-1) / 2$.
3 Maps each nonnegative integer to a binary word, using Binary or Gray mapping, as specified by the Symbol set ordering parameter.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the Samples per symbol parameter value, and the input can be a column vector.

- When you set Output type to Bit, the output width is $K$ times the number of input symbols.
- When you set Output type to Integer, the output width is the number of input symbols.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the Samples per symbol parameter value.

- When you set Output type to Bit, the output width equals the number of bits per symbol.
- When you set Output type to Integer, the output is a scalar.

## Traceback Depth and Output Delays

The Traceback depth parameter, $D$, is the number of trellis branches used to construct each traceback path. $D$ influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When the Rate options parameter is set to Allow multirate processing, and the model uses a variable-step solver or a fixed-step solver with the Tasking Mode parameter set to SingleTasking, then the delay vector consists of $D+1$ zero-value symbols.
- When the Rate options parameter is set to Enforce single-rate processing, the delay vector consists of $D$ zero-value symbols.

The optimal Traceback depth parameter value depends on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the five-times-the-constraint-length rule, which corresponds to $5 \cdot \log 2$ (numStates).

For a binary raised cosine pulse shape with a pulse length of 3 and $h=2 / 3$, applying this rule $\left(5 * \log 2\left(3 * 2^{2}\right)=18\right)$ gives a result that is close to the optimum value of 20.

## CPM Modulator Baseband

Modulate using continuous phase modulation
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / CPM

## Description

The CPM Modulator Baseband block modulates an input signal using continuous phase modulation (CPM). The output of the modulator is a baseband representation of the modulated signal:

$$
\begin{aligned}
& s(t)=\exp \left[j 2 \Pi \sum_{i=0}^{n} \alpha_{i} h_{i} q(t-i T)\right], \\
& n T<t<(n+1) T
\end{aligned}
$$

where:

- $\left\{\alpha_{\mathrm{i}}\right\}$ represents a sequence of $M$-ary data symbols selected from the alphabet $\pm 1, \pm 3, \pm(M-1)$.
- $M$ must have the form $2^{K}$ for some positive integer $K$, where $M$ is the modulation order and specifies the size of the symbol alphabet.
- $\left\{h_{\mathrm{i}}\right\}$ represents a sequence of modulation indices and $h_{\mathrm{i}}$ moves cyclically through a set of indices $\left\{h_{0}, h_{1}, h_{2}, \ldots, h_{H-1}\right\}$. When $H=1$, there is only one modulation index, $h_{0}$, which is denoted as $h$.

For more information about this modulation and the filtering applied, see "CPM Modulation" on page 5-152 and "Pulse Shape Filtering" on page 5-153.

## Ports

Input
In - Input signal
scalar | column vector
Input signal, specified as a scalar or column vector.
When the Input type parameter is set to Integer, the block accepts odd integers between -(M-1) and $M-1$. $M$ represents the $\mathbf{M}$-ary number parameter.

When the Input type parameter is set to Bit, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $K=\log _{2}(M)$ bits. $K$ is the number of bits per symbol and $M$ is the modulation order. The input vector length must be an integer multiple of $K$. The block maps each group of $K$ bits onto a symbol, as specified by the Symbol set ordering parameter. For each group of $K$ bits, the block outputs one modulated symbol, oversampled by the Samples per symbol parameter value.

## Supported Data Types

- Double-precision floating point
- Boolean (when Input type is set to Bit)
- 8-, 16-, and 32 -bit signed integers (when Input type is set to Integer)

## Data Types: double | Boolean | int8 | int16|int32

## Output

## Out - Output signal

scalar | column vector
Output signal, returned as a scalar or column vector.

- When the Input type parameter is set to Integer, the block outputs one modulated symbol for each input symbol.
- When the Input type parameter is set to Bit, the block outputs one modulated symbol for each group of $K$ bits.

In both cases, the modulated symbols are oversampled by the Samples per symbol parameter value.

## Data Types: double | single

For more information on the processing rates, see "Single-Rate Processing" on page 5-154, and "Multirate Processing" on page 5-154.

## Parameters

## M-ary number - Modulation order <br> 4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two. $M$ must have the form $2^{K}$ for some positive integer $K$, where $K$ is the number of bits per symbol.

## Input type - Integer or group of bits input indicator

Integer (default) |Bit
Indicates whether the input consists of integers or groups of bits, specified as Integer or Bit.

## Symbol set ordering - Bit mapping

Binary (default)|Gray
Bit mapping, specified as Binary or Gray. For more information, see "Symbol Sets" on page 5-154.

## Dependencies

To enable this parameter, set Input type to Bit.

## Modulation index - Modulation index $\left\{h_{i}\right\}$ <br> 0.5 (default) | nonnegative scalar | column vector

Modulation index $\left\{h_{\mathrm{i}}\right\}$, specified as a nonnegative scalar or column vector.
$\{h\}$ represents a sequence of modulation indices. For more information, see "CPM Modulation" on page 5-152.

## Frequency pulse shape - Type of pulse shaping <br> Rectangular (default)|Raised Cosine|Spectral Raised Cosine|Gaussian|Tamed FM

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as Rectangular, Raised Cosine, Spectral Raised Cosine, Gaussian, or Tamed FM. For more information on the filtering options, see "Pulse Shape Filtering" on page 5-153.

Main lobe pulse duration (symbol intervals) - Number of symbol intervals of largest lobe of spectral raised cosine pulse
1 (default) | positive scalar
Number of symbol intervals of the largest lobe of the spectral raised cosine pulse, specified as a positive scalar.

## Dependencies

To enable this parameter, set Frequency pulse shape to Spectral Raised Cosine.
Rolloff - Rolloff factor of spectral raised cosine pulse shape
0.2 (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse, specified as a scalar from 0 to 1.

## Dependencies

To enable this parameter, set Frequency pulse shape to Spectral Raised Cosine.

## BT product - Product of bandwidth and time

0.3 (default) | nonnegative scalar

Product of bandwidth and time, specified as a nonnegative scalar. Use BT product to reduce the bandwidth, at the expense of increased intersymbol interference.

## Dependencies

To enable this parameter, set Frequency pulse shape to Gaussian.

## Pulse length (symbol intervals) - Frequency pulse length

1 (default) | positive scalar
Frequency pulse length, specified as a positive scalar. Refer to $L T$ in "Pulse Shape Filtering" on page 5-153 for more information on the frequency pulse length.

## Symbol prehistory - Data symbols used before the start of simulation

1 (default) | scalar | vector
Data symbols used before the start of simulation, specified as a scalar or vector in reverse chronological order. If Symbol prehistory is a vector, then its length must be one less than the Pulse length (symbol intervals) parameter value.

## Phase offset (rad) - Initial phase offset <br> 0 (default) | scalar

Initial phase offset of output in radians, specified as a scalar.

## Samples per symbol - Symbol sampling rate

## 8 (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1 .

For more information, see "Upsample Signals and Rate Changes".

## Rate options - Block processing rate

Enforce single-rate processing (default)|Allow multirate processing
Block processing rate, specified as one of these options:

- Enforce single-rate processing - The input and output signals have the same sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the Samples per symbol parameter value.
- Allow multirate processing - The input and output signals have different sample times. The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Output data type - Output data type

double (default) | single
Output data type, specified as double or single.

## Block Characteristics

| Data Types | Boolean \| double \| integer \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## CPM Modulation

The output of the modulator is a baseband representation of the modulated signal:

$$
\begin{aligned}
& s(t)=\exp \left[j 2 \pi \sum_{i=0}^{n} \alpha_{i} h_{i} q(t-i T)\right], \\
& n T<t<(n+1) T
\end{aligned}
$$

where:

- $\left\{\alpha_{\mathrm{i}}\right\}$ represents a sequence of $M$-ary data symbols selected from the alphabet $\pm 1, \pm 3, \pm(M-1)$.
- $M$ must have the form $2^{K}$ for some positive integer $K$, where $M$ is the modulation order and specifies the size of the symbol alphabet.
- $\left\{h_{\mathrm{i}}\right\}$ represents a sequence of modulation indices and $h_{\mathrm{i}}$ moves cyclically through a set of indices $\left\{h_{0}, h_{1}, h_{2}, \ldots, h_{H-1}\right\}$. When $H=1$, there is only one modulation index, $h_{0}$, which is denoted as $h$.
$h_{i}$ specifies the modulation index. When $h_{i}$ varies from interval to interval, the block operates in multi$h$. To ensure a finite number of phase states, $h_{\mathrm{i}}$ must be a rational number.

## Pulse Shape Filtering

Continuous phase modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation: $q(t)=\int_{-\infty}^{t} g(t) d t$

The specified frequency pulse shape corresponds to these pulse shape expressions, $g(t)$.

| Pulse Shape | Expression |
| :---: | :---: |
| Rectangular | $g(t)=\left\{\begin{array}{cc}\frac{1}{2 L T}, & 0 \leq t \leq L T \\ 0 & \text { otherwise }\end{array}\right.$ |
| Raised Cosine | $g(t)=\left\{\begin{array}{cc} \frac{1}{2 L T}\left[1-\cos \left(\frac{2 \pi t}{L T}\right)\right], & 0 \leq t \leq L T \\ 0 & \text { otherwise } \end{array}\right.$ |
| Spectral Raised Cosine | $g(t)=\frac{1}{L_{\text {main }} T} \frac{\sin \left(\frac{2 \pi t}{L_{\text {main }} T}\right)}{\frac{2 \pi t}{L_{\text {main }} T}} 1-\left(\frac{4 \beta}{L_{\text {main }} T} t\right)^{2}\left(\beta \frac{2 \pi t}{L_{\text {muin }} T}\right), \quad 0 \leq \beta \leq 1$ |
| Gaussian | $\begin{aligned} & g(t)=\frac{1}{2 T}\left\{Q\left[2 \pi B_{b} \frac{t-\frac{T}{2}}{\sqrt{\ln 2}}\right]-Q\left[2 \pi B_{b} \frac{t+\frac{T}{2}}{\sqrt{\ln 2}}\right]\right\}, \text { where } \\ & Q(t)=\int_{t}^{\infty} \frac{1}{\sqrt{2 \pi}} e^{-\tau^{2} / 2} d \tau \end{aligned}$ |
| Tamed FM (tamed frequency modulation) | $\begin{aligned} & g(t)=\frac{1}{8}\left[g_{0}(t-T)+2 g_{0}(t)+g_{0}(t+T)\right], \text { where } \\ & g_{0}(t) \approx \frac{1}{T}\left[\frac{\sin \left(\frac{\pi t}{T}\right)}{\frac{\pi t}{T}}-\frac{\pi^{2}}{24} \frac{2 \sin \left(\frac{\pi t}{T}\right)-\frac{2 \pi t}{T} \cos \left(\frac{\pi z}{T}\right)-\left(\frac{k t}{T}\right)^{2} \sin \left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^{3}}\right. \end{aligned}$ |

- $L_{\text {main }}$ is the main lobe pulse duration in symbol intervals.
- $\quad \beta$ is the rolloff factor of the spectral raised cosine.
- $B_{\mathrm{b}}$ is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, $L T$, is the pulse length in symbol intervals. As defined by the expressions, the Spectral Raised Cosine, Gaussian, and Tamed FM pulse shapes have infinite length. For all practical purposes, $L T$ specifies the truncated finite length.

For more information on pulse shape filtering, see [1].

## Symbol Sets

In binary input mode, the block processing follows this procedure:
1 Maps each binary word to $k$, an integer from 0 to $M-1$. The binary word mapping options are Binary or Gray, as specified by the Symbol set ordering parameter.

2 Maps $k$ to the intermediate value $2 k$-(M-1)
3 Proceeds with block processing as in the integer input mode.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. In this mode, the input to the block can be multiple symbols. The block implicitly implements the rate change by making a size change at the output when compared to the input.

- When you set Input type to Integer, the input can be a scalar or a column vector with the length equal to the number of input symbols.
- When you set Input type to Bit, the input width must be an integer multiple of the number of bits per symbol.

The output width equals $N_{\mathrm{Sym}} \times N_{\mathrm{SPS}}$, where $N_{\mathrm{Sym}}$ is the number of symbols in the frame and $N_{\mathrm{SPS}}$ is the number of samples per symbol.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set Input type to Integer, the input must be a scalar.
- When you set Input type to Bit, the input width must equal the number of bits per symbol.

The output sample time equals $T_{\text {Sym }} / N_{\mathrm{SPS}}$, where $T_{\mathrm{Sym}}$ is the symbol period and $N_{\mathrm{SPs}}$ is the number of samples per symbol.

## CPM Phase Recovery

(Removed) Recover carrier phase using 2P-Power method

Note CPM Phase Recovery has been removed. Use the Carrier Synchronizer block instead.

## Library

Carrier Phase Recovery sublibrary of Synchronization

## Description

The CPM Phase Recovery block recovers the carrier phase of the input signal using the 2P-Power method. This feedforward, non-data-aided, clock-aided method is suitable for systems that use these types of baseband modulation: continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), and Gaussian minimum shift keying (GMSK). This block is suitable for use with blocks in the Baseband Continuous Phase Modulation library.

If you express the modulation index for CPM as a proper fraction, $\mathrm{h}=\mathrm{K} / \mathrm{P}$, then P is the number to which the name "2P-Power" refers. The observation interval parameter must be an integer multiple of the input signal vector length.

The 2P-Power method assumes that the carrier phase is constant over a series of consecutive symbols, and returns an estimate of the carrier phase for the series. The Observation interval parameter is the number of symbols for which the carrier phase is assumed constant. This number must be an integer multiple of the input signal's vector length.

## Input and Output Signals

This block accepts a scalar or column vector input signal of type double or single. The input signal represents a baseband signal at the symbol rate, so it must be complex-valued and must contain one sample per symbol.

The outputs are as follows:

- The output port labeled Sig gives the result of rotating the input signal counterclockwise, where the amount of rotation equals the carrier phase estimate. The Sig output is thus a corrected version of the input signal, and has the same sample time and vector size as the input signal.
- The output port labeled Ph outputs the carrier phase estimate, in degrees, for all symbols in the observation interval. The Ph output is a scalar signal.

Note Because the block internally computes the argument of a complex number, the carrier phase estimate has an inherent ambiguity. The carrier phase estimate is between -90/P and 90/P degrees and might differ from the actual carrier phase by an integer multiple of 180/P degrees.

## Delays and Latency

The block's algorithm requires it to collect symbols during a period of length Observation interval before computing a single estimate of the carrier phase. Therefore, each estimate is delayed by

Observation interval symbols and the corrected signal has a latency of Observation interval symbols, relative to the input signal.

## Parameters

## P

The denominator of the modulation index for CPM $(\mathrm{h}=\mathrm{K} / \mathrm{P})$ when expressed as a proper fraction.

## Observation interval

The number of symbols for which the carrier phase is assumed constant. The observation interval parameter must be an integer multiple of the input signal vector length.

When this parameter is exactly equal to the vector length of the input signal, then the block always works. When the integer multiple is not equal to 1, on the Simulation tab, select Model Settings. Then in the Solver > Solver selection section, choose Type: Fixed-step and clear the Treat each discrete rate as a separate task checkbox.

## Algorithm

If the symbols occurring during the observation interval are $x(1), x(2), x(3), \ldots, x(L)$, then the resulting carrier phase estimate is

$$
\frac{1}{2 P} \arg \left\{\sum_{k=1}^{L}(x(k))^{2 P}\right\}
$$

where the arg function returns values between - 180 degrees and 180 degrees.

CRC sublibrary of Error Detection and Correction

## Description

The CRC-N Generator block generates cyclic redundancy code (CRC) bits for each input data frame and appends them to the frame. The input must be a binary column vector. The CRC-N Generator block is a simplified version of the General CRC Generator block. With the CRC-N Generator block, you can select the generator polynomial for the CRC algorithm from a list of commonly used polynomials, given in the CRC-N method field in the block's dialog. N is degree of the generator polynomial. The table below lists the options for the generator polynomial.

| CRC Method | Generator Polynomial | Number of Bits |
| :--- | :--- | :--- |
| CRC-32 | $x^{32}+\mathrm{x}^{26}+\mathrm{x}^{23}+\mathrm{x}^{22}+\mathrm{x}^{16}+\mathrm{x}^{12}+\mathrm{x}^{11}$ <br> $+\mathrm{x}^{10}+\mathrm{x}^{8}+\mathrm{x}^{7}+\mathrm{x}^{5}+\mathrm{x}^{4}+\mathrm{x}^{2}+\mathrm{x}+1$ | 32 |
| CRC-24 | $\mathrm{x}^{24}+\mathrm{x}^{23}+\mathrm{x}^{14}+\mathrm{x}^{12}+\mathrm{x}^{8}+1$ | 24 |
| CRC-16 | $\mathrm{x}^{16}+\mathrm{x}^{15}+\mathrm{x}^{2}+1$ | 16 |
| Reversed CRC-16 | $\mathrm{x}^{16}+\mathrm{x}^{14}+\mathrm{x}+1$ | 16 |
| CRC-8 | $\mathrm{x}^{8}+\mathrm{x}^{7}+\mathrm{x}^{6}+\mathrm{x}^{4}+\mathrm{x}^{2}+1$ | 8 |
| CRC-4 | $\mathrm{x}^{4}+\mathrm{x}^{3}+\mathrm{x}^{2}+\mathrm{x}+1$ | 4 |

You specify the initial state of the internal shift register using the Initial states parameter. You specify the number of checksums that the block calculates for each input frame using the Checksums per frame parameter. For more detailed information, see the reference page for the General CRC Generator block.

This block supports double and boolean data types. The output data type is inherited from the input.

## Signal Attributes

The General CRC Generator block has one input port and one output port. Both ports accept binary column vector input signals.

## Parameters

## CRC-N method

The generator polynomial for the CRC algorithm.

## Initial states

A binary scalar or a binary row vector of length equal to the degree of the generator polynomial, specifying the initial state of the internal shift register.

## Checksums per frame

A positive integer specifying the number of checksums the block calculates for each input frame.

## Algorithm

For a description of the CRC algorithm as implemented by this block, see "CRC Non-Direct Algorithm" in Communications Toolbox User's Guide.

## Schematic of the CRC Implementation

The above circuit divides the polynomial $a(x)=a_{k-1} x^{k-1}+a_{k-2} x^{k-2}+\cdots+a_{1} x+a_{0}$ by $g(x)=g_{r-1} x^{r-1}+g_{r-2} x^{r-2}+\cdots+g_{1} x+g_{0}$, and returns the remainder $d(x)=d_{r-1} x^{r-1}+d_{r-2} x^{r-2}+\cdots+d_{1} x+d_{0}$.

The input symbols $\left\{a_{k-1}, a_{k-2}, \ldots, a_{2}, a_{1}, a_{0}\right\}$ are fed into the shift register one at a time in order of decreasing index. When the last symbol ( $a_{0}$ ) works its way out of the register (achieved by augmenting the message with r zeros), the register contains the coefficients of the remainder polynomial $d(x)$.

This remainder polynomial is the checksum that is appended to the original message, which is then transmitted.

## Description

The CRC-N Syndrome Detector block computes checksums for its entire input frame. This block has two output ports. The first output port contains the set of message words with the CRC bits removed. The second output port contains the checksum result, which is a vector of a size equal to the number of checksums. A value of 0 indicates no checksum errors. A value of 1 indicates a checksum error occurred.

The CRC-N Syndrome Detector block is a simplified version of the General CRC Syndrome Detector block. You can select the generator polynomial for the CRC algorithm from a list of commonly used polynomials, given in the CRC-N method field in the block's dialog. N is the degree of the generator polynomial. The reference page for the CRC-N Generator block contains a list of the options for the generator polynomial.

The parameter settings for the CRC-N Syndrome Detector block should match those of the CRC-N Generator block.

You specify the initial state of the internal shift register by the Initial states parameter. You specify the number of checksums that the block calculates for each input frame by the Checksums per frame parameter. For more detailed information, see the reference page for the General CRC Syndrome Detector block.

This block supports double and boolean data types. The output data type is inherited from the input.

## Signal Attributes

The CRC-N Syndrome Detector block has one input port and two output ports. All three ports accept binary column vector signals.

## Parameters

## CRC-N method

The generator polynomial for the CRC algorithm.

## Initial states

A binary scalar or a binary row vector of length equal to the degree of the generator polynomial, specifying the initial state of the internal shift register.

## Checksums per frame

A positive integer specifying the number of checksums the block calculates for each input frame.

## Algorithm

For a description of the CRC algorithm as implemented by this block, see "Cyclic Redundancy Check Codes".

## Data Mapper

Map integer symbols from one coding scheme to another
Library: Communications Toolbox / Utility Blocks

## Description

The Data Mapper block accepts integer inputs and maps them to integer outputs. The mapping types include: binary to Gray coded, Gray coded to binary, and user defined. Additionally, a pass through option is available.

Gray coding is an ordering of binary numbers such that all adjacent numbers differ by only one bit.

## Input/Output Ports

## Input

## Port_1 - Input port

scalar | column vector | matrix
Input signal, specified as a scalar, vector, or matrix of integers. Elements of the input signal must be nonnegative values. The block truncates noninteger values to integer values. When the input is a matrix, the columns are treated as independent channels.
Data Types: double | single | int8 | int16|int32 | uint8|uint16|uint32

## Output

## Port_2 - Output signal

scalar | column vector | matrix
Output signal, returned as a scalar, column vector, or matrix. The dimensions of the output signal match those of the input signal.
Data Types: double | single | int8 | int16| int32 | uint8|uint16|uint32

## Parameters

## Mapping mode - Mapping mode

Binary to Gray (default)|Gray to Binary|User Defined|Straight through
Mapping mode, specified as one of the four options. The mapping for the Binary to Gray and the Gray to Binary modes are shown in the following table when the inputs range from 0 to 7 .

| Binary to Gray Mode | Gray to Binary Mode |  |  |
| :--- | :--- | :--- | :--- |
| Input | Output | Input | Output |
| 0 | $0(000)$ | $0(000)$ | 0 |
| 1 | $1(001)$ | $1(001)$ | 1 |
| 2 | $3(011)$ | $2(010)$ | 3 |
| 3 | $2(010)$ | $3(011)$ | 2 |
| 4 | $6(110)$ | $4(100)$ | 7 |
| 5 | $7(111)$ | $5(101)$ | 6 |
| 6 | $5(101)$ | $6(110)$ | 4 |
| 7 | $4(100)$ | $7(111)$ | 5 |

When you select the User Defined mode, you can use any arbitrary mapping by providing a vector to specify the output ordering. When you select the Straight Through mode, the output equals the input.

Symbol set size (M) - Symbol set size
8 (default) | positive integer
Symbol set size, specified as a positive integer. This parameter restricts the inputs and outputs to integers in the range of 0 to $\mathrm{M}-1$.

## Mapping vector - Maps input elements to the output elements

## $\left.\begin{array}{lllllll}0 & 1 & 3 & 2 & 7 & 6 & 4\end{array}\right]$ (default) | vector

Mapping vector, specified as vector of nonnegative integers whose length equals . This parameter defines the relationship between the input and output integers. For example, the vector [1 5042 $3]$ defines the following mapping:

$$
\begin{aligned}
& 0 \rightarrow 1 \\
& 1 \rightarrow 5 \\
& 2 \rightarrow 0 \\
& 3 \rightarrow 4 \\
& 4 \rightarrow 2 \\
& 5 \rightarrow 3
\end{aligned}
$$

## DBPSK Demodulator Baseband

Demodulate DBPSK-modulated data

```
MMMW-
```

    DBPSK
    
## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The DBPSK Demodulator Baseband block demodulates a signal that was modulated using the differential binary phase shift keying method. The input is a baseband representation of the modulated signal.

The input must be a discrete-time complex signal. The block compares the current symbol to the previous symbol. It maps phase differences of $\theta$ and $\Pi+\theta$, respectively, to outputs of 0 and 1 , respectively, where $\theta$ is the Phase rotation parameter. The first element of the block's output is the initial condition of zero because there is no previous symbol with which to compare the first symbol.

This block accepts a scalar or column vector input signal. The input signal can be of data types single and double. For information about the data types each block port supports, see "Supported Data Types" on page 5-168.

## Dialog Box

## Phase rotation (rad)

This phase difference between the current and previous modulated symbols results in an output of zero.

Output data type
When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type single or double.

For additional information, see "Supported Data Types" on page 5-168.

## Supported Data Types

| Port | Supported Data Types |

## DBPSK Modulator Baseband

Modulate using differential binary phase shift keying method

```
\square-MMM
DBPSK
```

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The DBPSK Modulator Baseband block modulates using the differential binary phase shift keying method. The output is a baseband representation of the modulated signal.

This block accepts a scalar or column vector input signal. The input must be a discrete-time binaryvalued signal. For information about the data types each block port supports, see "Supported Data Types" on page 5-170.

The following rules govern this modulation method when the Phase rotation parameter is $\theta$ :

- If the first input bit is 0 or 1 , respectively, then the first modulated symbol is $\exp (\mathrm{j} \theta)$ or $-\exp (\mathrm{j} \theta)$, respectively.
- If a successive input bit is 0 or 1 , respectively, then the modulated symbol is the previous modulated symbol multiplied by $\exp (j \theta)$ or $-\exp (j \theta)$, respectively.

## Dialog Box

## Phase rotation (rad)

The phase difference between the previous and current modulated symbols when the input is zero.

## Output Data type

The output data type can be either single or double. By default, the block sets this to double.

## Supported Data Types

## Decision Feedback Equalizer

Equalize modulated signals using decision feedback filtering

## Library: Communications Toolbox / Equalizers

## Description

The Decision Feedback Equalizer block uses a decision feedback filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. Using an estimate of the channel modeled as a finite input response (FIR) filter, the block processes input frames and outputs the estimated signal.

This icon shows the block with all ports enabled for configurations that use the LMS or RLS adaptive algorithm.

This icon shows the block with all ports enabled for configurations that use the CMA adaptive algorithm.

## Ports

## Input

## in - Input signal

column vector
Input signal, specified as a column vector. The vector length of in must be equal to an integer multiple of the Number of input samples per symbol parameter. For more information, see "Symbol Tap Spacing" on page 5-465.

## Data Types: double

Complex Number Support: Yes

## Desired - Training symbols

column vector
Training symbols, specified as a column vector. The vector length of Desired must be less than or equal to the length of input in. The Desired input port is ignored when the Train input port is 0.

## Dependencies

To enable this port, set the Adaptive algorithm parameter to LMS or RLS.
Data Types: double
Complex Number Support: Yes

## Train - Train equalizer flag

boolean scalar
Train equalizer flag, specified as 1 or 0 . The block starts training when this value changes from 0 to 1 (at the rising edge). The block trains until all symbols in the Desired input port are processed.

## Dependencies

To enable this port, set the Adaptive algorithm parameter to LMS or RLS and select the Enable training control input parameter.
Data Types: Boolean
Update - Update tap weights flag 1|0

Update tap weights flag, specified as 1 or 0 . The tap weights are updated when this value is 1 .

## Dependencies

To enable this port, set the Adaptive algorithm parameter to CMA and the Source of adapt weights flag parameter to Input port.

Data Types: Boolean

## Reset - Reset equalizer flag

1 | 0
Reset equalizer flag, specified as 1 or 0 . If Reset is set to 1 , the block resets the tap weights before processing the incoming signal. The block performs initial training until all symbols in the Desired input port are processed.

## Dependencies

To enable this port, select the Enable reset input parameter.

## Data Types: Boolean

## Output

## Out - Equalized symbols

column vector
Equalized symbols, returned as a column vector that has the same length as input signal in.
This port is unnamed until you select the Output error signal or Output taps weights parameter.

## Err - Error signal

column vector
Error signal, returned as a column vector that has the same length as input signal in.

## w - Tap weights

column vector
Tap weights, returned as an $N_{\text {Taps }}$-by- 1 vector, where $N_{\text {Taps }}$ is equal to the sum of the Number of forward taps and Number of feedback taps parameter values. $\mathbf{w}$ contains the tap weights from the last tap weight update.

## Parameters

## Structure parameters

## Number of forward taps - Number of forward equalizer taps

5 (default) | positive integer
Number of forward equalizer taps, specified as a positive integer.

## Number of feedback taps - Number of feedback equalizer taps

3 (default) | positive integer
Number of feedback equalizer taps, specified as a positive integer.

## Signal constellation - Signal constellation

pskmod (0:3,4, pi/4) (default)| vector
Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: pskmod (0:3,4, pi/4).

Tunable: Yes
Number of input samples per symbol - Number of input samples per symbol
1 (default) | positive integer
Number of input samples per symbol, specified as a positive integer. Setting this parameter to any number greater than 1 effectively creates a fractionally spaced equalizer. For more information, see "Symbol Tap Spacing" on page 5-465.

## Algorithm parameters

## Adaptive algorithm - Adaptive algorithm

LMS (default) | RLS | CMA
Adaptive algorithm used for equalization, specified as one of these values:

- LMS - Update the equalizer tap weights using the "Least Mean Square (LMS) Algorithm" on page 5-466.
- RLS - Update the equalizer tap weights using the "Recursive Least Square (RLS) Algorithm" on page 5-466.
- CMA - Update the equalizer tap weights using the "Constant Modulus Algorithm (CMA)" on page 5-467.

## Step size - Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

## Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to LMS or CMA.

## Forgetting factor - Forgetting factor

0.99 (default) | scalar in the range ( 0,1 ]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range ( 0,1 ]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes
Dependencies
To enable this parameter, set Adaptive algorithm to RLS.

## Initial inverse correlation matrix - Initial inverse correlation matrix 0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an $N_{\text {Taps }}$-by- $N_{\text {Taps }}$ matrix. $N_{\text {Taps }}$ is equal to the sum of the Number of forward taps and Number of feedback taps parameter values. If you specify this value as a scalar, $a$, the equalizer sets the initial inverse correlation matrix to $a$ times the identity matrix: $a\left(\operatorname{eye}\left(N_{\text {Taps }}\right)\right)$.

Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to RLS.

## Control parameters

## Reference tap - Reference tap

3 (default) | positive integer
Reference tap, specified as a positive integer less than or equal to the Number of forward taps parameter value. The equalizer uses the reference tap location to track the main energy of the channel.

## Input signal delay (samples) - Input signal delay <br> 0 (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1 , then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the block and to the first call of the block after the Reset input port toggles to 1.

## Dependencies

To enable this parameter, set Adaptive algorithm to LMS or RLS.

## Source of adapt weights flag - Source of adapt tap weights request <br> Property (default)|Input port

Source of the adapt tap weights request, specified as one of these values:

- Property - Specify this value to use the Adaptive algorithm parameter to control when the block adapts tap weights.
- Input port - Specify this value to use the Update input port to control when the block adapts tap weights.

Dependencies
To enable this parameter, set Adaptive algorithm to CMA.
Adapt tap weights - Adapt tap weights
on (default) |off
Select this parameter to adaptively update the equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged.

Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to CMA and Source of adapt weights flag to Property.

Initial tap weights source - Source for initial tap weights
Auto (default)| Property
Source for initial tap weights, specified as one of these values:

- Auto - Initialize the tap weights to the algorithm-specific default values, as described in the Initial weights parameter.
- Property - Initialize the tap weights using the Initial weights parameter value.

## Initial weights - Initial tap weights

0 or $[0 ; 0 ; 1 ; 0 ; 0]$ (default) | scalar | column vector
Initial tap weights used by the adaptive algorithm, specified as a scalar or an $N_{\text {Taps-by- }}$ - vector. $N_{\text {Taps }}$ is equal to the sum of the Number of forward taps and Number of feedback taps parameter values. The default is 0 when the Adaptive algorithm parameter is set to LMS or RLS. The default is $[0 ; 0 ; 1 ; 0 ; 0]$ when the Adaptive algorithm parameter is set to CMA.

If you specify Initial weights as a vector, the vector length must be $N_{\text {Taps }}$. If you specify Initial weights as a scalar, the equalizer uses scalar expansion to create a vector of length $N_{\text {Taps }}$ with all values set to Initial weights.

Tunable: Yes

## Dependencies

To enable this parameter, set Initial tap weights source to Property.
Tap weight update period (symbols) - Tap weight update period
1 (default) | positive integer
Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

## Enable training control input - Enable training control input off (default) | on

Select this parameter to enable input port Train. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

Tunable: Yes
Dependencies
To enable this parameter, set Adaptive algorithm to LMS or RLS.

## Update tap weights when not training - Update tap weights when not training on (default) | off

Select this parameter to use decision directed mode to update equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged after training.

Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to LMS or RLS.

## Enable reset input - Enable reset input <br> off (default) | on

Select this parameter to enable input port Train. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

Tunable: Yes

## Diagnostic parameters

## Output error signal - Enable error signal output

off (default) | on
Select this parameter to enable output port Err containing the equalizer error signal.
Tunable: Yes

## Output taps weights - Enable tap weights output off (default) | on

Select this parameter to enable output port $\mathbf{w}$ containing tap weights from the last tap weight update.
Tunable: Yes

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbolspaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1 . Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

## Decision Feedback Equalizers

A decision feedback equalizer (DFE) is a nonlinear equalizer that reduces intersymbol interference (ISI) in frequency-selective channels. If a null exists in the frequency response of a channel, DFEs do not enhance the noise. A DFE consists of a tapped delay line that stores samples from the input signal and contains a forward filter and a feedback filter. The forward filter is similar to a linear equalizer. The feedback filter contains a tapped delay line whose inputs are the decisions made on the equalized signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

DFEs can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, $K$, is 1 . The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, $K$, is an integer greater than 1 . Typically, $K$ is 4 for fractional symbol-spaced equalizers. The output sample rate is $1 / T$ and the input sample rate is $K / T$. Tap weight updating occurs at the output rate.

This schematic shows a fractional symbol-spaced DFE with a total of $N$ weights, a symbol period of $T$, and $K$ samples per symbol. The filter has $L$ forward weights and $N-L$ feedback weights. The forward filter is at the top, and the feedback filter is at the bottom. If $K$ is 1 , the result is a symbol-spaced DFE instead of a fractional symbol-spaced DFE.

In each symbol period, the equalizer receives $K$ input samples at the forward filter and one decision or training sample at the feedback filter. The equalizer then outputs a weighted sum of the values in the forward and feedback delay lines and updates the weights to prepare for the next symbol period.

Note The algorithm for the Adaptive Algorithm block in the schematic jointly optimizes the forward and feedback weights. Joint optimization is especially important for convergence in the recursive least square (RLS) algorithm.

For more information, see "Equalization".

## Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, $w$ is a vector of all weights $w_{i}$, and $u$ is a vector of all inputs $u_{i}$. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of inputs, $u$, and the inverse correlation matrix, $P$, the RLS algorithm first computes the Kalman gain vector, $K$, as

$$
K=\frac{P u}{(\text { ForgettingFactor })+u^{H} P u} .
$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range $(0,1]$. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized output signal to be less stable. $H$ denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$
P_{\text {new }}=\frac{P_{\text {current }}\left(1-K u^{H}\right)}{\text { ForgettingFactor }} .
$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+K^{*} e .
$$

The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e .
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=y\left(R-|y|^{2}\right)$, where $R$ is a constant related to the signal constellation.

## Deinterlacer

Distribute elements of input vector alternately between two output vectors
Library: Communications Toolbox / Sequence Operations

## Description

The Deinterlacer block accepts an even length column vector input signal. The block alternately places the elements in two output vectors. As a result, each output vector size is half the input vector size. The outputs inherit the sample time from the Sample time parameter of the input block.

## Ports

Input

## In - Input signal

numeric column vector
Input signal, specified as an even length column vector.
Data Types: double

## Output

## 0 - Odd-numbered elements

numeric vector
Odd-numbered elements of the input vector, returned as a vector. If the input is a vector of length $N$, the output length is $N / 2$.

## E-Even-numbered elements

## numeric vector

Even-numbered elements of the input vector, returned as a vector. If the input is a vector of length $N$, the output length is $N / 2$.

## Derepeat

Reduce sampling rate by averaging consecutive samples
Library: Communications Toolbox / Sequence Operations

## Description

The Derepeat block resamples the discrete input at a rate $1 / N$ times the input sample rate by averaging $N$ consecutive samples. $N$ represents the Derepeat factor, $N$ parameter.

## Ports

## Input

In - Input signal
scalar | vector | matrix
Input signal, specified as a scalar, vector, or matrix.
Data Types: double
Complex Number Support: Yes

## Output

Out - Output signal
scalar | vector | matrix
Output signal, returned as a scalar or column vector.
Data Types: double
Complex Number Support: Yes
For more information on the processing rates, see "Single-Rate Processing" on page 5-183, and "Multirate Processing" on page 5-184.

## Parameters

## Derepeat factor, N - Derepeat factor

5 (default) | integer
Derepeat factor, specified as an integer. The derepeat factor is the number of consecutive input samples to average to produce each output sample.
Data Types: double
Input processing - Input processing control
Columns as channels (frame based) (default)|Elements as channels (sample based)
Input processing control, specified as one of these options:

- Columns as channels (frame based) - The block treats each column of the input as a separate channel.
- Elements as channels (sample based) - The block treats each element of the input as a separate channel.

## Rate options - Block processing rate

Allow multirate processing (default)|Enforce single-rate processing
Block processing rate, specified as one of these options:

- Allow multirate processing - The block downsamples the signal such that the output sample rate is Derepeat factor, N times slower than the input sample rate. For more information, see "Multirate Processing" on page 5-184.
- Enforce single-rate processing - The block maintains the input sample rate by decreasing the output frame size by a factor equal to the Derepeat factor, N parameter value. Also, in single-rate processing mode you can use this block in a triggered subsystem. For more information, see "Single-Rate Processing" on page 5-183

## Initial condition - Initial condition

0 (default) | scalar | vector | matrix
Initial condition, specified as a scalar, vector, or matrix. This parameter specifies values that are output when it is too early for the input data to show up in the output. If the dimensions of the Initial condition parameter match the output dimensions, then the parameter represents the initial output value. If Initial condition is a scalar, then it represents the initial value of each element in the output. The block does not support empty matrices for initial conditions.

## Data Types: double

## Block Characteristics

| Data Types | double \\| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Single-Rate Processing

The block derepeats each frame, treating distinct channels independently. Each element of the output is the average of $N$ consecutive elements along a column of the input matrix. $N$ must be less than the frame size. $N$ represents the Derepeat factor, N parameter.

When you set the Rate options parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. The block reduces the sampling rate by using a proportionally smaller frame size than the input. To process all input values, $N$ must be an integer factor of the number of rows in the input vector or matrix. For derepetition by a factor of $N$, the output frame size is $1 / N$ times the input frame size, but the input and output frame rates are equal. When you use this option, the Initial condition parameter does not apply and the block incurs no delay, because the input data immediately shows up in the output.

For example, for a single-channel input with 64 elements that is derepeated by a factor of 4 , the block outputs 16 elements. The input and output frame periods are equal.

Also, in single-rate processing mode you can use this block in a triggered subsystem.

## Multirate Processing

When you set the Rate options parameter to Allow multirate processing, the input and output of the block are the same size, but the sample rate of the output is $N$ times slower than the input. $N$ represents the Derepeat factor, $N$ parameter.

- When you set the Input processing parameter to Elements as channels (sample based), the block assumes that the input is a vector or matrix whose elements represent samples from independent channels. The block averages samples from each channel independently over time. The output period is $N$ times the input period, and the input and output sizes are identical. The output is delayed by one output period, and the first output value is the Initial condition value. If you set Rate options to Enforce single-rate processing, the block generates an error message.
- When you set the Input processing parameter to Columns as channels (frame based), the block reduces the sampling rate by using a proportionally longer frame period at the output port than at the input port. For derepetition by a factor of $N$, the output frame period is $N$ times the input frame period, but the input and output frame sizes are equal. The output is delayed by one output frame, and the first output frame is the Initial condition value. The block derepeats each frame, treating distinct channels independently. Each element of the output is the average of $N$ consecutive elements along a column of the input matrix. The derepeat factor must be less than the frame size.

For example, for a single-channel input with a frame period of 1 second that is derepeated by a factor of 4 , the output has a frame period of 4 seconds. The input and output frame sizes are equal.

## Descrambler

Descramble input signal

## Library: <br> Communications Toolbox / Sequence Operations

## Description

The Descrambler block descrambles a scalar or column vector input signal. The Descrambler block is the inverse of the Scrambler block. If you use the Scrambler block in a transmitter, then you use the Descrambler block in the related receiver.

This schematic shows the descrambler operation. The adders and subtracter operate modulo $N$, where $N$ is the value specified by the Calculation base parameter.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Scramble polynomial parameter, you specify the on or off state for each switch in the descrambler. To make the Descrambler block reverse the operation of the Scrambler block, use the same parameter settings in both blocks. If there is no signal delay between the scrambler and the descrambler, then the Initial states in the two blocks must be the same.

To achieve repeatable initial descrambler conditions, you can use one of these optional input ports:

- Select the Reset on nonzero input via port parameter and reset the scrambler with Rst.
- Set the Initial states source parameter to Input port and provide the initial states with ISt.

This block can accept input sequences that vary in length during simulation. For more information about sequences that vary in length, see "Variable-Size Signal Basics" (Simulink).

## Ports

## Input

## in - Input data signal

vector
Input data signal, specified as an $N_{\mathrm{S}}$-by-1 vector. $N_{\mathrm{S}}$ represents the number of samples in the input signal. The input values must be integers from 0 to Calculation base - 1 .

## Data Types: double

## Rst - Reset scrambler

scalar
Reset scrambler, specified as a scalar. The scrambler is reset if a nonzero input is applied to the port.

## Dependencies

To enable this port, set Initial states source to Dialog Parameter and select Reset on nonzero input via port.

## ISt - Initial states

scalar
Initial states of the descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of ISt must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1 .

## Dependencies

To enable this port, set Initial states source to Input port.

## Output

## Out1 - Output descrambled data

vector
Output descrambled data, returned as an $N_{\mathrm{S}}$-by-1 vector. $N_{\mathrm{S}}$ equals the number of samples in the input signal.

## Data Types: double

## Parameters

## Calculation base - Calculation base

4 (default) | nonnegative integer
Calculation base used in the descrambler for modulo operations, specified as a nonnegative integer.
The input and output of this block are integers from 0 to Calculation base - 1 .

## Scramble polynomial - Polynomial that defines connections in descrambler

'1 + $z^{\wedge-1 ~+~} z^{\wedge-2 ~+~} z^{\wedge-4 ' ~(d e f a u l t)|~ c h a r a c t e r ~ v e c t o r ~| i n t e g e r ~ v e c t o r \mid ~ b i n a r y ~ v e c t o r ~}$
Polynomial that defines the connections in the descrambler, specified as a character vector, integer vector, or binary vector. The Scramble polynomial parameter defines if each switch in the descrambler is on or off. Specify the polynomial as:

- A character vector, such as ' $1+z^{\wedge}-6+z^{\wedge}-8$ '. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0-6-8], listing the descrambler coefficients in order of descending powers of $z^{-1}$, where $p\left(z^{-1}\right)=1+p_{1} z^{-1}+p_{2} z^{-2}+\ldots$
- A binary vector, such as [ $\left.\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0\end{array}\right]$ ], listing the powers of $z$ that appear in the polynomial that has a coefficient of 1 . In this case, the order of the descramble polynomial is one less than the binary vector length.

polynomial:
$p\left(z^{-1}\right)=1+z^{-6}+z^{-8}$

## Initial states source - Set the source for descrambler initial states <br> Dialog Parameter (default)|Input port

- Dialog Parameter - Specify descrambler initial states by using the Initial states parameter.
- Input port - Specify descrambler initial states by using the ISt port.

## Initial states - Initial states of descrambler registers

[ $\left.0 \begin{array}{llll}0 & 1 & 2 & 3\end{array}\right]$ (default)| nonnegative integer vector
Initial states of descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of Initial states must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1 .

## Dependencies

This parameter is available when Initial states source is set to Dialog Parameter.

## Reset on nonzero input via port - Reset descrambler via input port

 off (default) | onSelect this parameter to reset the Descrambler block via input port Rst.

## Dependencies

This parameter is available when Initial states source is set to Dialog Parameter.

## Differential Decoder

Decode binary signal using differential coding

Decoder

## Library

Source Coding

## Description

The Differential Decoder block decodes the binary input signal. The output is the logical difference between the consecutive input element within a channel. More specifically, the block's input and output are related by

| $m\left(\mathrm{i}_{0}\right)$ | $=$ | $\mathrm{d}\left(\mathrm{i}_{0}\right)$ | XOR | Initial | condition |
| :--- | ---: | :--- | :---: | :---: | :---: |
| $\mathrm{m}\left(\mathrm{i}_{\mathrm{k}}\right)$ |  | $=$ | $\mathrm{d}\left(\mathrm{i}_{\mathrm{k}}\right)$ | parameter | value |
|  |  |  | XOR | $\mathrm{d}\left(\mathrm{i}_{\mathrm{k}-1}\right)$ |  |

where

- d is the differentially encoded input.
- $m$ is the output message.
- $\mathrm{i}_{\mathrm{k}}$ is the kth element.
- XOR is the logical exclusive-or operator.

This block accepts a scalar, column vector, or matrix input signal and treats columns as channels.

## Parameters

## Initial conditions

The logical exclusive-or of this value with the initial input value forms the initial output value.

## Description

The Differential Encoder block encodes the binary input signal within a channel. The output is the logical difference between the current input element and the previous output element. More specifically, the input and output are related by
$\mathrm{d}\left(\mathrm{i}_{0}\right)=\mathrm{m}\left(\mathrm{i}_{0}\right) \quad \mathrm{XOR}$ Initial condition parameter value
$\mathrm{d}\left(\mathrm{i}_{\mathrm{k}}\right) \quad=\quad \mathrm{d}\left(\mathrm{i}_{\mathrm{k}-1}\right) \quad \mathrm{XOR}\left(\mathrm{i}_{\mathrm{k}}\right)$
where

- $m$ is the input message.
- $d$ is the differentially encoded output.
- $i_{k}$ is the kth element.
- XOR is the logical exclusive-or operator.

This block accepts a scalar or column vector input signal and treats columns as channels.

## Parameters

## Initial conditions

The logical exclusive-or of this value with the initial input value forms the initial output value.

## Discrete-Time VCO

Implement voltage-controlled oscillator in discrete time

## Library

Components sublibrary of Synchronization

## Description

The Discrete-Time VCO (voltage-controlled oscillator) block generates a signal whose frequency shift from the Quiescent frequency parameter is proportional to the input signal. The input signal is interpreted as a voltage. If the input signal is $u(t)$, then the output signal is

$$
y(t)=A_{C} \cos \left(2 \pi f_{C} t+2 \pi k_{c} \int_{D}^{t} u(\tau) d \tau+\varphi\right)
$$

where $A_{\mathrm{c}}$ is the Output amplitude, $f_{\mathrm{c}}$ is the Quiescent frequency, $k_{\mathrm{c}}$ is the Input sensitivity, and $\varphi$ is the Initial phase

This block uses a discrete-time integrator to interpret the equation above.
This block accepts a scalar-valued input signal with a data type of single or double. The output signal inherits its data type from the input signal. The block supports double precision only for code generation.

## Parameters

## Output amplitude

The amplitude of the output.

## Quiescent frequency ( Hz )

The frequency of the oscillator output when the input signal is zero.

## Input sensitivity

This value scales the input voltage and, consequently, the shift from the Quiescent frequency value. The units of Input sensitivity are Hertz per volt.

## Initial phase (rad)

The initial phase of the oscillator in radians.

## Sample time

The calculation sample time.

## Extended Capabilities

## DPD

Digital predistorter
Library:
Communications Toolbox / RF Impairments Correction

## Description

Apply digital predistortion (DPD) to a complex baseband signal using a memory polynomial to compensate for nonlinearities in a power amplifier. For more information, see "Digital Predistortion" on page 5-197.

This icon shows the block with all ports enabled.

## Ports

## Input

## In - Input baseband signal

column vector
Input baseband signal, specified as a column vector. This port is unnamed until the Coefficient source parameter is set to Input port.
Data Types: double
Complex Number Support: Yes

## Coef - Memory-polynomial coefficients

matrix
Memory-polynomial coefficients, specified as a matrix. The number of rows in the matrix must equal the memory depth of the memory polynomial.

- If the Polynomial type parameter is set to Memory polynomial, the number of columns in the matrix is the degree of the memory polynomial.
- If Polynomial type is set to Cross-term memory polynomial, the number of columns in the matrix must equal $m(n-1)+1 . m$ is the memory depth of the polynomial, and $n$ is the degree of the memory polynomial.

## Example: complex([1 0 0 0 0; 00000 0; 000000$])$

## Dependencies

To enable this port, set the Coefficient source parameter to Input port.

Data Types: double
Complex Number Support: Yes

## Output

Out - Predistorted baseband signal
column vector
Predistorted baseband signal, returned as a column vector of the same length as the input signal.

## Parameters

## Polynomial type - Polynomial type

Memory polynomial (default)|Cross-term memory polynomial
Polynomial type used for predistortion, specified as one of these values:

- Memory polynomial - Computes predistortion coefficients by using a memory polynomial without cross terms
- Cross-term memory polynomial - Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see "Digital Predistortion" on page 5-197.

## Coefficient source - Source of memory-polynomial coefficients <br> Property (default)|Input port

Source of the memory polynomial coefficients, specified as one of these values:

- Property - Specify this value to use the Coefficients parameter to define the memorypolynomial coefficients
- Input port - Specify this value to use the Coef input port to define the memory-polynomial coefficients

## Coefficients - Memory-polynomial coefficients

```
complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0]) (default)|matrix
```

Memory-polynomial coefficients, specified as a matrix. The number of rows must equal the memory depth of the memory polynomial.

- If the Polynomial type is set to Memory polynomial, the number of columns is the degree of the memory polynomial.
- If the Polynomial type is set to Cross-term memory polynomial, the number of columns must equal $m(n-1)+1$. $m$ is the memory depth of the polynomial, and $n$ is the degree of the memory polynomial.

For more information, see "Digital Predistortion" on page 5-197.

## Dependencies

To enable this parameter, set Coefficient source to Property.

## Simulate using - Type of simulation to run

Code generation (default)|Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

## More About

## Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where $G$ is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} c_{m} \times u(n-m)+\sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{m j k} \times u(n-m) \times|u(n-j)|^{k} .
$$

The memory polynomial with cross terms has ( $M+M \times M \times(K-1)$ ) coefficients for $c_{m}$ and $a_{\text {mjk }}$.

- The memory polynomial without cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{m k} \times u(n-m) \times|u(n-m)|^{k} .
$$

The polynomial without cross terms has $M \times K$ coefficients for $a_{m k}$.

## Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n) / G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memorypolynomial coefficients:

- $\quad c_{m}$ and $a_{m j k}$ for a memory polynomial with cross terms
- $a_{m k}$ for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n) / G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see "Power Amplifier Characterization with DPD for Reduced Signal Distortion".

For background reference material, see the works listed in [1] and [2].

Complex Number Support: Yes

## Forgetting Factor - Forgetting factor

scalar in the range $(0,1]$
Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range ( 0 , 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

## Dependencies

To enable this port, set Algorithm to Recursive least squares and set Forgetting factor source to Input port.

Data Types: double

## Output

## Out - Memory-polynomial coefficients

matrix
Memory-polynomial coefficients, returned as a matrix. For more information, see "Digital Predistortion" on page 5-204.

## Parameters

## Desired amplitude gain (dB) - Desired amplitude gain

10 (default) | scalar
Desired amplitude gain in dB , specified as a scalar. This parameter value expresses the desired signal gain at the compensated amplifier output.

Tunable: Yes
Data Types: double

## Polynomial type - Polynomial type

Memory polynomial (default)|Cross-term memory polynomial
Polynomial type used for predistortion, specified as one of these values:

- Memory polynomial - Computes predistortion coefficients by using a memory polynomial without cross terms
- Cross-term memory polynomial - Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see "Digital Predistortion" on page 5-204.

## Degree - Memory-polynomial degree

5 (default) | positive integer
Memory-polynomial degree, specified as a positive integer.

## Data Types: double

## Memory depth - Memory-polynomial depth

3 (default) | positive integer
Memory-polynomial depth in samples, specified as a positive integer.

## Data Types: double

## Algorithm - Estimation algorithm

Least squares (default)|Recursive least squares
Adaptive algorithm used for equalization, specified as one of these values:

- Least squares - Estimate the memory-polynomial coefficients by using a least squares algorithm
- Recursive least squares - Estimate the memory-polynomial coefficients by using a recursive least squares algorithm

For algorithm reference material, see the works listed in [1] and [2].
Data Types: char | string
Forgetting factor source - Source of forgetting factor
Property (default)|Input port
Source of the forgetting factor, specified as one of these values:

- Property - Specify this value to use the Forgetting factor parameter to specify the forgetting factor.
- Input port - Specify this value to use the Forgetting Factor input port to specify the forgetting factor.

## Dependencies

To enable this parameter, set Algorithm to Recursive least squares.

## Data Types: double

## Forgetting factor - Forgetting factor

0.99 (default) | scalar in the range ( 0,1 ]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range ( 0 , 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

## Dependencies

To enable this parameter, set Algorithm to Recursive least squares and set Forgetting factor source to Property.
Data Types: double

## Initial coefficient estimate - Initial coefficient estimate <br> [] (default) | matrix

Initial coefficient estimate for the recursive least squares algorithm, specified as a matrix.

- If you specify this value as an empty matrix, the initial coefficient estimate for the recursive least squares algorithm is chosen automatically to correspond to a memory polynomial that is an identity function, so that the output is equal to input.
- If you specify this value as a nonempty matrix, the number of rows must be equal to the Memory depth parameter value.
- If the Polynomial type parameter is set to Memory polynomial, the number of columns is the degree of the memory polynomial.
- If the Polynomial type parameter is set to Cross-term memory polynomial, the number of columns must equal $m(n-1)+1 . m$ is the memory depth of the polynomial, and $n$ is the degree of the memory polynomial.

For more information, see "Digital Predistortion" on page 5-204.

## Dependencies

To enable this parameter, set Algorithm to Recursive least squares.
Data Types: double
Complex Number Support: Yes

## Simulate using - Type of simulation to run

Code generation (default) | Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where $G$ is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} c_{m} \times u(n-m)+\sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{m j k} \times u(n-m) \times|u(n-j)|^{k} .
$$

The memory polynomial with cross terms has ( $M+M \times M \times(K-1)$ ) coefficients for $c_{m}$ and $a_{\mathrm{mjk}}$.

- The memory polynomial without cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{m k} \times u(n-m) \times|u(n-m)|^{k} .
$$

The polynomial without cross terms has $M \times K$ coefficients for $a_{m k}$.

## Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n) / G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memorypolynomial coefficients:

- $\quad c_{m}$ and $a_{m j k}$ for a memory polynomial with cross terms
- $a_{m k}$ for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n) / G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see "Power Amplifier Characterization with DPD for Reduced Signal Distortion".

For background reference material, see the works listed in [1] and [2].

# DQPSK Demodulator Baseband 

Demodulate DQPSK-modulated data
WMW-
DQPSK

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The DQPSK Demodulator Baseband block demodulates a signal that was modulated using the differential quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

The input must be a discrete-time complex signal. The output depends on the phase difference between the current symbol and the previous symbol. The first integer (or binary pair, if you set the Output type parameter to Bit) at the block output is the initial condition of zero because there is no previous symbol.

This block accepts either a scalar or column vector input signal. For information about the data types each block port supports, see "Supported Data Types" on page 5-209.

## Outputs and Constellation Types

When you set Output type parameter to Integer, the block maps a phase difference of
to $m$, where $\theta$ represents the Phase rotation parameter and $m$ is $0,1,2$, or 3 .
When you set the Output type parameter to Bit, then the output contains pairs of binary values. The reference page for the DQPSK Modulator Baseband block shows which phase differences map to each binary pair, for the cases when the Constellation ordering parameter is either Binary or Gray.

## Dialog Box

## Output type

Determines whether the output consists of integers or pairs of bits.

## Constellation ordering

Determines how the block maps each integer to a pair of output bits.

## Phase rotation (rad)

This phase difference between the current and previous modulated symbols results in an output of zero.

## Output data type

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type single or double.

For integer outputs, this block can output the data types int8, uint8, int16, uint16, int32, uint32, single, and double. For bit outputs, output can be int8, uint8, int16, uint16, int32, uint32, boolean, single, or double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point |
| Output | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean when Output type isBit <br> - 8 -, 16 -, and 32 -bit signed integers <br> - 8 -, 16-, and 32 -bit unsigned integers |

## DQPSK Modulator Baseband

Modulate using differential quadrature phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The DQPSK Modulator Baseband block modulates using the differential quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

The input must be a discrete-time signal. For information about the data types each block port supports, see "Supported Data Types" on page 5-213.

## Integer-Valued Signals and Binary-Valued Signals

When you set the Input type parameter to Integer, the valid input values are $0,1,2$, and 3 . In this case, the block accepts a scalar or column vector input signal. If the first input is $m$, then the modulated symbol is
$\exp (\mathrm{j} \theta \quad+$
where $\theta$ represents the Phase rotation parameter. If a successive input is $m$, then the modulated symbol is the previous modulated symbol multiplied by $\exp (\mathrm{j} \theta+\mathrm{j} \pi \mathrm{m} / 2)$.

When you set the Input type parameter to Bit, the input contains pairs of binary values. In this case, the block accepts a column vector whose length is an even integer. The following figure shows the complex numbers by which the block multiples the previous symbol to compute the current symbol, depending on whether you set the Constellation ordering parameter to Binary or Gray. The following figure assumes that you set the Phase rotation parameter to $\frac{\Pi}{4}$; in other cases, the two schematics would be rotated accordingly.

The following figure shows the signal constellation for the DQPSK modulation method when you set the Phase rotation parameter to $\frac{\Pi}{4}$. The arrows indicate the four possible transitions from each symbol to the next symbol. The Binary and Gray options determine which transition is associated with each pair of input values.

More generally, if the Phase rotation parameter has the form $\frac{\Pi}{k}$ for some integer $k$, then the signal constellation has $2 k$ points.

## Dialog Box

## Input type

Indicates whether the input consists of integers or pairs of bits.

## Constellation ordering

Determines how the block maps each pair of input bits to a corresponding integer, using either a Binary or Gray mapping scheme.

## Phase rotation (rad)

The phase difference between the previous and current modulated symbols when the input is zero.

## Output Data type

The output data type can be either single or double. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean when Input type is Bit <br> - $8-, 16$-, and 32 -bit signed integers <br> - 8 -, 16 -, and 32 -bit unsigned integers |
| Output | - Double-precision floating point <br> - Single-precision floating point |

# DSB AM Demodulator Passband 

Demodulate DSB-AM-modulated data

```
NW%
    DSB AM
```

## Library

Analog Passband Modulation, in Modulation

## Description

The DSB AM Demodulator Passband block demodulates a signal that was modulated using doublesideband amplitude modulation. The block uses the envelope detection method. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

In the course of demodulating, this block uses a filter whose order, coefficients, passband ripple and stopband ripple are described by their respective lowpass filter parameters.

Typically, an appropriate Carrier frequency value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Input signal offset

The same as the Input signal offset parameter in the corresponding DSB AM Modulator Passband block.

## Carrier frequency (Hz)

The frequency of the carrier in the corresponding DSB AM Modulator Passband block.

## Initial phase (rad)

The initial phase of the carrier in radians.

## Lowpass filter design method

The method used to generate the filter. Available methods are Butterworth, Chebyshev type I, Chebyshev type II, and Elliptic.
Filter order
The order of the lowpass digital filter specified in the Lowpass filter design method field .

## Cutoff frequency (Hz)

The cutoff frequency of the lowpass digital filter specified in the Lowpass filter design method field in Hertz.

## Passband ripple (dB)

Applies to Chebyshev type I and Elliptic filters only. This is peak-to-peak ripple in the passband in dB.
Stopband ripple (dB)
Applies to Chebyshev type II and Elliptic filters only. This is the peak-to-peak ripple in the stopband in dB.

## Pair Block

DSB AM Modulator Passband
Introduced before R2006a

## DSB AM Modulator Passband

Modulate using double-sideband amplitude modulation

## Library

Analog Passband Modulation, in Modulation

## Description

The DSB AM Modulator Passband block modulates using double-sideband amplitude modulation. The output is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

If the input is $u(t)$ as a function of time $t$, then the output is

$$
(u(t)+k) \cos \left(2 \pi f_{c} t+\theta\right)
$$

where:

- $k$ is the Input signal offset parameter.
- $f_{\mathrm{c}}$ is the Carrier frequency parameter.
- $\theta$ is the Initial phase parameter.

It is common to set the value of $k$ to the maximum absolute value of the negative part of the input signal $u(t)$.

Typically, an appropriate Carrier frequency value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Input signal offset

The offset factor $k$. This value should be greater than or equal to the absolute value of the minimum of the input signal.

## Carrier frequency (Hz)

The frequency of the carrier.

## Initial phase (rad)

The initial phase of the carrier.

## Pair Block

DSB AM Demodulator Passband

# DVBS-APSK Demodulator Baseband 

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) demodulation
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / APM
Communications Toolbox / Modulation / Digital Baseband Modulation / Standard-Compliant

## Description

The DVBS-APSK Demodulator Baseband block demodulates the input signal using Digital Video Broadcasting ("DVB-S2/S2X/SH" on page 5-226) standard-specific amplitude phase shift keying (APSK) demodulation. For a description of DVB-compliant APSK demodulation, see "DVB Compliant APSK Hard Demodulation" on page 5-227 and "DVB Compliant APSK Soft Demodulation" on page 5227.

This icon shows the block with all ports enabled:

## Ports

Input
In - DVB-S2/S2X/SH standard-specific APSK modulated signal
scalar | vector | matrix
DVB-S2/S2X/SH standard-specific APSK modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the Var port is enabled.
Data Types: double | single
Complex Number Support: Yes

## Var - Noise variance

positive scalar | vector of positive values
Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "DVB Compliant APSK Soft Demodulation" on page 5-227 for demodulation decision type considerations.

## Dependencies

This parameter applies when Noise variance source is set to Input port.
Data Types: double | single

## Output

## Out - Demodulated signal

scalar | vector | matrix
Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the demodulated signal depend on the specified Output type and Decision type. This port is unnamed on the block.

| Output <br> type | Decision <br> type | Demodulated Signal <br> Description | Dimensions of Demodulated Signal |
| :--- | :--- | :--- | :--- |
| Integer | - | Demodulated integer values <br> in the range $[0,(M-1)]$ | The output signal has the same <br> dimensions as the input signal. |
| Bit | Hard <br> decision | Demodulated bits | The number of rows in the output signal is <br> $\log _{2}(M)$ times the number of rows in the <br> input signal. Each demodulated symbol is <br> mapped to a group of $\log _{2}(M)$ elements in <br> a column, where the first element <br> represents the MSB and the last element <br> represents the LSB. |
| Log- <br> likelihood <br> latio | Log-likelihood ratio value <br> for each bit | Approximat <br> e log- <br> likelihood <br> ratio | Approximate log-likelihood <br> ratio value for each bit |

Use Output data type to specify the output data type.

## Parameters

## DVB standard suffix - Standard suffix

S2 | S2X | SH
Standard suffix for DVB modulation variant, specified as $\mathrm{S} 2, \mathrm{~S} 2 \mathrm{X}$, or SH .

## Frame length - Frame length

Normal (default) | Short
Frame length, specified as Normal or Short.

## Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

## Modulation order - Modulation order

16 (default) | integer
Modulation order, specified as a power of two. The modulation order specifies the total number of points in the constellation of the input signal. The list of valid modulation orders varies depending on the setting for DVB standard suffix and Frame length.

| DVB standard suffix | Frame length | Modulation order Options |
| :--- | :--- | :--- |
| S2 | Normal or Short | 16 or 32 |

| DVB standard suffix | Frame length | Modulation order Options |
| :--- | :--- | :--- |
| S2X | Normal | $8,16,32,64$, or 256 |
|  | Short | 16 or 32 |
| SH | Not applicable | 16 |

## Code identifier - Code identifier

## 2/3 | character vector

Code identifier, specified as a character vector. The list of valid code identifier values varies depending on the setting for DVB standard suffix, Frame length, and Modulation order. This table lists the available options for Code identifier values.

| Modulation order | DVB standard suffix | Frame length | Code identifier Options |
| :---: | :---: | :---: | :---: |
| 8 | S2X | Normal | 100/180 or 104/180 |
| 16 | S2 or S2X | Normal | $\begin{aligned} & 2 / 3,3 / 4,4 / 5,5 / 6, \\ & 8 / 9, \text { or } 9 / 10 \end{aligned}$ |
|  |  | Short | $\begin{aligned} & 2 / 3,3 / 4,4 / 5,5 / 6, \text { or } \\ & 8 / 9 \end{aligned}$ |
| 16 | S2X | Normal | $\begin{aligned} & 26 / 45,3 / 5,28 / 45, \\ & 23 / 36,25 / 36,13 / 18, \\ & 140 / 180,154 / 180, \\ & 100 / 180,96 / 180, \\ & 90 / 180,18 / 30, \text { or } \\ & 20 / 30 \end{aligned}$ |
|  |  | Short | $\begin{aligned} & 7 / 15,8 / 16,26 / 45, \\ & 3 / 5, \text { or } 32 / 45 \end{aligned}$ |
| 32 | S2 or S2X | Normal | $\begin{aligned} & 3 / 4,4 / 5,5 / 6,8 / 9, \text { or } \\ & 9 / 10 \end{aligned}$ |
|  |  | Short | 3/4, 4/5, 5/6, or 8/9 |
| 32 | S2X | Normal | $\begin{aligned} & 128 / 180,132 / 180, \\ & 140 / 180, \text { or } 2 / 3 \end{aligned}$ |
|  |  | Short | $2 / 3$ or $32 / 45$ |
| 64 | S2X | Normal | $\begin{aligned} & 128 / 180,132 / 180, \\ & 7 / 9,4 / 5, \text { or } 5 / 6 \end{aligned}$ |
| 128 | S2X | Normal | 135/180 or 140/180 |
| 256 | S2X | Normal | $\begin{aligned} & 116 / 180,124 / 180, \\ & 128 / 180,20 / 30 \text {, or } \\ & 135 / 180 \end{aligned}$ |

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVBS2X standard [2].

## Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

## Constellation scaling - Constellation scaling

Outer radius as 1 (default)|Unit average power
Constellation scaling, specified as Outer radius as 1 or Unit average power.

## Dependencies

This input argument applies only when DVB standard suffix is set to S2 or S2X.

## Output type - Output type

Integer (default)|Bit
Output type, specified as Integer or Bit.
Data Types: char|string

## Decision type - Demodulation decision type

Hard decision (default)|Log-likelihood ratio|Approximate log-likelihood ratio
Demodulation decision type, specified as Hard decision, Log-likelihood ratio, or
Approximate log-likelihood ratio. See "DVB Compliant APSK Soft Demodulation" on page 5227 for algorithm selection considerations.

## Dependencies

This parameter applies when Output type is set to Bit.

## Noise variance source - Noise variance source

Property (default)|Input port
Noise variance source, specified as:

- Property - The noise variance is set using the Noise variance parameter.
- Input port - The noise variance is set using the Var input port.

## Noise variance - Noise variance

1 (default) | positive scalar | vector of positive values
Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "DVB Compliant APSK Soft Demodulation" on page 5-227 for demodulation decision type considerations.

## Dependencies

This parameter applies when Noise variance source is set to Property and Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.
Data Types: double

## Output data type - Output data type

double (default) | ...
Output data type, specified as one of the acceptable values from this table. Acceptable Output data type values depend on the Output type and Decision type parameter values.

| Output type | Decision type | Output data type Options |
| :--- | :--- | :--- |
| Integer | Not applicable | double, single, int8, uint8, int16, uint16, int32, or <br> uint32 |
| Bit | Hard decision | double, single, int8, uint8, int16, uint16, int32, <br> uint32, or logical |
|  | Log-likelihood <br> ratio or <br> Approximate <br> log-likelihood <br> ratio | The output signal is the same data type as the input signal. |

## Dependencies

This parameter applies only when Output type is set to Integer or when Output type is set to Bit and Decision type is set to Hard decision.

## Simulate using - Type of simulation to run

Interpreted execution (default) |Code generation
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

For information on execution speed, see "Tips" on page 5-228.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | no |

## More About

## DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see [1], [2], and [3], respectively.

## DVB Compliant APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [4].

## DVB Compliant APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

| Algorithm | Accuracy | Execution Speed |
| :--- | :--- | :--- |
| Exact LLR | more accurate | slower execution |
| Approximate LLR | less accurate | faster execution |

For further description of these algorithms, see "Exact LLR Algorithm" and "Approximate LLR Algorithm".

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or -Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## Tips

- For faster execution of the DVBS-APSK Demodulator Baseband block, set the Simulate using parameter to:
- Code generation when using hard decision demodulation.
- Interpreted execution when using soft decision demodulation.

## DVBS-APSK Modulator Baseband

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) modulation

Library: Communications Toolbox / Modulation / Digital Baseband Modulation / APM<br>Communications Toolbox / Modulation / Digital Baseband Modulation / Standard-Compliant

## Description

The DVBS-APSK Modulator Baseband block modulates the input signal using Digital Video Broadcasting ("DVB-S2/S2X/SH" on page 5-232) standard-specific amplitude phase shift keying (APSK) modulation.

## Ports

Input

## In - Input signal

scalar | vector | matrix
Input signal, specified as a scalar, vector, or matrix. The input signal must be binary values or integers in the range [ $0,(M-1)$ ], where $M$ is the Modulation order. This port is unnamed on the block.

Note To process the input signal as binary elements, set the Input type parameter value to Bit. For binary inputs, the number of rows must be an integer multiple of $\log _{2}(M)$. Groups of $\log _{2}(M)$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: single | double | int8 | int16| int32 |uint8|uint16|uint32 | Boolean

## Output

## Out - DVB-S2/S2X/SH standard-specific APSK modulated signal

scalar | vector | matrix
DVB-S2/S2X/SH standard-specific APSK modulated signal, returned as a complex scalar, vector, or matrix. The output signal dimensions depend on the specified Input type value. This port is unnamed on the block.

| Input type | Dimensions of Output Signal |
| :--- | :--- |
| Integer | The output signal has the same dimensions as the input signal. |
| Bit | The number of rows in the output signal equals the number of rows in the <br> input signal divided by $\log _{2}(M)$, where $M$ is the Modulation order. |

Use Output data type to specify the output data type.

## Parameters

DVB standard suffix - Standard suffix
S2 (default) | S2X | SH
Standard suffix for DVB modulation variant, specified as S2, S2X, or SH.

## Frame length - Frame length

Normal (default) | Short
Frame length, specified as Normal or Short.

## Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

## Modulation order - Modulation order

16 (default) | 8 | 32 | 64 | 256
Modulation order, $M$, specified as a power of two. The modulation order specifies the total number of points in the constellation of the output signal. The list of valid modulation orders varies depending on the values of DVB standard suffix and Frame length.

| DVB standard suffix | Frame length | Modulation order Options |
| :--- | :--- | :--- |
| S2 | Normal or Short | 16 or 32 |
| S2X | Normal | $8,16,32,64$, or 256 |
|  | Short | 16 or 32 |
| SH | Not applicable | 16 |

## Code identifier - Code identifier

## 2/3 | character vector

Code identifier, specified as a character vector. The list of valid code identifier values varies depending on the specified values of DVB standard suffix, Frame length, and Modulation order. This table lists the options for Code identifier values.

| Modulation order | DVB standard suffix | Frame length | Code identifier Options |
| :---: | :---: | :---: | :---: |
| 8 | S2X | Normal | 100/180 or 104/180 |
| 16 | S2 or S2X | Normal | $\begin{aligned} & 2 / 3,3 / 4,4 / 5,5 / 6, \\ & 8 / 9, \text { or } 9 / 10 \end{aligned}$ |
|  |  | Short | $\begin{aligned} & 2 / 3,3 / 4,4 / 5,5 / 6 \text {, or } \\ & 8 / 9 \end{aligned}$ |
| 16 | S2X | Normal | $\begin{aligned} & 26 / 45,3 / 5,28 / 45, \\ & 23 / 36,25 / 36,13 / 18, \\ & 140 / 180,154 / 180, \\ & 100 / 180,96 / 180, \\ & 90 / 180,18 / 30, \text { or } \\ & 20 / 30 \end{aligned}$ |

| Modulation order | DVB standard suffix | Frame length | Code identifier Options |
| :---: | :---: | :---: | :---: |
|  |  | Short | $\begin{aligned} & 7 / 15,8 / 16,26 / 45, \\ & 3 / 5, \text { or } 32 / 45 \end{aligned}$ |
| 32 | S2 or S2X | Normal | $\begin{aligned} & 3 / 4,4 / 5,5 / 6,8 / 9 \text {, or } \\ & 9 / 10 \end{aligned}$ |
|  |  | Short | 3/4, 4/5, 5/6, or 8/9 |
| 32 | S2X | Normal | $\begin{aligned} & 128 / 180,132 / 180, \\ & 140 / 180, \text { or } 2 / 3 \end{aligned}$ |
|  |  | Short | 2/3 or 32/45 |
| 64 | S2X | Normal | $\begin{aligned} & 128 / 180,132 / 180, \\ & 7 / 9,4 / 5, \text { or } 5 / 6 \end{aligned}$ |
| 128 | S2X | Normal | 135/180 or 140/180 |
| 256 | S2X | Normal | $\begin{aligned} & 116 / 180,124 / 180, \\ & 128 / 180,20 / 30 \text {, or } \\ & 135 / 180 \end{aligned}$ |

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVBS2X standard [2].

## Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

## Constellation scaling - Constellation scaling

Outer radius as 1 (default)|Unit average power
Constellation scaling, specified as Outer radius as 1 or Unit average power.

## Dependencies

This parameter applies only when DVB standard suffix is set to S2 or S2X.

## Input type - Input type

Integer (default)|Bit
Input type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range $[0,(M-1)]$. To use Bit, the input data must contain binary values, and the number of rows must be an integer multiple of $\log _{2}(M)$, where $M$ is the Modulation order.

## Output data type - Output data type

double (default) | single
Output data type, specified as double or single.

## View Constellation - Plot reference constellation

## button

To plot the reference constellation, click the View Constellation button.

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution

Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates $C$ code for the block. The $C$ code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | no |

## More About

## DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see [1], [2], and [3], respectively.

## Error Rate Calculation

Compute bit error rate or symbol error rate of input data

## Library

Comm Sinks

## Description

The Error Rate Calculation block compares input data from a transmitter with input data from a receiver. It calculates the error rate as a running statistic, by dividing the total number of unequal pairs of data elements by the total number of input data elements from one source.

Use this block to compute either symbol or bit error rate, because it does not consider the magnitude of the difference between input data elements. If the inputs are bits, then the block computes the bit error rate. If the inputs are symbols, then it computes the symbol error rate.

Note When you set the Output data parameter to Workspace, the block generates no code. Similarly, no data is saved to the workspace if the Simulation mode is set to Accelerator or Rapid Accelerator. If you need error rate information in these cases, set Output data to Port.

## Input Data

This block has between two and four input ports, depending on how you set the dialog parameters. The input ports marked Tx and Rx accept transmitted and received signals, respectively. The Tx and $R x$ signals must share the same sampling rate.

The Tx and $R x$ input ports accept scalar or column vector signals. For information about the data types each block port supports, see the "Supported Data Types" on page 5-238 table on this page.

If Tx is a scalar and $R x$ is a vector, or vice-versa, then the block compares the scalar with each element of the vector. In this case, the block behaves as if you had preprocessed the scalar signal by using the Repeat block with the Rate options parameter set to Enforce single rate.

If you select Reset port, then an additional input port appears, labeled Rst. The Rst input accepts only a scalar signal (of type double or boolean) and must have the same port sample time as the Tx and Rx ports. When the Rst input is nonzero, the block clears and then recomputes the error statistics.

If you set the Computation mode parameter to Select samples from port, then an additional input port appears, labeled Sel. The Sel input indicates which elements of a frame are relevant for the computation. The Sel input can be a column vector of type double.

The guidelines below indicate how you should configure the inputs and the dialog parameters depending on how you want this block to interpret your $T x$ and $R x$ data.

- If both data signals are scalar, then this block compares the Tx scalar signal with the Rx scalar signal. For this configuration, use the Computation mode parameter default value, Entire frame.
- If both data signals are vectors, then this block compares some or all of the Tx and Rx data:
- If you set the Computation mode parameter to Entire frame, then the block compares all of the Tx frame with all of the Rx frame.
- If you set the Computation mode parameter to Select samples from mask, then the Selected samples from frame field appears in the dialog. This parameter field accepts a vector that lists the indices of those elements of the Rx frame that you want the block to consider. For example, to consider only the first and last elements of a length-six receiver frame, set the Selected samples from frame parameter to [1 6]. If the Selected samples from frame vector includes zeros, then the block ignores them.
- If you set the Computation mode parameter to Select samples from port, then an additional input port, labeled Sel, appears on the block icon. The data at this input port must have the same format as that of the Selected samples from frame parameter described above.
- If one data signal is a scalar and the other is a vector, then the scalar is with each entry of the vector. In this case, if $R x$ is a scalar, then the phrase " $R x$ frame" above refers to the vector expansion of Rx.

Note This block does not support variable-size signals. If you choose the Select samples from port option and want the number of elements in the subframe to vary during the simulation, then you should pad the Sel signal with zeros. The Error Rate Calculation block ignores zeros in the Sel signal.

## Output Data

This block produces a vector of length three, whose entries correspond to:

- The error rate
- The total number of errors, that is, the number of instances that an Rx element does not match the corresponding Tx element
- The total number of comparisons that the block made

The block sends this output data to the base MATLAB workspace or to an output port, depending on how you set the Output data parameter:

- If you set the Output data parameter to Workspace and fill in the Variable name parameter, then that variable in the base MATLAB workspace contains the current value when the simulation ends. Pausing the simulation does not cause the block to write interim data to the variable.

If you plan to use this block along with the Simulink Coder software, then you should not use the Workspace option. Instead, use the Port option and connect the output port to a Simulink To Workspace block.

- If you set the Output data parameter to Port, then an output port appears. This output port contains the running error statistics.

## Delays

The Receive delay and Computation delay parameters implement two different types of delays for this block. One delay is useful if you want this block to compensate for the delay in the received signal. The other is useful if you want to ignore the initial transient behavior of both input signals.

- The Receive delay parameter represents the number of samples by which the received data lags behind the transmitted data. The transmit signal is implicitly delayed by that same amount before the block compares it to the received data. This value is helpful when you delay the transmit signal so that it aligns with the received signal. The receive delay persists throughout the simulation.
- The Computation delay parameter represents the number of samples the block ignores at the beginning of the comparison.

Use the Find Delay block to determine the delay, and then set the Receive delay to the delay reported by the Find Delay block.

If you use the Select samples from mask or Select samples from port option, then each delay parameter refers to the number of samples that the block receives, whether the block ultimately ignores some of them or not.

If using the Sel port to calculate errors on a delayed signal, the delay must be added to the Sel indices. For more information, see "Calculate Errors for Delayed Selected Samples".

## Stopping the Simulation Based on Error Statistics

You can configure this block so that its error statistics control the duration of simulation. This is useful for computing reliable steady-state error statistics without knowing in advance how long transient effects might last. To use this mode, check Stop simulation. The block attempts to run the simulation until it detects the number of errors the Target number of errors parameter specifies. However, the simulation stops before detecting enough errors if the time reaches the model's Stop time setting (in the Configuration Parameters dialog box), if the Error Rate Calculation block makes Maximum number of symbols comparisons, or if another block in the model directs the simulation to stop.

To ignore either of the two stopping criteria in this block, set the corresponding parameter (Target number of errors or Maximum number of symbols) to Inf. For example, to reach a target number of errors without stopping the simulation early, set Maximum number of symbols to Inf and set the model's Stop time to Inf.

## Tuning Parameters in an RSim Executable (Simulink Coder Software)

If you use the Simulink Coder rapid simulation (RSim) target to build an RSim executable, then you can tune the Target number of errors and Maximum number of symbols parameters without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

## Examples

## Full Frame Error Calculation

The figure below shows how the block compares pairs of elements and counts the number of error events. The $T x$ and $R x$ inputs are column vectors.

This example assumes that the sample time of each input signal is 1 second and that the block's parameters are as follows:

- Receive delay $=2$
- Computation delay $=0$
- Computation mode $=$ Entire frame

Both input signals are column vectors of length three. However, the schematic arranges each column vector horizontally and aligns pairs of vectors so as to reflect a receive delay of two samples. At each time step, the block compares elements of the Rx signal with those of the Tx signal that appear directly above them in the schematic. For instance, at time 1 , the block compares 2,4 , and 1 from the $R x$ signal with 2,3 , and 1 from the Tx signal.

The values of the first two elements of Rx appear as asterisks because they do not influence the output. Similarly, the 6 and 5 in the Tx signal do not influence the output up to time 3 , though they would influence the output at time 4 .

In the error rates on the right side of the figure, each numerator at time $t$ reflects the number of errors when considering the elements of Rx up through time $t$.

## Full Frame Error Calculation with Reset

If the block's Reset port box had been checked and a reset had occurred at time $=3$ seconds, then the last error rate would have been $2 / 3$ instead of $4 / 10$. This value $2 / 3$ would reflect the comparison of 3,2 , and 1 from the Rx signal with 7, 7, and 1 from the Tx signal. The figure below illustrates this scenario. The Tx and Rx inputs are column vectors.

## Error Calculation on Selected Samples in the Frame

If using the Sel port to calculate errors on a delayed signal, the delay must be added to the Sel indices. For more information, see "Calculate Errors for Delayed Selected Samples".

## Parameters

## Receive delay

Number of samples by which the received data lags behind the transmitted data. (If Tx or Rx is a vector, then each entry represents a sample.)

## Computation delay

Number of samples that the block should ignore at the beginning of the comparison.

## Computation mode

Either Entire frame, Select samples from mask, or Select samples from port, depending on whether the block should consider all or only part of the input frames.

## Selected samples from frame

A vector that lists the indices of the elements of the $R x$ frame vector that the block should consider when making comparisons. This field appears only if Computation mode is set to Select samples from mask.

## Output data

Either Workspace or Port, depending on where you want to send the output data.

## Variable name

Name of variable for the output data vector in the base MATLAB workspace. This field appears only if Output data is set to Workspace.

## Reset port

If you check this box, then an additional input port appears, labeled Rst.

## Stop simulation

If you check this box, then the simulation runs only until this block detects a specified number of errors or performs a specified number of comparisons, whichever comes first.

## Target number of errors

The simulation stops after detecting this number of errors. This field is active only if Stop simulation is checked.

## Maximum number of symbols

The simulation stops after making this number of comparisons. This field is active only if Stop simulation is checked.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Tx | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean <br> - 8 -, 16 -, and 32 -bit signed integers <br> - $8-, 16$-, and 32 -bit unsigned integers |

| Port | Supported Data Types |
| :---: | :---: |

## EVM Measurement

Measure error vector magnitude

## Library

Utility Blocks

## Description

The EVM Measurement block measures the error vector magnitude (EVM), which is an indication of modulator or demodulator performance.

The block has one or two input signals: a received signal and, optionally, a reference signal. You must select if the block uses a reference from an input port or from a reference constellation.

The block normalizes to the average reference signal power, average constellation power, or peak constellation power. For RMS EVM, maximum EVM, and $X$-percentile EVM, the output computations reflect the normalization method.

The default EVM output is the RMS EVM in percent, with an option of maximum EVM or $X$-percentile EVM values. The maximum EVM represents the worst-case EVM value per burst. For the $X$-percentile option, you can enable an output port that returns the number of symbols processed in the percentile computations.

The table shows the output type, the parameter that selects the output type, the computation units, and the corresponding measurement interval.

| Output | Activation Parameter | Units | Measurement Interval |
| :--- | :--- | :--- | :--- |
| RMS EVM | None (output by <br> default) | Percentage | Current length \| <br> Entire history <br> Custom \| Custom with <br> periodic reset |
| Maximum EVM | Output maximum <br> EVM | Percentage | Current length \| <br> Entire history <br> Custom \| Custom with <br> periodic reset |
| Percentile EVM | Output X-percentile <br> EVM | Percentage | Entire history |

| Output | Activation Parameter | Units | Measurement Interval |
| :--- | :--- | :--- | :--- |
| Number of symbols | Output X-percentile <br> EVM and Output the <br> number of symbols <br> processed | None | Entire history |

## Data Type

The block accepts double, single, and fixed-point data types. The output of the block is always double.

## Parameters

## Normalize RMS error vector by

Selects the method by which the block normalizes measurements:

- Average reference signal power
- Average constellation power
- Peak constellation power

The default is Average reference signal power.

## Average constellation power

Normalizes EVM measurement by the average constellation power. This parameter is available only when you set Normalize RMS error vector to Average constellation power.

## Peak constellation power

Normalizes EVM measurement by the peak constellation power. This parameter only is available if you set Normalize RMS error vector to Peak constellation power.

## Reference signal

Specifies the reference signal source as either Input port or Estimated from reference constellation.

## Reference constellation

Specifies the reference constellation points as a vector. This parameter is available only when Reference signal is Estimated from reference constellation. The default is constellation(comm. QPSKModulator).

## Measurement interval

Specify the measurement interval as: Input length, Entire history, Custom, or Custom with periodic reset. This parameter affects the RMS and maximum EVM outputs only.

- To calculate EVM using only the current samples, set this parameter to 'Input length'.
- To calculate EVM for all samples, set this parameter to 'Entire history'.
- To calculate EVM over an interval you specify and to use a sliding window, set this parameter to 'Custom'.
- To calculate EVM over an interval you specify and to reset the object each time the measurement interval is filled, set this parameter to 'Custom with periodic reset'.

## Custom measurement interval

Specify the custom measurement interval in samples as a real positive integer. This is the interval over which the EVM is calculated. This parameter is available when Measurement interval is Custom or Custom with periodic reset. The default is 100 .

## Averaging dimensions

Specify the dimensions over which to average the EVM measurements as a scalar or row vector whose elements are positive integers. For example, to average across the rows, set this parameter to 2 . The default is 1 .

This block supports var-size inputs of the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must be constant. For example, if the input size is [1000 3 2] and Averaging dimensions is [1 3], then the output size is [1 3 1]. The number of elements in the second dimension is fixed at 3.

## Output maximum EVM

Outputs the maximum EVM of an input vector or frame.

## Output X-percentile EVM

Enables an output $X$-percentile EVM measurement. When you select this option, specify $\mathbf{X}$ percentile value (\%).

## X -percentile value (\%)

This parameter is available only when you select Output X-percentile EVM. The Xth percentile is the EVM value below which X\% of all the computed EVM values lie. The parameter defaults to the 95th percentile. That is, $95 \%$ of all EVM values are below this value.

## Output the number of symbols processed

Outputs the number of symbols that the block uses to compute the $X$-percentile value. This parameter is available only when you select Output X-percentile EVM.

## Simulate using

Select the simulation mode.
Code generation
On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects corresponding to the blocks accept a maximum of nine inputs.
Interpreted execution
Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## Examples

## Measure RMS and 90th Percentile EVM

Measure the RMS and 90th percentile EVM for an 8-PSK signal in an AWGN channel.
Open the model by typing doc_evm_example on the command line.

Run the model. The Display block shows the number of symbols used to estimate the EVM. The Time Scope shows the RMS and 90th percentile EVM values.

Observe that $90 \%$ of the symbols had an EVM value of less than $28 \%$ and that the average EVM is approximately $17 \%$.

Experiment with the model by changing the signal-to-noise ratio in the AWGN Channel block. Examine its effect on the EVM values.

## Algorithms

Both the EVM block and the EVM object provide three normalization methods. You can normalize measurements according to the average power of the reference signal, average constellation power, or peak constellation power. Different industry standards follow one of these normalization methods.

The block or object calculates the RMS EVM value differently for each normalization method.

| EVM Normalization Method | Algorithm |
| :---: | :---: |
| Reference signal | $E V M_{R M S}=\sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{\frac{1}{N} \sum_{k=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}} * 100$ |
| Average power | $\operatorname{EVM}_{\mathrm{RMS}}(\%)=100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{P_{\mathrm{avg}}}}$ |
| Peak power | $\operatorname{EVM}_{\mathrm{RMS}}(\%)=100 \sqrt{\frac{\frac{1}{N} \sum_{k=1}^{N}\left(e_{k}\right)}{P_{\max }}}$ |

Where:

- $e_{k}=e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}$
- $I_{k}=$ In-phase measurement of the $k$ th symbol in the burst
- $Q_{k}=$ Quadrature phase measurement of the $k$ th symbol in the burst
- $N=$ Input vector length
- $P_{\text {avg }}=$ The value for Average constellation power
- $P_{\max }=$ The value for Peak constellation power
- $I_{k}$ and $Q_{k}$ represent ideal (reference) values. $\tilde{I}_{k}$ and $\widetilde{Q}_{k}$ represent measured (received) symbols.

The max EVM is the maximum EVM value in a frame or $E V M_{\max }=\max _{k \in[1, \ldots, N]}\left\{\mathrm{EVM}_{k}\right\}$, where $k$ is the $k$ th symbol in a burst of length $N$.

The definition for $\mathrm{EVM}_{\mathrm{k}}$ varies depending upon which normalization method you select for computing measurements. The block or object supports these algorithms.

| EVM Normalization | Algorithm |
| :---: | :---: |
| Reference signal | $E V M_{k}=\sqrt{\frac{e_{k}}{\frac{1}{N_{k}} \sum_{k=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}} * 100$ |
| Average power |  |
| Peak power | $\text { HTNANA } \sim \sqrt{\overbrace{K}}$ |

The block or object computes the $X$-percentile EVM by creating a histogram of all the incoming $E V M_{k}$ values. The output provides the EVM value below which X\% of the EVM values fall.

## Eye Diagram Scope

Display eye diagram of time-domain signal
Library: Communications Toolbox / Comm Sinks
Communications Toolbox HDL Support / Comm Sinks
Mixed-Signal Blockset / Utilities
SerDes Toolbox / Utilities

## Description

The Eye Diagram block displays multiple traces of a modulated signal to produce an eye diagram. You can use the block to reveal the modulation characteristics of the signal, such as the effects of pulse shaping or channel distortions. For more information, see "Eye Diagram Analysis".

The Eye Diagram block has one input port. This block accepts a column vector or scalar input signal. The block accepts a signal with the following data types: double, single, base integer, and fixed point. All data types are cast as double before the block displays results.

To modify the eye diagram display, select View > Configuration Properties or click the Configuration Properties button (§). Then select the Main, 2D color histogram, Axes, or Export tabs and modify the settings.

## Ports

Input
In - Input signal
scalar | column vector
Input signal, specified as a scalar or column vector.
Data Types: double

## Parameters

## Main Tab

Display mode - Display mode
Line plot (default)|2D color Histogram
Display mode of the eye diagram, specified as Line plot or 2D color histogram. Selecting 2D color histogram makes the histogram tab available.

Tunable: Yes
Enable measurements - Enable measurements
off (default) | on
Select this check box to enable eye measurements of the input signal.

## Show horizontal (jitter) histogram - Display jitter histogram off (default) |on

Select this radio button to display the jitter histogram. This can also be accessed by using the histogram button drop down on the toolbar.

## Dependencies

This parameter is available when Display mode is 2D color histogram and Enable measurements is selected.

Show vertical (noise) histogram - Display noise histogram off (default) | on

Select this radio button to display the noise histogram. This can also be accessed by using the histogram button drop down on the toolbar.

## Dependencies

This parameter is available when Display mode is 2D color histogram and Enable measurements is selected.

Do not show horizontal or vertical histogram - Do not show horizontal or vertical histogram
on (default) | off
Select this radio button to display neither the histogram noise nor the histogram jitter.

## Dependencies

This parameter is available when Display mode is 2D color histogram and Enable measurements is selected.

## Show horizontal bathtub curve - Show horizontal bathtub curve off (default) | on

Select this check box to display the horizontal bathtub curve. This can also be accessed by using the bathtub curve button on the toolbar.

## Dependencies

This parameter is available when Enable measurements is selected.

## Show vertical bathtub curve - Show vertical bathtub curve off (default) | on

Select this check box to display the vertical bathtub curve. This can also be accessed by using the bathtub curve button on the toolbar.

## Dependencies

This parameter is available when Enable measurements is selected.
Eye diagram to display - Eye diagram to display
Real only (default)|Real and imaginary
Select either Real only or Real and imaginary to display one or both eye diagrams. To make eye measurements, this parameter must be Real only.

Tunable: Yes

## Color fading - Color fading

off (default) | on
Select this check box to fade the points in the display as the interval of time after they are first plotted increases.

Tunable: Yes
Dependencies
This parameter is available only when the Display mode is Line plot.

## Samples per symbol - Samples per symbol

8 (default) | positive integer
Number of samples per symbol, specified as a positive integer. Use with Symbols per trace to determine the number of samples per trace.

Tunable: Yes

## Sample offset - Sample offset

0 (default) | nonnegative integer

Sample offset, specified as a nonnegative integer smaller than the product of Samples per symbol and Symbols per trace. The offset provides the number of samples to omit before plotting the first point.

Tunable: Yes
Symbols per trace - Symbols per trace
2 (default) | positive integer
Number of symbols plotted per trace, specified as a positive integer.
Tunable: Yes
Traces to display - Number of traces to display
40 (default) | positive integer
Number of traces plotted, specified as a positive integer.
Tunable: Yes

## Dependencies

This parameter is available only when the Display mode is Line plot

## Axes Tab

## Title - Title label

None (default)
Label that appears above the eye diagram plot.
Tunable: Yes
Show grid - Toggle scope grid
on (default) | off
Toggle this check box to turn the grid on and off.
Tunable: Yes
$Y$-limits (Minimum) - Lower limit of $\boldsymbol{y}$-axis
-1.1 (default) | scalar
Minimum value of the $y$-axis.
Tunable: Yes
Y-limits (Maximum) - Upper limit of $\boldsymbol{y}$-axis
1.1 (default) | scalar

Maximum value of the $y$-axis.
Tunable: Yes
Real axis label - Real axis label
Real Amplitude (default)

Text that the scope displays along the real axis.
Tunable: Yes

## Imaginary axis label - Imaginary axis label

Imaginary Amplitude (default)
Text that the scope displays along the imaginary axis.
Tunable: Yes

## 2D Histogram Tab

The 2D histogram tab is available when you click the histogram button or when the display mode is set to 2D color histogram.

## Oversampling method - Oversampling method

None (default)|Input interpolation|Histogram interpolation
Oversampling method, specified as None, Input interpolation, or Histogram interpolation.
To plot eye diagrams as quickly as possible, set the Oversampling method to None. The drawback to not oversampling is that the plots look pixelated when the number of samples per trace is small. To create smoother, less-pixelated plots using a small number of samples per trace, set the Oversampling method to Input interpolation or Histogram interpolation. Input interpolation is the faster of the two interpolation methods and produces good results when the signal-to-noise ratio (SNR) is high. With a lower SNR, this oversampling method is not recommended because it introduces a bias to the centers of the histogram ranges. Histogram interpolation is not as fast as the other techniques, but it provides good results even when the SNR is low.

Tunable: Yes

## Color scale - Color scale

Linear (default) | Logarithmic
Color scale of the histogram plot, specified as either Linear or Logarithmic. Set Color scale to Logarithmic if certain areas of the eye diagram include a disproportionate number of points.

Tunable: Yes

The toolbar contains a histogram reset button $\stackrel{C}{c}$, which resets the internal histogram buffers and clears the display. This button is not available when the display mode is set to Line plot.

## Export Tab

Export measurements, histograms and bathtub curves - Export measurements, histograms and bathtub curves
Off (default) |off
Select this check box export the eye diagram measurements to the MATLAB workspace.
Tunable: Yes
Variable name - Variable name
EyeData (default)

Specify the name of the variable to which the eye diagram measurements are saved. The data is saved as a structure having these fields:

- MeasurementSettings
- Measurements
- JitterHistogram
- NoiseHistogram
- HorizontalBathtub
- VerticalBathtub
- BlockName

Tunable: Yes

## Style Dialog Box

In the Style dialog box, you can customize the style of the active display. You can change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. To open this dialog box, select View > Style.

## Figure color - Figure color

 black (default)Specify the background color of the scope figure.

## Axes colors - Axes colors

black| gray (default)
Specify the fill and line colors for the axes.

## Line - Line style, thickness and color for line plots

continuous | 0.5 | yellow (default)
Specify the line style, line width, and line color for the displayed signal.

## Dependencies

This parameter is available only when the Display mode is Line plot.

## Marker - Data point marker

None (default) | ...
Data point marker for the selected signal, specified as one of the choices in this table data point markers. This parameter is similar to the Marker property for MATLABHandle Graphics ${ }^{\circledR}$ plot objects.

| Specifier | Marker Type |
| :--- | :--- |
| none | No marker (default) |
| $\bigcirc$ | Circle |
| $\square$ | Square |
| $\times$ | Cross |

| Specifier | Marker Type |
| :---: | :---: |
| - | Point |
| + | Plus sign |
| * | Asterisk |
| $\bigcirc$ | Diamond |
| $\nabla$ | Downward-pointing triangle |
| $\triangle$ | Upward-pointing triangle |
| $\checkmark$ | Left-pointing triangle |
| 1 | Right-pointing triangle |
| 盛 | Five-pointed star (pentagram) |
| \% | Six-pointed star (hexagram) |

## Dependencies

This parameter is available only when the Display mode is Line plot.

## Colormap - Colormap for histograms

Hot (default) | Parula | Jet | HSV | Cool | SpringSummer | Autumn | Winter | Gray | Bone | Copper | Pink | Lines | Custom

Specify the colormap of the histogram plots as one of these schemes: Parula, Jet, HSV, Hot, Cool, Spring, Summer, Autumn, Winter, Gray, Bone, Copper, Pink, Lines, or Custom. If you select Custom, a dialog box pops up from which you can enter code to specify your own colormap.

## Dependencies

This parameter is available only when the Display mode is 2D color histogram.

## Measurement Settings Pane

To change measurement settings, first select Enable measurements. Then, in the Eye Measurements pane, click the arrow next to Settings. You can control these measurement settings.

Eye level boundaries - Time range for calculating eye levels
[40 60] (default)|two-element vector
Time range for calculating eye levels, specified as a two-element vector. These values are expressed as a percentage of the symbol duration.

Tunable: Yes

## Decision boundary - Amplitude level threshold <br> 0 (default) | scalar

Amplitude level threshold in V, specified as a scalar. This parameter separates the different signaling regions for horizontal (jitter) histograms. This parameter is tunable, but the jitter histograms reset when the parameter changes.

For non-return-to-zero (NRZ) signals, set Decision boundary to 0. For return-to-zero (RZ) signals, set Decision boundary to half the maximum amplitude.

Tunable: Yes

## Rise/Fall thresholds - Amplitude levels of the rise and fall transitions

[10 90] (default)|two-element vector
Amplitude levels of the rise and fall transitions, specified as a two-element vector. These values are expressed as a percentage of the eye amplitude. This parameter is tunable, but the crossing histograms of the rise and fall thresholds reset when the parameter changes.

Tunable: Yes
Hysteresis - Amplitude tolerance of the horizontal crossings
0 (default) | scalar
Amplitude tolerance of the horizontal crossings in V, specified as a scalar. Increase hysteresis to provide more tolerance to spurious crossings due to noise. This parameter is tunable, but the jitter and the rise and fall histograms reset when the parameter changes.

Tunable: Yes
BER threshold - BER used for eye measurements
1e-12 (default) | nonnegative scalar from 0 to 0.5
BER used for eye measurements, specified as a nonnegative scalar from 0 to 0.5 . The value is used to make measurements of random jitter, total jitter, horizontal eye openings, and vertical eye openings.

Tunable: Yes
Bathtub BERs - BER values used to calculate openings of bathtub curves
[0.5 0. 10.010 .001 0.0001 1e-05 1e-06 1e-07 1e-08 1e-09 1e-10 1e-11 1e-12] (default) | vector

BER values used to calculate openings of bathtub curves, specified as a vector whose elements range from 0 to 0.5 . Horizontal and vertical eye openings are calculated for each of the values specified by this parameter.

Tunable: Yes

## Dependencies

To enable this parameter, select Show horizontal bathtub curve, Show vertical bathtub curve, or both.

Measurement delay - Duration of initial data discarded from measurements
0 (default) | nonnegative scalar
Duration of initial data discarded from measurements, in seconds, specified as a nonnegative scalar.

## Block Characteristics

| Data Types | Boolean \| double | enumerated \| fixed point \| integer | single |
| :--- | :--- |
| Direct Feedthrough | no |

| Multidimensional <br> Signals | no |
| :--- | :--- |
| Variable-Size Signals | no |
| Zero-Crossing <br> Detection | no |

## More About

## Using Eye Diagram in Conditionally Executed Subsystems

When an Eye Diagram block is placed in a conditionally executed subsystem, for example in a triggered or enabled subsystem:

- Input size must be an integer multiple of SamplesPerSymbol * SymbolsPerTrace
- Sample offset must be zero
- The rightmost part of the display is intentionally omitted. This figure compares typical eye diagram display when placed in a normal system versus one placed in a conditionally executed subsystem.

## Measurements

Measurements assume that the eye diagram object has valid data. A valid eye diagram has two distinct eye crossing points and two distinct eye levels.

To open the measurements pane, click on the Eye Measurements button or select Tools > Measurements > Eye Measurements from the toolbar menu.

## Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.
- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.
- When an eye crossing time measurement falls within the $[-0.5 / \mathrm{Fs}, 0$ ) seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by $2 \times T_{\mathrm{s}}$ seconds (where $T_{\mathrm{s}}$ is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid time-wrapping or a warning, add a half-symbol duration delay to the current value in the MeasurementDelay property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

Eye Levels - Amplitude level used to represent data bits
Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are -1 V and +1 V . The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries. For example, when the EyeLevelBoundaries property is set to [40 60], that is, $40 \%$ and $60 \%$ of the symbol duration, the eye levels are calculated by estimating the mean value of the vertical histogram in this window marked by the eye level boundaries.

Eye Amplitude - Distance between eye levels
Eye amplitude is the distance in V between the mean value of two eye levels.

Eye Height - Statistical minimum distance between eye levels
Eye height is the distance between $\mu-3 \sigma$ of the upper eye level and $\mu+3 \sigma$ of the lower eye level. $\mu$ is the mean of the eye level, and $\sigma$ is the standard deviation.

Vertical Opening - Distance between BER threshold points
The vertical opening is the distance between the two points that correspond to the BERThreshold property. For example, for a BER threshold of $10^{-12}$, these points correspond to the $7 \sigma$ distance from each eye level.

## Eye SNR - Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$
\mathrm{SNR}=\frac{L_{1}-L_{0}}{\sigma_{1}-\sigma_{0}}
$$

where $L_{1}$ and $L_{0}$ represent the means of the upper and lower eye levels and $\sigma_{1}$ and $\sigma_{0}$ represent their standard deviations.
Q Factor - Quality factor
The Q factor is the quality factor and is calculated using the same formula as the eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.
Crossing Levels - Amplitude levels for eye crossings
The crossing levels are the amplitude levels at which the eye crossings occur.
The level at which the input signal crosses the amplitude value is specified by the DecisionBoundary property.

Crossing Times - Times for which crossings occur
The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.

Eye Delay - Mean time between eye crossings
Eye delay is the midpoint between the two crossing times.

Eye Width - Statistical minimum time between eye crossings
Eye width is the horizontal distance between $\mu+3 \sigma$ of the left crossing time and $\mu-3 \sigma$ of the right crossing time. $\mu$ is the mean of the jitter histogram, and $\sigma$ is the standard deviation.

Horizontal Opening - Time between BER threshold points
The horizontal opening is the distance between the two points that correspond to the BERThreshold property. For example, for a $10^{-12} \mathrm{BER}$, these two points correspond to the $7 \sigma$ distance from each crossing time.

Rise Time - Time to transition from low to high
Rise time is the mean time between the low and high rise/fall thresholds defined in the eye diagram. The default thresholds are $10 \%$ and $90 \%$ of the eye amplitude.

Fall Time - Time to transition from high to low
Fall time is the mean time between the high and low rise/fall thresholds defined in the eye diagram. The default thresholds are $10 \%$ and $90 \%$ of the eye amplitude.

Deterministic Jitter - Deterministic deviation from ideal signal timing Jitter is the deviation of a signal's timing event from its intended (ideal) occurrence in time [2]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ).

DJ is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.

Random Jitter - Random deviation from ideal signal timing
RJ is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation of $\sigma$. The RJ is computed as:

$$
\mathrm{RJ}=\left(Q_{L}+Q_{R}\right) \sigma,
$$

where

$$
Q=\sqrt{2} \operatorname{erfc}^{-1}\left(2 \frac{B E R}{\rho}\right) .
$$

BER is the specified BER threshold. $\rho$ is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

Total Jitter - Deviation from ideal signal timing
Total jitter ( TJ ) is the sum of the deterministic and random jitter, such that $\mathrm{TJ}=\mathrm{DJ}+\mathrm{RJ}$.

The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.

RMS Jitter - Standard deviation of jitter
RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.

Peak-to-Peak Jitter - Distance between extreme data points of histogram
Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.

## View Eye Diagram

Display the eye diagram of a filtered QPSK signal using the Eye Diagram block.
Load the doc_eye_diagram_scope model from the MATLAB command prompt.
doc_eye_diagram_scope

Run the model and observe that two symbols are displayed.

Open the configuration parameters dialog box. Change the Symbols per trace parameter to 4. Run the simulation and observe that four symbols are displayed.

Try changing the Raised Cosine Transmit Filter parameters or changing additional Eye Diagram parameters to see their effects on the eye diagram.

## Histogram Plots

Display histogram plots of a noisy GMSK signal.
Load the doc_eye_diagram_gmsk model from the MATLAB command prompt.
doc_eye_diagram_gmsk

Run the model. The eye diagram is configured to show a histogram without interpolation.

The lack of interpolation results in a plot having piecewise-continuous behavior.
Open the 2D Histogram tab of the Configuration Properties dialog box. Set the Oversampling method to Input interpolation. Run the model.

The interpolation smooths the eye diagram.
On the AWGN Channel block, change SNR (dB) from 25 to 10. Run the model.

Observe that vertical striping is present in the eye diagram. This striping is the result of input interpolation, which has limited accuracy in low-SNR conditions.

Set the Oversampling method to Histogram interpolation. Run the model.

The eye diagram plot now renders accurately because the histogram interpolation method works for all SNR values. This method is not as fast as the other techniques and results in increased execution time.

## Programmatic Configuration

You can programmatically configure the scope properties with callbacks or within scripts by using a scope configuration object as describe in "Control Scope Blocks Programmatically" (Simulink).

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.
This block is excluded from the generated code when code generation is performed on a system containing this block.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\text {™ }}$.
This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

## Find Delay

Find delay between two signals
Library: Communications Toolbox / Utility Blocks

## Description

The Find Delay block finds the delay between a signal and a delayed, and possibly distorted, version of itself. This is useful when you want to compare a transmitted and received signal to find the bit error rate, but do not know the delay in the received signal. This block accepts a column vector or matrix input signal. For a matrix input, the block outputs a row vector, and finds the delay in each channel of the matrix independently. See "Delays" for more information about signal delays.

## Ports

## Input

## sRef - Reference signal

vector | matrix
Original reference signal, specified as a vector or matrix. Dimensions and sample times of sRef and sDel must match.
Data Types: double

## sDel - Delayed signal

vector | matrix
Delayed or distorted version of reference signal, specified as a vector or matrix. Dimensions and sample times of sRef and sDel must match.

## Data Types: double

## Output

delay - Delay output
scalar | vector
The output port labeled delay outputs the delay in units of samples.
For a matrix input, the output is a row vector, and finds the delay in each channel of the matrix independently

The delay output is a nonnegative integer less than the Correlation window length.
Data Types: double
chg - Delay flag
0 | 1

The chg output port outputs 1 when there is a change from the delay computed at the previous sample, and 0 when there is no change

## Dependencies

This output port becomes visible only when Include "change signal" output port is selected.
Data Types: Boolean

## Parameters

## Correlation window length (samples) - Number of samples <br> 200 (default) | positive integer

The number of samples the block uses to calculate the cross-correlations of the two signals.
As the Correlation window length is increased, the reliability of the computed delay also increases. However, the processing time to compute the delay increases as well.

## Include "change signal" output port - Enable chg port off (default) | on

If you select this option, then the block has an extra output port that emits a value of 1 when the current computed delay differs from the previous computed delay and emits a value of 0 when there is no delay.

## Disable recurring updates - Disable recurring updates

off (default) |on
Selecting this option causes the block to stop computing the delay after it computes the same delay value for a specified number of samples.

Number of constant delay outputs to disable updates - Number of constant delay outputs to disable updates
3 (default) | positive integer
A positive integer specifying how many times the block must compute the same delay before ceasing to update.

Dependencies
This field becomes visible only when Disable recurring updates is selected.

## Block Characteristics

| Data Types | double \| enumerated \| integer ${ }^{\text {a } \mid \text { single }}$ |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Finding the Delay Before Calculating an Error Rate

A typical use of this block is to determine the correct Receive delay parameter in the Error Rate Calculation block. This is illustrated in "Use the Find Delay Block". In that example, the modulation/ demodulation operation introduces a computational delay into the received signal and the Find Delay block determines that the delay is 6 samples. This value of 6 becomes a parameter in the Error Rate Calculation block, which computes the bit error rate of the system.

Another example of this usage is in "Delays".

## Finding the Delay to Help Align Words

Another typical use of this block is to determine how to align the boundaries of frames with the boundaries of codewords or other types of data blocks. "Delays" describes when such alignment is necessary and also illustrates, in the "Aligning Words of a Block Code" discussion, how to use the Find Delay block to solve the problem.

## Tips for Using the Block Effectively

- Set Correlation window length sufficiently large so that the computed delay eventually stabilizes at a constant value. When this occurs, the signal from the optional chg output port stabilizes at the constant value of zero. If the computed delay is not constant, you should increase Correlation window length. If the increased value of Correlation window length exceeds the duration of the simulation, then you should also increase the duration of the simulation accordingly. If you can roughly estimate the delay, then the Correlation window length will produce a stable delay estimate at four times that value.
- If the cross-correlation between the two signals is broad, then the Correlation window length value should be much larger than the expected delay, or else the algorithm might stabilize at an incorrect value. For example, a CPM signal has a broad autocorrelation, so it has a broad crosscorrelation with a delayed version of itself. In this case, the Correlation window length value should be much larger than the expected delay.
- If the block calculates a delay that is greater than 75 percent of the Correlation window length, the signal sRef is probably delayed relative to the signal sDel. In this case, you should switch the signal lines leading into the two input ports.
- You can make the Find Delay block stop updating the delay after it computes the same delay value for a specified number of samples. To do so, select Disable recurring updates, and enter a positive integer in the Number of constant delay outputs to disable updates field. For example, if you set Number of constant delay outputs to disable updates to 20, the block will stop recalculating and updating the delay after it calculates the same value 20 times in succession. Disabling recurring updates causes the simulation to run faster after the target number of constant delays occurs.

## Algorithms

The Find Delay block finds the delay by calculating the cross-correlations of the first signal with timeshifted versions of the second signal, and then finding the index at which the cross-correlation is maximized.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## FM Broadcast Demodulator Baseband

Demodulate using broadcast FM method

## Library

Modulation > Analog Baseband Modulation

## Description

The FM Broadcast Demodulator Baseband block demodulates a complex baseband FM signal by using the conjugate delay method, and filters the signal by using a de-emphasis filter. To demodulate stereo audio using 38 kHz , enable stereo demodulation. To demodulate RBDS signals from the 57 kHz band, enable RBDS demodulation.

## Parameters

## Sample rate (Hz)

Specify the input signal sample rate as a positive real scalar.

## Frequency deviation (Hz)

Specify the frequency deviation of the modulator in Hz as a positive real scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

## De-emphasis filter time constant (s)

Specify the de-emphasis lowpass filter time constant in seconds as a positive real scalar. FM broadcast standards specify a value of $75 \mu \mathrm{~s}$ in the United States and $50 \mu \mathrm{~s}$ in Europe.

## Output audio sample rate (Hz)

Specify the output audio sample rate as a positive real scalar.

## Play audio device

Select this check box to play sound from a default audio device.

## Buffer size (samples)

Specify the buffer size the block uses to communicate with an audio device as a positive integer scalar. This parameter is available only when the Play audio device check box is selected.

## Stereo audio

Select this check box to enable demodulation of a stereo audio signal. If not selected, the audio signal is assumed to be monophonic.

## RBDS demodulation

Select this check box to demodulate the RBDS signal from the input complex baseband FM signal. By default, this check box is not selected.

## Number of samples per RBDS symbol

Specify the number of samples of the RBDS output as a positive integer. The RBDS sample rate is given by Number of samples per RBDS symbol $\times 1187.5 \mathrm{~Hz}$. According to the RBDS standard, the sample rate of each bit is 1187.5 Hz .

This parameter appears when you select the RBDS demodulation check box.
The default is 10 .

## RBDS Costas loop

Specify whether a Costas loop is used to recover the phase of the RBDS signal. Select this check box for radio stations that do not lock the 57 kHz RBDS signal in phase with the third harmonic of the 19 kHz pilot tone.

This parameter appears when you select the RBDS demodulation check box.
By default, this check box is not selected.

## Simulate using

Select the type of simulation to run.

- Code generation. Simulate model using generate C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.
- Interpreted execution. Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Algorithms

The FM Broadcast demodulator includes the functionality of the baseband FM demodulator, deemphasis filtering, and the ability to receive stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in comm. FMDemodulator.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$
H_{p}(f)=1+j 2 \Pi f \tau_{s}
$$

where $\tau_{s}$ is the filter time constant. The time constant is $50 \mu \mathrm{~s}$ in Europe and $75 \mu \mathrm{~s}$ in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$
H_{d}(f)=\frac{1}{1+j 2 \Pi f \tau_{s}}
$$

For an audio sample rate of 44.1 kHz , the de-emphasis filter has the following response.

## Figure 1: Magnitude Response (dB) <br> Figure 2: Magnitude Response (dB) $\times$

## Stereo and RDS/RBDS FM - Multiplex Signal

The FM broadcast demodulator supports stereophonic and monophonic operations. To support stereo transmission, the left ( L ) and right ( R ) channel information ( $\mathrm{L}+\mathrm{R}$ ) is assigned to the mono portion of the spectrum ( 0 to 15 kHz ). The ( $\mathrm{L}-\mathrm{R}$ ) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals.

Here is the spectrum of the multiplex baseband signal, $m(t)$.

$m(t)$ is given by
$m(t)=C_{0}[L(t)+R(t)]+C_{1} \cos (2 \Pi \times 19 k H z \times t)+C_{0}[L(t)-R(t)] \cos (2 \Pi \times 38 k H z \times t)+C_{2} R B D S(t$ $) \cos (2 \Pi \times 57 \mathrm{kHz} \times t)$,
where $C_{0}, C_{1}$, and $C_{2}$ are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the $(L(t) \pm R(t)$ ) signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

The demodulator applies $m(t)$ to three bandpass filters with center frequencies at 19 , 38 , and 57 kHz , and to a lowpass filter with a $3-\mathrm{dB}$ cutoff frequency of 15 kHz . The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the ( $L-R$ ) and RDS/RBDS signals, respectively. To generate a scaled version of the left and right channels that produce the stereo sound, the $(L+R)$ and $(L-R)$ signals are added and subtracted. The RDS/RBDS signal is recovered by mixing with the 57 kHz signal.

Here is the block diagram of the FM broadcast demodulator.

## Examples

## Modulate and Demodulate an Audio Signal

Load an audio input file, modulate and demodulate using the FM broadcast blocks. Compare the input signal spectrum with the demodulated signal spectrum.

Open the doc_fmbroadcast model.

Run the model. The spectrum of the baseband FM signal is attenuated at the higher frequencies relative to the original waveform.

Experiment with the model by changing the Frequency deviation (Hz) and the Pre-emphasis filter time constant (s) parameters on the modulator and demodulator and observe the impact on the FM signal spectrum.

## Limitations

The input length must be an integer multiple of the audio decimation factor. If the RBDS demodulation check box is selected, the input length in addition must be an integer multiple of the RBDS decimation factor.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Signal Input | - Double-precision floating point <br> - Single-precision floating point |
| Signal Output | - Double-precision floating point <br> - Single-precision floating point |

# FM Broadcast Modulator Baseband 

Modulate using broadcast FM method

## Library

Modulation > Analog Baseband Modulation

## Description

The FM Broadcast Modulator Baseband block pre-emphasizes an audio signal and modulates it onto a baseband FM signal. If you select the Stereo audio check box, the block modulates the stereo audio $(L-R)$ at the 38 kHz band, in addition to the baseband $(L+R)$. If you select the RBDS modulation check box, the block also modulates a baseband RBDS signal at 57 kHz . For more details, see "Algorithms" on page 5-287.

## Parameters

## Sample rate (Hz)

Specify the output signal sample rate as a positive real scalar.

## Frequency deviation (Hz)

Specify the frequency deviation of the modulator in Hz as a positive real scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth. FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

## Pre-emphasis filter time constant (s)

Specify the pre-emphasis highpass filter time constant as a positive real scalar. FM broadcast standards specify a value of $75 \mu \mathrm{~s}$ in the United States and $50 \mu \mathrm{~s}$ in Europe.

## Sample rate of audio input signal (Hz)

Specify the input audio sample rate as a positive real scalar.

## Stereo audio

Select this check box if the input signal is a stereophonic audio signal.

## RBDS modulation

Select this check box to modulate a baseband RBDS signal at 57 kHz . By default, this check box is not selected.

## Oversampling factor of RBDS input

Specify the number of samples per RBDS symbol as a positive integer. The RBDS sample rate is given by Oversampling factor of RBDS input $\times 1187.5 \mathrm{~Hz}$. According to the RBDS standard, the sample rate of each bit is 1187.5 Hz .

This parameter appears when you select the RBDS modulation check box.
The default is 10 .

## Simulate using

Select the type of simulation to run.

- Code generation. Simulate model using generate C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.
- Interpreted execution. Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Algorithms

The FM Broadcast modulator includes the functionality of the baseband FM modulator, pre-emphasis filtering, and the ability to transmit stereophonic signals. The algorithms which govern basic FM modulation and demodulation are covered in comm. FMModulator.

## Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$
H_{p}(f)=1+j 2 \pi f \tau_{s},
$$

where $\tau_{s}$ is the filter time constant. The time constant is $50 \mu \mathrm{~s}$ in Europe and $75 \mu \mathrm{~s}$ in the United States. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$
H_{d}(f)=\frac{1}{1+j 2 \pi f \tau_{s}} .
$$

Irrespective of the audio sampling rate, the signal is converted to a 152 kHz output sampling rate. For an audio sample rate of 44.1 kHz , the pre-emphasis filter has the following response.

## Stereo and RDS/RBDS FM - Multiplex Signal

The FM broadcast modulator supports stereophonic and monophonic operations. To support stereo transmission, the left ( L ) and right ( R ) channel information ( $\mathrm{L}+\mathrm{R}$ ) is assigned to the mono portion of the spectrum ( 0 to 15 kHz ). The ( $\mathrm{L}-\mathrm{R}$ ) information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal. A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS/RBDS signals. Here is the spectrum of the multiplex baseband signal.

Here is the block diagram of the FM broadcast modulator, which is used to generate the multiplex baseband signal. $L(t)$ and $R(t)$ denote the time-domain waveforms from the left and right channels. RBDS $(t)$ denotes the time-domain waveform of the RDS/RBDS signal.

## MPX Encoder

The multiplex message signal, $m(t)$ is given by

$$
\begin{aligned}
& m(t)=C_{0}[L(t)+R(t)]+C_{1} \cos (2 \Pi \times 19 k H z \times t)+C_{0}[L(t)-R(t)] \cos (2 \Pi \times 38 k H z \times t)+C_{2} R B D S(t \\
& ) \cos (2 \Pi \times 57 k H z \times t)
\end{aligned}
$$

where $C_{0}, C_{1}$, and $C_{2}$ are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the $(L(t) \pm R(t)$ ) signals, the 19 kHz pilot tone, and the RDS/RBDS subcarrier, respectively.

## Limitations

- If you select the RBDS modulation check box, both the audio and RBDS inputs must satisfy the following equation:

$$
\frac{\text { audioLength }}{\text { audioSampleRate }}=\frac{\text { RBDSLength }}{\text { RBDSSampleRate }}
$$

- The input length of the audio signal must be an integer multiple of the audio decimation factor. The input length of the RBDS signal must be an integer multiple of the RBDS decimation factor.

## Examples

## Modulate and Demodulate an Audio Signal

Load an audio input file, modulate and demodulate using the FM broadcast blocks. Compare the input signal spectrum with the demodulated signal spectrum.

Open the doc_fmbroadcast model.

Run the model. The spectrum of the baseband FM signal is attenuated at the higher frequencies relative to the original waveform.

Experiment with the model by changing the Frequency deviation (Hz) and the Pre-emphasis filter time constant (s) parameters on the modulator and demodulator and observe the impact on the FM signal spectrum.

Demodulate using FM method
Library: $\begin{array}{ll}\text { Communications Toolbox / Modulation / Analog Baseband } \\ & \text { Modulation }\end{array}$

## Description

The FM Demodulator Baseband block demodulates a complex input signal and returns a real output signal.

## Ports

Input
In - Input data signal
scalar|vector|matrix
Input signal, specified as a real scalar, vector, or matrix.
Data Types: double | single
Output
Out - Output data signal
scalar|vector | matrix
Output signal, returned as a real scalar, vector, or matrix. The data at this port has the same data type and size as the input signal.
Data Types: double | single

## Parameters

Frequency deviation ( Hz ) - Frequency deviation of demodulator
75e3 (default)| positive scalar
Frequency deviation of the demodulator, in Hz , specified as a positive scalar. The system bandwidth is equal to twice the sum of the frequency deviation and the message bandwidth.

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent
simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## Algorithms

Represent a frequency modulated passband signal, $Y(t)$, as

$$
Y(t)=A \cos \left(2 \pi f_{C} t+2 \pi f_{\Delta} \int_{d}^{t} x(\tau) d \tau\right),
$$

where $A$ is the carrier amplitude, $f_{c}$ is the carrier frequency, $x(\tau)$ is the baseband input signal, and $f_{\Delta}$ is the frequency deviation in Hz . The frequency deviation is the maximum shift from $f_{c}$ in one direction, assuming $|x(t)| \leq 1$.

A baseband FM signal can be derived from the passband representation by downconverting it by $f_{c}$ such that

$$
\left.\begin{array}{c}
y_{S}(t)=Y(t) e^{-j 2 \pi f_{C} t}
\end{array}=\frac{A}{2}\left[e^{j\left(2 \pi f_{C} t+2 \pi f_{\Delta}\right.} \int_{b}^{t} x(\tau) d \tau\right)+e^{-j\left(2 \pi f_{C} t+2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau\right)}\right] e^{-j 2 \pi f_{C} t} .
$$

Removing the component at $-2 f_{c}$ from $y_{s}(t)$ leaves the baseband signal representation, $y(t)$, which is expressed as

$$
y(t)=\frac{A}{2} e^{j 2 \pi f} \Delta \int_{0}^{t} x(\tau) d \tau .
$$

The expression for $y(t)$ is rewritten as

$$
y(t)=\frac{A}{2} e^{j \phi(t)},
$$

where $\phi(t)=2 \pi f_{\Delta} \int_{0}^{t} x(\tau) d \tau$, which implies that the input signal is a scaled version of the derivative of the phase, $\phi(t)$.

A baseband delay demodulator is used to recover the input signal from $y(t)$.

A delayed and conjugated copy of the received signal is subtracted from the signal itself,

$$
w(t)=\frac{A^{2}}{4} e^{j \phi(t)} e^{-j \phi(t-T)}=\frac{A^{2}}{4} e^{j[\phi(t)-\phi(t-T)]},
$$

where $T$ is the sample period. In discrete terms, $w_{n}=w(n T)$, and

$$
\begin{aligned}
& w_{n}=\frac{A^{2}}{4} e^{j\left[\phi_{n}-\phi_{n}-1\right]}, \\
& v_{n}=\phi_{n}-\phi_{n-1} .
\end{aligned}
$$

The signal $v_{n}$ is the approximate derivative of $\phi_{n}$, such that $v_{n} \approx x_{n}$.

## FM Demodulator Passband

Demodulate FM-modulated data

## Library

Analog Passband Modulation, in Modulation

## Description

The FM Demodulator Passband block demodulates a signal that was modulated using frequency modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

For best results, use a carrier frequency which is estimated to be larger than $10 \%$ of the reciprocal of your input signal's sample rate. This is due to the implementation of the Hilbert transform by means of a filter.

In the following example, we sample a 10 Hz input signal at 8000 samples per second. We then designate a Hilbert Transform filter of order 100. Below is the response of the Hilbert Transform filter as returned by fvtool.

Note the bandwidth of the filter's magnitude response. By choosing a carrier frequency larger than $10 \%$ (but less than $90 \%$ ) of the reciprocal of your input signal's sample time ( 8000 samples per second, in this example) or equivalently, a carrier frequency larger than 400 Hz , we ensure that the Hilbert Transform Filter will be operating in the flat section of the filter's magnitude response (shown in blue), and that our modulated signal will have the desired magnitude and form.

Typically, an appropriate Carrier frequency value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Carrier frequency (Hz)

The frequency of the carrier.

## Initial phase (rad)

The initial phase of the carrier in radians.

## Frequency deviation (Hz)

The frequency deviation of the carrier frequency in Hertz. Sometimes it is referred to as the "variation" in the frequency.

## Hilbert transform filter order

The length of the FIR filter used to compute the Hilbert transform.

## FM Modulator Passband

Modulate using frequency modulation
$=\sim \mathrm{Fm}$

## Library

Analog Passband Modulation, in Modulation

## Description

The FM Modulator Passband block modulates using frequency modulation. The output is a passband representation of the modulated signal. The output signal's frequency varies with the input signal's amplitude. Both the input and output signals are real scalar signals.

If the input is $u(t)$ as a function of time $t$, then the output is

$$
\cos \left(2 \pi f_{c} t+2 \pi K_{c} \int_{b}^{t} u(\tau) d \tau+\theta\right)
$$

where:

- $f_{\mathrm{c}}$ represents the Carrier frequency parameter.
- $\theta$ represents the Initial phase parameter.
- $K_{\mathrm{c}}$ represents the Frequency deviation parameter.

Typically, an appropriate Carrier frequency value is much higher than the highest frequency of the input signal.

By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Carrier frequency (Hz)

The frequency of the carrier.

## Free Space Path Loss

Reduce amplitude of input signal by amount specified

$\sqrt{$|  Free Space  |
| :---: |
|  Path Loss  |
| 10 dB |$}$

## Library

RF Impairments

## Description

The Free Space Path Loss block simulates the loss of signal power due to the distance between transmitter and receiver. The block reduces the amplitude of the input signal by an amount that is determined in either of two ways:

- By the Distance (km) and Carrier frequency (MHz) parameters, if you specify Distance and Frequency in the Mode field
- By the Loss (dB) parameter, if you specify Decibels in the Mode field

This block accepts a column vector input signal. The input signal to this block must be a complex signal.

## Parameters

## Mode

Method of specifying the amount by which the signal power is reduced. The choices are Decibels and Distance and Frequency.

## Loss

The signal loss in decibels. This parameter appears when you set Mode to Decibels. The decibel amount shown on the mask is rounded for display purposes only.

## Distance

Distance between transmitter and receiver in kilometers. This parameter appears when you set Mode to Distance and Frequency.

## Carrier frequency (MHz)

The carrier frequency in megahertz. This parameter appears when you set Mode to Distance and Frequency.

## Examples

The model below illustrates the effect of the Free Space Path Loss block with the following parameter settings:

- Mode is set to Distance and Frequency.
- Distance (km) is set to 0.5
- Carrier frequency (MHz) is set to 180

## Gaussian Filter

(Removed) Filter input signal using Gaussian FIR filter

Note The Gaussian Filter block has been removed. Use the gaussdesign function and the Discrete FIR Filter block instead. For more information, see "Compatibility Considerations".

## Library

Comm Filters

## Description

The Gaussian Filter block filters the input signal using a Gaussian FIR filter. The block expects the input signal to be upsampled as its input, so that the Input samples per symbol parameter, N , is at least 2. The block's icon shows the filter's impulse response."

## Characteristics of the Filter

The impulse response of the Gaussian filter is

$$
h(t)=\frac{\exp \left(\frac{-t^{2}}{2 \delta^{2}}\right)}{\sqrt{2 \Pi} \cdot \delta}
$$

where

$$
\delta=\frac{\sqrt{\ln (2)}}{2 \pi B T}
$$

and B is the filter's $3-\mathrm{dB}$ bandwidth. The BT product parameter is B times the input signal's symbol period. For a given BT product, the Signal Processing Toolbox gaussfir function generates a filter that is half the bandwidth of the filter generated by the Communications Toolbox Gaussian Filter block.

The Group delay parameter is the number of symbol periods between the start of the filter's response and the peak of the filter's response. The group delay and N determine the length of the filter's impulse response, which is $2 * \mathrm{~N}^{*}$ Group delay +1 .

The Filter coefficient normalization parameter indicates how the block scales the set of filter coefficients:

- Sum of coefficients means that the sum of the coefficients equals 1 .
- Filter energy means that the sum of the squares of the coefficients equals 1.
- Peak amplitude means that the maximum coefficient equals 1.

After the block normalizes the set of filter coefficients as above, it multiplies all coefficients by the
Linear amplitude filter gain parameter. As a result, the output is scaled by $\sqrt{N}$. If the output of this block feeds the input to the AWGN Channel block, specify the AWGN signal power parameter to be 1/N.

## Input and Output Signals

This block accepts scalar, column vector, and $M$-by- $N$ matrix input signals. The block filters an $M$-by- $N$ input matrix as follows:

- When you set the Input processing parameter to Columns as channels (frame based), the block treats each column as a separate channel. In this mode, the block creates $N$ instances of the same filter, each with its own independent state buffer. Each of the $N$ filters process $M$ input samples at every Simulink time step.
- When you set the Input processing parameter to Elements as channels (sample based), the block treats each element as a separate channel. In this mode, the block creates $M^{*} N$ instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

The output dimensions always equal those of the input signal. For information about the data types each block port supports, see the table on this page.

## Exporting Filter Coefficients to the MATLAB Workspace

To examine or manipulate the coefficients of the filter that this block designs, select Export filter coefficients to workspace. Then set the Coefficient variable name parameter to the name of a variable that you want the block to create in the MATLAB workspace. Running the simulation causes the block to create the variable, overwriting any previous contents in case the variable already exists.

## Parameters

## Input samples per symbol

A positive integer representing the number of samples per symbol in the input signal.
BT product
The product of the filter's 3-dB bandwidth and the input signal's symbol period

## Group delay

A positive integer that represents the number of symbol periods between the start of the filter response and its peak.

## Filter coefficient normalization

The block scales the set of filter coefficients so that this quantity equals 1 . Choices are Sum of coefficients, Filter energy, and Peak amplitude.

## Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- Columns as channels (frame based) - When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) - When you select this option, the block treats each element of the input as a separate channel.

## Linear amplitude filter gain

A positive scalar used to scale the filter coefficients after the block uses the normalization specified in the Filter coefficient normalization parameter.

## Export filter coefficients to workspace

If you check this box, then the block creates a variable in the MATLAB workspace that contains the filter coefficients.

## Coefficient variable name

The name of the variable to create in the MATLAB workspace. This field appears only if Export filter coefficients to workspace is selected.

## Visualize filter with FVTool

If you click this button, then MATLAB launches the Filter Visualization Tool, fvtool, to analyze the Gaussian filter whenever you apply any changes to the block's parameters. If you launch fvtool for the filter, and subsequently change parameters in the mask, fvtool will not update. You will need to launch a new fvtool in order to see the new filter characteristics. Also note that if you have launched fvtool, then it will remain open even after the model is closed.

## Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to Nearest. The block uses the Rounding selection if a number cannot be represented exactly by the specified data type and scaling, it is rounded to a
representable number. For more information, see Rounding Modes (DSP System Toolbox) or "Rounding Mode: Simplest" (Fixed-Point Designer).

## Overflow mode

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

## Coefficients

The block implementation uses a Direct-Form FIR filter. The Coefficients parameter controls which data type represents the coefficients when the input data is a fixed-point signal.

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See "Filter Structure Diagrams" (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

- When you select Same word length as input, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Specify word length, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the Rounding mode and the Overflow mode parameters; they are always saturated and rounded to Nearest.

## Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Multiplication Data Types" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

## Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as product output, these characteristics match those of the product output.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

## Output

Choose how you specify the output word length and fraction length:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as accumulator, these characteristics match those of the accumulator.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

## Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Supported Data Type

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed-point |
| Out | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed-point |

## Compatibility Considerations

## Gaussian Filter has been removed

Errors starting in R2020a
Gaussian Filter has been removed. Use Discrete FIR Filter instead.

- To model a Gaussian filter use a Discrete FIR Filter block. Use gaussdesign to generate filter coefficients for the Discrete FIR Filter block.
- "Model Gaussian Filter in Simulink" demonstrates using the gaussdesign function along with the Discrete FIR Filter block to model a Gaussian filter. You can specify coefficients for Gaussian filter designs that apply various normalization methods, that you assign in a Discrete FIR Filter block. Call gaussdesign directly in the Discrete FIR Filter block mask to assign the coefficients or use the PreLoadFcn callback to specify the filter coefficients as workspace variables.

## Gaussian Noise Generator

(To be removed) Generate Gaussian distributed noise with given mean and variance values

Note Gaussian Noise Generator will be removed in a future release. Use the MATLAB Function block and randn function instead.

## Library

Noise Generators sublibrary of Comm Sources

## Description

The Gaussian Noise Generator block generates discrete-time white Gaussian noise. You must specify the Initial seed vector in the simulation.

The Mean Value and the Variance can be either scalars or vectors. If either of these is a scalar, then the block applies the same value to each element of a sample-based output or each column of a frame-based output. Individual elements or columns, respectively, are uncorrelated with each other.

When the Variance is a vector, its length must be the same as that of the Initial seed vector. In this case, the covariance matrix is a diagonal matrix whose diagonal elements come from the Variance vector. Since the off-diagonal elements are zero, the output Gaussian random variables are uncorrelated.

When the Variance is a square matrix, it represents the covariance matrix. Its off-diagonal elements are the correlations between pairs of output Gaussian random variables. In this case, the Variance matrix must be positive definite, and it must be N -by- N , where N is the length of the Initial seed.

The probability density function of $n$-dimensional Gaussian noise is

$$
f(x)=\left((2 \pi)^{n} \operatorname{det} K\right)^{-1 / 2} \exp \left(-(x-\mu)^{T} K^{-1}(x-\mu) / 2\right)
$$

where $x$ is a length- $n$ vector, $K$ is the $n$-by- $n$ covariance matrix, $\mu$ is the mean value vector, and the superscript $T$ indicates matrix transpose.

## Initial Seed

The Initial seed parameter initializes the random number generator that the Gaussian Noise Generator block uses to add noise to the input signal. When multiple blocks in a model have the Initial seed parameter, you can choose different initial seeds for each block to ensure different random streams are used in each block. Set Initial seed to an integer value for repeatable results or use the randi function to randomize your results.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a samplebased one-dimensional array. These attributes are controlled by the Frame-based outputs, Samples per frame, and Interpret vector parameters as 1-D parameters. For additional information, see "Sources and Sinks".

If the Initial seed parameter is a vector, then its length becomes the number of columns in a framebased output or the number of elements in a sample-based vector output. In this case, the shape (row or column) of the Initial seed parameter becomes the shape of a sample-based two-dimensional output signal. If the Initial seed parameter is a scalar but either the Mean value or Variance parameter is a vector, then the vector length determines the output attributes mentioned above.

## Parameters

## Mean value

The mean value of the random variable output.

## Variance

The covariance among the output random variables.

## Initial seed

The initial seed value for the random number generator.

## Sample time

The period of each sample-based vector or each row of a frame-based matrix.

## Frame-based outputs

Determines whether the output is frame-based or sample-based. This box is active only if Interpret vector parameters as 1-D is unchecked.

## Samples per frame

The number of samples in each column of a frame-based output signal. This field is active only if Frame-based outputs is checked.

## Interpret vector parameters as 1-D

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a twodimensional signal. This box is active only if Frame-based outputs is unchecked.

## Output data type

The output can be set to double or single data types.

## General Block Deinterleaver

Restore ordering of symbols in input vector

```
General
    Block
Deinterleaver
```

## Library

Block sublibrary of Interleaving

## Description

The General Block Deinterleaver block rearranges the elements of its input vector without repeating or omitting any elements. If the input contains $N$ elements, then the Permutation vector parameter is a column vector of length $N$. The column vector indicates the indices, in order, of the output elements that came from the input vector. That is, for each integer $k$ between 1 and $N$,

Output(Permutation $\quad$ vector $(k)) \quad=\quad \operatorname{Input}(k)$
The Permutation vector parameter must contain unique integers between 1 and $N$.
Both the input and the Permutation vector parameter must be column vector signals.
This block can output sequences that vary in length during simulation. For more information about sequences that vary in length, or variable-size signals, see "Variable-Size Signal Basics" (Simulink).

This block accept the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

To use this block as an inverse of the General Block Interleaver block, use the same Permutation vector parameter in both blocks. In that case, the two blocks are inverses in the sense that applying the General Block Interleaver block followed by the General Block Deinterleaver block leaves data unchanged.

## Parameters

## Permutation vector source

A selection that specifies the source of the permutation vector. The source can be either Dialog or Input port. The default value is Dialog.

## Permutation vector

A vector of length N that lists the indices of the output elements that came from the input vector. This parameter is available only when Permutation vector source is set to Dialog.

## Examples

This example reverses the operation in the example on the General Block Interleaver block reference page. If you set Permutation vector to $[4,1,3,2]$ ' and you set the General Block Deinterleaver
block input to $[1 ; 40 ; 59 ; 32$ ], then the output of the General Block Deinterleaver block is [40;32;59;1].

## General CRC Generator

Generate CRC code bits according to generator polynomial and append to input data frames
Library: Communications Toolbox / Error Detection and Correction / CRC

## Description

The General CRC Generator block generates cyclic redundancy check (CRC) code bits for each input data frame and appends them to the frame. For more information, see "CRC Generator Operation" on page 5-318.

## Ports

## Input

## In - Input signal

binary column vector
Input signal, specified as a binary column vector. The length of the input frame must be a multiple of the value of the Checksums per frame parameter.

Data Types: double | Boolean

## Output

## Out - Output codeword frame

binary column vector
Output codeword frame, returned as a binary column vector that inherits the data type of the input signal. The output contains the input data frames with the CRC bit sequences appended to them.

The length of the output frame is $m+k^{*} r$, where $m$ is the size of the input frame, $k$ is the number of checksums per frame, and $r$ is the degree of the generator polynomial.

## Parameters

Generator polynomial - Generator polynomial
${ }^{\prime} z^{\wedge} 16+z^{\wedge} 12+z^{\wedge} 5+1^{\prime}($ default $) \mid$ polynomial character vector $\mid$ binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as ' $z^{\wedge} 3+z^{\wedge} 2+1$.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial. For example, $\left[\begin{array}{lll}1 & 1 & 0\end{array} 1\right]$ represents the polynomial $x^{3}+z^{2}+1$.
- An integer row vector containing the exponents of $z$ for the nonzero terms in the polynomial in descending order. For example, [llll 3200$]$ represents the polynomial $z^{3}+z^{2}+1$.

For more information, see "Character Representation of Polynomials".
Some commonly used generator polynomials include:

| CRC <br> method | Generator polynomial |
| :--- | :--- |
| CRC-32 |  <br>  <br> $+z^{\wedge} 32+z^{\wedge} 26+z^{\wedge} 23+z^{\wedge} 22+z^{\wedge} 16+z^{\wedge} 12+z^{\wedge} 11+z^{\wedge} 10+z^{\wedge} 8+z^{\wedge} 7$ <br> CRC-24 |
| CRC-16 $z^{\wedge} 24+z^{\wedge} 23+z^{\wedge} 14+z^{\wedge} 12+z^{\wedge} 8+1^{\prime}$ |  |
| Reversed <br> CRC-16 | ${ }^{\prime} z^{\wedge} 16+z^{\wedge} 15+z^{\wedge} 2+1^{\prime}$ |
| CRC-8 $16+z^{\wedge} 14+z+1^{\prime}$ |  |
| CRC-4 | $' z^{\wedge} 8+z^{\wedge} 7+z^{\wedge} 6+z^{\wedge} 4+z^{\wedge} 2+1^{\prime}$ |

Example: ' $z^{\wedge} 7$ + $z^{\wedge} 2+1 ',[10000101]$, and [7 2 0] represent the same polynomial, $p(z)=z^{7}+z^{2}+1$.

## Initial states - Initial states of internal shift register

0 (default) | 1 | binary row vector
Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

## Direct method - Use direct algorithm for CRC checksum calculations <br> off (default) | on

Select to use the direct algorithm for CRC checksum calculations. When cleared, the block uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see "Error Detection and Correction".

## Reflect input bytes - Reflect input bytes

off (default) | on
Select to flip the input data on a bytewise basis before entering the data into the shift register. When Reflect input bytes is selected, the input frame length divided by the value of the Checksums per frame parameter must be an integer and a multiple of 8. When Reflect input bytes is cleared, the block does not flip the input data.

## Reflect checksums before final XOR - Reflect checksums before final XOR off (default) | on

Select to flip the CRC checksums around their centers after the input data are completely through the shift register. When Reflect checksums before final XOR is cleared, the block does not flip the CRC checksums.

## Final XOR - Final XOR

0 (default) | 1 | binary row vector
Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the Final XOR parameter the CRC
checksum before appending the CRC to the input data. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.

## Checksums per frame - Number of checksums calculated for each frame <br> 1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer.

## Block Characteristics

| Data Types | Boolean \| double |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the checksum or syndrome, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1 , the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see "Cyclic Redundancy Check Codes".

## CRC Generator Operation

The CRC generator appends CRC checksums to the input frame according to the specified generator polynomial and number of checksums per frame.

For a specific initial state of the internal shift register and $k$ checksums per input frame:
1 The input signal is divided into $k$ subframes of equal size.
2 Each of the $k$ subframes are prefixed with the initial states vector.
3 The CRC algorithm is applied to each subframe.
4 The resulting checksums are appended to the end of each subframe.
5 The subframes are concatenated and output as a column vector.
For the scenario shown here, a 10-bit frame is input, a third degree generator polynomial computes the CRC checksum, the initial state is 0 , and the number of checksums per frame is 2 .

The input frame is divided into two subframes of size 5 and checksums of size 3 are computed and appended to each subframe. The initial states are not shown, because an initial state of [0] does not affect the output of the CRC algorithm. The output transmitted codeword frame has the size $5+3+$ $5+3=16$.

$$

## Description

The General CRC Generator HDL Optimized block, which is similar to the General CRC Generator block, generates a cyclic redundancy check (CRC) checksum and appends it to the input message. The General CRC Generator HDL Optimized block processing is optimized for HDL code generation. Instead of processing an entire frame at once, the block accepts and returns a data sample stream with accompanying control signals. The control signals indicate the validity of the samples and the boundaries of the frame. To achieve higher throughput, the block accepts vector data up to the CRC length and implements a parallel architecture.

## Ports

## Input

## dataIn - Input data

scalar | vector
Input data, specified as one of these options.

- Scalar - Specify an integer representing several bits. For this case, the block supports an unsigned integer (uint8, uint16, or uint32) or fixdt ( $0, \mathrm{~N}, 0$ ) data type.
- Vector - Specify a vector of binary values. For this case, the block supports a double or Boolean data type.

The data width must be less than or equal to the CRC length, and the CRC length must be divisible by the data width. For CRC-CCITT/CRC-16, the valid data widths are $16,8,4,2$, and 1.
Example: The uint8 vector input [ $\left.0 \begin{array}{lllllll}0 & 0 & 1 & 0 & 0 & 1 & 1\end{array}\right]$ is equivalent to 19 .
Data Types: double |uint8|uint16|uint32|fixed point | Boolean

## startIn - Start of input frame indicator

Boolean scalar
Start of input frame indicator, specified as a Boolean scalar.
Data Types: Boolean
endIn - End of input frame indicator
Boolean scalar
End of input frame indicator, specified as a Boolean scalar.
Data Types: Boolean

## validIn - Valid input data indicator

Boolean scalar
Valid input data indicator, specified as a Boolean scalar.
This is a control signal that indicates if the data on the dataIn port is valid.

## Data Types: Boolean

## Output

## dataOut - Output data

scalar | vector
Output data with appended checksum, returned as a scalar or vector. The output data type and size are the same as the input data.
Data Types: double|uint8|uint16|uint32|Boolean|fixed point

## startOut - Start of output frame indicator

Boolean scalar
Start of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## endOut - End of output frame indicator

Boolean scalar
End of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## validOut - Valid output data indicator <br> Boolean scalar

Valid output data indicator, returned as a Boolean scalar.
This port is a control signal that indicates if the data on the dataOut port is valid.
Data Types: Boolean

## Parameters

Polynomial - Generator polynomial

```
[1 0 0 0 l 0 0 0 0 0 0 l 0 0 0 0 1] (default)| binary vector
```

Specify the generator polynomial as a binary vector with coefficients in descending order of powers. The vector length is equal to the degree of the polynomial plus 1.

## Initial state - Initial conditions of shift register

0 (default) | binary scalar | binary vector
Specify initial conditions of the internal shift register as a binary, double-precision, or single-precision scalar or vector. For vector inputs, the length of the initial state must be equal to the degree of the generator polynomial.

## Direct method - Method of calculating checksum

off (default) | on
Specify the direct or indirect method for calculating the checksum.

- Select this parameter for the block to use the direct algorithm for CRC checksum calculations.
- Clear this parameter for the block to use the nondirect algorithm for CRC checksum calculations.

For more information about direct and nondirect algorithms, see "Cyclic Redundancy Check Codes".

## Reflect input - Input byte order

off (default) | on
Specify the input byte order.

- Select this parameter for the block to flip each input byte before it enters the shift register.
- Clear this parameter for the block to pass the message data to the shift register unchanged.

The input data width must be a multiple of 8 .

## Reflect CRC checksum - Checksum byte order

off (default) | on
Specify the checksum byte order.

- Select this parameter for the block to flip each checksum byte before passing it to the final XOR stage.
- Clear this parameter for the block to pass the checksum byte to the final XOR stage unchanged.

The input data width must be a multiple of 8 .

## Final XOR value - Checksum

0 (default) | binary scalar | binary vector
Specify the checksum as a binary, double-precision, or single-precision data type scalar or vector. The block performs XOR operation on the CRC checksum with this value before appending it to the input data.

If you specify a vector input, the vector length must be equal to the degree of the generator polynomial.

## Algorithms

When you use a vector or integer input, the block implements a parallel CRC algorithm [1].
To provide high throughput for modern communications systems, the block implements the CRC algorithm with a parallel architecture. This architecture recursively calculates $M$ bits of a CRC checksum for each $W$ input bits. At the end of the frame, the final checksum result is appended to the message. For a polynomial length of $M$, the recursive checksum calculation for $W$ bits in parallel is
$F_{W}$ is an $M$-by- $M$ matrix that selects elements of the current state for the polynomial calculation with the new input bits. $D$ is an $M$-element vector that provides the new input bits, ordered in relation to the generator polynomial and padded with zeros. The block implements the ( $x$ ) with logical AND and (+) with logical XOR.

## Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with an 8-bit binary vector input. To insert the checksum word, input frames must have enough space between the.

This waveform diagram shows continuous input data. The block also supports noncontinuous data. The output valid signal matches the input valid pattern.

## Initial Delay

The General CRC Generator HDL Optimized block introduces a latency on the output. Assuming the input data is continuous, you can compute the latency by using the equation.

```
initialdelay = (CRC length/input data width) + 2.
```

## General CRC Syndrome Detector

Detect errors in received codeword frames according to generator polynomial
Library: Communications Toolbox / Error Detection and Correction / CRC

## Description

The General CRC Syndrome Detector block computes cyclic redundancy check (CRC) checksums for received codeword frames. For successful CRC detection in a communications system link, you must align the parameter settings of the General CRC Syndrome Detector block with the paired General CRC Generator block.

For more information, see "CRC Syndrome Detector Operation" on page 5-327.

## Ports

## Input

## In - Received codeword

binary column vector
Received codeword, specified as a binary column vector.
Data Types: double | Boolean

## Output

Out - Output frame
binary column vector
Output frame, returned as a binary column vector that inherits the data type of the input signal. The output frame contains the received codeword with the checksums removed.

The length of the output frame is $n-k * r$ bits, where $n$ is the size of the received codeword, $k$ is the number of checksums per frame, and $r$ is the degree of the generator polynomial.

## Err - Checksum error signal

binary column vector
Checksum error signal, returned as a binary column vector that inherits the data type of the input signal. The length of Err equals the value of Checksums per frame. For each checksum computation, an element value of 0 in Err indicates no checksum error, and an element value of 1 in Err indicates a checksum error.

## Parameters

Generator polynomial - Generator polynomial
' $z^{\wedge} 16+z^{\wedge} 12+z^{\wedge} 5+1$ ' (default) | polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as ' $z^{\wedge} 3+z^{\wedge} 2+1$ '.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial. For example, $\left[\begin{array}{lll}1 & 1 & 0\end{array} 1\right]$ represents the polynomial $x^{3}+z^{2}+1$.
- An integer row vector containing the exponents of $z$ for the nonzero terms in the polynomial in descending order. For example, [ $\left.\begin{array}{lll}3 & 2 & 0\end{array}\right]$ represents the polynomial $z^{3}+z^{2}+1$.

For more information, see "Character Representation of Polynomials".
Some commonly used generator polynomials include:

| CRC <br> method | Generator polynomial |
| :--- | :--- |
| CRC-32 | ' $z^{\wedge} 32+z^{\wedge} 26+z^{\wedge} 23+z^{\wedge} 22+z^{\wedge} 16+z^{\wedge} 12+z^{\wedge} 11+z^{\wedge} 10+z^{\wedge} 8+z^{\wedge} 7$ <br> $+z^{\wedge} 5+z^{\wedge} 4+z^{\wedge} 2+z+1^{\prime}$ |
| CRC-24 | $' z^{\wedge} 24+z^{\wedge} 23+z^{\wedge} 14+z^{\wedge} 12+z^{\wedge} 8+1^{\prime}$ |
| CRC-16 | $' z^{\wedge} 16+z^{\wedge} 15+z^{\wedge} 2+1^{\prime}$ |
| Reversed <br> CRC-16 | ' $z^{\wedge} 16+z^{\wedge} 14+z+1^{\prime}$ |
| CRC-8 | $' z^{\wedge} 8+z^{\wedge} 7+z^{\wedge} 6+z^{\wedge} 4+z^{\wedge} 2+1^{\prime}$ |
| CRC-4 | $z^{\wedge} 4+z^{\wedge} 3+z^{\wedge} 2+z+1^{\prime}$ |

Example: 'z^7 + z^2 + 1', [1 00001011 , and [7 2 0] represent the same polynomial, $p(z)=z^{7}+z^{2}+1$.

## Initial states - Initial states of internal shift register <br> 0 (default) | 1 | binary row vector

Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.

## Direct method - Use direct algorithm for CRC checksum calculations

off (default) | on
Select to use the direct algorithm for CRC checksum calculations. When cleared, the block uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see "Error Detection and Correction".

## Reflect input bytes - Reflect input bytes

off (default) | on
Select to flip the received codeword on a bytewise basis before entering the data into the shift register. When Reflect input bytes is selected, the received codeword length divided by the value of the Checksums per frame parameter must be an integer and a multiple of 8. When Reflect input bytes is cleared, the block does not flip the input data.

Reflect checksums before final XOR - Reflect checksums before final XOR off (default) | on

Select Reflect checksums before final XOR to flip the CRC checksums around their centers after the input data are completely through the shift register. When Reflect checksums before final XOR is cleared, the block does not flip the CRC checksums.

## Final XOR - Final XOR

## 0 (default) | 1 | binary row vector

Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the Final XOR parameter and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.

## Checksums per frame - Number of checksums calculated for each frame <br> 1 (default) | positive integer

Number of checksums calculated for each frame, specified as a positive integer.

## Block Characteristics

| Data Types | Boolean \| double |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the checksum or syndrome, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1, the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see "Cyclic Redundancy Check Codes".

## CRC Syndrome Detector Operation

The CRC syndrome detector outputs the received message frame and a checksum error vector according to the specified generator polynomial and number of checksums per frame.

The checksum bits are removed from each subframe, so that the resulting the output frame length is $n-k \times r$, where $n$ is the size of the received codeword, $k$ is the number of checksums per frame, and $r$ is the degree of the generator polynomial. The input frame must be evenly divisible by $k$.

For a specific initial state of the internal shift register:
1 The received codeword is divided into $k$ equal sized subframes.
2 The CRC is removed from each of the $k$ subframes and compared to the checksum calculated on the received codeword subframes.
3 The output frame is assembled by concatenating the subframe bits of the $k$ subframes and then output as a column vector.
4 The checksum error is output as a binary column vector of length $k$. An element value of 0 indicates an error-free received subframe, and an element value of 1 indicates an error occurred in the received subframe.

For the scenario shown here, a 16-bit codeword is received, a third degree generator polynomial computes the CRC checksum, the initial state is 0 , and the number of checksums per frame is 2 .

Since the number of checksums per frame is 2 and the generator polynomial degree is 3 , the received codeword is split in half and two checksums of size 3 are computed, one for each half of the received codeword. The initial states are not shown, because an initial state of [0] does not affect the output of the CRC algorithm. The output frame contains the concatenation of the two halves of the received codeword as a single vector of size 10. The checksum error signal output contains a 2-by-1 binary frame vector whose entries depend on whether the computed checksums are zero. As shown in the figure, the first checksum is nonzero and the second checksum is zero, indicating an error occurred in reception of the first half of the codeword.

| CRC |

## Description

The General CRC Syndrome Detector HDL Optimized block performs a cyclic redundancy check (CRC) on data and compares the resulting checksum with the appended checksum. The General CRC Syndrome Detector HDL Optimized block processing is optimized for HDL code generation. If the two checksums do not match, the block reports an error. Instead of processing an entire frame at once, the block accepts and returns a data sample stream with accompanying control signals. The control signals indicate the validity of the samples and the boundaries of the frame. To achieve higher throughput, the block accepts vector data up to the CRC length and implements a parallel architecture.

## Ports

## Input

dataIn - Input data
scalar | vector
Input data, specified as one of these options.

- Scalar - Specify an integer representing several bits. For this case, the block supports an unsigned integer (uint8, uint16, or uint32) or fixdt ( $0, \mathrm{~N}, 0$ ) data type.
- Vector - Specify a vector of binary values. For this case, the block supports a double or Boolean data type.

The data width must be less than or equal to the CRC length, and the CRC length must be divisible by the data width. For CRC-CCITT/CRC-16, the valid data widths are $16,8,4,2$, and 1.
Example: The uint8 vector input [ $\left.0 \begin{array}{llllll}0 & 0 & 1 & 0 & 0 & 1\end{array}\right]$ is equivalent to 19 .
Data Types: double |uint8|uint16|uint32|fixed point | Boolean
startIn - Start of input frame indicator
Boolean scalar
Start of input frame indicator, specified as a Boolean scalar.
Data Types: Boolean
endIn - End of input frame indicator
Boolean scalar
End of input frame indicator, specified as a Boolean scalar.

## Data Types: Boolean

## validIn - Valid input data indicator

Boolean scalar
Valid input data indicator, specified as a Boolean scalar.
This a control signal that indicates if the data on the dataIn port is valid.
Data Types: Boolean

## Output

## data0ut - Output data

scalar | vector
Output data, returned as a scalar or vector. The output data type and size are the same as the input data.

Data Types: double|uint8|uint16|uint32|Boolean|fixed point

## start0ut - Start of output frame indicator

Boolean scalar
Start of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## endOut - End of output frame indicator

Boolean scalar
End of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## validOut - Valid output data indicator

Boolean scalar
Valid output data indicator, returned as a Boolean scalar.
This is a control signal that indicates if the data on the dataOut port is valid.
Data Types: Boolean
err - Error indicator
Boolean scalar
Error indicator for the corruption of the received data, returned as a Boolean scalar.
When this value is 1 , the message contains at least one error. When this value is 0 , the message contains zero errors.

Data Types: Boolean

## Parameters

Polynomial - Generator polynomial

```
[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default)| binary vector
```

Specify the generator polynomial as a binary vector with coefficients in descending order of powers. The vector length is equal to the degree of the polynomial plus 1.

## Initial state - Initial conditions of shift register <br> 0 (default) | binary scalar | binary vector

Specify initial conditions of the internal shift register as a binary, double-precision, or single-precision scalar or vector. For vector inputs, the length of the initial state must be equal to the degree of the generator polynomial.

## Direct method - Method of calculating checksum

off (default) | on
Specify the method of calculating checksum as a Boolean scalar.

- Select this parameter to use the direct algorithm for CRC checksum calculations.
- Clear this parameter to use the nondirect algorithm for CRC checksum calculations.

To learn about the direct and non-direct algorithms, see "Cyclic Redundancy Check Codes".

## Reflect input - Input byte order

off (default) | on
Specify the input byte order.

- Select this parameter for the block to flip each input byte before it enters the shift register.
- Clear this parameter for the block to pass the message data to the shift register unchanged.

The input data width must be a multiple of 8 .

## Reflect CRC checksum - Checksum byte order <br> off (default) | on

Specify the checksum byte order.

- Select this parameter for the block to flip each checksum byte before passing it to the final XOR stage.
- Clear this parameter for the block to pass the checksum byte to the final XOR stage unchanged.

The input data width must be a multiple of 8 .

## Final XOR value - Checksum

0 (default) | binary scalar | binary vector
Specify the checksum as a binary, double-precision, or single-precision data type scalar or vector. The block performs XOR operation on the CRC checksum with this value before appending it to the input data.

If you specify a vector input, the vector length must be equal to the degree of the generator polynomial.

## Algorithms

When you use vector or integer input, the block implements a parallel CRC algorithm .

To provide high throughput for modern communications systems, the block implements the CRC algorithm with a parallel architecture. This architecture recursively calculates $M$ bits of a CRC checksum for each $W$ input bits. At the end of the frame, the final checksum result is appended to the message. For a polynomial length of $M$, the recursive checksum calculation for $W$ bits in parallel is

$$
X^{\prime}=F_{W}(\times) X(+) D
$$

$F_{W}$ is an $M$-by- $M$ matrix that selects elements of the current state for the polynomial calculation with the new input bits. $D$ is an $M$-element vector that provides the new input bits, ordered in relation to the generator polynomial and padded with zeros. The block implements the ( $x$ ) with logical AND and $(+)$ with logical XOR.

## Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous. The output frames include space between them because the detector block removes the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported.

## Initial Delay

The General CRC Syndrome Detector HDL Optimized block introduces a latency on the output. This latency can be computed with the following equation, assuming the input data is continuous:

```
initialdelay = 3* (CRC length/input data width) + 2.
```

## General Multiplexed Deinterleaver

Restore ordering of symbols using specified-delay shift registers

```
General
Multiplexed
Deinterleaver
```

## Library

Convolutional sublibrary of Interleaving

## Description

The General Multiplexed Deinterleaver block restores the original ordering of a sequence that was interleaved using the General Multiplexed Interleaver block.

In typical usage, the parameters in the two blocks have the same values. As a result, the Interleaver delay parameter, $V$, specifies the delays for each shift register in the corresponding interleaver, so that the delays of the deinterleaver's shift registers are actually $\max (V)-V$.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

The block can accept the data types int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The data type of the output will be the same as that of the input signal.

## Parameters

## Interleaver delay (samples)

A vector that lists the number of symbols that fit in each shift register of the corresponding interleaver. The length of this vector is the number of shift registers.
Initial conditions
The values that fill each shift register when the simulation begins.

## Pair Block

General Multiplexed Interleaver

Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\mathrm{TM}}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

The implementation for the General Multiplexed Deinterleaver block is shift register based. If you want to suppress generation of reset logic, set the implementation parameter ResetType tonone.

When you set ResetType to none, reset is not applied to the shift registers. When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the Ignore output data checking (number of samples) option accordingly. (If you are using the command-line interface, you can use the IgnoreDataChecking property for this purpose.)

## General Multiplexed Interleaver

Permute input symbols using set of shift registers with specified delays

```
General
Multiplexed
Interleaver
```

## Library

Convolutional sublibrary of Interleaving

## Description

The General Multiplexed Interleaver block permutes the symbols in the input signal. Internally, it uses a set of shift registers, each with its own delay value.

This block accepts a scalar or column vector input signal, which can be real or complex. The input and output signals have the same sample time.

The block can accept the data types int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal has the same data type as the input signal.

## Parameters

## Interleaver delay (samples)

A column vector listing the number of symbols that fit into each shift register. The length of this vector is the number of shift registers. (In sample-based mode, it can also be a row vector.)

## Initial conditions

The values that fill each shift register at the beginning of the simulation.
If Initial conditions is a scalar, then its value fills all shift registers. If Initial conditions is a column vector, then each entry fills the corresponding shift register. (In sample-based mode, Initial conditions can also be a row vector.) If a given shift register has zero delay, then the value of the corresponding entry in the Initial conditions vector is unimportant.

# General QAM Demodulator Baseband 

Demodulate QAM-modulated data
$\sqrt{\substack{\text { Guht } \\ \text { General } \\ \text { QAM }}}$

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The General QAM Demodulator Baseband block demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

The input must be a discrete-time complex signal. The Signal constellation parameter defines the constellation by listing its points in a length-M vector of complex numbers. The block maps the $m$ th point in the Signal constellation vector to the integer $m-1$.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see the "Supported Data Types" on page 5-346 table on this page.

## Parameters

## Signal constellation

A real or complex vector that lists the constellation points.

## Output type

Determines whether the block produces integers or binary representations of integers.
If you set this parameter to Integer, the block produces integers.
If you set this parameter to Bit, the block produces a group of K bits, called a binary word, for each symbol, when Decision type is set to Hard decision. If Decision type is set to Loglikelihood ratio or Approximate log-likelihood ratio, the block outputs bitwise LLR and approximate LLR, respectively.

## Decision type

This field appears when Bit is selected in the pull-down list Output type.
Specifies the use of hard decision, LLR, or approximate LLR during demodulation. See "Exact LLR Algorithm" and "Approximate LLR Algorithm" in the Communications Toolbox User's Guide for algorithm details.

## Noise variance source

This field appears when you set Approximate log-likelihood ratio or Log-likelihood ratio for Decision type.

When you set this parameter to Dialog, you can then specify the noise variance in the Noise variance field. When you set this option to Port, a port appears on the block through which the noise variance can be input.

## Noise variance

This parameter appears when the Noise variance source is set to Dialog and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- Inf to - Inf if Noise variance is very high
- NaN if Noise variance and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Fixed-Point Signal Flow Diagrams

Fixed-Point Signal Flow Diagram for Hard Decision Mode

Note In the figure above, $M$ represents the size of the Signal constellation .

The general QAM Demodulator Baseband block supports fixed-point operations for computing Hard Decision (Output type set to Bit and Decision type is set to Hard decision) and Approximate LLR (Output type is set to Bit and Decision type is set to Approximate Log-Likelihood ratio) output values. The input values must have fixed-point data type for fixed-point operations.

Note Fixed-Point operations are NOT yet supported for Exact LLR output values.

## Fixed-Point Signal Flow Diagram for Approximate LLR Mode

Note In the figure above, $M$ represents the size of the Signal constellation.

Fixed-Point Signal Flow Diagram for Approximate LLR Mode: Noise Variance Operation Modes

Note If Noise variance is set to Dialog, the block performs the operations shown inside the dotted line once during initialization. The block also performs these operations if the Noise variance value changes during simulation.

## Data Types Attributes

## Output

The block supports the following Output options:
When you set the parameter to Inherit via internal rule (default setting), the block inherits the output data type from the input port. The output data type is the same as the input data type if the input is of type single or double.

For integer outputs, you can set this block's output to Inherit via internal rule (default setting), Smallest unsigned integer, int8, uint8, int16, uint16, int32, uint32, single, and double.

For bit outputs, when you set Decision type to Hard decision, you can set the output to Inherit via internal rule, Smallest unsigned integer, int8, uint8, int16, uint16, int32, uint32, boolean, single, or double.

When you set Decision type to Hard decision or Approximate log-likelihood ratio and the input is a floating point data type, then the output inherits its data type from the input. For example, if the input is of data type double, the output is also of data type double. When you set Decision type to Hard decision or Approximate log-likelihood ratio, and the input is a fixed-point signal, the Output parameter, located in the Fixed-Point algorithm parameters region of the Data-Type tab, specifies the output data type.

When you set the parameter to Smallest unsigned integer, the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box. If you select ASIC/FPGA in the Hardware Implementation pane, the output data type is the ideal minimum size, i.e., ufix (1) for bit outputs, and ufix( $\left.\left[\log _{2} M\right\rceil\right)$ for integer outputs. For all other choices, the Output data type is an unsigned integer with the smallest available word length large enough to fit the ideal minimum size, usually corresponding to the size of a char (e.g., uint8).

## Rounding Mode Parameter

Use this parameter to specify the rounding method to be used when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result.

For more information, see "Rounding Modes" (DSP System Toolbox) or "Rounding Mode: Simplest" (Fixed-Point Designer).

## Saturate on integer overflow

Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result:

- Saturate represents positive overflows as the largest positive number in the range being used, and negative overflows as the largest negative number in the range being used.
- Wrap uses modulo arithmetic to cast an overflow back into the representable range of the data type. See Modulo Arithmetic (Fixed-Point Designer) for more information.

For more information, see the Saturate on integer overflow parameter subsection of "Specify Fixed-Point Attributes for Blocks" (DSP System Toolbox).

## Signal constellation

Use this parameter to define the data type of the Signal constellation parameter.

- When you select Same word length as input the word length of the Signal constellation parameter matches that of the input to the block. The fraction length is computed to provide the best precision for given signal constellation values.
- When you select Specify word length, the Word Length field appears, and you may enter a value for the word length. The fraction length is computed to provide the best precision for given signal constellation values.

## Accumulator 1

Use this parameter to specify the data type for Accumulator 1:

- When you select Inherit via internal rule, the block automatically calculates the output word and fraction lengths. For more information, see the "Inherit via Internal Rule" (DSP System Toolbox) subsection of the DSP System Toolbox ${ }^{\mathrm{TM}}$ User's Guide.
- When you select Binary point scaling, you can enter the word length and the fraction length of Accumulator 1, in bits.

## Product Input

Use this parameter to specify the data type for Product input.

- When you select Same as accumulator 1, the Product Input characteristics match those of Accumulator 1.
- When you select Binary point scaling you can enter the word length and the fraction length of Product input, in bits.

## Product Output

Use this parameter to select the data type for Product output.

- When you select Inherit via internal rule, the block automatically calculates the output signal type. For more information, see the Inherit via Internal Rule (DSP System Toolbox) subsection of the DSP System Toolbox User's Guide.
- When you select Binary point scaling enter the word length and the fraction length for Product output, in bits.

## Accumulator 2

Use this parameter to specify the data type for Accumulator 2:

- When you select Inherit via internal rule, the block automatically calculates the accumulator data type. The internal rule calculates the ideal, full-precision word length and fraction length as follows:
$W L_{\text {ideal accumulator } 2}=W L_{\text {input to accumulator } 2}$
$F L_{\text {ideal accumulator 2 }}=F L_{\text {input to accumulator 2 }}$
After the full-precision result is calculated, your particular hardware may still affect the final word and fraction lengths set by the internal rule. For more information, see The Effect of the

Hardware Implementation Pane on the Internal Rule (DSP System Toolbox) subsection of the DSP System Toolbox User's Guide.

The internal rule always sets the sign of data-type to Unsigned.

- When you select Binary point scaling, you are able to enter the word length and the fraction length of Accumulator 2, in bits.

The settings for the following fixed-point parameters only apply when you set Decision type to Approximate log-likelihood ratio.

## Accumulator 3

When you select Inherit via internal rule, the block automatically calculates the accumulator data type. The internal rule first calculates ideal, full-precision word length and fraction length as follows:
$W L_{\text {ideal accumulator } 3}=W L_{\text {input to accumulator } 3}+1$
$F L_{\text {ideal accumulator } 3}=F L_{\text {input to accumulator 3 }}$.
After the full-precision result is calculated, your particular hardware may still affect the final word and fraction lengths set by the internal rule. For more information, see The Effect of the Hardware Implementation Pane on the Internal Rule (DSP System Toolbox) subsection of the DSP System Toolbox User's Guide.

The internal rule always sets the sign of data-type to Signed.

## Noise scaling input

- When you select Same as accumulator 3, the Noise scaling input characteristics match those of Accumulator 3.
- When you select Binary point scaling you are able to enter the word length and the fraction length of Noise scaling input, in bits.

## Inverse noise variance

This field appears when Noise variance source is set to Dialog.

- When you select Same word length as input the word length of the Inverse noise variance parameter matches that of the input to the block. The fraction length is computed to provide the best precision for a given inverse noise variance value.
- When you select Specify word length, the Word Length field appears, and you may enter a value for the word length. The fraction length is computed to provide the best precision for a given inverse noise variance value.

## Output

When you select Inherit via internal rule, the Output data type is automatically set for you.

If you set the Noise variance source parameter to Dialog, the output is a result of product operation as shown in the Noise Variance Operation Modes Signal Flow Diagram "Fixed-Point Signal Flow Diagram for Approximate LLR Mode: Noise Variance Operation Modes" on page 5342. In this case, it follows the internal rule for Product data types specified in the Inherit via Internal Rule (DSP System Toolbox) subsection of the DSP System Toolbox User's Guide.

If the Noise variance source parameter is set to Port, the output is a result of division operation as shown in the signal flow diagram. In this case, the internal rule calculates the ideal, full-precision word length and fraction length as follows:
$W L_{\text {output }}=\max \left(W L_{\text {Noise scaling input }} W L_{\text {Noise variance }}\right)$
$F L_{\text {output }}=F L_{\text {Noise scaling input (dividend) }}-F L_{\text {Noise variance (divisor) }}$.
After the full-precision result is calculated, your particular hardware may still affect the final word and fraction lengths set by the internal rule. For more information, see "The Effect of the Hardware Implementation Pane on the Internal Rule" (DSP System Toolbox) subsection of the DSP System Toolbox User's Guide.

The internal rule for Output always sets the sign of data-type to Signed.
For additional information about the parameters pertaining to fixed-point applications, see "Specify Fixed-Point Attributes for Blocks" (DSP System Toolbox).

# General QAM Modulator Baseband 

Modulate using quadrature amplitude modulation

| G—ll $N M$ General QAM |
| :---: |

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The General QAM Modulator Baseband block modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

The Signal constellation parameter defines the constellation by listing its points in a length-M vector of complex numbers. The input signal values must be integers between 0 and $\mathrm{M}-1$. The block maps an input integer $m$ to the $(m+1)$ st value in the Signal constellation vector.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see the "Supported Data Types" on page 5-349 table on this page.

## Constellation Visualization

The General QAM Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the Communications Toolbox User's Guide.

## Parameters

## Signal constellation

A real or complex vector that lists the constellation points.

## Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this to Fixed-point or User-defined will enable fields in which you can further specify details. Setting this to Inherit via back propagation, sets the output data type and scaling to match the following block..

## Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select Fixed-point for the Output data type parameter.

## User-defined data type

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the sfix, sint, sfrac, and fixdt functions from Fixed-Point Designer software. This parameter is only visible when you select User-defined for the Output data type parameter.
Set output fraction length to
Specify the scaling of the fixed-point output by either of the following two methods:

- Choose Best precision to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose User-defined to specify the output scaling in the Output fraction length parameter.

This parameter is only visible when you select Fixed-point for the Output data type parameter, or when you select User-defined and the specified output data type is a fixed-point data type.
Output fraction length
For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select Fixed-point or User-defined for the Output data type parameter and User-defined for the Set output fraction length to parameter.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - 8-, 16-, 32 -bit signed integers <br> - 8-, 16-, 32 -bit unsigned integers <br> - ufix( $\left.\left(\log _{2} M\right\rceil\right)$ |
| Output | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed-point |

## General TCM Decoder

Decode trellis-coded modulation data, mapped using arbitrary constellation

```
General
    TCM
```

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The General TCM Decoder block uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

The Trellis structure and Signal constellation parameters in this block should match those in the General TCM Encoder block, to ensure proper decoding. In particular, the Signal constellation parameter must be in set-partitioned order.

## Input and Output Signals

This block accepts a column vector input signal containing complex numbers. The input signal must be double or single. The reset port signal must be double or Boolean. For information about the data types each block port supports, see "Supported Data Types" on page 5-352.

If the convolutional encoder described by the trellis structure represents a rate $k / n$ code, then the General TCM Decoder block's output is a binary column vector whose length is $k$ times the vector length of the input signal.

## Operation Modes

The block has three possible methods for transitioning between successive frames. The Operation mode parameter controls which method the block uses. This parameter also affects the range of possible values for the Traceback depth parameter, D.

- In Continuous mode, the block initializes all state metrics to zero at the beginning of the simulation, waits until it accumulates D symbols, and then uses a sequence of D symbols to compute each of the traceback paths. D can be any positive integer. At the end of each frame, the block saves its internal state metric for use with the next frame.

If you select Enable the reset input port, the block displays another input port, labeled Rst. This port receives an integer scalar signal. Whenever the value at the Rst port is nonzero, the block resets all state metrics to zero and sets the traceback memory to zero.

- In Truncated mode, the block treats each frame independently. The traceback path starts at the state with the lowest metric. D must be less than or equal to the vector length of the input.
- In Terminated mode, the block treats each frame independently. The traceback path always starts at the all-zeros state. D must be less than or equal to the vector length of the input. If you
know that each frame of data typically ends at the all-zeros state, then this mode is an appropriate choice.

## Decoding Delay

If you set Operation mode to Continuous, then this block introduces a decoding delay equal to Traceback depth*k bits for a rate $\mathrm{k} / \mathrm{n}$ convolutional code. The decoding delay is the number of zeros that precede the first decoded bit in the output.

The block incurs no delay for other values of Operation mode.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## Signal constellation

A complex vector that lists the points in the signal constellation in set-partitioned order.

## Traceback depth

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

## Operation mode

The operation mode of the Viterbi decoder. The choices are Continuous, Truncated, and Terminated.

## Enable the reset input port

When you select this check box, the block has a second input port labeled Rst. Providing a nonzero value to this port causes the block to set its internal memory to the initial state before processing the input data. This field appears only if you set Operation mode to Continuous.

## Output data type

Select the data type for the block output signal as boolean or single. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :--- | :--- |
| Input | $\bullet \quad$ Double-precision floating point |
|  | $\bullet$ Single-precision floating point |
| Reset | $\bullet$ |
| Output | •Boolean |
|  | Double-precision floating point |

## General TCM Encoder

Convolutionally encode binary data and map using arbitrary constellation

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The General TCM Encoder block implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to an arbitrary signal constellation. The Signal constellation parameter lists the signal constellation points in set-partitioned order. This parameter is a complex vector with a length, $M$, equal to the number of possible output symbols from the convolutional encoder. (That is, $\log _{2} M$ is equal to $n$ for a rate $k / n$ convolutional code.)

## Input Signals and Output Signals

If the convolutional encoder represents a rate $k / n$ code, then the General TCM Encoder block's input must be a binary column vector with a length of $L^{*} k$ for some positive integer $L$.

This block accepts a binary-valued input signal. The output signal is a complex column vector of length $L$. For information about the data types each block port supports, see "Supported Data Types" on page 5-356.

## Specifying the Encoder

To define the convolutional encoder, use the Trellis structure parameter. This parameter is a MATLAB structure whose format is described in "Trellis Description of a Convolutional Code". You can use this parameter field in two ways:

- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, then use a poly2trellis command within the Trellis structure field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the Trellis structure parameter to
poly2trellis(7,[171 133],171)
- If you have a variable in the MATLAB workspace that contains the trellis structure, then enter its name as the Trellis structure parameter. This way is faster because it causes Simulink software to spend less time updating the diagram at the beginning of each simulation, compared to the usage in the previous bulleted item.

The encoder registers begin in the all-zeros state. You can configure the encoder so that it resets its registers to the all-zeros state during the course of the simulation. To do this, set the Operation
mode to Reset on nonzero input via port. The block then opens a second input port, labeled Rst. The signal at the Rst port is a scalar signal. When it is nonzero, the encoder resets before processing the data at the first input port.

## Signal Constellations

The trellis-coded modulation technique partitions the constellation into subsets called cosets so as to maximize the minimum distance between pairs of points in each coset.

Note When you set the Signal constellation parameter, you must ensure that the constellation vector is already in set-partitioned order. Otherwise, the block might produce unexpected or suboptimal results.

As an example, the diagram below shows one way to devise a set-partitioned order for the points for an 8-PSK signal constellation. The figure at the top of the tree is the entire 8-PSK signal constellation, while the eight figures at the bottom of the tree contain one constellation point each. Each level of the tree corresponds to a different bit in a binary sequence ( $\mathrm{b}_{3}, \mathrm{~b}_{2}, \mathrm{~b}_{1}$ ), while each branch in a given level of the tree corresponds to a particular value for that bit. Listing the constellation points using the sequence at the bottom of the tree leads to the vector
$\exp \left(2 *\right.$ pi*j* $\left.\left.^{*} \begin{array}{llllllll}0 & 4 & 2 & 6 & 1 & 5 & 3 & 7\end{array}\right] / 8\right)$
which is a valid value for the Signal constellation parameter in this block.

For other examples of signal constellations in set-partitioned order, see [1] or the reference pages for the M-PSK TCM Encoder and Rectangular QAM TCM Encoder blocks.

## Coding Gains

Coding gains of 3 to 6 decibels, relative to the uncoded case can be achieved in the presence of AWGN with multiphase trellis codes [3].

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## Operation mode

In Continuous mode (default setting), the block retains the encoder states at the end of each frame, for use with the next frame.

In Truncated (reset every frame) mode, the block treats each frame independently. I.e., the encoder states are reset to all-zeros state at the start of each frame.

In Terminate trellis by appending bits mode, the block treats each frame independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by $y=n \cdot(x+s) / k$, where $x$ is the number of input bits, and $s=$ constraint length -1 (or, in the case of multiple constraint lengths, $s=\operatorname{sum}($ ConstraintLength(i)-1)). The block supports this mode for column vector input signals.

In Reset on nonzero input via port mode, the block has an additional input port, labeled Rst. When the Rst input is nonzero, the encoder resets to the all-zeros state.

## Signal constellation

A complex vector that lists the points in the signal constellation in set-partitioned order.

## Output data type

The output type of the block can be specified as a single or double. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean <br> - 8 -, 16 -, and 32 -bit signed integers <br> - 8 -, 16 -, and 32 -bit unsigned integers <br> - ufix(1) |

# GMSK Demodulator Baseband 

Demodulate GMSK-modulated data

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The GMSK Demodulator Baseband block uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying method. The input to this block is a baseband representation of the modulated signal.

## Integer-Valued Signals and Binary-Valued Signals

This block accepts a scalar-valued or column vector input signal with a data type of single or double. If you set the Output type parameter to Integer, then the block produces values of 1 and -1. If you set the Output type parameter to Bit, then the block produces values of 0 and 1 .

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the Samples per symbol parameter value, and the input can be a column vector.

- When you set Output type to Bit, the output width is two times the number of input symbols.
- When you set Output type to Integer, the output width is the number of input symbols.

For a column vector input signal, the width of the input equals the product of the number of symbols and the value for the Samples per symbol parameter.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the Samples per symbol parameter value.

- When you set Output type to Bit, the output width equals the number of bits per symbol.
- When you set Output type to Integer, the output is a scalar.

## Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The Traceback depth parameter, $D$, in this block is the number of trellis branches used to
construct each traceback path. D influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the Rate options parameter to Allow multirate processing, and the model uses a variable-step solver or a fixed-step solver with the Tasking Mode parameter set to SingleTasking, then the delay consists of $\mathrm{D}+1$ zero symbols.
- When you set the Rate options parameter to Enforce single-rate processing, then the delay consists of $D$ zero symbols.

The optimal Traceback depth parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the five-times-the-constraint-length rule, which corresponds to $5 \cdot \log 2$ (numStates). The number of states is determined by the following equation:

$$
\text { numStates }=\left\{\begin{array}{l}
p \cdot 2^{(L-1)}, \text { for even } m \\
2 p \cdot 2^{(L-1)}, \text { for odd } m
\end{array}\right\}
$$

where:

- $h=m / p$ is the modulation index in proper rational form
- $m=$ numerator of modulation index
- $p=$ denominator of modulation index
- $L$ is the Pulse length

## Parameters

## Output type

Determines whether the output consists of bipolar or binary values.

## BT product

The product of bandwidth and time.

## Pulse length (symbol intervals)

The length of the frequency pulse shape.

## Symbol prehistory

The data symbols the modulator uses before the start of the simulation.

## Phase offset (rad)

The initial phase of the modulated waveform.

## Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see "Upsample Signals and Rate Changes" in Communications Toolbox User's Guide.

## Rate options

Select the rate processing method for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of
symbols (which is given by dividing the input length by the Samples per symbol parameter value when the Output type parameter is set to Integer).
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the Samples per symbol parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

## Traceback depth

The number of trellis branches that the GMSK Demodulator Baseband block uses to construct each traceback path.

## Output data type

The output data type can be boolean, int8, int16, int32, or double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point |
| Output | - Double-precision floating point <br> - Boolean (When Output type set to Bit) <br> - 8 -, 16-, and 32 -bit signed integers (When Output type set to Integer) |

## Blocks

CPM Demodulator Baseband | GMSK Modulator Baseband | Viterbi Decoder

## GMSK Modulator Baseband

Modulate using Gaussian minimum shift keying method

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The GMSK Modulator Baseband block modulates using the Gaussian minimum shift keying method. The output is a baseband representation of the modulated signal.

The BT product parameter represents bandwidth multiplied by time. This parameter is a nonnegative scalar. It is used to reduce the bandwidth at the expense of increased intersymbol interference. The Pulse length parameter measures the length of the Gaussian pulse shape, in symbol intervals. For an explanation of the pulse shape, see the work by Anderson, Aulin, and Sundberg among the references on page 5-363 listed below. The frequency pulse shape is defined by the following equations.

$$
\begin{aligned}
& g(t)=\frac{1}{2 T}\left\{Q\left[2 \pi B_{b} \frac{t-\frac{T}{2}}{\sqrt{\ln (2)}}\right]-Q\left[2 \pi B_{b} \frac{t+\frac{T}{2}}{\sqrt{\ln (2)}}\right]\right\} \\
& Q(t)=\int_{t}^{\infty} \frac{1}{\sqrt{2 \Pi}} e^{-\tau^{2} / 2} d \tau
\end{aligned}
$$

For this block, an input symbol of 1 causes a phase shift of $\pi / 2$ radians.
The group delay is the number of samples between the start of a filter's response and its peak. The group delay that the block introduces is Pulse length/2 * Samples per symbol (using a reference of output sample periods). For GMSK, Pulse length denotes the truncated frequency pulse length in symbols. The net delay effect at the receiver (demodulator) is due to the Traceback depth parameter, which in most cases would be larger than the group delay.

## Integer-Valued Signals and Binary-Valued Signals

When you set the Input type parameter to Integer, then the block accepts values of 1 and -1 .
When you set the Input type parameter to Bit, then the block accepts values of 0 and 1 .
This block accepts a scalar-valued or column vector input signal. For a column vector input signal, the width of the output equals the product of the number of symbols and the value for the Samples per symbol parameter.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set Input type to Integer, the input can be a column vector, the length of which is the number of input symbols.
- When you set Input type to Bit, the input width must be an integer multiple of 2 .

The output width equals the product of the number of input symbols and the Samples per symbol parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set Input type to Integer, the input must be a scalar.
- When you set Input type to Bit, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Parameters

## Input type

Indicates whether the input consists of bipolar or binary values.

## BT product

The product of bandwidth and time.
The block uses this parameter to reduce bandwidth at the expense of increased intersymbol interference. Enter a nonnegative scalar value for this parameter.

## Pulse length (symbol intervals)

The length of the frequency pulse shape.

## Symbol prehistory

A scalar or vector value that specifies the data symbols the block uses before the start of the simulation, in reverse chronological order. If it is a vector, then its length must be one less than the Pulse length parameter.

## Phase offset (rad)

The initial phase of the output waveform, measured in radians.

## Samples per symbol

The number of output samples that the block produces for each integer or bit in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1 .

For more information, see "Upsample Signals and Rate Changes" in Communications ToolboxUser's Guide.

## Rate options

Select the rate processing option for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the Samples per symbol parameter value.
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Output data type

The output type of the block can be specified as a single or double. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :--- | :--- |
| Input | - |
|  | Double-precision floating point |
|  | - Boolean (When Input type set to Bit) |
|  | 8-, 16-, and 32-bit signed integers (When Input type set to Integer) |
| Output | - Double-precision floating point |
|  | - |
| Single-precision floating point |  |

## Gold Sequence Generator

Generate Gold sequence from set of sequences
Library: $\quad \begin{array}{ll}\text { Communications Toolbox / Comm Sources / Sequence } \\ \text { Generators }\end{array}$

> Gold Sequence
> Generator

## Description

The Gold Sequence Generator block generates a binary sequence with small periodic crosscorrelation properties from a bounded set of sequences. For more information on Gold sequences, see "Gold Sequences" on page 5-368.

This block can output sequences that vary in length during simulation. For more information about variable-size signals, see "Variable-Size Signal Basics" (Simulink).

## Ports

Input
oSiz - Current output size
scalar | two-element row vector
Current output size, specified as a scalar or a two-element row vector. The second element of the vector must be 1 .

Example: [10 1] indicates the current output column vector will be of size 10-by-1.

## Dependencies

To enable this port select the Output variable-size signals parameter and set Maximum output size source to Dialog parameter.
Data Types: double
Ref - Reference input signal
scalar | column vector
Reference input signal, specified as a scalar, column vector.

## Dependencies

To enable this port select the Output variable-size signals parameter and set Maximum output size source to Inherit from reference input.
Data Types: double

## Rst - Reset signal

scalar | column vector
Reset signal, specified in one of these forms.

- When the output size is variable specify as a scalar.
- Otherwise, specify as a scalar or a 2-D column vector with a length equal to Samples per frame.

The output signal resets for nonzero Rst input values. For more information, see "Reset Behavior" on page 5-370

Dependencies
To enable this port, select the Reset on nonzero input parameter.
Data Types: double

## Output

Out - Output signal
binary column vector
Output signal, returned as a binary column vector. At least one element of the Initial states (1) or Initial states (2) vector must be nonzero in order for the block to generate a nonzero sequence.
Data Types: double

## Parameters

Preferred polynomial (1) - First sequence polynomial
'z^6 + z + 1' (default)| polynomial character vector | binary row vector | integer row vector
First sequence polynomial, specified in one of these forms.

- A polynomial character vector such as ' $z^{\wedge} 3+z^{\wedge} 2+1$.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial. For example, $\left[\begin{array}{llll}1 & 1 & 0 & 1\end{array}\right]$ represents the polynomial $x^{3}+z^{2}+1$.
- An integer row vector containing the exponents of $z$ for the nonzero terms in the polynomial in descending order. For example, [3 240 ] represents the polynomial $z^{3}+z^{2}+1$.

For more information, see "Character Representation of Polynomials" and "Preferred Pairs of Sequences" on page 5-371.

## Initial states (1) - Initial states for first sequence polynomial

[0 0 0 0 0 1] (default)| binary vector
Initial states of the shift register for first sequence polynomial of the preferred pair, specified as a binary vector with length equal to the degree of Preferred polynomial (1).

## Preferred polynomial (2) - Second sequence polynomial

'z^6 + $z^{\wedge} 5+z^{\wedge} 2+z+1$ (default)| polynomial character vector | binary row vector | integer row vector

Second sequence polynomial, specified in one of these forms.

- A polynomial character vector such as 'z^3 + $z^{\wedge} 2+1$.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial. For example, $\left[\begin{array}{lll}1 & 1 & 0\end{array} 1\right]$ represents the polynomial $x^{3}+z^{2}+1$.
- An integer row vector containing the exponents of $z$ for the nonzero terms in the polynomial in descending order. For example, [3 240 ] represents the polynomial $z^{3}+z^{2}+1$.

For more information, see "Character Representation of Polynomials".

## Initial states (2) - Initial states for second sequence polynomial

[0 0 0 0 0 1] (default) | binary vector
Initial states of the shift register for second sequence polynomial of the preferred pair, specified as a binary vector with length equal to the degree of Preferred polynomial (2).

## Sequence index - Sequence index

0 (default) | integer scalar in the range [-2, $\left.2^{n}-2\right]$
Sequence index of the output sequence from the set of sequences, specified as an integer scalar in the range $\left[-2,2^{n}-2\right]$. $n$ is the degree of the preferred polynomials.

## Shift - Offset of Gold sequence

0 (default) | integer scalar
Offset of Gold sequence from the initial time, specified as an integer scalar.

```
Output variable-size signals - Output variable-size signals
off (default) | on
```

Select this parameter to permit variable length output sequences during simulation. When set to off, fixed-length sequences are output. When set to on, variable-length sequences can be output. For information about variable-size signals, see "Variable-Size Signal Basics" (Simulink).

## Maximum output size source - Maximum output size source <br> Dialog parameter (default)|Inherit from reference port

Maximum output size source, which indicates how the maximum sequence output size is specified.

- Dialog parameter configures the block to use the Maximum output size parameter setting as the maximum permitted output sequence length. When you make this selection, the oSiz input port specifies the current size of the output signal and the block output inherits sample time from the input signal. The input value of oSiz must be less than or equal to the Maximum output size parameter.
- Inherit from reference port adds the Ref input port and configures the block to inherit the sample time, maximum size, and the current output size from the variable-sized signal at the Ref input port to set the maximum permitted output sequence length.

## Dependencies

To enable this parameter, select Output variable-size signals.

## Maximum output size - Maximum output size

[10 1] (default) | two-element row vector
Maximum output size, specified as a two-element row vector that denotes the maximum output size for the block. The second element of the vector must be 1 .

Example: [10 1] gives a 10-by-1 maximum sized output signal.

## Dependencies

To enable this parameter select Output variable-size signals and set Maximum output size source to Dialog parameter.

Data Types: double

## Sample time - Output sample time

1 (default)
Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1 , the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-368.

## Dependencies

To enable this parameter do not select Output variable-size signals.

## Samples per frame - Samples per frame <br> 1 (default) | positive integer

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-368.

## Dependencies

To enable this parameter do not select Output variable-size signals.

## Reset on nonzero input - Reset output signal

off (default) | on
Select this parameter to enable the Rst port. When a nonzero value is input at the Rst port, the internal shift registers are reset to the original values of the Initial states (1) and Initial states (2) parameters.

## Output data type - Output data type

double (default)| boolean | Smallest unsigned integer
Output data type, specified as boolean, double, or Smallest unsigned integer.
When set to Smallest unsigned integer, the output data type is selected based on the settings used in the "Hardware Implementation Pane" (Simulink) of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is the ideal minimum one-bit size (ufix(1)). For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (uint8).

## Block Characteristics

| Data Types | Boolean \| double | fixed point |
| :--- | :--- |
| Multidimensional <br> Signals | no |

## Variable-Size Signals yes

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10 , then a 10 -by- 1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Gold Sequences

The characteristic cross-correlation properties of Gold sequences make them useful when multiple devices are broadcasting in the same frequency range. The Gold sequences are defined using a specified pair of sequences $u$ and $v$, of period $N=2^{n}-1$, called a preferred pair, as defined in "Preferred Pairs of Sequences" on page 5-371. The set $G(u, v)$ of Gold sequences is defined by

$$
G(u, v)=\left\{u, v, u \oplus v, u \oplus T v, u \oplus T^{2} v, \ldots, u \oplus T^{N-1} v\right\}
$$

where $T$ represents the operator that shifts vectors cyclically to the left by one place, and $\oplus$ represents addition modulo 2. Note that $G(u, v)$ contains $N+2$ sequences of period $N$. The Gold Sequence Generator block outputs one Gold sequence according to the configured parameters and inputs.

Gold sequences have the property that the cross-correlation between any two, or between shifted versions of them, takes on one of three values: $-t(n),-1$, or $t(n)-2$, where

$$
t(n)=\left\{\begin{array}{l}
1+2^{(n+1) / 2} n \text { even } \\
1+2^{(n+2) / 2} n \text { odd }
\end{array}\right.
$$

The Gold Sequence Generator block uses two PN Sequence Generator blocks to generate the preferred pair of sequences, and then XORs these sequences to produce the output sequence, as shown in the following diagram.

You can specify the preferred pair by the Preferred polynomial (1) and Preferred polynomial (2) parameters in the dialog for the Gold Sequence Generator block. These polynomials, both of which must have degree $n$, describe the shift registers that the PN Sequence Generator blocks use to generate their output. For more details on how these sequences are generated, see the reference
page for the PN Sequence Generator block. You can specify the preferred polynomials using these formats:

- A polynomial character vector that includes the number 1 , for example, ' $z^{\wedge} 4+z+1$ '.
- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1 . Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 .

For example, the polynomial $z^{5}+z^{2}+1$ can be represented by the character vector ' $z^{\wedge} 5+z^{\wedge} 2+$ $1^{\prime}$, the vector $\left[\begin{array}{lll}5 & 2 & 0\end{array}\right]$, and the vector $\left[\begin{array}{lllll}1 & 0 & 0 & 1 & 0\end{array}\right]$.

The following table provides a short list of preferred pairs.

| n | N | Preferred Polynomial (1) | Preferred Polynomial (2) |
| :---: | :---: | :---: | :---: |
| 5 | 31 | [5 200$]$ | $\left[\begin{array}{lllll}5 & 4 & 3 & 2 & 0\end{array}\right]$ |
| 6 | 63 | $\left[\begin{array}{lll}6 & 1 & 0\end{array}\right]$ | $\left[\begin{array}{lllll}6 & 5 & 2 & 1 & 0\end{array}\right]$ |
| 7 | 127 | $\left[\begin{array}{lll}7 & 3 & 0\end{array}\right]$ | [ $\left.\begin{array}{llllll}7 & 3 & 2 & 1 & 0\end{array}\right]$ |
| 9 | 511 | $\left[\begin{array}{llll}9 & 4 & 0\end{array}\right]$ | [9 $\left.964 \begin{array}{llll} & 4 & 0\end{array}\right]$ |
| 10 | 1023 | $\left[\begin{array}{lll}10 & 3 & 0\end{array}\right]$ | $\left[\begin{array}{lllll}10 & 8 & 3 & 2 & 0\end{array}\right]$ |
| 11 | 2047 | [11 200$]$ | $\left[\begin{array}{lllll}11 & 8 & 5 & 2 & 0\end{array}\right]$ |

The Initial states (1) and Initial states (2) parameters are vectors specifying the initial values of the registers corresponding to Preferred polynomial (1) and Preferred polynomial (2), respectively. These parameters must satisfy these criteria:

- All elements of the Initial states (1) and Initial states (2) vectors must be binary numbers.
- The length of the Initial states (1) vector must equal the degree of the Preferred polynomial (1), and the length of the Initial states (2) vector must equal the degree of the Preferred polynomial (2).

Note At least one element of the initial states vectors ( Initial states (1) or Initial states (2)) must be nonzero in order for the block to generate a nonzero sequence. Specifically, the initial state of at least one of the registers must be nonzero.

The Sequence index parameter specifies which Gold sequence in the set $G(u, v)$ is output. The range of Sequence index is $\left[-2,-1,0,1,2, \ldots, 2^{\mathrm{n}}-2\right]$, where $n$ is the degree of the generator polynomials specified by the Preferred polynomial (1) and Preferred polynomial (2) parameters. This table shows the correspondence between Sequence index and the output sequence.

| Sequence Index | Output Sequence |
| :--- | :--- |
| -2 | $u$ |
| -1 | $v$ |
| 0 | $u \oplus v$ |
| 1 | $u \oplus T v$ |

| Sequence Index | Output Sequence |
| :--- | :--- |
| 2 | $u \oplus T^{2} v$ |
| $\ldots$ | $\ldots$ |
| $2^{\mathrm{n}}-2$ | $u \oplus T^{2^{n}-2} v$ |

$T$ represents the operator that shifts vectors cyclically to the left by one place, and $\oplus$ represents addition modulo 2 .

You can shift the starting point of the Gold sequence with the Shift parameter, which is an integer representing the length of the shift.

You can use an external signal to reset the values of the internal shift register to the initial state by selecting Reset on nonzero input. This creates an input port for the external signal in the Gold Sequence Generator block. The way the block resets the internal shift register depends on whether its output signal and the reset signal are scalar or vector. For more information, see "Reset Behavior" on page 5-370.

## Reset Behavior

To reset the generator sequence, you must first select Reset on nonzero input to add the Rst input.
 reset. The following table shows the effect on the Gold Sequence Generator block output for the property values indicated.

|  | Reset Signal Properties | Gold Sequence Generator block | Reset Signal Output Signal |
| :---: | :---: | :---: | :---: |
| No reset |  |  | Rat 0 0 0 0 0 0 0 0 <br> Out 1 0 0 1 1 0 1 1 |
| Scalar reset signal |  | $\begin{aligned} & \text { Sample time = 1 } \\ & \text { Samples per } \\ & \text { frame = 1 } \end{aligned}$ |  |
| Vector reset signal | $\begin{aligned} & \text { Sample time }=1 \\ & \begin{array}{l} \text { Samples per } \\ \text { frame }=8 \end{array} \\ & \begin{array}{l} \text { Rst }=\left[\begin{array}{lllll} 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right] \end{array} \end{aligned}$ | $\begin{aligned} & \text { Sample time = } 1 \\ & \text { Samples per } \\ & \text { frame = 8 } \end{aligned}$ |  |

For the no reset case, the sequence is output without being reset. For the scalar and vector reset signal cases, the reset signal [00010000] is input to the Rst port. The sequence output is reset at the fourth bit, because the fourth bit of the reset signal is a 1 and the Sample time is 1 .

For variable-sized outputs, the block only supports scalar reset signal inputs.
The "Gold Sequence Generator Reset Behavior" example demonstrates the reset behavior in a Simulinkmodel.

## Preferred Pairs of Sequences

The requirements for a pair of sequences $u, v$ of period $N=2^{n}-1$ to be a preferred pair are as follows:

- $n$ is not divisible by 4
- $v=u[q]$, where
- $q$ is odd
- $q=2^{k}+1$ or $q=2^{2 k}-2^{k}+1$
- $v$ is obtained by sampling every $q$ th symbol of $u$
- $\operatorname{gcd}(n, k)=\left\{\begin{array}{l}1 \quad n \equiv 1 \bmod 2 \\ 2 n \equiv 2 \bmod 4\end{array}\right.$

## Compatibility Considerations

## Existing models automatically update this block to current version

Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the Gold Sequence Generator block version available before R2015b.

Existing models automatically update to load the Gold Sequence Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes. For more information on block forwarding, see "Forwarding Tables" (Simulink).

## Hadamard Code Generator

Generate Hadamard code from orthogonal set of codes
Hadamard
Code Generator

## Library

Sequence Generators sublibrary of Comm Sources

## Description

The Hadamard Code Generator block generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. Orthogonal codes can be used for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, as the codes are decorrelated completely.

The Hadamard codes are the individual rows of a Hadamard matrix. Hadamard matrices are square matrices whose entries are +1 or -1 , and whose rows and columns are mutually orthogonal. If $N$ is a nonnegative power of 2 , the $N$-by- $N$ Hadamard matrix, denoted $H_{\mathrm{N}}$, is defined recursively as follows.

$$
\begin{gathered}
H_{1}=[1] \\
H_{2 N}=\left[\begin{array}{cc}
H_{N} & H_{N} \\
H_{N} & -H_{N}
\end{array}\right]
\end{gathered}
$$

The N-by-N Hadamard matrix has the property that

$$
H_{\mathrm{N}} H_{\mathrm{N}}{ }^{\mathrm{T}} \quad=\quad N I_{\mathrm{N}}
$$

where $I_{\mathrm{N}}$ is the $N$-by- $N$ identity matrix.
The Hadamard Code Generator block outputs a row of $H_{\mathrm{N}}$. The output is bipolar. You specify the length of the code, $N$, by the Code length parameter. The Code length must be a power of 2 . You specify the index of the row of the Hadamard matrix, which is an integer in the range $[0,1, \ldots, N-1]$, by the Code index parameter.

## Parameters

## Code length

A positive integer that is a power of two specifying the length of the Hadamard code.

## Code index

An integer between 0 and $N-1$, where $N$ is the Code length, specifying a row of the Hadamard matrix.

## Sample time

Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1 , the sample time is inherited from
downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-376.

## Samples per frame

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-376.

## Output data type

The output type of the block can be specified as an int8 or double. By default, the block sets this to double.

## Simulate using

Select the simulation mode.
Code generation
On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects corresponding to the blocks accept a maximum of nine inputs.
Interpreted execution
Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## Examples

## Orthogonal Spreading - Single-User vs. Two-User Comparison

This example model compares a single-user system vs. a two-user data transmission system with the two data streams being independently spread by different orthogonal codes.

The model uses random binary data which is BPSK modulated (real), spread by Hadamard codes of length 64 and then transmitted over an AWGN channel. The receiver consists of a despreader followed by a BPSK demodulator. Open the model here: hadamard_block_example1.

```
modelname = 'hadamard_block_example1';
open_system(modelname);
sim(modelname);
```

For the same data and channel settings, the model calculates the performance for one- and two-user transmissions.

Note that for the individual users, the error rates are exactly the same in both cases. This shows that perfect despreading is possible due to the ideal cross-correlation properties of the Hadamard codes.

To experiment with this model further, specify a different Code length or Code index for the individual users to examine the variations in relative performance.
close_system(modelname, 0);

## Orthogonal Spreading - Multipath Scenario

This example model considers a single-user system in which the signal is transmitted over multiple paths. This is similar to a mobile channel environment where the signals are received over multiple paths, each of which have different amplitudes and delays. To take advantage of the multipath transmission, the receiver employs diversity reception which combines the independent paths coherently.

Note, to keep the system simple, no shadowing effects are considered and the receiver has a priori knowledge of the number of paths and their respective delays. Open the model here: hadamard_block_example2.

```
modelname = 'hadamard_block_example2';
open_system(modelname);
sim(modelname);
```

For the data transmission with the same spreading code that was used in the first example, we now see deterioration in performance when compared with that example (compare the 180 errors with 81 in the previous case). This can be attributed to the non-ideal auto-correlation values of the orthogonal spreading codes chosen, which prevents perfect resolution of the individual paths. Consequently, we don't see the merits of diversity combining.

To experiment with this model further, try selecting other path delays to see how the performance varies for the same code. Also try different codes with the same delays.
close_system(modelname, 0);

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

## Existing models automatically update this block to current version

Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the Hadamard Code Generator block version available before R2015b.

Existing models automatically update to load the Hadamard Code Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the

## Hamming Decoder

Decode Hamming code to recover binary vector data

## Library

Block sublibrary of Error Detection and Correction

## Description

The Hamming Decoder block recovers a binary message vector from a binary Hamming codeword vector. For proper decoding, the parameter values in this block should match those in the corresponding Hamming Encoder block.

If the Hamming code has message length $K$ and codeword length $N$, then $N$ must have the form $2^{\mathrm{M}}-1$ for some integer $M$ greater than or equal to 3 . Also, $K$ must equal $N-M$.

This block accepts a column vector input signal of length $N$. The output signal is a column vector of length $K$.

The coding scheme uses elements of the finite field $\mathrm{GF}\left(2^{\mathrm{M}}\right)$. You can either specify the primitive polynomial that the algorithm should use, or you can rely on the default setting:

- To use the default primitive polynomial, simply enter $N$ and $K$ as the first and second dialog parameters, respectively. The algorithm uses gfprimdf(M) as the primitive polynomial for $\mathrm{GF}\left(2^{\mathrm{M}}\right)$.
- To specify the primitive polynomial, enter $N$ as the first parameter and a binary vector as the second parameter. The vector represents the primitive polynomial by listing its coefficients in order of ascending exponents. You can create primitive polynomials using the Communications Toolbox gfprimfd function.
- In addition, you can specify the primitive polynomial as a character vector, for example, 'D^3 + D + 1'.

For information about the data types each block port supports, see the "Supported Data Type" on page 5-379 table on this page.

## Parameters

## Codeword length $\mathbf{N}$

The codeword length $N$, which is also the input vector length.

## Message length K, or M-degree primitive polynomial

The message length, which is also the input vector length or a binary vector that represents a primitive polynomial for $\mathrm{GF}\left(2^{\mathrm{M}}\right)$ or a polynomial character vector.

## Helical Deinterleaver

Restore ordering of symbols permuted by helical interleaver

Deinterleaver

## Library

Convolutional sublibrary of Interleaving

## Description

The Helical Deinterleaver block permutes the symbols in the input signal by placing them in an array row by row and then selecting groups in a helical fashion to send to the output port.

The block uses the array internally for its computations. If $C$ is the Number of columns in helical array parameter, then the array has $C$ columns and unlimited rows. If $N$ is the Group size parameter, then the block accepts an input of length $C \cdot N$ at each time step and inserts them into the next $N$ rows of the array. The block also places the Initial condition parameter into certain positions in the top few rows of the array (not only to accommodate the helical pattern but also to preserve the vector indices of symbols that pass through the Helical Interleaver and Helical Deinterleaver blocks in turn).

The output consists of consecutive groups of $N$ symbols. Counting from the beginning of the simulation, the block selects the kth output group in the array from column $k \bmod C$. The selection is helical because of the reduction modulo C and because the first symbol in the $k^{\text {th }}$ group is in row $1+$ $(k-1) *$ s, where $s$ is the Helical array step size parameter.

This block accepts a column vector input signal containing $C \cdot N$ elements.
The block can accept the data types int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The data type of this output will be the same as that of the input signal.

## Delay of Interleaver-Deinterleaver Pair

After processing a message with the Helical Interleaver block and the Helical Deinterleaver block, the deinterleaved data lags the original message by

$$
C N\left\lceil\frac{s(C-1)}{N}\right\rceil
$$

samples. Before this delay elapses, the deinterleaver output is either the Initial condition parameter in the Helical Deinterleaver block or the Initial condition parameter in the Helical Interleaver block.

If your model incurs an additional delay between the interleaver output and the deinterleaver input, then the restored sequence lags the original sequence by the sum of the additional delay and the amount in the formula above. For proper synchronization, the delay between the interleaver and
deinterleaver must be m• $C \cdot N$ for some nonnegative integer $m$. You can use the DSP System Toolbox Delay block to adjust delays manually, if necessary.

## Parameters

## Number of columns in helical array

The number of columns, $C$, in the helical array.

## Group size

The size, $N$, of each group of symbols. The input width is $C$ times $N$.

## Helical array step size

The number of rows of separation between consecutive output groups as the block selects them from their respective columns of the helical array.

## Initial conditions

A scalar that fills the array before the first input is placed.

## Pair Block

Helical Interleaver

## Description

The Helical Interleaver block permutes the symbols in the input signal by placing them in an array in a helical fashion and then sending rows of the array to the output port.

The block uses the array internally for its computations. If $C$ is the Number of columns in helical array parameter, then the array has $C$ columns and unlimited rows. If $N$ is the Group size parameter, then the block accepts an input of length $C \cdot N$ at each time step and partitions the input into consecutive groups of $N$ symbols. Counting from the beginning of the simulation, the block places the $k^{\text {th }}$ group in the array along column $k \bmod C$. The placement is helical because of the reduction modulo $C$ and because the first symbol in the $k^{\text {th }}$ group is in row $1+(k-1) \cdot s$, where $s$ is the Helical array step size parameter. Positions in the array that do not contain input symbols have default contents specified by the Initial condition parameter.

The block sends $C \cdot N$ symbols from the array to the output port by reading the next $N$ rows sequentially. At a given time step, the output symbols might be the Initial condition parameter value, symbols from that time step's input vector, or symbols left in the array from a previous time step.

This block accepts a column vector input signal containing $C \cdot N$ elements.
The block can accept the data types int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The data type of this output will be the same as that of the input signal.

## Parameters

## Number of columns in helical array

The number of columns, $C$, in the helical array.

## Group size

The size, N , of each group of input symbols. The input width is C times N .

## Helical array step size

The number of rows of separation between consecutive input groups in their respective columns of the helical array.

## Initial conditions

A scalar that fills the array before the first input is placed.

## Examples

Suppose that $C=3, N=2$, the Helical array step size parameter is 1 , and the Initial condition parameter is -1. After receiving inputs of [1:6]', [7:12]', and [13:18]', the block's internal array looks like the schematic below. The coloring of the inputs and the array indicate how the input symbols are placed within the array. The outputs at the first three time steps are
[1; -1; -1; 2; 3; -1], [7; 4; 5; 8; 9; 6], and [13; 10; 11; 14; 15; 12]. (The outputs are not color-coded in the schematic.)

# Ideal Rectangular Pulse Filter 

Shape input signal using ideal rectangular pulses

## Library

Comm Filters

## Description

The Ideal Rectangular Pulse Filter block upsamples and shapes the input signal using rectangular pulses. The block replicates each input sample N times, where N is the Pulse length parameter. After replicating input samples, the block can also normalize the output signal and/or apply a linear amplitude gain.

If the Pulse delay parameter is nonzero, then the block outputs that number of zeros at the beginning of the simulation, before starting to replicate any of the input values.

This block accepts a scalar, column vector, or matrix input signal. For information about the data types each block port supports, see the "Supported Data Type" on page 5-389 table on this page.

The vector size, the pulse length, and the pulse delay are mutually independent. They do not need to satisfy any conditions with respect to each other.

## Single-Rate Processing

When you set the Rate options parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To generate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output $\left(M_{o}\right)$ is $L$ times larger than that of the input $\left(M_{o}=M_{i}{ }^{*} L\right)$, where $L$ is the Pulse length (number of samples) parameter value.

## Multirate Processing

When you set the Rate options parameter to Allow multirate processing, the input and output of the block are the same size. However, the sample rate of the output is $L$ times faster than that of the input (i.e. the output sample time is $1 / \mathrm{N}$ times the input sample time). When the block is in multirate processing mode, you must also specify a value for the Input processing parameter:

- When you set the Input processing parameter to Elements as channels (sample based), the block treats an $M$-by- $N$ matrix input as $M^{*} N$ independent channels, and processes each channel over time. The output sample period ( $T_{s o}$ ) is $L$ times shorter than the input sample period ( $T_{s o}=T_{s i} / L$ ), while the input and output sizes remain identical.
- When you set the Input processing parameter to Columns as channels (frame based), the block treats an $M_{i}$-by- $N$ matrix input as $N$ independent channels. The block processes each column of the input over time by keeping the frame size constant $\left(M_{i}=M_{o}\right)$, while making the output frame $\operatorname{period}\left(T_{f o}\right) L$ times shorter than the input frame period $\left(T_{f o}=T_{f i} / L\right)$.

## Normalization Methods

You determine the block's normalization behavior using the Normalize output signal and Linear amplitude gain parameters.

- If you clear Normalize output signal, then the block multiplies the set of replicated values by the Linear amplitude gain parameter. This parameter must be a scalar.
- If you select Normalize output signal, then the Normalization method parameter appears. The block scales the set of replicated values so that one of these conditions is true:
- The sum of the samples in each pulse equals the original input value that the block replicated.
- The energy in each pulse equals the energy of the original input value that the block replicated. That is, the sum of the squared samples in each pulse equals the square of the input value.

After the block applies the scaling specified in the Normalization method parameter, it multiplies the scaled signal by the constant scalar value specified in the Linear amplitude gain parameter.

The output is scaled by $\sqrt{N}$. If the output of this block feeds the input to the AWGN Channel block, specify the AWGN signal power parameter to be $1 / \mathrm{N}$.

## Parameters

## Pulse length (number of samples)

The number of samples in each output pulse; that is, the number of times the block replicates each input value when creating the output signal.

## Pulse delay (number of samples)

The number of zeros that appear in the output at the beginning of the simulation, before the block replicates any input values.

## Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- Columns as channels (frame based) - When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) - When you select this option, the block treats each element of the input as a separate channel.

## Rate options

Specify the method by which the block should upsample and shape the input signal. You can select one of the following options:

- Enforce single-rate processing - When you select this option, the block maintains the input sample rate, and processes the signal by increasing the output frame size by a factor of L. To select this option, you must set the Input processing parameter to Columns as channels (frame based).
- Allow multirate processing - When you select this option, the block processes the signal such that the output sample rate is $L$ times faster than the input sample rate.

## Normalize output signal

If you select this, then the block scales the set of replicated values before applying the linear amplitude gain.

## Normalization method

The quantity that the block considers when scaling the set of replicated values. Choices are Sum of samples and Energy per pulse. This field appears only if you select Normalize method.

## Linear amplitude gain

A positive scalar used to scale the output signal.

## Rounding mode

Use this parameter to specify the rounding method to be used when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to Nearest.

For more information, see Rounding Modes (DSP System Toolbox) or "Rounding Mode: Simplest" (Fixed-Point Designer).

## Saturate on integer overflow

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

## Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See "Filter Structure Diagrams" (DSP System Toolbox) in DSP System Toolbox Reference Guide for illustrations depicting the use of the coefficient data types in this block:

- When you select Same word length as input, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Specify word length, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the Rounding mode and the Saturate on integer overflow parameters; they are always saturated and rounded to Nearest.

## Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) in DSP System Toolbox Reference Guide for illustrations depicting the use of the product output data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

## Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as product output, these characteristics match those of the product output.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

## Output

Choose how you specify the output word length and fraction length:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as accumulator, these characteristics match those of the accumulator.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

## Lock scaling against changes by the autoscaling tool

Select this check box to prevent any fixed-point scaling you specify in the block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Supported Data Type

| Port | Supported Data Types |
| :--- | :--- |
| In | • Double-precision floating point <br>  <br>  <br>  <br> Out Single-precision floating point <br> $\quad$• Fixed-point |

## Examples

If Pulse length is 4 and Pulse delay is the scalar 3, then the table below shows how the block treats the beginning of a ramp ( $1,2,3, \ldots$ ) in several situations. (The values shown in the table do not reflect vector sizes but merely indicate numerical values.)

| Normalization Method, If Any | Linear Amplitude Gain | First Several Output Values |
| :---: | :---: | :---: |
| None (Normalize output signal cleared) | 1 | $\begin{aligned} & 0,0,0,1,1,1,1,2,2,2,2,3,3, \\ & 3,3, \ldots \end{aligned}$ |
| None (Normalize output signal cleared) | 10 | $\begin{aligned} & 0,0,0,10,10,10,10,20,20, \\ & 20,20,30,30,30,30, \ldots \end{aligned}$ |
| Sum of samples | 1 | $\begin{aligned} & 0,0,0,0.25,0.25,0.25, \\ & 0.25,0.5,0.5,0.5,0.5 \\ & 0.75,0.75,0.75,0.75, \ldots, \\ & \text { where } 0.25 * 4=1 \end{aligned}$ |
| Sum of samples | 10 | $\begin{aligned} & 0,0,0,2.5,2.5,2.5,2.5,5, \\ & 5,5,5,7.5,7.5,7.5,7.5, \ldots \end{aligned}$ |
| Energy per pulse | 1 | $\begin{aligned} & 0,0,0,0.5,0.5,0.5,0.5, \\ & 1.0,1.0,1.0,1.0,1.5,1.5 \\ & 1.5,1.5, \ldots, \text { where } \\ & (0.5)^{\wedge} 2^{*} 4=1 \wedge 2 \end{aligned}$ |
| Energy per pulse | 10 | $\begin{aligned} & 0,0,0,5,5,5,5,10,10,10, \\ & 10,15,15,15,15, \ldots \end{aligned}$ |

## Insert Zero

(To be removed) Distribute input elements in output vector

Note will be removed in a future release. Use MATLAB ${ }^{\circledR}$ code in a MATLAB Function block instead. For more information, see "Compatibility Considerations".

## Insert Zero

## Library

Sequence Operations

## Description

The Insert Zero block constructs an output vector by inserting zeros among the elements of the input vector. The input signal can be real or complex. Both the input signal and the Insert zero vector parameter are column vector signals. The number of 1 s in the Insert zero vector parameter must be evenly divisible by the input data length. If the input vector length is greater than the number of 1 s in the Insert zero vector parameter, then the block repeats the insertion pattern until it has placed all input elements in the output vector.

The block determines where to place the zeros by using the Insert zero vector parameter.

- For each 1 the block places the next element of the input vector in the output vector
- For each 0 the block places a 0 in the output vector

The block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

To implement punctured coding using the Puncture and Insert Zero blocks, use the same vector for the Insert zero vector parameter in this block and for the Puncture vector parameter in the Puncture block.

## Parameters

## Insert zero vector

A binary vector with a pattern of 0 s and 1 s that indicate where the block places either 0 s or input vector elements in the output vector.

## Compatibility Considerations

## Insert Zero will be removed

Not recommended starting in R2020a

- Insert Zero will be removed in a future release. Use MATLAB code in a MATLAB Function block instead.
- This code can be used in a MATLAB Function block to insert zeros into a data stream.

```
function y = fcn(u,insertZeroVector)
    numSeg = length(u)/sum(insertZeroVector);
    c = zeros(length(insertZeroVector), numSeg,'like',u);
    c(logical(insertZeroVector),:) = reshape(u,[],numSeg);
    y = c(:);
end
```

As with Insert Zero, the input length must be an integer multiple of the number of ones in the Insert zero vector parameter.

- For an example using this code, see "Insert Zeros into a Random Number Stream".

## Integer-Input RS Encoder

Create Reed-Solomon code from integer vector data

$$
\text { Library: } \begin{aligned}
& \text { Communications Toolbox / Error Detection and Correction / } \\
& \text { Block }
\end{aligned}
$$

## Description

The Integer-Input RS Encoder block creates a Reed-Solomon code.
The symbols for the code are integers between 0 and $2^{M}-1$, which represent elements of the finite field $G F\left(2^{M}\right)$. The default value of $M$ is the smallest integer that is greater than or equal to $\log 2(N+1)$, that is, ceil $(\log 2(N+1))$. You can change the default value of $M$ by specifying the primitive polynomial for $G F\left(2^{M}\right)$, as described in "Specify the Primitive Polynomial" on page 5-397 below. Restrictions on $M$ and $N$ are described in "Restrictions on M and the Codeword Length N " on page 5397.

The input and output are integer-valued signals that represent messages and codewords, respectively. For more information, see "Input and Output Signal Length in RS Blocks" on page 5-396.

An $(N, K)$ Reed-Solomon code can correct up to floor ( $(N-K) / 2)$ symbol errors (not bit errors) in each codeword.

Suppose $\mathrm{M}=3, \mathrm{~N}=2^{3}-1=7$, and $\mathrm{K}=5$. Then a message is a vector of length 5 whose entries are integers between 0 and 7. A corresponding codeword is a vector of length 7 whose entries are integers between 0 and 7. The following figure illustrates possible input and output signals to this block when Codeword length $\mathbf{N}$ is set to 7 , Message length $\mathbf{K}$ is set to 5 , and the default primitive and generator polynomials are used.

## Ports

## Input

## In - Message

integer column vector
Message, specified as one of the following:

- When there is no message shortening, a ( $N_{\mathrm{C}} \times K$ )-by-1 integer column vector.
- When there is message shortening, a ( $N_{\mathrm{C}} \times S$ )-by-1 integer column vector.
$N_{\mathrm{C}}$ is the number of message words, $K$ is the Message length $K$, and $S$ is the Shortened message length $S$.

Note The number of decoded message words equals the number of codewords.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-396.
Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 |uint32

## Output

## Out - Reed-Solomon codeword

integer column vector
Reed-Solomon codeword, returned as an $\left(N_{\mathrm{C}} \times(N-K+S-P)\right.$-by- 1 integer column vector. $N_{\mathrm{C}}$ is the number of codewords, $N$ is the Codeword length $\mathbf{N}, K$ is the Message length $K, S$ is the Shortened message length $\mathbf{S}, P$ is the number of punctures per codeword.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-396.
Data Types: single | double | int8 | int16|int32 |uint8|uint16|uint32
For more information, see "Supported Data Types" on page 5-398.

## Parameters

Codeword length N - Codeword length
7 (default) | integer
Codeword length, specified as an integer.
For more information, see "Restrictions on M and the Codeword Length N" on page 5-397 and "Input and Output Signal Length in RS Blocks" on page 5-396.

Message length $K$ - Message word length
3 (default) | integer
Message word length, specified as an integer in the range [1, $N-2$ ], where $N$ is the codeword length.

## Shortened message length S - Shortened message word length

3 (default) | integer
Shortened message word length, specified as an integer, such that $S \leq K$. When Shortened message length $\mathbf{S}$ < Message length $K$, the Reed-Solomon code is shortened.

You still specify $N$ and $K$ values for the full-length ( $N, K$ ) code but the decoding is shortened to an ( $N$ $K+S, S$ ) code.

Dependencies
To enable this parameter, select Specify shortened message length.

## Generator polynomial - Generator polynomial

rsgenpoly(7, 3, [], [], 'double') (default)| polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values in the range [ 0 to $2^{M}-1$ ], in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see "Specify the Generator Polynomial" on page 5-397.
Example: $\left[\begin{array}{lllll}1 & 3 & 1 & 2 & 3\end{array}\right]$, which is equivalent to $\operatorname{rsgenpoly}(7,3)$

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Primitive polynomial - Primitive polynomial

```
'X^3 + X + 1' (default)| polynomial character vector | binary row vector
```

Primitive polynomial in order of descending power. This polynomial is of order $M$ and defines the finite Galois field $\mathrm{GF}\left(2^{\mathrm{M}}\right)$ corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see "Specify the Primitive Polynomial" on page 5-397.
Example: ' $X^{\wedge} 3+X+1$ ', which is the primitive polynomial used for a $(7,3)$ code, de2bi(primpoly(3,'nodisplay'),'left-msb')

## Dependencies

To enable this parameter, select Specify primitive polynomial.

## Puncture vector - Puncture vector

[ones (2,1) ; zeros(2,1)] (default) | binary column vector
Puncture vector, specified as an ( $N-K$ )-by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see "Puncturing and Erasures" on page 5-398.

Note If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

## Dependencies

To enable this parameter, select Puncture code.

## Block Characteristics

| Data Types | double $\mid$ integer $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length, $K$, or shortened message word length, $S$. The codeword length is $N-K+S-P$, where $N$ is the full codeword length and $P$ is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N-P$, because $K=S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y=N_{\mathrm{C}} \times x$ denotes that $y$ is an integer multiple of $x$.

|  | Input, Erasure, and Output Vector Lengths |  |
| :--- | :--- | :--- |
| RS Block Coder | No Message Shortening Used | Message Shortening Used |
| Integer-Input RS Encoder | Input Length (symbols): | Input Length (symbols): |
|  | $N_{\mathrm{C}} \times K$ | $N_{\mathrm{C}} \times S$ |
|  | Output Length (symbols): | Output Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
| Integer-Output RS Decoder | Input Length (symbols): | Input Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
|  | Erasures Length (symbols): | Erasures Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
|  | Output Length (symbols): | Output Length (symbols): |
|  | $N_{\mathrm{C}} \times K$ | $N_{\mathrm{C}} \times S$ |

- $N$ is the codeword length.
- $K$ is the message word length.
- $S$ is the shortened message word length.
- $\quad N_{\mathrm{C}}$ is the number of codewords (and message words).
- $P$ is the number of punctures, and is equal to the number of zeros in the puncture vector.
- $M$ is the degree of the primitive polynomial. Each group of $M$ bits represents an integer between 0 and $2^{M}-1$ that belongs to the finite Galois field GF $\left(2^{M}\right)$.

For more information on representing data for Reed-Solomon codes, see "Integer Format (ReedSolomon Only)".

## Restrictions on M and the Codeword Length N

- If you do not select Specify primitive polynomial, valid values for the codeword length, $N$, are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree $M=$ ceil ( $\log 2(N+1))$. You can display the default primitive polynomial by running primpoly(ceil(log2(N+1))).
- If you select Specify primitive polynomial, valid values for the primitive polynomial degree, $M$, are from 3 to 16. The valid values for $N$ in this case are from 7 to $2^{M}-1$. Selecting Specify primitive polynomial enables you to specify the primitive polynomial that defines the finite field $G F\left(2^{M}\right)$, which corresponds to the values that form message words and codewords.

## Specify the Primitive Polynomial

You can specify the primitive polynomial that defines the finite field $G F\left(2^{M}\right)$, corresponding to the integers that form messages and codewords. To do so, first select Specify primitive polynomial. Then, in the Primitive polynomial text box, enter a binary row vector that represents a primitive polynomial over $G F\left(2^{M}\right)$, in descending order of powers. For example, to specify the polynomial $x^{3}+x$ +1 , enter the vector $\left[\begin{array}{llll}1 & 0 & 1 & 1\end{array}\right]$.

If you do not select Specify primitive polynomial, the block uses the default primitive polynomial of degree $M=$ ceil(log2(N+1)). You can display the default polynomial by entering primpoly (ceil( $\log 2(N+1))$ ) at the MATLAB prompt.

## Specify the Generator Polynomial

Select Specify generator polynomial to enable the Generator polynomial parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to $2^{M}-1$. The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $G F\left(2^{M}\right)$ represented in integer format. For more information about integer and binary format, see "Integer Format (Reed-Solomon Only)". The generator polynomial must be equal to a polynomial with this factored form:
$\mathrm{g}(\mathrm{x})$

$$
=\quad\left(\mathrm{x}+\alpha^{\mathrm{b}}\right)\left(\mathrm{x}+\alpha^{\mathrm{b}+1}\right)\left(\mathrm{x}+\alpha^{\mathrm{b}+2}\right) \ldots\left(\mathrm{x}+\alpha^{\mathrm{b}+\mathrm{N}-\mathrm{K}-1}\right)
$$

$\alpha$ is the primitive element of the Galois field over which the input message is defined, and $b$ is an integer.

If you do not select Specify generator polynomial, the block uses the default generator polynomial, corresponding to $b=1$, for Reed-Solomon encoding. You can display the default generator polynomial by running rsgenpoly.

- If you are using the default primitive polynomial (Specify primitive polynomial is not selected), the default generator polynomial is rsgenpoly $(N, K)$, where $N=2^{\mathrm{M}}$ - 1 .
- If you are not using the default primitive polynomial (Specify primitive polynomial is selected) and you specify the primitive polynomial as poly, the generator polynomial is rsgenpoly (N, K, poly).

Note The degree of the generator polynomial is $N-K$, where $N$ is the codeword length and $K$ is the message word length.

## Puncturing and Erasures

1 s and 0 s have precisely opposite meanings for the puncture and erasure vectors.
In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see "Shortening, Puncturing, and Erasures".

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Single-precision floating point <br> - 8-, 16-, and 32 -bit signed integers <br> - $8-, 16$-, and 32 -bit unsigned integers |
| Out | - Double-precision floating point <br> - Single-precision floating point <br> - $8-, 16$-, and 32 -bit signed integers <br> - $8-, 16$-, and 32 -bit unsigned integers |

## Integer-Input RS Encoder HDL Optimized

Encode data using a Reed-Solomon encoder

Library: Communications Toolbox HDL Support / Error Detection and Correction / Block Communications Toolbox / Error Detection and Correction / Block

## Description

The Integer-Intput RS Encoder HDL Optimized decodes data using RS encoder. The RS encoding follows the same standards as any other cyclic redundancy code. Use this block to model communications system forward error correction (FEC) codes.

For more about the RS encoder, see the Integer-Input RS Encoder block. For more information on representing data for RS codes, see "Integer Format (Reed-Solomon Only)"..

## Ports

## Input

dataIn - Input data
scalar
Input data, specified as a scalar representing one symbol. For binary point scaling, the input data type must be an integer or fixdt. The word length of each symbol must be equal to ceil $\left(\log _{2}(\right.$ Codeword length (N) $)+1$. The double data type is allowed for simulation, but not for HDL code generation.
Data Types: double|int8|int16|int32|int64|fixed point

## startIn - Start of input frame indicator

Boolean scalar
Start of input frame indicator, specified as a Boolean scalar.
Data Types: Boolean
endIn - End of input frame indicator
Boolean scalar
End of input frame indicator, specified as a Boolean scalar.
Data Types: Boolean
validIn - Valid input data indicator
Boolean scalar
Valid input data indicator, specified as a Boolean scalar.
This is a control signal that indicates if the data on the dataIn port is valid.
Data Types: Boolean

## Output <br> data0ut - Output data

scalar
Output data, returned as a scalar. This output data width is the same size as the input data.
Data Types: double|int8|int16|int32|int64|fixed point

## start0ut - Start of output frame indicator

Boolean scalar
Start of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## endOut - End of output frame indicator

Boolean scalar
End of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## validOut - Valid output data indicator

Boolean scalar
Valid output data indicator, returned as a Boolean scalar.
This is a control signal that indicates if the data on the dataOut port is valid.
Data Types: Boolean

## Parameters

## Codeword length - Length of codeword

7 (default) | range from 7 to 65, 535
Specify the codeword length.
The codeword length $N$ must be an integer equal to $2^{M}-1$, where $M$ is an integer in the range from 3 to 16. For more information on representing data for RS codes, see "Integer Format (Reed-Solomon Only)".

## Message length - Length of message

3 (default) | positive integer
Specify the length of the message.
For more information on representing data for RS codes, see "Integer Format (Reed-Solomon Only)".
Each input frame, that is, the number of valid data samples between startIn and endIn port values, must contain more than $N-K$ symbols and less than or equal to $K$ symbols. A shortened code is inferred anytime the number of input data samples in a frame is less than $K$.

## Source of primitive polynomial - Primitive polynomial source

Auto (default) | Property

Specify the source of the primitive polynomial.

- Select Auto to specify the primitive polynomial based on the Codeword length (N) parameter value. The degree of the primitive polynomial is calculated as $M=$ ceil $\left(\log _{2}(\right.$ Codeword length (N)). .
- Select Property to specify the primitive polynomial using the Primitive polynomial parameter.

Primitive polynomial - Primitive polynomial provider
[ $\left.1 \begin{array}{llll}1 & 1 & 1\end{array}\right]$ (default) | binary row vector
Specify a binary row vector representing the primitive polynomial in descending order of powers.
For more information on how to specify a primitive polynomial, see "Primitive Polynomials and Element Representations".

## Dependencies

To enable this parameter, set the Source of primitive polynomial parameter to Property.

## Source of puncture pattern - Puncture pattern source

None (default)| Property
Select Property to enable the Puncture pattern vector parameter.

## Puncture pattern vector - Puncture vector

[ones $(2,1)$; zeros $(2,1)$ ] (default) | binary column vector
Specify a column vector of length $N-K$. In a puncture vector, a value of 1 represents that the data symbol passes unaltered. A value of 0 represents that the data symbol is punctured, or removed, from the data stream.

## Dependencies

To enable this parameter, set the Source of puncture pattern parameter to Property.
Source of B, the starting power for roots of the primitive polynomial Starting power for roots of primitive polynomial
Auto (default)| Property
Specify the source of the starting power for roots of the primitive polynomial.

- Select Property to enable the $\mathbf{B}$ value parameter.
- Select Auto, to use the $\mathbf{B}$ value parameter default value of 1 .

B value - Starting exponent of roots
1 (default) | positive integer
The starting exponent of the roots.

## Dependencies

To enable this parameter, set the Source of B, the starting power for roots of the primitive polynomial parameter to Property.

## Algorithms

This figure shows a sample output of the Integer-Input RS Encoder HDL Optimized block with a default configuration.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.
Not recommended for production code.
HDL Code Generation
Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\mathrm{TM}}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

This block has a single, default HDL architecture.
HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |

## Restrictions

- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

## Integer-Output RS Decoder

Decode Reed-Solomon code to recover integer vector data
Library: Communications Toolbox / Error Detection and Correction / Block

## Description

The Integer-Output RS Decoder block recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the parameter values in this block must match those in the corresponding Integer-Input RS Encoder block.

The Reed-Solomon code has message length $K$, and codeword length $N$ - number of punctures. You specify $N$ and $K$ directly in the block dialog. The symbols for the code are integers in the range [0, $\left.2^{M}-1\right]$, which represent elements of the finite field $G F\left(2^{M}\right)$. Restrictions on $M$ and $N$ are described in "Restrictions on the M and the Codeword Length N " on page 5-410 below.

This icon shows optional ports.

The input and output are integer-valued signals that represent codewords and messages, respectively. For more information, see "Input and Output Signal Length in RS Blocks" on page 5-409. The block inherits the output data type from the input data type. For information about the data types each block port supports, see "Supported Data Types" on page 5-411.

For more information on representing data for Reed-Solomon codes, see the section "Integer Format (Reed-Solomon Only)".

If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

The default value of M is ceil $(\log 2(N+1))$, that is, the smallest integer greater than or equal to $\log 2(N+1)$. You can change the value of M from the default by specifying the primitive polynomial for GF $\left(2^{\mathrm{M}}\right)$, as described in "Specify the Primitive Polynomial" on page 5-410 below.

You can also specify the generator polynomial for the Reed-Solomon code, as described in "Specify the Generator Polynomial" on page 5-410.

An ( $N, K$ ) Reed-Solomon code can correct up to floor ( $(N-K) / 2$ ) symbol errors (not bit errors) in each codeword.

If decoding fails, the message portion of the decoder input is returned unchanged as the decoder output.

The sample times of the input and output signals are equal.

## Ports

## Input

## In - Reed-Solomon codeword

integer column vector
Reed-Solomon codeword, specified as an $\left(N_{\mathrm{C}} \times(N-K+S-P)\right.$-by-1 integer column vector. $N_{\mathrm{C}}$ is the number of codewords, $N$ is the Codeword length $\mathbf{N}, K$ is the Message length $K, S$ is the
Shortened message length $\mathbf{S}, P$ is the number of punctures per codeword.
For more information, see "Input and Output Signal Length in RS Blocks" on page 5-409.
Data Types: single | double | integer

## Era - Erasure vector

binary column vector
Erasure vector, specified as a binary column vector input signal with the same size as the input ReedSolomon codeword.

Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased. For more information, see "Puncturing and Erasures" on page 5-411.

Dependencies
To enable this port, select Enable erasures input port.
Data Types: double | Boolean

## Output

Out - Decoded message
integer column vector
Decoded message, returned as one of the following:

- When there is no message shortening, a ( $N_{\mathrm{C}} \times K$ )-by-1 integer column vector.
- When there is message shortening, a ( $N_{\mathrm{C}} \times S$ )-by-1 integer column vector.
$N_{\mathrm{C}}$ is the number of message words, $K$ is the Message length K (symbols), and $S$ is the Shortened message length $S$ (symbols).

Note The number of decoded message words equals the number of codewords.

For more information, see "Input and Output Signal Length in RS Blocks" on page 5-409.

## Err - Decoding errors

## integer vector

Symbol decoding errors, returned as an integer vector with $N_{\mathrm{C}}$ elements, where $N_{\mathrm{C}}$ is the number of codewords. This port indicates the number of symbol errors detected during decoding of each codeword. A negative integer indicates that the block detected more errors than it could correct by using the specified coding scheme.

Note An ( $N, K$ ) Reed-Solomon code can correct up to floor ( ( $N-K$ ) /2) symbol errors (not bit errors) in each codeword. When a received codeword contains more than ( $N-K$ )/2 symbol errors, a decoding failure occurs.

## Dependencies

To enable this port, select Output number of corrected symbol errors.

## Data Types: double

For more information, see "Supported Data Types" on page 5-411.

## Parameters

## Codeword length N - Codeword length

7 (default) | integer
Codeword length, specified as an integer.
For more information, see"Restrictions on the M and the Codeword Length N" on page 5-410 and "Input and Output Signal Length in RS Blocks" on page 5-409.

## Message length K - Message word length

3 (default) | integer
Message word length, specified as an integer in the range [1, $N-2$ ], where $N$ is the codeword length.

## Shortened message length S-Shortened message word length <br> 3 (default) | integer

Shortened message word length, specified as an integer, such that $S \leq K$. When Shortened message length $\mathbf{S}$ < Message length $K$, the Reed-Solomon code is shortened.

You still specify $N$ and $K$ values for the full-length ( $N, K$ ) code but the decoding is shortened to an ( $N$ $K+S, S$ ) code.

## Dependencies

To enable this parameter, select Specify shortened message length.

## Generator polynomial - Generator polynomial

rsgenpoly(7, 3, [], [], 'double') (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial with values in the range [ $\left.0,2^{M}-1\right]$, in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see "Specify the Generator Polynomial" on page 5-397.

Example: [ $\left.\begin{array}{lllll}1 & 3 & 1 & 2 & 3\end{array}\right]$, which is equivalent to $\operatorname{rsgenpoly}(7,3)$

## Dependencies

To enable this parameter, select Specify generator polynomial.

## Primitive polynomial - Primitive polynomial

' $X^{\wedge} 3+X+1$ (default) | polynomial character vector $\mid$ binary row vector
Primitive polynomial in order of descending power. This polynomial is of order $M$ and defines the finite Galois field $\mathrm{GF}\left(2^{\mathrm{M}}\right)$ corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see "Character Representation of Polynomials".
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see "Specify the Primitive Polynomial" on page 5-397.
Example: ' $\mathrm{X}^{\wedge} 3+X+1$ ', which is the primitive polynomial used for a $(7,3)$ code, de2bi(primpoly(3,'nodisplay'),'left-msb')

## Dependencies

To enable this parameter, select Specify primitive polynomial.

## Puncture vector - Puncture vector

```
[ones(2,1); zeros(2,1)] (default)| binary column vector
```

Puncture vector, specified as an ( $N-K$ )-by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see "Puncturing and Erasures" on page 5-411.

Note If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

## Dependencies

To enable this parameter, select Puncture code.

## Enable erasures input port - Enable erasures input port <br> off (default) | on

Selecting this check box enables the erasures port, Era. For more information, see "Puncturing and Erasures" on page 5-411.

## Output number of corrected symbol errors - Enable port to output number of corrected symbol errors

off (default) | on

Selecting this check box enables an additional output port, Err, which indicates the number of symbol errors the block corrected in the input codeword.

## Block Characteristics

| Data Types | double $\mid$ integer $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Input and Output Signal Length in RS Blocks

The Reed-Solomon code has a message word length, $K$, or shortened message word length, $S$. The codeword length is $N-K+S-P$, where $N$ is the full codeword length and $P$ is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N-P$, because $K=S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y=N_{\mathrm{C}} \times x$ denotes that $y$ is an integer multiple of $x$.

|  | Input, Erasure, and Output Vector Lengths |  |
| :--- | :--- | :--- |
| RS Block Coder | No Message Shortening Used | Message Shortening Used |
| Integer-Input RS Encoder | Input Length (symbols): | Input Length (symbols): |
|  | $N_{\mathrm{C}} \times K$ | $N_{\mathrm{C}} \times S$ |
|  | Output Length (symbols): | Output Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
| Integer-Output RS Decoder | Input Length (symbols): | Input Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
|  | Erasures Length (symbols): | Erasures Length (symbols): |
|  | $N_{\mathrm{C}} \times(N-P)$ | $N_{\mathrm{C}} \times(N-K+S-P)$ |
|  | Output Length (symbols): | Output Length (symbols): |
|  | $N_{\mathrm{C}} \times K$ | $N_{\mathrm{C}} \times S$ |

- $N$ is the codeword length.
- $K$ is the message word length.
- $S$ is the shortened message word length.
- $N_{\mathrm{C}}$ is the number of codewords (and message words).
- $\quad P$ is the number of punctures, and is equal to the number of zeros in the puncture vector.
- $M$ is the degree of the primitive polynomial. Each group of $M$ bits represents an integer between 0 and $2^{M}-1$ that belongs to the finite Galois field GF $\left(2^{M}\right)$.

For more information on representing data for Reed-Solomon codes, see "Integer Format (ReedSolomon Only)".

## Restrictions on the M and the Codeword Length N

- If you do not select Specify primitive polynomial, valid values for the codeword length, $N$, are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree $M=$ ceil ( $\log 2(N+1))$. You can display the default primitive polynomial by running primpoly(ceil(log2(N+1))).
- If you select Specify primitive polynomial, valid values for the primitive polynomial degree, $M$, are from 3 to 16 . The valid values for $N$ in this case are from 7 to $2^{M}-1$. Selecting Specify primitive polynomial enables you to specify the primitive polynomial that defines the finite field $G F\left(2^{M}\right)$, which corresponds to the values that form message words and codewords.

## Specify the Primitive Polynomial

You can specify the primitive polynomial that defines the finite field $G F\left(2^{M}\right)$, corresponding to the integers that form messages and codewords. To do so, first select Specify primitive polynomial. Then, in the Primitive polynomial text box, enter a binary row vector that represents a primitive polynomial over $G F\left(2^{M}\right)$, in descending order of powers. For example, to specify the polynomial $x^{3}+x$ +1 , enter the vector [llll 10011$]$.

If you do not select Specify primitive polynomial, the block uses the default primitive polynomial of degree $M=\operatorname{ceil}(\log 2(N+1))$. You can display the default polynomial by entering
primpoly (ceil( $\log 2(N+1))$ ) at the MATLAB prompt.

## Specify the Generator Polynomial

Select Specify generator polynomial to enable the Generator polynomial parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to $2^{M}-1$. The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $G F\left(2^{M}\right)$ represented in integer format. For more information about integer and binary format, see "Integer Format (Reed-Solomon Only)". The generator polynomial must be equal to a polynomial with this factored form:
$\mathrm{g}(\mathrm{x})$

$$
=\quad\left(\mathrm{x}+\alpha^{\mathrm{b}}\right)\left(\mathrm{x}+\alpha^{\mathrm{b}+1}\right)\left(\mathrm{x}+\alpha^{\mathrm{b}+2}\right) \ldots\left(\mathrm{x}+\alpha^{\mathrm{b}+\mathrm{N}-\mathrm{K}-1}\right)
$$

$\alpha$ is the primitive element of the Galois field over which the input message is defined, and $b$ is an integer.

If you do not select Specify generator polynomial, the block uses the default generator polynomial, corresponding to $b=1$, for Reed-Solomon encoding. You can display the default generator polynomial by running rsgenpoly.

- If you are using the default primitive polynomial (Specify primitive polynomial is not selected), the default generator polynomial is rsgenpoly $(N, K)$, where $N=2^{M}-1$.
- If you are not using the default primitive polynomial (Specify primitive polynomial is selected) and you specify the primitive polynomial as poly, the generator polynomial is rsgenpoly (N, K, poly).

Note The degree of the generator polynomial is $N-K$, where $N$ is the codeword length and $K$ is the message word length.

## Puncturing and Erasures

1 s and 0 s have precisely opposite meanings for the puncture and erasure vectors.
In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see "Shortening, Puncturing, and Erasures".

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Single-precision floating point <br> - 8-, 16-, and 32 -bit signed integers <br> - 8 -, 16 -, and 32 -bit unsigned integers |
| Out | - Double-precision floating point <br> - Single-precision floating point <br> - 8-, 16-, and 32-bit signed integers <br> - 8 -, 16 -, and 32 -bit unsigned integers |
| Era | - Double-precision floating point <br> - Boolean |
| Err | - Double-precision floating point <br> - Single-precision floating point <br> - 8-, 16-, and 32 -bit signed integers <br> - If the input is uint8, uint16, or uint32, then the number of errors output datatype is int8, int16, or int32, respectively. |

## Pair Block

Integer-Input RS Encoder

## Algorithms

This block uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see "Algorithms for BCH and RS Errors-only Decoding".

## Integer-Output RS Decoder HDL Optimized

Decode data using Reed-Solomon (RS) decoder
Library

> Communications Toolbox HDL Support / Error Detection and Correction / Block Communications Toolbox / Error Detection and Correction / Block

## Description

The Integer-Output RS Decoder HDL Optimized decodes data using RS decoder. The RS decoding follows the same standards as any other cyclic redundancy code. Use this block to model communications system forward error correction (FEC) codes.

For more information about the RS decoder, see the Integer-Output RS Decoder block. For more information on representing data for RS codes, see "Integer Format (Reed-Solomon Only)".

## Ports

## Input

dataIn - Input data
scalar
Input data, specified as a scalar representing one symbol. For binary point scaling, the input data type must be an integer or fixdt. The double data type is allowed for simulation, but not for HDL code generation.

Data Types: double |int8|int16|int32|int64|fixed point
startIn - Start of input frame indicator
Boolean scalar
Start of input frame indicator, specified as a Boolean scalar.
Data Types: Boolean
endIn - End of input frame indicator
Boolean scalar
End of input frame indicator, specified as a Boolean scalar.

## Data Types: Boolean

## validIn - Valid input data indicator

Boolean scalar
Valid input data indicator, specified as a Boolean scalar.
This is a control signal that indicates if the data on the dataIn port is valid.
Data Types: Boolean

## Output <br> data0ut - Decoded message data <br> scalar

Decoded message data, returned as a scalar. This output data width is the same size as the input data.

Data Types: double|int8|int16|int32|int64|fixed point

## start0ut - Start of output frame indicator

Boolean scalar
Start of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean

## endOut - End of output frame indicator

Boolean scalar
End of output frame indicator, returned as a Boolean scalar.
Data Types: Boolean
validOut - Valid output data indicator
Boolean scalar
Valid output data indicator, returned as a Boolean scalar.
This is a control signal that indicates if the data on the dataOut port is valid.
Data Types: Boolean
errOut - Indications of corruption of received data
Boolean scalar
Indications of corruption of the received data, returned as a Boolean scalar.
Data Types: Boolean
numErrors - Number of detected errors
nonnegative scalar
Number of detected errors, returned as a nonnegative scalar.

## Dependencies

To enable this port, select the Output number of corrected symbol errors parameter.
Data Types: uint8

## Parameters

Codeword length - Length of codeword
7 (default) | range from 7 to 65, 535
Specify the codeword length.

The codeword length $N$ must be an integer equal to $2^{M}-1$, where $M$ is an integer in the range from 3 to 16 . For more information on representing data for RS codes, see "Integer Format (Reed-Solomon Only)".

## Message length - Length of message

3 (default) | positive integer
Specify the length of the message.
For more information on representing data for RS codes, see "Integer Format (Reed-Solomon Only)".

## Source of primitive polynomial - Primitive polynomial source

Auto (default) | Property
Specify the source of the primitive polynomial.

- Select Auto to specify the primitive polynomial based on the Codeword length (N) parameter value. The degree of the primitive polynomial is calculated as $M=$ ceil $\left(\log _{2}(\right.$ Codeword length (N)). .
- Select Property to specify the primitive polynomial using the Primitive polynomial parameter.

Primitive polynomial - Primitive polynomial
[ $\left.1 \begin{array}{llll}1 & 0 & 1 & 1\end{array}\right]$ (default) | binary row vector
Specify a binary row vector representing the primitive polynomial in descending order of powers.
For more information on how to specify a primitive polynomial, see "Primitive Polynomials and Element Representations".

## Dependencies

To enable this parameter, set the Source of primitive polynomial parameter to Property.
Source of B, the starting power for roots of the primitive polynomial - Source of starting power for roots of primitive polynomial
Auto (default) | Property
Specify the source of the starting power for roots of the primitive polynomial.

- Select Property to enable the $\mathbf{B}$ value parameter.
- Select Auto, to use the $\mathbf{B}$ value parameter default value of 1 .

## B value - Starting exponent of roots

1 (default) | positive integer
The starting exponent of the roots.

## Dependencies

To enable this parameter, set the Source of B, the starting power for roots of the primitive polynomial parameter to Property.

Output number of corrected symbol errors - Number of corrected symbol errors off (default) | on

Select this parameter to enable the numErrors output port. This port outputs the detected symbol error count.

## Algorithms

This figure shows a sample output of the Integer-Output RS Decoder HDL Optimized block with a default configuration.

## Troubleshooting

- Each input frame must contain more than ( $N-K$ ) x 2 symbols and less than or equal to $N$ symbols. A shortened code is inferred when the number of valid data samples between startIn and endIn is less than $N$. A shortened code still requires $N$ cycles to perform the Chien search. If the input is less than $N$ symbols, leave a guard interval of at least N -size inactive cycles before starting the next frame.
- The decoder can operate on up to four messages at a time. If the block receives the start of a fifth message before completely decoding the first message, the block drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.
- The generator polynomial is not specified explicitly. However, it is defined by the codeword length, message length, and the $\mathbf{B}$ value for the starting exponent of the roots.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink $®$ Coder ${ }^{\mathrm{Tm}}$.
Not recommended for production code.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\mathrm{TM}}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

This block has a single, default HDL architecture.

## HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |

## Integer to Bit Converter

Map vector of integers to vector of bits
Library:
Communications Toolbox / Utility Blocks

Integer to Bit Converter

## Description

The Integer to Bit Converter block maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

This block is single-rate and single-channel. The block maps each integer value (or stored integer when you use a fixed point input) to a group of $M$ bits, using the selection for the Output bit order to determine the most significant bit. The resulting output vector length is $M$ times the input vector length.

## Ports

Input

## In - Input signal

integer | integer column vector
Input signal, specified as an integer or a length $N$ column vector of integers.
If $M$ is specified by the Number of bits per integer(M) parameter:

- When the Number of bits per integer parameter is set to Unsigned, input values must be integers in the range $\left[0,\left(2^{M}-1\right)\right]$.
- When the Number of bits per integer parameter is set to Signed, input values must be integers in the range $\left[\left(-2^{M-1}\right),\left(2^{M-1}-1\right)\right]$.

During simulation, the block performs a run-time check and issues an error if any input value is outside of the appropriate range. When the block generates code, it does not perform this run-time check.
Data Types: double

## Output

## Out - Output signal

bit scalar | bit column vector
Output signal, returned as a scalar or column vector of bits of length $M \cdot N$.

## Parameters

## Number of bits per integer(M) - Number of bits per integer

3 (default) | integer in the range [1, 32]

Number of input bits mapped to each integer in the input, specified as an integer in the range [1, 32].

## Treat input values as - Treat input values as

Unsigned (default) | Signed
Indicate if the integer value input ranges should be treated as signed or unsigned.

## Output bit order - Output bit order

MSB first (default)|LSB first
Define whether the first bit of the output signal is the most significant bit (MSB) or the least significant bit (LSB).

## Output data type - Output data type

Inherit via internal rule (default)|Smallest unsigned integer|Same as input| double | single | int8|uint8|int16|uint16|int32|uint32|boolean

Specify the data type of the output bits. You can choose one of the following Output data type options:

- Inherit via internal rule -- The block determines the output data type based on the input data type.
- If the input signal is floating-point (either single or double), the output data type is the same as the input data type.
- If the input data type is not floating-point, the output data type is determined as if the parameter is set to Smallest integer.
- Smallest integer --The block selects the output data type based on settings used in the "Hardware Implementation Pane" (Simulink) of the Configuration Parameters dialog box.
- If you select ASIC/FPGA for the device vendor, the output data type is the ideal one-bit size (ufix1).
- For all other device vendor selections, the output data type is an unsigned integer with the smallest available word length, as defined in the Hardware Implementation settings (for example, uint8)
- Same as input
- double
- single
- uint8
- uint16
- uint32

## Block Characteristics

## Integrate and Dump

Integrate discrete-time signal, resetting to zero periodically

```
Integrate
and Dump
```

## Library

Comm Filters

## Description

The Integrate and Dump block creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the block discards the number of samples specified in the Offset parameter. After this initial period, the block sums the input signal along columns and resets the sum to zero every $N$ input samples, where $N$ is the Integration period parameter value. The reset occurs after the block produces its output at that time step.

Receiver models often use the integrate-and-dump operation when the system's transmitter uses a simple square-pulse model. Fiber optics and in spread-spectrum communication systems, such as CDMA (code division multiple access) applications, also use the operation.

This block accepts a scalar, column vector, or matrix input signal. When the input signal is not a scalar value, it must contain $k \cdot N$ rows for some positive integer $k$. For these input signals, the block processes each column independently.

Selecting Output intermediate values affects the contents, dimensions, and sample time as follows:

- If you clear the check box, then the block outputs the cumulative sum at each reset time.
- If the input is a scalar value, then the output sample time is $N$ times the input sample time and the block experiences a delay whose duration is one output sample period. In this case, the output dimensions match the input dimensions.
- If the input is a $(k \cdot N)$-by- $n$ matrix, then the output is $k$-by- $n$. In this case, the block experiences no delay and the output period matches the input period.
- If you select the check box, then the block outputs the cumulative sum at each time step. The output has the same sample time and the same matrix dimensions as the input.

## Transients and Delays

A nonzero value in the Offset parameter causes the block to output one or more zeros during the initial period while it discards input samples. If the input is a matrix with $n$ columns and the Offset parameter is a length- $n$ vector, then the $m^{\text {th }}$ element of the Offset vector is the offset for the $m^{\text {th }}$ column of data. If Offset is a scalar, then the block applies the same offset to each column of data. The output of initial zeros due to a nonzero Offset value is a transient effect, not a persistent delay.

When you clear Output intermediate values, the block's output is delayed, relative to its input, throughout the simulation:

- If the input is a scalar value, then the output is delayed by one sample after any transient effect is over. That is, after removing transients from the input and output, you can see the result of the $m^{\text {th }}$ integration period in the output sample indexed by $\mathrm{m}+1$.
- If the input is a column vector or matrix and the Offset parameter is nonzero, then after the transient effect is over, the result of each integration period appears in the output frame corresponding to the last input sample of that integration period. This is one frame later than the output frame corresponding to the first input sample of that integration period, in cases where an integration period spans two input frames. For an example of this situation, see "Example of Transient and Delay" on page 5-424.

## Parameters

## Integration period

The number of input samples between resets.

## Offset

A nonnegative integer vector or scalar specifying the number of input samples to discard from each column of input data at the beginning of the simulation.

## Output intermediate values

Determines whether the block outputs the intermediate cumulative sums between successive resets.

## Fixed-Point Signal Flow Diagram

## Fixed-Point Attributes

The settings for the following parameters only apply when block inputs are fixed-point signals.

## Rounding mode

Use this parameter to specify the rounding method to be used when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result.

For more information, see "Rounding Modes" (DSP System Toolbox) or "Rounding Mode: Simplest" (Fixed-Point Designer).

## Saturate on integer overflow

Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result:

- Saturate represents positive overflows as the largest positive number in the range being used, and negative overflows as the largest negative number in the range being used.
- Wrap uses modulo arithmetic to cast an overflow back into the representable range of the data type. See "Modulo Arithmetic" (Fixed-Point Designer) for more information.

## Accumulator-Mode

Use the Accumulator-Mode parameter to specify how you would like to designate the accumulator word and fraction lengths:

- When you select Inherit via internal rule, the block automatically calculates the accumulator output word and fraction lengths.
- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator.

## Output

Use the Output parameter to choose how you specify the word length and fraction length of the output of the block:

- When you select Same as accumulator, these characteristics match those of the accumulator.
- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, enter the word length and the fraction length of the output, in bits.
- When you select Slope and bias scaling, enter the word length, in bits, and the slope of the output.

For additional information about the parameters pertaining to fixed-point applications, see "Specify Fixed-Point Attributes for Blocks" (DSP System Toolbox).

## Supported Data Type

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Single-precision floating point <br> - Fixed-point |
| Out | - Double-precision floating point <br> - Single-precision floating point <br> - Fixed-point |

## Examples

If Integration period is 4 and Offset is the scalar 3, then the table below shows how the block treats the beginning of a ramp ( $1,2,3,4, \ldots$ ) in several situations. (The values shown in the table do not reflect vector sizes but merely indicate numerical values.)

| Output intermediate <br> values Check Box | Input Signal Properties | First Several Output Values |
| :--- | :--- | :--- |
| Cleared | Scalar | $0,0,4+5+6+7$, and $8+9+10+11$, where one <br> 0 is an initial transient value and the other <br> 0 is a delay value that results from the <br> cleared check box and scalar value input. |
| Cleared | Column vector of length 4 | $0,4+5+6+7$, and $8+9+10+11$, where 0 is an <br> initial delay value that results from the <br> nonzero offset. The output is a scalar value. |
| Selected | Scalar | $0,0,0,4,4+5,4+5+6,4+5+6+7,8,8+9$, <br> $8+9+10,8+9+10+11$, and 12, where the <br> three 0s are initial transient values. |
| Selected | Column vector of length 4 | $0,0,0,4,4+5,4+5+6,4+5+6+7,8,8+9$, <br> $8+9+10,8+9+10+11$, and 12, where the <br> three 0 s are initial transient values. The <br> output is a column vector of length 4. |

In all cases, the block discards the first three input samples (1, 2, and 3 ).

## Example of Transient and Delay

The figure below illustrates a situation in which the block exhibits both a transient effect for three output samples, as well as a one-sample delay in alternate subsequent output samples for the rest of the simulation. The figure also indicates how the input and output values are organized as column vectors. In each vector in the figure, the last sample of each integration period is underlined, discarded input samples are white, and transient zeros in the output are white.

The transient effect lasts for ceil(13/5) output samples because the block discards 13 input samples and the integration period is 5 . The first output sample after the transient effect is over, 80 , corresponds to the sum $14+15+16+17+18$ and appears at the time of the input sample 18. The next output sample, 105 , corresponds to the sum $19+20+21+22+23$ and appears at the time of the input sample 23. Notice that the input sample 23 is one frame later than the input sample 19; that is, this five-sample integration period spans two input frames. As a result, the output of 105 is delayed compared to the first input (19) that contributes to that sum.

## Interlacer

Alternately select elements from two input vectors to generate output vector Library: Communications Toolbox / Sequence Operations

## Description

The Interlacer block accepts two vector with the size, complexity, and sample time. It produces one output vector by alternating elements from the first input (labeled 0 for odd) and the second input (labeled E for even).

## Ports

Input
0 - Odd-numbered elements
numeric vector
Odd-numbered elements, specified as a vector. The complexity of inputs 0 and E must match.
Data Types: double

## E - Even-numbered elements

numeric vector
Even-numbered elements, specified as a vector. The complexity of inputs 0 and E must match.
Data Types: double

## Output

## Out - Output signal

numeric column vector
Output signal, returned as an even length column vector. Odd numbered elements in the output vector contain the elements from input 0 and even numbered elements in the output vector contain the elements from input E . The output vector has the same data type and sample time as the input.

## I/Q Imbalance

Create complex baseband model of signal impairments caused by imbalances between in-phase and quadrature receiver components

## Library

RF Impairments

## Description

The I/Q Imbalance block creates a complex baseband model of the signal impairments caused by imbalances between in-phase and quadrature receiver components. Typically, these are caused by differences in the physical channels for the two components of the signal.

The I/Q Imbalance block applies amplitude and phase imbalances to the in-phase and quadrature components of the input signal, and then combines the results into a complex signal. The block

1 Separates the signal into its in-phase and quadrature components.
2 Applies amplitude and phase imbalances, specified by the $\mathbf{I} / \mathbf{Q}$ amplitude imbalance (dB) and I/Q phase imbalance (deg) parameters, respectively, to both components.
3 Combines the in-phase and quadrature components into a complex signal.
4 Applies an in-phase dc offset, specified by the I dc offset parameter, and a quadrature offset, specified by the $\mathbf{Q}$ dc offset parameter, to the signal.

The block performs these operations in the subsystem shown in the following diagram, which you can view by right-clicking the block and selecting Mask > Look under mask:

Let
$I_{a}=\mathrm{I} / \mathrm{Q}$ amplitude imbalance
$I_{p}=\mathrm{I} / \mathrm{Q}$ phase imbalance
$I_{D C}=$ in-phase DC offset
$Q_{D C}=$ quadrature DC offset
Also let $x=x_{r}+j x_{i}$ be the complex input to the block, with $x_{r}$ and $x_{i}$ being the real and imaginary parts, respectively, of $x$. Let $y$ be the complex output of the block.

Then, for an I/Q amplitude imbalance, $I_{a}$
$y_{\text {AmplitudeImbalance }}=\left[10^{\left(0.5 * \frac{I_{a}}{20}\right)} * x_{r}\right]+j\left[10^{\left(-0.5 * \frac{I_{a}}{20}\right)} * x_{i}\right]$
$\triangleq y$ $\qquad$ $+\mathrm{j}^{*} \mathrm{y}_{i}$
Amplitudemblalanee
For an I/Q phase imbalance $I_{p}$
$y_{\text {PhaseImbalance }}=$
$\left[\exp \left(-0.5 * j *{ }_{\Pi} * \frac{I_{p}}{180}\right) * y_{r_{\text {AmplitudeImbalance }}}\right]+\left\{\exp \left[j\left(\frac{\Pi}{2}+0.5 * \Pi_{\Pi} * \frac{I_{p}}{180}\right)\right] * y_{i_{\text {AmplitudeImbalance }}}\right\}$
$\triangleq y_{r_{\text {Phosemmbalanee }}}+j * y_{i_{\text {Phasemmbalanee }}}$
For DC offsets $I_{D C}$ and $Q_{D C}$
$\mathrm{y}=\left(\mathrm{y}_{\mathrm{r}_{\text {Phasesmbalance }}}+I_{D C}\right)+\mathrm{j} *\left(\mathrm{y}_{\text {Phnsesemboancee }}+Q_{D C}\right)$
The value of the $\mathbf{I} / \mathbf{Q}$ amplitude imbalance ( $\mathbf{d B}$ ) parameter is divided between the in-phase and quadrature components such that the block applies a gain of $+X / 2 \mathrm{~dB}$ to the in-phase component and a gain of $-X / 2 \mathrm{~dB}$ to the quadrature component where $X$ can be positive or negative.

The effects of changing the block's parameters are illustrated by the following scatter plots of a signal modulated by 16-ary quadrature amplitude modulation (QAM) with an average power of 0.01 watts. The usual 16-ary QAM constellation without distortion is shown in the first scatter plot:

The following figure shows a scatter plot of an output signal, modulated by 16-ary QAM, from the I/Q block with I/Q amplitude imbalance (dB) set to 8 and all other parameters set to 0:

Observe that the scatter plot is stretched horizontally and compressed vertically compared to the undistorted constellation.

If you set IQ phase imbalance (deg) to 30 and all other parameters to 0 , the scatter plot is skewed clockwise by 30 degrees, as shown below:

Setting the $\mathbf{I}$ dc offset to 0.02 and the $\mathbf{Q}$ dc offset to 0.04 shifts the constellation 0.02 to the right and 0.04 up, as shown below:

See "Illustrate RF Impairments That Distort a Signal" for a description of the model that generates this plot.

## Parameters

## I/Q Compensator Coefficient to Imbalance

Convert compensator coefficient into amplitude and phase imbalance

## Library

RF Impairments Correction

## Description

The I/Q Compensator Coefficient to Imbalance block converts a compensator coefficient into its equivalent amplitude and phase imbalance.

This block has a single input port, which accepts a complex coefficient or a vector of coefficients. There are amplitude and phase imbalance output ports both of which are real. The amplitude imbalance is expressed in dB while the phase imbalance is expressed in degrees.

## Algorithms

See the iqcoef2imbal function reference page for more information on the inputs, outputs, and algorithms.

## Supported Data Types

## I/Q Imbalance Compensator

Compensate for imbalance between in-phase and quadrature components

## Library

RF Impairments Correction

## Description

The I/Q Imbalance Compensator mitigates the effects of an amplitude and phase imbalance between the in-phase and quadrature components of a modulated signal. The supported modulation schemes include OFDM, M-PSK, and M-QAM, where M > 2 .

This block accepts up to three input ports, of which one is the input signal. When you set the Source of compensator coefficient parameter to Estimated from input signal, two additional input ports are enabled. The first is enabled when you set the Source of adaptation step size parameter to Input port and the second is enabled when you check the Coefficient adaptation input port box. The two options are independent. Additionally, you can check the Estimated coefficient output port box to create an optional output port from which the estimated compensator coefficients are made available.

When you set the Source of compensator coefficient parameter to Input port, only one possible configuration is possible (input signal port, coefficient input port, and output signal port).

## Parameters

## Source of compensator coefficient

Specify the source of the compensator coefficients as Estimated from input signal or Input port. If set to Estimated from input signal, the compensator calculates the coefficients from the input signal. If set to Input port, all other properties are disabled and you must provide the coefficients through the input port. The default value is Estimated from input signal.

## Initial compensator coefficient

Specify the initial coefficient used by the internal algorithm to compensate for the I/Q imbalance. The default value is $0+0 \mathrm{j}$.

## Source of adaptation step size

Specify the source of the adaptation step size as Property or Input port. If set to Property, specify the step size in the Adaptation step size field. If set to Input port, you must specify the step size through an input port. The default value is Property.

## Adaptation step size

Specify the step size of the adaptation algorithm as a real scalar. This parameter is available only when Source of adaptation step size is set to Property. The default value is 0.00001 .
Coefficient adaptation input port
Select this check box to create an input port that permits a signal to control the adaptation process. If the check box is selected and if the input signal is true, the estimated compensation coefficients are updated. If the adaptation port is not enabled or if the input signal is false, the compensation coefficients do not change. By default, the check box is not selected.

## Estimated coefficient output port

Select this check box to provide the estimated compensation coefficients to an output port. By default, the check box is not selected.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the comm. IQImbalanceCompensator reference page. The object properties correspond to the block parameters.

## Examples

## Compensate for I/Q Imbalance

This example shows how to use the I/Q Imbalance Compensator block to remove the effects of an amplitude and phase imbalance on a modulated signal.

Open the model, doc_iqimbcomp, from the MATLAB command prompt.
doc_iqimbcomp
The model includes these blocks:

- Random Integer Generator
- M-PSK Modulator Baseband
- I/Q Imbalance
- I/Q Imbalance Compensator
- Constellation Diagram

Double-click the I/Q Imbalance block. You can see that the I/Q amplitude imbalance (dB) parameter is set to 5 and the $\mathbf{I} / \mathbf{Q}$ phase imbalance (deg) parameter is also set to 5 .

## Function Block Parameters: I/Q Imbalance

## E3

I/Q Imbalance (mask) (link)
Create complex baseband model of signal impairments caused by imbalances between in-phase and quadrature receiver components.

This block accepts a scalar or column vector input signal.

## Parameters

I/Q amplitude imbalance (dB):
5
I/Q phase imbalance (deg):
5
I dc offset:
0
Q dc offset:
0

Run the model. In the Signal with I/Q Imbalance constellation diagram, observe the effects of the amplitude imbalance and phase imbalance on the 8-PSK signal.

Look at the Compensated Signal constellation diagram. Observe that the signal is not well aligned with the reference constellation (shown in red).

Increase the simulation time from 20 seconds to 100 seconds and run the model again. You can see that the constellation is now well aligned with the reference constellation. This is because the compensation algorithm is adaptive; consequently, it requires time to accurately estimate the I/Q imbalance.

Try changing other simulation parameters such as the step size in the I/Q Imbalance Compensator block, the amplitude and phase imbalance in the I/Q Imbalance block, the modulation type etc. Observe the effects on the Compensated Signal constellation diagram.

## Supported Data Types

## I/Q Imbalance to Compensator Coefficient

Converts amplitude and phase imbalance into I/Q compensator coefficient

## Library

RF Impairments Correction

## Description

The I/Q Imbalance to Compensator Coefficient block returns a complex coefficient to compensate for amplitude and phase imbalance.

This block has an amplitude imbalance input port and a phase imbalance input port, where the amplitude imbalance is a real number expressed in dB and the phase imbalance is a real number expressed in degrees. The imbalance inputs are vectors. The complex coefficients are returned from a single output port.

## Algorithms

See iqimbal2coef for more information on the inputs, outputs, and algorithms.

## Kasami Sequence Generator

Generate Kasami sequence from set of Kasami sequences

## Library

Sequence Generators sublibrary of Comm Sources

## Description

The Kasami Sequence Generator block generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have good cross-correlation properties.

This block can output sequences that vary in length during simulation. For more information about variable-size signals, see "Variable-Size Signal Basics" (Simulink).

## Kasami Sequences

There are two sets of Kasami sequences: the small set and the large set. The large set contains all the sequences in the small set. Only the small set is optimal in the sense of matching Welch's lower bound for correlation functions.

Kasami sequences have period $N=2^{\mathrm{n}}-1$, where $n$ is a nonnegative, even integer. Let $u$ be a binary sequence of length $N$, and let $w$ be the sequence obtained by decimating u by $2^{n / 2}+1$. The small set of Kasami sequences is defined by the following formulas, in which $T$ denotes the left shift operator, $m$ is the shift parameter for $w$, and $\oplus$ denotes addition modulo 2 .

$$
K_{s}(u, n, m)= \begin{cases}u & m=-1 \\ u \oplus T^{m} w & m=0, \ldots, 2^{n / 2}-2\end{cases}
$$

## Small Set of Kasami Sequences for $\mathbf{n}$ Even

Note that the small set contains $2^{\mathrm{n} / 2}$ sequences.
For $\bmod (n, 4)=2$, the large set of Kasami sequences is defined as follows. Let $v$ be the sequence formed by decimating the sequence $u$ by $2^{\mathrm{n} / 2+1}+1$. The large set is defined by the following table, in which $k$ and $m$ are the shift parameters for the sequences $v$ and $w$, respectively.

$$
K_{L}(u, n, k, m)= \begin{cases}u & k=-2 ; m=-1 \\ v & k=-1 ; m=-1 \\ u \oplus T^{k} v & k=0, \ldots, 2^{n}-2 ; m=-1 \\ u \oplus T^{m} w & k=-2 ; m=0, \ldots, 2^{n / 2}-2 \\ v \oplus T^{m} w & k=-1 ; m=0, \ldots, 2^{n / 2}-2 \\ u \oplus T^{k} v \oplus T^{m} w k=0, \ldots, 2^{n}-2 ; m=0, \ldots, 2^{n / 2}-2\end{cases}
$$

## Large Set of Kasami Sequences for $\bmod (n, 4)=2$

The sequences described in the first three rows of the preceding figure correspond to the Gold sequences for $\bmod (n, 4)=2$. See the reference page for the Gold Sequence Generator block for a description of Gold sequences. However, the Kasami sequences form a larger set than the Gold sequences.

The correlation functions for the sequences takes on the values
$\{-t(n), \quad-s(n)$,
$-1, \quad s(n)$
-2
$t(n)$
2\}
where

$$
\begin{gathered}
t(n)=1+2^{(n+2) / 2}, n \text { even } \\
s(n)=\frac{1}{2}(t(n)+1)
\end{gathered}
$$

## Block Parameters

The Generator polynomial parameter specifies the generator polynomial, which determines the connections in the shift register that generates the sequence $u$. You can specify the Generator polynomial parameter using these formats:

- A polynomial character vector that includes the number 1 , for example, ' $z \wedge 4+z+1$ '.
- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1 . Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 .

For example, ' $z^{\wedge} 8+z^{\wedge} 2+1 ',[100000101]$, and [8 20 0] represent the same polynomial, $p(z)=z^{8}+z^{2}+1$.

The Initial states parameter specifies the initial states of the shift register that generates the sequence u. Initial States is a binary scalar or row vector of length equal to the degree of the Generator polynomial. If you choose a binary scalar, the block expands the scalar to a row vector of length equal to the degree of the Generator polynomial, all of whose entries equal the scalar.

The Sequence index parameter specifies the shifts of the sequences $v$ and $w$ used to generate the output sequence. You can specify the parameter in either of two ways:

- To generate sequences from the small set, for $n$ is even, you can specify the Sequence index as an integer $m$. The range of $m$ is $\left[-1, \ldots, 2^{n / 2}-2\right]$. The following table describes the output sequences corresponding to Sequence index m:

| Sequence Index | Range of Indices | Output Sequence |
| :--- | :--- | :--- |
| -1 | $m=-1$ | u |
| $m$ | $m=0, \ldots, 2^{\mathrm{n} / 2}-2$ | $u \oplus T^{m} w$ |

- To generate sequences from the large set, for $\bmod (n, 4)=2$, where $n$ is the degree of the Generator polynomial, you can specify Sequence index as an integer vector [ $k \mathrm{~m}$ ]. In this case, the output sequence is from the large set. The range for $k$ is $\left[-2, \ldots, 2^{n}-2\right]$, and the range for $m$ is $\left[-1, \ldots, 2^{\mathrm{n} / 2}-2\right]$. The following table describes the output sequences corresponding to Sequence index [k m]:

| Sequence Index [k m] | Range of Indices | Output Sequence |
| :--- | :--- | :--- |
| $\left[\begin{array}{ll}-2 & -1\end{array}\right]$ | $k=-2, m=-1$ | u |
| $\left[\begin{array}{ll}-1 & -1\end{array}\right]$ | $k=-1, m=-1$ | v |
| $\left[\begin{array}{ll}\mathrm{k} & -1\end{array}\right]$ | $k=0,1, \ldots, 2^{\mathrm{n}}-2$ <br> $m=-1$ | $u \oplus T^{k} v$ |
| $\left[\begin{array}{ll}-2 & \mathrm{~m}]\end{array}\right.$ | $k=-2$ <br> $m=0,1, \ldots, 2^{\mathrm{n} / 2}-2$ | $u \oplus T^{m} w$ |
| $\left[\begin{array}{ll}-1 & \mathrm{~m}]\end{array}\right.$ | $k=-1$ <br> $m=0, \ldots, 2^{\mathrm{n} / 2}-2$ | $v \oplus T^{m} w$ |
| $\left[\begin{array}{ll}\mathrm{k}\end{array}\right]$ | $k=0, \ldots, 2^{\mathrm{n}}-2$ <br> $m=0, \ldots, 2^{\mathrm{n} / 2}-2$ | $u \oplus T^{k} v \oplus T^{m} w$ |

You can shift the starting point of the Kasami sequence with the Shift parameter, which is an integer representing the length of the shift.

You can use an external signal to reset the values of the internal shift register to the initial state by selecting Reset on nonzero input. This creates an input port for the external signal in the Kasami Sequence Generator block. The way the block resets the internal shift register depends on whether its output signal and the reset signal are sample-based or frame-based. See "Reset Behavior" on page 5-671 for an example.

## Polynomials for Generating Kasami Sequences

The following table lists some of the polynomials that you can use to generate the Kasami set of sequences.

| $\mathbf{n}$ | $\mathbf{N}$ | Polynomial | Set |
| :--- | :--- | :--- | :--- |
| 4 | 15 | $\left[\begin{array}{lll}4 & 1 & 0\end{array}\right]$ | Small |
| 6 | 63 | $\left[\begin{array}{lll}6 & 1 & 0\end{array}\right]$ | Large |
| 8 | 255 | $\left[\begin{array}{llll}8 & 4 & 3 & 2\end{array}\right]$ |  |
| 10 | 1023 | $\left[\begin{array}{llll}1 & 3 & 0\end{array}\right]$ | Small |
| 12 | 4095 | $\left[\begin{array}{lllll}2 & 6 & 4 & 1 & 0\end{array}\right]$ | Large |

## Parameters

## Generator polynomial

Character vector or binary vector specifying the generator polynomial for the sequence $u$.

## Initial states

Binary scalar or row vector of length equal to the degree of the Generator polynomial, which specifies the initial states of the shift register that generates the sequence $u$.

## Sequence index

Integer or vector specifying the shifts of the sequences $v$ and $w$ used to generate the output sequence.

## Shift

Integer scalar that determines the offset of the Kasami sequence from the initial time.

## Output variable-size signals

Select this if you want the output sequences to vary in length during simulation. The default selection outputs fixed-length signals.

## Maximum output size source

Specify how the block defines maximum output size for a signal.

- When you select Dialog parameter, the value you enter in the Maximum output size parameter specifies the maximum size of the output. When you make this selection, the oSiz input port specifies the current size of the output signal and the block output inherits sample time from the input signal. The input value must be less than or equal to the Maximum output size parameter.
- When you select Inherit from reference port, the block output inherits sample time, maximum size, and current size from the variable-sized signal at the Ref input port.

This parameter only appears when you select Output variable-size signals. The default selection is Dialog parameter.

## Maximum output size

Specify a two-element row vector denoting the maximum output size for the block. The second element of the vector must be 1. For example, [10 1] gives a 10 -by- 1 maximum sized output signal. This parameter only appears when you select Output variable-size signals.

## Sample time

Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1, the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-449.

## Samples per frame

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-449.

## Reset on nonzero input

When selected, you can specify an input signal that resets the internal shift registers to the original values of the Initial states.

## Output data type

The output type of the block can be specified as a boolean or double. By default, the block sets this to double.

## Example

## Kasami Spreading with Two Users and Multipath

This model considers Kasami spreading for a combined two-user transmission in a multipath environment.

Open the model here: kasami_sequence_block_example

```
modelname = 'kasami_sequence_block_example';
open_system(modelname);
sim(modelname);
```

You can see very good user separation over multiple paths with the gains of combining. This can be attributed to the "good" correlation properties of Kasami sequences, which provide a balance between the ideal cross-correlation properties of orthogonal codes and the ideal auto-correlation properties of PN sequences. See the relevant examples on the Hadamard Code Generator and PN Sequence Generator reference pages.

To experiment with this model further, try selecting other path delays to see how the performance varies for the same code. Also try different codes with the same delays.
close_system(modelname, 0);

## Blocks

Gold Sequence Generator | Hadamard Code Generator | PN Sequence Generator

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10 , then a 10 -by- 1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Reset Behavior

To reset the generator sequence, you must first select Reset on nonzero input to add the Rst input. Suppose that the Kasami Sequence Generator block outputs [ $\left.\begin{array}{llllllll}1 & 0 & 0 & 1 & 1 & 0 & 1 & 1\end{array}\right]$ when there is no reset. The following table shows the effect on the Kasami Sequence Generator block output for the property values indicated.

|  | Reset Signal Properties | Kasami Sequence Generator block | Reset Signal Output Signal |
| :---: | :---: | :---: | :---: |
| No reset | $\begin{aligned} & \text { Sample time }=1 \\ & \text { Samples per } \\ & \text { frame }=1 \\ & \text { Rst }=\left[\begin{array}{lllll} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right] \end{aligned}$ | $\begin{aligned} & \text { Sample time }=1 \\ & \text { Samples per } \\ & \text { frame = } \\ & \left.\begin{array}{llllll} \text { Out }=\left[\begin{array}{lllll} 1 & 0 & 0 & 1 & 1 \end{array}\right. \\ 0 & 1 & 1 \end{array}\right] \end{aligned}$ | $\begin{array}{\|lllllllll} \text { Ret } & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \text { Out } & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 1 \end{array}$ |
| Scalar reset signal | $\begin{aligned} & \text { Sample time }=1 \\ & \text { Samples per } \\ & \text { frame }=1 \\ & \text { Ret } \\ & \begin{array}{llllll} \text { Rst } \\ 0 & 0 & 0 & 0 & 0 & 1 \end{array} \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { Sample time = 1 } \\ & \text { Samples per } \\ & \text { frame = 1 } \end{aligned}$ |  |

|  | Reset Signal <br> Properties | Kasami Sequence <br> Generator block | Reset Signal <br> Output Signal |
| :--- | :--- | :--- | :--- |
| Vector reset signal | Sample time $=1$ <br> Samples per <br> frame $=8$ <br> Rst $=\left[\begin{array}{lllll}0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0\end{array}\right]$ | Sample time $=1$ <br> Samples per <br> frame $=8$ |  |

For the no reset case, the sequence is output without being reset. For the scalar and vector reset signal cases, the reset signal [00010000] is input to the Rst port. The sequence output is reset at the fourth bit, because the fourth bit of the reset signal is a 1 and the Sample time is 1 .

For variable-sized outputs, the block only supports scalar reset signal inputs.

## Compatibility Considerations

Existing models automatically update this block to current version
Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the Kasami Sequence Generator block version available before R2015b.

Existing models automatically update to load the Kasami Sequence Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes. For more information on block forwarding, see "Forwarding Tables" (Simulink).

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.

## LDPC Decoder

Decode binary low-density parity-check (LDPC) code

## Library:

Communications Toolbox / Error Detection and Correction / Block

## Description

The LDPC Decoder block uses the belief propagation algorithm to decode a binary LDPC code, which is input to the block as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The block decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see "Belief Propagation Decoding" on page 5-454.

The input and output are discrete-time signals. The ratio of the output sample time to the input sample time is:

- $N / K$ when only the information-part of the codeword is decoded
- 1 when the entire codeword is decoded
$N$ is the length of the received signal and must be in the range $\left(0,2^{31}\right)$. $K$ is the length of the uncoded message and must be less than $N$.

This icon shows all ports, including optional ports, for the LDPC Decoder block.

## Ports

## Input

## In - Log-likelihood ratios

column vector
Log-likelihood ratios, specified as an $N$-by-1 column vector containing the soft-decision output from demodulation. $N$ is the number of bits in the LDPC codeword before modulation. Each element is the $\log$-likelihood ratio for a received bit and the value is more likely to be 0 if the log-likelihood ratio is positive. The first $K$ elements correspond to the information-part of the input message.

Data Types: double

## Output

## Out - Decoded data

column vector

Decoded data, returned as a column vector. The Decision type parameter specifies whether the block outputs hard decisions or soft decisions (log-likelihood ratios).

- If the Output format parameter is set to Information part, the output includes only the information-part of the received codeword.
- If the Output format parameter is set to Whole codeword, the output includes the whole loglikelihood ratio vector.

Data Types: double | Boolean

## Iter - Number of executed decoding iterations

positive integer
Number of executed decoding iterations, returned as a positive integer.

## Dependencies

To enable this port, select the Output number of iterations executed parameter.
Data Types: double

## ParChk - Final parity checks

column vector
Final parity checks after decoding the input LDPC code, returned as an ( $N-K$ )-by- 1 column vector. $N$ is the number of bits in the LDPC codeword before modulation. $K$ is the length of the uncoded message.

## Dependencies

To enable this port, select the Output final parity checks parameter.

## Parameters

## Parity-check matrix (sparse binary (N-K)-by-N matrix) - Parity-check matrix dvbs2ldpc(1/2) (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse ( $N-K$ )-by- $N$ binary-valued matrix. $N$ is the length of the received signal and must be in the range ( $0,2^{31}$ ). $K$ is the length of the uncoded message and must be less than $N$. The last ( $N-K$ ) columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, $g f(2)$.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, I, that defines the row and column indices of the 1 s in the parity-check matrix such that sparse(I(:,1),I(:,2),1).

This parameter accepts numeric data types. When you set this parameter to a sparse binary matrix, this parameter also accepts the Boolean data type.

The default value uses the dvbs2ldpc function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S. 2 standard.
Example: dvbs2ldpc ( R , 'indices') configures the index matrix for the DVB-S. 2 standard, where $R$ is the code rate, and 'indices' specifies the output format of dvbs2ldpc as a two-column doubleprecision matrix that defines the row and column indices of the 1 s in the parity-check matrix.
Data Types: double | Boolean

## Output format - Output value format

Information part (default)|Whole codeword
Output value format, specified as one of these values:

- Information part - The block outputs a K-by-1 column vector containing only the informationpart of the received log-likelihood ratio vector. $K$ is the length of the uncoded message.
- Whole codeword - The block outputs an $N$-by-1 column vector containing the whole loglikelihood ratio vector. $N$ is the length of the received signal.
$N$ and $K$ must align with the dimension of the $(N-K)$-by- $K$ parity-check matrix.

## Decision type - Decision method

Hard decision (default)|Soft decision
Decision method used for decoding, specified as one of these values:

- Hard decision - The block outputs decoded data of data type double or boolean. Specify this data type using the Output data type parameter.
- Soft decision - The block outputs log-likelihood ratios of data type double.

## Output data type - Output value data type

double (default) | boolean
Output value data type, specified as double or boolean.

## Dependencies

To enable this parameter, set the Decision type parameter to Hard decision.

## Number of iterations - Maximum number of decoding iterations

50 (default) | positive integer
Maximum number of decoding iterations, specified as a positive integer.

## Stop iterating when all parity-checks are satisfied - Condition for iteration termination <br> off (default) | on

Select this parameter to terminate decoding after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the Number of iterations parameter.

## Output number of iterations executed - Output number of iterations executed off (default) | on

Select this parameter to enable the Iter output port.

## Output final parity-checks - Output number of iterations executed off (default) | on

Select this parameter to enable the ParChk output port.

## Block Characteristics

| Data Types | Boolean \| double |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## Algorithms

This block performs LDPC decoding using the belief propagation algorithm, also known as a messagepassing algorithm.

## Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager.

For transmitted LDPC-encoded codeword $c=c_{0}, c_{1}, \ldots, c_{n-1}$, the input to the LDPC decoder is the loglikelihood ratio (LLR) value $L\left(c_{i}\right)=\log \left(\frac{\operatorname{Pr}\left(c_{i}=0 \mid \text { channel output for } c_{i}\right)}{\operatorname{Pr}\left(c_{i}=1 \mid \text { channel output for } c_{i}\right)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:
$L\left(r_{j i}\right)=2 \operatorname{atanh}\left(\prod_{i^{\prime} \in V_{j}(i} \tanh \left(\frac{1}{2} L\left(q_{i^{\prime} j}\right)\right)\right)$,
$L\left(q_{i j}\right)=L\left(c_{i}\right)+\sum_{j^{\prime} \in C_{i} \backslash j} L\left(r_{j^{\prime} i}\right)$, initialized as $L\left(q_{i j}\right)=L\left(c_{i}\right)$ before the first iteration, and
$L\left(Q_{i}\right)=L\left(c_{i}\right)+\sum_{j^{\prime} \in C_{i}} L\left(r_{j^{\prime}}\right)$.
At the end of each iteration, $L\left(Q_{i}\right)$ contains the updated estimate of the LLR value for transmitted bit $c_{i}$. The value $L\left(Q_{i}\right)$ is the soft-decision output for $c_{i}$. If $L\left(Q_{i}\right)<0$, the hard-decision output for $c_{i}$ is 1 . Otherwise, the hard-decision output for $c_{i}$ is 0 .

If configured to stop when all parity checks are satisfied, the algorithm verifies the parity-check equation $\left(H c^{\prime}=0\right)$ at the end of each iteration. When all parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_{i} \backslash j$ and $V_{j} \backslash i$ are based on the parity-check matrix (PCM). Index sets $C_{i}$ and $V_{j}$ correspond to all nonzero elements in column $i$ and row $j$ of the PCM, respectively.

This figure highlights the computation of these index sets in a given PCM for $i=5$ and $j=3$.

To avoid infinite numbers in the algorithm equations, $\operatorname{atanh}(1)$ and atanh( -1 ) are set to 19.07 and 19.07, respectively. Due to finite precision, MATLAB returns 1 for $\tanh (19.07)$ and -1 for $\tanh (-19.07)$.

## LDPC Encoder

Encode binary low-density parity-check (LDPC) code
Library: Communications Toolbox / Error Detection and Correction / Block

## Description

The LDPC Encoder block applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

The input and output are discrete-time signals. The ratio of the output sample time to the input sample time is $K / N$, where:

- $N$ is the length of the received signal and must be in the range $\left(0,2^{31}\right)$.
- $K$ is the length of the uncoded message and must be less than $N$.

## Ports

## Input

## In - Input message

binary column vector
Input message, specified as a $K$-by- 1 column vector containing binary-valued elements. $K$ is the length of the uncoded message.
Data Types: double | Boolean

## Output

## Out - LDPC codeword

column vector
LDPC codeword, returned as an $N$-by- 1 column vector. $N$ is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first $K$ bits of the LDPC codeword output, and the parity check comprises the remaining $(N-K)$ bits.
Data Types: double | Boolean

## Parameters

Parity-check matrix (sparse binary (N-K)-by-N matrix) - Parity-check matrix dvbs2ldpc(1/2) (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse ( $N-K$ )-by- $N$ binary-valued matrix. $N$ is the length of the output LDPC codeword and must be in the range ( $0,2^{31}$ ). $K$ is the length of the uncoded message and
must be less than $N$. The last $(N-K)$ columns in the parity-check matrix must be an invertible matrix in the Galois field of order $2, \mathrm{gf}(2)$.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, $I$, that defines the row and column indices of the 1 s in the parity-check matrix such that sparse(I(:,1),I(: 2),1).

This parameter accepts numeric data types. When you set this parameter to a sparse binary matrix, this parameter also accepts the Boolean data type.

The default value uses the dvbs2ldpc function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S. 2 standard.

## Note

- When the last $(N-K)$ columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.
- When the last $(N-K)$ columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.

Example: dvbs2ldpc (R, 'indices') configures the index matrix for the DVB-S. 2 standard, where R is the code rate, and 'indices ' specifies the output format of dvbs2ldpc as a two-column doubleprecision matrix that defines the row and column indices of the 1 s in the parity-check matrix.
Data Types: double | Boolean

## Linear Equalizer

Equalize modulated signals using linear filtering<br>Library: Communications Toolbox / Equalizers

## Description

The Linear Equalizer block uses a tapped delay line filter to equalize a linearly modulated signal through a dispersive channel. Using an estimate of the channel modeled as a finite input response (FIR) filter, the block processes input frames and outputs the estimated signal.

This icon shows the block with all ports enabled for configurations that use the LMS or RLS adaptive algorithm.

This icon shows the block with all ports enabled for configurations that use the CMA adaptive algorithm.

## Ports

Input
in - Input signal
column vector
Input signal, specified as a column vector. The vector length of in must be equal to an integer multiple of the Number of input samples per symbol parameter. For more information, see "Symbol Tap Spacing" on page 5-465.

Data Types: double
Complex Number Support: Yes

## Desired - Training symbols

column vector
Training symbols, specified as a column vector. The vector length of Desired must be less than or equal to the length of input in. The Desired input port is ignored when the Train input port is 0 .

## Dependencies

To enable this port, set the Adaptive algorithm parameter to LMS or RLS.
Data Types: double
Complex Number Support: Yes

## Train - Train equalizer flag

$1 \mid 0$
Train equalizer flag, specified as 1 or 0 . The block starts training when this value changes from 0 to 1 (at the rising edge). The block trains until all symbols in the Desired input port are processed.

## Dependencies

To enable this port, set the Adaptive algorithm parameter to LMS or RLS and select the Enable training control input parameter.
Data Types: Boolean
Update - Update tap weights flag
1|0
Update tap weights flag, specified as 1 or 0 . The tap weights are updated when this value is 1 .

## Dependencies

To enable this port, set the Adaptive algorithm parameter to CMA and the Source of adapt weights flag parameter to Input port.

Data Types: Boolean

## Reset - Reset equalizer flag

1 | 0
Reset equalizer flag, specified as 1 or 0 . If Reset is set to 1 , the block resets the tap weights before processing the incoming signal. The block performs initial training until all symbols in the Desired input port are processed.

## Dependencies

To enable this port, select the Enable reset input parameter.

## Data Types: Boolean

## Output

## Out - Equalized symbols

column vector
Equalized symbols, returned as a column vector that has the same length as input signal in.
This port is unnamed until you select the Output error signal or Output taps weights parameter.

## Err - Error signal

column vector
Error signal, returned as a column vector that has the same length as input signal in.

## w - Tap weights

column vector
Tap weights, returned as an $N_{\text {Taps }}$-by- 1 vector, where $N_{\text {Taps }}$ is the value of the Number of Taps parameter. w contains the tap weights from the last tap weight update.

## Parameters

## Structure parameters

Number of taps - Number of equalizer taps
5 (default) | positive integer
Number of equalizer taps, specified as a positive integer.

## Signal constellation - Signal constellation

pskmod(0:3,4,pi/4) (default)| vector
Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: pskmod ( $0: 3,4, \mathrm{pi} / 4$ ).

Tunable: Yes
Number of input samples per symbol - Number of input samples per symbol
1 (default) | positive integer
Number of input samples per symbol, specified as a positive integer. Setting this parameter to any number greater than 1 effectively creates a fractionally spaced equalizer. For more information, see "Symbol Tap Spacing" on page 5-465.

## Algorithm parameters

## Adaptive algorithm - Adaptive algorithm

LMS (default) | RLS | CMA
Adaptive algorithm used for equalization, specified as one of these values:

- LMS - Update the equalizer tap weights using the "Least Mean Square (LMS) Algorithm" on page 5-466.
- RLS - Update the equalizer tap weights using the "Recursive Least Square (RLS) Algorithm" on page 5-466.
- CMA - Update the equalizer tap weights using the "Constant Modulus Algorithm (CMA)" on page 5-467.

## Step size - Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes
Dependencies
To enable this parameter, set Adaptive algorithm to LMS or CMA.

## Forgetting factor - Forgetting factor

0.99 (default) | scalar in the range ( 0,1 ]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range ( 0,1 ]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to RLS.

## Initial inverse correlation matrix - Initial inverse correlation matrix 0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an $N_{\text {Taps }}$-by- $N_{\text {Taps }}$ matrix. $N_{\text {Taps }}$ is equal to the Number of Taps parameter value. If you specify this value as a scalar, $a$, the equalizer sets the initial inverse correlation matrix to $a$ times the identity matrix: $a\left(\operatorname{eye}\left(N_{\text {Taps }}\right)\right)$.

Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to RLS.

## Control parameters

## Reference tap - Reference tap

3 (default) | positive integer
Reference tap, specified as a positive integer less than or equal to the Number of Taps parameter value. The equalizer uses the reference tap location to track the main energy of the channel.

## Input signal delay (samples) - Input signal delay <br> 0 (default) | nonnegative integer

Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1, then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the block and to the first call of the block after the Reset input port toggles to 1.

## Dependencies

To enable this parameter, set Adaptive algorithm to LMS or RLS.

## Source of adapt weights flag - Source of adapt tap weights request Property (default)|Input port

Source of the adapt tap weights request, specified as one of these values:

- Property - Specify this value to use the Adaptive algorithm parameter to control when the block adapts tap weights.
- Input port - Specify this value to use the Update input port to control when the block adapts tap weights.

## Dependencies

To enable this parameter, set Adaptive algorithm to CMA.

## Adapt tap weights - Adapt tap weights

on (default) | off
Select this parameter to adaptively update the equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged.

Tunable: Yes
Dependencies
To enable this parameter, set Adaptive algorithm to CMA and Source of adapt weights flag to Property.

## Initial tap weights source - Source for initial tap weights <br> Auto (default) | Property

Source for initial tap weights, specified as one of these values:

- Auto - Initialize the tap weights to the algorithm-specific default values, as described in the Initial weights parameter.
- Property - Initialize the tap weights using the Initial weights parameter value.

## Initial weights - Initial tap weights

0 or $[0 ; 0 ; 1 ; 0 ; 0]$ (default) | scalar | column vector
Initial tap weights used by the adaptive algorithm, specified as a scalar or an $N_{\text {Taps }}$-by- 1 vector. $N_{\text {Taps }}$ is equal to the Number of Taps parameter value. The default is 0 when the Adaptive algorithm parameter is set to LMS or RLS. The default is $[0 ; 0 ; 1 ; 0 ; 0]$ when the Adaptive algorithm parameter is set to CMA.

If you specify Initial weights as a vector, the vector length must be equal to the Number of Taps parameter value. If you specify Initial weights as a scalar, the equalizer uses scalar expansion to create a vector of length Number of Taps with all values set to Initial weights.

Tunable: Yes
Dependencies
To enable this parameter, set Initial tap weights source to Property.

## Tap weight update period (symbols) - Tap weight update period

1 (default) | positive integer
Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.

## Enable training control input - Enable training control input off (default)| on

Select this parameter to enable input port Train. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

Tunable: Yes

## Dependencies

To enable this parameter, set Adaptive algorithm to LMS or RLS.

## Update tap weights when not training - Update tap weights when not training on (default) | off

Select this parameter to use decision directed mode to update equalizer tap weights. If this parameter is cleared, the block keeps the equalizer tap weights unchanged after training.

Tunable: Yes
Dependencies
To enable this parameter, set Adaptive algorithm to LMS or RLS.

## Enable reset input - Enable reset input <br> off (default) | on

Select this parameter to enable input port Train. If this parameter is cleared, the block does not reenter training mode after the initial tap training.

Tunable: Yes
Diagnostic parameters

```
Output error signal - Enable error signal output
off (default) | on
```

Select this parameter to enable output port Err containing the equalizer error signal.
Tunable: Yes

## Output taps weights - Enable tap weights output

off (default) | on
Select this parameter to enable output port $\mathbf{w}$ containing tap weights from the last tap weight update.
Tunable: Yes

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbolspaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1. Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

## Linear Equalizers

Linear equalizers can remove intersymbol interference (ISI) when the frequency response of a channel has no null. If a null exists in the frequency response of a channel, linear equalizers tend to enhance the noise. In this case, use decision feedback equalizers to avoid enhancing the noise.

A linear equalizer consists of a tapped delay line that stores samples from the input signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

Linear equalizers can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, $K$, is 1 . The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, $K$, is an integer greater than 1. Typically, $K$ is 4 for fractionally spaced equalizers. The output sample rate is $1 / T$ and the input sample rate is $K / T$, where $T$ is the symbol period. Tap-weight updating occurs at the output rate.

This schematic shows a linear equalizer with $L$ weights, a symbol period of $T$, and $K$ samples per symbol. If $K$ is 1 , the result is a symbol-spaced linear equalizer instead of a fractional symbol-spaced linear equalizer.

In each symbol period, the equalizer receives $K$ input samples at the tapped delay line. The equalizer then outputs a weighted sum of the values in the tapped delay line and updates the weights to prepare for the next symbol period.

For more information, see "Equalization".

## Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, $w$ is a vector of all weights $w_{i}$, and $u$ is a vector of all inputs $u_{i}$. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of inputs, $u$, and the inverse correlation matrix, $P$, the RLS algorithm first computes the Kalman gain vector, $K$, as

$$
K=\frac{P u}{(\text { ForgettingFactor })+u^{H} P u} .
$$

The forgetting factor used by the adaptive algorithm is specified as a scalar in the range $(0,1]$. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalized
output signal to be less stable. $H$ denotes the Hermitian transpose. Based on the current inverse correlation matrix, the new inverse correlation matrix is

$$
P_{\text {new }}=\frac{P_{\text {current }}\left(1-K u^{H}\right)}{\text { ForgettingFactor }} .
$$

Based on the current set of weights, the RLS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+K^{*} e .
$$

The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Constant Modulus Algorithm (CMA)

For the CMA adaptive algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of weights, the CMA adaptive algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e .
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed by the CMA adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=y\left(R-|y|^{2}\right)$, where $R$ is a constant related to the signal constellation.

## Linearized Baseband PLL

Implement linearized version of baseband phase-locked loop

```
Linearized Filt*
Baseband PD =
    PLL VCO.
```

## Library

Components sublibrary of Synchronization

## Description

The Linearized Baseband PLL block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. Unlike the Phase-Locked Loop block, this block uses a baseband model method. Unlike the Baseband PLL block, which uses a nonlinear model, this block simplifies the computations by using $x$ to approximate $\sin (x)$. The baseband PLL model depends on the amplitude of the incoming signal but does not depend on a carrier frequency.

This PLL has these three components:

- An integrator used as a phase detector.
- A filter. You specify the filter's transfer function using the Lowpass filter numerator and Lowpass filter denominator parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of $s$.

To design a filter, you can use functions such as butter, cheby1, and cheby 2 in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.
[num, den] = cheby2(3,40,100,'s')

- A voltage-controlled oscillator (VCO). You specify the sensitivity of the VCO signal to its input using the VCO input sensitivity parameter. This parameter, measured in Hertz per volt, is a scale factor that determines how much the VCO shifts from its quiescent frequency.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

## Parameters

## Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO's quiescent frequency.

## LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with LMS algorithm

Note will be removed in a future release. Use Decision Feedback Equalizer instead.

## Library

## Equalizers

## Description

The LMS Decision Feedback Equalizer block uses a decision feedback equalizer and the LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the LMS algorithm to update the weights, once per symbol. If the Number of samples per symbol parameter is 1 , then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of forward taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+($ Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

## Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

## Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of forward taps in the equalizer.

## Step size

The step size of the LMS algorithm.

## Leakage factor

The leakage factor of the LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Initial weights

A vector that concatenates the initial weights for the forward and feedback taps.

## Mode input port

If you select this check box, the block has an input port that enables you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0 . For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

## Output error

If you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

If you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## LMS Linear Equalizer

(To be removed) Equalize using linear equalizer that updates weights with LMS algorithm

Note will be removed in a future release. Use Linear Equalizer instead.

## Library

## Equalizers

## Description

The LMS Linear Equalizer block uses a linear equalizer and the LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the LMS algorithm to update the weights, once per symbol. When you set the Number of samples per symbol parameter to 1 , then the block implements a symbol-spaced (i.e. T-spaced) equalizer. When you set the Number of samples per symbol parameter to a value greater than one, the block updates the weights once every $N^{\text {th }}$ sample for a T/N-spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of taps parameter.

The Equalized port outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+$ (Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap.

## Parameters

## Number of taps

The number of taps in the filter of the linear equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulated signal, as determined by the modulator in your model

## Reference tap

A positive integer less than or equal to the number of taps in the equalizer.

## Step size

The step size of the LMS algorithm.

## Leakage factor

The leakage factor of the LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Initial weights

A vector that lists the initial weights for the taps.

## Mode input port

If you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0 . For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

## Output error

If you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.
Output weights
If you select this check box, the block outputs the current weights.

## Matrix Deinterleaver

Permute input symbols by filling matrix by columns and emptying it by rows

## Library

Block sublibrary of Interleaving

## Description

The Matrix Deinterleaver block performs block deinterleaving by filling a matrix with the input symbols column by column and then sending the matrix contents to the output port row by row. The Number of rows and Number of columns parameters are the dimensions of the matrix that the block uses internally for its computations.

This block accepts a column vector input signal. The length of the input vector must be Number of rows times Number of columns.

The block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

## Number of rows

The number of rows in the matrix that the block uses for its computations.

## Number of columns

The number of columns in the matrix that the block uses for its computations.

## Examples

If the Number of rows and Number of columns parameters are 2 and 3 , respectively, then the deinterleaver uses a 2 -by-3 matrix for its internal computations. Given an input signal of
[1; 2; 3; 4; 5; 6], the block produces an output of $[1 ; 3 ; 5 ; 2 ; 4 ; 6]$.

# Matrix Helical Scan Deinterleaver 

Restore ordering of input symbols by filling matrix along diagonals

## Library

Block sublibrary of Interleaving

## Description

The Matrix Helical Scan Deinterleaver block performs block deinterleaving by filling a matrix with the input symbols in a helical fashion and then sending the matrix contents to the output port row by row. The Number of rows and Number of columns parameters are the dimensions of the matrix that the block uses internally for its computations.

Helical fashion means that the block places input symbols along diagonals of the matrix. The number of elements in each diagonal matches the Number of columns parameter, after the block wraps past the edges of the matrix when necessary. The block traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

The Array step size parameter is the slope of each diagonal, that is, the amount by which the row index increases as the column index increases by one. This parameter must be an integer between zero and the Number of rows parameter. If the Array step size parameter is zero, then the block does not deinterleave and the output is the same as the input.

This block accepts a column vector input signal. The number of elements of the input vector must be the product of Number of rows and Number of columns.

The block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

## Number of rows

The number of rows in the matrix that the block uses for its computations.

## Number of columns

The number of columns in the matrix that the block uses for its computations.

## Array step size

The slope of the diagonals that the block writes.

## Description

The Matrix Helical Scan Interleaver block performs block interleaving by filling a matrix with the input symbols row by row and then sending the matrix contents to the output port in a helical fashion. The Number of rows and Number of columns parameters are the dimensions of the matrix that the block uses internally for its computations.

Helical fashion means that the block selects output symbols by selecting elements along diagonals of the matrix. The number of elements in each diagonal matches the Number of columns parameter, after the block wraps past the edges of the matrix when necessary. The block traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

The Array step size parameter is the slope of each diagonal, that is, the amount by which the row index increases as the column index increases by one. This parameter must be an integer between zero and the Number of rows parameter. If the Array step size parameter is zero, then the block does not interleave and the output is the same as the input.

This block accepts a column vector input signal. The number of elements of the input vector must be the product of Number of rows and Number of columns.

The block accepts the following data types: int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

## Number of rows

The number of rows in the matrix that the block uses for its computations.

## Number of columns

The number of columns in the matrix that the block uses for its computations.

## Array step size

The slope of the diagonals that the block reads.

## Examples

If the Number of rows and Number of columns parameters are 6 and 4, respectively, then the interleaver uses a 6-by-4 matrix for its internal computations. If the Array step size parameter is 1, then the diagonals are as shown in the figure below. Positions with the same color form part of the same diagonal, and diagonals with darker colors precede those with lighter colors in the output signal.

Given an input signal of [1:24] ', the block produces an output of

[1; 6; 11; 16; $5 ; 10 ; 15 ; 20 ; 9 ; 14 ; 19 ; 24 ; 13 ; 18 ; 23 ; .$.

# M-DPSK Demodulator Baseband 

Demodulate DPSK-modulated data

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The M-DPSK Demodulator Baseband block demodulates a signal that was modulated using the M-ary differential phase shift keying method. The input is a baseband representation of the modulated signal. The input and output for this block are discrete-time signals. This block accepts a scalarvalued or column vector input signal. For information about the data types each block port supports, see the "Supported Data Types" on page 5-486 table on this page.

The M-ary number parameter, M , is the number of possible output symbols that can immediately follow a given output symbol. The block compares the current symbol to the previous symbol. The block's first output is the initial condition of zero (or a group of zeros, if the Output type parameter is set to Bit) because there is no previous symbol.

## Integer-Valued Signals and Binary-Valued Signals

If you set the Output type parameter to Integer, then the block demodulates a phase difference of

```
\(\theta\)
```

to $k$, where $\theta$ represents the Phase rotation parameter and $k$ represents an integer between 0 and M-1.

When you set the Output type parameter to Bit, the block outputs binary-valued signals that represent integers. The block represents each integer using a group of $K=\log _{2}(M)$ bits, where $K$ represents the number of bits per symbol. The output vector length must be an integer multiple of $K$.

In binary output mode, the symbols can be either binary-demapped or Gray-demapped. The Constellation ordering parameter indicates how the block maps an integer to a corresponding group of $K$ output bits. See the reference pages for the M-DPSK Modulator Baseband and M-PSK Modulator Baseband blocks for details.

## Dialog Box

## M-ary number

The number of possible modulated symbols that can immediately follow a given symbol.

## Output type

Determines whether the output consists of integers or groups of bits.

## Constellation ordering

Determines how the block maps each integer to a group of output bits.

## Phase rotation (rad)

This phase difference between the current and previous modulated symbols that results in an output of zero.

## Output data type

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type single or double.

For integer outputs, this block can output the data types int8, uint8, int16, uint16, int32, uint32, single, and double. For bit outputs, output can be int8, uint8, int16, uint16, int32, uint32, boolean, single, or double.

## Supported Data Types

## M-DPSK Modulator Baseband

Modulate using M-ary differential phase shift keying method

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The M-DPSK Modulator Baseband block modulates using the M-ary differential phase shift keying method. The output is a baseband representation of the modulated signal. The M-ary number parameter, M , is the number of possible output symbols that can immediately follow a given output symbol.

The input must be a discrete-time signal. For integer inputs, the block can accept the data types int8, uint8, int16, uint16, int32, uint32, single, and double. For bit inputs, the block can accept int8, uint8, int16, uint16, int32, uint32, boolean, single, and double.

The input can be either bits or integers, which are binary-mapped or Gray-mapped into symbols.
This block accepts column vector input signals. For a bit input, the input width must be an integer multiple of the number of bits per symbol.

## Integer-Valued Signals and Binary-Valued Signals

If you set the Input type parameter to Integer, then valid input values are integers between 0 and $\mathrm{M}-1$. In this case, the input can be either a scalar or a frame-based column vector. If the first input is $\mathrm{k}_{1}$, then the modulated symbol is

$$
\exp \left(j \theta+j 2 \pi \frac{k_{1}}{m}\right)
$$

where $\theta$ represents the Phase rotation parameter. If a successive input is $k$, then the modulated symbol is

$$
\exp \left(j \theta+j 2 \Pi \frac{k}{m}\right) \cdot(\text { previous modulated symbol })
$$

When you set the Input type parameter to Bit, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $K=\log _{2}(M)$ bits
where
$K$ represents the number of bits per symbol.

The input vector length must be an integer multiple of $K$. In this configuration, the block accepts a group of $K$ bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol for each group of $K$ bits.

The input can be a column vector with a length that is an integer multiple of $K$.
In binary input mode, the Constellation ordering parameter indicates how the block maps a group of $K$ input bits to a corresponding phase difference. The Binary option uses a natural binary-tointeger mapping, while the Gray option uses a Gray-coded assignment of phase differences. For example, the following table indicates the assignment of phase difference to three-bit inputs, for both the Binary and Gray options. $\theta$ is the Phase rotation parameter. The phase difference is between the previous symbol and the current symbol.

| Current Input | Binary-Coded Phase Difference | Gray-Coded Phase Difference |
| :---: | :---: | :---: |
| [0000] | j $\theta$ | j $\theta$ |
| [ $\left.\begin{array}{lll}0 & 0 & 1\end{array}\right]$ | j $\theta+\mathrm{j} \pi / 4$ | j $\theta+\mathrm{j} п 1 / 4$ |
| [010] | j $\theta+\mathrm{j}$ п $2 / 4$ | j $\theta+\mathrm{j} п 3 / 4$ |
| [ $\left.\begin{array}{lll}0 & 1 & 1\end{array}\right]$ | j $\theta+$ jп3/4 | j $\theta+$ jп2/4 |
| [100] | j $\theta+$ јп $4 / 4$ | j $\theta+$ jп7/4 |
| $\left[\begin{array}{lll}1 & 0 & 1\end{array}\right]$ | j $\theta+$ jп5/4 | j $\theta+$ јп6/4 |
| [1110] | j $\theta+$ јп6/4 | j $\theta+$ jп $4 / 4$ |
| $\left[\begin{array}{lll}1 & 1 & 1\end{array}\right]$ | j $\theta+\mathrm{j} \mathbf{7} 7 / 4$ | j $\theta+\mathrm{j} \ddagger 5 / 4$ |

For more details about the Binary and Gray options, see the reference page for the M-PSK Modulator Baseband block. The signal constellation for that block corresponds to the arrangement of phase differences for this block.

## Dialog Box

## M-ary number

The number of possible output symbols that can immediately follow a given output symbol.

## Input type

Indicates whether the input consists of integers or groups of bits. If this parameter is set to Bit, then the $\mathbf{M}$-ary number parameter must be $2^{\mathrm{K}}$ for some positive integer K .

## Constellation ordering

Determines how the block maps each group of input bits to a corresponding integer.

## Phase rotation (rad)

The phase difference between the previous and current modulated symbols when the input is zero.
Output data type
The output data type can be either single or double. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean (binary input mode only) <br> - 8 -, 16 -, and 32 -bit signed integers <br> - 8 -, 16-, and 32 -bit unsigned integers |
| Output | - Double-precision floating point <br> - Single-precision floating point |

## Memoryless Nonlinearity

Apply memoryless nonlinearity to complex baseband signal
Library: Communications Toolbox / RF Impairments

Polynomial

## Description

The Memoryless Nonlinearity block applies memoryless nonlinear impairments to a complex baseband signal. Use this block to model memoryless nonlinear impairments caused by signal amplification in the radio frequency (RF) transmitter or receiver. For more information, see "Memoryless Nonlinear Impairments" on page 5-495.

Note All values of power assume a nominal impedance of 1 ohm .

## Ports

Input
In1 - Input RF baseband signal
numeric scalar | numeric column vector
Input RF baseband signal, specified as a numeric scalar or numeric column vector. Values in this input must be complex.
Data Types: double
Complex Number Support: Yes
Output
Out1 - Output RF baseband signal
numeric scalar | numeric column vector
Output RF baseband signal, returned as a numeric scalar or numeric column vector. The output is of the same data type as the input.

## Parameters

## Method - Nonlinearity modeling method

Cubic polynomial (default)|Hyperbolic tangent|Saleh model|Ghorbani model|Rapp model

Nonlinearity modeling method, specified as Cubic polynomial, Hyperbolic tangent, Saleh model, Ghorbani model, Rapp model, or Lookup table. For more information, see "Memoryless Nonlinear Impairments" on page 5-495.

Linear gain (dB) - Linear gain
0 (default) | numeric scalar

Linear gain in decibels, specified as a numeric scalar. This parameter scales the power gain of the output signal.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Cubic polynomial, Hyperbolic tangent, or Rapp model.

Data Types: double
IIP3 (dBm) - Third-order input intercept point
30 (default) | numeric scalar
Third-order input intercept point in dBm , specified as a numeric scalar.
Tunable: Yes
Dependencies
To enable this parameter, set the Method to Cubic polynomial or Hyperbolic tangent.
Data Types: double
AM/PM conversion (degrees per dB) - AM/PM conversion factor
10 (default) | numeric scalar
AM/PM conversion factor in degrees per decibel, specified as a numeric scalar. For more information, see "Cubic Polynomial and Hyperbolic Tangent Model Methods" on page 5-496.

Tunable: Yes

## Dependencies

To enable this parameter, set the Method to Cubic polynomial or Hyperbolic tangent.

## Data Types: double

Lower input power limit for AM/PM conversion (dBm) - Input power lower limit 10 (default)

Input power lower limit in dBm , specified as a numeric scalar less than the Upper input power limit for AM/PM conversion (dBm) parameter value. The AM/PM conversion scales linearly for input power values in the range [Lower input power limit for AM/PM conversion (dBm), Upper input power limit for $\mathbf{A M} / \mathbf{P M}$ conversion ( $\mathbf{d B m}$ )]. If the input signal power is below the input power lower limit, the phase shift resulting from AM/PM conversion is zero. For more information, see "Cubic Polynomial and Hyperbolic Tangent Model Methods" on page 5-496.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Cubic polynomial or Hyperbolic tangent.
Data Types: double
Upper input power limit for AM/PM conversion (dBm) - Input power upper limit inf (default) | numeric scalar

Input power upper limit in dBm, specified as a numeric scalar greater than the Lower input power limit for AM/PM conversion (dBm) parameter value. The AM/PM conversion scales linearly for input power values in the range [Lower input power limit for AM/PM conversion (dBm), Upper input power limit for AM/PM conversion (dBm)]. If the input signal power is below the input power lower limit, the phase shift resulting from AM/PM conversion is zero. For more information, see "Cubic Polynomial and Hyperbolic Tangent Model Methods" on page 5-496.

Tunable: Yes

## Dependencies

To enable this parameter, set the Method to Cubic polynomial or Hyperbolic tangent.
Data Types: double
Input scaling (dB) - Input signal scaling factor
0 (default) | numeric scalar
Input signal scaling factor in decibels, specified as a numeric scalar. This parameter scales the power gain of the input signal.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Saleh model or Ghorbani model.

## Data Types: double

AM/AM parameters [alpha beta] - AM/AM parameters for Saleh model
[2.1587 1.1517] (default)| two-element numeric vector
AM/AM parameters for Saleh model, used to compute the amplitude gain for an input signal, specified as a two-element numeric vector. For more information, see "Saleh Model Method" on page 5-497.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Saleh model.

## Data Types: double

AM/PM parameters [alpha beta] - AM/PM parameters for Saleh model
[4.0033 9.1040] (default) | two-element numeric vector
AM/PM parameters for Saleh model, used to compute the phase change for an input signal, specified as a two-element numeric vector. For more information, see "Saleh Model Method" on page 5-497.

Tunable: Yes

## Dependencies

To enable this parameter, set the Method to Saleh model.
AM/AM parameters [x1 x2 x3 x4] - AM/AM parameters for Ghorbani model
[8.1081 1.5413 6.5202-0.0718] (default) | four-element numeric vector

AM/AM parameters for Ghorbani model, used to compute the amplitude gain for an input signal, specified as a four-element numeric vector. For more information, see "Ghorbani Model Method" on page 5-497.

Tunable: Yes

## Dependencies

To enable this parameter, set the Method to Ghorbani model.

## Data Types: double

AM/PM parameters [y1 y2 y3 y4] - AM/PM parameters for Ghorbani model [4.6645 2.0965 10.88-0.003] (default)| four-element numeric vector

AM/PM parameters for Ghorbani model, used to compute the phase change for an input signal, specified as a four-element numeric vector. For more information, see "Ghorbani Model Method" on page 5-497.

Tunable: Yes

## Dependencies

To enable this parameter, set the Method to Ghorbani model.
Data Types: double
Output scaling (dB) - Output signal scaling factor
0 (default) | numeric scalar
Output signal scaling factor in decibels, specified as a numeric scalar. This parameter scales the power gain of the output signal.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Saleh model or Ghorbani model.
Data Types: double

## Smoothness factor - Smoothness factor <br> 0.5 (default) | numeric scalar

Smoothness factor, specified as a numeric scalar. For more information, see "Rapp Model Method" on page 5-498.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Rapp model.
Data Types: double
Output saturation level - Output saturation level
1 (default) | numeric scalar

Output saturation level, specified as a numeric scalar. For more information, see "Rapp Model Method" on page 5-498.

Tunable: Yes
Dependencies
To enable this parameter, set the Method to Rapp model.
Data Types: double

## Block Characteristics

| Variable-Size Signals | no |

## More About

## Memoryless Nonlinear Impairments

Memoryless nonlinear impairments distort the input signal amplitude and phase. The amplitude distortion is amplitude-to-amplitude modulation (AM/AM) and the phase distortion is amplitude-tophase modulation (AM/PM).

| Model Method | Memoryless Nonlinear Impairment |
| :--- | :--- |
| Cubic polynomial | AM/AM and AM/PM |
| Hyperbolic tangent |  |
| Saleh model |  |
| Ghorbani model | AM/AM only |
| Rapp model |  |

The modeled impairments apply the AM/AM and AM/PM distortions differently, according to the model method you specify. The models apply the memoryless nonlinear impairment to the input signal by following these steps.

1 Multiply the signal by an input gain factor.

Note You can normalize the signal to 1 by setting the input scaling gain to the inverse of the input signal amplitude.
2 Split the complex signal into its magnitude and angle components.
3 Apply an AM/AM distortion to the magnitude of the signal, according to the selected model method, to produce the magnitude of the output signal.
4 Apply an AM/PM distortion to the phase of the signal, according to the selected model method, to produce the angle of the output signal.

Note This step does not apply for the Rapp model.

5 Combine the new magnitude and angle components into a complex signal. Then, multiply the result by an output gain factor.

The first four model methods (cubic polynomial, hyperbolic tangent, Saleh model, and Ghorbani model) apply AM/AM and AM/PM impairments as shown in this figure.

The Rapp model method applies AM/AM distortion as shown in this figure.

## Cubic Polynomial and Hyperbolic Tangent Model Methods

This figure shows the AM/PM conversion behavior for the cubic polynomial and hyperbolic tangent model methods.

The AM/PM conversion scales linearly with an input power value between the lower and upper limits of the input power level. Outside this range, the AM/PM conversion is constant at the values corresponding to the lower and upper input power limits, which are zero and (AM/PM conversion) $\times$ (upper input power limit - lower input power limit), respectively.

## Saleh Model Method

This figure shows the AM/AM behavior (output voltage versus input voltage for the AM/AM distortion) and the AM/PM behavior (output phase versus input voltage for the AM/PM distortion) for the Saleh model method.

The AM/AM parameters, $\alpha_{\text {AMAM }}$ and $\beta_{\text {AMAM }}$, are used to compute the amplitude distortion of the input signal by using

$$
F_{\mathrm{AMAM}}(u)=\frac{\alpha_{\mathrm{AMAM}} \times u}{1+\beta_{\mathrm{AMAM}} \times u^{2}},
$$

where $u$ is the magnitude of the scaled signal.
The AM/PM parameters, $\alpha_{\text {AMPM }}$ and $\beta_{\text {AMPM }}$, are used to compute the phase distortion of the input signal by using

$$
F_{\mathrm{AMPM}}(u)=\frac{\alpha_{\mathrm{AMPM}} \times u^{2}}{1+\beta_{\mathrm{AMPM}} \times u^{2}},
$$

where $u$ is the magnitude of the scaled signal. The $\alpha$ and $\beta$ parameters for AM/AM and AM/PM are similarly named but distinct.

Ghorbani Model Method
The Ghorbani model method applies AM/AM and AM/PM distortion as described in this section.

The AM/AM parameters ( $x_{1}, x_{2}, x_{3}$, and $x_{4}$ ) are used to compute the amplitude distortion of the input signal by using

$$
F_{\mathrm{AMAM}}(u)=\frac{x_{1} u^{x_{2}}}{1+x_{3} u^{x_{2}}}+x_{4} u
$$

where $u$ is the magnitude of the scaled signal.
The AM/PM parameters ( $y_{1}, y_{2}, y_{3}$, and $y_{4}$ ) are used to compute the phase distortion of the input signal by using

$$
F_{\mathrm{AMPM}}(u)=\frac{y_{1} u^{y_{2}}}{1+y_{3} u^{y_{2}}}+y_{4} u,
$$

where $u$ is the magnitude of the scaled signal.

## Rapp Model Method

The Rapp model method applies AM/AM distortion as described in this section. The Rapp model does not apply AM/PM distortion to the input signal.

The smoothness factor and output saturation level are used to compute the amplitude distortion of the input signal given by

$$
F_{\mathrm{AMAM}}(u)=\frac{u}{\left(1+\left(\frac{u}{O_{\mathrm{sat}}}\right)^{2 \mathrm{~S}}\right)^{1 / 2 \mathrm{~S}}}
$$

where

- $u$ is the magnitude of the scaled signal.
- $S$ is the smoothness factor.
- $O_{\text {sat }}$ is the output saturation level.

# M-FSK Demodulator Baseband 

Demodulate FSK-modulated data

## Library

FM, in Digital Baseband sublibrary of Modulation

## Description

The M-FSK Demodulator Baseband block demodulates a signal that was modulated using the M-ary frequency shift keying method. The input is a baseband representation of the modulated signal. The input and output for this block are discrete-time signals. This block accepts a scalar value or column vector input signal of type single or double. For information about the data types each block port supports, see "Supported Data Types" on page 5-503.

The M-ary number parameter, $M$, is the number of frequencies in the modulated signal. The Frequency separation parameter is the distance, in Hz , between successive frequencies of the modulated signal.

The M-FSK Demodulator Baseband block implements a non-coherent energy detector. To obtain the same BER performance as that of coherent FSK demodulation, use the CPFSK Demodulator Baseband block.

## Integer-Valued Signals and Binary-Valued Signals

When you set the Output type parameter to Integer, the block outputs integer values between 0 and $M-1$. $M$ represents the $\mathbf{M}$-ary number block parameter.

When you set the Output type parameter to Bit, the block outputs binary-valued signals that represent integers. The block represents each integer using a group of $K=\log _{2}(M)$ bits, where $K$ represents the number of bits per symbol. The output vector length must be an integer multiple of $K$.

The Symbol set ordering parameter indicates how the block maps a symbol to a group of $K$ output bits. When you set the parameter to Binary, the block maps the integer, I, to $[u(1) u(2) \ldots u(\mathrm{~K})]$ bits, where the individual $u(i)$ are given by

$$
I=\sum_{i=1}^{K} u(i) 2^{K-i}
$$

$u(1)$ is the most significant bit.
For example, if $M=8$, you set Symbol set ordering to Binary, and the demodulated integer symbol value is 6 , then the binary output word is [lllll 110 .

When you set Symbol set ordering to Gray, the block assigns binary outputs from points of a predefined Gray-coded signal constellation. The predefined M-ary Gray-coded signal constellation assigns the binary representation
$M=8 ; P=[0: M-1] ' ;$
de2bi(bitxor(P,floor(P/2)), log2(M),'left-msb')
to the $P^{\text {th }}$ integer.
The typical Binary to Gray mapping for $M=8$ is shown in the following tables.

## Binary to Gray Mapping for Bits

| Binary Code | Gray Code |
| :--- | :--- |
| 000 | 000 |
| 001 | 001 |
| 010 | 011 |
| 011 | 010 |
| 100 | 110 |
| 101 | 111 |
| 110 | 101 |
| 111 | 100 |

## Binary to Gray Mapping for Integers

| Binary Code | Gray Code |
| :--- | :--- |
| 0 | 0 |
| 1 | 1 |
| 2 | 3 |
| 3 | 2 |
| 4 | 6 |
| 5 | 7 |
| 6 | 5 |
| 7 | 4 |

Whether the output is an integer or a binary representation of an integer, the block maps the highest frequency to the integer 0 and maps the lowest frequency to the integer M-1. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the Samples per symbol parameter value, and the input can be a column vector.

- When you set Output type to Bit, the output width is $K$ times the number of input symbols.
- When you set Output type to Integer, the output width is the number of input symbols.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the Samples per symbol parameter value.

- When you set Output type to Bit, the output width equals the number of bits per symbol.
- When you set Output type to Integer, the output is a scalar.

To run the M-FSK Demodulator block in multirate mode, clear the Treat each discrete rate as a separate task checkbox (in Simulation > Configuration Parameters > Solver).

## Parameters

## M-ary number

The number of frequencies in the modulated signal.

## Output type

Determines whether the output consists of integers or groups of bits. If this parameter is set to Bit, then the M-ary number parameter must be $2^{\mathrm{K}}$ for some positive integer K .

## Symbol set ordering

Determines how the block maps each integer to a group of output bits.

## Frequency separation (Hz)

The distance between successive frequencies in the modulated signal.

## Samples per symbol

The number of input samples that represent each modulated symbol.

## Rate options

Select the rate processing method for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample times. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the Samples per symbol parameter value when the Output type parameter is set to Integer).
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the Samples per symbol parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

## Output data type

The output type of the block can be specified here as boolean, int8, uint8, int16, uint16, int32, uint32, or double. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point |
| Output | - Double-precision floating point <br> - Boolean <br> - $8-16$-, and 32 -bit signed integers <br> - 8 -, 16 -, and 32 -bit unsigned integers |

Introduced before R2006a

# M-FSK Modulator Baseband 

Modulate using M-ary frequency shift keying method

## Library

FM, in Digital Baseband sublibrary of Modulation

## Description

The M-FSK Modulator Baseband block modulates using the M-ary frequency shift keying method. The output is a baseband representation of the modulated signal. For information about the data types each block port supports, see "Supported Data Types" on page 5-507.

To prevent aliasing from occurring in the output signal, set the sampling frequency greater than the product of $M$ and the Frequency separation parameter. Sampling frequency is Samples per symbol divided by the input symbol period (in seconds).

## Integer-Valued Signals and Binary-Valued Signals

The input and output signals for this block are discrete-time signals.
When you set the Input type parameter to Integer, the block accepts integer values between 0 and $M-1 . M$ represents the $\mathbf{M}$-ary number block parameter.

When you set the Input type parameter to Bit, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $K=\log _{2}(M)$ bits
where
$K$ represents the number of bits per symbol.
The input vector length must be an integer multiple of $K$. In this configuration, the block accepts a group of $K$ bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol, oversampled by the Samples per symbol parameter value, for each group of $K$ bits.

The Symbol set ordering parameter indicates how the block maps a group of $K$ input bits to a corresponding symbol. When you set the parameter to Binary, the block maps $[u(1) u(2) \ldots u(\mathrm{~K})]$ to the integer

$$
\sum_{i=1}^{K} u(i) 2^{K-i}
$$

and assumes that this integer is the input value. $u(1)$ is the most significant bit.

If you set $M=8$, Symbol set ordering to Binary, and the binary input word is [110], the block converts [110] to the integer 6. The block produces the same output when the input is 6 and the Input type parameter is Integer.

When you set Symbol set ordering to Gray, the block uses a Gray-coded arrangement and assigns binary inputs to points of a predefined Gray-coded signal constellation. The predefined M-ary Graycoded signal constellation assigns the binary representation
$M=8 ; P=[0: M-1]^{\prime} ;$
de2bi(bitxor(P,floor(P/2)), log2(M),'left-msb')
to the $P^{\text {th }}$ integer.
The following tables show the typical Binary to Gray mapping for $M=8$.
Binary to Gray Mapping for Bits

| Binary Code | Gray Code |
| :--- | :--- |
| 000 | 000 |
| 001 | 001 |
| 010 | 011 |
| 011 | 010 |
| 100 | 110 |
| 101 | 111 |
| 110 | 101 |
| 111 | 100 |

Binary to Gray Mapping for Integers

| Binary Code | Gray Code |
| :--- | :--- |
| 0 | 0 |
| 1 | 1 |
| 2 | 3 |
| 3 | 2 |
| 4 | 6 |
| 5 | 7 |
| 6 | 5 |
| 7 | 4 |

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set Input type to Integer, the input can be a column vector, the length of which is the number of input symbols.
- When you set Input type to Bit, the input width must be an integer multiple of $K$, the number of bits per symbol.

The output width equals the product of the number of input symbols and the Samples per symbol parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set Input type to Integer, the input must be a scalar.
- When you set Input type to Bit, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the Samples per symbol parameter value.

To run the M-FSK Modulator block in multirate mode, clear the Treat each discrete rate as a separate task checkbox (in Simulation > Configuration Parameters > Solver).

## Parameters

## M-ary number

The number of frequencies in the modulated signal.

## Input type

Indicates whether the input consists of integers or groups of bits. If you set this parameter to Bit, then the $\mathbf{M}$-ary number parameter must be $2^{\mathrm{K}}$ for some positive integer K .

## Symbol set ordering

Determines how the block maps each group of input bits to a corresponding integer.

## Frequency separation (Hz)

The distance between successive frequencies in the modulated signal.

## Phase continuity

Determines whether the modulated signal changes phases in a continuous or discontinuous way.
If you set the Phase continuity parameter to Continuous, then the modulated signal maintains its phase even when it changes its frequency. If you set the Phase continuity parameter to Discontinuous, then the modulated signal comprises portions of $M$ sinusoids of different frequencies. Thus, a change in the input value sometimes causes a change in the phase of the modulated signal.

## Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input.

## Rate options

Select the rate processing option for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the Samples per symbol parameter value.
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Output data type

You can specify the output type of the block as either a double or a single. By default, the block sets this value to double.

## Supported Data Types

| Port | Supported Data Types |
| :--- | :--- |
| Input | $\bullet$ Double-precision floating point |
|  | $\bullet$ Boolean (bit input mode only) |
|  | $\bullet$ 8-, 16-, and 32-bit signed integers (integer input mode only) |
|  | • 8-, 16-, and 32-bit unsigned integers (integer input mode only) |
| Output | $\bullet$ Double-precision floating point |
|  | $\bullet$ |
|  | Single-precision floating point |

## MIL-188 QAM Demodulator Baseband

MIL-STD-188-110 B/C standard-specific quadrature amplitude demodulation
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / AM
Communications Toolbox / Modulation / Digital Baseband Modulation / Standard-Compliant

## Description

The MIL-188 QAM Demodulator Baseband block demodulates the input signal using "MIL-STD-188-110" on page 5-511 standard-specific quadrature amplitude modulation (QAM). For a description of MIL-STD-188 compliant demodulation, see "MIL-STD-188-110 QAM Hard Demodulation" on page 5-511 and "MIL-STD-188-110 QAM Soft Demodulation" on page 5-512.

This icon shows the block with all ports enabled:

## Ports

Input
In - MIL-STD-188 standard-specific QAM modulated signal
scalar | vector | matrix
MIL-STD-188 standard-specific QAM modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the Var port is enabled.

## Data Types: single | double <br> Complex Number Support: Yes

## Var - Noise variance

positive scalar | vector of positive values
Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "MIL-STD-188-110 QAM Soft Demodulation" on page 5-512 for demodulation decision type considerations.

## Dependencies

To enable this port set the Noise variance source parameter to Input port.

## Output

Out - Demodulated signal
scalar | vector | matrix

Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the demodulated signal depend on the specified Output type and Decision type parameter values. This port is unnamed on the block.

| Output <br> type | Decision <br> type | Demodulated Signal <br> Description | Dimensions of Demodulated Signal |
| :--- | :--- | :--- | :--- |
| Integer | - | Demodulated integer values <br> in the range $[0,(M-1)]$ | The output signal has the same <br> dimensions as input signal. |
| Bit | Hard <br> decision | Demodulated bits | The number of rows in the output signal is <br> $\log _{2}(M)$ times the number of rows in the <br> input signal. Each demodulated symbol is <br> mapped to a group of $\log _{2}(M)$ elements in <br> a column, where the first element <br> represents the MSB, and the last element <br> represents the LSB. |
| Log- <br> likelihood <br> ratio | Log-likelihood ratio value <br> for each bit | Approximat <br> e log- <br> likelihood <br> ratio | Approximate log-likelihood <br> ratio value for each bit |

Use Output data type to specify the output data type.

## Parameters

Modulation order - Modulation order
16 (default) | 32 | 64 | 256
Modulation order, $M$, specified as $16,32,64$, or 256 . The modulation order specifies the total number of points in the constellation of the input signal.

## Constellation scaling - Constellation scaling

As specified in standard (default)|Unit average power
Constellation scaling preference, specified as:

- As specified in standard - The block scales the constellation based on specifications in the relevant standard [1].
- Unit average power - The block scales the constellation to an average power of 1 watt referenced to 1 ohm.

## Output type - Input type

Integer (default) |Bit
Output type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range $[0,(M-1)]$. To use Bit, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log _{2}(M)$, where $M$ is the Modulation order.

## Decision type - Demodulation decision type

Hard decision (default)|Log-likelihood ratio|Approximate log-likelihood ratio
Demodulation decision type, specified as Hard decision, Log-likelihood ratio, or Approximate log-likelihood ratio. See "MIL-STD-188-110 QAM Soft Demodulation" on page 5-512 for algorithm selection considerations.

## Dependencies

This parameter applies when Output type is set to Bit.

## Noise variance source - Noise variance source

Property (default)|Input port
Noise variance source, specified as:

- Property - The noise variance is set using the Noise variance parameter.
- Input port - The noise variance is set using the Var input port.

## Dependencies

This parameter applies only when Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

## Noise variance - Noise variance

1 (default) | positive scalar | vector of positive values
Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "MIL-STD-188-110 QAM Soft Demodulation" on page 5-512 for demodulation decision type considerations.

## Dependencies

This parameter applies only when Noise variance is set to Property and Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.
Data Types: double

## Output data type - Output data type

double (default) | . . .
Output data type, specified as one of the acceptable values from this table. Acceptable Output data type values depend on the Output type and Decision type parameter values.

| Output type | Decision type | Output data type Options |
| :--- | :--- | :--- |
| Integer | Not applicable | double, single, int8, uint8, int16, uint16, int32, or <br> uint32 |
| Bit | Hard decision | double, single, int8, uint8, int16, uint16, int32, <br> uint32, or logical |
|  |  |  |

| Output type | Decision type | Output data type Options |
| :--- | :--- | :--- |
|  | Log-likelihood <br> ratio or <br> Approximate <br> log-likelihood <br> ratio |  |

## Dependencies

This parameter applies only when Output type is set to Integer or when Output type is set to Bit and Decision type is set to Hard decision.

## Simulate using - Type of simulation to run

Interpreted execution (default)|Code generation
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

For information on execution speed, see "Tips" on page 5-512.

## Block Characteristics

| Data Types | Boolean \| double \| integer \| single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | no |

## More About

## MIL-STD-188-110

MIL-STD-188-110 is a US Department of Defense standard for HF communications using serial PSK mode of both data and voice signals.

The standard specifies physical layer modulation schemes for tactical and long-haul communications. The modulation scheme specified by the standard is a mix of QAM and APSK. For a detailed description of the modulation scheme, see [1].

## MIL-STD-188-110 QAM Hard Demodulation

The hard demodulation algorithm uses optimum decision region-based demodulation. Since all the constellation points are equally probable, maximum a posteriori probability (MAP) detection reduces to a maximum likelihood (ML) detection. The ML detection rule is equivalent to choosing the closest constellation point to the received symbol. The decision region for each constellation point is designed by drawing perpendicular bisectors between adjacent points. A received symbol is mapped to the proper constellation point based on which decision region it lies in.

Since all MIL-STD constellations are quadrant-based symmetric, for each symbol the optimum decision region-based demodulation:

- Maps the received symbol into the first quadrant
- Chooses the decision region for the symbol
- Maps the constellation point back to its original quadrant using the sign of real and imaginary parts of the received symbol

## MIL-STD-188-110 QAM Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

| Algorithm | Accuracy | Execution Speed |
| :--- | :--- | :--- |
| Exact LLR | more accurate | slower execution |
| Approximate LLR | less accurate | faster execution |

For further description of these algorithms, see "Exact LLR Algorithm" and "Approximate LLR Algorithm".

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or - Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## Tips

- For faster execution of the MIL-188 QAM Demodulator Baseband block, set the Simulate using parameter to:
- Code generation when using hard decision demodulation.
- Interpreted execution when using soft decision demodulation.

## MIL-188 QAM Modulator Baseband

MIL-STD-188-110 B/C standard-specific quadrature amplitude modulation (QAM)
Library: $\quad$ Communications Toolbox / Modulation / Digital Baseband Modulation / AM
Communications Toolbox / Modulation / Digital Baseband Modulation / Standard-Compliant

## Description

The MIL-188 QAM Modulator Baseband block modulates the input signal using "MIL-STD-188-110" on page 5-516 standard-specific quadrature amplitude modulation (QAM).

## Ports

## Input

## In - Input signal

scalar | vector | matrix
Input signal, specified as a scalar, vector, or matrix. The input signal must be binary values or integers in the range [ $0,(M-1)$ ], where $M$ is the Modulation order. This port is unnamed on the block.

Note To process the input signal as binary elements, set the Input type parameter value to Bit. For binary inputs, the number of rows must be an integer multiple of $\log _{2}(M)$. Groups of $\log _{2}(M)$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: single | double | int8|int16| int32 | uint8|uint16|uint32|Boolean

## Output

## Out - MIL-STD-188 standard-specific QAM modulated signal

scalar | vector | matrix
MIL-STD-188 standard-specific QAM modulated signal, returned as a complex scalar, vector, or matrix. The output signal dimensions depend on the specified Input type parameter value. This port is unnamed on the block.

| Input type | Dimensions of Output Signal |
| :--- | :--- |
| Integer | The output signal has the same dimensions as the input signal. |
| Bit | The number of rows in the output signal equals the number of rows in the <br> input signal divided by $\log _{2}(M)$, where $M$ is the Modulation order. |

## Parameters

Modulation order - Modulation order
16 (default) | 32 | 64 | 256
Modulation order, $M$, specified as $16,32,64$, or 256 . The modulation order specifies the total number of points in the constellation of the output signal.

Constellation scaling - Constellation scaling
As specified in standard (default)|Unit average power
Constellation scaling preference, specified as:

- As specified in standard - The block scales the constellation based on specifications in the relevant standard [1].
- Unit average power - The block scales the constellation to an average power of 1 watt referenced to 1 ohm.

## Input type - Input type

Integer (default) |Bit
Input type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range [0, (M-1)]. To use Bit, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log _{2}(M)$, where $M$ is the Modulation order.

## Output data type - Output data type

double (default) | single
Output data type, specified as double or single.

## View Constellation - Plot reference constellation

button
To plot the reference constellation, click the View Constellation button.

## Simulate using - Type of simulation to run

Code generation (default) | Interpreted execution
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is comparable to Interpreted execution.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time and has a simulation speed comparable to Code generation. In Interpreted execution mode, you can debug the source code of the block.

## Block Characteristics

Data Types $\quad$ Boolean | double | integer | single

## MIMO Fading Channel

Filter input signal through MIMO multipath fading channel

Library:<br>Communications Toolbox / Channels Communications Toolbox / MIMO

## Description

The MIMO Fading Channel block filters an input signal using a multi-input/multi-output (MIMO) multipath fading channel. This block models both Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 5-526 section.

## Signal Dimensions

The availability and dimensions of input and output port signals depends on:

- The Antenna selection parameter setting on the Main tab
- The Initial time source parameter setting on the Realization tab
- The Output channel path gains selection on the Realization tab

| Antenna Selection Parameter | Signal Input (in) | Transmit Selection Input (Tx Sel) | Receive Selection Input (Rx Sel) | Initial Time Offset Input (Init Time) | Signal Output (Out1) | Optional <br> Channel Gain Output (Gain) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0ff | $N_{\mathrm{S}}$-by- $N_{\mathrm{T}}$ | N/A | N/A | nonnegative scalar | $N_{\text {S }}$-by- $N_{\text {R }}$ | $\begin{aligned} & N_{\mathrm{S}} \text {-by- } N_{\mathrm{P}} \text {-by- } \\ & N_{\mathrm{T}} \text {-by- } N_{\mathrm{R}} \end{aligned}$ |
| Tx | $N_{\text {S }}$-by- $N_{\text {ST }}$ | 1 -by- $N_{\text {T }}$ | N/A |  | $N_{\text {S }}$-by $-N_{\text {R }}$ |  |
| Rx | $N_{\mathrm{S}^{-} \text {-by- }-N_{\mathrm{T}}}$ | N/A | 1-by- $N_{\mathrm{R}}$ |  | $N_{\text {S }}$-by- $N_{\text {SR }}$ |  |
| Tx and Rx | $N_{\text {S }}$-by- $N_{\text {ST }}$ | 1-by- $N_{T}$ | 1 -by- $N_{\mathrm{R}}$ |  | $N_{\text {S }}$-by- $N_{\text {SR }}$ |  |

- $N_{\mathrm{S}}$ represents the number of samples in the input signal.
- $N_{\mathrm{T}}$ represents the number of transmit antennas, as determined by:
- Transmit spatial correlation when Specify spatial correlation is set to Separate Tx Rx
- Number of transmit antennas when Specify spatial correlation is set to None or Combined
- $N_{\mathrm{R}}$ represents the number of receive antennas, as determined by:
- Receive spatial correlation when Specify spatial correlation is set to Separate Tx Rx
- Number of receive antennas when Specify spatial correlation is set to None
- Combined spatial correlation and Number of transmit antennas when Specify spatial correlation is set to Combined
- $N_{\mathrm{P}}$ represents the number of channel paths, as determined by the Discrete path delays (s) or Average path gains (dB).
- $N_{\text {ST }}$ represents the number of selected transmit antennas, as determined by the number of elements set to 1 in the vector provided to the Tx Sel input port.
- $N_{\mathrm{SR}}$ represents the number of selected receive antennas, as determined by the number of elements set to 1 in the vector provided to the Rx Sel input port.

## Ports

## Input

## in - Input data signal

vector
Input data signal, specified as an $N_{\mathrm{S}}$-by- $N_{\mathrm{T}}$ or $N_{\mathrm{S}}$-by- $N_{\mathrm{ST}}$ matrix.

- $N_{\mathrm{S}}$ represents the number of samples in the input signal.
- $N_{\mathrm{T}}$ represents the number of transmit antennas.
- $N_{\text {ST }}$ represents the number of selected transmit antennas.

Data Types: double | single
Complex Number Support: Yes

## Tx Sel - Select active transmit antennas

binary vector
Select active transmit antennas, specified as a 1-by- $N_{\mathrm{T}}$ binary vector. $N_{\mathrm{T}}$ represents the number of transmit antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

## Dependencies

To enable this port, on the Main tab, set Antenna selection to Tx or Tx and Rx .

## Data Types: double

## Rx Sel - Select active receive antennas

binary vector
Select active receive antennas, specified as a 1-by- $N_{\mathrm{R}}$ binary vector. $N_{\mathrm{R}}$ represents the number of receive antennas. Elements set to 1 identify selected antenna indices and 0 identify nonselected antenna indices.

## Dependencies

To enable this port, on the Main tab, set Antenna selection to Rx or Tx and Rx.
Data Types: double

## Init Time - Initial time offset

nonnegative scalar
Initial time offset for the fading model in seconds, specified as a nonnegative scalar.
Init Time must be greater than the last frame end time. When Init Time is not a multiple of 1/ Sample Rate ( Hz ), it is rounded up to the nearest sample position.

## Dependencies

To enable this port, on the Realization tab, set Initial time source to Input port.
Data Types: double

## Output

## Out1 - Output data signal for fading channel

vector
Output data signal for the fading channel, returned as an $N_{\mathrm{S}}$-by- $N_{\mathrm{R}}$ or $N_{\mathrm{S}}$-by- $N_{\mathrm{SR}}$ matrix.

- $N_{\mathrm{S}}$ represents the number of samples in the input signal.
- $\quad N_{\mathrm{R}}$ represents the number of receive antennas.
- $\quad N_{\text {SR }}$ represents the number of selected receive antennas.

## Gain - Discrete path gains

4-D array
Discrete path gains of the underlying fading process, returned as an $N_{\mathrm{S}}$-by $-N_{\mathrm{P}}-$ by $-N_{\mathrm{T}}$-by $-N_{\mathrm{R}}$ array.

- $N_{\mathrm{S}}$ represents the number of samples in the input signal.
- $\quad N_{P}$ represents the number of channel paths.
- $N_{\mathrm{T}}$ represents the number of transmit antennas.
- $\quad N_{\mathrm{R}}$ represents the number of receive antennas.

Entries for nonselected paths are filled with NaN.

## Dependencies

To enable this port, on the Realization tab, select Output channel path gains.

## Parameters

## Main Tab

Multipath parameters (frequency selectivity)
Inherit sample rate from input - Option to inherit the sample rate from input on (default) | off

Select this parameter to use the sample rate of the input signal when processing. When Inherit sample rate from input is selected, the sample rate is $N_{\mathrm{S}} / T_{\mathrm{S}}$, where $N_{\mathrm{S}}$ is the number of input samples, and $T_{\mathrm{S}}$ is the model sample time.

## Sample rate (Hz) - Input signal sample rate

1 (default) | positive scalar
Input signal sample rate, specified in hertz as a positive scalar. To match the model settings, set the sample rate to $N_{\mathrm{S}} / T_{\mathrm{S}}$, where $N_{\mathrm{S}}$ is the number of input samples, and $T_{\mathrm{S}}$ is the model sample time.

## Dependencies

This parameter appears when Inherit sample rate from input is not selected.

## Data Types: double

## Discrete path delays (s) - Delays for each discrete path <br> 0 (default) | nonnegative scalar | row vector

Delays for each discrete path in seconds, specified as a nonnegative scalar or row vector.

- When you set Discrete path delays (s) to a scalar, the MIMO channel is frequency flat.
- When you set Discrete path delays (s) to a vector, the MIMO channel is frequency selective.

## Data Types: double

Average path gains (dB) - Average gain for each discrete path
0 (default) | scalar | row vector
Average gain for each discrete path in decibels, specified as a scalar or row vector. Average path gains (dB) must have the same size as Discrete path delays (s).
Data Types: double

## Normalize average path gains to 0 dB - Option to normalize average path gains to 0 dB <br> on (default) | off

Select this parameter to normalize the fading processes so that the total power of the path gains, averaged over time, is 0 dB .

## Fading distribution - Fading distribution of channel <br> Rayleigh (default)|Rician

Select the fading distribution of the channel, either Rayleigh or Rician.

## K-factors - K-factor of Rician fading channel

3 (default) | positive scalar | row vector of nonnegative values
K-factor of a Rician fading channel, specified as a positive scalar or a 1 -by- $N_{\mathrm{P}}$ vector of nonnegative values. $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

- If you set K-factors to a scalar, the first discrete path is a Rician fading process with a Rician Kfactor of K-factors. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set K-factors to a row vector, the discrete path corresponding to a positive element of the K-factors vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to any zero-valued elements of the K-factors vector are Rayleigh fading processes. At least one element value must be nonzero.

## Dependencies

This parameter appears when Fading distribution is Rician.
Data Types: double

## LOS path Doppler shifts ( Hz ) - Doppler shifts for line-of-sight components 0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set LOS path Doppler shifts (Hz) to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set LOS path Doppler shifts (Hz) to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of LOS path Doppler shifts (Hz) that correspond to positive elements in the K-factors vector.

## Dependencies

This parameter appears when Fading distribution is Rician.
Data Types: double

## LOS path initial phases (rad) - Initial phases for line-of-sight components <br> 0 (default) | scalar | row vector

Initial phases for the line-of-sight component of the Rician fading channel in radians, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set LOS path initial phases (rad) to a scalar, it is the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set LOS path initial phases (rad) to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the elements of LOS path initial phases (rad) that correspond to positive elements in the K-factors vector.

## Dependencies

This parameter appears when Fading distribution is Rician.
Data Types: double

## Doppler parameters (time dispersion)

Maximum Doppler shift ( Hz ) - Maximum Doppler shift for all channel paths
0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.
Maximum Doppler shift (Hz) must be smaller than (Sample Rate $(\mathrm{Hz}) / 10) / f_{\mathrm{c}}$ for each path, where $f_{\mathrm{c}}$ is the cutoff frequency factor of the path. For more information, see "Cutoff Frequency Factor" on page 5-526.
Data Types: double

## Doppler spectrum - Doppler spectrum shape for all channel paths

doppler('Jakes') (default)|doppler('Flat')|doppler('Rounded', ....)|
doppler('Bell', ...)|doppler('Asymmetric Jakes', ...)|doppler('Restricted Jakes', ...)|doppler('Gaussian', ...)|doppler('BiGaussian', ....)

Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the doppler function or a 1-by- $N_{\mathrm{P}}$ cell array of such structures. The default value of this parameter is the Jakes Doppler spectrum (doppler('Jakes')).

- If you assign a single call to doppler, all paths have the same specified Doppler spectrum.
- If you assign a 1 -by- $N_{\mathrm{P}}$ cell array of calls to doppler using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case, $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

## Dependencies

This parameter applies when Maximum Doppler shift (Hz) is greater than zero.
If the Technique for generating fading samples parameter is set to Sum of sinusoids, Doppler spectrum must be doppler('Jakes').

## Antenna parameters (spatial dispersion)

## Specify spatial correlation - Spatial correlation mode

None (default)|Separate Tx Rx|Combined
Select the spatial correlation mode: None, Separate Tx Rx, or Combined.

- Choose 'None' to specify the number of transmit and receive antennas.
- Choose 'Spatial Tx Rx' to specify the transmit and receive spatial correlation matrices separately. The number of transmit ( $N_{T}$ ) and receive ( $N_{R}$ ) antennas are derived from the dimensions of the Transmit spatial correlation and Receive spatial correlation parameters, respectively.
- Choose 'Combined ' to specify a single correlation matrix for the whole channel. The product of $N_{\mathrm{T}}$ and $N_{\mathrm{R}}$ is derived from the dimension of Combined spatial correlation.

## Number of transmit antennas - Number of transmit antennas

2 (default) | positive integer
Number of transmit antennas, specified as a positive integer.

## Dependencies

This parameter appears when Specify spatial correlation is None or Combined.
Data Types: double

## Number of receive antennas - Number of receive antennas <br> 2 (default) | positive integer

Number of receive antennas, specified as a positive integer.

## Dependencies

This parameter appears when Specify spatial correlation is None.
Data Types: double

## Transmit spatial correlation - Spatial correlation of transmitter <br> [1 0; 0 1] (default) | matrix|3-D array

Specify the spatial correlation of the transmitter as an $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$ matrix or $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$-by- $N_{\mathrm{P}}$ array. $N_{\mathrm{T}}$ is the number of transmit antennas, and $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

- If Discrete path delays (s) is a scalar, the channel is frequency flat, and Transmit spatial correlation is an $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$ Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If Discrete path delays (s) is a vector, the channel is frequency selective, and you can specify Transmit spatial correlation as a matrix. Each path has the same transmit spatial correlation matrix.
- Alternatively, you can specify Transmit spatial correlation as an $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$-by- $N_{\mathrm{P}}$ array, where each path can have its own different transmit spatial correlation matrix.

## Dependencies

This parameter appears when Specify spatial correlation is Separate Tx Rx.
Data Types: double
Complex Number Support: Yes

## Receive spatial correlation - Spatial correlation of receiver

[1 0; 0 1] (default) | matrix | 3-D array
Specify the spatial correlation of the receiver as an $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$ matrix or $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$-by- $N_{\mathrm{P}}$ array. $N_{\mathrm{R}}$ is the number of receive antennas, and $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

- If Discrete path delays (s) is a scalar, the channel is frequency flat, and Receive spatial correlation is an $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$ Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If Discrete path delays (s) is a vector, the channel is frequency selective, and you can specify Receive spatial correlation as a matrix. Each path has the same receive spatial correlation matrix.
- Alternatively, you can specify Receive spatial correlation as an $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$-by- $N_{\mathrm{P}}$ array, where each path can have its own different receive spatial correlation matrix.

## Dependencies

This parameter appears when Specify spatial correlation is Separate Tx Rx.
Data Types: double
Complex Number Support: Yes
Combined spatial correlation - Combined spatial correlation matrix [1 $0000 ; 0100 ; 0010 ; 0001]$ (default) | matrix 1 3-D array

Specify the combined spatial correlation matrix as an $N_{T R}$-by- $N_{\mathrm{TR}}$ matrix or $N_{\mathrm{TR}}$-by- $N_{\mathrm{TR}}$-by- $N_{\mathrm{P}}$ array, where $N_{\mathrm{TR}}=\left(N_{\mathrm{T}} \times N_{\mathrm{R}}\right)$, and $N_{\mathrm{P}}$ equals the number of delay paths specified by the Discrete path delays (s) parameter.

- If Discrete path delays (s) is a scalar, the channel is frequency flat, and Combined spatial correlation is an $N_{\mathrm{TR}}$-by- $N_{\mathrm{TR}}$ Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If Discrete path delays (s) is a vector, the channel is frequency selective, and you can specify Combined spatial correlation as a matrix. Each path has the same spatial correlation matrix.
- Alternatively, you can specify Combined spatial correlation as an $N_{\mathrm{TR}}$-by- $N_{\mathrm{TR}}$-by- $N_{\mathrm{P}}$ array, where each path can have its own different combined spatial correlation matrix.

## Dependencies

This parameter appears when Specify spatial correlation is Combined.

```
Data Types: double
```

Normalize outputs by number of receive antennas - Normalize channel output on (default) | off

Select this parameter to normalize the channel outputs by the number of receive antennas.

## Simulate using - Compilation type

Interpreted execution (default) | Code generation
Compilation type, specified as Interpreted execution or Code generation.
Antenna selection - Antenna mode
Off (default) |Tx|Rx|Tx and Rx
The antenna mode you select corresponds to additional input ports on the block.

| Antenna selection Setting | Input Ports Added |
| :--- | :--- |
| $0 f f$ | None |
| Tx | Tx Sel |
| Rx | Rx Sel |
| Tx and Rx | Tx Sel, Rx Sel |

## Realization Tab

Technique for generating fading samples - Channel modeling technique
Filtered Gaussian noise (default)|Sum of sinusoids
Select the channel modeling technique, either Filtered Gaussian noise or Sum of sinusoids.

## Number of sinusoids - Number of sinusoids used

48 (default) | positive integer
Number of sinusoids used to model the fading process, specified as a positive integer.

## Dependencies

This parameter appears when Technique for generating fading samples is Sum of sinusoids.

## Initial time source - Source of initial time offset

Property (default)|Input port
Indicate the source of the initial time offset for the fading model, either Property or Input port.

- When you set Initial time source to Property, use Initial time (s) to set the initial time offset.
- When you set Initial time source to Input port, use the input port Init Time to set the initial time offset.

## Dependencies

This parameter appears when Technique for generating fading samples is Sum of sinusoids.

## Initial time (s) - Initial time offset

0 (default) | nonnegative scalar
Initial time offset for the fading model, specified as a nonnegative scalar.
When Initial time ( $s$ ) is not a multiple of $1 /$ Sample Rate $(\mathrm{Hz})$, it is rounded up to the nearest sample position.

## Dependencies

This parameter appears when Technique for generating fading samples is Sum of sinusoids and Initial time source is set to Property.

## Initial seed - Random number generator initial seed

73 (default) | nonnegative integer
Random number generator initial seed for this block, specified as a nonnegative integer.

## Output channel path gains - Option to output channel path gains off (default) | on

Select this parameter to add the Gain output port to the block and output the channel path gains of the underlying fading process.

## Visualization Tab

## Channel visualization - Select the channel visualization

Off (default)| Impulse response|Frequency response|Doppler spectrum|Impulse and frequency responses

Select the channel visualization: Off, Impulse response, Frequency response, Doppler spectrum, or Impulse and frequency responses. When visualization is on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

Antenna pair to display - Transmit-receive antenna pair to display [1,1] (default) | vector

Transmit-receive antenna pair to display, specified as a 1-by-2 vector, where the first element corresponds to the desired transmit antenna and the second corresponds to the desired receive antenna. At this time, only a single pair can be displayed.

## Dependencies

This parameter appears when Channel visualization is not Off.
Percentage of samples to display - Percentage of samples to display $25 \%$ (default) | $10 \%$ | $50 \%$ | 100\%

Select the percentage of samples to display: $10 \%, 25 \%, 50 \%$, or $100 \%$. Increasing the percentage improves display accuracy at the expense of simulation speed.

## Dependencies

This parameter appears when Channel visualization is Impulse response, Frequency response, or Impulse and frequency responses.

## Path for Doppler spectrum display - Path for which Doppler spectrum is displayed 1 (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to $N_{\mathrm{P}}$, where $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

## Dependencies

This parameter appears when Channel visualization is Doppler spectrum.

## Block Characteristics

| Data Types | double \| single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | yes |

## Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all $\left(N_{T} \times N_{R}\right)$ links of the MIMO channel. Each link comprises all multipaths for that link.

## The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$
R_{H}=E\left[R_{t} \otimes R_{r}\right]
$$

- The $\otimes$ symbol represents the Kronecker product.
- $R_{\mathrm{t}}$ represents the correlation matrix at the transmit side: $R_{t}=E\left[H^{H} H\right]$, of size $N_{\mathrm{T}}$-by- $N_{\mathrm{T}}$.
- $R_{\mathrm{r}}$ represents the correlation matrix at the receive side: $R_{r}=E\left[H H^{H}\right]$, of size $N_{\mathrm{R}}$-by- $N_{\mathrm{R}}$.

You can obtain a realization of the MIMO channel matrix as:

$$
H=R_{r}^{\frac{1}{2}} A R_{t}^{\frac{1}{2}}
$$

$A$ is an $N_{\mathrm{R}}$-by- $N_{\mathrm{T}}$ matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

## Cutoff Frequency Factor

The cutoff frequency factor, $f_{c}$, is determined for different Doppler spectrum types.

- For any Doppler spectrum type other than Gaussian and biGaussian, $f_{\mathrm{c}}$ equals 1.
- For a doppler('Gaussian') spectrum type, $f_{\mathrm{c}}$ equals NormalizedStandardDeviation $\times \sqrt{2 \log 2}$.
- For a doppler('BiGaussian') spectrum type:
- If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0 , then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation(1) $\times \sqrt{2 \log 2}$.
- If the PowerGains (2) and NormalizedCenterFrequencies(1) field values are both 0 , then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation (2) $\times \sqrt{2 \log 2}$.
- If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation(1) $\times \sqrt{2 \log 2}$.
- In all other cases, $f_{\mathrm{c}}$ equals 1 .

## Antenna Selection

When the object is in antenna selection mode, it uses the following algorithms to process an input signal:

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the non-selected links are populated with NaN .
- The spatial correlation only applies to the selected transmit and/or receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. In other words, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

## MLSE Equalizer

Equalize using Viterbi algorithm

## Library

## Equalizer Block

## Description

The MLSE Equalizer block uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The block processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal, using an estimate of the channel modeled as a finite input response (FIR) filter.

This block supports single and double data types.

## Channel Estimates

The channel estimate takes the form of a column vector containing the coefficients of an FIR filter in descending order of powers. The length of this vector is the channel memory, which must be a multiple of the block's Samples per input symbol parameter.

To specify the channel estimate vector, use one of these methods:

- Set Specify channel via to Dialog and enter the vector in the Channel coefficients field.
- Set Specify channel via to Input port and the block displays an additional input port, labeled Ch , which accepts a column vector input signal.

## Signal Constellation

The Signal constellation parameter specifies the constellation for the modulated signal, as determined by the modulator in your model. Signal constellation is a vector of complex numbers, where the kth complex number in the vector is the constellation point to which the modulator maps the integer $\mathrm{k}-1$.

Note The sequence of constellation points must be consistent between the modulator in your model and the Signal constellation parameter in this block.

For example, to specify the constellation given by the mapping

$$
\begin{aligned}
& 0 \rightarrow+1+i \\
& 1 \rightarrow-1+i \\
& 2 \rightarrow-1-i \\
& 3 \rightarrow+1-i
\end{aligned}
$$

set Constellation points to [1+i, -1+i, -1-i, 1-i]. Note that the sequence of numbers in the vector indicates how the modulator maps integers to the set of constellation points. The labeled constellation is shown below.

## Preamble and Postamble

If your data is accompanied by a preamble (prefix) or postamble (suffix), then configure the block accordingly:

- If you select Input contains preamble, then the Expected preamble parameter specifies the preamble that you expect to precede the data in the input signal.
- If you check the Input contains postamble, then the Expected postamble parameter specifies the postamble that you expect to follow the data in the input signal.

The Expected preamble or Expected postamble parameter must be a vector of integers between 0 and M-1, where M is the number of constellation points. An integer value of $k-1$ in the vector corresponds to the kth entry in the Constellation points vector and, consequently, to a modulator input of $\mathrm{k}-1$.

The preamble or postamble must already be included at the beginning or end, respectively, of the input signal to this block. If necessary, you can concatenate vectors in Simulink software using the Matrix Concatenation block.

To learn how the block uses the preamble and postamble, see ""Reset Every Frame" Operation Mode" on page 5-530 below.

## "Reset Every Frame" Operation Mode

One way that the Viterbi algorithm can transition between successive frames is called Reset every frame mode. You can choose this mode using the Operation mode parameter.

In Reset every frame mode, the block decodes each frame of data independently, resetting the state metric at the end of each frame. The traceback decoding always starts at the state with the minimum state metric.

The initialization of state metrics depends on whether you specify a preamble and/or postamble:

- If you do not specify a preamble, the decoder initializes the metrics of all states to 0 at the beginning of each frame of data.
- If you specify a preamble, the block uses it to initialize the state metrics at the beginning of each frame of data. More specifically, the block decodes the preamble and assigns a metric of 0 to the decoded state. If the preamble does not decode to a unique state -- that is, if the length of the preamble is less than the channel memory -- the decoder assigns a metric of 0 to all states that can be represented by the preamble. Whenever you specify a preamble, the traceback path ends at one of the states represented by the preamble.
- If you do not specify a postamble, the traceback path starts at the state with the smallest metric.
- If you specify a postamble, the traceback path begins at the state represented by the postamble. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble and begins traceback decoding at that state.

Note In Reset every frame mode, the input to the MLSE Equalizer block must contain at least T symbols, not including an optional preamble, where T is the Traceback depth parameter.

## Continuous Operation Mode

An alternative way that the Viterbi algorithm can transition between successive frames is called Continuous with reset option mode. You can choose this mode using the Operation mode parameter.

In Continuous with reset option mode, the block initializes the metrics of all states to 0 at the beginning of the simulation. At the end of each frame, the block saves the internal state metric for use in computing the traceback paths in the next frame.

If you select Enable the reset input port, the block displays another input port, labeled Rst. In this case, the block resets the state metrics whenever the scalar value at the Rst port is nonzero.

## Decoding Delay

The MLSE Equalizer block introduces an output delay equal to the Traceback depth in the Continuous with reset option mode, and no delay in the Reset every frame mode.

## Parameters

## Specify channel via

The method for specifying the channel estimate. If you select Input port, the block displays a second input port that receives the channel estimate. If you select Dialog, you can specify the channel estimate as a vector of coefficients for an FIR filter in the Channel coefficients field.

## Channel coefficients

Vector containing the coefficients of the FIR filter that the block uses for the channel estimate. This field is visible only if you set Specify channel via to Dialog.

## Signal constellation

Vector of complex numbers that specifies the constellation for the modulation.

## Traceback depth

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

## Operation mode

The operation mode of the Viterbi decoder. Choices are Continuous with reset option and Reset every frame.

## Input contains preamble

When checked, you can set the preamble in the Expected preamble field. This option appears only if you set Operation mode to Reset every frame.

## Expected preamble

Vector of integers between 0 and $\mathrm{M}-1$ representing the preamble, where M is the size of the constellation. This field is visible and active only if you set Operation mode to Reset every frame and then select Input contains preamble.

## Input contains postamble

When checked, you can set the postamble in the Expected postamble field. This option appears only if you set Operation mode to Reset every frame.

## Expected postamble

Vector of integers between 0 and $\mathrm{M}-1$ representing the postamble, where M is the size of the constellation. This field is visible and active only if you set Operation mode to Reset every frame and then select Input contains postamble.

## Samples per input symbol

The number of input samples for each constellation point.

## Enable the reset input port

When you check this box, the block has a second input port labeled Rst. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data. This option appears only if you set Operation mode to Continuous with reset option.

## MER Measurement

Measure signal-to-noise ratio (SNR) in digital modulation applications

## Library

Utility Blocks

## Description

The MER Measurement block outputs the modulation error ratio (MER). MER is a measure of the signal-to-noise ratio (SNR) in digital modulation applications. The block measures all outputs in dB .

The MER Measurement block accepts a received signal at input port Rcv. It may use an ideal input signal at reference port Ref or, optionally, a reference constellation. The MER block then outputs a measure of the modulation accuracy by comparing these inputs. The modulation error ratio is the ratio of the average reference signal power to the mean square error. This ratio corresponds to the SNR of the AWGN channel.

The block output always outputs MER in dB, with an option to output minimum MER and $X$-percentile MER values. The minimum MER represents the best-case MER value per burst. For the $X$-percentile option, you can select to output the number of symbols processed in the percentile computations.

The table shows the output type, the parameter that selects the output type, the computation units, and the corresponding measurement interval.

| Output | Activation Parameter | Units | Measurement Interval |
| :--- | :--- | :--- | :--- |
| MER | None (output by <br> default) | dB | Current length \| <br> Entire history <br> Custom \| Custom with <br> periodic reset |
| Minimum MER | Output minimum <br> MER | dB | Current length \| <br> Entire history \| <br> Custom \| Custom with <br> periodic reset |
| Percentile MER | Output X-percentile <br> EVM | dB | Entire history |
| Number of symbols | Output X-percentile <br> EVM and Output the <br> number of symbols <br> processed | None | Entire history |

## Data Type

The block accepts double, single, and fixed-point data types. The output of the block is always double.

## Algorithms

## Parameters

## Reference signal

Specifies the reference signal source as either Input port or Estimated from reference constellation.

## Reference constellation

Specifies the reference constellation points as a vector. This parameter is available only when Reference signal is Estimated from reference constellation. The default is constellation(comm. QPSKModulator).

## Measurement interval

Specify the measurement interval as: Input length, Entire history, Custom, or Custom with periodic reset. This parameter affects the RMS and minimum MER outputs only.

- To calculate MER using only the current samples, set this parameter to 'Input length'.
- To calculate MER for all samples, set this parameter to 'Entire history'.
- To calculate MER over an interval you specify and to use a sliding window, set this parameter to 'Custom'.
- To calculate MER over an interval you specify and to reset the object each time the measurement interval is filled, set this parameter to 'Custom with periodic reset'.

## Custom measurement interval

Specify the custom measurement interval in samples as a real positive integer. This is the interval over which the MER is calculated. This parameter is available when Measurement interval is Custom or Custom with periodic reset. The default is 100 .

## Averaging dimensions

Specify the dimensions over which to average the MER measurements as a scalar or row vector whose elements are positive integers. For example, to average across the rows, set this parameter to 2 . The default is 1 .

This block supports var-size inputs of the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must be constant. For example, if the input size is [lllll 1000 3 2] and Averaging dimensions is [13], then the output size is [1 3 1]. The number of elements in the second dimension is fixed at 3 .

## Output minimum MER

Outputs the minimum MER of an input vector or frame.

## Output X-percentile MER

Enables an output $X$-percentile MER measurement. When you select this option, specify $\mathbf{X}$ percentile value (\%).

## X -Percentile value (\%)

This parameter is available only when you select Output X-percentile MER. The Xth percentile is the MER value above which X\% of all the computed MER values lie. The parameter defaults to the 95th percentile. That is, $95 \%$ of all MER values are above this output.

## Output the number of symbols processed

Outputs the number of symbols that the block uses to compute the Output X-percentile MER. This parameter is available only when you select Output X-percentile MER.

## Simulate using

Select the simulation mode.

## Code generation

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects corresponding to the blocks accept a maximum of nine inputs.
Interpreted execution
Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## Examples

## Measure MER of Noisy PSK Signal

Measure the MER of a noisy 8-PSK signal.
Load the model by typing doc_mer_example at the command line.

Run the model. The MER is shown in the Display block and is approximately equal to the SNR, which is set by using the Constant block. Experiment with different SNR values, and observe the effect on the estimated MER.

## Algorithms

MER is a measure of the SNR in a modulated signal calculated in dB. The MER over $N$ symbols is

$$
\operatorname{MER}=10 \cdot \log _{10}\left(\frac{\sum_{n=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}{\sum_{n=1}^{N}\left(e_{k}\right)}\right) \mathrm{dB}
$$

The MER for the $k$ th symbol is

$$
M E R_{k}=10 * \log _{10}\left(\frac{\frac{1}{N} \sum_{n=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}{e_{k}}\right) \mathrm{dB} .
$$

The minimum MER represents the minimum MER value in a burst, or
$M E R_{\min }=\min _{k \in[1, \ldots, N]}\left\{M E R_{k}\right\}$,
where:

- $e_{k}=e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}$
- $I_{k}=$ In-phase measurement of the $k$ th symbol in the burst
- $Q_{k}=$ Quadrature phase measurement of the $k$ th symbol in the burst
- $I_{k}$ and $Q_{k}$ represent ideal (reference) values. $\tilde{I}_{k}$ and $\widetilde{Q}_{k}$ represent measured (received) symbols.

The block computes the $X$-percentile MER by creating a histogram of all the incoming $M E R_{k}$ values. The output provides the MER value above which X\% of the MER values fall.

## M-APSK Demodulator Baseband

$M$-ary amplitude phase shift keying (APSK) demodulation
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / APM

## Description

The M-APSK Demodulator Baseband block demodulates a baseband representation of an $M$-ary amplitude phase shift keying (APSK) modulated signal. $M$ is the "Modulation Order for M-APSK" on page 5-543. For a description of M-APSK demodulation, see "APSK Hard Demodulation" on page 5543 and "APSK Soft Demodulation" on page 5-544.

Note M-APSK Demodulator Baseband specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use M-PSK Demodulator Baseband.

This icon shows the block with all ports enabled:

## Ports

Input
In - APSK modulated signal
scalar | vector | matrix
APSK modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the Var port is enabled.
Data Types: double | single
Complex Number Support: Yes

## Var - Noise variance

positive scalar | vector of positive values
Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "APSK Soft Demodulation" on page 5-544 for demodulation decision type considerations.

## Dependencies

To enable this port, set Noise variance source to Input port.
Data Types: double | single

## Output

## Out - Demodulated signal

scalar | vector | matrix
Demodulated signal, returned as a scalar, vector, or matrix. The data type and dimensions of the demodulated signal depend on the values specified by the Output type and Decision type parameters. This port is unnamed on the block.

Use Output data type to specify the output data type.
Data Types: single | double

## Parameters

Constellation points per circle - Constellation points per PSK ring
[4,12] (default) | vector
Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The sum of the elements in Constellation points per circle determines the modulation order. Element values must be multiples of four, and the modulation order must be a power of two.

Example: $[4,12,16]$ specifies a three PSK ring constellation with a modulation order of 32 .

## Radius of each circle - Radius per PSK ring

[0.5,1] (default) | vector
Radius per PSK ring, specified as a vector with the same length as Constellation points per circle. Each vector element indicates the radius of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. These element values must be positive values arranged in increasing order.
Example: [0.5,1,2] defines radii for three constellation PSK rings. The inner ring has a radius of 0.5 , the second ring has a radius of 1.0 , and the outer ring has a radius of 2.0 .

## Phase offset of each circle (rad) - Phase offset per PSK ring

[pi/4,pi/12] (default) | scalar | vector
Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as Constellation points per circle. Each vector element indicates the phase offset of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The Phase offset of each circle (rad) can be a scalar only if all the elements of Constellation points per circle are the same value.

Example: [pi/4, pi/12, pi/16] defines phase offsets for three constellation PSK rings. The inner ring has a phase offset of $\pi / 4$, the second ring has a phase offset of $\pi / 12$, and the outer ring has a phase offset of $\pi / 16$.

## Symbol mapping - Symbol mapping

Auto (default)|Contourwise-gray|Gray|User-defined
Symbol mapping, specified as one of the following:

- Contourwise-gray - Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- Gray - Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all elements in Constellation points per circle must be equal, and all elements in Phase offset of each circle (rad) must be equal. For a description of the Gray mapping used, see [2].
- User-defined - See Custom symbol mapping.

The default symbol mapping depends on the Constellation points per circle and Phase offset of each circle (rad) parameters. When all elements in Constellation points per circle are equal, and all elements in Phase offset of each circle (rad) are equal, the default is Gray. For all other cases, the default is Contourwise-gray.

## Custom symbol mapping - Custom symbol mapping

$[0,4,12,8,1,3,2,6,7,5,13,15,14,10,11,9]$ (default) | integer vector
Custom symbol mapping, specified as an integer vector. This vector must consist of $M$ unique elements with values in the range [ $0,(M-1)$ ], where $M$ is the "Modulation Order for M-APSK" on page 5-543. The first element in Custom symbol mapping corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.
Example: The default value, $[0,4,12,8,1,3,2,6,7,5,13,15,14,10,11,9]$, specifies contourwise-gray symbol mapping. The distribution of constellation points is nonuniform on all contours.

## Dependencies

To enable this parameter, set Symbol mapping to User-defined.

## Output type - Output type

Integer (default)|Bit
Output type, specified as Integer or Bit.
Data Types: char \| string

## Decision type - Demodulation decision type

Hard decision (default)|Log-likelihood ratio|Approximate log-likelihood ratio
Demodulation decision type, specified as Hard decision, Log-likelihood ratio, or
Approximate log-likelihood ratio. See "APSK Soft Demodulation" on page 5-544 for algorithm selection considerations.

## Dependencies

This parameter applies only when Output type is set to Bit.

## Noise variance source - Noise variance source

Property (default) | Input port
Noise variance source, specified as:

- Property - The noise variance is set using the Noise variance parameter.
- Input port - The noise variance is set using the Var input port.

## Dependencies

This parameter applies only when Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.

## Noise variance - Noise variance

1 (default) | positive scalar | vector of positive values
Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "APSK Soft Demodulation" on page 5-544 for Decision type specification considerations.

## Dependencies

This parameter applies only when Noise variance source is set to Property and Decision type is set to either Log-likelihood ratio or Approximate log-likelihood ratio.
Data Types: double

## Output data type - Output data type <br> double (default) | . . .

Output data type, specified as one of the acceptable values from this table. Acceptable Output data type values depend on the Output type and Decision type parameter values.

| Output type | Decision type | Output data type Options |
| :--- | :--- | :--- |
| Integer | Not applicable | double, single, int8, uint8, int16, uint16, int32, or <br> uint32 |

| Output type | Decision type | Output data type Options |
| :--- | :--- | :--- |
| Bit | Hard decision | double, single, int8, uint8, int16, uint16, int32, <br> uint32, or logical |
|  | Log-likelihood <br> ratio or <br> Approximate <br> log-likelihood <br> ratio | The output signal is the same data type as the input signal. |

## Dependencies

This parameter applies only when Output type is set to Integer or when Output type is set to Bit and Decision type is set to Hard decision.

## Simulate using - Type of simulation to run

Interpreted execution (default)|Code generation
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated $C$ code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

For information on execution speed, see "Tips" on page 5-545.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | no |

## More About

## Modulation Order for M-APSK

The modulation order, $M$, for $M$-APSK equals the sum of the vector elements in the Constellation points per circle parameter and is the total number of points in the signal constellation. Element values in Constellation points per circle must be multiples of four, and $M$ must be a power of two.

## APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding, as described in [1].

## APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

| Algorithm | Accuracy | Execution Speed |
| :--- | :--- | :--- |
| Exact LLR | more accurate | slower execution |
| Approximate LLR | less accurate | faster execution |

For further description of these algorithms, see "Exact LLR Algorithm" and "Approximate LLR Algorithm".

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or - Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## Tips

- For faster execution of the M-APSK Demodulator Baseband block, set the Simulate using parameter to:
- Code generation when using hard decision demodulation.
- Interpreted execution when using soft decision demodulation.

## M-APSK Modulator Baseband

M-ary amplitude phase shift keying (APSK) modulation
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / APM

## Description

The M-APSK Modulator Baseband block modulates the input signal using $M$-ary amplitude phase shift keying (APSK) modulation. The output is a baseband representation of the modulated signal. $M$, the "Modulation Order for M-APSK" on page 5-549, equals the sum of the elements in Constellation points per circle. For a description of M-APSK modulation, see "Algorithms" on page 5-549.

Note M-APSK Modulator Baseband specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use M-PSK Modulator Baseband.

## Ports

## Input

## In - Input signal

scalar | vector | matrix
Input signal, specified as a scalar, vector, or matrix. The input signal must consist of binary values or integers in the range [0, (M-1)], where $M$ is the "Modulation Order for M-APSK" on page 5-549.
This port is unnamed on the block.

Note To process the input signal as binary elements, set the Input type parameter value to Bit. For binary inputs, the number of rows must be an integer multiple of $\log _{2}(M)$. Groups of $\log _{2}(M)$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: single | double | int8| int16| int32|uint8|uint16|uint32|Boolean

## Output

## Out - APSK modulated signal

scalar | vector | matrix
APSK modulated signal, returned as a complex scalar, vector, or matrix. The output signal dimensions depend on the specified Input type value. This port is unnamed on the block.

| Input type | Dimensions of Output Signal |
| :--- | :--- |
| Integer | The output signal has the same dimensions as the input signal. |

| Input type | Dimensions of Output Signal |
| :--- | :--- |
| Bit | The number of rows in the output signal equals the number of rows in the <br> input signal divided by $\log _{2}(M)$, where $M$ is the "Modulation Order for M- <br> APSK" on page 5-549. |

Use Output data type to specify the output data type.

## Parameters

## Constellation points per circle - Constellation points per PSK ring

[4,12] (default) | vector
Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The sum of the elements in Constellation points per circle determines the modulation order. Element values must be multiples of four, and the modulation order must be a power of two.

Example: $[4,12,16]$ specifies a three PSK ring constellation with a modulation order of 32 .

## Radius of each circle - Radius per PSK ring

[0.5,1] (default)| vector
Radius per PSK ring, specified as a vector with the same length as Constellation points per circle. Each vector element indicates the radius of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. These element values must be positive and arranged in increasing order.
Example: [0.5, 1, 2] defines radii for three constellation PSK rings. The inner ring has a radius of 0.5 , the second ring has a radius of 1.0 , and the outer ring has a radius of 2.0 .

## Phase offset of each circle (rad) - Phase offset per PSK ring

[pi/4,pi/12] (default) | scalar | vector
Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as Constellation points per circle. Each vector element indicates the phase offset of its corresponding PSK ring. The first element corresponds to the innermost circle, and so on until the last element, which corresponds to the outermost circle. The Phase offset of each circle (rad) can be a scalar only if all the elements of Constellation points per circle are the same value.
Example: [pi/4, pi/12,pi/16] defines phase offsets for three constellation PSK rings. The inner ring has a phase offset of $\pi / 4$, the second ring has a phase offset of $\pi / 12$, and the outer ring has a phase offset of $\pi / 16$.

## Symbol mapping - Symbol mapping

Auto (default)|Contourwise-gray|Gray|User-defined
Symbol mapping, specified as one of the following:

- Contourwise-gray - Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- Gray - Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for Constellation points per circle must be equal and all the
values for Phase offset of each circle (rad) must be equal. For a description of the Gray mapping used, see [2].
- User-defined - See Custom symbol mapping.

The default symbol mapping depends on Constellation points per circle and Phase offset of each circle (rad). When all the elements of Constellation points per circle are equal and all the elements of Phase offset of each circle (rad) are equal, the default is Gray. For all other cases, the default is Contourwise-gray.

## Custom symbol mapping - Custom symbol mapping

$[0,4,12,8,1,3,2,6,7,5,13,15,14,10,11,9]$ (default) | integer vector
Custom symbol mapping, specified as an integer vector. This vector must consist of $M$ unique elements with values in the range [ $0,(M-1)$ ], where $M$ is the "Modulation Order for M-APSK" on page 5-549. The first element in Custom symbol mapping corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

Example: The default value, $[0,4,12,8,1,3,2,6,7,5,13,15,14,10,11,9]$, specifies contourwise-gray symbol mapping. The distribution of constellation points is nonuniform on all contours.

## Dependencies

To enable this parameter, set Symbol mapping to User-defined.

## Input type - Input type

Integer (default)|Bit
Input type, specified as Integer or Bit. To use Integer, the input signal must consist of integers in the range $[0,(M-1)]$. To use Bit, the input signal must contain binary values, and the number of rows must be an integer multiple of $\log _{2}(M)$, where $M$ is the "Modulation Order for M-APSK" on page 5-549.

## Output data type - Output data type

double (default) | single
Output data type, specified as double or single.

## View Constellation - Plot reference constellation

 buttonTo plot the reference constellation, click the View Constellation button.

Tip Click Apply before clicking the View Constellation to view latest parameter values.

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | Boolean \| double \| integer \| single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | no |

## More About

## Modulation Order for M-APSK

The modulation order, $M$, for $M$-APSK is the total number of points in the signal constellation. $M$ equals the sum of the elements in Constellation points per circle. The element values in
Constellation points per circle must be multiples of four. $M$ must be a power of two.

## Algorithms

The block implements a pure APSK constellation.
A pure M-APSK constellation is composed of $N_{\mathrm{C}}$ concentric rings or contours, each with uniformly spaced PSK points. The M-APSK constellation set is

$$
\chi=\left\{\begin{array}{cc}
R_{1} \exp \left(j\left(\frac{2 \pi}{M_{1}} i+\theta_{1}\right)\right), & i=0, \ldots, M_{1}-1, \\
R_{2} \exp \left(j\left(\frac{2 \pi}{M_{2}} i+\theta_{2}\right)\right), & i=0, \ldots, M_{2}-1, \\
\vdots & \vdots \\
R_{N_{\mathrm{C}}} \exp \left(j\left(\frac{2 \Pi}{M_{N_{\mathrm{C}}}} i+\theta_{\mathrm{Nc}}\right)\right), & i=0, \ldots, M_{N_{\mathrm{C}}}-1,
\end{array}\right.
$$

where

- The modulation order is equal to the sum of all $M_{l}$ for $l=1,2, \ldots, N_{C}$.
- $N_{\mathrm{C}}$ is the number of concentric rings. $N_{\mathrm{C}} \geq 2$.
- $M_{l}$ is the number of constellation points in the lth ring.
- $R_{l}$ is the radius of the lth ring.
- $\theta_{l}$ is the phase offset of the lth ring.
- $j=\sqrt{-1}$

# M-PAM Demodulator Baseband 

Demodulate PAM-modulated data

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The M-PAM Demodulator Baseband block demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

The signal constellation has M points, where M is the $\mathbf{M}$-ary number parameter. M must be an even integer. The block scales the signal constellation based on how you set the Normalization method parameter. For details on the constellation and its scaling, see the reference page for the M-PAM Modulator Baseband block.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see "Supported Data Types" on page 5-556.

Note All values of power assume a nominal impedance of 1 ohm .

## Integer-Valued Signals and Binary-Valued Signals

When you set the Output type parameter to Integer, the block outputs integer values between 0 and $M-1$. $M$ represents the $\mathbf{M}$-ary number block parameter.

When you set the Output type parameter to Bit, the block outputs binary-valued signals that represent integers. The block represents each integer using a group of $K=\log _{2}(M)$ bits, where $K$ represents the number of bits per symbol. The output vector length must be an integer multiple of $K$.

The Constellation ordering parameter indicates how the block assigns binary words to points of the signal constellation. More details are on the reference page for the M-PAM Modulator Baseband block.

## Algorithm

The demodulator algorithm maps received input signal constellation values to M-ary integer symbol indices between 0 and $\mathrm{M}-1$ and then maps these demodulated symbol indices to formatted output values.

The integer symbol index computation is performed by first scaling the real part of the input signal constellation (possibly with noise) by a denormalization factor derived from the Normalization
method and related parameters. This denormalized value is added to M-1 to translate it into an approximate range between 0 and $2 \mathrm{x}(\mathrm{M}-1)$ plus noise. The resulting value is then rescaled via a divide-by-two (or, equivalently, a right-shift by one bit for fixed-point operation) to obtain a range approximately between 0 and $\mathrm{M}-1$ (plus noise). The noisy index value is rounded to the nearest integer and clipped, via saturation, to the exact range of [0 M-1]. Finally, based on other block parameters, the integer index is mapped to a symbol value that is formatted and cast to the selected Output data type.

The following figures contains signal flow diagrams for floating-point and fixed-point algorithm operation. The floating-point diagrams apply when the input signal data type is double or single. The fixed-point diagrams apply when the input signal is a signed fixed-point data type. Note that the diagram is simplified when using normalized constellations (i.e., denormalization factor is 1 ).

Signal-Flow Diagrams with Denormalization Factor Equal to 1

Signal-Flow Diagrams with Nonunity Denormalization Factor
Parameters

## M-ary number

The number of points in the signal constellation. It must be an even integer.

## Output type

Determines whether the output consists of integers or groups of bits. If this parameter is set to Bit, then the $\mathbf{M}$-ary number parameter must be $2^{\mathrm{K}}$ for some positive integer K .

## Constellation ordering

Determines how the block maps each integer to a group of output bits.

## Normalization method

Determines how the block scales the signal constellation. Choices are Min. distance between symbols, Average Power, and Peak Power.

## Minimum distance

The distance between two nearest constellation points. This field appears only when Normalization method is set to Min. distance between symbols.

## Average power, referenced to 1 ohm (watts)

The average power of the symbols in the constellation, referenced to 1 ohm. This field appears only when Normalization method is set to Average Power.
Peak power, referenced to 1 ohm (watts)
The maximum power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Peak Power.

## Output

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type single or double. Otherwise, the output data type will be as if this parameter is set to 'Smallest unsigned integer'.

When the parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is the ideal minimum size, i.e., ufix(1) for bit outputs, and ufix(ceil( $\log 2(M))$ ) for integer outputs. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit the ideal minimum size, usually corresponding to the size of a char (e.g., uint8).

For integer outputs, this parameter can be set to Smallest unsigned integer, int8, uint8, int16, uint16, int32, uint32, single, and double. For bit outputs, the options are Smallest unsigned integer, int8, uint8, int16, uint16, int32, uint32, boolean, single, or double.

## Denormalization factor

This parameter applies when a fixed-point input is not normalized. It can be set to Same word length as input or Specify word length, in which case a field is enabled for user input. A best-precision fraction length is always used.

## Product output

This parameter only applies when the input is a fixed-point signal and there is a nonunity (not equal to 1) denormalized factor. It can be set to Inherit via internal rule or Specify word length, which enables a field for user input.

Setting to Inherit via internal rule computes the full-precision product word length and fraction length. Internal Rule for Product Data Types (DSP System Toolbox) in DSP System Toolbox User's Guide describes the full-precision Product output internal rule.

Setting to Specify word length allows you to define the word length. The block computes a best-precision fraction length based on the word length specified and the pre-computed worstcase ( $\min / \max$ ) real world value Product output result. The worst-case Product output result is precomputed by multiplying the denormalized factor with the worst-case ( $\mathrm{min} / \mathrm{max}$ ) input signal range, purely based on the input signal data type.

The block uses the Rounding method when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. For more information, see "Rounding Modes" (DSP System Toolbox) or "Rounding Mode: Simplest" (FixedPoint Designer).

## Sum

This parameter only applies when the input is a fixed-point signal. It can be set to Inherit via internal rule, Same as product output, or Specify word length, in which case a field is enabled for user input

Setting Inherit via internal rule computes the full-precision sum word length and fraction length, based on the two inputs to the Sum in the fixed-point Hard Decision Algorithm on page 5-551 signal flow diagram. The rule is the same as the fixed-point inherit rule of the internal Accumulator data type parameter in the Simulink Sum block.

Setting Specify word length allows you to define the word length. A best precision fraction length is computed based on the word length specified in the pre-computed maximum range necessary for the demodulated algorithm to produce accurate results. The signed fixed-point data type that has the best precision fully contains the values in the range $2 *(\mathrm{M}-1)$ for the specified word length.

Setting to Same as product output allows the Sum data type to be the same as the Product output data type (when Product output is used). If the Product output is not used, then this setting will be ignored and the Inherit via internal rule Sum setting will be used.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed-point |
| Output | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean when Output type is Bit <br> - 8-, 16-, and 32 -bit signed integers <br> - $8-16$-, and 32 -bit unsigned integers <br> - ufix(1) in ASIC/FPGA when Output type is Bit <br> - $u f i x\left(\left[\log _{2} M\right\rceil\right)$ in ASIC/FPGA when Output type is Integer |

## M-PAM Modulator Baseband

Modulate using M-ary pulse amplitude modulation

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The M-PAM Modulator Baseband block modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The $\mathbf{M}$-ary number parameter, M , is the number of points in the signal constellation. It must be an even integer.

Note All values of power assume a nominal impedance of 1 ohm.

## Constellation Size and Scaling

Baseband M-ary pulse amplitude modulation using the block's default signal constellation maps an integer $m$ between 0 and M-1 to the complex value
$2 \mathrm{~m} \quad-$

Note This value is actually a real number. The block's output signal is a complex data-type signal whose imaginary part is zero.

The block scales the default signal constellation based on how you set the Normalization method parameter. The following table lists the possible scaling conditions.

| Value of Normalization Method Parameter | Scaling Condition |
| :--- | :--- |
| Min. distance between symbols | The nearest pair of points in the constellation is <br> separated by the value of the Minimum <br> distance parameter |
| Average Power | The average power of the symbols in the <br> constellation is the Average power parameter |
| Peak Power | The maximum power of the symbols in the <br> constellation is the Peak power parameter |

## Integer-Valued Signals and Binary-Valued Signals

This block accepts a scalar or column vector input signal.

When you set the Input type parameter to Integer, the block accepts integer values between 0 and $M-1 . M$ represents the $\mathbf{M}$-ary number block parameter.

When you set the Input type parameter to Bit, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $K=\log _{2}(M)$ bits
where
$K$ represents the number of bits per symbol.
The input vector length must be an integer multiple of $K$. In this configuration, the block accepts a group of $K$ bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol for each group of $K$ bits.

The Constellation ordering parameter indicates how the block assigns binary words to points of the signal constellation.

- If Constellation ordering is set to Binary, then the block uses a natural binary-coded constellation.
- If Constellation ordering is set to Gray, then the block uses a Gray-coded constellation.

For details about the Gray coding, see the reference page for the M-PSK Modulator Baseband block.

## Constellation Visualization

The M-PAM Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the Communications Toolbox User's Guide.

## Parameters

## M-ary number

The number of points in the signal constellation. It must be an even integer.

## Input type

Indicates whether the input consists of integers or groups of bits. If this parameter is set to Bit, then the $\mathbf{M}$-ary number parameter must be $2^{\mathrm{K}}$ for some positive integer K .

## Constellation ordering

Determines how the block maps each group of input bits to a corresponding integer.

## Normalization method

Determines how the block scales the signal constellation. Choices are Min. distance between symbols, Average Power, and Peak Power.

## Minimum distance

The distance between two nearest constellation points. This field appears only when Normalization method is set to Min. distance between symbols.

## Average power, referenced to 1 ohm (watts)

The average power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Average Power.

## Peak power, referenced to 1 ohm (watts)

The maximum power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Peak Power.

## Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this parameter to Fixed-point or User-defined enables fields in which you can further specify details. Setting this parameter to Inherit via back propagation, sets the output data type and scaling to match the following block.

## Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select Fixed-point for the Output data type parameter.

## User-defined data type

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the sfix, sint, sfrac, and fixdt functions from Fixed-Point Designer software. This parameter is only visible when you select User-defined for the Output data type parameter.

## Set output fraction length to

Specify the scaling of the fixed-point output by either of the following methods:

- Choose Best precision to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose User-defined to specify the output scaling in the Output fraction length parameter.

This parameter is only visible when you select Fixed-point for the Output data type parameter or when you select User-defined and the specified output data type is a fixed-point data type.
Output fraction length
For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select Fixed-point or User-defined for the Output data type parameter and User-defined for the Set output fraction length to parameter.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean when Input type is Bit <br> - 8-, 16-, 32-bit signed integers <br> - 8 -, 16-, 32 -bit unsigned integers <br> - ufix( $\left.\left(\log _{2} M\right]\right)$ when Input type is Integer |

| Port | Supported Data Types |
| :--- | :--- |
| Output | $\bullet \quad$ Double-precision floating point |
|  | • |
|  | - Single-precision floating point |
|  | Signed fixed-point |

\& \begin{tabular}{c}
Modulation / PM <br>
Communications Toolbox HDL Support / Modulation / PM

,$\quad$

M.PSK
\end{tabular},

\end{tabular}

## Description

The M-PSK Demodulator Baseband block demodulates a baseband representation of a PSK-modulated signal. The modulation order, $M$, is equivalent to the number of points in the signal constellation and is determined by the $\mathbf{M}$-ary number parameter. The block accepts scalar or column vector input signals.

## Input/Output Ports

## Input

## Port_1 - Input signal

scalar | vector
Input port accepting a baseband representation of a PSK-modulated signal.
Data Types: single | double | int8|int16|int32 |uint8|uint16|uint32|Boolean

## Output

## Port_1 - Output signal

scalar | vector
Output signal, returned as a scalar or vector. The output is a demodulated version of the PSKmodulated signal.
Data Types: single|double|fixed point

## Parameters

## M-ary number - Modulation order of the PSK constellation

8 (default) | scalar
Specify the modulation order as a positive integer power of two.
Example: 2 | 16

## Output type - Output signal data type

Integer (default)|Bit
Specify the elements of the input signal as integers or bits. If Output type is Bit, the number of samples per frame is an integer multiple of the number of bits per symbol, $\log _{2}(M)$.

## Decision type - Demodulator output

Hard decision (default)|Log-likelihood ratio|Approximate log-likelihood ratio

Specify the demodulator output to be hard decision, log-likelihood ratio (LLR), or approximate LLR. The LLR and approximate LLR outputs are used with error decoders that support soft-decision inputs such as a Viterbi decoder, to achieve superior performance. This parameter is available when Output type is Bit.

See "Phase Modulation" for algorithm details. The output values for Log-likelihood ratio and Approximate log-likelihood ratio decision types are of the same data type as the input values

## Noise variance source - Source of noise variance

Dialog (default)|Port
Specify the source of the noise variance estimate. This parameter is available when Decision type is Log-likelihood ratio or Approximate log-likelihood ratio.

- To specify the noise variance from the dialog box, select Dialog.
- To input the noise variance from an input port, select Port.

## Noise variance - Estimate of noise variance

1 (default) | positive scalar
Specify the estimate of the noise variance as a positive scalar. This parameter is available when Noise variance source is Dialog.

This parameter is tunable in all simulation modes. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. Avoiding recompilation is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or - Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## Constellation ordering - Symbol mapping <br> Gray (default) | Binary | User-defined

Specify how the integer or group of $\log _{2}(M)$ bits is mapped to the corresponding symbol.

- When Constellation ordering is set to Gray, the output symbol is mapped to the input signal using a Gray-encoded signal constellation.
- When Constellation ordering is set to Binary, the modulated symbol is $\exp (j \phi+j 2 \pi m / M)$, where $\phi$ is the phase offset in radians, $m$ is the integer output such that $0 \leq m \leq M-1$, and $M$ is the modulation order.
- When Constellation ordering is User-defined, specify a vector of size $M$, which has unique integer values in the range [ $0, M-1$ ]. The first element of this vector corresponds to the constellation point having a value of $\mathrm{e}^{i \phi}$ with subsequent elements running counterclockwise.

Example: [0 3021$]$

## Constellation mapping - User-defined symbol mapping

## [0:7] (default)| vector

Specify the order in which input integers are mapped to output integers. The parameter is available when Constellation ordering is User-defined, and must be a row or column vector of size $M$ having unique integer values in the range $[0, M-1]$.

The first element of this vector corresponds to the constellation point at $0+$ Phase offset angle, with subsequent elements running counterclockwise. The last element corresponds to the $-2 \pi / \mathrm{M}+\mathbf{P h a s e}$ offset constellation point.

## Phase offset (rad) - Phase offset in radians

 pi/8 (default) | scalarSpecify, in radians, the phase offset of the initial constellation as a real scalar.
Example: pi/4

## Output data type - Output data type

```
Inherit via internal rule (default)|Smallest unsigned integer|double|single|
int8 | uint8 | int16 | uint16 | int32 | uint32
```

Specify the data type of the demodulated output signal.

## Block Characteristics

| Data Types | Boolean \| double | fixed pointabc| integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

a. $\quad M=2,4,8$ only.
b. Fixed-point inputs must be signed.
c. When ASIC/FPGA is selected in the Hardware Implementation Pane, output is ufix(1) for bit outputs, and ufix(ceil(log2(M))) for integer outputs.

# M-PSK Modulator Baseband 

Modulate using M-ary phase shift keying

Library:<br>Communications Toolbox / Modulation / Digital Baseband Modulation / PM<br>Communications Toolbox HDL Support / Modulation / PM

## Description

The M-PSK Modulator Baseband block modulates an input signal using M-ary phase shift keying (PSK) and returns a complex baseband output. The modulation order, $M$, which is equivalent to the number of points in the signal constellation, is determined by the $\mathbf{M}$-ary number parameter. The block accepts scalar or column vector input signals.

## Input/Output Ports

Input
Port_1 - Input signal
scalar | vector
Specify the input signal as an integer scalar, integer vector, or binary vector.

- When Input type is Integer, specify the input signal elements as integers from 0 to $M-1$.
- When Input type is Bit, specify the input signal as a binary vector in which the number of elements is an integer multiple of the bits per symbol. The bits per symbol is equal to $\log _{2}(M)$.

Data Types: single | double | int8|int16|int32|uint8|uint16|uint32|Boolean

## Output

## Port_1 - Output signal

scalar | vector
Output signal, returned as a complex scalar or vector. The output is the complex baseband representation of the PSK-modulated signal.
Data Types: single|double|fixed point

## Parameters

## M-ary number - Modulation order of the PSK constellation

8 (default) | scalar
Specify the modulation order as a positive integer power of two.
Example: $2 \mid 16$

## Input type - Type of input signal

Integer (default) | Bit

Specify the elements of the input signal as integers or bits. If Input type is Bit, the number of samples per frame must be an integer multiple of the number of bits per symbol. The number of bits per symbol is $\log _{2}(M)$.

## Constellation ordering - Symbol mapping <br> Gray (default) | Binary | User-defined

Specify how the integer or group of $\log _{2}(M)$ bits is mapped to the corresponding symbol.

- When Constellation ordering is set to Gray, the input signal is mapped to the output symbols using a Gray-encoded signal constellation.
- When Constellation ordering is set to Binary, the modulated symbol is $\exp (j \phi+j 2 \pi m / M)$, where $\phi$ is the phase offset in radians, $m$ is the integer input such that $0 \leq m \leq M-1$, and $M$ is the modulation order.
- When Constellation ordering is User-defined, specify a vector of size $M$, which has unique integer values in the range [ $0, M-1$ ]. The first element of this vector corresponds to the constellation point having an value of $\mathrm{e}^{i \phi}$ with subsequent elements running counterclockwise.

## Example: [0 32 1]

## Constellation mapping - User-defined symbol mapping <br> [0:7] (default) | vector

Specify the order in which input integers are mapped to output integers. The parameter is available when Constellation ordering is User-defined, and must be a row or column vector of size $M$ having unique integer values in the range [ $0, M-1$ ].

The first element of this vector corresponds to the constellation point at $0+$ Phase offset angle, with subsequent elements running counterclockwise. The last element corresponds to the $-2 \pi / M+\mathbf{P h a s e}$ offset constellation point.

## Phase offset (rad) - Phase offset in radians

pi/8 (default) | scalar
Specify, in radians, the phase offset of the initial constellation as a real scalar.
Example: pi/4

## Output data type - Output data type

double (default)|single|Inherit via back propagation|fixdt(1,16)|fixdt(1,16,0) |<data type expression>

Specify the data type of the modulated output signal. Set this parameter to one of the fixed point options or <data type expression> to enable parameters in which you specify additional details. Set this parameter to Inherit via back propagation, to match the output data type and scaling to the following block in the model.

## Block Characteristics

| Data Types | Boolean \| double | fixed point ${ }^{\text {ab } \mid \text { integer \| single }}$ |
| :--- | :--- |
| Multidimensional <br> Signals | no |

## Variable-Size Signals yes

a. ufix(1) at the input if "input type" is set to "bit". ufix(ceil(log2(M))) at input if "input type" is set to "integer" for M-ary modulation.
b. Fixed-point outputs must be signed.

## Tips

The M-PSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. Clicking the View Constellation button allows you to visualize a signal constellation for the specified block parameters.

## Algorithms

The block outputs a baseband signal by mapping input bits or integers to complex symbols according to the following:

$$
s_{n}(t)=\exp \left(j \Pi\left(\frac{2 n+1}{M}\right)\right) ; \quad n \in\{0,1, \ldots, M-1\} .
$$

This applies when a natural binary ordering is used. Another common mapping is Gray coding, which has the advantage that only one bit changes between adjacent constellation points. This results in better bit error rate performance. For 8-PSK modulation with Gray coding, the mapping between the input and output symbols is shown.

| Input | Output |
| :--- | :--- |
| 0 | $0(000)$ |
| 1 | $1(001)$ |
| 2 | $3(011)$ |
| 3 | $2(010)$ |
| 4 | $6(110)$ |
| 5 | $7(111)$ |
| 6 | $5(101)$ |
| 7 | $4(100)$ |

The corresponding constellation diagram follows.

When the input signal is composed of bits, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $\log _{2}(M)$ bits.

## Extended Capabilities

## M-PSK Phase Recovery

(Removed) Recover carrier phase using M-Power method

Note M-PSK Phase Recovery has been removed. Use the Carrier Synchronizer block instead.

## Library

Carrier Phase Recovery sublibrary of Synchronization

## Description

The M-PSK Phase Recovery block recovers the carrier phase of the input signal using the M-Power method. This feedforward, non-data-aided, clock-aided method is suitable for systems that use baseband phase shift keying (PSK) modulation. It is also suitable for systems that use baseband quadrature amplitude modulation (QAM), although the results are less accurate than those for comparable PSK systems. The alphabet size for the modulation must be an even integer.

For PSK signals, the M-ary number parameter represents the alphabet size. For QAM signals, the $\mathbf{M}$-ary number should be 4 regardless of the alphabet size because the 4 -power method is the most appropriate for QAM signals.

The M-Power method assumes that the carrier phase is constant over a series of consecutive symbols, and returns an estimate of the carrier phase for the series. The Observation interval parameter is the number of symbols for which the carrier phase is assumed constant. This number must be an integer multiple of the input signal's vector length.

## Input and Output Signals

This block accepts a scalar or column vector input signal of type double or single. The input signal represents a baseband signal at the symbol rate, so it must be complex-valued and must contain one sample per symbol.

The outputs are as follows:

- The output port labeled Sig gives the result of rotating the input signal counterclockwise, where the amount of rotation equals the carrier phase estimate. The Sig output is thus a corrected version of the input signal, and has the same sample time and vector size as the input signal.
- The output port labeled Ph outputs the carrier phase estimate, in degrees, for all symbols in the observation interval. The Ph output is a scalar signal.

Note Because the block internally computes the argument of a complex number, the carrier phase estimate has an inherent ambiguity. The carrier phase estimate is between $-180 / \mathrm{M}$ and 180/M degrees and might differ from the actual carrier phase by an integer multiple of 360/M degrees.

## Delays and Latency

The block's algorithm requires it to collect symbols during a period of length Observation interval before computing a single estimate of the carrier phase. Therefore, each estimate is delayed by

Observation interval symbols and the corrected signal has a latency of Observation interval symbols, relative to the input signal.

## Parameters

## M-ary number

The number of points in the signal constellation of the transmitted PSK signal. This value as an even integer.

## Observation interval

The number of symbols for which the carrier phase is assumed constant. The observation interval parameter must be an integer multiple of the input signal vector length.

When this parameter is exactly equal to the vector length of the input signal, then the block always works. When the integer multiple is not equal to 1, on the Simulation tab, select Model Settings. Then in the Solver > Solver selection section, choose Type: Fixed-step and clear the Treat each discrete rate as a separate task checkbox.

## Algorithm

If the symbols occurring during the observation interval are $x(1), x(2), x(3), \ldots, x(L)$, then the resulting carrier phase estimate is

$$
\frac{1}{M} \arg \left\{\sum_{k=1}^{L}(x(k))^{M}\right\}
$$

where the arg function returns values between -180 degrees and 180 degrees.

## M-PSK TCM Decoder

Decode trellis-coded modulation data, modulated using PSK method

| M-PSK <br> TCM |
| :---: |

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The M-PSK TCM Decoder block uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

The M-ary number parameter represents the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is, $\log _{2}(\mathbf{M}$ ary number) is the number of output bit streams from the convolutional encoder.)

The Trellis structure and M-ary number parameters in this block should match those in the M-PSK TCM Encoder block, to ensure proper decoding.

## Input and Output Signals

This block accepts a column vector input signal containing complex numbers. The input signal must be double or single. The reset port signal must be double or Boolean. For information about the data types each block port supports, see "Supported Data Types" on page 5-580.

If the convolutional encoder described by the trellis structure represents a rate $k / n$ code, then the MPSK TCM Decoder block's output is a binary column vector whose length is $k$ times the vector length of the input signal.

## Operation Modes

The block has three possible methods for transitioning between successive frames. The Operation mode parameter controls which method the block uses. This parameter also affects the range of possible values for the Traceback depth parameter, D.

- In Continuous mode, the block initializes all state metrics to zero at the beginning of the simulation, waits until it accumulates D symbols, and then uses a sequence of D symbols to compute each of the traceback paths. D can be any positive integer. At the end of each frame, the block saves its internal state metric for use with the next frame.

If you select Enable the reset input, the block displays another input port, labeled Rst. This port receives an integer scalar signal. Whenever the value at the Rst port is nonzero, the block resets all state metrics to zero and sets the traceback memory to zero.

- In Truncated mode, the block treats each frame independently. The traceback path starts at the state with the lowest metric. D must be less than or equal to the vector length of the input.
- In Terminated mode, the block treats each frame independently. The traceback path always starts at the all-zeros state. D must be less than or equal to the vector length of the input. If you know that each frame of data typically ends at the all-zeros state, then this mode is an appropriate choice.

## Decoding Delay

If you set Operation mode to Continuous, then this block introduces a decoding delay equal to Traceback depth* $k$ bits, for a rate $\mathrm{k} / \mathrm{n}$ convolutional code. The decoding delay is the number of zeros that precede the first decoded bit in the output.

The block incurs no delay for other values of Operation mode.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## M-ary number

The number of points in the signal constellation.

## Traceback depth

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

## Operation mode

The operation mode of the Viterbi decoder. Choices are Continuous, Truncated, and Terminated.

## Enable the reset input port

When you check this box, the block has a second input port labeled Rst. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data. This option appears only if you set Operation mode to Continuous.
Output data type
The output type of the block can be specified as a boolean or double. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :--- | :--- |

## M-PSK TCM Encoder

Convolutionally encode binary data and modulate using PSK method

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The M-PSK TCM Encoder block implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a PSK signal constellation.

The $\mathbf{M}$-ary number parameter is the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is, $\log _{2}$ (M-ary number) is equal to n for a rate $\mathrm{k} / \mathrm{n}$ convolutional code.)

## Input Signals and Output Signals

If the convolutional encoder described by the trellis structure represents a rate $k / n$ code, then the block input signal must be a binary column vector with a length of $L^{*} k$ for some positive integer $L$.

This block accepts a binary-valued input signal. The output signal is a complex column vector of length $L$.

## Specifying the Encoder

To define the convolutional encoder, use the Trellis structure parameter. This parameter is a MATLAB structure whose format is described in "Trellis Description of a Convolutional Code". You can use this parameter field in two ways:

- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, then use a poly2trellis command within the Trellis structure field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the Trellis structure parameter to
poly2trellis(7,[171 133],171)
- If you have a variable in the MATLAB workspace that contains the trellis structure, then enter its name as the Trellis structure parameter. This way is faster because it causes Simulink software to spend less time updating the diagram at the beginning of each simulation, compared to the usage in the previous bulleted item.

The encoder registers begin in the all-zeros state. You can configure the encoder so that it resets its registers to the all-zeros state during the course of the simulation. To do this, set the Operation
mode to Reset on nonzero input via port. The block then opens a second input port, labeled Rst. The signal at the Rst port is a scalar signal. When it is nonzero, the encoder resets before processing the data at the first input port.

## Signal Constellations

The trellis-coded modulation technique partitions the constellation into subsets called cosets, so as to maximize the minimum distance between pairs of points in each coset. This block internally forms a valid partition based on the value you choose for the $\mathbf{M}$-ary number parameter.

The figure below shows the labeled set-partitioned signal constellation that the block uses when $\mathbf{M}$ ary number is 8 . For constellations of other sizes, see [1].

## Coding Gains

Coding gains of 3 to 6 decibels, relative to the uncoded case can be achieved in the presence of AWGN with multiphase trellis codes [3].

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## Operation mode

In Continuous mode (default setting), the block retains the encoder states at the end of each frame, for use with the next frame.

In Truncated (reset every frame) mode, the block treats each frame independently. I.e., the encoder states are reset to all-zeros state at the start of each frame.

In Terminate trellis by appending bits mode, the block treats each frame independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by $y=n \cdot(x+s) / k$, where $x$ is the number of input bits, and $s=$ constraint length -1 (or, in the case of multiple constraint lengths, $s=\operatorname{sum}($ ConstraintLength(i)-1)). The block supports this mode for column vector input signals.

In Reset on nonzero input via port mode, the block has an additional input port, labeled Rst. When the Rst input is nonzero, the encoder resets to the all-zeros state.

## M-ary number

The number of points in the signal constellation.

## Output data type

The output type of the block can be specified as a single or double. By default, the block sets this to double.

## Pair Block

## MSK Demodulator Baseband

Demodulate differentially encoded MSK-modulated data

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The MSK Demodulator Baseband block demodulates a signal that was modulated using the differentially encoded minimum shift keying method. The block expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. The Phase offset parameter represents the initial phase of the modulated waveform.

## Pulse Shape Filtering

Differentially encoded minimum shift keying modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the
frequency pulse, $g(t)$, through this relation:

$$
q(t)=\int_{-\infty}^{t} g(t) d t
$$

The specified frequency pulse shape corresponds to this rectangular pulse shape expression, $g(t)$.

| Pulse Shape | Expression |
| :--- | :--- |
| Rectangular | $g(t)=\left\{\begin{array}{cl\|}\frac{1}{2 L T}, & 0 \leq t \leq L T \\ 0 & \text { otherwise }\end{array}\right.$ |

- $L_{\text {main }}$ is the main lobe pulse duration in symbol intervals.
- The duration of the pulse, $L T$, is the pulse length in symbol intervals.

## Integer-Valued Signals and Binary-Valued Signals

This block accepts a scalar-valued or column vector input signal with a data type of single or double. If you set the Output type parameter to Integer, then the block produces values of 1 and -1. If you set the Output type parameter to Bit, then the block produces values of 0 and 1 .

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the Samples per symbol parameter value, and the input can be a column vector.

- When you set Output type to Bit, the output width is $K$ times the number of input symbols.
- When you set Output type to Integer, the output width is the number of input symbols.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the Samples per symbol parameter value.

- When you set Output type to Bit, the output width equals the number of bits per symbol.
- When you set Output type to Integer, the output is a scalar.

## Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The Traceback depth parameter, D, in this block is the number of trellis branches used to construct each traceback path. D influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the Rate options parameter to Allow multirate processing, and the model uses a variable-step solver or a fixed-step solver with the Tasking Mode parameter set to SingleTasking, then the delay consists of $\mathrm{D}+1$ zero symbols.
- When you set the Rate options parameter to Enforce single-rate processing, then the delay consists of D zero symbols.

The optimal Traceback depth parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the "five-times-the-constraint-length" rule, which corresponds to $5 \times \log 2$ (numStates). The number of states is determined by the following equation:
numStates $=\left\{\begin{array}{l}p \cdot 2^{(L-1)}, \text { for even } m \\ 2 p \cdot 2^{(L-1)}, \text { for odd } m\end{array}\right\}$
where:

- $h=m / p$ is the modulation index proper rational form
- $m=$ numerator of modulation index
- $p=$ denominator of modulation index
- $L$ is the Pulse length

## Parameters

## Output type

Determines whether the output consists of bipolar or binary values.

## Phase offset (rad)

The initial phase of the modulated waveform.

## Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see "Upsample Signals and Rate Changes".

## Rate options

Select the rate processing method for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the Samples per symbol parameter value when the Output type parameter is set to Integer).
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the Samples per symbol parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

## Traceback depth

The number of trellis branches that the MSK Demodulator Baseband block uses to construct each traceback path.

## Output data type

The output data type can be boolean, int8, int16, int32, or double.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point |
| Output | - Double-precision floating point <br> - Boolean (When Output type set to Bit) <br> - $8-16$-, and 32 -bit signed integers (When Output type set to Integer) |

Modulate using differentially encoded minimum shift keying method

## Library

CPM, in Digital Baseband sublibrary of Modulation

## Description

The MSK Modulator Baseband block modulates using the differentially encoded minimum shift keying method. The output is a baseband representation of the modulated signal.

This block accepts a scalar-valued or column vector input signal. For a column vector input signal, the width of the output equals the product of the number of symbols and the value for the Samples per symbol parameter.

## Pulse Shape Filtering

Differentially encoded minimum shift keying modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the
frequency pulse, $g(t)$, through this relation: $q(t)=\int_{-\infty}^{t} g(t) d t$
The specified frequency pulse shape corresponds to this rectangular pulse shape expression, $g(t)$.

| Pulse Shape | Expression |
| :--- | :--- |
| Rectangular | $g(t)=\left\{\begin{array}{cl\|}\frac{1}{2 L T}, & 0 \leq t \leq L T \\ 0 & \text { otherwise }\end{array}\right.$ |

- $L_{\text {main }}$ is the main lobe pulse duration in symbol intervals.
- The duration of the pulse, $L T$, is the pulse length in symbol intervals.

## Integer-Valued Signals and Binary-Valued Signals

When you set the Input type parameter to Integer, then the block accepts values of 1 and -1 .
When you set the Input type parameter to Bit, then the block accepts values of 0 and 1 .
For information about the data types each block port supports, see the "Supported Data Types" on page 5-591 table on this page.

## Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set Input type to Integer, the input can be a column vector, the length of which is the number of input symbols.
- When you set Input type to Bit, the input width must be an integer multiple of $K$, the number of bits per symbol.

The output width equals the product of the number of input symbols and the Samples per symbol parameter value.

## Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set Input type to Integer, the input must be a scalar.
- When you set Input type to Bit, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Parameters

## Input type

Indicates whether the input consists of bipolar or binary values.

## Phase offset (rad)

The initial phase of the output waveform, measured in radians.

## Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1 .

For more information, see "Upsample Signals and Rate Changes" in Communications ToolboxUser's Guide.

## Rate options

Select the rate processing option for the block.

- Enforce single-rate processing - When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the Samples per symbol parameter value.
- Allow multirate processing - When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the Samples per symbol parameter value.

## Output data type

Specify the block output data type as double and single. By default, the block sets this to double.

## Supported Data Types

| Port | Supported Data Types |
| :--- | :--- |
| Input | - |
|  | Double-precision floating point |
|  | $-\quad$ Boolean (when Input type set to Bit) |
|  | - $8-, 16-$, and 32-bit signed integers (when Input type set to Integer) |
| Output | -Double-precision floating point |

## MSK-Type Signal Timing Recovery

Recover symbol timing phase using fourth-order nonlinearity method

## Library

Timing Phase Recovery sublibrary of Synchronization

## Description

The MSK-Type Signal Timing Recovery block recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method that is independent of carrier phase recovery but requires prior compensation for the carrier frequency offset. This block is suitable for systems that use baseband minimum shift keying (MSK) modulation or Gaussian minimum shift keying (GMSK) modulation.

## Inputs

By default, the block has one input port. The input signal could be (but is not required to be) the output of a receive filter that is matched to the transmitting pulse shape, or the output of a lowpass filter that limits the amount of noise entering this block.

This block accepts a scalar-valued or column vector input signal. The input uses $N$ samples to represent each symbol, where $N>1$ is the Samples per symbol parameter.

- For a column vector input signal, the block operates in single-rate processing mode. In this mode, the output signal inherits its sample rate from the input signal. The input length must be a multiple of $N$.
- For a scalar input signal, the block operates in multirate processing mode. In this mode, the input and output signals have different sample rates. The output sample rate equals $N$ multiplied by the input sample rate.
- This block accepts input signals of type Double or Single

If you set the Reset parameter to On nonzero input via port, then the block has a second input port, labeled Rst. The Rst input determines when the timing estimation process restarts, and must be a scalar.

- If the input signal is a scalar value, the sample time of the Rst input equals the symbol period
- If the input signal is a column vector, the sample time of the Rst input equals the input port sample time
- This block accepts reset signals of type Double or Boolean

## Outputs

The block has two output ports, labeled Sym and Ph:

- The Sym output is the result of applying the estimated phase correction to the input signal. This output is the signal value for each symbol, which can be used for decision purposes. The values in the Sym output occur at the symbol rate:
- For a column vector input signal of length $N^{*} R$, the Sym output is a column vector of length $R$ having the same sample rate as the input signal.
- For a scalar input signal, the sample rate of the Sym output equals $N$ multiplied by the input sample rate.
- The Ph output gives the phase estimate for each symbol in the input.

The Ph output contains nonnegative real numbers less than $N$. Noninteger values for the phase estimate correspond to interpolated values that lie between two values of the input signal. The sample time of the Ph output is the same as that of the Sym output.

Note If the Ph output is very close to either zero or Samples per symbol, or if the actual timing phase offset in your input signal is very close to zero, then the block's accuracy might be compromised by small amounts of noise or jitter. The block works well when the timing phase offset is significant rather than very close to zero.

- The output signal inherits its data type from the input signal.

## Delays

When the input signal is a vector, this block incurs a delay of two symbols. When the input signal is a scalar, this block incurs a delay of three symbols.

## Parameters

## Modulation type

The type of modulation in the system. Choices are MSK and GMSK.

## Samples per symbol

The number of samples, N , that represent each symbol in the input signal. This must be greater than 1.

## Error update gain

A positive real number representing the step size that the block uses for updating successive phase estimates. Typically, this number is less than $1 / \mathrm{N}$, which corresponds to a slowly varying phase.

This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. For more information, see Tunable Parameters (Simulink).

## Reset

Determines whether and under what circumstances the block restarts the phase estimation process. Choices are None, Every frame, and On nonzero input via port. The last option causes the block to have a second input port, labeled Rst.

## Algorithm

This block's algorithm extracts timing information by passing the sampled baseband signal through a fourth-order nonlinearity followed by a digital differentiator whose output is smoothed to yield an error signal. The algorithm then uses the error signal to make the sampling adjustments.

More specifically, this block uses a timing error detector whose result for the kth symbol is $\mathrm{e}(\mathrm{k})$, given in [2] by

$$
\begin{aligned}
& e(k)=\left({ }^{-} \operatorname{Re}\left\{r^{2}\left(k T-T_{S}+d_{k-1}\right) r^{* 2}\left((k-1) T-T_{S}+d_{k-2}\right)\right\}\right. \\
& -\left({ }^{-} \operatorname{Re}\left\{r^{2}\left(k T+T_{s}+d_{k-1}\right) r^{* 2}\left((k-1) T+T_{S}+d_{k-1}\right)\right\}\right.
\end{aligned}
$$

where

- $r$ is the block's input signal
- T is the symbol period
- $\mathrm{T}_{\mathrm{s}}$ is the sampling period
-     * means complex conjugate
- $d_{k}$ is the phase estimate for the kth symbol
- D is 1 for MSK and 2 for Gaussian MSK modulation

## Multipath Rayleigh Fading Channel

(To be removed) Simulate multipath Rayleigh fading propagation channel

Note Multipath Rayleigh Fading Channel will be removed in a future release. Use SISO Fading Channel instead.

## Library

Channels

## Description

The Multipath Rayleigh Fading Channel block implements a baseband simulation of a multipath Rayleigh fading propagation channel. You can use this block to model mobile wireless communication systems. For details about fading channels, see the references listed below.

This block accepts a scalar value or column vector input signal. The block inherits sample time from the input signal. The input signal must have a discrete sample time greater than 0 .

Relative motion between the transmitter and receiver causes Doppler shifts in the signal frequency. You can specify the Doppler spectrum of the Rayleigh process using the Doppler spectrum type parameter. For channels with multiple paths, you can assign each path a different Doppler spectrum, by entering a vector of doppler objects in the Doppler spectrum field.

Because a multipath channel reflects signals at multiple places, a transmitted signal travels to the receiver along several paths, each of which may have differing lengths and associated time delays. In the block's parameter dialog box, the Discrete path delay vector specifies the time delay for each path. If you do not check Normalize gain vector to 0 dB overall gain, then the Average path gain vector specifies the gain for each path. When you check the box, the block uses a multiple of Average path gain vector instead of the Average path gain vector itself, choosing the scaling factor so that the channel's effective gain, considering all paths, is 0 dB .

The number of paths is implicitly indicated via the number of elements in Discrete path delay vector or Average path gain vector. If both of these parameters are vectors, then they must have the same length; if exactly one of these parameters contains a scalar value, then the block expands it into a vector whose size matches that of the other vector parameter.

The block multiplies the input signal by samples of a Rayleigh-distributed complex random process. The scalar Initial seed parameter seeds the random number generator and the block generates random numbers using the Ziggurat method.

Double-clicking this block during simulation or selecting Open channel visualization at start of simulation plots the channel characteristics using the channel visualization tool. For more information, see "Channel Visualization".

## Parameters

## Maximum Doppler shift (Hz)

A positive scalar value that indicates the maximum Doppler shift.

## Doppler spectrum type

Specifies the Doppler spectrum of the Rayleigh process.
This parameter defaults to Jakes Doppler spectrum. Alternatively, you can also choose any of the following types:

- Flat on page 2-282
- Gaussian on page 2-284
- Rounded on page 2-291
- Restricted Jakes on page 2-288
- Asymmetrical Jakes on page 2-274
- Bi-Gaussian on page 2-279
- Bell on page 2-277

For all Doppler spectrum types except Jakes and Flat, you can choose one or more parameters to control the shape of the spectrum.

You can also select Specify as dialog parameter for the Doppler spectrum type. Specify the Doppler spectrum by entering an object in the Doppler spectrum field. See the doppler function reference for details on how to construct Doppler objects, and also for the meaning of the parameters associated with the various Doppler spectrum types.

## Discrete path delay vector (s)

A vector that specifies the propagation delay for each path.

## Average path gain vector (dB)

A vector that specifies the gain for each path.

## Normalize gain vector to 0 dB overall gain

Checking this box causes the block to scale the Gain vector parameter so that the channel's effective gain (considering all paths) is 0 dB .

## Initial seed

The scalar seed for the Gaussian noise generator.

## Open channel visualization at start of simulation

Select this check box to open the channel visualization tool when a simulation begins.

## Complex path gains port

Select this check box to create a port that outputs the values of the complex path gains for each path. In this $N$-by- $M$ multichannel output, $N$ represents the number of samples the input signal contains and $M$ represents the number of discrete paths (number of delays).

## Channel filter delay port

Select this check box to create a port that outputs the value of the delay (in samples) that results from the filtering operation of this block. This delay is zero if only one path is simulated, but can be greater than zero if more than one path is present. See "Methodology for Simulating Multipath Fading Channels" for a definition of this delay, where it is denoted as $N_{1}$.

## Algorithm

This implementation is based on the direct-form simulator described in Reference [1]. A detailed explanation of the implementation, including a review of the different Doppler spectra, can be found in [4].

Some wireless applications prefer to specify Doppler shifts in terms of the speed of the mobile. If the mobile moves at speed $v$ making an angle of $\theta$ with the direction of wave motion, then the Doppler shift is
$f_{\mathrm{d}} \quad=\quad(\mathrm{vf} / \mathrm{c}) \cos \quad \theta$
where $f$ is the transmission carrier frequency and $c$ is the speed of light. The Doppler frequency represents the maximum Doppler shift arising from motion of the mobile.

## Example

## Generating Ideal Theoretical BER Results for a Rayleigh Fading Channel

This example illustrates how to generate ideal theoretical BER results for a flat Rayleigh fading channel. The model reproduces known theoretical results and shows the correct BER performance for a flat Rayleigh fading channel. In this example, you will run the model and compare the simulation results to the BERTool theoretical results for verification purposes. Note that the EbNo value for the model's AWGN block is 5 dB . You can change the noise power by double-clicking the AWGN block and entering another numeric value in the EbNo parameter.

## Opening the Model

You can open the model by clicking here in the MATLAB Help browser. Alternatively, you can type doc_qpsk_rayleigh_derotated at the MATLAB command line.

Running the Model and Comparing Results
1 To run the example, select Run in the Simulate of the Simulation, Debug, or Modeling tab.
2 After the model collects more than 5000 errors, click the stop button.
3 Close the three scopes.
4 In the Simulink model window, double-click the Transmitter Output block. In the mask window, click the Figure Properties tab, uncheck Open scope at start of Simulation, then click OK.

5 In the Simulink model window, double-click the Rayleigh Channel Output block. In the mask window, click the Figure Properties tab, uncheck Open scope at start of Simulation, then click OK.
6 In the Simulink model window, double-click the Noisy Rayleigh Channel Output block. In the mask window, click the Figure Properties tab, uncheck Open scope at start of Simulation, then click $\mathbf{O K}$.
7 In the Simulink model window, double-click the Error Rate Calculation block, check Stop simulation, enter 5000 for Target number of error, then click OK.
8 Click the play button to rerun the example.
9 Open BERTool by typing bertool at the MATLAB command line.
10 In BERTool, click the Theoretical tab and make the following selections:

- For $\mathbf{E b} /$ No range enter 0:10
- For Channel type, select Rayleigh
- For Diversity Order enter 1
- For Modulation Type, select PSK
- For Modulation order, select 4

11 Click Plot.
12 Since the Simulink model uses an EbNo value of 5 dB , verify the probability of error on the BERTool curve at 5 dB . The two values should be approximately equal.

Click the Data Cursor button (second from right) and click on the BERTool curve at 5 dB .

# Multipath Rician Fading Channel 

(To be removed) Simulate multipath Rician fading propagation channel

Note Multipath Rician Fading Channel will be removed in a future release. Use SISO Fading Channel instead.

## Library

## Channels

## Description

The Multipath Rician Fading Channel block implements a baseband simulation of a multipath Rician fading propagation channel. You can use this block to model mobile wireless communication systems when the transmitted signal can travel to the receiver along a dominant line-of-sight or direct path. For more details, see "Fading Channels".

This block accepts a scalar value or column vector input signal. The block inherits sample time from the input signal. The input signal must have a discrete sample time greater than 0 .

Relative motion between the transmitter and receiver causes Doppler shifts in the signal frequency. You can specify the Doppler spectrum of the Rician process using the Doppler spectrum type popup menu. For channels with multiple paths, you can assign each path a different Doppler spectrum, by entering a vector of doppler objects in the Doppler spectrum field.

Because a multipath channel reflects signals at multiple places, a transmitted signal travels to the receiver along several paths, each of which may have differing lengths and associated time delays. In the block's parameter dialog box, the Discrete path delay vector specifies the time delay for each path. If you do not check the Normalize gain vector to $\mathbf{0} \mathbf{d B}$ overall gain box, then the Average path gain vector specifies the gain for each path. When you check the box, the block uses a multiple of Average path gain vector instead of the Average path gain vector itself, choosing the scaling factor so that the channel's effective gain considering all paths is 0 dB .

The number of paths is implicitly indicated via the number of elements in Discrete path delay vector or Average path gain vector. If both of these parameters are vectors, they must have the same length; if exactly one of these parameters contains a scalar value, the block expands it into a vector whose size matches that of the other vector parameter.

Fading causes the signal to become diffuse. The K-factor parameter, which is part of the statistical description of the Rician distribution, represents the ratio between the power in the line-of-sight component and the power in the diffuse component. The ratio is expressed linearly, not in decibels. While the Average path gain vector parameter controls the overall gain through the channel, the Kfactor parameter controls the gain's partition into line-of-sight and diffuse components.

You can specify the K-factor parameter as a scalar or a vector. If the K-factor parameter is a scalar, then the first discrete path of the channel is a Rician fading process (it contains a line-of-sight component) with the specified $\mathbf{K}$-factor, while the remaining discrete paths indicate independent Rayleigh fading processes (with no line-of-sight component). If the K-factor parameter is a vector of the same size as Discrete path delay vector, then each discrete path is a Rician fading process with a K-factor given by the corresponding element of the vector. You can attribute the line-of-sight component a Doppler shift, through the Doppler shift(s) of line-of-sight component(s) parameter, and an initial phase, through the Initial phase(s) of line-of-sight component(s). The Doppler shift(s) of line-of-sight component(s) and Initial phase(s) of line-of-sight component(s) parameters must be of the same size as the K-factor parameter.

The block multiplies the input signal by samples of a Rician-distributed complex random process. The scalar Initial seed parameter seeds the random number generator and the block generates random numbers using the Ziggurat method.

Double-clicking this block during simulation or selecting the block dialog's check box labeled Open channel visualization at start of simulation plots the channel characteristics using the channel visualization tool. For more information, see "Channel Visualization".

## Parameters

## K-factor

The ratio of power in the line-of-sight component to the power in the diffuse component. The ratio is expressed linearly, not in decibels. If K-factor is a scalar value, then the first discrete path is a Rician fading process (it contains a line-of-sight component) with the specified K-factor, while the remaining discrete paths are independent Rayleigh fading processes (with no line-of-sight component). If $\mathbf{K}$-factor is a vector of the same size as Discrete path delay vector, then each discrete path is a Rician fading process with a K-factor given by the corresponding element of the vector.

## Doppler shift(s) of line-of-sight components(s) (Hz)

The Doppler shift of the line-of-sight component. It must be a scalar (if K-factor is a scalar) or a vector of the same size as K-factor. If this parameter contains a scalar value, then the line-ofsight component of the first discrete path has the specified Doppler shift, while the remaining discrete paths become independent Rayleigh fading processes. If the parameter contains a vector, then the line-of-sight component of each discrete path has a Doppler shift given by the corresponding element of the vector.

## Initial phase(s) of line-of-sight component(s) (rad)

The initial phase of the line-of-sight component. It must be either a scalar (if K-factor is a scalar value) or a vector of the same size as $\mathbf{K}$-factor.

## Maximum diffuse Doppler shift (Hz)

A positive scalar value that indicates the maximum diffuse Doppler shift.

## Doppler spectrum type

Specifies the Doppler spectrum of the Rician process.
This parameter defaults to Jakes Doppler spectrum. Alternately, you can choose any of the following types:

- Flat on page 2-282
- Gaussian on page 2-284
- Rounded on page 2-291
- Restricted Jakes on page 2-288
- Asymmetrical Jakes on page 2-274
- Bi-Gaussian on page 2-279
- Bell on page 2-277

For all Doppler spectrum types except Jakes and Flat, You can use one or more parameters to control the shape of the spectrum.

You can also select Specify as dialog parameter for the Doppler spectrum type. Specify the Doppler spectrum by entering an object in the Doppler spectrum field. See the doppler function reference for details on how to construct doppler objects, and for the meaning of the parameters associated with the various Doppler spectrum types.

## Discrete delay vector(s)

A vector that specifies the propagation delay for each path.

## Average path gain vector (dB)

A vector that specifies the gain for each path.

## Initial seed

The scalar seed for the Gaussian noise generator.
Open channel visualization at start of simulation
Select this check box to open the channel visualization tool when a simulation begins. This block supports channel visualization for a column vector input signal.

## Complex path gains port

Select this check box to create a port that outputs the values of the complex path gains for each path. In this $N$-by- $M$ multichannel output, $N$ represents the number of samples the input contains and $M$ represents the number of discrete paths (number of delays).

## Channel filter delay port

Select this check box to create a port that outputs the value of the delay (in samples) that results from the filtering operation of this block. This delay is zero if only one path is simulated, but can be greater than zero if more than one path is present. See "Methodology for Simulating Multipath Fading Channels" for a definition of this delay, where it is denoted as $N_{1}$.

## Algorithm

This implementation is based on the direct form simulator described in Reference [1]. A detailed explanation of the implementation, including a review of the different Doppler spectra, can be found in [4].

Some wireless applications prefer to specify Doppler shifts in terms of the speed of the mobile. If the mobile moves at speed $v$ making an angle of $\theta$ with the direction of wave motion, the Doppler shift is
$f_{\mathrm{d}} \quad=\quad(\mathrm{vf} / \mathrm{c}) \cos$
where $f$ is the transmission carrier frequency and $c$ is the speed of light. The Doppler frequency is the maximum Doppler shift arising from the motion of the mobile.

## Description

The Mu-Law Compressor block implements a $\mu$-law compressor for the input signal. The formula for the $\mu$-law compressor is

$$
y=\frac{V \log (1+\mu|x| / V)}{\log (1+\mu)} \operatorname{sgn}(x)
$$

where $\mu$ is the $\mu$-law parameter of the compressor, $V$ is the peak magnitude of $x, \log$ is the natural logarithm, and sgn is the signum function (sign in MATLAB).

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

## mu value

The $\mu$-law parameter of the compressor.

## Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output.

## Normalized LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with normalized LMS algorithm

Note will be removed in a future release. Consider using Decision Feedback Equalizer instead.

## Library

## Equalizer Block

## Description

The Normalized LMS Decision Feedback Equalizer block uses a decision feedback equalizer and the normalized LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the normalized LMS algorithm to update the weights, once per symbol. When you set the Number of samples per symbol parameter to 1 , then the block implements a symbol-spaced (i.e. T-spaced) equalizer. When you set the Number of samples per symbol parameter to a value greater than 1 , , the weights are updated once every $N^{\text {th }}$ sample, for a $T / N$-spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of forward taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+$ (Reference tap-1)/(Number of samples per symbol)

Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

## Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

## Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of forward taps in the equalizer.

## Step size

The step size of the normalized LMS algorithm.

## Leakage factor

The leakage factor of the normalized LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Bias

The bias parameter of the normalized LMS algorithm, a nonnegative real number. This parameter is used to overcome difficulties when the algorithm's input signal is small.

## Initial weights

A vector that concatenates the initial weights for the forward and feedback taps.

## Mode input port

If you select this check box, the block has an input port that enables you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0 . The equalizer will train for the length of the Desired signal. If the mode input is not present, the equalizer will train at the beginning of every frame for the length of the Desired signal.

## Output error

If you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

If you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## Compatibility Considerations

## Normalized LMS Decision Feedback Equalizer will be removed

Warns starting in R2020a

- Normalized LMS Decision Feedback Equalizer will be removed in a future release. Consider using Decision Feedback Equalizer instead with the adaptive algorithm set to LMS.
- The Enable training control input parameter of the Decision Feedback Equalizer block is equivalent to the Mode input port parameter of the Normalized LMS Decision Feedback Equalizer block.
- The Decision Feedback Equalizer block does not have a leakage factor parameter. This is equivalent to setting the Leakage factor parameter to 1 in the Normalized LMS Decision Feedback Equalizer block.

## Normalized LMS Linear Equalizer

(To be removed) Equalize using linear equalizer that updates weights with normalized LMS algorithm

Note will be removed in a future release. Consider using Linear Equalizer instead.

## Library

## Equalizers

## Description

The Normalized LMS Linear Equalizer block uses a linear equalizer and the normalized LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the normalized LMS algorithm to update the weights, once per symbol. When you set the Number of samples per symbol parameter to 1 , the block implements a symbolspaced (i.e. T-spaced) equalizer and updates the filter weights once for each symbol. When you set the Number of samples per symbol parameter to a value greater than 1 , the weights are updated once every $N^{\mathrm{th}}$ sample, for a $T / N$-spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+$ (Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap.

## Parameters

## Number of taps

The number of taps in the filter of the linear equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of taps in the equalizer.

## Step size

The step size of the normalized LMS algorithm.

## Leakage factor

The leakage factor of the normalized LMS algorithm, a number between 0 and 1 . A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Bias

The bias parameter of the normalized LMS algorithm, a nonnegative real number. This parameter is used to overcome difficulties when the algorithm's input signal is small.

## Initial weights

A vector that lists the initial weights for the taps.

## Mode input port

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0 . For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

## Output error

If you check this box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

If you check this box, the block outputs the current weights.

## OFDM Demodulator Baseband

Demodulate orthogonal frequency division modulated data

## Library

OFDM, in Digital Baseband sublibrary of Modulation

## Description

The Orthogonal Frequency Division Modulation (OFDM) Demodulator Baseband block demodulates an OFDM input signal. The block accepts a single input and has one or two output ports, depending on the status of Pilot output port.

## Signal Dimensions

| Pilot Output Port | Pilot Carrier Indices | Signal Input | Signal Output | Pilot Output |
| :---: | :---: | :---: | :---: | :---: |
| false | N/A | $\mathrm{N}_{\text {CPTotal }}$ <br> $+\mathrm{N}_{\mathrm{FFT}} \times \mathrm{N}_{\text {sym }}$-by- $\mathrm{N}_{\mathrm{r}}$ | $\mathrm{N}_{\text {data }}-$ by $-\mathrm{N}_{\text {sym }}-$ by- $\mathrm{N}_{\mathrm{r}}$ | N/A |
| true | 2-D |  |  | $\mathrm{N}_{\text {pilot }}$-by- $\mathrm{N}_{\text {sym }}$-by- $\mathrm{N}_{\mathrm{r}}$ |
|  | 3-D |  |  | $\begin{array}{\|l\|} \hline \begin{array}{l} \mathrm{N}_{\text {pilot- }}-\mathrm{by}-\mathrm{N}_{\text {sym }}-\mathrm{by}-\mathrm{N}_{\mathrm{t}^{-}} \\ \text {by- } \end{array} \\ \hline \end{array}$ |

where

- $\mathrm{N}_{\mathrm{CP}}$ represents the cyclic prefix length as determined by Cyclic prefix length.
- $\mathrm{N}_{\text {CPTotal }}$ represents the cyclic prefix length over all the symbols. When $\mathrm{N}_{\mathrm{CP}}$ is a scalar, $\mathrm{N}_{\mathrm{CPTotal}}=\mathrm{N}_{\mathrm{CP}}$ $\times \mathrm{N}_{\mathrm{sym}}$. When $\mathrm{N}_{\mathrm{CP}}$ is a row vector, $\mathrm{N}_{\mathrm{CPTotal}}=\sum \mathrm{N}_{\mathrm{CP}}$.
- $\mathrm{N}_{\mathrm{FFT}}$ represents the number of subcarriers as determined by FFT length.
- $\mathrm{N}_{\text {sym }}$ represents the number of symbols as determined by Number of OFDM symbols.
- $\mathrm{N}_{\mathrm{r}}$ represents the number of receive antennas as determined by Number of receive antennas.
- $\mathrm{N}_{\text {data }}$ represents the number of data subcarriers. For further information on how $\mathrm{N}_{\text {data }}$ is determined, see the info reference page.
- $\mathrm{N}_{\text {pilot }}$ represents the number of pilot symbols determined by the second dimension in the Pilot subcarrier indices array.
- $N_{t}$ represents the number of transmit antennas. This parameter is derived from the third dimension of the Pilot subcarrier indices array.

## Parameters

## FFT Length

Specify the FFT length, which is equivalent to the number of subcarriers. The length of the FFT, $\mathrm{N}_{\mathrm{FFT}}$, must be greater than or equal to 8 .

## Number of guard bands

Assign the number of subcarriers to the left, $\mathrm{N}_{\mathrm{leftG}}$, and right, $\mathrm{N}_{\mathrm{rightG}}$, guard bands. The input is a 2-by-1 vector. The number of subcarriers must fall within $\left[0, \mathrm{~N}_{\mathrm{FFT}} / 2-1\right]$.

## Remove DC carrier

Select to remove the DC subcarrier.

## Pilot output port

Select to separate the data from the pilot signal and output the demodulated pilot signal.

## Pilot subcarrier indices

Specify the pilot subcarrier indices. This field is available only when the Pilot output port check box is selected. You can assign the indices can be assigned to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the indices' array vary from 1 to 3 . Valid pilot indices fall in the range

$$
\left[N_{\text {leftG }}+1, N_{\mathrm{FFT}} / 2\right] \cup\left[N_{\mathrm{FFT}} / 2+2, N_{\mathrm{FFT}}-N_{\mathrm{rightG}}\right],
$$

where the index value cannot exceed the number of subcarriers. If the number of transmit antennas is greater than one, ensure that the indices per symbol are mutually distinct across antennas to minimize interference.

## Cyclic prefix length

Specify the length of the cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length $\mathrm{N}_{\text {sym }}$, the prefix length can vary across symbols but remains the same length through all antennas.

## Number of OFDM symbols

Specify the number of OFDM symbols, $\mathrm{N}_{\text {sym }}$, in the time-frequency grid.

## Number of receive antennas

Specify the number of receive antennas, $\mathrm{N}_{\mathrm{r}}$, as a positive integer such that $\mathrm{N}_{\mathrm{r}} \leq 64$.

## Simulate using

Select the simulation type from these choices:

- Code generation
- Interpreted execution

## Algorithms

This block implements the algorithm, inputs, and outputs described in the OFDM Demodulator System object reference page. The object properties correspond to the block parameters.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point |
| Pilot (optional) | - Double-precision floating point |
| Output | - Double-precision floating point |

## OFDM Modulator Baseband

Modulate using orthogonal frequency division modulation
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / OFDM

## Description

The OFDM Modulator Baseband block applies Orthogonal Frequency Division Multiplexing modulation to an incoming data signal. The output is a baseband representation of the OFDM modulated signal.

## Ports

Input

## In - Input signal

3-D array
Input signal, specified as a 3D vector. The block accepts one or two inputs depending on the state of the Pilot input port. The input signal dimensions are :

| Pilot Input Port | Signal Input | Pilot Input |
| :--- | :--- | :--- |
| off | $N_{\text {data }}-$ by- $\mathrm{N}_{\text {sym }}-$ by $-\mathrm{N}_{\mathrm{t}}$ | $\mathrm{N} / \mathrm{A}$ |
| on |  | $\mathrm{N}_{\text {pilot }}-$ by $-\mathrm{N}_{\text {sym }}-$ by- $\mathrm{N}_{\mathrm{t}}$ |

where

- $\mathrm{N}_{\text {data }}$ represents the number of data subcarriers. For further information on how $\mathrm{N}_{\text {data }}$ is determined, see the info reference page.
- $\mathrm{N}_{\text {sym }}$ represents the number of symbols determined by Number of OFDM symbols.
- $\mathrm{N}_{\mathrm{t}}$ represents the number of transmit antennas determined by Number of transmit antennas.
- $\mathrm{N}_{\text {pilot }}$ represents the number of pilot symbols determined by the first dimension size in the Pilot subcarrier indices array.
- $\mathrm{N}_{\mathrm{CP}}$ represents the cyclic prefix length as determined by Cyclic prefix length.
- $\mathrm{N}_{\mathrm{CPTotal}}$ represents the cyclic prefix length over all the symbols. When $\mathrm{N}_{\mathrm{CP}}$ is a scalar, $\mathrm{N}_{\mathrm{CPTotal}}=\mathrm{N}_{\mathrm{CP}}$ $\times \mathrm{N}_{\mathrm{sym}}$. When $\mathrm{N}_{\mathrm{CP}}$ is a row vector, $\mathrm{N}_{\mathrm{CPTotal}}=\sum \mathrm{N}_{\mathrm{CP}}$.
- $\mathrm{N}_{\mathrm{FFT}}$ represents the number of subcarriers as determined by FFT length.

## Data Types: double

Complex Number Support: Yes

## Output

## Out - Baseband modulated signal <br> 3-D array

Baseband modulated signal, returned as a3D array. The datatype of the output follows the input datatype. The output signal has dimension $\mathrm{N}_{\text {CPTotal }}+\mathrm{N}_{\text {FFT }} \times \mathrm{N}_{\text {sym }}$-by $-\mathrm{N}_{\mathrm{t}}$.

## Parameters

## FFT Length - Number of DFT points

positive integer
Number of DFT points, specified as a positive integer. The length of the FFT, $\mathrm{N}_{\mathrm{FFT}}$, must be greater than or equal to 8 and is equivalent to the number of subcarriers.

## Number of guard bands - Number of subcarriers to the left and right guard bands [6;5] (default) | 2-by-1 integer-valued vector

Number of subcarriers allocated to the left and right guard bands, specified as a 2-by-1 integervalued vector. The number of subcarriers must fall within [0, $\left.\mathrm{N}_{\mathrm{FFT}} / 2\right]-1$ ] where you specify the left, $N_{\text {leftG }}$, and right, $N_{\text {rightG }}$, guard bands independently in a 2 -by- 1 column vector.

Insert DC null - Option to insert DC null
off (default) | on
Select this parameter to insert a null on the DC subcarrier.

## Pilot input port - Option to specify pilot input port

off (default) | on
Select this parameter to allow the specifying of pilot input port.

## Pilot subcarrier indices - Pilot subcarrier indices

[12; 26; 40; 54] (default) | column vector
Pilot subcarrier indices, specified as a column vector. This field is available only when the Pilot input port check box is selected. You can assign the indices to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the indices array vary. Valid pilot indices fall in the range

$$
\left[N_{\text {leftG }}+1, N_{\mathrm{FFT}} / 2\right] \cup\left[N_{\mathrm{FFT}} / 2+2, N_{\mathrm{FFT}}-N_{\text {rightG }}\right],
$$

where the index value cannot exceed the number of subcarriers. When the pilot indices are the same for every symbol and transmit antenna, the property has dimensions $\mathrm{N}_{\text {pilot }}$-by- 1 . When the pilot indices vary across symbols, the property has dimensions of $N_{\text {pilot }}$-by- $\mathrm{N}_{\text {sym }}$. If there is only one symbol but multiple transmit antennas, the property has dimensions of $\mathrm{N}_{\text {pilot }}$-by-1-by- $\mathrm{N}_{\mathrm{t}}$. If the indices vary across the number of symbols and transmit antennas, the property will have dimensions of $\mathrm{N}_{\text {pilot }}$-by$\mathrm{N}_{\text {sym }}$-by- $\mathrm{N}_{\mathrm{t}}$. If the number of transmit antennas is greater than one, ensure that the indices per symbol are mutually distinct across antennas to minimize interference. The default value is [12; 26; 40; 54].

## Cyclic prefix length - Length of cyclic prefix

[^3]Length of cyclic prefix, specified as a positive integer. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length $\mathrm{N}_{\text {sym }}$, the prefix length can vary across symbols but remains the same through all antennas.

## Apply raised cosine windowing between OFDM symbols - Option to apply raised cosine window between OFDM symbols

off (default) | on
Select this parameter to apply raised cosine windowing between OFDM symbols. Windowing is the process in which the OFDM symbol is multiplied by a raised cosine window before transmission to reduce the power of out-of-band subcarriers, which serves to reduce spectral regrowth.

## Window length - Length of raised cosine window

1 (default) | positive scalar
Length of raised cosine window, specified as a positive scalar. This field is available only when Apply raised cosine windowing between OFDM symbols is selected. Use positive integers having a maximum value no greater than the minimum cyclic prefix length. For example, in a configuration in which there are four symbols with cyclic prefix lengths of [ $\left.\begin{array}{llll}12 & 16 & 14 & 18\end{array}\right]$, the window length cannot exceed 12.

## Number of OFDM symbols - Number of OFDM symbols

1 (default) | positive scalar
Number of OFDM symbols in the time-frequency grid, specified as a positive scalar.

## Number of transmit antennas - Number of transmit antennas

positive scalar
Number of transmit antennas, specified as a real positive scalar. Specify the number of transmit antennas, $\mathrm{N}_{\mathrm{t}}$, as a positive integer such that $\mathrm{N}_{\mathrm{t}} \leq 64$.

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | no |

## More About

## Orthogonal Frequency Division Modulation

Orthogonal frequency division modulation (OFDM) divides a high-rate transmit data stream into $N$ lower-rate streams, each of which has a symbol duration larger than the channel delay spread and, therefore, mitigates intersymbol interference (ISI). The individual substreams are sent over $N$ parallel subchannels which are orthogonal to each other. Through the use of an inverse fast Fourier transform (IFFT), OFDM can be transmitted using a single radio. The output is a baseband representation of the modulated signal:

$$
v(t)=\sum_{k=0}^{N-1} X_{k} e^{j 2 \pi k \Delta f t}, \quad 0 \leq t \leq T,
$$

where $\left\{X_{k}\right\}$ are data symbols, $N$ is the number of subcarriers, and $T$ is the OFDM symbol time. The subcarrier spacing of $\Delta f=1 / T$ makes the symbols orthogonal over each symbol period. This orthogonality is expressed as:

$$
\frac{1}{T} \int_{0}^{T}\left(e^{j 2 \pi m \Delta f t}\right) *\left(e^{j 2 \pi n \Delta f t}\right) d t=\frac{1}{T} \int_{0}^{T} e^{j 2 \pi(m-n) \Delta f t} d t=0 \quad \text { for } m \neq n
$$

The data symbols, $X_{k}$, are usually complex and can be from any modulation alphabet such as QPSK, 16-QAM, or 64-QAM.

This figure shows an OFDM modulator consisting of a bank of $N$ complex modulators, where each modulator corresponds to one OFDM subcarrier.

## Guard Bands and Intervals

OFDM has three types of subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data, and pilot subcarriers are used for channel estimation. Null subcarriers, which provide a DC null and provide buffers between OFDM resource blocks, are not transmitted. These buffers are referred
to as guard bands whose purpose is to prevent intersymbol interference. The allocation of nulls and guard bands vary depending on the applicable standard such as 802.11 n differs from LTE.

Analogous to the concept of guard bands, the OFDM also supports guard intervals, which to provide temporal separation between OFDM symbols so that the signal does not lose orthogonality due to time-dispersive channels. As long as the guard interval is longer than the delay spread, symbols do not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. Using a cyclic prefix increases overhead.

## Raised Cosine Windowing

While the cyclic prefix creates a guard period in time domain to preserve orthogonality, an OFDM symbol rarely begins with the same amplitude and phase exhibited at the end of the prior OFDM symbol causing spectral regrowth and therefore, spreading of signal bandwidth due to intermodulation distortion. To limit this spectral regrowth, it is desired to create a smooth transition between the last sample of a symbol and the first sample of the next symbol. This can be done by using a cyclic suffix and raised cosine windowing.

To create the cyclic suffix, the first $N_{\text {WIN }}$ samples of a given symbol are appended to the end of that symbol. However, in order to comply with the 802.11 g standard, for example, the length of a symbol cannot be arbitrarily lengthened. Instead, the cyclic suffix must overlap in time and is effectively summed with the cyclic prefix of the following symbol. This overlapped segment is where windowing is applied. Two windows are applied, one of which is the mathematical inverse of the other. The first
raised cosine window is applied to the cyclic suffix of symbol $k$ and decreases from 1 to 0 over its duration. The second raised cosine window is applied to the cyclic prefix of symbol $k+1$ and increases from 0 to 1 over its duration. This process provides a smooth transition from one symbol to the next.

The raised cosine window, $w(t)$, in the time domain can be expressed as:

$$
w(t)=\left\{\begin{array}{l}
1,0 \leq|t|<\frac{T-T_{W}}{2} \\
\frac{1}{2}\left\{1+\cos \left[\frac{\Pi}{T_{W}}\left(|t|-\frac{T-T_{W}}{2}\right)\right]\right\}, \frac{T-T_{W}}{2} \leq|t| \leq \frac{T+T_{W}}{2} \\
0, \text { otherwise }
\end{array}\right.
$$

where:

- $T$ is the OFDM symbol duration including the guard interval.
- $T_{\mathrm{W}}$ is the duration of the window.

Adjust the length of the cyclic suffix via the window length setting property, with suffix lengths set between 1 and the minimum cyclic prefix length. While windowing improves spectral regrowth, it does so at the expense of multipath fading immunity. This occurs because redundancy in the guard band is reduced because the guard band sample values are compromised by the smoothing.

The following figures display the application of raised cosine windowing.

## OQPSK Demodulator Baseband

Demodulation using OQPSK method

Library:<br>Communications Toolbox / Modulation / Digital Baseband Modulation / PM

## Description

The OQPSK Demodulator Baseband block applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see "Pulse Shaping Filter" on page 5-629. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see "Modulation Delays" on page 5-628.

## Ports

Input
In - Input baseband waveform
scalar | column vector
Input baseband waveform, specified as a discrete-time complex scalar or column vector.
The block processes the input signal based on the Output type setting.
Data Types: double
Complex Number Support: Yes

## Output

## Out - Output data

integer column vector | bit column vector
Output data, returned as an integer or bit column vector.

## Parameters

## Modulation

## Output type - Output type

Integer (default)|Bit
Output type, specified as Integer or Bit.

- When you set Output type to Integer, the block outputs a vector of integer symbols with values from 0 to 3 , the length of which is the number of output symbols.
- When you set Output type to Bit, the block outputs a 2-bit binary representation of integers, in a binary-valued, even-length vector.

The input period for each integer or bit pair is the Samples per symbol times the output sample period.

Phase offset (rad) - Phase of zeroth point of signal constellation
0 (default) | scalar
Phase of zeroth point of the signal constellation in radians, specified as a scalar.
Example: Setting Phase offset (rad) to 0 aligns the OQPSK signal constellation points on the axes, $\{(1,0),(0, j),(-1,0),(0,-j)\}$.

## Symbol mapping - Signal constellation bit mapping

Gray (default) | Binary | custom 4-element numeric vector of integers with values from 0 to 3
Signal constellation bit mapping, specified as Gray, Binary, or a custom 4-element numeric vector of integers with values from 0 to 3 .

| Setting | Constellation Mapping for Integers |  | Constellation Mapping for Bits |  | Comment |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Gray | 1 3 | $0$ $2$ | 01 <br> 11 | 00 -10 | The signal constellation mapping is Grayencoded. |
| Binary | 1 2 | 0 <br> 3 | 01 <br> 10 |  | The signal constellation mapping for the input integer $m(0 \leq m \leq 3)$ is the complex value $\mathrm{e}^{\left(\mathrm{j}^{*}(\text { Phaseoffset }+\pi / 4)\right.}+$ $\left.\mathrm{j}^{*} \mathrm{2}^{*} \mathrm{~m}^{*} \mathrm{~m}_{\mathrm{m}} / 4\right)$. |
| Custom 4-element numeric vector of integers with values from 0 to 3 | b c | a <br> d | de2bi(b) <br> de2bi(c) | de2bi(a) <br> de2bi(d) | Elements [a b c d] must be composed of the set of values $[0,1,2,3]$ in any order. |

## Filtering

## Pulse shape - Filtering pulse shape

Half sine (default)|Normal raised cosine |Root raised cosine|Custom
Select the filtering pulse shape: Half sine, Normal raised cosine, Root raised cosine, or Custom.

## Rolloff factor - Raised cosine filter rolloff factor

## 0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1 .

## Dependencies

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.
Data Types: double
Filter span (in symbols) - Filter length
10 (default) | scalar
Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to Filter span (in symbols) symbols.

## Dependencies

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.
Data Types: double
Filter numerator - Filter numerator
[0.7071 0.7071] (default) | row vector
Filter numerator, specified as a row vector.

## Dependencies

This parameter appears when Pulse shape is Custom.
Data Types: double
Samples per symbol - Number of samples per symbol
4 (default) | positive even integer
Number of samples per symbol, specified as a positive even integer.
Data Types: double

## Other Parameters

## Rate options - Processing rate option

Enforce single-rate processing (default)|Allow multirate processing

- Enforce single-rate processing - Executes the model, ensuring that the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. For integer outputs, the output width equals 1 / Samples per symbol times the input width.

For more information, see Single-Rate Processing with OQPSK Demodulator Block.

- Allow multirate processing - Executes the model, allowing the input and output signals to have different port sample times. The output symbol time is Samples per symbol times the input sample time.

For more information, see Multirate Processing with OQPSK Demodulator Block.

## Output data type - Output data type

double (default) | single |uint8
Select the output data type: double, single, or uint8.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## OQPSK Signal Flow Diagram

Every Samples per symbol input samples produce one output symbol. In this figure, the dotted line represents the region comprising the input sample processing.

## Modulation Delays

Digital modulation and demodulation blocks incur delays between their inputs and outputs that result in an offset in the arrival time of the received data. Data that enters a modulation or demodulation block at time $T$ appears in the output at time $T+$ delay. Take system delays into account when comparing transmitted data with received data, such as in overlaid plots or when computing error statistics. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter, input/output data setting, and simulation configuration.

## Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

## OQPSK Modulator Baseband

Modulation using OQPSK method
Library: Communications Toolbox / Modulation / Digital Baseband Modulation / PM

## Description

The OQPSK Modulator Baseband block modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the waveform. For more information, see "Pulse Shaping Filter" on page 5-635. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see "Modulation Delays" on page 5-634.

## Ports

Input

## In - Input data

integer column vector | bit column vector
Input data, specified as an integer or bit column vector.
The input signal is processed based on the setting selected for Input type.
Data Types: double
Output
Out - Output baseband waveform
column vector
Output baseband waveform, returned as a column vector of complex data.

## Parameters

## Modulation

## Input type - Input type

Integer (default)|Bit
Input type, specified as Integer or Bit.

- When you set Input type to Integer, the input can be a scalar value or column vector, the length of which is the number of input symbols.
- When you set Input type to Bit, the input width must be an integer multiple of two.

The output sample period is the period of each integer or bit pair in the input divided by Samples per symbol.

## Phase offset (rad) - Phase of zeroth point of signal constellation <br> 0 (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.
Example: Setting Phase offset (rad) to 0 aligns the OQPSK signal constellation points on the axes, $\{(1,0),(0, j),(-1,0),(0,-j)\}$.

## Symbol mapping - Signal constellation bit mapping

Gray (default) | Binary | custom 4-element numeric vector of integers with values from 0 to 3
Signal constellation bit mapping, specified as Gray, Binary, or a custom 4-element numeric vector of integers with values from 0 to 3 .

| Setting | Constellation Mapping for Integers |  | Constellation Mapping for Bits |  | Comment |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Gray | 1 | 0 | 0100 |  | The signal constellation mapping is Grayencoded. |
|  | 3 | 2 | 11 | 10 |  |
| Binary | 1 | 0 | 01 00 |  | The signal constellation mapping for the input integer $m(0 \leq m \leq 3)$ is |
|  | 2 | 3 | $10 \quad 11$ |  | the complex value $\mathrm{e}^{(j *(\text { PhaseOffset }+\pi / 4)+}$ $\mathrm{j} * 2 * \pi^{*}{ }^{\mathrm{m} / 4)}$. |
| Custom 4-element numeric vector of integers with values from 0 to 3 | b c | a <br> d | de2bi(b) <br> de2bi(c) | $\begin{gathered} \text { de2bi(a) } \\ \text { de2bi(d) } \end{gathered}$ | Elements [a b c d] must be composed of the set of values $[0,1,2,3]$ in any order. |

## Filtering

## Pulse shape - Filtering pulse shape

Half sine (default) | Normal raised cosine | Root raised cosine | Custom
Select the filtering pulse shape: Half sine, Normal raised cosine, Root raised cosine, or Custom.

## Rolloff factor - Raised cosine filter rolloff factor

## 0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar in the range [0, 1].

## Dependencies

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.

## Data Types: double

Filter span (in symbols) - Filter length
10 (default) | scalar
Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to Filter span (in symbols) symbols.

## Dependencies

This property appears when Pulse shape is Normal raised cosine or Root raised cosine.
Data Types: double

## Filter numerator - Filter numerator

## [0.7071 0.7071] (default)| row vector

Filter numerator, specified as a row vector.

## Dependencies

This parameter appears when Pulse shape is Custom.
Data Types: double

## Samples per symbol - Number of samples per symbol

4 (default) | positive even integer
Number of samples per symbol, specified as a positive even integer.
Data Types: double

## Other Parameters

## Rate options - Processing rate option

Enforce single-rate processing (default)|Allow multirate processing

- Enforce single-rate processing - Executes the model, ensuring that the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. For integer inputs, the output width equals Samples per symbol times the number of symbols.

For more information, see Single-Rate Processing with OQPSK Modulator Block.

- Allow multirate processing - Executes the model, allowing the input and output signals to have different port sample times. The output sample time equals the symbol period divided by Samples per symbol.

For more information, see Single-Rate Processing with OQPSK Modulator Block.

## Output data type - Output data type

double (default) | single
Select the output data type: double or single.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Modulation Delays

Digital modulation and demodulation blocks incur delays between their inputs and outputs that result in an offset in the arrival time of the received data. Data that enters a modulation or demodulation block at time $T$ appears in the output at time $T+$ delay. Take system delays into account when comparing transmitted data with received data, such as in overlaid plots or when computing error statistics. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter, input/output data setting, and simulation configuration.

| Pulse Shape | Rate Options | Treat Each Discrete Rate as a Separate Task? | Input/Output Data (*) | End-to-End Delay Incurred by an OQPSK ModulatorDemodulator Block Pair (in samples) |
| :---: | :---: | :---: | :---: | :---: |
| Half sine or Custom | Enforce single-rate operation | N/A | Integer | 1 |
|  |  |  | Bit | 2 |
|  | Allow multirate processing | false (single tasking) | Integer | $\begin{aligned} & \text { length(data) }+1+ \\ & 1 \end{aligned}$ |
|  |  |  | Bit | $\begin{aligned} & \text { length(data) }+2+ \\ & 2 \end{aligned}$ |
|  |  | true (multitasking) | Integer | $\begin{aligned} & \text { length(data) }+1+ \\ & 2 \end{aligned}$ |
|  |  |  | Bit | $\begin{aligned} & \text { length(data) }+2+ \\ & 4 \end{aligned}$ |
| Normal raised cosine or Root raised cosine | Enforce single-rate operation | N/A | Integer | Filter span (in symbols) |
|  |  |  | Bit | 2*Filter span (in symbols) |
|  | Allow multirate processing | false (single tasking) | Integer | length(data) + Filter span (in symbols) +1 |
|  |  |  | Bit | length(data) + 2*Filter span (in symbols) +2 |

| Pulse Shape | Rate Options | Treat Each <br> Discrete Rate as <br> a Separate Task? | Input/Output <br> Data (*) | End-to-End Delay <br> Incurred by an <br> OQPSK <br> Modulator- <br> Demodulator <br> Block Pair (in <br> samples) |
| :--- | :--- | :--- | :--- | :--- |
|  |  | true <br> (multitasking) | Integer | 2*length(data) + <br> Filter span (in <br> symbols) + 2 |
|  |  |  | 2*length(data) + <br> 2*Filter span (in <br> symbols) + 4 |  |

## Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

## OSTBC Combiner

Combine inputs for received signals and channel estimate according to orthogonal space-time block code (OSTBC)

## Library

MIMO

## Description

The OSTBC Combiner block combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols that were encoded using an OSTBC. The input channel estimate may not be constant during each codeword block transmission and the combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner block in a MIMO communications system.

The block conducts the combining operation for each symbol independently. The combining algorithm depends on the structure of the OSTBC. For more information, see the OSTBC Combining Algorithms on page 5-638 section of this help page.

## Dimension

Along with the time and spatial domains for OSTBC transmission, the block supports an optional dimension, over which the combining calculation is independent. This dimension can be thought of as the frequency domain for OFDM-based applications. The following illustration indicates the supported dimensions for inputs and output of the OSTBC Combiner block.

The following table describes each variable for the block.

| Variable | Description |
| :--- | :--- |
| F | The additional dimension; typically the frequency dimension. The <br> combining calculation is independent of this dimension. |

| Variable | Description |
| :--- | :--- |
| N | Number of transmit antennas. |
| M | Number of receive antennas. |
| T | Output symbol sequence length in time domain. |
| R | Symbol rate of the code. |

Note On the two inputs, T/R is the symbol sequence length in the time domain.
$F$ can be any positive integers. $M$ can be 1 through 8 , indicated by the Number of receive antennas parameter. $N$ can be 2,3 or 4, indicated by the Number of transmit antennas parameter. The time domain length T/R must be a multiple of the codeword block length ( 2 for Alamouti; 4 for all other OSTBC). For $N=2, \mathrm{~T} / \mathrm{R}$ must be a multiple of 2 . When $N>2, \mathrm{~T} / \mathrm{R}$ must be a multiple of $4 . R$ defaults to 1 for 2 antennas. $R$ can be either $\frac{3}{4}$ or $\frac{1}{2}$ for more than 2 antennas.

The supported dimensions for the block depend upon the values of $F$ and $M$. For one receive antenna ( $M=1$ ), the received signal input must be a column vector or a full 2-D matrix, depending on the value for $F$. The corresponding channel estimate input must be a full 2-D or 3-D matrix.

For more than one receive antenna ( $M>1$ ), the received signal input must be a full 2-D or 3-D matrix, depending on the value for $F$. Correspondingly, the channel estimate input must be a 3-D or 4D matrix, depending on the value for $F$.

To understand the block's dimension propagation, refer to the following table.

|  | Input 1 (Received <br> Signal) | Input 2 (Channel <br> Estimate) | Output |
| :--- | :--- | :--- | :--- |
| $\mathrm{F}=1$ and $\mathrm{M}=1$ | Column vector | $2-\mathrm{D}$ | Column vector |
| $\mathrm{F}=1$ and $\mathrm{M}>1$ | $2-\mathrm{D}$ | $3-\mathrm{D}$ | Column vector |
| $\mathrm{F}>1$ and $\mathrm{M}=1$ | $2-\mathrm{D}$ | $3-\mathrm{D}$ | 2-D |
| $\mathrm{F}>1$ and $\mathrm{M}>1$ | $3-\mathrm{D}$ | $4-\mathrm{D}$ | 2-D |

## Data Type

For information about the data types each block port supports, see the "Supported Data Type" on page 5-641 table on this page. The output signal inherits the data type from the inputs. The block supports different fixed-point properties for the two inputs. For fixed-point signals, the output word length and fractional length depend on the block's mask parameter settings. See Fixed-Point Signals for more information about fixed-point data propagation of this block.

## Frames

The output inherits the frameness of the received signal input. For either column vector or full 2-D matrix input signal, the input can be either frame-based or sample-based. A 3-D or 4-D matrix input signal must have sample-based input.

## OSTBC Combining Algorithms

The OSTBC Combiner block supports five different OSTBC combining computation algorithms.
Depending on the selection for Rate and Number of transmit antennas, you can select one of the algorithms shown in the following table.

| Transmit Antenna | Rate | Computational Algorithm per Codeword Block Length |
| :---: | :---: | :---: |
| 2 | 1 | $\binom{\widehat{S}_{1}}{\widehat{S}_{2}}=\frac{1}{\\|H\\|^{2}} \sum_{j=1}^{M}\binom{h_{1, j}^{*} r_{1, j}+h_{2, j} r_{2, j}^{*}}{h_{2, j}^{*} r_{1, j}-h_{1, j} r_{2, j}^{*}}$. |
| 3 | 1/2 | $\binom{\widehat{s}_{1}}{\widehat{s}_{2}}=\frac{1}{\\|H\\|^{2}} \sum_{j=1}^{M}\binom{h_{1, j}^{*} r_{1, j}+h_{2, j} r_{2, j}^{*}+h_{3, j}^{*} r_{3, j}}{h_{2, j}^{*} r_{1, j}-h_{1, j} r_{2, j}^{*}-h_{3, j} r_{4, j}^{*}}$. |
| 3 | 3/4 | $\left(\begin{array}{l}\widehat{s}_{1} \\ \widehat{s}_{2} \\ \widehat{s}_{3}\end{array}\right)=\frac{1}{\\|H\\|^{2}} \sum_{j=1}^{M}\left(\begin{array}{l}h_{1, j}^{*} r_{1, j}+h_{2, j} r_{2, j}^{*}-h_{3, j} r_{3, j}^{*} \\ h_{2, j}^{*} r_{1, j}-h_{1, j} r_{2, j}^{*}-h_{3, j} r_{4, j}^{*} \\ h_{3, j}^{*} r_{1, j}+h_{1, j} r_{3, j}^{*}+h_{2, j} r_{4, j}^{*}\end{array}\right)$. |
| 4 | 1/2 | $\binom{\widehat{s}_{1}}{\widehat{s}_{2}}=\frac{1}{\\|H\\|^{2}} \sum_{j=1}^{M}\binom{h_{1, j}^{*} r_{1, j}+h_{2, j} r_{2, j}^{*}+h_{3, j 3, j}^{*} r_{3, j}+h_{4, j} r_{4, j}^{*}}{h_{2, j}^{*} r_{1, j}-h_{1, j} r_{2, j}^{*}+h_{4, j}^{*} r_{3, j}-h_{3, j} r_{4, j}^{*}}$. |
| 4 | 3/4 | $\left(\begin{array}{l}\widehat{s}_{1} \\ \widehat{s}_{2} \\ \widehat{s}_{3}\end{array}\right)=\frac{1}{\\|H\\|^{2}} \sum_{j=1}^{M}\left(\begin{array}{l}h_{1, j}^{*} r_{1, j}+h_{2, j} r_{2, j}^{*}-h_{3, j} r_{3, j}^{*}-h_{4, j}^{*} r_{4 j} \\ h_{2, j}^{*} r_{1 j}-h_{1, j} r_{2, j}^{*}+h_{4, j}^{*} r_{3, j}-h_{3, j} r_{4, j}^{*} \\ h_{3, j}^{*} r_{1 j}+h_{4, j}^{*} r_{2, j}+h_{1, j} r_{3, j}^{*}+h_{2, j} r_{4, j}^{*}\end{array}\right)$. |

$\widehat{s}_{k}$ represents the estimated $k$ th symbol in the OSTBC codeword matrix. $h_{i j}$ represents the estimate for the channel from the $i$ th transmit antenna and the $j$ th receive antenna. The values of $i$ and $j$ can range from 1 to $N$ (the number of transmit antennas) and to $M$ (the number of receive antennas) respectively. $r_{l j}$ represents the lth symbol at the $j$ th receive antenna per codeword block. The value of $l$ can range from 1 to the codeword block length. $\|H\|^{2}$ represents the summation of channel power per link, i.e., $\|H\|^{2}=\sum_{i=1}^{N} \sum_{j=1}^{M}\left\|h_{i j}\right\|^{2}$

## Fixed-Point Signals

Use the following formula for $\widehat{s}_{1}$ for Alamouti code with 1 receive antenna to highlight the data types used for fixed-point signals.
$\widehat{s}_{1}=\frac{h_{1,1}^{*}, r_{1,1}+h_{2,1}, r_{2,1}^{*}}{\|H\|^{2}}=\frac{h_{1,1}^{*}, r_{1,1}+h_{2,1,} r_{2,1}^{*}}{h_{1,1} h_{1,1}^{*}+h_{2,1, h_{2,1}^{*}}}$

In this equation, the data types for Product output and Accumulator correspond to the product and summation in the numerator. Similarly, the types for Energy product output and Energy accumulator correspond to the product and summation in the denominator.

## Signal Flow Diagram for $\mathbf{s}_{1}$ Combining Calculation of Alamouti Code with One Receive Antenna

The following formula shows the data types used within the OSTBC Combiner block for fixed-point signals for more than one receive antenna for Alamouti code, where $M$ represents the number of receive antennas.
$\widehat{s}_{1}=\frac{h_{1,1,}^{*} r_{1,1}+h_{2,1} r_{2,1}^{*}+h_{1,2}^{*} r_{1,2}+h_{2,2} r_{2,2}^{*}+\ldots+h_{1, M,}^{*} r_{1, M}+h_{2, M} r_{2, M}^{*}}{h_{1,1} h_{1,1}^{*}+h_{2,1} h_{2,1}^{*}+h_{1,2} h_{1,2}^{*}+h_{2,2} h_{2,2}^{*}+\ldots+h_{1, M} h_{1, M}^{*}+h_{2, M,} h_{2, M}^{*}}$

## Signal Flow Diagram for Complex Multiply of $\boldsymbol{a}+\boldsymbol{i b}$ and $\boldsymbol{c}+\boldsymbol{i d}$

For Binary point scaling, you cannot specify $W L_{p}$ and $F L_{p}$. Instead, the blocks determine these values implicitly from $W L_{a}$ and $F L_{a}$

The Internal Rule for Product output and Energy product output are:

- When you select Inherit via internal rule, the internal rule (DSP System Toolbox) determines $W L_{p}$ and $F L_{p}$. Therefore, $W L_{a}=W L_{p}+1$ and $F L_{a}=F L_{p}$
- For Binary point scaling, you specify $W L_{a}$ and $F L_{a}$. Therefore, $W L_{p}=W L_{a}-1$ and $F L_{a}=F L_{p}$.

For information on how the Internal Rule applies to the Accumulator and Energy Accumulator, see Inherit via Internal Rule (DSP System Toolbox).

## Parameters

## Number of transmit antennas

Sets the number of transmit antennas. The block supports 2, 3, or 4 transmit antennas. This value defaults to 2 .

## Rate

Sets the symbol rate of the code. You can specify either $3 / 4$ or $1 / 2$. This field only appears when you use more than 2 transmit antennas. This field defaults to $\frac{3}{4}$ for more than 2 transmit antennas. For 2 transmit antennas, there is no rate option and the implicit (default) rate defaults to 1.

## Number of receive antennas

The number of antennas the block uses to receive signal streams. The block supports from 1 to 8 receive antennas. This value defaults to 1 .

## Rounding mode

Sets the rounding mode for fixed-point calculations. The block uses the rounding mode if a value cannot be represented exactly by the specified data type and scaling. When this occurs, the value is rounded to a representable number. For more information refer to Rounding (Fixed-Point Designer).

## Saturate on integer overflow

Sets the overflow mode for fixed-point calculations. Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result. For more information refer to Precision and Range (DSP System Toolbox).

## Product Output

Complex product in the numerator for the diversity combining. For more information refer to the Fixed-Point Signals section of this help page.

## Accumulator

Summation in the numerator for the diversity combining.
Fixed-point Communications Toolbox blocks that must hold summation results for further calculation usually allow you to specify the data type and scaling of the accumulator. Most such blocks cast to the accumulator data type prior to summation:

Use the Accumulator-Mode parameter to specify how you would like to designate the accumulator word and fraction lengths:

- When you select Inherit via internal rule, the accumulator output word and fraction lengths are automatically calculated for you. Refer to Inherit via Internal Rule (DSP System Toolbox) for more information.
- When you select Same as product output, these characteristics match those of the product output.
- When you select Same as input, these characteristics match those of the first input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator. The bias of all signals in DSP System Toolbox software is zero.

## Energy product output

Complex product in the denominator for calculating total energy in the MIMO channel .

## Energy accumulator

Summation in the denominator for calculating total energy in the MIMO channel.

## Division output

Normalized diversity combining by total energy in the MIMO channel.

## Supported Data Type

| Port | Supported Data Types |
| :---: | :---: |
| Rx | - Double-precision floating point <br> - Single-precision floating point <br> - Signed Fixed-point |
| cEst | - Double-precision floating point <br> - Single-precision floating point <br> - Signed Fixed-point |

| Port | Supported Data Types |
| :--- | :--- |
| Out | $\bullet \quad$ Double-precision floating point |
|  | $\bullet \quad$ Single-precision floating point |
|  | $\bullet \quad$ Signed Fixed-point |

## Examples

For an example of this block in use, see OSTBC Over 3x2 Rayleigh Fading Channel. The model shows the use of a rate $3 / 4$ OSTBC for 3 transmit and 2 receive antennas with BPSK modulation using independent fading links and AWGN.

You can also see the block in the Concatenated OSTBC with TCM example by typing commtcmostbc at the MATLAB command line.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink® Coder ${ }^{\mathrm{TM}}$.

## See Also

## Blocks

OSTBC Encoder

## Introduced in R2009a

## OSTBC Encoder

Encode input message using orthogonal space-time block code (OSTBC)

## Library

MIMO

## Description

The OSTBC Encoder block encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain. For more information, see the OSTBC Encoding Algorithms on page 5644 section of this help page.

## Dimension

The block supports time and spatial domains for OSTBC transmission. It also supports an optional dimension, over which the encoding calculation is independent. This dimension can be thought of as the frequency domain. The following illustration indicates the supported dimensions for the inputs and output of the OSTBC Encoder block.

The following table describes the variables.

| Variable | Description |
| :--- | :--- |
| F | The additional dimension; typically the frequency <br> domain. The encoding does not depend on this <br> dimension. |
| T | Input symbol sequence length for the time <br> domain. |
| R | Symbol rate of the code. |
| N | Number of transmit antennas. |

Note On the output, T/R is the symbol sequence length in time domain.
$F$ can be any positive integer. $N$ can be 2,3 or 4 , indicated by Number of transmit antennas. For $N$ $=2, R$ must be 1 . For $N=3$ or $4, R$ can be $3 / 4$ or $1 / 2$, indicated by Rate. The time domain length $T$ must be a multiple of the number of symbols in each codeword matrix. Specifically, for $N=2$ or $R=$ $1 / 2, T$ must be a multiple of 2 and when $R=3 / 4, T$ must be a multiple of 3 .

To understand the block's dimension propagation, refer to the following table.

| Dimension | Input | Output |
| :--- | :--- | :--- |
| $\mathrm{F}=1$ | Column vector | $2-\mathrm{D}$ |
| $\mathrm{F}>1$ | 2-D | 3-D |

## Data Type

For information about the data types each block port supports, see the "Supported Data Type" on page 5-645 table on this page. The output signal inherits the data type from the input signal. For fixed-point signals, the complex conjugation may cause overflows which the fixed-point parameter Saturate on integer overflow must handle.

## Frames

The output signal inherits frame type from the input signal. A column vector input requires either frame-based or sample-based input; otherwise, the input must be sample-based.

## OSTBC Encoding Algorithms

The OSTBC Encoder block supports five different OSTBC encoding algorithms. Depending on the selection for Rate and Number of transmit antennas, the block implements one of the algorithms in the following table:

| Transmit <br> Antenna | Rate | OSTBC Codeword Matrix |
| :--- | :--- | :--- |
| 2 | 1 | $\left(\begin{array}{ccc}s_{1} & s_{2} \\ -s_{2}^{*} & s_{1}^{*}\end{array}\right)$ |
| 3 | $1 / 2$ | $\left(\begin{array}{ccc}s_{1} & s_{2} & 0 \\ -s_{2}^{*} & s_{1}^{*} & 0 \\ 0 & 0 & s_{1} \\ 0 & 0 & -s_{2}^{*}\end{array}\right)$ |
| 3 | $3 / 4$ | $\left(\begin{array}{ccc}s_{1} & s_{2} & s_{3} \\ -s_{2}^{*} & s_{1}^{*} & 0 \\ s_{3}^{*} & 0 & -s_{1}^{*} \\ 0 & s_{3}^{*} & -s_{2}^{*}\end{array}\right)$ |

| Transmit <br> Antenna | Rate | OSTBC Codeword Matrix |
| :--- | :--- | :--- |
| 4 | $1 / 2$ | $\left(\begin{array}{cccc}s_{1} & s_{2} & 0 & 0 \\ -s_{2}^{*} & s_{1}^{*} & 0 & 0 \\ 0 & 0 & s_{1} & s_{2} \\ 0 & 0 & -s_{2}^{*} & s_{1}^{*}\end{array}\right)$ |
| 4 | $3 / 4$ | $\left(\begin{array}{cccc}s_{1} & s_{2} & s_{3} & 0 \\ -s_{2}^{*} & s_{1}^{*} & 0 & s_{3} \\ s_{3}^{*} & 0 & -s_{1}^{*} & s_{2} \\ 0 & s_{3}^{*} & -s_{2}^{*} & -s_{1}\end{array}\right)$ |

In each matrix, its $(l, i)$ entry indicates the symbol transmitted from the $i$ th antenna in the lth time slot of the block. The value of $i$ can range from 1 to $N$ (the number of transmit antennas). The value of $l$ can range from 1 to the codeword block length.

## Parameters

## Number of transmit antennas

Sets the number of antennas at the transmitter side. The block supports 2 , 3 , or 4 transmit antennas. The value defaults to 2 .

## Rate

Sets the symbol rate of the code. You can specify either $3 / 4$ or $1 / 2$. This field only appears when using more than 2 transmit antennas. This field defaults to $\frac{3}{4}$ for more than 2 transmit antennas. For 2 transmit antennas, there is no rate option and the rate defaults to 1 .

## Saturate on integer overflow

Sets the overflow mode for fixed-point calculations. Use this parameter to specify the method to be used if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result. For more information refer to "Precision and Range" (DSP System Toolbox).

## Supported Data Type

| Port | Supported Data Types |
| :--- | :--- |
| In | - Double-precision floating point |
|  | - Single-precision floating point |
|  | - Signed Fixed-point |
| Out | - Double-precision floating point |
|  | - Single-precision floating point |
|  | - Signed Fixed-point |

## Examples

For an example of this block in use, see "OSTBC Over 3x2 Rayleigh Fading Channel" . The model shows the use of a rate $3 / 4$ OSTBC for 3 transmit and 2 receive antennas with BPSK modulation using independent fading links and AWGN

You can also see the block in the Concatenated OSTBC with TCM example by typing commtcmostbc at the MATLAB command line.

## OVSF Code Generator

Generate orthogonal variable spreading factor (OVSF) code from set of orthogonal codes

```
OVSF Code
```

Generator

## Library

Spreading Codes

## Description

The OVSF Code Generator block generates an OVSF code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. OVSF codes are primarily used to preserve orthogonality between different channels in a communication system.

OVSF codes are defined as the rows of an N -by-N matrix, $\mathrm{C}_{\mathrm{N}}$, which is defined recursively as follows. First, define $C_{1}=[1]$. Next, assume that $C_{N}$ is defined and let $C_{N}(k)$ denote the kth row of $C_{N}$. Define $\mathrm{C}_{2 \mathrm{~N}}$ by

$$
C_{2 N}=\left[\begin{array}{cc}
C_{N}(0) & C_{N}(0) \\
C_{N}(0) & -C_{N}(0) \\
C_{N}(1) & C_{N}(1) \\
C_{N}(1) & -C_{N}(1) \\
\ldots & \ldots \\
C_{N}(N-1) & C_{N}(N-1) \\
C_{N}(N-1) & -C_{N}(N-1)
\end{array}\right]
$$

Note that $C_{\mathrm{N}}$ is only defined for $N$ a power of 2 . It follows by induction that the rows of $C_{\mathrm{N}}$ are orthogonal.

The OVSF codes can also be defined recursively by a tree structure, as shown in the following figure.

If $[\mathrm{C}]$ is a code length $2^{\mathrm{r}}$ at depth r in the tree, where the root has depth 0 , the two branches leading out of C are labeled by the sequences [C C] and [C -C], which have length $2^{\mathrm{r}+1}$. The codes at depth r in the tree are the rows of the matrix $\mathrm{C}_{\mathrm{N}}$, where $\mathrm{N}=2^{\mathrm{r}}$.

Note that two OVSF codes are orthogonal if and only if neither code lies on the path from the other code to the root. Since codes assigned to different users in the same cell must be orthogonal, this restricts the number of available codes for a given cell. For example, if the code $\mathrm{C}_{41}$ in the tree is assigned to a user, the codes $\mathrm{C}_{10}, \mathrm{C}_{20}, \mathrm{C}_{82}, \mathrm{C}_{83}$, and so on, cannot be assigned to any other user in the same cell.

## Block Parameters

You specify the code the OVSF Code Generator block outputs by two parameters in the block's dialog: the Spreading factor, which is the length of the code, and the Code index, which must be an integer in the range $[0,1, \ldots, N-1]$, where $N$ is the spreading factor. If the code appears at depth $r$ in the preceding tree, the Spreading factor is $2^{\mathrm{r}}$. The Code index specifies how far down the column of the tree at depth r the code appears, counting from 0 to $N-1$. For $\mathrm{C}_{\mathrm{N}, \mathrm{k}}$ in the preceding diagram, $N$ is the Spreading factor and $k$ is the Code index.

You can recover the code from the Spreading factor and the Code index as follows. Convert the Code index to the corresponding binary number, and then add 0 s to the left, if necessary, so that the resulting binary sequence $x_{1} \chi_{2} \ldots x_{\mathrm{r}}$ has length $r$, where $r$ is the logarithm base 2 of the Spreading factor. This sequence describes the path from the root to the code. The path takes the upper branch from the code at depth $i$ if $\mathrm{x}_{\mathrm{i}}=0$, and the lower branch if $\mathrm{x}_{\mathrm{i}}=1$.

To reconstruct the code, recursively define a sequence of codes $\mathrm{C}_{\mathrm{i}}$ for as follows. Let $\mathrm{C}_{0}$ be the root [1]. Assuming that $\mathrm{C}_{\mathrm{i}}$ has been defined, for $i<r$, define $\mathrm{C}_{\mathrm{i}+1}$ by

$$
C_{i+1}= \begin{cases}C_{i} C_{i} & \text { if } x_{i}=0 \\ C_{i}\left(-C_{i}\right) & \text { if } x_{i}=1\end{cases}
$$

The code $\mathrm{C}_{\mathrm{N}}$ has the specified Spreading factor and Code index.
For example, to find the code with Spreading factor 16 and Code index 6, do the following:
1 Convert 6 to the binary number 110.
2 Add one 0 to the left to obtain 0110 , which has length $4=\log _{2} 16$.
3 Construct the sequences $\mathrm{C}_{\mathrm{i}}$ according to the following table.

| i | $\mathrm{x}_{\mathrm{i}}$ | $\mathrm{C}_{\mathrm{i}}$ |
| :---: | :---: | :---: |
| 0 |  | $\mathrm{C}_{0}=[1]$ |
| 1 | 0 | $\mathrm{C}_{1}=\mathrm{C}_{0} \mathrm{C}_{0}=[1][1]$ |
| 2 | 1 | $\mathrm{C}_{2}=\mathrm{C}_{1}-\mathrm{C}_{1}=[11][-1-1]$ |
| 3 | 1 | $\mathrm{C}_{3}=\mathrm{C}_{2}-\mathrm{C}_{2}=\left[\begin{array}{lllll}1 & -1 & -1\end{array}\right]\left[\begin{array}{lllll}-1 & 1 & 1\end{array}\right]$ |
| 4 | 0 |  |

The code $\mathrm{C}_{4}$ has Spreading factor 16 and Code index 6.

## Parameters

## Spreading factor

Positive integer that is a power of 2 , specifying the length of the code.

## Code index

Integer in the range $[0,1, \ldots, \mathrm{~N}-1]$ specifying the code, where N is the Spreading factor.

## Sample time

Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1 , the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-650.

## Samples per frame

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-650.

## Output data type

The output type of the block can be specified as an int8 or double. By default, the block sets this to double.

## Simulate using

Select the simulation mode.

## Code generation

On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects corresponding to the blocks accept a maximum of nine inputs.
Interpreted execution
Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

## Existing models automatically update this block to current version

Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the OVSF Code Generator block version available before R2015b.

Existing models automatically update to load the OVSF Code Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes. For more information on block forwarding, see "Forwarding Tables" (Simulink).

## Extended Capabilities

## Phase/Frequency Offset

Apply phase and frequency offsets to complex baseband signal

## Library

RF Impairments

## Description

The Phase/Frequency Offset block applies phase and frequency offsets to an incoming signal.
The block inherits its output data type from the input signal. If the input signal is $u(t)$, then the output signal is:

$$
y(t)=u(t) \cdot\left(\cos \left(2 \pi \int_{0}^{t} f(\tau) d \tau+\varphi(t)\right)+j \sin \left(2 \pi \int_{0}^{t} f(\tau) d \tau+\varphi(t)\right)\right)
$$

where
$f(t)=$ Frequency offset
$\varphi(t)=$ Phase offset
The discrete-time output is:

$$
\begin{aligned}
& y(0)=u(0)(\cos (\varphi(0))+j \sin (\varphi(0))) \\
& y(i)=u(i)\left(\cos \left(2 \pi \sum_{n=0}^{i-1} f(n) \Delta t+\varphi(i)\right)+j \sin \left(2 \pi \sum_{n=0}^{i-1} f(n) \Delta t+\varphi(i)\right)\right)
\end{aligned}
$$

where
$\Delta t=$ Sample time
This block accepts real and complex inputs of data type double or single.

## Phase Offset

The block applies a phase offset to the input signal, specified by the Phase offset parameter.

## Frequency Offset

The block applies a frequency offset to the input signal, specified by the Frequency offset parameter. Alternatively, when you select Frequency offset from port, the Frq input port provides the offset to the block. The frequency offset must be a scalar value, vector with the same number of rows or columns as the data input, or a matrix with the same size as the data input. For more information, see "Interdependent Parameter-Port Dimensions" on page 5-653.

The effects of changing the block's parameters are illustrated by the following scatter plots of a signal modulated by 16 -ary quadrature amplitude modulation (QAM). The usual 16-ary QAM constellation without the effect of the Phase/Frequency Offset block is shown in the first scatter plot:

The following figure shows a scatter plot of an output signal, modulated by 16-ary QAM, from the Phase/Frequency Offset block with Phase offset set to 20 and Frequency offset set to 0 :

Observe that each point in the constellation is rotated by a 20 degree angle counterclockwise.
If you set Frequency offset to 2 and Phase offset to 0, the angles of points in the constellation change linearly over time. This causes points in the scatter plot to shift radially, as shown in the following figure:

Note that every point in the scatter plot has magnitude equal to a point in the original constellation.
See "Illustrate RF Impairments That Distort a Signal" for a description of the model that generates this plot.

## Interdependent Parameter-Port Dimensions

| Number of Dimensions | Data I/O Dimension | Frame Size | Number of Channels | Frequency/Phase Offset Parameter Dimension | Frequency Offset Input Port Dimension |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Any | Scalar | 1 | 1 | Scalar | Scalar |
| 2 | M-by-1 | M | 1 | M-by-1, 1-by-M, 1-by-1 | M, M-by-1, 1, 1-by-1 |
| 2 | 1-by-N | 1 | $N$ | $N$-by-1, 1-by-N, 1-by-1 | N, 1-by-N, 1, 1-by-1 |
| 2 | M-by-N | M | $N$ | $M$-by-N, N-by-1, 1-by-N, M by-1, 1-by-M, 1-by-1 | M-by-N, N, 1-by-N, 1, 1-by-1, $M, M$-by-1 |

- When you specify a scalar offset parameter the block applies the same offset to all elements of the input signal
- When you specify a 2-by-1 offset parameter for a 2-by-3 input signal (one offset value per sample), the block applies the same sample offset across the three channels.
- When you specify a 1 -by-3 offset parameter for a 2 -by- 3 input signal (one offset value per channel), the same channel offset is applied across the two samples of a channel.
- When you specify a 2-by-3 offset parameter for a 2-by-3 input signal (one offset value per sample for each channel), the offsets are applied element-wise to the input signal.

## Parameters

## Frequency offset from port

Selecting this option opens a port on the block through which you can input the frequency offset information.

## Frequency offset

Specifies the frequency offset in hertz.
This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. For more information, see Tunable Parameters (Simulink) in the Simulink User's Guide.

## Phase offset

Specifies the phase offset in degrees.
This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. For more information, see Tunable Parameters (Simulink) in the Simulink User's Guide.

If Frequency offset and Phase offset are both vectors or both matrices, their dimensions (vector lengths, or number of rows and columns) must be the same.

## Blocks

Phase Noise

Introduced before R2006a

## Phase-Locked Loop

Implement phase-locked loop to recover phase of input signal

## Library

Components sublibrary of Synchronization

## Description

The Phase-Locked Loop (PLL) block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. This block is most appropriate when the input is a narrowband signal.

This PLL has these three components:

- A multiplier used as a phase detector.
- A filter. You specify the filter transfer function using the Lowpass filter numerator and Lowpass filter denominator parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of $s$.

To design a filter, you can use functions such as butter, cheby1, and cheby2 in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.
[num, den] = cheby2(3,40,100,'s')

- A voltage-controlled oscillator (VCO). You specify characteristics of the VCO using the VCO quiescent frequency, VCO initial phase, and VCO output amplitude parameters.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

## Parameters

## Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of $s$.

## VCO input sensitivity ( $\mathrm{Hz} / \mathrm{V}$ )

This value scales the input to the VCO and, consequently, the shift from the VCO quiescent frequency value. The units of VCO input sensitivity are Hertz per volt.

## VCO quiescent frequency ( Hz )

The frequency of the VCO signal when the voltage applied to it is zero. This should match the carrier frequency of the input signal.

## VCO initial phase (rad)

The initial phase of the VCO signal.

## VCO output amplitude

The amplitude of the VCO signal.

## References

For more information about phase-locked loops, see the works listed in "Selected Bibliography for Synchronization".

## Phase Noise

Apply receiver phase noise to complex baseband signal
Library: Communications Toolbox / RF Impairments

## Description

The Phase Noise block adds phase noise to a complex signal. This block emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The block generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see "Algorithms" on page 5-659.

## Ports

## Input

## In - Input signal

complex column vector
Input signal, specified as an $N_{\mathrm{S}}$-by- 1 vector of complex values. $N_{\mathrm{S}}$ represents the number of samples in the input signal.

Data Types: double
Complex Number Support: Yes

## Output

Out - Output signal
complex column vector
Output signal, returned as an $N_{\mathrm{S}}$-by-1 vector of complex values. $N_{\mathrm{S}}$ equals the number of samples in the input signal.

Data Types: double
Complex Number Support: Yes

## Parameters

## Phase noise level (dBc/Hz) - Phase noise level

[-60-80] (default) | vector of negative scalars
Phase noise level in decibels relative to carrier per hertz ( $\mathrm{dBc} / \mathrm{Hz}$ ), specified as a vector of negative scalars. The Phase noise level ( $\mathbf{d B c} / \mathbf{H z}$ ) and Frequency offset (Hz) parameters must have the same length.

Tunable: Yes
Frequency offset (Hz) - Frequency offset
[20 200] (default) | vector of positive increasing values

Frequency offset in Hz, specified as a vector of positive increasing values. The Phase noise level $(\mathbf{d B c} / \mathbf{H z})$ and Frequency offset $(\mathbf{H z})$ parameters must have the same length.

Tunable: Yes
Data Types: double
Sample rate (Hz) - Sample rate
1024 (default) | positive scalar
Sample rate in samples per second, specified as a positive scalar. To avoid aliasing, the sample rate must be greater than twice the largest value specified by Frequency offset (Hz).

Tunable: Yes
Data Types: double
Initial seed - Initial seed of noise generator
2137 (default) | positive scalar
Initial seed of noise generator, specified as a positive scalar.
This block uses the Random Source block to generate noise. The block generates random numbers using the Ziggurat method (V5 RANDN algorithm). Every time you rerun the simulation, the block reuses the same initial seed. That way, the block outputs the same signal each time you run a simulation.

Tunable: Yes
Data Types: double

## View Filter Response - Display magnitude response of filter <br> button

Display magnitude response of filter defined by the Phase Noise block. The block uses the fvtool function to display the magnitude response.

## Simulate using - Specify type of simulation to run

Interpreted execution (default) | Code generation

- Interpreted execution -- Simulate model using the MATLAB interpreter. This option shortens startup time speed, but the speed of the subsequent simulations is slower than Code generation. In this mode, you can debug the source code of the block.
- Code generation -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.

## Block Characteristics

| Data Types | double \| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |

## Variable-Size Signals no

## Algorithms

The output signal, $y_{k}$, is related to input sequence $x_{k}$ by $y_{k}=x_{k} e^{j \varphi_{k},}$ where $\varphi_{k}$ is the phase noise. The phase noise is filtered Gaussian noise such that $\varphi_{\mathrm{k}}=f\left(n_{\mathrm{k}}\right)$, where $n_{\mathrm{k}}$ is the noise sequence and $f$ represents a filtering operation.

To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a 1/f characteristic that passes through the specified point.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across $\log 10(f)$. It is flat from DC to the lowest frequency offset, and from the highest frequency offset to half the sample rate.

## IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$
\lambda=\sqrt{2 \pi f_{o f f s e t} 10^{L / 10}},
$$

where $f_{\text {offset }}$ is the frequency offset in Hz and $L$ is the phase noise level in $\mathrm{dBc} / \mathrm{Hz}$. The denominator coefficients, $\gamma_{\mathrm{i}}$, are recursively determined as

$$
\gamma_{i}=(i-2.5) \frac{\gamma_{i}-1}{i-1}
$$

where $\gamma_{1}=1, i=\left\{1,2, \ldots, N_{\mathrm{t}}\right\}$, and $N_{\mathrm{t}}$ is the number of filter coefficients. $N_{\mathrm{t}}$ is a power of 2 , from $2^{7}$ to $2^{19}$. The value of $N_{\mathrm{t}}$ grows as the phase noise offset decreases towards 0 Hz .

## FIR Filter

For the FIR filter, the phase noise level is determined through $\log 10(f)$ interpolation for frequency offsets over the range [ $d f, f_{s} / 2$ ], where $d f$ is the frequency resolution and $f_{s}$ is the sample rate. The phase noise is flat from 0 Hz to the smallest frequency offset, and from the largest frequency offset to $f_{\mathrm{s}} / 2$. The frequency resolution is equal to $\frac{f_{s}}{2}\left(\frac{1}{N_{t}}\right)$, where $N_{\mathrm{t}}$ is the number of coefficients, and is a
power of 2 less than or equal to $2^{16}$. If $N_{\mathrm{t}}<2^{8}$, a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases $N_{\mathrm{t}}$ until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.
- The maximum number of FIR filter taps is $2^{16}$.

## PM Demodulator Passband

Demodulate PM-modulated data

## Library

Analog Passband Modulation, in Modulation

## Description

The PM Demodulator Passband block demodulates a signal that was modulated using phase modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

For best results, use a carrier frequency which is estimated to be larger than $10 \%$ of your input signal's sample rate. This is due to the implementation of the Hilbert transform by means of a filter.

In the following example, we sample a 10 Hz input signal at 8000 samples per second. We then designate a Hilbert Transform filter of order 100. Below is the response of the Hilbert Transform filter as returned by fvtool.

Note the bandwidth of the filter's magnitude response. By choosing a carrier frequency larger than $10 \%$ (but less than $90 \%$ ) of the input signal's sample rate ( 8000 samples per second, in this example) or equivalently, a carrier frequency larger than 400 Hz , we ensure that the Hilbert Transform Filter
will be operating in the flat section of the filter's magnitude response (shown in blue), and that our modulated signal will have the desired magnitude and form.

Typically, an appropriate Carrier frequency value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Carrier frequency (Hz)

The frequency of the carrier.

## Initial phase (rad)

The initial phase of the carrier in radians.
Phase deviation (rad)
The phase deviation of the carrier frequency in radians. Sometimes it is referred to as the "variation" in the phase.

## Hilbert transform filter order

The length of the FIR filter used to compute the Hilbert transform.

## PM Modulator Passband

Modulate using phase modulation

## Library

Analog Passband Modulation, in Modulation

## Description

The PM Modulator Passband block modulates using phase modulation. The output is a passband representation of the modulated signal. The output signal's frequency varies with the input signal's amplitude. Both the input and output signals are real scalar signals.

If the input is $u(t)$ as a function of time $t$, then the output is

$$
\cos \left(2 \pi f_{c} t+K_{c} u(t)+\theta\right)
$$

where

- $f_{\mathrm{c}}$ represents the Carrier frequency parameter
- $\theta$ represents the Initial phase parameter
- $K_{\mathrm{c}}$ represents the Phase deviation parameter

An appropriate Carrier frequency value is generally much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Carrier frequency (Hz)

The frequency of the carrier.

## Initial phase (rad)

The initial phase of the carrier in radians.

## Phase deviation (rad)

The phase deviation of the carrier frequency in radians. This is sometimes referred to as the "variation" in the phase.

## PN Sequence Generator

Generate pseudonoise sequence

Library: Communications Toolbox / Comm Sources / Sequence Generators Communications Toolbox HDL Support / Comm Sources

## Description

The PN Sequence Generator block generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR). Pseudonoise sequences are typically used for pseudorandom scrambling, and in direct-sequence spread-spectrum systems. For more information, see "More About" on page 5-670.

These icons shows the block with all ports enabled.

| Mask |
| :--- |
| OSiz |
| RN Sequence |
| Renerator |

[^4]
## Ports

Input
Mask - Output mask
binary vector
Output mask to delay the PN sequence from initial time, specified as a binary vector with $N$ elements. $N$ is the degree of the generator polynomial.

## Dependencies

To enable this port, set Output mask source to Input port.

## Data Types: double |uint8 | ufix1

## oSiz - Output size

integer
Output size for variable-size output signals, specified as an integer. For information about variablesize signals, see "Variable-Size Signal Basics" (Simulink).

## Dependencies

To enable this port, select Output variable-size signals and set Maximum output size source to Dialog parameter.

## Data Types: double

## Ref - Reference input

column vector

Reference input, specified as a column vector that determines the maximum and current output sequence length. The Ref input must be a variable-size signal. For information about variable-size signals, see "Variable-Size Signal Basics" (Simulink).

## Dependencies

To enable this port, select Output variable-size signals and set Maximum output size source to Inherit from reference input.

Data Types: double
Rst - Reset sequence generator
$0 \mid 1$
Reset sequence generator, specified as 0 or 1. For more information, see "Reset Behavior" on page 5671.

Dependencies
To enable this port, select Reset on nonzero input.
Data Types: Boolean
Output

## Out - Pseudorandom noise sequence

binary vector
PN sequence, returned as a binary vector.

## Parameters

## Generator polynomial - Generator polynomial

'z^6 + z + 1' (default) | polynomial character vector | binary row vector
Generator polynomial, specified as one of the following:

- A polynomial character vector that includes the number 1.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The first and last entries must be 1 . The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial.
- A vector containing the exponents of $z$ for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 .

For more information, see "Character Representation of Polynomials".
Example: 'z^8 + $z^{\wedge} 2+1^{\prime}$ ', [100000101], and [8 2 0] represent the same polynomial, $p(z)=z^{8}+z^{2}+1$.
Data Types: double | char

## Initial states - Initial shift register states

[0 0 0 0 0 1] (default) | binary row vector
Initial shift register states, specified as a binary row vector of length $N$, where $N$ is the degree of the generator polynomial.

Note For the block to generate a nonzero sequence, the Initial states vector must contain at least one nonzero element.

## Data Types: double

Output mask source - Output mask source
Dialog parameter (default)|Input port
Output mask source that indicates how the output mask information is given to the block, specified as:

- Dialog parameter to use the Output mask vector (or scalar shift value) parameter setting.
- Input port to add and use the Mask input port.

Output mask vector (or scalar shift value) - Output mask vector or scalar shift value
0 (default) | integer scalar | binary vector
Output mask vector or scalar shift value, specified as an integer scalar or binary row vector of length $N$, where $N$ is the degree of the generator polynomial. This parameter determines the delay of the PN sequence from the initial time. For more information, see "Shifting PN Sequence Starting Point" on page 5-671.

## Dependencies

To enable this parameter, set Output mask source to Dialog parameter.

## Data Types: double

## Output variable-size signals - Output variable-size signals

off (default) | on
Select this parameter to permit variable length output sequences during simulation. When set to off, fixed-length sequences are output. When set to on, variable-length sequences can be output. For information about variable-size signals, see "Variable-Size Signal Basics" (Simulink).

Maximum output size source - Maximum output size source
Dialog parameter (default)|Inherit from reference port
Maximum output size source, which indicates how the maximum sequence output size is specified.

- Dialog parameter configures the block to use the Maximum output size parameter setting as the maximum permitted output sequence length. When you make this selection, the oSiz input port specifies the current size of the output signal and the block output inherits sample time from the input signal. The input value of $\mathbf{o S i z}$ must be less than or equal to the Maximum output size parameter.
- Inherit from reference port adds the Ref input port and configures the block to inherit the sample time, maximum size, and the current output size from the variable-sized signal at the Ref input port to set the maximum permitted output sequence length.

## Dependencies

To enable this parameter, select Output variable-size signals.

## Maximum output size - Maximum output size

## [10 1] (default)| two-element row vector

Maximum output size, specified as a two-element row vector that denotes the maximum output size for the block. The second element of the vector must be 1.

## Example: [10 1] gives a 10-by-1 maximum sized output signal.

## Dependencies

To enable this parameter select Output variable-size signals and set Maximum output size source to Dialog parameter.
Data Types: double

## Sample time - Output sample time

1 (default) | -1 | positive scalar
Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1 , the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-673.
Example: 1 specifies a sample time of 1 second.

## Dependencies

To enable this parameter, clear Output variable-size signals.

## Data Types: double

## Samples per frame - Samples per frame <br> 1 (default) | positive integer

Samples per frame in one channel of the output signal, specified as a positive integer. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5673.

## Dependencies

To enable this parameter, clear Output variable-size signals.

## Data Types: double

Reset on nonzero input - Reset on nonzero input
off (default) | on
Select this parameter to add the Rst input port. For more information, see "Reset Behavior" on page 5-671.

## Enable bit-packed outputs - Enable bit-packed outputs <br> off (default) | on

Select this parameter to make the Number of packed bits and Interpret bit-packed values as signed parameters available.

```
Number of packed bits - Number of packed bits
```

8 (default) | integer

Number of packed bits, specified as an integer in the range $[1,32]$.

## Dependencies

To enable this parameter, select Enable bit-packed outputs.
Data Types: double
Interpret bit-packed values as signed - Interpret bit-packed values as signed off (default) | on

Interpret bit-packed values as signed integer data values when selected or unsigned integer data values when cleared. When selected, a 1 in the most significant bit (sign bit) indicates a negative value.

## Dependencies

To enable this parameter, select Enable bit-packed outputs.

## Output data type - Output data type

double (default)| boolean | Smallest unsigned integer
Output data type, specified as double, boolean, or Smallest unsigned integer.

- When Enable bit-packed outputs is cleared, the output data type can be specified as a double, boolean, or Smallest unsigned integer. When the Output data type parameter is set to Smallest unsigned integer, the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type ufix (1) = ideal minimum one-bit size. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (for example, uint8).
- When Enable bit-packed outputs is selected, the output data type can be specified as double or Smallest unsigned integer. When the Output data type parameter is set to Smallest unsigned integer, the output data type is selected based on the Interpret bit-packed values as signed and Number of packed bits parameters, and the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is the ideal minimum $n$-bit size, such as sfix ( $n$ ) or ufix ( $n$ ), based on the Interpret bit-packed values as signed parameter. For all other selections, it is a signed or unsigned integer with the smallest available word length large enough to fit $n$ bits.

## Block Characteristics

| Data Types | Boolean \| double | fixed point |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Simple Shift Register Generator

A linear-feedback shift register (LFSR), implemented as a simple shift register generator (SSRG), is used to generate PN sequences. This type of shift register is also known as a Fibonacci implementation. For an example, see "Model PN Sequence Generation With Linear Feedback Shift Register".

The Generator Polynomial parameter determines the feedback connections of the shift register. It is a primitive binary polynomial in $z, g_{r} z^{r}+g_{r-1} z^{r-1}+g_{r-2} z^{r-2}+\ldots+g_{0}$. For the coefficient, $g_{k=0}$ to $r$, the coefficient $g_{k}$ is 1 if there is a connection from the kth register to the adder. The leading term, $g_{r}$, and the constant term, $g_{0}$, of the Generator Polynomial parameter must be 1 because the polynomial must be primitive. The Initial states parameter specifies the initial values of the registers. For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of $\mathrm{p}(z)=z^{8}+z^{2}+1$.

| Quantity | Example 1 | Example 2 |
| :--- | :--- | :--- |
| Generator <br> polynomial | $g 1=\left[\begin{array}{lllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1\end{array}\right]$ | $g 2=\left[\begin{array}{llllll\|}8 & 2 & 0\end{array}\right]$ |
| Degree of generator <br> polynomial | 8 , which is length $(g 1)-1$ | 8 |
| Initial states | $\left[\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0\end{array}\right]$ | $\left[\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0\end{array}\right]$ |

At each time step, all $r$ registers in the generator update their values according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The output of the LFSR reflects the sum of all connections in the $m$ mask vector.

The Output mask vector (or scalar shift value) parameter, $m$, determines the shift of the PN sequence starting point. For more information, see "Shifting PN Sequence Starting Point" on page 5671.

## Shifting PN Sequence Starting Point

To shift the starting point of the PN sequence, specify the Output mask vector (or scalar shift value) parameter as:

- An integer representing the length of the shift.

The default Output mask vector (or scalar shift value) setting of 0 corresponds to no shift. As illustrated in the LFSR shift register diagram in "Simple Shift Register Generator" on page 5-670, there is no shift when the only connection is along the arrow labeled $m_{0}$.

This table shows the shift that occurs when you set Output mask vector (or scalar shift value) to 0 versus a positive integer $d$.

|  | T = 0 | T = 1 | T = 2 | $\cdots$ | T = d | T = d+1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Shift $=0$ | $x_{0}$ | $x_{1}$ | $x_{2}$ | $\ldots$ | $x_{d}$ | $x_{d+1}$ |
| Shift $=d$ | $x_{d}$ | $x_{d+1}$ | $x_{d+2}$ | $\ldots$ | $x_{2 d}$ | $x_{2 d+1}$ |

- A binary vector whose length is equal to the degree of the generator polynomial. The LFSR shift register diagram in "Simple Shift Register Generator" on page $5-670$ shows Output mask vector (or scalar shift value) specified as a mask vector, $m$. The binary vector must have $N$ elements, where $N$ is the degree of the generator polynomial. To calculate the mask vector, use the shift2mask function.

The binary vector corresponds to a polynomial in $z, m_{r-1} z^{r-1}+m_{r-2} z^{r-2}+\ldots+m_{1} z+m_{0}$, of degree at most $r-1$. The mask vector that correspond to a shift of $d$ is the vector that represents $m(z)=z^{d}$ modulo $g(z)$, where $g(z)$ is the generator polynomial.

For example, if the degree of the generator polynomial is 4 , then the mask vector that corresponds to $d=2$ is [ $\left.\begin{array}{llll}0 & 1 & 0 & 0\end{array}\right]$, which represents the polynomial $m(z)=z^{2}$.

## Reset Behavior

To reset the generator sequence, you must first select Reset on nonzero input to add the Rst input. Suppose that the PN Sequence Generator block outputs [ $\left.\begin{array}{llllllll}1 & 0 & 0 & 1 & 1 & 0 & 1 & 1\end{array}\right]$ when there is no reset. The following table shows the effect on the PN Sequence Generator block output for the property values indicated.

|  | Reset Signal Properties | PN Sequence Generator block | Reset Signal Output Signal |
| :---: | :---: | :---: | :---: |
| No reset | $\begin{aligned} & \text { Sample time }=1 \\ & \begin{array}{l} \text { Samples per } \\ \text { frame }=1 \end{array} \\ & \text { Rst }=\left[\begin{array}{lllll} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right] \end{aligned}$ | $\begin{aligned} & \text { Sample time }=1 \\ & \text { Samples per } \\ & \text { frame }=1 \\ & \begin{array}{llllll} \text { Out }=1 & 1 & 0 & 0 & 1 & 1 \end{array} \\ & 0 \end{aligned} 1$ | $\begin{array}{\|llllllllll} \hline \text { Ret } & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \text { out } & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 1 \end{array}$ |

|  | Reset Signal Properties | PN Sequence Generator block | Reset Signal Output Signal |
| :---: | :---: | :---: | :---: |
| Scalar reset signal | $\begin{aligned} & \text { Sample time }=1 \\ & \begin{array}{l} \text { Samples per } \\ \text { frame }=1 \end{array} \\ & \begin{array}{l} \text { Rst }=\left[\begin{array}{lllll} 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right] \end{array} \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { Sample time }=1 \\ & \text { Samples per } \\ & \text { frame }=1 \end{aligned}$ |  |
| Vector reset signal |  | Sample time $=1$ <br> Samples per <br> frame $=8$ |  |

For the no reset case, the sequence is output without being reset. For the scalar and vector reset signal cases, the reset signal [00010000] is input to the Rst port. The sequence output is reset at the fourth bit, because the fourth bit of the reset signal is a 1 and the Sample time is 1 .

For variable-sized outputs, the block only supports scalar reset signal inputs.

## Sequences of Maximum Length

To generate a maximum length sequence for a generator polynomial that has the degree $r$, set
Generator polynomial to a value from the following table. The maximum sequence length is $2^{r}-1$.

| r | Generator Polynomial | r | Generator Polynomial | r | Generator Polynomial | r | Generator Polynomial |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | [2 1200$]$ | 15 | $\left[\begin{array}{lll}15 & 14 & 0\end{array}\right]$ | 28 | $\left[\begin{array}{lll}28 & 25 & 0\end{array}\right]$ | 41 | [41 3 0] |
| 3 | $\left[\begin{array}{lll}3 & 2 & 0\end{array}\right]$ | 16 | $\left[\begin{array}{lllll}16 & 15 & 13 & 4 & 0\end{array}\right]$ | 29 | $\left[\begin{array}{llll}29 & 27 & 0\end{array}\right]$ | 42 | $\left[\begin{array}{lllll}42 & 23 & 22 & 1 & 0\end{array}\right]$ |
| 4 | $\left[\begin{array}{lll}4 & 3 & 0\end{array}\right]$ | 17 | $\left[\begin{array}{llll}17 & 14 & 0\end{array}\right]$ | 30 | $\left[\begin{array}{lllll}30 & 29 & 28 & 7 & 0\end{array}\right]$ | 43 | $\left[\begin{array}{llllll}43 & 6 & 4 & 3 & 0\end{array}\right]$ |
| 5 | $\left[\begin{array}{lll}5 & 3 & 0\end{array}\right]$ | 18 | $\left[\begin{array}{llll}18 & 11 & 0\end{array}\right]$ | 31 | $\left[\begin{array}{lll}31 & 28 & 0\end{array}\right]$ | 44 | [44 6 5 2 200 |
| 6 | [6 500$]$ | 19 | $\begin{array}{llll} {[19} & 18 & 17 & 14 \\ 0] \end{array}$ | 32 | $\begin{array}{llll} {\left[\begin{array}{llll} 32 & 31 & 30 & 10 \\ 0 \end{array}\right]} \end{array}$ | 45 | [45 4 3 3100$]$ |
| 7 | $\left[\begin{array}{lll}7 & 6 & 0\end{array}\right]$ | 20 | $\left[\begin{array}{ccc}20 & 17 & 0\end{array}\right]$ | 33 | [33 20 0] | 46 | $\left[\begin{array}{lllll}46 & 21 & 10 & 1 & 0\end{array}\right]$ |
| 8 | [8 66540$]$ | 21 | $\left[\begin{array}{ccc}21 & 19 & 0\end{array}\right]$ | 34 | $\left[\begin{array}{lllll}34 & 15 & 14 & 1 & 0\end{array}\right]$ | 47 | [47 14 0] |
| 9 | [9 5 0] | 22 | $\left[\begin{array}{llll}22 & 21 & 0\end{array}\right]$ | 35 | $\left[\begin{array}{lll}35 & 2 & 0\end{array}\right]$ | 48 | [482827 10 0] |
| 10 | [10 7 0] | 23 | $\left[\begin{array}{lll}23 & 18 & 0\end{array}\right]$ | 36 | $\left[\begin{array}{llll}36 & 11 & 0\end{array}\right]$ | 49 | [49 9 0] |
| 11 | [11 9 0] | 24 | $\begin{array}{llll} {\left[\begin{array}{llll} 24 & 23 & 22 & 17 \\ 0 \end{array}\right]} \end{array}$ | 37 | [37 121020 0] | 50 | [50 4 3 2 0] |
| 12 | $\left[\begin{array}{lllll}12 & 11 & 8 & 6 & 0\end{array}\right]$ | 25 | $\left[\begin{array}{lll}25 & 22 & 0\end{array}\right]$ | 38 | [38 65100 | 51 | [51 631100 |
| 13 | $\left[\begin{array}{lllll}13 & 12 & 10 & 9 & 0\end{array}\right]$ | 26 | $\begin{array}{llll} {\left[\begin{array}{llll} 26 & 25 & 24 & 20 \\ 0 \end{array}\right]} \end{array}$ | 39 | [39 800 | 52 | [52 300 |

| $\mathbf{r}$ | Generator <br> Polynomial | $\mathbf{r}$ | Generator <br> Polynomial | $\mathbf{r}$ | Generator <br> Polynomial | $\mathbf{r}$ | Generator <br> Polynomial |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 14 | $\left[\begin{array}{lllllll}14 & 13 & 8 & 4 & 0\end{array}\right]$ | 27 | $\left.\begin{array}{lllllll}{\left[\begin{array}{llllll}27 & 26 & 25 & 22 \\ 0\end{array}\right]} & 40 & {\left[\begin{array}{lllll}40 & 5 & 4 & 3 & 0\end{array}\right]} & 53 & {\left[\begin{array}{llll}53 & 6 & 2 & 1\end{array} 0\right.}\end{array}\right]$ |  |  |  |  |

For more information about the shift-register configurations that these polynomials represent, see Digital Communications by John Proakis.[1].

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

## Existing models automatically update this block to current version

Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the PN Sequence Generator block version available before R2015b.

Existing models automatically update to load the PN Sequence Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes. For more information on block forwarding, see "Forwarding Tables" (Simulink).

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using Simulink $\circledR^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\text {TM }}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |

## Restrictions

- You can select Input port as the Output mask source on the block. In this case, the Mask input signal must be a vector of data type ufix1.
- If you select Reset on nonzero input, the input to the Rst port must have data type Boolean.
- Outputs of type double are not supported for HDL code generation. All other output types (including bit-packed outputs) are supported.
- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.
- You cannot generate HDL for this block inside a Triggered Subsystem if the Use trigger signal as clock option is selected. See "Using Triggered Subsystems for HDL Code Generation" (HDL Coder).

## Poisson Integer Generator

Generate Poisson-distributed random integers

## Library

Random Data Sources sublibrary of Comm Sources

## Description

The Poisson Integer Generator block generates random integers using a Poisson distribution. The probability of generating a nonnegative integer $k$ is

$$
\lambda^{k} \exp (-\lambda) /(k!)
$$

where $\lambda$ is a positive number known as the Poisson parameter.
You can use the Poisson Integer Generator to generate noise in a binary transmission channel. In this case, the Poisson parameter Lambda should be less than 1, usually much less.

## Attributes of Output Signal

The output signal can be a column or row vector, a two-dimensional matrix, or a scalar. The number of rows in the output signal corresponds to the number of samples in one frame and is determined by the Samples per frame parameter. The number of columns in the output signal corresponds to the number of channels and is determined by the number of elements in the Lambda parameter. See "Sources and Sinks" in Communications Toolbox User's Guide for more details.

## Parameters

## Lambda

The Poisson parameter $\lambda$. Specify $\lambda$ as a scalar or row vector whose elements are real numbers. If Lambda is a scalar, then every element in the output vector shares the same Poisson parameter. If Lambda is a row vector, then the number of elements correspond to the number of independent channels output from the block.

## Source of initial seed

The source of the initial seed for the random number generator. Specify the source as either Auto or Parameter. When set to Auto, the block uses the global random number stream.

Note When Source of initial seed is Auto in Code generation mode, the random number generator uses an initial seed of zero. Therefore, the block generates the same random numbers each time it is started. Use Interpreted execution to ensure that the model uses different initial seeds. If Interpreted execution is run in Rapid accelerator mode, then it behaves the same as Code generation mode.

## Initial seed

The initial seed value for the random number generator. Specify the seed as a nonnegative integer scalar. Initial seed is available when the Source of initial seed parameter is set to Parameter.

## Sample time

Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1, the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-676.

## Samples per frame

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-676.

## Output data type

The output type of the block can be specified as a boolean, uint8, uint16, uint32, single, or double. The default is double.

## Simulate using

Select the simulation mode.
Code generation
On the first model run, simulate and generate code. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects corresponding to the blocks accept a maximum of nine inputs.
Interpreted execution
Simulate model without generating code. This option results in faster start times but can slow subsequent simulation performance.

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10 , then a 10 -by- 1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

Existing models automatically update this block to current version
Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the Poisson Integer Generator block version available before R2015b.

- Existing models automatically update to load the Poisson Integer Generator block version announced in R2015b. For more information on block forwarding, see "Forwarding Tables" (Simulink).
- Behavior of the random number generator is changed. The statistics are improved. For more information, see "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes.

## Preamble Detector

Detect preamble in data packet
Library:
Communications Toolbox / Synchronization

## Description

The Preamble Detector block detects the end of preambles in data packets. A preamble is a set of symbols or bits used in packet-based communications systems to indicate the start of a packet. Packets consist of preamble data and user data. The length of the user data portion of the packet can vary during a simulation run.

This icon shows the block with all ports enabled:

## Input/Output Ports

Input

## In - Input data

scalar | column vector
Input data of symbols or bits, specified as a scalar or column vector. The input data can contain multiple packets. This port is unnamed on the block.
Data Types: single | double | Boolean | int8 | uint8

## Output

## Idx - Index of last preamble symbol

scalar | column vector
Index of the last preamble symbol, returned as a scalar or column vector of the same size and data type as the input data.

- When the Detections parameter is set to All, Idx outputs the index corresponding to the last element of each detected preamble.
- When the Detections parameter is set to First, Idx outputs the index corresponding to the last element of the first detected preamble.

This port is unnamed until the DtMt port is enabled.

## DtMt - Detection metric

scalar | column vector
Detection metric, returned as a scalar or column vector of the same size and data type as the input data packet.

- If either the preamble or input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input data.
- If both the preamble and input data are real, the detection metric is the cross-correlation of the preamble and the input data.

## Dependencies

To enable this port, set the Input parameter to Symbol, and select the Output detection metric parameter.

## Parameters

## Input - Input type

Symbol (default)|Bit
Input type, specified as Symbol or Bit.

- For binary inputs, set this parameter to Bit.
- For all other inputs, set this parameter to Symbol.

For information on execution speed, see "Tips" on page 5-680.

## Preamble - Preamble sequence

[1 + 1i; 1 - 1i] (default)|column vector
Preamble sequence, specified as a column vector.

- If the Input parameter is set to Bit, the preamble must be binary.
- If the Input parameter is set to Symbol, the preamble can be any real or complex sequence.

## Detection threshold - Detection threshold

3 (default) | nonnegative scalar
Detection threshold, specified as a nonnegative scalar. When the detection metric is greater than or equal to the threshold, the block detects the preamble and updates Idx.

Tunable: Yes

## Dependencies

To enable this parameter, set the Input parameter to Symbol.

## Output detection metric - Option to output detection metric off (default) | on

Select this parameter to output the detection metric and enable the DtMt output port.

## Dependencies

To enable this parameter, set the Input parameter to Symbol.

## Detections - Detections returned <br> All (default) | First

Detections returned, specified as All or First. Specifying All returns all detected preambles. Specifying First returns only the first detected preamble.

Tunable: Yes

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated $C$ code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

For information on execution speed, see "Tips" on page 5-680.

## Block Characteristics

| Data Types | Boolean $\mid$ double \| integer $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## Tips

- For faster execution of the Preamble Detector block, set the Simulate using parameter to:
- Code generation when the Input parameter is set to Symbol
- Interpreted execution when the Input parameter is set to Bit

## Algorithms

## Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

## Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples match the preamble, the filter output reaches its peak. The index of the peak corresponds to the end of the preamble sequence in the input data. See Discrete FIR Filter for further information on the FIR filter algorithm.

The cross-correlation values that are greater than or equal to the specified threshold are reported as peaks.

- If the detection threshold is too low, the algorithm will detect false peaks, or, in the extreme case, detect as many detected peaks as there are input samples.
- If the detection threshold is too high, the algorithm will miss detecting peaks, or, in the extreme case, detect no peaks.

Consequently, the selection of the detection threshold is critical.

## Puncture

Output elements that correspond to 1 s in binary puncture vector
Library: Communications Toolbox / Sequence Operations

## Description

The Puncture block creates an output vector by removing selected elements of the input vector and preserving others. The block determines which elements to remove and preserve by using the binary Puncture vector parameter. The block repeats the puncturing pattern, as necessary, to include all input elements. The preserved elements appear in the output vector in the same order in which they appear in the input vector.

## Ports

## Input

In - Input signal
numeric column vector
Input signal, specified as a numeric column vector. The input length must be an integer multiple of the Puncture vector parameter length.
Data Types: double

## Output

Out - Output signal
numeric column vector
Output signal, returned as a column vector. The length of the output vector is an integer multiple of the number of 1 s in the Puncture vector parameter. The output signal contains only elements from the input signal that align with integer multiples of the element location of 1 s in the Puncture vector.

## Parameters

## Puncture vector - Puncture pattern

Puncture pattern, specified as a column vector of binary values. The input signal length must be an integer multiple of the Puncture vector parameter length. The block repeats the puncturing pattern, as necessary, to include all input elements.

- The element locations of 0 s in Puncture vector indicate which elements are removed from the input signal to construct the output signal.
- The element locations of 1 s in Puncture vector indicate which elements are preserved from the input signal to construct the output signal.

## Block Characteristics

# QPSK Demodulator Baseband 

Demodulate QPSK-modulated data

## Library

PM, in Digital Baseband sublibrary of Modulation

## Description

The QPSK Demodulator Baseband block demodulates a signal that was modulated using the quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

The input must be a complex signal. This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see "Supported Data Types" on page 5690.

Algorithm

Hard-Decision QPSK Demodulator Signal Diagram for Trivial Phase Offset (odd multiple of m/4)

Hard-Decision QPSK Demodulator Floating-Point Signal Diagram for Nontrivial Phase Offset

Hard-Decision QPSK Demodulator Fixed-Point Signal Diagram for Nontrivial Phase Offset
The exact LLR and approximate LLR cases (soft-decision) are described in "Exact LLR Algorithm" and "Approximate LLR Algorithm".

## Dialog Box

## Phase offset (rad)

The phase of the zeroth point of the signal constellation.

## Constellation ordering

Determines how the block maps each integer to a pair of output bits.

## Output type

Determines whether the output consists of integers or bits.
If the Output type parameter is set to Integer and Constellation ordering is set to Binary, then the block maps the point
$\exp (\mathrm{j} \theta \quad+$
to $m$, where $\theta$ is the Phase offset parameter and $m$ is $0,1,2$, or 3 .
The reference page for the QPSK Modulator Baseband block shows the signal constellations for the cases when Constellation ordering is set to either Binary or Gray.

If the Output type is set to Bit, then the output contains pairs of binary values if Decision type is set to Hard decision. The most significant bit (i.e. the left-most bit in the vector), is the first bit the block outputs.

If the Decision type is set to Log-likelihood ratio or Approximate log-likelihood ratio, then the output contains bitwise LLR or approximate LLR values, respectively.

## Decision type

Specifies the use of hard decision, LLR, or approximate LLR during demodulation. This parameter appears when you select Bit from the Output type drop-down list. The output values for Loglikelihood ratio and Approximate log-likelihood ratio decision types are of the same data type as the input values. For integer output, the block always performs Hard decision demodulation.

See "Exact LLR Algorithm" and "Approximate LLR Algorithm" for algorithm details.

## Noise variance source

This field appears when Approximate log-likelihood ratio or Log-likelihood ratio is selected for Decision type.

When set to Dialog, the noise variance can be specified in the Noise variance field. When set to Port, a port appears on the block through which the noise variance can be input.

## Noise variance

This parameter appears when the Noise variance source is set to Dialog and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- Inf to - Inf if Noise variance is very high
- NaN if Noise variance and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Data Types Pane for Hard-Decision

## Output

For bit outputs, when Decision type is set to Hard decision, the output data type can be set to 'Inherit via internal rule','Smallest unsigned integer', double, single, int8, uint8, int16, uint16, int32, uint32, or boolean.

For integer outputs, the output data type can be set to 'Inherit via internal rule', 'Smallest unsigned integer', double, single, int8, uint8, int16, uint16, int32, or uint32.

When this parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is a floating-point type (single or double). If the input data type is fixed-point, the output data type will work as if this parameter is set to 'Smallest unsigned integer'.

When this parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model.

If ASIC/FPGA is selected in the Hardware Implementation pane, and Output type is Bit, the output data type is the ideal minimum one-bit size, i.e., ufix (1). For all other selections, it is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a char (e.g., uint8).

If ASIC/FPGA is selected in the Hardware Implementation pane, and Output type is Integer, the output data type is the ideal minimum two-bit size, i.e., ufix (2). For all other selections, it is an unsigned integer with the smallest available word length large enough to fit two bits, usually corresponding to the size of a char (e.g., uint8).

## Derotate factor

This parameter only applies when the input is fixed-point and Phase offset is not an even multiple of $\pi / 4$.

You can select Same word length as input or Specify word length, in which case you define the word length using an input field.

## Data Types Pane for Soft-Decision

For bit outputs, when Decision type is set to Log-likelihood ratio or Approximate loglikelihood ratio, the output data type is inherited from the input (e.g., if the input is of data type double, the output is also of data type double).

## Examples

## Demodulate Noisy QPSK Signal

Modulate and demodulate a noisy QPSK signal.
Open the QPSK demodulation model.

Run the simulation. The results are saved to the base workspace, where the variable ErrorVec is a 1 -by- 3 row vector. The BER is found in the first element.

Display the error statistics. For the Eb/No provided, 4.3 dB , the resultant BER is approximately 0.01 . Your results may vary slightly.

```
ans =
```

0.0112

Increase the $\mathrm{Eb} / \mathrm{No}$ to 7 dB . Rerun the simulation, and observe that the BER has decreased.

## QPSK Modulator Baseband

Modulate using quadrature phase shift keying method

```
\square-MM
    QPSK
```

## Library

PM in Digital Baseband sublibrary of Modulation

## Description

The QPSK Modulator Baseband block modulates using the quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

## Integer-Valued Signals and Binary-Valued Signals

If you set the Input type parameter to Integer, then valid input values are $0,1,2$, and 3 . When you set Constellation ordering to Binary for input $m$ the output symbol is

```
exp(j0
+
jпm/2)
```

where $\theta$ represents the Phase offset parameter (see the following figure for Gray constellation ordering). In this case, the block accepts a scalar or column vector signal.

If you set the Input type parameter to Bit, then the input contains pairs of binary values. For this configuration, the block accepts column vectors with even lengths. When you set the Phase offset parameter to $\frac{\Pi}{4}$, then the block uses one of the signal constellations in the following figure, depending on whether you set the Constellation ordering parameter to Binary or Gray.

In the previous figure, the most significant bit (i.e. the left-most bit), is the first bit input to the block. For additional information about Gray mapping, see the M-PSK Modulator Baseband help page.

## Constellation Visualization

The QPSK Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the Communications Toolbox User's Guide.

## Dialog Box

## Phase offset (rad)

The phase of the zeroth point of the signal constellation.

## Constellation ordering

Determines how the block maps each pair of input bits or input integers to constellation symbols.

## Input type

Indicates whether the input consists of integers or pairs of bits.

## Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this parameter to Fixed-point or User-defined enables fields in which you can further specify details. Setting this parameter to Inherit via back propagation, sets the output data type and scaling to match the following block.

## Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select Fixed-point for the Output data type parameter.

## Set output fraction length to

Specify the scaling of the fixed-point output by either of the following methods:

- Choose Best precision to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose User-defined to specify the output scaling in the Output fraction length parameter.

This parameter is only visible when you select Fixed-point for the Output data type parameter or when you select User-defined and the specified output data type is a fixed-point data type.

## User-defined data type

Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the sfix, sint, sfrac, and fixdt functions from Fixed-Point Designer. This parameter is only visible when you select User-defined for the Output data type parameter.

## Output fraction length

For fixed-point output data types, specify the number of fractional bits or bits to the right of the binary point. This parameter is only visible when you select Fixed-point or User-defined for the Output data type parameter and User-defined for the Set output fraction length to parameter.

## Examples

## Plot Noisy QPSK Constellation

Open the QPSK model. The model generates QPSK data, applies white noise, and displays the resulting constellation diagram.

Run the model.

Change the Eb/No of the AWGN Channel block from 15 dB to 10 dB .

The noise level increases as shown by the greater distance between the samples.

## Supported Data Types

## Quantizing Decoder

Decode quantization index according to codebook

## Library

Source Coding

## Description

The Quantizing Decoder block converts quantization indices to the corresponding codebook values. The Quantization codebook parameter, a vector of length N, prescribes the possible output values. If the input is an integer $k$ between 0 and $N-1$, then the output is the $(k+1)$ st element of Quantization codebook.

The input must be a discrete-time signal. This block processes each vector element independently. For information about the data types each block port supports, see the "Supported Data Type" on page 5-699 table on this page.
$\overline{\text { Note The Quantizing Encoder block also uses a Quantization codebook parameter. The first output }}$ of that block corresponds to the input of Quantizing Decoder, while the second output of that block corresponds to the output of Quantizing Decoder.

## Parameters

## Quantization codebook

A real vector that prescribes the output value corresponding to each nonnegative integer of the input.

## Quantized output data type

Select the output data type.

## Supported Data Type

| Port | Supported Data Types |
| :---: | :---: |

## Quantizing Encoder

Quantize signal using partition and codebook
U Quantizing $\operatorname{ldx}$
Encoder $\mathrm{Q}(\mathrm{U})$

## Library

## Source Coding

## Description

The Quantizing Encoder block quantizes the input signal according to the Partition vector and encodes the input signal according to the Codebook vector. This block processes each vector element independently. The input must be a discrete-time signal. This block processes each vector element independently. For information about the data types each block port supports, see the "Supported Data Type" on page 5-702 table on this page.

The first output is the quantization index. The second output is the quantized signal. The values for the quantized signal are taken from the Codebook vector.

The Quantization partition parameter, $P$, is a real vector of length n whose entries are in strictly ascending order. The quantization index (second output signal value) corresponding to an input value of $x$ is

- 0 if $x \leq P(1)$
- m if $P(\mathrm{~m})<x \leq P(\mathrm{~m}+1)$
- n if $P(\mathrm{n})<x$

The Quantization codebook parameter, whose length is $\mathrm{n}+1$, prescribes a value for each partition in the quantization. The first element of Quantization codebook is the value for the interval between negative infinity and the first element of $P$. The second output signal from this block contains the quantization of the input signal based on the quantization indices and prescribed values.

Use the lloyds function with a representative sample of your data as training data, to obtain appropriate partition and codebook parameters.

## Parameters

## Quantization partition

The vector of endpoints of the partition intervals.

## Quantization codebook

The vector of output values assigned to each partition.

## Index output data type

Select the output data type.

## Raised Cosine Receive Filter

Apply pulse shaping by downsampling signal using raised cosine FIR filter

## Library

## Comm Filters

## Description

The Raised Cosine Receive Filter block filters the input signal using a normal raised cosine FIR filter or a square root raised cosine FIR filter. It also downsamples the filtered signal if you set the Output mode parameter to Downsampling. The FIR Decimation block implements this functionality. The Raised Cosine Receive Filter block's icon shows the filter's impulse response.

## Characteristics of the Filter

Characteristics of the raised cosine filter are the same as in the Raised Cosine Transmit Filter block, except that the length of the filter's input response has a slightly different expression: $L^{*}$ Filter span in symbols +1 , where $L$ is the value of the Input samples per symbol parameter (not the Output samples per symbol parameter, as in the case of the Raised Cosine Transmit Filter block).

The block normalizes the filter coefficients to unit energy. If you specify a Linear amplitude filter gain other than 1, then the block scales the normalized filter coefficients using the gain value you specify.

## Decimating the Filtered Signal

To have the block decimate the filtered signal, set the Decimation factor parameter to a value greater than 1.

If K represents the Decimation factor parameter value, then the block retains $1 / K$ of the samples, choosing them as follows:

- If the Decimation offset parameter is zero, then the block selects the samples of the filtered signal indexed by $1, K+1,2 * K+1,3^{*} K+1$, etc.
- If the Decimation offset parameter is a positive integer less than $M$, then the block initially discards that number of samples from the filtered signal and downsamples the remaining data as in the previous case.

To preserve the entire filtered signal and avoid decimation, set Decimation factor to 1. This setting is appropriate, for example, when the output from the filter block forms the input to a timing phase recovery block such as Symbol Synchronizer. The timing phase recovery block performs the downsampling in that case.

## Input Signals and Output Signals

This block accepts a column vector or matrix input signal. For information about the data types each block port supports, see the "Supported Data Type" on page 5-707 table on this page.

If you set Decimation factor to 1 , then the input and output signals share the same sampling mode, sample time, and vector length.

If you set Decimation factor to $K$, which is greater than 1 , then $K$ and the input sampling mode determine characteristics of the output signal:

## Single-Rate Processing

When you set the Rate options parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To generate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output ( $M_{o}$ ) is $1 / K$ times that of the input ( $M_{o}=M_{i} / K$ ), In this mode, the input frame size, $M_{i}$, must be a multiple of $K$.

## Multirate Processing

When you set the Rate options parameter to Allow multirate processing, the input and output of the block are the same size, but the sample rate of the output is $K$ times slower than that of the input. When the block is in multirate processing mode, you must also specify a value for the Input processing parameter:

- When you set the Input processing parameter to Elements as channels (sample based), the block treats an $M$-by- $N$ matrix input as $M^{*} N$ independent channels, and processes each channel over time. The output sample period ( $T_{s o}$ ) is $K$ times longer than the input sample period ( $T_{s o}=K^{*} T_{s i}$ ), and the input and output sizes are identical.
- When you set the Input processing parameter to Columns as channels (frame based), the block treats an $M_{i}$-by- $N$ matrix input as $N$ independent channels. The block processes each column of the input over time by keeping the frame size constant $\left(M_{i}=M_{o}\right)$, and making the output frame period ( $T_{f_{0}}$ ) $K$ times longer than the input frame period ( $T_{f o}=K^{*} T_{f)}$ ).

## Exporting Filter Coefficients to the MATLAB Workspace

To examine or manipulate the coefficients of the filter that this block designs, select Export filter coefficients to workspace. Then set the Coefficient variable name parameter to the name of a variable that you want the block to create in the MATLAB workspace. Running the simulation causes the block to create the variable, overwriting any previous contents in case the variable already exists.

## Latency

For information pertaining to the latency of the block, see details in FIR Decimation.

## Parameters

## Filter shape

Specify the filter shape as Square root or Normal.

## Rolloff factor

Specify the rolloff factor of the filter. Use a real number between 0 and 1.

## Filter span in symbols

Specify the number of symbols the filter spans as an even, integer-valued positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the block truncates the impulse response to the number of symbols that this parameter specifies.
Input samples per symbol
An integer greater than 1 representing the number of samples that represent one symbol in the input signal.
Decimation factor
Specify the decimation factor the block applies to the input signal. The output samples per symbol equals the value of the input samples per symbol divided by the decimation factor. If the decimation factor is one, then the block only applies filtering. There is no decimation.

## Decimation offset

Specify the decimation offset in samples. Use a value between 0 and Decimation factor -1.

## Linear amplitude filter gain

Specify a positive scalar value that the block uses to scale the filter coefficients. By default, the block normalizes filter coefficients to provide unit energy gain. If you specify a gain other than 1 , the block scales the normalized filter coefficients using the gain value you specify.

## Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- Columns as channels (frame based) - When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) - When you select this option, the block treats each element of the input as a separate channel.

## Rate options

Specify the method by which the block should filter and downsample the input signal. You can select one of the following options:

- Enforce single-rate processing - When you select this option, the block maintains the input sample rate and processes the signal by decreasing the output frame size by a factor of K. To select this option, you must set the Input processing parameter to Columns as channels (frame based).
- Allow multirate processing - When you select this option, the block processes the signal such that the output sample rate is $K$ times slower than the input sample rate.

## Export filter coefficients to workspace

Select this check box to create a variable in the MATLAB workspace that contains the filter coefficients.

## Coefficient variable name

The name of the variable to create in the MATLAB workspace. This field appears only if Export filter coefficients to workspace is selected.
Visualize filter with FVTool
If you click this button, then MATLAB launches the Filter Visualization Tool, fvtool, to analyze the raised cosine filter whenever you apply any changes to the block's parameters. If you launch fvtool for the filter, and subsequently change parameters in the mask, fvtool will not update.

You will need to launch a new fvtool in order to see the new filter characteristics. Also note that if you have launched fvtool, then it will remain open even after the model is closed.

## Rounding mode

Select the rounding mode for fixed-point operations. The block uses the Rounding mode when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to Nearest. For more information, see Rounding Modes (DSP System Toolbox) or "Rounding Mode: Simplest" (Fixed-Point Designer).

## Saturate on integer overflow

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

## Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator).

See the Coefficients section of the FIR Decimation help page and "Filter Structure Diagrams" (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

See the Coefficients subsection of the Digital Filter help page for descriptions of parameter settings.

- When you select Same word length as input, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Specify word length, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the Rounding mode and the Saturate on integer overflow parameters; they are always saturated and rounded to Nearest.

## Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

## Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as product output, these characteristics match those of the product output.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

## Output

Choose how you specify the output word length and fraction length:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as accumulator, these characteristics match those of the accumulator.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

## Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Supported Data Type

## Raised Cosine Transmit Filter

Apply pulse shaping by upsampling signal using raised cosine FIR filter

## Library

Comm Filters

## Description

The Raised Cosine Transmit Filter block upsamples and filters the input signal using a normal raised cosine FIR filter or a square root raised cosine FIR filter. The block's icon shows the filter's impulse response.

## Characteristics of the Filter

The Filter shape parameter determines which type of filter the block uses; choices are Normal and Square root.

The impulse response of a normal raised cosine filter with rolloff factor R and symbol period T is

$$
h(t)=\frac{\sin (\Pi t / T)}{(\Pi t / T)} \cdot \frac{\cos (\Pi R t / T)}{\left(1-4 R^{2} t^{2} / T^{2}\right)}
$$

The impulse response of a square root raised cosine filter with rolloff factor $R$ is

$$
h(t)=4 R \frac{\cos ((1+R) \pi t / T)+\frac{\sin ((1-R) \pi t / T)}{(4 R t / T)}}{\pi \sqrt{T}\left(1-(4 R t / T)^{2}\right)}
$$

The impulse response of a square root raised cosine filter convolved with itself is approximately equal to the impulse response of a normal raised cosine filter.

Because the ideal raised cosine filter has an infinite impulse response, the block truncates the impulse response to the number of symbols that the Filter span in symbols parameter specifies. The Filter span in symbols, N , and the Output samples per symbol, L, determine the length of the filter's impulse response, which is $L^{*}$ Filter span in symbols +1 .

The Rolloff factor parameter is the filter's rolloff factor. It must be a real number between 0 and 1 . The rolloff factor determines the excess bandwidth of the filter. For example, a rolloff factor of .5 means that the bandwidth of the filter is 1.5 times the input sampling frequency.

The block normalizes the filter coefficients to unit energy. If you specify a Linear amplitude filter gain other than 1 , then the block scales the normalized filter coefficients using the gain value you specify.

## Input Signals and Output Signals

The input must be a discrete-time signal. This block accepts a column vector or matrix input signal. For information about the data types each block port supports, see the "Supported Data Type" on page 5-713 table on this page.

The Rate options method and the value of the Output samples per symbol, $L$, parameter determine the characteristics of the output signal:

## Single-Rate Processing

When you set the Rate options parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To generate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output $\left(M_{o}\right)$ is $L$ times larger than that of the input ( $M_{o}=M_{i} * L$ ), where $L$ represents the value of the Output samples per symbol parameter.

## Multirate Processing

When you set the Rate options parameter to Allow multirate processing, the input and output of the block are the same size. However, the sample rate of the output is $L$ times faster than that of the input (i.e. the output sample time is $1 / \mathrm{L}$ times the input sample time). When the block is in multirate processing mode, you must also specify a value for the Input processing parameter:

- When you set the Input processing parameter to Elements as channels (sample based), the block treats an $M$-by- $L$ matrix input as $M^{*} N$ independent channels, and processes each channel over time. The output sample period ( $T_{s o}$ ) is $L$ times shorter than the input sample period ( $T_{s o}=T_{s i} / L$ ), while the input and output sizes remain identical.
- When you set the Input processing parameter to Columns as channels (frame based), the block treats an $M_{i}$-by- $N$ matrix input as $N$ independent channels. The block processes each column of the input over time by keeping the frame size constant $\left(M_{i}=M_{o}\right)$, while making the output frame $\operatorname{period}\left(T_{f_{0}}\right) L$ times shorter than the input frame period ( $T_{f o}=T_{f i} / L$ ).

## Exporting Filter Coefficients to the MATLAB Workspace

To examine or manipulate the coefficients of the filter that this block designs, select Export filter coefficients to workspace. Then set the Coefficient variable name parameter to the name of a variable that you want the block to create in the MATLAB workspace. Running the simulation causes the block to create the variable, overwriting any previous contents in case the variable already exists.

## Parameters

## Filter shape

Specify the filter shape as Square root or Normal.

## Rolloff factor

Specify the rolloff factor of the filter. Use a real number between 0 and 1.

## Filter span in symbols

Specify the number of symbols the filter spans as an even, integer-valued positive scalar. The default is 10. Because the ideal raised cosine filter has an infinite impulse response, the block truncates the impulse response to the number of symbols that this parameter specifies.

## Output samples per symbol

Specify the number of output samples for each input symbol. The default is 8 . This property accepts an integer-valued, positive scalar. The number of taps for the raised cosine filter equals the value of this parameter multiplied by the value of the Filter span in symbols parameter.

## Linear amplitude filter gain

Specify a positive scalar value that the block uses to scale the filter coefficients. By default, the block normalizes filter coefficients to provide unit energy gain. If you specify a gain other than 1 , the block scales the normalized filter coefficients using the gain value you specify.

## Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- Columns as channels (frame based) - When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) - When you select this option, the block treats each element of the input as a separate channel.

## Rate options

Specify the method by which the block should upsample and filter the input signal. You can select one of the following options:

- Enforce single-rate processing - When you select this option, the block maintains the input sample rate, and processes the signal by increasing the output frame size by a factor of $N$. To select this option, you must set the Input processing parameter to Columns as channels (frame based).
- Allow multirate processing - When you select this option, the block processes the signal such that the output sample rate is $N$ times faster than the input sample rate.

## Export filter coefficients to workspace

Select this check box to create a variable in the MATLAB workspace that contains the filter coefficients.

## Visualize filter with FVTool

If you click this button, then MATLAB launches the Filter Visualization Tool, fvtool, to analyze the raised cosine filter whenever you apply any changes to the block's parameters. If you launch fvtool for the filter, and subsequently change parameters in the mask, fvtool will not update. You will need to launch a new fvtool in order to see the new filter characteristics. Also note that if you have launched fvtool, then it will remain open even after the model is closed.

## Rounding mode

Select the rounding mode for fixed-point operations. The block uses the Rounding mode when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to Nearest. For more information, see Rounding Modes (DSP System Toolbox) or "Rounding Mode: Simplest" (Fixed-Point Designer).

## Saturate on integer overflow

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

## Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See "Filter Structure Diagrams" (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

- When you select Same word length as input, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Specify word length, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the Rounding mode and the Saturate on integer overflow parameters; they are always saturated and rounded to Nearest.

## Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

## Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as product output, these characteristics match those of the product output.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

## Output

Choose how you specify the output word length and fraction length:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as accumulator, these characteristics match those of the accumulator.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

## Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Random Deinterleaver

Restore ordering of input symbols using random permutation

## Library

Block sublibrary of Interleaving

## Description

The Random Deinterleaver block rearranges the elements of its input vector using a random permutation. The Initial seed parameter initializes the random number generator that the block uses to determine the permutation. If this block and the Random Interleaver block have the same value for Initial seed, then the two blocks are inverses of each other.

This block accepts a column vector input signal. The Number of elements parameter indicates how many numbers are in the input vector.

The block accepts the following data types int8, uint8, int16, uint16, int32, uint32, boolean, single, double, and fixed-point. The output signal inherits its data type from the input signal.

## Parameters

## Number of elements

The number of elements in the input vector.

## Initial seed

The initial seed value for the random number generator.

## Pair Block

Random Interleaver

## Extended Capabilities

## Random Integer Generator

Generate integers randomly distributed in specified range

Library: $\quad$| Communications Toolbox / Comm Sources / Random Data |
| :--- |
|  |
| Sources |

## Description

The Random Integer Generator block generates uniformly distributed random integers in the range [ $0, M-1$ ], where $M$ is specified by the Set size parameter. Use this block to generate random binaryvalued or integer-valued data.

To ensure that the model uses different initial seeds, set the Simulate using parameter to Interpreted execution, and run the simulation in Normal or Accelerator mode. For more information, see "Limitations" on page 5-717.

## Limitations

- In Rapid Accelerator simulation mode, when you set Simulate using to Interpreted execution and Source of initial seed to Auto, the block generates the same numbers every time the simulation runs. This behavior is equivalent to setting Source of initial seed to Parameter and setting Initial seed to 0 .
- In all simulation modes (Normal, Accelerator, and Rapid Accelerator), when you set Simulate using to Code generation and Source of initial seed to Auto, the block generates the same numbers every time the simulation runs. This behavior is equivalent to setting Source of initial seed to Parameter and Initial seed to 0.

For more information, see "Choosing a Simulation Mode" (Simulink).

## Ports

## Output

## Out - Random integer output

scalar | vector | matrix
Random integer output, returned as a scalar, vector, or matrix. This port is unnamed on the block. The data type is set using the Output data type parameter.

The number of rows in the output data equals the value of the Samples per frame parameter and corresponds to the number of samples in one frame. The number of columns in the output data equals the number of elements in the Set size parameter and corresponds to the number of channels.

## Parameters

## Set size - Set size

8 (default) | positive integer | row vector of positive integers

Set size, $M$, specified as a positive integer or row vector of positive integers. The block generates integers in the range [0, (M-1)]. The number of elements in Set size corresponds to the number of independent channels output from the block.

- If Set size is a scalar, then all output random variables are independent and identically distributed (i.i.d.).
- If Set size is a vector, then the length of the vector determines the number of output channels. The channels can have differing output ranges.

## Source of initial seed - Source of initial seed <br> Auto (default) | Parameter

Source of the initial seed for the random number generator, specified as either:

- Auto -- the block uses the global random number stream
- Parameter -- the block sets the random number generator seed to Initial seed

## Initial seed - Initial seed value

0 (default) | nonnegative integer
Initial seed value for the random number generator, specified as a nonnegative integer. If the Initial seed parameter is a constant, then the resulting sequence is repeatable.

## Dependencies

To enable this parameter, set the Source of initial seed parameter to Parameter.

## Sample time - Sample time

1 (default) |-1 | positive scalar
Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1, the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-719.

## Samples per frame - Samples per frame

1 (default) | positive integer
Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-719.

## Output data type - Output data type

double (default) | single | uint8 | uint16 | uint32 | boolean
Output data type, specified as double, single, uint8, uint16, uint32, or boolean. If this parameter is set to boolean, you must set the Set size parameter to 2 .

## Simulate using - Type of simulation to run

Interpreted execution (default) |Code generation
Type of simulation to run, specified as:

- Code generation -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- Interpreted execution -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | Boolean \| double | integer | single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | no |

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

## Random Integer Generator block update supported in Upgrade Advisor

Behavior changed in R2020a
Starting in R2020a, Random Integer Generator block allows you to use the Upgrade Advisor. You can update to the block version announced in R2015b or keep the block version available before R2015b.

- Use the Upgrade Advisor to update existing models that include the Random Integer Generator block.
- Behavior of the random number generator is changed. The statistics are improved. For more information, see "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes.

## Rayleigh Noise Generator

(To be removed) Generate Rayleigh distributed noise

Note Rayleigh Noise Generator will be removed in a future release. Use the MATLAB Function block and randn function instead.

## Library

Noise Generators sublibrary of Comm Sources

## Description

The Rayleigh Noise Generator block generates Rayleigh distributed noise. The Rayleigh probability density function is given by

$$
f(x)= \begin{cases}\frac{x}{\sigma^{2}} \exp \left(-\frac{x^{2}}{2 \sigma^{2}}\right) & x \geq 0 \\ 0 & x<0\end{cases}
$$

where $\sigma^{2}$ is known as the fading envelope of the Rayleigh distribution.
The block requires you to specify the Initial seed for the random number generator. If it is a constant, then the resulting noise is repeatable. The sigma parameter can be either a vector of the same length as the Initial seed, or a scalar. When sigma is a scalar, every element of the output signal shares that same value.

## Initial Seed

The Initial seed parameter initializes the random number generator that the Rayleigh Noise Generator block uses to add noise to the input signal. When multiple blocks in a model have the Initial seed parameter, you can choose different initial seeds for each block to ensure different random streams are used in each block. Set Initial seed to an integer value for repeatable results or use the randi function to randomize your results.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a samplebased one-dimensional array. These attributes are controlled by the Frame-based outputs, Samples per frame, and Interpret vector parameters as 1-D parameters. See "Sources and Sinks" for more details.

The number of elements in the Initial seed parameter becomes the number of columns in a framebased output or the number of elements in a sample-based vector output. Also, the shape (row or column) of the Initial seed parameter becomes the shape of a sample-based two-dimensional output signal.

## Parameters

## Sigma

Specify $\sigma$ as defined in the Rayleigh probability density function.

## Initial seed

The initial seed value for the random number generator.

## Sample time

The period of each sample-based vector or each row of a frame-based matrix.

## Frame-based outputs

Determines whether the output is frame-based or sample-based. This box is active only if Interpret vector parameters as 1-D is unchecked.

## Samples per frame

The number of samples in each column of a frame-based output signal. This field is active only if Frame-based outputs is checked.

## Interpret vector parameters as 1-D

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a twodimensional signal. This box is active only if Frame-based outputs is unchecked.

## Output data type

The output can be set to double or single data types.

## Receiver Thermal Noise

Apply receiver thermal noise to complex baseband signal

## Library

RF Impairments

## Description

The Receiver Thermal Noise block simulates the effects of thermal noise on a complex, baseband signal. You can specify the amount of thermal noise in three ways, according to which Specification method you select:

- Noise temperature specifies the noise in degrees K.
- Noise figure specifies the receiver noise in dB for an input noise temperature of 290 K . This is the decibel equivalent of the noise factor.
- Noise factor specifies the receiver noise for an input noise temperature of 290 K . This is the linear equivalent of the noise figure.

The following scatter plot shows the effect of the Receiver Thermal Noise block, with Specification method set to Noise figure and Noise figure (dB) set to 3.01, on a signal modulated by 16QAM.

This plot is generated by the model described in "Illustrate RF Impairments That Distort a Signal" with the following parameter settings:

- Rectangular QAM Modulator Baseband
- Normalization method set to Average Power
- Average power (watts) set to $1 \mathrm{e}-12$
- Receiver Thermal Noise
- Specification method set to Noise figure
- Noise figure (dB) set to 3.01

## Parameters

## Specification method

The method by which you specify the amount of noise. The choices are Noise temperature, Noise figure, and Noise factor.

## Noise temperature (K)

Scalar specifying the amount of noise in degrees K.

## Noise figure (dB)

Scalar specifying the amount of noise in dB relative to a noise temperature of 290 degrees K . This parameter specifies the noise contribution of the receiver circuitry only. To add the effects of antenna noise, select the Add 290K antenna noise check box.

## Noise factor

Scalar specifying the amount of noise relative to a noise temperature of 290 degrees K. This parameter specifies the noise contribution of the receiver circuitry only. To add the effects of antenna noise, select the Add 290K antenna noise check box.
Add 290K antenna noise
Select this check box to add 290 K antenna noise to the signal. This parameter is available when Specification method is Noise figure or Noise factor.

## Initial seed

The initial seed value for the random number generator that generates the noise.

# Rectangular QAM Demodulator Baseband 

Demodulate rectangular-QAM-modulated data
Mrubl
Rectangular

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM Demodulator Baseband block demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

Note All values of power assume a nominal impedance of 1 ohm .

The signal constellation has M points, where M is the $\mathbf{M}$-ary number parameter. M must have the form $2^{\mathrm{K}}$ for some positive integer K . The block scales the signal constellation based on how you set the Normalization method parameter. For details, see the reference page for the Rectangular QAM Modulator Baseband block.

This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see the "Supported Data Types" on page 5-734 table on this page.

## Hard Decision Algorithm

The demodulator algorithm maps received input signal constellation values to M-ary integer I and Q symbol indices between 0 and $\sqrt{M}-1$ and then maps these demodulated symbol indices to formatted output values.

The integer symbol index computation is performed by first derotating and scaling the complex input signal constellation (possibly with noise) by a derotate factor and denormalization factor, respectively. These factors are derived from the Phase offset, Normalization method, and related parameters. These derotated and denormalized values are added to $\sqrt{M}-1$ to translate them into an approximate range between 0 and $2 \times(\sqrt{M}-1)$ (plus noise). The resulting values are then rescaled via a divide-bytwo (or, equivalently, a right-shift by one bit for fixed-point operation) to obtain a range approximately between 0 and $\sqrt{M}-1$ (plus noise) for I and Q. The noisy index values are rounded to the nearest integer and clipped, via saturation, and mapped to integer symbol values in the range [0 M-1]. Finally, based on other block parameters, the integer index is mapped to a symbol value that is formatted and cast to the selected Output data type.

The following figures contains signal flow diagrams for floating-point and fixed-point algorithm operation. The floating-point diagrams apply when the input signal data type is double or single. The fixed-point diagrams apply when the input signal is a signed fixed-point data type. Note that the
diagram is simplified when Phase offset is a multiple of $\pi / 2$, and/or the derived denormalization factor is 1 .

## Floating Point

Divide-by- 2 with round to nearest Cast to integer
Clip range to [0 sqrt(M)-1]

Demodulator output

## Fixed Point

Signal-Flow Diagrams with Trivial Phase Offset and Denormalization Factor Equal to 1

Signal-Flow Diagrams with Nontrivial Phase Offset and Nonunity Denormalization Factor

## Parameters

## M-ary number

The number of points in the signal constellation. It must have the form $2^{K}$ for some positive integer K.

## Normalization method

Determines how the block scales the signal constellation. Choices are Min. distance between symbols, Average Power, and Peak Power.

## Minimum distance

This parameter appears when Normalization method is set to Min. distance between symbols.

The distance between two nearest constellation points.

## Average power, referenced to 1 ohm (watts)

The average power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Average Power.

## Peak power, referenced to 1 ohm (watts)

The maximum power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Peak Power.

## Phase offset (rad)

The rotation of the signal constellation, in radians.

## Constellation ordering

Determines how the block assigns binary words to points of the signal constellation. More details are on the reference page for the Rectangular QAM Modulator Baseband block.

Selecting User-defined displays the field Constellation mapping, allowing for user-specified mapping.

## Constellation mapping

This parameter appears when User-defined is selected in the pull-down list Constellation ordering.

This is a row or column vector of size M and must have unique integer values in the range [0, $\mathrm{M}-1]$. The values must be of data type double.

The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point.

## Output type

Determines whether the block produces integers or binary representations of integers.
If set to Integer, the block produces integers.
If set to Bit, the block produces a group of K bits, called a binary word, for each symbol, when Decision type is set to Hard decision. If Decision type is set to Log-likelihood ratio or Approximate log-likelihood ratio, the block outputs bitwise LLR and approximate LLR, respectively.

## Decision type

This parameter appears when Bit is selected in the pull-down list Output type.
Specifies the use of hard decision, LLR, or approximate LLR during demodulation. See "Exact LLR Algorithm" and "Approximate LLR Algorithm" in the Communications Toolbox User's Guide for algorithm details.

## Noise variance source

This parameter appears when Approximate log-likelihood ratio or Log-likelihood ratio is selected for Decision type.

When set to Dialog, the noise variance can be specified in the Noise variance field. When set to Port, a port appears on the block through which the noise variance can be input.

## Noise variance

This parameter appears when the Noise variance source is set to Dialog and specifies the noise variance in the input signal. This parameter is tunable in normal mode, Accelerator mode and Rapid Accelerator mode.

If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- Inf to - Inf if Noise variance is very high
- NaN if Noise variance and signal power are both very small

In such cases, use approximate LLR, as its algorithm does not involve computing exponentials.

## Output

When the parameter is set to 'Inherit via internal rule' (default setting), the block will inherit the output data type from the input port. The output data type will be the same as the input data type if the input is of type single or double. Otherwise, the output data type will be as if this parameter is set to 'Smallest unsigned integer'.

When the parameter is set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is the ideal minimum size, i.e., ufix(1) for bit outputs, and ufix (ceil(log2(M))) for integer outputs. For all other selections, it is an unsigned integer with the smallest available word length large enough to fit the ideal minimum size, usually corresponding to the size of a char (e.g., uint8).

For integer outputs, this parameter can be set to Smallest unsigned integer, int8, uint8, int16, uint16, int32, uint32, single, and double. For bit outputs, the options are Smallest unsigned integer, int8, uint8, int16, uint16, int32, uint32, boolean, single, or double.

## Derotate factor

This parameter only applies when the input is fixed-point and Phase offset is not a multiple of п/2.

This can be set to Same word length as input or Specify word length, in which case a field is enabled for user input.

## Denormalization factor

This parameter only applies when the input is fixed-point and the derived denormalization factor is nonunity (not equal to 1). This scaling factor is derived from Normalization method and other parameter values in the block dialog.

This can be set to Same word length as input or Specify word length, in which case a field is enabled for user input. A best-precision fraction length is always used.

## Product output

This parameter only applies when the input is a fixed-point signal and there is a nonunity (not equal to 1) denormalized factor. It can be set to Inherit via internal rule or Specify word length, which enables a field for user input.

Setting to Inherit via internal rule computes the full-precision product word length and fraction length. Internal Rule for Product Data Types (DSP System Toolbox) in DSP System Toolbox User's Guide describes the full-precision Product output internal rule.

Setting to Specify word length allows you to define the word length. The block computes a best-precision fraction length based on the word length specified and the pre-computed worstcase ( $\mathrm{min} / \mathrm{max}$ ) real world value Product output result. The worst-case Product output result is precomputed by multiplying the denormalized factor with the worst-case ( $\mathrm{min} / \mathrm{max}$ ) input signal range, purely based on the input signal data type.

The block uses the Rounding mode when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. For more information, see "Rounding Modes" (DSP System Toolbox) or "Rounding Mode: Simplest" (FixedPoint Designer).

## Sum

This parameter only applies when the input is a fixed-point signal. It can be set to Inherit via internal rule, Same as product output, or Specify word length, in which case a field is enabled for user input

Setting to Inherit via internal rule computes the full-precision sum word length and fraction length, based on the two inputs to the Sum in the fixed-point Hard Decision Algorithm on
page 5-727 signal flow diagram. The rule is the same as the fixed-point inherit rule of the internal Accumulator data type parameter in the Simulink Sum block.

Setting to Specify word length allows you to define the word length. A best precision fraction length is computed based on the word length specified in the pre-computed maximum range necessary for the demodulated algorithm to produce accurate results. The signed fixed-point data type that has the best precision fully contains the values in the range $2 *(\sqrt{M}-1)$ for the specified word length.

Setting to Same as product output allows the Sum data type to be the same as the Product output data type (when Product output is used). If the Product output is not used, then this setting will be ignored and the Inherit via internal rule Sum setting will be used.

## Examples

## Demodulate Noisy QAM Signal

Modulate and demodulate a noisy QAM signal.
Open the QAM demodulation model.

Run the simulation. The results are saved to the base workspace, where the variable ErrorVec is a 1 -by- 3 row vector. The BER is found in the first element.

Display the error statistics. For the Eb/No provided, 2 dB , the resultant BER is approximately 0.1. Your results may vary slightly.
ans =
0.0948

Increase the $\mathrm{Eb} / \mathrm{No}$ to 4 dB . Rerun the simulation, and observe that the BER has decreased.

## Supported Data Types

## HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |

## Restrictions

- The block does not support single or double data types for HDL code generation.
- HDL Coder supports the following Output type options:
- Integer
- Bit is supported only if the Decision Type is Hard decision.
- You must set Normalization Method to Minimum Distance Between Symbols, with a Minimum distance of 2.
- You must set Phase offset (rad) to a value that is a multiple of $\mathrm{pi} / 4$.

# Rectangular QAM Modulator Baseband 

Modulate using rectangular quadrature amplitude modulation

$\sqrt{$| $\square \text { WMM }$ |
| :---: |
|  Rectangular  |
|  QAM  |$}$

## Library

AM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM Modulator Baseband block modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal. For information about the data types each block port supports, see "Supported Data Types" on page 5-741.

Note All values of power assume a nominal impedance of 1 ohm .

## Integer-Valued Signals and Binary-Valued Signals

When you set the Input type parameter to Integer, the block accepts integer values between 0 and $M-1$. $M$ represents the $\mathbf{M}$-ary number block parameter.

When you set the Input type parameter to Bit, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $K=\log _{2}(M)$ bits where
$K$ represents the number of bits per symbol.
The input vector length must be an integer multiple of $K$. In this configuration, the block accepts a group of $K$ bits and maps that group onto a symbol at the block output. The block outputs one modulated symbol for each group of $K$ bits.

The Constellation ordering parameter indicates how the block assigns binary words to points of the signal constellation. Such assignments apply independently to the in-phase and quadrature components of the input:

- If Constellation ordering is set to Binary, the block uses a natural binary-coded constellation.
- If Constellation ordering is set to Gray and K is even, the block uses a Gray-coded constellation.
- If Constellation ordering is set to Gray and K is odd, the block codes the constellation so that pairs of nearest points differ in one or two bits. The constellation is cross-shaped, and the schematic below indicates which pairs of points differ in two bits. The schematic uses $\mathrm{M}=128$, but suggests the general case.

Hollow vertical pairs of odjacent points differ by two bits

Other pairs of adjocent points differ by one bit

For details about the Gray coding, see the reference page for the M-PSK Modulator Baseband block and the paper listed in References on page 5-742. Because the in-phase and quadrature components are assigned independently, the Gray and binary orderings coincide when $\mathrm{M}=4$.

## Constellation Size and Scaling

The signal constellation has $M$ points, where $M$ is the $\mathbf{M}$-ary number parameter. $M$ must have the form $2^{\mathrm{K}}$ for some positive integer K . The block scales the signal constellation based on how you set the Normalization method parameter. The following table lists the possible scaling conditions.

| Value of Normalization Method Parameter | Scaling Condition |
| :--- | :--- |
| Min. distance between symbols | The nearest pair of points in the constellation is <br> separated by the value of the Minimum <br> distance parameter |
| Average Power | The average power of the symbols in the <br> constellation is the Average power parameter |
| Peak Power | The maximum power of the symbols in the <br> constellation is the Peak power parameter |

## Constellation Visualization

The Rectangular QAM Modulator Baseband block provides the capability to visualize a signal constellation from the block mask. This Constellation Visualization feature allows you to visualize a signal constellation for specific block parameters. For more information, see the Constellation Visualization section of the Communications Toolbox User's Guide.

## Parameters

## M-ary number

The number of points in the signal constellation. It must have the form $2^{\mathrm{K}}$ for some positive integer K.

## Input type

Indicates whether the input consists of integers or groups of bits.

## Constellation ordering

Determines how the block maps each symbol to a group of output bits or integer.
Selecting User-defined displays the field Constellation mapping, which allows for userspecified mapping.

## Constellation mapping

This parameter is a row or column vector of size M and must have unique integer values in the range $[0, \mathrm{M}-1]$. The values must be of data type double.

The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point.

This field appears when User-defined is selected in the drop-down list Constellation ordering.

## Normalization method

Determines how the block scales the signal constellation. Choices are Min. distance between symbols, Average Power, and Peak Power.

## Minimum distance

The distance between two nearest constellation points. This field appears only when Normalization method is set to Min. distance between symbols.

## Average power, referenced to 1 ohm (watts)

The average power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Average Power.
Peak power, referenced to $\mathbf{1}$ ohm (watts)
The maximum power of the symbols in the constellation, referenced to 1 ohm . This field appears only when Normalization method is set to Peak Power.
Phase offset (rad)
The rotation of the signal constellation, in radians.

## Output data type

The output data type can be set to double, single, Fixed-point, User-defined, or Inherit via back propagation.

Setting this parameter to Fixed-point or User-defined enables fields in which you can further specify details. Setting this parameter to Inherit via back propagation, sets the output data type and scaling to match the following block.

## Output word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select Fixed-point for the Output data type parameter.
User-defined data type
Specify any signed built-in or signed fixed-point data type. You can specify fixed-point data types using the sfix, sint, sfrac, and fixdt functions from Fixed-Point Designer software. This parameter is only visible when you select User-defined for the Output data type parameter.
Set output fraction length to
Specify the scaling of the fixed-point output by either of the following methods:

- Choose Best precision to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose User-defined to specify the output scaling in the Output fraction length parameter.

This parameter is only visible when you select Fixed-point for the Output data type parameter or when you select User-defined and the specified output data type is a fixed-point data type.

## Output fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select Fixed-point or User-defined for the Output data type parameter and User-defined for the Set output fraction length to parameter.

## Examples

## Plot Noisy 16-QAM Constellation

Open the 16-QAM model. The model generates a QAM signal, applies white noise, and displays the resulting constellation diagram.

Run the model.

Change the Eb/No of the AWGN Channel block from 20 dB to 10 dB . Observe the increase in the noise.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean when Input type is Bit <br> - 8 -, 16-, 32 -bit signed integers <br> - 8 -, 16 -, 32 -bit unsigned integers <br> - ufix $\left(\log _{2} M\right)$ when Input type is Integer |
| Output | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed-point |

HDL Architecture
This block has a single, default HDL architecture.
HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |

## Restrictions

- The block does not support single or double data types for HDL code generation.
- When Input Type is set to Bit, the block does not support HDL code generation for input types other than boolean or ufixl.

When the input type is set to Bit, but the block input is actually multibit (uint16, for example), the Rectangular QAM Modulator Baseband block does not support HDL code generation.

## Rectangular QAM TCM Decoder

Decode trellis-coded modulation data, modulated using QAM method

```
Rectangular
QAM TCM
```

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM TCM Decoder block uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a QAM signal constellation.

The M-ary number parameter represents the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is, $\log _{2}(\mathbf{M}$ ary number) is the number of output bit streams from the convolutional encoder.)

The Trellis structure and $\mathbf{M}$-ary number parameters in this block should match those in the Rectangular QAM TCM Encoder block, to ensure proper decoding.

## Input and Output Signals

This block accepts a column vector input signal containing complex numbers. For information about the data types each block port supports, see "Supported Data Types" on page 5-744.

If the convolutional encoder described by the trellis structure represents a rate $k / n$ code, then the Rectangular QAM TCM Decoder block's output is a binary column vector with a length of $k$ times the vector length of the input signal.

## Operation Modes

The block has three possible methods for transitioning between successive frames. The Operation mode parameter controls which method the block uses. This parameter also affects the range of possible values for the Traceback depth parameter, D.

- In Continuous mode, the block initializes all state metrics to zero at the beginning of the simulation, waits until it accumulates D symbols, and then uses a sequence of D symbols to compute each of the traceback paths. D can be any positive integer. At the end of each frame, the block saves its internal state metric for use with the next frame.

If you select Enable the reset input, the block displays another input port, labeled Rst. This port receives an integer scalar signal. Whenever the value at the Rst port is nonzero, the block resets all state metrics to zero and sets the traceback memory to zero.

- In Truncated mode, the block treats each frame independently. The traceback path starts at the state with the lowest metric. D must be less than or equal to the vector length of the input.
- In Terminated mode, the block treats each frame independently. The traceback path always starts at the all-zeros state. D must be less than or equal to the vector length of the input. If you know that each frame of data typically ends at the all-zeros state, then this mode is an appropriate choice.

## Decoding Delay

If you set Operation mode to Continuous, then this block introduces a decoding delay equal to Traceback depth*k bits, for a rate $\mathrm{k} / \mathrm{n}$ convolutional code. The decoding delay is the number of zeros that precede the first decoded bit in the output.

The block incurs no delay for other values of Operation mode.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## $\mathbf{M}$-ary number

The number of points in the signal constellation.

## Traceback depth

The number of trellis branches (equivalently, the number of symbols) the block uses in the Viterbi algorithm to construct each traceback path.

## Operation mode

The operation mode of the Viterbi decoder. Choices are Continuous, Truncated, and Terminated.

## Enable the reset input port

When you select this check box, the block has a second input port labeled Rst. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data. This option appears only if you set Operation mode to Continuous.

## Output data type

Select the data type for the block output signal as boolean or single. By default, the block sets this to double.

## Supported Data Types

## Rectangular QAM TCM Encoder

Convolutionally encode binary data and modulate using QAM method

```
Rectangular
QAM TCM
```

## Library

TCM, in Digital Baseband sublibrary of Modulation

## Description

The Rectangular QAM TCM Encoder block implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a QAM signal constellation.

The $\mathbf{M}$-ary number parameter is the number of points in the signal constellation, which also equals the number of possible output symbols from the convolutional encoder. (That is, $\log _{2}$ (M-ary number) is equal to n for a rate $\mathrm{k} / \mathrm{n}$ convolutional code.)

## Input Signals and Output Signals

If the convolutional encoder described by the trellis structure represents a rate $k / n$ code, then the Rectangular QAM TCM Encoder block's input must be a binary column vector with a length of $L^{*} k$ for some positive integer $L$.

The output from the Rectangular QAM TCM Encoder block is a complex column vector of length $L$.

## Specifying the Encoder

To define the convolutional encoder, use the Trellis structure parameter. This parameter is a MATLAB structure whose format is described in "Trellis Description of a Convolutional Code". You can use this parameter field in two ways:

- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, then use a poly2trellis command within the Trellis structure field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the Trellis structure parameter to
poly2trellis(7,[171 133],171)
- If you have a variable in the MATLAB workspace that contains the trellis structure, then enter its name as the Trellis structure parameter. This way is faster because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage in the previous bulleted item.

The encoder registers begin in the all-zeros state. You can configure the encoder so that it resets its registers to the all-zeros state during the course of the simulation. To do this, set the Operation
mode to Reset on nonzero input via port. The block then opens a second input port, labeled Rst. The signal at the Rst port is a scalar signal. When it is nonzero, the encoder resets before processing the data at the first input port.

## Signal Constellations

The trellis-coded modulation technique partitions the constellation into subsets called cosets, so as to maximize the minimum distance between pairs of points in each coset. This block internally forms a valid partition based on the value you choose for the $\mathbf{M}$-ary number parameter.

The figures below show the labeled set-partitioned signal constellations that the block uses when Mary number is 16,32 , and 64 . For constellations of other sizes, see Biglieri, E., D. Divsalar, P. J. McLane and M. K. Simon, Introduction to Trellis-Coded Modulation with Applications, New York, Macmillan, 1991.

## Coding Gains

Coding gains of 3 to 6 decibels, relative to the uncoded case can be achieved in the presence of AWGN with multiphase trellis codes. For more information, see Biglieri, E., D. Divsalar, P. J. McLane
and M. K. Simon, Introduction to Trellis-Coded Modulation with Applications, New York, Macmillan, 1991.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

## Operation mode

In Continuous mode (default setting), the block retains the encoder states at the end of each frame, for use with the next frame.

In Truncated (reset every frame) mode, the block treats each frame independently. I.e., the encoder states are reset to all-zeros state at the start of each frame.

In Terminate trellis by appending bits mode, the block treats each frame independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by $y=n \cdot(x+s) / k$, where $x$ is the number of input bits, and $s=$ constraint length -1 (or, in the case of multiple constraint lengths, $s=$ sum (ConstraintLength(i)-1)). The block supports this mode for column vector input signals.

In Reset on nonzero input via port mode, the block has an additional input port, labeled Rst. When the Rst input is nonzero, the encoder resets to the all-zeros state.

## M-ary number

The number of points in the signal constellation.

## Output data type

The output type of the block can be specified as a single or double. By default, the block sets this to double.

## Pair Block

Rectangular QAM TCM Decoder

## Rician Noise Generator

(To be removed) Generate Rician distributed noise

Note Rician Noise Generator will be removed in a future release. Use the MATLAB Function block and randn function instead.

## Library

Noise Generators sublibrary of Comm Sources

## Description

The Rician Noise Generator block generates Rician distributed noise. The Rician probability density function is given by

$$
f(x)=\left\{\begin{array}{cl}
\frac{x}{\sigma^{2}} I_{0}\left(\frac{m x}{\sigma^{2}}\right) \exp \left(-\frac{x^{2}+m^{2}}{2 \sigma^{2}}\right) & x \geq 0 \\
0 & x<0
\end{array}\right.
$$

where:

- $\sigma$ is the standard deviation of the Gaussian distribution that underlies the Rician distribution noise
- $\mathrm{m}^{2}=\mathrm{m}_{\mathrm{I}}{ }^{2}+\mathrm{m}_{\mathrm{Q}}{ }^{2}$, where $m_{\mathrm{I}}$ and $m_{\mathrm{Q}}$ are the mean values of two independent Gaussian components
- $I_{0}$ is the modified 0th-order Bessel function of the first kind given by

$$
I_{0}(y)=\frac{1}{2 \Pi} \int_{-\Pi}^{\Pi} e^{y \cos t} d t
$$

Note that $m$ and $\sigma$ are not the mean value and standard deviation for the Rician noise.
You must specify the Initial seed for the random number generator. When it is a constant, the resulting noise is repeatable. The vector length of the Initial seed parameter should equal the number of columns in a frame-based output or the number of elements in a sample-based output. The set of numerical parameters above the Initial seed parameter in the dialog box can consist of vectors having the same length as the Initial seed, or scalars.

## Initial Seed

The scalar Initial seed parameter initializes the random number generator that the block uses to generate its Rician-distributed complex random process. When multiple blocks in a model have the Initial seed parameter, you can choose different initial seeds for each block to ensure different random streams are used in each block. Set Initial seed to an integer value for repeatable results or use the randi function to randomize your results.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a samplebased one-dimensional array. These attributes are controlled by the Frame-based outputs, Samples
per frame, and Interpret vector parameters as 1-D parameters. See "Sources and Sinks" in Communications Toolbox User's Guide for more details.

The number of elements in the Initial seed and Sigma parameters becomes the number of columns in a frame-based output or the number of elements in a sample-based vector output. Also, the shape (row or column) of the Initial seed and Sigma parameters becomes the shape of a sample-based two-dimensional output signal.

## Parameters

## Specification method

Either K-factor or Quadrature components.

## Rician K-factor

$K=m^{2} /\left(2 \sigma^{2}\right)$, where $m$ is as in the Rician probability density function. This field appears only if Specification method is K-factor.

## In-phase component (mean), Quadrature component (mean)

The mean values $m_{I}$ and $m_{\mathrm{Q}}$, respectively, of the Gaussian components. These fields appear only if Specification method is Quadrature components.

## Sigma

The variable $\sigma$ in the Rician probability density function.

## Initial seed

The initial seed value for the random number generator.

## Sample time

The period of each sample-based vector or each row of a frame-based matrix.

## Frame-based outputs

Determines whether the output is frame-based or sample-based. This box is active only if Interpret vector parameters as 1-D is unchecked.
Samples per frame
The number of samples in each column of a frame-based output signal. This field is active only if Frame-based outputs is checked.

## Interpret vector parameters as 1-D

If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a twodimensional signal. This box is active only if Frame-based outputs is unchecked.

## Output data type

The output can be set to double or single data types.

## RLS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with RLS algorithm

Note will be removed in a future release. Use Decision Feedback Equalizer instead.

## Library

## Equalizers

## Description

The RLS Decision Feedback Equalizer block uses a decision feedback equalizer and the RLS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the RLS algorithm to update the weights, once per symbol. When you set the Number of samples per symbol parameter to 1 , the block implements a symbol-spaced equalizer and updates the filter weights once for each symbol. When you set the Number of samples per symbol parameter to a value greater than 1, the weights are updated once every $N^{\text {th }}$ sample, for a fractionally spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of forward taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+($ Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

## Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

## Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of forward taps in the equalizer.

## Forgetting factor

The forgetting factor of the RLS algorithm, a number between 0 and 1.

## Inverse correlation matrix

The initial value for the inverse correlation matrix. The matrix must be N -by- N , where N is the total number of forward and feedback taps.

## Initial weights

A vector that concatenates the initial weights for the forward and feedback taps.

## Mode input port

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0 . For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

## Output error

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

When you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## RLS Linear Equalizer

(To be removed) Equalize using linear equalizer that updates weights using RLS algorithm

Note will be removed in a future release. Use Linear Equalizer instead.

## Library

## Equalizers

## Description

The RLS Linear Equalizer block uses a linear equalizer and the RLS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the RLS algorithm to update the weights, once per symbol. When you set the Number of samples per symbol parameter to 1 , then the block implements a symbol-spaced (i.e. T-spaced) equalizer and updates the filter weights once for each symbol. When you set the Number of samples per symbol parameter to a value greater than 1 , the block updates the weights once every $N^{\text {th }}$ sample, for a fractionally spaced (i.e. $\mathrm{T} / \mathrm{N}$-spaced) equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to

1+(Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap.

## Parameters

## Number of taps

The number of taps in the filter of the linear equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of taps in the equalizer.

## Forgetting factor

The forgetting factor of the RLS algorithm, a number between 0 and 1.

## Inverse correlation matrix

The initial value for the inverse correlation matrix. The matrix must be N -by- N , where N is the number of taps.

## Initial weights

A vector that lists the initial weights for the taps.

## Mode input port

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, and for decision directed, the mode must be 0 . For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

## Output error

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

When you select this check box, the block outputs the current weights.

## Scrambler

Scramble input signal

## Library: Communications Toolbox / Sequence Operations

## Description

The Scrambler block scrambles a scalar or column vector input signal.
One purpose of scrambling is to reduce the length of consecutive 0 s or 1 s in a transmitted signal.
Long sequences of 0 s or 1 s can cause transmission synchronization problems. This schematic shows the scrambler operation. All adders perform addition modulo $N$, where $N$ is the value specified by the Calculation base parameter.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Scramble polynomial parameter, you specify the on or off state for each switch in the scrambler.

To achieve repeatable initial scrambler conditions, you can use one of these optional input ports:

- Select the Reset on nonzero input via port parameter and reset the scrambler with Rst.
- Set the Initial states source parameter to Input port and provide the initial states with ISt.

This block can accept input sequences that vary in length during simulation. For more information about sequences that vary in length, see Variable-Size Signal Basics (Simulink).

## Ports

## Input

## in - Input data signal

vector
Input data signal, specified as an $N_{\mathrm{S}}$-by-1 vector. $N_{\mathrm{S}}$ represents the number of samples in the input signal. The input values must be integers from 0 to Calculation base - 1 .
Data Types: double

## Rst - Reset scrambler

scalar
Reset scrambler, specified as a scalar. The scrambler is reset if a nonzero input is applied to the port.

## Dependencies

To enable this port, set Initial states source to Dialog Parameter and select Reset on nonzero input via port.

## ISt - Initial states

vector
Initial states of the scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of ISt must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1 .

## Dependencies

To enable this port, set Initial states source to Input port.

## Output

## Out1 - Output scrambled data

vector
Output scrambled data, returned as an $N_{\mathrm{S}}$-by-1 vector. $N_{\mathrm{S}}$ equals the number of samples in the input signal.
Data Types: double

## Parameters

## Calculation base - Calculation base

4 (default) | nonnegative integer
Calculation base used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this block are integers from 0 to Calculation base - 1 .

## Scramble polynomial - Polynomial that defines connections in scrambler <br> ' $1+z^{\wedge}-1+z^{\wedge}-2+z^{\wedge}-4$ ' (default) $\mid$ character vector $\mid$ integer vector $\mid$ binary vector

Polynomial that defines the connections in the scrambler, specified as a character vector, integer vector, or binary vector. The Scramble polynomial parameter defines if each switch in the scrambler is on or off. Specify the polynomial as:

- A character vector, such as ' $1+z^{\wedge}-6+z^{\wedge}-8$ '. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0-6-8], listing the descrambler coefficients in order of descending powers of $z^{-1}$, where $p\left(z^{-1}\right)=1+p_{1} z^{-1}+p_{2} z^{-2}+\ldots$
- A binary vector, such as [ $\left.\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0\end{array}\right]$ ], listing the powers of $z$ that appear in the polynomial that has a coefficient of 1 . In this case, the order of the scramble polynomial is one less than the binary vector length.

polynomial:
$p\left(z^{-1}\right)=1+z^{-6}+z^{-8}$

## Initial states source - Set the source for scrambler initial states <br> Dialog Parameter (default)|Input port

- Dialog Parameter - Specify scrambler initial states by using the Initial states parameter.
- Input port - Specify scrambler initial states by using the ISt port.

## Initial states - Initial states of scrambler registers

[0 1223 3] (default)| nonnegative integer vector
Initial states of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of Initial states must equal the order of the Scramble polynomial parameter. The vector element values must be integers from 0 to Calculation base - 1 .

## Dependencies

This parameter is available when Initial states source is set to Dialog Parameter.

## Reset on nonzero input via port - Reset scrambler via input port

 off (default) | onSelect this parameter to reset the Scrambler block via input port Rst.

## Dependencies

This parameter is available when Initial states source is set to Dialog Parameter.

## Sign LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with signed LMS algorithm

Note will be removed in a future release. Consider using Decision Feedback Equalizer instead.

## Library

## Equalizers

## Description

The Sign LMS Decision Feedback Equalizer block uses a decision feedback equalizer and an algorithm from the family of signed LMS algorithms to equalize a linearly modulated baseband signal through a dispersive channel.

The supported algorithms, corresponding to the Update algorithm parameter, are

- Sign LMS
- Sign Regressor LMS
- Sign Sign LMS

During the simulation, the block uses the particular signed LMS algorithm to update the weights, once per symbol. If the Number of samples per symbol parameter is 1 , then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of forward taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+($ Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

## Update algorithm

The specific type of signed LMS algorithm that the block uses to update the equalizer weights.

## Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

## Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

- When you set this parameter to 1 , the filter weights are updated once for each symbol, for a symbol spaced (i.e. T-spaced) equalizer.
- When you set this parameter to a value greater than 1 , the weights are updated once every $N^{\text {th }}$ sample, for a T/N-spaced equalizer.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of forward taps in the equalizer.

## Step size

The step size of the signed LMS algorithm.

## Leakage factor

The leakage factor of the signed LMS algorithm, a number between 0 and 1 . A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Initial weights

A vector that concatenates the initial weights for the forward and feedback taps.

## Mode input port

When you select this check box, the block has an input port that allows you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision directed, the mode should be 0 . For every frame in which the mode input is 1 or not present, the equalizer trains at the beginning of the frame for the length of the desired signal.

## Output error

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

When you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## SISO Fading Channel

Filter input signal through SISO multipath fading channel
Library: Communications Toolbox / Channels

## Description

The SISO Fading Channel block filters an input signal using a single-input/single-output (SISO) multipath fading channel. This block models both Rayleigh and Rician fading. For processing details, see the Algorithms on page 5-775 section.

## Ports

Input
in - Input data signal
vector
Input data signal, specified as an $N_{\mathrm{S}}$-by-1 vector. $N_{\mathrm{S}}$ represents the number of samples in the input signal.
Data Types: double | single
Complex Number Support: Yes

## Output

## Out1 - Output data signal for fading channel

vector
Output data signal for the fading channel, returned as an $N_{\mathrm{S}}$-by-1 vector. $N_{\mathrm{S}}$ represents the number of samples in the input signal.

## Gain - Discrete path gains

matrix
Discrete path gains of the underlying fading process, returned as an $N_{\mathrm{S}}$-by- $N_{\mathrm{P}}$ matrix.

- $N_{\mathrm{S}}$ represents the number of samples in the input signal.
- $N_{\mathrm{P}}$ represents the number of channel paths.

## Dependencies

To enable this port, on the Main tab, select Output channel path gains.

## Delay - Channel filter delay

scalar
Channel filter delay, returned as a scalar.

## Dependencies

To enable this port, on the Main tab, select Output channel filter delay.

## Parameters

## Main Tab

Multipath parameters (frequency selectivity)
Inherit sample rate from input - Option to inherit the sample rate from input on (default) | off

Select this parameter to use the sample rate of the input signal when processing. When Inherit sample rate from input is selected, the sample rate is $N_{\mathrm{S}} / T_{\mathrm{S}}$, where $N_{\mathrm{S}}$ is the number of input samples, and $T_{\mathrm{S}}$ is the model sample time.

## Sample rate ( Hz ) - Input signal sample rate

1 (default) | positive scalar
Input signal sample rate in hertz, specified as a positive scalar. To match the model settings, set the sample rate to $N_{\mathrm{S}} / T_{\mathrm{S}}$, where $N_{\mathrm{S}}$ is the number of input samples, and $T_{\mathrm{S}}$ is the model sample time.

## Dependencies

This parameter appears when Inherit sample rate from input is not selected.

## Data Types: double

## Discrete path delays (s) - Delays for each discrete path

0 (default) | nonnegative scalar | row vector
Delays for each discrete path in seconds, specified as a nonnegative scalar or row vector.

- When you set Discrete path delays (s) to a scalar, the SISO channel is frequency flat.
- When you set Discrete path delays (s) to a vector, the SISO channel is frequency selective.

Data Types: double
Average path gains (dB) - Average gain for each discrete path
0 (default) | scalar | row vector
Average gain for each discrete path in decibels, specified as a scalar or row vector. Average path gains (dB) must have the same size as Discrete path delays (s).
Data Types: double
Normalize average path gains to 0 dB - Option to normalize average path gains to 0 dB
on (default) | off
Select this parameter to normalize the fading processes so that the total power of the path gains, averaged over time, is 0 dB .

Fading distribution - Fading distribution of channel
Rayleigh (default)|Rician

Select the fading distribution of the channel, either Rayleigh or Rician.

## K-factors - K-factor of Rician fading channel

3 (default) | positive scalar | row vector of nonnegative values
K-factor of a Rician fading channel, specified as a positive scalar or a 1 -by- $N_{\mathrm{P}}$ vector of nonnegative values. $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

- If you set K-factors to a scalar, the first discrete path is a Rician fading process with a Rician Kfactor of K-factors. Any remaining discrete paths are independent Rayleigh fading processes.
- If you set K-factors to a row vector, the discrete path corresponding to a positive element of the K-factors vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to any zero-valued elements of the K-factors vector are Rayleigh fading processes. At least one element value must be nonzero.

## Dependencies

This parameter appears when Fading distribution is Rician.
Data Types: double
LOS path Doppler shifts ( Hz ) - Doppler shifts for line-of-sight components
0 (default) | scalar | row vector
Doppler shifts for the line-of-sight components of the Rician fading channel in hertz, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set LOS path Doppler shifts (Hz) to a scalar, it represents the line-of-sight component Doppler shift of the first discrete path that is a Rician fading process.
- If you set LOS path Doppler shifts (Hz) to a row vector, the discrete path that is a Rician fading process has its line-of-sight component Doppler shift specified by the elements of LOS path Doppler shifts (Hz) that correspond to positive elements in the K-factors vector.

## Dependencies

This parameter appears when Fading distribution is Rician.

## Data Types: double

LOS path initial phases (rad) - Initial phases for line-of-sight components
0 (default) | scalar | row vector
Initial phases for the line-of-sight component of the Rician fading channel in radians, specified as a scalar or row vector. This parameter must have the same size as K-factors.

- If you set LOS path initial phases (rad) to a scalar, it is the line-of-sight component initial phase of the first discrete path that is a Rician fading process.
- If you set LOS path initial phases (rad) to a row vector, the discrete path that is a Rician fading process has its line-of-sight component initial phase specified by the elements of LOS path initial phases (rad) that correspond to positive elements in the K-factors vector.

## Dependencies

This parameter appears when Fading distribution is Rician.
Data Types: double

## Doppler parameters (time dispersion)

## Maximum Doppler shift (Hz) - Maximum Doppler shift for all channel paths <br> 0.001 (default)|nonnegative scalar

Maximum Doppler shift for all channel paths in hertz, specified as a nonnegative scalar.
Maximum Doppler shift (Hz) must be smaller than $\left(f_{s} / 10\right) / f_{c}$ for each path. $f_{\mathrm{s}}$ is the sampling rate at the input to the SISO Fading Channel block. $f_{c}$ is the cutoff frequency factor of the path. For more information, see Cutoff Frequency Factor on page 5-526.
Data Types: double
Doppler spectrum - Doppler spectrum shape for all channel paths
doppler('Jakes') (default)|doppler('Flat')|doppler('Rounded', ...)|
doppler('Bell', ...) |doppler('Asymmetric Jakes', ...)|doppler('Restricted
Jakes', ...)|doppler('Gaussian', ...)|doppler('BiGaussian', ...)
Doppler spectrum shape for all channel paths, specified as a single Doppler spectrum structure returned from the doppler function or a 1-by- $N_{P}$ cell array of such structures. The default value of this parameter is the Jakes Doppler spectrum (doppler('Jakes ')).

- If you assign a single call to doppler, all paths have the same specified Doppler spectrum.
- If you assign a 1-by- $N_{P}$ cell array of calls to doppler using any of the specified syntaxes, each path has the Doppler spectrum specified by the corresponding Doppler spectrum structure in the array. In this case, $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

## Dependencies

This parameter applies when Maximum Doppler shift ( Hz ) is greater than zero.

## Other parameters

## Initial seed - Random number generator initial seed

73 (default) | nonnegative integer
Random number generator initial seed for this block, specified as a nonnegative integer.

## Output channel path gains - Option to output channel path gains off (default) | on

Select this parameter to add the Gain output port to the block and output the channel path gains of the underlying fading process.

## Output channel filter delay - Option to output channel filter delay off (default) | on

Select this parameter to add the Delay output port to the block and output the channel filter delay of the underlying fading process.

## Simulate using - Compilation type

Interpreted execution (default)|Code generation
Compilation type, specified as Interpreted execution or Code generation.

- Interpreted execution - Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.
- Code generation - Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

## Visualization Tab

## Channel visualization - Select the channel visualization

Off (default)| Impulse response|Frequency response|Doppler spectrum|Impulse and frequency responses

Select the channel visualization: Off, Impulse response, Frequency response, Doppler spectrum, or Impulse and frequency responses. When visualization is on, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see Channel Visualization.

## Percentage of samples to display - Percentage of samples to display 25\% (default) | 10\% | 50\% | 100\%

Select the percentage of samples to display: $10 \%, 25 \%, 50 \%$, or $100 \%$. Increasing the percentage improves display accuracy at the expense of simulation speed.

## Dependencies

This parameter appears when Channel visualization is Impulse response, Frequency response, or Impulse and frequency responses.

## Path for Doppler spectrum display - Path for which Doppler spectrum is displayed 1 (default) | positive integer

Path for which the Doppler spectrum is displayed, specified as a positive integer from 1 to $N_{\mathrm{P}}$, where $N_{\mathrm{P}}$ equals the value of the Discrete path delays (s) parameter.

## Dependencies

This parameter appears when Channel visualization is Doppler spectrum.

## Block Characteristics

| Data Types | double $\mid$ single |
| :--- | :--- |
| Multidimensional <br> Signals | yes |
| Variable-Size Signals | yes |

## Algorithms

The fading process for the SISO channel is described in Methodology for Simulating Multipath Fading Channels.

## Cutoff Frequency Factor

The cutoff frequency factor, $f_{\mathrm{c}}$, is determined for different Doppler spectrum types.

- For any Doppler spectrum type other than Gaussian and biGaussian, $f_{c}$ equals 1.
- For a doppler('Gaussian') spectrum type, $f_{c}$ equals NormalizedStandardDeviation $\times \sqrt{2 \log 2}$.
- For a doppler('BiGaussian') spectrum type:
- If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation (1) $\times \sqrt{2 \log 2}$.
- If the PowerGains (2) and NormalizedCenterFrequencies (1) field values are both 0, then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation $(2) \times \sqrt{2 \log 2}$.
- If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then $f_{\mathrm{c}}$ equals NormalizedStandardDeviation(1) $\times \sqrt{2 \log 2}$.
- In all other cases, $f_{\mathrm{c}}$ equals 1.

## Sphere Decoder

Decode input using a sphere decoder

## Library

MIMO

## Description

This block decodes the symbols sent over Nt antennas using the sphere decoding algorithm.

## Data Type

For information about the data types each block port supports, see the "Supported Data Type" on page 5-779 table on this page. The output signal inherits the data type from the inputs.

## Algorithm

This block implements the algorithm, inputs, and outputs described on the comm. SphereDecoder System object block reference page. The object properties correspond to the block parameters.

## Parameters

## Signal constellation

Specify the number of points in the signal constellation to which the bits are mapped. This value must be a complex column vector. The length of the vector must be a power of two. The block uses the same constellation for each transmit antenna. The default setting is a QPSK constellation with an average power of 1 .

## Bit mapping per constellation point

Specify the bit mapping that the block uses for each constellation point. This value must be a numerical matrix. he matrix size must be [ConstellationLength bitsPerSymbol], where ConstellationLength represents the length of the Signal constellation parameter value and bitsPerSymbol represents the number of bits that each symbol encodes. The default matrix size is [00; $01 ; 10 ; 11$ ], which matches the default value of the Signal constellation property.

## Initial search radius

Specify the initial search radius for the decoding algorithm as Infinity or ZF solution.
When you select Infinity, the block sets the initial search radius to Inf. When you select ZF solution, the block 'sets the initial search radius to the zero-forcing solution. The zero-forcing solution is calculated by the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the ZF Solution will not provide a benefit.

## Decision method

Specify the decoding decision method as Soft or Hard. When you select Soft the block outputs log-likelihood ratios (LLRs), or soft bits. When you select set to Hard, the block converts the soft LLRs to bits. The hard decision output logical array follows the mapping of a 0 for a negative LLR and 1 for all other values.

## Simulation using

Specify if the block simulates using Code generation or Interpreted execution. The default is Interpreted execution.

## Supported Data Type

| Port | Supported Data Types |
| :--- | :--- |
| Rx | $\bullet$ Double-precision floating point |
| cEst | $\bullet$ Double-precision floating point |
| Output | $\bullet$ Double-precision floating point |
|  | $\bullet$ Boolean (Hard-decision method) |

## Limitations

- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

## Algorithms

This block implements the algorithm, inputs, and outputs described on the Sphere Decoder System object reference page. The object properties correspond to the block parameters.

# SSB AM Demodulator Passband 

Demodulate SSB-AM-modulated data

## Library

Analog Passband Modulation, in Modulation

## Description

The SSB AM Demodulator Passband block demodulates a signal that was modulated using singlesideband amplitude modulation. The input is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Carrier frequency (Hz)

The carrier frequency in the corresponding SSB AM Modulator Passband block.

## Initial phase (rad)

The phase offset, $\theta$, of the modulated signal.

## Lowpass filter design method

The method used to generate the filter. Available methods are Butterworth, Chebyshev type I, Chebyshev type II, and Elliptic.

## Filter order

The order of the lowpass digital filter specified in the Lowpass filter design method field .

## Cutoff frequency

The cutoff frequency of the lowpass digital filter specified in the Lowpass filter design method field in Hertz.

## Passband ripple

Applies to Chebyshev type I and Elliptic filters only. This is peak-to-peak ripple in the passband in dB.

## Stopband ripple

Applies to Chebyshev type II and Elliptic filters only. This is the peak-to-peak ripple in the stopband in dB .

## Pair Block

## SSB AM Modulator Passband

Modulate using single-sideband amplitude modulation

## Library

Analog Passband Modulation, in Modulation

## Description

The SSB AM Modulator Passband block modulates using single-sideband amplitude modulation with a Hilbert transform filter. The output is a passband representation of the modulated signal. Both the input and output signals are real scalar signals.

SSB AM Modulator Passband transmits either the lower or upper sideband signal, but not both. To control which sideband it transmits, use the Sideband to modulate parameter.

If the input is $u(t)$ as a function of time $t$, then the output is

$$
u(t) \cos \left(f_{c} t+\theta\right) \mp \widehat{u}(t) \sin \left(f_{c} t+\theta\right)
$$

where:

- $f_{\mathrm{c}}$ is the Carrier frequency parameter.
- $\theta$ is the Initial phase parameter.
- $\hat{u}(t)$ is the Hilbert transform of the input $u(t)$.
- The minus sign indicates the upper sideband and the plus sign indicates the lower sideband.

## Hilbert Transform Filter

This block uses the Analytic Signal block from the DSP System Toolbox Transforms block library.
The Analytic Signal block computes the complex analytic signal corresponding to each channel of the real M-by-N input, u

$$
y=u+j H\{u\}
$$

where $j=\sqrt{-1}$ and $H\}$ denotes the Hilbert transform. The real part of the output in each channel is a replica of the real input in that channel; the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal retains the positive frequency content of the original signal while zeroing-out negative frequencies and doubling the DC component.

The block computes the Hilbert transform using an equiripple FIR filter with the order specified by the Filter order parameter, n . The linear phase filter is designed using the Remez exchange algorithm, and imposes a delay of $n / 2$ on the input samples.

For best results, use a carrier frequency which is estimated to be larger than $10 \%$ of your input signal's sample rate. This is due to the implementation of the Hilbert transform by means of a filter.

In the following example, we sample a 10 Hz input signal at 8000 samples per second. We then designate a Hilbert Transform filter of order 100. Below is the response of the Hilbert Transform filter as returned by fvtool.

Note the bandwidth of the filter's magnitude response. By choosing a carrier frequency larger than $10 \%$ (but less than $90 \%$ ) of the input signal's sample time ( 8000 samples per second, in this example) or equivalently, a carrier frequency larger than 400 Hz , we ensure that the Hilbert Transform Filter will be operating in the flat section of the filter's magnitude response (shown in blue), and that our modulated signal will have the desired magnitude and form.

Typically, an appropriate Carrier frequency value is much higher than the highest frequency of the input signal. By the Nyquist sampling theorem, the reciprocal of the model's sample time (defined by the model's signal source) must exceed twice the Carrier frequency parameter.

This block works only with real inputs of type double. This block does not work inside a triggered subsystem.

## Parameters

## Carrier frequency (Hz)

The frequency of the carrier.

## Initial phase (rad)

The phase offset, $\theta$, of the modulated signal.

## Sideband to modulate

This parameter specifies whether to transmit the upper or lower sideband.

Hilbert Transform filter order
The length of the FIR filter used to compute the Hilbert transform.

## Symbol Synchronizer

Correct symbol timing clock skew
Library: Communications Toolbox / Synchronization

## Description

The Symbol Synchronizer block corrects symbol timing clock skew for PAM, PSK, QAM, or OQPSK modulation schemes between a single-carrier transmitter and receiver. For more information, see "Symbol Synchronization Overview" on page 5-787.

Note The input signal operates on a sample rate basis, while the output signal operates on a symbol rate basis.

## Ports

Input

## samples - Input samples

scalar (default) | column vector
Input samples, specified as a scalar or column vector of a PAM, PSK, QAM, or OQPSK modulated single-carrier signal. This port in unnamed on the block.

Data Types: double | single
Complex Number Support: Yes

## Output

Sym - Output signal symbols
scalar | column vector
Output signal symbols, returned as a variable-size scalar or column vector that has the same data type as the input. For an input with dimensions of $N_{\text {samp }}$-by-1, the output at Sym has dimensions of $N_{\text {sym }}$-by-1. $N_{\text {sym }}$ is approximately equal to $N_{\text {samp }}$ divided by the $N_{\text {sps }} . N_{\text {sps }}$ is equal to the Samples per symbol parameter. If the output exceeds the maximum output size of $\left\lceil\frac{N_{\text {samp }}}{N_{\mathrm{sps}}} \times 1.1\right\rceil$, it is truncated.

This port is unnamed when Normalized timing error output port is not selected.

## Err - Estimated timing error

scalar | column vector
Estimated timing error for each input sample, returned as a scalar or column vector with values in the range $[0,1]$. The estimated timing error is normalized by the input sample time. Err has the same data type and size as the input signal.

## Dependencies

To enable this port, select Normalized timing error output port.

## Parameters

Modulation type - Modulation type
PAM/PSK/QAM (default) | OQPSK
Modulation type, specified as PAM/PSK/QAM, or OQPSK.
Timing error detector - Type of timing error detector
Zero-Crossing (decision-directed) (default)|Gardner (non-data-aided)|Early-Late (non-data-aided)|Mueller-Muller (decision-directed)

Type of timing error detector, specified as Zero-Crossing (decision-directed), Gardner (non-data-aided), Early-Late (non-data-aided), or Mueller-Muller (decisiondirected). This parameter assigns the timing error detection scheme used in the synchronizer.

For more information, see "Timing Error Detection (TED)" on page 5-788.

## Samples per symbol - Samples per symbol

2 (default) | positive integer greater than 1
Samples per symbol, specified as a positive integer greater than 1.
Data Types: double

## Damping factor - Damping factor of the loop filter

1 (default) | positive scalar
Damping factor of the loop filter, specified as a positive scalar. For more information, see "Loop Filter" on page 5-791.

Tunable: Yes
Data Types: double | single

## Normalized loop bandwidth - Normalized bandwidth of loop filter

0.01 (default) | positive scalar less than 1

Normalized bandwidth of the loop filter, specified as a positive scalar less than 1. The loop bandwidth is normalized by the sample rate of the input signal. For more information, see "Loop Filter" on page 5-791.

Note To ensure that the symbol synchronizer locks, set the Normalized loop bandwidth parameter to a value less than 0.1.

Tunable: Yes
Data Types: double | single
Detector gain - Phase detector gain
2.7 (default) | positive scalar

Phase detector gain, specified as a positive scalar.
Tunable: Yes
Data Types: double | single
Normalized timing error output port - Enable normalized timing error output port on (default) | off

Select this parameter to output normalized timing error data at the output port Err.

## Simulate using - Type of simulation to run

Code generation (default)|Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Block Characteristics

| Data Types | double \\| single |
| :--- | :--- |
| Multidimensional <br> Signals | no |
| Variable-Size Signals | yes |

## More About

## Symbol Synchronization Overview

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:

- A timing error detector (TED)
- An interpolator
- An interpolation controller
- A loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on $\chi(t)$, the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal, $\chi\left(k T_{\mathrm{s}}+\widehat{\tau}\right)$, after correcting for the clock skew between the transmitter and receiver.

## Timing Error Detection (TED)

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.

| TED Method | Expression |
| :---: | :---: |
| Zero- <br> crossing (decisiondirected) | $e(k)=x\left((k-1 / 2) T_{s}+\widehat{\tau}\right)\left[\widehat{a}_{0}(k-1)-\widehat{a}_{0}(k)\right]+y\left((k-1 / 2) T_{s}+\widehat{\tau}\right)\left[\widehat{a}_{1}(k-1)-\widehat{a}_{1}(k)\right]$ |
| Gardner (non-dataaided) | $\begin{aligned} & e(k)=x\left((k-1 / 2) T_{S}+\widehat{\tau}\right)\left[x\left((k-1) T_{S}+\widehat{\tau}\right)-x\left(k T_{S}+\widehat{\tau}\right)\right] \\ & +y\left((k-1 / 2) T_{S}+\widehat{\tau}\right)\left[y\left((k-1) T_{S}+\widehat{\tau}\right)-y\left(k T_{S}+\widehat{\tau}\right)\right] \end{aligned}$ |
| Early-late (non-dataaided) | $\begin{aligned} & e(k)=x\left(k T_{S}+\widehat{\tau}\right)\left[x\left((k+1 / 2) T_{S}+\widehat{\tau}\right)-x\left((k-1 / 2) T_{S}+\widehat{\tau}\right)\right]+y\left(k T_{S}+\widehat{\tau}\right. \\ & )\left[y\left((k+1 / 2) T_{S}+\widehat{\tau}\right)-y\left((k-1 / 2) T_{S}+\widehat{\tau}\right)\right] \end{aligned}$ |
| MuellerMuller (decisiondirected) | $e(k)=\widehat{a}_{0}(k-1) x\left(k T_{s}+\widehat{\tau}\right)-\widehat{a}_{0}(k) x\left((k-1) T_{s}+\widehat{\tau}\right)+\widehat{a}_{1}(k-1) y\left(k T_{s}+\widehat{\tau}\right)-\widehat{a}_{1}(k) y\left((k-1) T_{S}+\widehat{\tau}\right)$ |

Non-data-aided TED uses received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at $\{1+0 i, 0+1 i,-1+0 i, 0-1 i\}$ and BPSK-modulated signals with a zero phase offset.

- Gardner method - The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately $40 \%$ and $100 \%$. Examples include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1 . In the presence of noise, the
performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.
- Early-late method - The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

The early-late method is similar to the Gardner method. The Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

Decision-directed TED uses the sign function to estimate the in-phase and quadrature components of received samples, which result in lower computational complexity than non-data-aided TED.

- Zero-crossing method - The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6 ].
- Mueller-Muller method - The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component. $x\left(k T_{\mathrm{s}}+\widehat{\tau}\right)$ and $y\left(k T_{\mathrm{s}}+\widehat{\tau}\right)$ are the in-phase and quadrature components of the input signals to the timing error detector, where $\widehat{\tau}$ is the estimated timing error. The Mueller-Muller method coefficients $\widehat{a}_{0}(k)$ and $\widehat{a}_{1}(k)$ are the estimates of $x\left(k T_{\mathrm{s}}+\widehat{\tau}\right)$ and $y\left(k T_{\mathrm{s}}+\widehat{\tau}\right)$. The timing estimates are made by applying the sign function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

## Interpolator

The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.

The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient $\alpha$ set to 1/2 (see Rice, Michael, Digital Communications: A Discrete-Time Approach).

## Interpolation Control

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.

Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

## Loop Filter

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain, $K_{1}$, and the integrator gain, $K_{2}$, are calculated by

$$
K_{1}=\frac{-4 \zeta \theta}{\left(1+2 \zeta \theta+\theta^{2}\right) K_{p}}
$$

and

$$
K_{2}=\frac{-4 \theta^{2}}{\left(1+2 \zeta \theta+\theta^{2}\right) K_{p}} .
$$

The interim term, $\theta$, is given by

$$
\theta=\frac{\frac{B_{n} T_{s}}{N}}{\zeta+\frac{1}{4 \zeta}},
$$

where:

- $N$ is the number of samples per symbol.
- $\zeta$ is the damping factor.
- $B_{n} T_{\mathrm{s}}$ is the normalized loop bandwidth.
- $K_{\mathrm{p}}$ is the detector gain.

## Description

The TPC Decoder block performs 2-D turbo product code (TPC) decoding of the soft input LLRs corresponding to the product code iteratively, using Chase-Pyndiah algorithm. The product code is a 2-D concatenation of linear block codes. The linear block code can be a parity check code, a Hamming code, or a BCH code capable of correcting two errors. Extended and shortened codes can be applied independently on each dimension. For a description of 2-D TPC decoding, see "Algorithms" on page 5-797.

For information about valid code pairs and the error-correcting capability for each valid code pair, see "Component Code Pairs" on page 5-796.

## Ports

## Input

## In - Log likelihood ratios

column vector
Log likelihood ratios, specified as a column vector.

- For full-length input messages, the length of the column vector is the product of Number of rows in code, Nr and Number of columns in code, Nc.
- For shortened input messages, the length of the column vector is the product of $\left(N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}\right)$ and $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$, where:
- $N_{\mathrm{R}}$ is the value of Number of rows in code, Nr .
- $K_{\mathrm{R}}$ is the value of Number of rows in message, Kr .
- $S_{\mathrm{R}}$ is the value of Number of rows in shortened message, Sr .
- $N_{\mathrm{C}}$ is the value of Number of columns in code, Nc.
- $K_{\mathrm{C}}$ is the value of Number of columns in message, Kc.
- $S_{\mathrm{C}}$ is the value of Number of columns in shortened message, Sc.

## Data Types: double | single

## Output

Out - TPC decoded message
column vector
TPC decoded message, returned as a column vector of binary values.

- For full-length input messages, the length of the column vector is the product of Number of rows in message, Kr and Number of columns in message, Kc.
- For shortened input messages, the length of the column vector is the product of Number of rows in shortened message, Sr and Number of columns in shortened message, Sc.

Data Types: Boolean

## Iter - Actual number of decoding iterations

positive integer
Actual number of decoding iterations, returned as a positive integer.

## Dependencies

To enable this port, select Output number of itereations executed.
Data Types: double

## Parameters

## Row TPC parameters

## Extended codes - Extended codes indicator for TPC row parameters on (default) | off

- When Extended codes is selected, the lists for Number of rows in code, Nr and Number of rows in message, Kr contain the valid values for extended individual code pairs ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ).
- When Extended codes is cleared, the lists for Number of rows in code, Nr and Number of rows in message, Kr contain the valid values for nonextended individual code pairs ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ).

Number of rows in code, Nr - Number of rows in product code matrix 16 (default) | integer

Number of rows in the product code matrix, $N_{\mathrm{R}}$. The list of integer values varies depending on the setting for Extended codes.

## Number of rows in message, Kr - Number of rows in message matrix

11 (default) | integer
Number of rows in the message matrix, $K_{\mathrm{R}}$. The list of integer values varies depending on the setting for Extended codes and Number of rows in code, Nr.

## Specify shortened message length - Specify shortened message length for rows off (default) | on

Select Specify shortened message length to specify a value for Number of rows in shortened message, Sr.

## Number of rows in shortened message, Sr - Number of rows in shortened message matrix <br> 9 (default) | integer

Number of rows in the shortened message matrix, $S_{R}$, specified as an integer less than or equal to $K_{R}$. When you specify this parameter, provide full-length $N_{\mathrm{R}}$ and $K_{\mathrm{R}}$ values to specify the ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. This code pair is then shortened to the ( $N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}, S_{\mathrm{R}}$ ) code pair, where:

- $\quad N_{\mathrm{R}}$ is the value of Number of rows in code, Nr.
- $K_{\mathrm{R}}$ is the value of Number of rows in message, Kr.
- $S_{\mathrm{R}}$ is the value of Number of rows in shortened message, Sr .

## Dependencies

To enable this parameter, select Specify shortened message length.
Data Types: double
Column TPC parameters

## Extended codes - Extended codes indicator for TPC column parameters on (default) |off

- When Extended codes is selected, the lists for Number of columns in code, Nc and Number of columns in message, Kc contain the valid values for extended individual code pairs ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ).
- When Extended codes is cleared, the lists for Number of columns in code, Nc and Number of columns in message, Kc contain the valid values for nonextended individual code pairs ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ).

## Number of columns in code, Nc - Number of columns in product code matrix 32 (default) | integer

Number of columns in the product code matrix, $N_{\mathrm{C}}$. The list of integer values varies depending on the setting for Extended codes.

## Number of columns in message, Kc - Number of columns in message matrix 26 (default) | integer

Number of columns in the message matrix, $K_{C}$. The list of integer values varies depending on the setting for Extended codes and Number of columns in code, Nc.

## Specify shortened message length - Specify shortened message length for columns off (default) | on

Select Specify shortened message length to specify a value for Number of columns in shortened message, Sc.

Number of columns in shortened message, Sc-Number of columns in shortened message matrix
22 (default) | integer
Number of columns in the shortened message matrix, $S_{C}$, specified as an integer. When you specify this parameter, provide full-length $N_{\mathrm{C}}$ and $K_{\mathrm{C}}$ values to specify the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair. This code pair is then shortened to the $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}, S_{\mathrm{C}}\right)$ code pair, where:

- $N_{\mathrm{C}}$ is the value of Number of columns in code, Nc.
- $K_{C}$ is the value of Number of columns in message, Kc.
- $S_{\mathrm{C}}$ is the value of Number of columns in shortened message, Sc.

## Dependencies

To enable this parameter, select Specify shortened message length.
Data Types: double

## Maximum number of iterations - Maximum number of decoding iterations 4 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.
Data Types: double
Stop iterating when code converges - Stop decoding based on the calculated syndrome or parity-check of the component code
on (default) | off
Select Stop iterating when code converges to terminate decoding early if the calculated syndrome or parity-check of the component code evaluates to zero before Maximum number of iterations.

## Output number of iterations executed - Output number of iterations executed off (default) | on

Select this parameter to add the Iter output port and output the actual number of TPC decoding iterations performed.

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Component Code Pairs

This table lists the supported component code pairs for the row ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) and column ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) parameters.

- $N_{\mathrm{R}}$ and $K_{\mathrm{R}}$ represent the number of rows in the product code matrix and message matrix, respectively.
- $N_{\mathrm{C}}$ and $K_{\mathrm{C}}$ represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

| Code type | $\begin{array}{\|l} \hline \text { Component Code Pairs }\left(N_{\mathrm{R}}, K_{\mathrm{R}}\right) \\ \text { and }\left(N_{\mathrm{C}}, K_{\mathrm{C}}\right) \end{array}$ | Error-Correction Capability (T) |

## Algorithms

Turbo product codes (TPC) are a form of concatenated codes used as forward error correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. For a
detailed description, see [1] and [2]. This decoder implements an iterative soft input, soft output 2-D product code decoding, as described in [2], using two "Linear Block Codes". The decoder expects the soft bit log likelihood ratios (LLRs) obtained from digital demodulation as the input signal.

## TPC Decoding Full-Length Messages

TPC encoded full-length input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair and column-wise decoding uses the ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. The input vector length must be $N_{\mathrm{R}} \times N_{\mathrm{C}}$. To perform the 2-D TPC decoding, the column vector of the input LLRs, composed of the message and parity bits, is arranged into an $N_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix.

The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. Chase decoding forms a set of possible codewords for each row or column. The Pyndiah algorithm calculates soft information required for the next decoding step.

## Iterative Soft Input, Soft Output Decoder

The iterative soft input, soft output decoding, as shown in the block diagram, carries out two decoding steps for each iteration.

The soft inputs for decoding are $\boldsymbol{R}(m)=\boldsymbol{R}+\alpha(m) \boldsymbol{W}(m)$.

- Iteration loop counter $i$ increments from $i=1$ to the specified number of iterations.
- $m=2 i-1$ is the decoding step index.
- $\boldsymbol{R}$ is the received LLR matrix.
- $\boldsymbol{R}(m)$ is the soft input for the $m$ th decoding step.
- $\boldsymbol{W}(m)$ is the input extrinsic information for the $m$ th decoding step.
- $\alpha(m)=[0,0.2,0.3,0.5,0.7,0.9,1,1, \ldots]$, where $\alpha$ is a weighting factor applied based on the decoding step index. For higher decoding steps, $\alpha=1$.
- $\beta(m)=[0.2,0.4,0.6,0.8,1,1, \ldots]$, where $\beta$ is a reliability factor applied based on the decoding step index. For higher decoding steps, $\beta=1$.
- D contains the decoded message bits. The output message bits are formed from $\boldsymbol{D}$ by mapping -1 to 0 and +1 to 1 , then reshaping the message block into a column vector.

The output message bits are formed after iterating through the specified number of iterations, or, if early termination is enabled, after code convergence.

## Early Termination of TPC Decoding

If early termination is enabled, a code convergence check is performed on the hard decision of the soft input in each row-wise and column-wise decoding step. Early termination can be triggered after either the row-wise decoding or column-wise decoding converges.

The code is converged if, for all rows or all columns,

- The syndrome evaluates to zero in the codes (Hamming codes, Extended Hamming codes, BCH codes, or Extended BCH codes).
- The parity check is evaluated to zero in parity check codes.

The reported number of iterations evaluates to the iteration value that is currently in progress. For example, if the code convergence check is satisfied after row-wise decoding in the third iteration (after 2.5 decoding steps), then the number of iteration returned is 3 .

## TPC Decoding Shortened Messages

TPC encoded shortened input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the ( $N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}, S_{\mathrm{C}}$ ) code pair and column-wise decoding uses the ( $N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}, S_{\mathrm{R}}$ ) code pair. The input vector length must be $\left(N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}\right) \times\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$. To perform the 2-D TPC decoding of shortened messages, the column vector of the input LLRs, composed of the shortened message and parity bits, is arranged into an ( $N_{R}-K_{R}+S_{R}$ )-by- $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$ matrix.

The TPC decoder processes the received shortened message LLRs similar to full length codes, with these exceptions:

- The shortened bit positions in the received codeword are set to -1 .
- The Chase algorithm does not consider the shortened bit positions while choosing the least reliable bits.

## TPC Encoder

## Turbo product code (TPC) encoder <br> Library: <br> Communications Toolbox / Error Detection and Correction / Block

## Description

The TPC Encoder block performs 2-D turbo product code (TPC) encoding of an input message. The product code is a 2-D concatenation of linear block codes. The linear block codes can be a parity check code, a Hamming code, or a BCH code capable of correcting two errors. Extended and shortened codes can be applied independently on each dimension. For a description of 2-D TPC encoding, see "Algorithms" on page 5-806.

For information about valid code pairs and the error-correcting capability for each valid code pair, see "Component Code Pairs" on page 5-805.

## Ports

## Input

## In - Message to encode

column vector
Input message bits to encode, specified as a column vector.

- For full-length input messages, the length of the column vector must be the product of Number of rows in message, Kr and Number of columns in message, Kc.
- For shortened input messages, the length of the column vector must be the product of Number of rows in shortened message, Sr and Number of columns in shortened message, Sc.

Data Types: single | double | int8|int16|int32|uint8|uint16|uint32|Boolean

## Output

## Out - TPC-encoded message

column vector
TPC-encoded message, returned as a column vector with the same data type as the input signal.

- For full-length input messages, the length of the column vector is the product of Number of rows in code, Nr and Number of columns in code, Nc.
- For shortened input messages, the length of the column vector is the product of $\left(N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}\right)$ and $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$, where:
- $N_{\mathrm{R}}$ is the value of Number of rows in code, Nr .
- $K_{\mathrm{R}}$ is the value of Number of rows in message, Kr .
- $S_{\mathrm{R}}$ is the value of Number of rows in shortened message, Sr .
- $\quad N_{\mathrm{C}}$ is the value of Number of columns in code, Nc.
- $K_{\mathrm{C}}$ is the value of Number of columns in message, Kc.
- $S_{\mathrm{C}}$ is the value of Number of columns in shortened message, Sc.

## Parameters

## Row TPC parameters

## Extended codes - Extended codes indicator for TPC row parameters

on (default) | off

- When Extended codes is selected, the lists for Number of rows in code, Nr and Number of rows in message, Kr contain the valid values for extended individual code pairs ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ).
- When Extended codes is cleared, the lists for Number of rows in code, Nr and Number of rows in message, Kr contain the valid values for nonextended individual code pairs ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ).

## Number of rows in code, Nr - Number of rows in product code matrix

 16 (default) | integerNumber of rows in the product code matrix, $N_{R}$. The list of integer values varies depending on the setting for Extended codes.

## Number of rows in message, Kr - Number of rows in message matrix 11 (default) | integer

Number of rows in the message matrix, $K_{\mathrm{R}}$. The list of integer values varies depending on the setting for Extended codes and Number of rows in code, Nr.

## Specify shortened message length - Specify shortened message length for rows off (default) |on

Select Specify shortened message length to specify a value for Number of rows in shortened message, Sr.

## Number of rows in shortened message, Sr - Number of rows in shortened message matrix

9 (default) | integer
Number of rows in the shortened message matrix, $S_{R}$, specified as an integer less than or equal to $K_{\mathrm{R}}$. When you specify this parameter, provide full-length $N_{\mathrm{R}}$ and $K_{\mathrm{R}}$ values to specify the ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. This code pair is then shortened to the ( $N_{R}-K_{R}+S_{R}, S_{R}$ ) code pair, where:

- $\quad N_{\mathrm{R}}$ is the value of Number of rows in code, Nr.
- $K_{\mathrm{R}}$ is the value of Number of rows in message, Kr .
- $S_{\mathrm{R}}$ is the value of Number of rows in shortened message, Sr .

## Dependencies

To enable this parameter, select Specify shortened message length.
Data Types: double

## Column TPC parameters

## Extended codes - Extended codes indicator for TPC column parameters <br> on (default) | off

- When Extended codes is selected, the lists for Number of columns in code, Nc and Number of columns in message, Kc contain the valid values for extended individual code pairs ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ).
- When Extended codes is cleared, the lists for Number of columns in code, Nc and Number of columns in message, Kc contain the valid values for nonextended individual code pairs ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ).

## Number of columns in code, Nc - Number of columns in product code matrix <br> 32 (default) | integer

Number of columns in the product code matrix, $N_{\mathrm{C}}$. The list of integer values varies depending on the setting for Extended codes.

## Number of columns in message, Kc - Number of columns in message matrix 26 (default) | integer

Number of columns in the message matrix, $K_{\mathrm{C}}$. The list of integer values varies depending on the setting for Extended codes and Number of columns in code, Nc.

## Specify shortened message length - Specify shortened message length for columns off (default) | on

Select Specify shortened message length to specify a value for Number of columns in shortened message, Sc.

Number of columns in shortened message, Sc - Number of columns in shortened message matrix
22 (default) | integer
Number of columns in the shortened message matrix, $S_{C}$, specified as an integer. When you specify this parameter, provide full-length $N_{\mathrm{C}}$ and $K_{\mathrm{C}}$ values to specify the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair. This code pair is then shortened to the ( $N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}, S_{\mathrm{C}}$ ) code pair, where:

- $N_{\mathrm{C}}$ is the value of Number of columns in code, Nc.
- $K_{C}$ is the value of Number of columns in message, Kc.
- $S_{\mathrm{C}}$ is the value of Number of columns in shortened message, Sc.

## Dependencies

To enable this parameter, select Specify shortened message length.

## Data Types: double

## Simulate using - Type of simulation to run

Code generation (default)| Interpreted execution
Type of simulation to run, specified as Code generation or Interpreted execution.

- Code generation -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- Interpreted execution -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

## Algorithms

Turbo product codes (TPC) are a form of concatenated codes used as forward error-correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. This encoder implements 2-D product code encoding, as described in [1], using two "Linear Block Codes".

## Construction of Full-Length Message Product Codes

Full-length input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair and column-wise encoding uses the ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. The input vector length must be $K_{\mathrm{R}} \cdot K_{\mathrm{C}}$. The input message bits vector is arranged into a $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix.

Row-wise encoding uses an ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) systematic linear block encoder with $K_{\mathrm{C}}$ bits per row. The rowwise encoding results in a $K_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix that includes parity bits added to each row.

Next, column-wise encoding uses an ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) systematic linear block encoder on each of the $N_{\mathrm{C}}$ columns. Applying this 2-D TPC encoding to the initial $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix results in an $N_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix that includes parity bits added to each row and column.

The 2-D TPC full-code matrix is reshaped into a column vector of length $N_{\mathrm{R}} \cdot N_{\mathrm{C}}$ and returned as the TPC-encoded output.

## Construction of Shortened Message Product Codes

Shortened input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair and column-wise encoding uses an ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. The input vector length must be $S_{\mathrm{R}} \cdot S_{\mathrm{C}}$. The input shortened message bits vector is arranged into an $S_{\mathrm{R}}$-by- $S_{\mathrm{C}}$ matrix. The shortened message matrix prepends two dimensions by padding the beginning of the message matrix with zeros. The resulting matrix is a $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix.

Row-wise encoding uses an ( $N_{C}, K_{C}$ ) systematic linear block encoder with $K_{C}$ bits per row. The rowwise encoding results in a $K_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix that includes parity bits added to each row.

Next, the column-wise encoding uses an $\left(N_{\mathrm{R}}, K_{\mathrm{R}}\right)$ systematic linear block encoder on each of the $N_{\mathrm{C}}$ columns.

Applying this 2-D TPC encoding to the initial $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix and excluding the zero-padded bits from the output results in an ( $N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}$ )-by- $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$ matrix. This matrix includes parity bits added to each row and column.

The 2-D TPC shortened-code matrix is reshaped into a column vector of length $\left(N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}\right) \cdot\left(N_{\mathrm{C}}-K_{\mathrm{C}}\right.$ $+S_{\mathrm{C}}$ ) and returned as the TPC-encoded output.

## Introduced in R2018b

## Turbo Decoder

Decode input signal using parallel concatenated decoding scheme

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Turbo Decoder block decodes the input signal using a parallel concatenated decoding scheme. The iterative decoding scheme uses the a posteriori probability (APP) decoder as the constituent decoder, an interleaver, and a deinterleaver.

The two constituent decoders use the same trellis structure and decoding algorithm.

## Block Diagram of Iterative Turbo Decoding

The previous block diagram illustrates that the APP decoders (labeled as SISO modules in the previous image) output an updated sequence of log-likelihoods of the encoder input bits, $\Pi(u ; O)$. This sequence is based on the received sequence of log-likelihoods of the channel (coded) bits, $\Pi$ ( $c ; \mathrm{I}$ ), and code parameters.

The decoder block iteratively updates these likelihoods for a fixed number of decoding iterations and then outputs the decision bits. The interleaver (п) that the decoder uses is identical to the one the encoder uses. The deinterleaver $\left(\pi^{-1}\right)$ performs the inverse permutation with respect to the interleaver. The decoder does not assume knowledge of the tail bits and excludes these bits from the iterations.

## Dimensions

This block accepts an $M$-by-1 column vector input signal and outputs an $L$-by- 1 column vector signal. For a given trellis, $L$ and $M$ are related by:

$$
L=\frac{(M-2 \cdot n u m T a i l s)}{(2 \cdot n-1)}
$$

and

$$
M=L \cdot(2 \cdot n-1)+2 \cdot \text { numTails }
$$

where
$M=$ decoder input length
$L=$ decoder output length
$n=\log 2$ (trellis.NumOutputSymbols), for a rate $1 / 2$ trellis, $n=2$
numTails $=\log 2($ trellis.numStates $) * n$

## Bit Stream Ordering

The bit ordering subsystem reorganizes the incoming data into the two log likelihood ratio (LLR) streams input to the constituent decoders. This subsystem reconstructs the second systematic stream and reorders the bits so that they match the two constituent encoder outputs at the transmitter. This ordering subsystem is the inverse of the reordering subsystem at the turbo encoder.

## Parameters

## Trellis structure

Trellis structure of constituent convolutional code.
Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Alternatively, use the poly2trellis function to create a custom trellis using the constraint length, code generator (octal), and feedback connection (octal).

The default structure is the result of poly2trellis(4, [13 15], 13).

## Source of interleaver indices

Specify the source of the interleaver indices as Property or Input port.
When you set this parameter to Property, the block uses the Interleaver indices parameter to specify the interleaver indices.

When you set this parameter to Input port, the block uses the secondary input port, IntrInd, to specify the interleaver indices.

## Interleaver indices

Specify the mapping that the Turbo encoder block uses to permute the input bits as a column vector of integers. The default is (64:-1:1).'. This mapping is a vector with the number of elements equal to $L$, the length of the output signal. Each element must be an integer between 1 and $L$, with no repeated values.

## Decoding algorithm

Specify the decoding algorithm that the constituent APP decoders use to decode the input signal as True APP, Max*, Max. When you set this parameter to:

- True APP - the block implements true a posteriori probability decoding
- Max* or Max - the block uses approximations to increase the speed of the computations.

## Number of scaling bits

Specify the number of bits which the constituent APP decoders must use to scale the input data to avoid losing precision during computations. The decoder multiplies the input by $2^{\wedge}$ Number of
scaling bits and divides the pre-output by the same factor. The value for this parameter must be a scalar integer between 0 and 8. This parameter only applies when you set Decoding algorithm to Max*. The default is 3 .

## Number of decoding iterations

Specify the number of decoding iterations the block uses. The default is 6 . The block iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the block is the hard-decision output of the final LLR update.

## Simulate using

Specify if the block simulates using Code generation or Interpreted execution. The default is Interpreted execution.

## Supported Data Type

## Turbo Encoder

Encode binary data using parallel concatenated encoding scheme

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Turbo Encoder block encodes a binary input signal using a parallel concatenated coding scheme. This coding scheme employs two identical convolutional encoders and one internal interleaver. Each constituent encoder is independently terminated by tail bits.

## Block Diagram of Parallel Concatenated Convolutional Code

The previous block diagram illustrates that the output of the Turbo Encoder block consists of the systematic and parity bits streams of the first encoder, and only the parity bit streams of the second encoder.

For a rate one-half constituent encoder, the block interlaces the three streams and multiplexes the tail bits to the end of the encoded data streams.

For more information about tail bits, see the terminate Operation mode on the Convolutional Encoder block reference page.

## Dimensions

This block accepts an $L$-by-1 column vector input signal and outputs an $M$-by-1 column vector signal. For a given trellis, $M$ and $L$ are related by:

$$
M=L \cdot(2 \cdot n-1)+2 \cdot n u m T a i l s
$$

and

$$
L=\frac{(M-2 \cdot n u m T a i l s)}{(2 \cdot n-1)}
$$

where
$L=$ encoder input length
$M=$ encoder output length
$n=\log 2$ (trellis.NumOutputSymbols), for a rate $1 / 2$ trellis, $n=2$
numTails $=\log 2$ (trellis.numStates) $* n$

## Encoder Schematic for Rate 1/3 Turbo Code Example

The previous schematic shows the encoder configuration for a trellis specified by the default value of the Trellis structure parameter, poly2trellis(4, [13 15], 13). For an input vector length of 64 bits, the output of the encoder block is 204 bits. The first 192 bits correspond to the three 64 bit streams (systematic $\left(\mathrm{X}_{\mathrm{k}}\right)$ and parity $\left(\mathrm{Z}_{\mathrm{k}}\right)$ bit streams from the first encoder and the parity ( $\mathrm{Z}_{\mathrm{k}}^{\prime}$ ) bit stream of the second encoder), interlaced as per $\mathrm{X}_{\mathrm{k}}, \mathrm{Z}_{\mathrm{k}}, \mathrm{Z}_{\mathrm{k}}^{\prime}$. The last 12 bits correspond to the tail bits from the two encoders, when the switches are in the lower position corresponding to the dashed lines. The first group of six bits (three systematic bits and three parity bits) are the output tail bits from the first constituent encoder. The second group of six bits (three systematic bits and three parity bits) are the output tail bits from the second constituent encoder.

Due to the tail bits, the encoder output code rate is slightly less than $1 / 3$.

## Parameters

## Trellis structure

Trellis structure of constituent convolutional code.

Specify the trellis as a MATLAB structure that contains the trellis description of the constituent convolutional code. Alternatively, use the poly2trellis function to create a custom trellis using the constraint length, code generator (octal), and feedback connections (octal).

This block supports only rate 1 -by- $N$ trellises where $N$ is an integer.
The default structure is the result of poly2trellis(4, [13 15], 13).

## Source of interleaver indices

Specify the source of the interleaver indices as Property or Input port.
When you set this parameter to Property, the block uses the Interleaver indices parameter to specify the interleaver indices.

When you set this parameter to Input port, the block uses the secondary input port, IntrInd, to specify the interleaver indices.

## Interleaver indices

Specify the mapping that the block uses to permute the input bits as a column vector of integers. The default is (64:-1:1).'. This mapping is a vector with the number of elements equal to the length, $L$, of the input signal. Each element must be an integer between 1 and $L$, with no repeated values.

## Simulate using

Specify if the block simulates using Code generation or Interpreted execution. The default is Interpreted execution.

## Supported Data Type

| Port | Supported Data Types |
| :--- | :--- |
| In | $\bullet$$\bullet$ Double <br>  $\bullet$ Single <br>  • Fixed-point <br> Out $\bullet$ Double <br>  $\bullet$ Single <br>  $\bullet$ Fixed-point |

## Examples

For an example that uses the Turbo Encoder and Turbo Decoder blocks, see the "Parallel Concatenated Convolutional Coding: Turbo Codes" example.

## Uniform Noise Generator

(To be removed) Generate uniformly distributed noise between upper and lower bounds

Note Uniform Noise Generator will be removed in a future release. Use the MATLAB Function block and rand function instead.

## Library

Noise Generators sublibrary of Comm Sources

## Description

The Uniform Noise Generator block generates uniformly distributed noise. The output data of this block is uniformly distributed between the specified lower and upper bounds. The upper bound must be greater than or equal to the lower bound.

You must specify the Initial seed in the simulation. When it is a constant, the resulting noise is repeatable.

If all the elements of the output vector are to be independent and identically distributed (i.i.d.), then you can use a scalar for the Noise lower bound and Noise upper bound parameters. Alternatively, you can specify the range for each element of the output vector individually, by using vectors for the Noise lower bound and Noise upper bound parameters. If the bounds are vectors, then their length must equal the length of the Initial seed parameter.

## Attributes of Output Signal

The output signal can be a frame-based matrix, a sample-based row or column vector, or a samplebased one-dimensional array. These attributes are controlled by the Frame-based outputs, Samples per frame, and Interpret vector parameters as 1-D parameters.

The number of elements in the Initial seed parameter becomes the number of columns in a framebased output or the number of elements in a sample-based vector output. Also, the shape (row or column) of the Initial seed parameter becomes the shape of a sample-based two-dimensional output signal.

## Parameters

## Noise lower bound, Noise upper bound

The lower and upper bounds of the interval over which noise is uniformly distributed.

## Initial seed

The initial seed value for the random number generator.

## Sample time

The period of each sample-based vector or each row of a frame-based matrix.

## Frame-based outputs

Determines whether the output is frame-based or sample-based. This box is active only if Interpret vector parameters as 1-D is unchecked.
Samples per frame
The number of samples in each column of a frame-based output signal. This field is active only if Frame-based outputs is checked.
Interpret vector parameters as 1-D
If this box is checked, then the output is a one-dimensional signal. Otherwise, the output is a twodimensional signal. This box is active only if Frame-based outputs is unchecked.
Output data type
The output can be set to double or single data types.

## Unipolar to Bipolar Converter

Map unipolar signal in range [0, M-1] into bipolar signal

| Unipolar to |
| :---: |
| Bipolar |
| Converter |

## Library

Utility Blocks

## Description

The Unipolar to Bipolar Converter block maps the unipolar input signal to a bipolar output signal. If the input consists of integers between 0 and $\mathrm{M}-1$, where M is the $\mathbf{M}$-ary number parameter, then the output consists of integers between -(M-1) and $\mathrm{M}-1$. If M is even, then the output is odd. If M is odd, then the output is even. This block is only designed to work when the input value is within the set $\{0,1,2 \ldots(\mathrm{M}-1)\}$, where M is the $\mathbf{M}$-ary number parameter. If the input value is outside of this set of integers the output may not be valid.

The table below shows how the block's mapping depends on the Polarity parameter.

| Polarity Parameter Value | Output Corresponding to Input Value of k |
| :--- | :--- |
| Positive | $2 \mathrm{k}-(\mathrm{M}-1)$ |
| Negative | $-2 \mathrm{k}+(\mathrm{M}-1)$ |

## Parameters

## M-ary number

The number of symbols in the bipolar or unipolar alphabet.

## Polarity

A value of Positive causes the block to maintain the relative ordering of symbols in the alphabets. A value of Negative causes the block to reverse the relative ordering of symbols in the alphabets.

## Output Data Type

The type of bipolar signal produced at the block's output.
The block supports the following output data types:

- Inherit via internal rule
- Same as input
- double
- int8
- int16
- int32

When the parameter is set to its default setting, Inherit via internal rule, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either single or double), the output data type is the same as the input data type.
- If the input data type is not floating-point:
- Based on the M-ary number parameter, an ideal signed integer output word length required to contain the range $[-(\mathrm{M}-1) \mathrm{M}-1]$ is computed as follows:
ideal word length $=\operatorname{ceil}(\log 2(\mathrm{M}))+1$

Note The +1 is associated with the need for the sign bit.

- The block sets the output data type to be a signed integer, based on the smallest word length (in bits) that can fit best the computed ideal word length.

Note The selections in the "Hardware Implementation Pane" (Simulink) pertaining to word length constraints do not affect how this block determines output data types.

## Examples

If the input is $[0 ; 1 ; 2 ; 3]$, the $\mathbf{M}$-ary number parameter is 4 , and the Polarity parameter is Positive, then the output is $[-3 ;-1 ; 1 ; 3]$. Changing the Polarity parameter to Negative changes the output to [3; 1; -1; -3].

If the value for the $\mathbf{M}$-ary number is $2^{7}$ the block gives an output of int8.
If the value for the $\mathbf{M}$-ary number is $2^{7}+1$ the block gives an output of int16.

## Variable Step LMS Decision Feedback Equalizer

(To be removed) Equalize using decision feedback equalizer that updates weights with variable-stepsize LMS algorithm

Note will be removed in a future release. Consider using Decision Feedback Equalizer instead.

## Library

## Equalizers

## Description

The Variable Step LMS Decision Feedback Equalizer block uses a decision feedback equalizer and the variable-step-size LMS algorithm to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the variable-step-size LMS algorithm to update the weights, once per symbol. When you set the Number of samples per symbol parameter to 1 , then the block implements a symbol-spaced equalizer and updates the filter weights once for each symbol. When you set the Number of samples per symbol parameter to a value greater than 1 , the weights are updated once every $N^{\text {th }}$ sample, for a $T / N$-spaced equalizer.

## Input and Output Signals

The Input port accepts a column vector input signal. The Desired port receives a training sequence with a length that is less than or equal to the number of symbols in the Input signal. Valid training symbols are those symbols listed in the Signal constellation vector.

Set the Reference tap parameter so it is greater than zero and less than the value for the Number of forward taps parameter.

The port labeled Equalized outputs the result of the equalization process.
You can configure the block to have one or more of these extra ports:

- Mode input.
- Err output for the error signal, which is the difference between the Equalized output and the reference signal. The reference signal consists of training symbols in training mode, and detected symbols otherwise.
- Weights output.

## Decision-Directed Mode and Training Mode

To learn the conditions under which the equalizer operates in training or decision-directed mode, see "Equalization".

## Equalizer Delay

For proper equalization, you should set the Reference tap parameter so that it exceeds the delay, in symbols, between the transmitter's modulator output and the equalizer input. When this condition is satisfied, the total delay, in symbols, between the modulator output and the equalizer output is equal to
$1+$ (Reference tap-1)/(Number of samples per symbol)
Because the channel delay is typically unknown, a common practice is to set the reference tap to the center tap of the forward filter.

## Parameters

## Number of forward taps

The number of taps in the forward filter of the decision feedback equalizer.

## Number of feedback taps

The number of taps in the feedback filter of the decision feedback equalizer.

## Number of samples per symbol

The number of input samples for each symbol.

## Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

## Reference tap

A positive integer less than or equal to the number of forward taps in the equalizer.

## Initial step size

The step size that the variable-step-size LMS algorithm uses at the beginning of the simulation.

## Increment step size

The increment by which the step size changes from iteration to iteration

## Minimum step size

The smallest value that the step size can assume.

## Maximum step size

The largest value that the step size can assume.

## Leakage factor

The leakage factor of the variable-step-size LMS algorithm, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Initial weights

A vector that concatenates the initial weights for the forward and feedback taps.

## Mode input port

When you select this check box, the block has an input port that enables you to toggle between training and decision-directed mode. For training, the mode input must be 1, for decision
directed, the mode should be 0 . The equalizer will train for the length of the Desired signal. If the mode input is not present, the equalizer will train at the beginning of every frame for the length of the Desired signal.

## Output error

When you select this check box, the block outputs the error signal, which is the difference between the equalized signal and the reference signal.

## Output weights

When you select this check box, the block outputs the current forward and feedback weights, concatenated into one vector.

## Compatibility Considerations

## Variable Step LMS Decision Feedback Equalizer will be removed

Warns starting in R2020a

- Variable Step LMS Decision Feedback Equalizer will be removed in a future release. Consider using Decision Feedback Equalizer instead with the adaptive algorithm set to LMS.
- The Enable training control input parameter of the Decision Feedback Equalizer block is equivalent to the Mode input port parameter of the Variable Step LMS Decision Feedback Equalizer block.
- The Decision Feedback Equalizer block does not have a leakage factor parameter. This is equivalent to setting the Leakage factor parameter to 1 in the Variable Step LMS Decision Feedback Equalizer block.

## Viterbi Decoder

Decode convolutionally encoded data using Viterbi algorithm

## Library

Convolutional sublibrary of Error Detection and Correction

## Description

The Viterbi Decoder block decodes input symbols to produce binary output symbols. This block can process several symbols at a time for faster performance.

This block can output sequences that vary in length during simulation. For more information about sequences that vary in length, or variable-size signals, see "Variable-Size Signal Basics" (Simulink).

## Input and Output Sizes

If the convolutional code uses an alphabet of $2^{n}$ possible symbols, this block's input vector length is $L^{*} n$ for some positive integer $L$. Similarly, if the decoded data uses an alphabet of $2^{k}$ possible output symbols, this block's output vector length is $L^{*} k$.

This block accepts a column vector input signal with any positive integer value for $L$. For variablesized inputs, the L can vary during simulation. The operation of the block is governed by the operation mode parameter.

For information about the data types each block port supports, see the "Supported Data Types" on page 5-837 table on this page.

## Input Values and Decision Types

The entries of the input vector are either bipolar, binary, or integer data, depending on the Decision type parameter.

| Decision type <br> Parameter | Possible Entries in <br> Decoder Input | Interpretation of <br> Values | Branch metric <br> calculation |
| :--- | :--- | :--- | :--- |
| Unquantized | Real numbers | Positive real: logical <br> zero <br> Negative real: logical <br> one | Euclidean distance |
| Hard Decision | 0,1 | 0: logical zero <br> 1: logical one | Hamming distance |

| Decision type <br> Parameter | Possible Entries in <br> Decoder Input | Interpretation of <br> Values | Branch metric <br> calculation |
| :--- | :--- | :--- | :--- |
| Soft Decision | Integers between 0 and <br> $2^{\text {b}}-1$, where $b$ is the <br> Number of soft <br> decision bits <br> parameter. | 0: most confident <br> decision for logical zero | Hamming distance |
| $2^{\text {b }-1: ~ m o s t ~ c o n f i d e n t ~}$ |  |  |  |
| decision for logical one |  |  |  |
| Other values represent |  |  |  |
| less confident decisions. |  |  |  |$\quad$.

To illustrate the soft decision situation more explicitly, the following table lists interpretations of values for 3-bit soft decisions.

| Input Value | Interpretation |
| :--- | :--- |
| 0 | Most confident zero |
| 1 | Second most confident zero |
| 2 | Third most confident zero |
| 3 | Least confident zero |
| 4 | Least confident one |
| 5 | Third most confident one |
| 6 | Second most confident one |
| 7 | Most confident one |

## Operation Modes for Inputs

The Viterbi decoder block has three possible methods for transitioning between successive input frames. The Operation mode parameter controls which method the block uses:

- In Continuous mode, the block saves its internal state metric at the end of each input, for use with the next frame. Each traceback path is treated independently.
- In Truncated mode, the block treats each input independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state. This mode is appropriate when the corresponding Convolutional Encoder block has its Operation mode set to Truncated (reset every frame).
- In Terminated mode, the block treats each input independently, and the traceback path always starts and ends in the all-zeros state. This mode is appropriate when the uncoded message signal (that is, the input to the corresponding Convolutional Encoder block) has enough zeros at the end of each input to fill all memory registers of the feed-forward encoder. If the encoder has k input streams and constraint length vector constr (using the polynomial description), "enough" means $k * \max$ (constr-1). For feedback encoders, this mode is appropriate if the corresponding Convolutional Encoder block has Operation mode set to Terminate trellis by appending bits.

Note When this block outputs sequences that vary in length during simulation and you set the Operation mode to Truncated or Terminated, the block's state resets at every input time step.

Use the Continuous mode when the input signal contains only one symbol.

## Reset Port

The reset port is usable only when the Operation mode parameter is set to Continuous. Selecting Enable reset input port gives the block an additional input port, labeled Rst. When the Rst input is nonzero, the decoder returns to its initial state by configuring its internal memory as follows:

- Sets the all-zeros state metric to zero.
- Sets all other state metrics to the maximum value.
- Sets the traceback memory to zero.

Using a reset port on this block is analogous to setting Operation mode in the Convolutional Encoder block to Reset on nonzero input via port.

The reset port supports double or boolean typed signals.

## Fixed-Point Signal Flow Diagram

There are three main components to the Viterbi decoding algorithm. They are branch metric computation (BMC), add-compare and select (ACS), and traceback decoding (TBD). The following diagram illustrates the signal flow for a $k / n$ rate code.

As an example of a BMC diagram, a $1 / 2$ rate, nsdec $=3$ signal flow would be as follows.

$$
\begin{aligned}
W L & =n s d e c+n-1 \\
n & =2 \Rightarrow W L=4
\end{aligned}
$$

The ACS component is generally illustrated as shown in the following diagram.

Where WL2 is specified on the mask by the user.
In the flow diagrams above, inNT, bMetNT, stMetNT, and outNT are numerictype objects, and bMetFIMATH and stMetFIMATH, are fimath objects.

## Puncture Pattern Examples

For some commonly used puncture patterns for specific rates and polynomials, see the last three references.

## Fixed-Point Viterbi Decoding Examples

The following two example models showcase the fixed-point Viterbi decoder block used for both hardand soft-decision convolutional decoding.

If you are reading this reference page in the MATLAB Help Browser, click Fixed-point Hard-Decision Viterbi Decoding and Fixed-point Soft-Decision Viterbi Decoding to open the models. These can also be found as doc_fixpt_vitharddec.mdl and doc_fixpt_vitsoftdec.mdl under help \toolbox\comm\examples.

Fixed-point Hard-Decision Viterbi Decoding

Fixed-point Soft-Decision Viterbi Decoding

The layout of the soft decision model example is also similar to the existing doc example on SoftDecision Decoding, which can be found at help\toolbox\comm\examples \doc_softdecision.mdl

The purpose of this model is to highlight the fixed-point modeling attributes of the Viterbi decoder, using a familiar layout.

## Overview of the Simulations

The two simulations have a similar structure and have most parameters in common. A data source produces a random binary sequence that is convolutionally encoded, BPSK modulated, and passed through an AWGN channel.

The Convolutional encoder is configured as a rate $1 / 2$ encoder. For every 2 bits, the encoder adds another 2 redundant bits. To accommodate this, and add the correct amount of noise, the $\mathbf{E b} / \mathbf{N o}$ (dB) parameter of the AWGN block is in effect halved by subtracting $10 * \log 10(2)$.

For the hard-decision case, the BPSK demodulator produces hard decisions, at the receiver, which are passed onto the decoder.

For the soft-decision case, the BPSK demodulator produces soft decisions, at the receiver, using the log-likelihood ratio. These soft outputs are 3-bit quantized and passed onto the decoder.

After the decoding, the simulation compares the received decoded symbols with the original transmitted symbols in order to compute the bit error rate. The simulation ends after processing 100 bit errors or 1 e6 bits, whichever comes first.

## Fixed-Point Modeling

Fixed-point modeling enables bit-true simulations which take into account hardware implementation considerations and the dynamic range of the data/parameters. For example, if the target hardware is a DSP microprocessor, some of the possible word lengths are 8,16 , or 32 bits, whereas if the target hardware is an ASIC or FPGA, there may be more flexibility in the word length selection.

To enable fixed-point Viterbi decoding, the block input must be of type ufix1 (unsigned integer of word length 1) for hard decisions. Based on this input (either a 0 or a 1 ), the internal branch metrics are calculated using an unsigned integer of word length = (number of output bits), as specified by the trellis structure (which equals 2 for the hard-decision example).

For soft decisions, the block input must be of type ufixN (unsigned integer of word length N), where N is the number of soft-decision bits, to enable fixed-point decoding. The block inputs must be integers in the range 0 to $2^{\mathrm{N}-1}$. The internal branch metrics are calculated using an unsigned integer of word length $=(\mathrm{N}+$ number of output bits -1$)$, as specified by the trellis structure (which equals 4 for the soft-decision example).

The State metric word length is specified by the user and usually must be greater than the branch metric word length already calculated. You can tune this to be the most suitable value (based on hardware and/or data considerations) by reviewing the logged data for the system.

Enable the logging by selecting Apps > Fixed-Point Tool. In the Fixed-Point Setting GUI, set the Fixed-point instruments mode to Minimums, maximums and overflows, and rerun the simulation. If you see overflows, it implies the data did not fit in the selected container. You could either increase the size of the word length (if your hardware allows it) or try scaling the data prior to processing it. Based on the minimum and maximum values of the data, you are also able to determine whether the selected container is of the appropriate size.

Try running simulations with different values of State metric word length to get an idea of its effect on the algorithm. You should be able to narrow down the parameter to a suitable value that has no adverse effect on the BER results.

## Comparisons with Double-Precision Data

To run the same model with double precision data, Select Apps > Fixed-Point Tool. In the FixedPoint Tool GUI, select the Data type override to be Double. This selection overrides all data type settings in all the blocks to use double precision. For the Viterbi Decoder block, as Output type was set to Boolean, this parameter should also be set to double.

Upon simulating the model, note that the double-precision and fixed-point BER results are the same. They are the same because the fixed-point parameters for the model have been selected to avoid any loss of precision while still being most efficient.

## Comparisons Between Hard and Soft-Decision Decoding

The two models are set up to run from within BERTool to generate a simulation curve that compares the BER performance for hard-decision versus soft-decision decoding.

To generate simulation results for doc_fixpt_vitharddec.mdl, do the following:
1 Type bertool at the MATLAB command prompt.
2 Go to the Monte Carlo pane.
3 Set the $\mathbf{E b} / \mathbf{N o}$ range to 2:5.
4 Set the Simulation model to doc_fixpt_vitharddec.mdl. Make sure that the model is on path.
5 Set the BER variable name to BER.
6 Set the Number of errors to 100, and the Number of bits to $1 e 6$.
7 Press Run and a plot is generated.

To generate simulation results for doc_fixpt_vitsoftdec.mdl, just change the Simulation model in step 4 and press Run.

Notice that, as expected, 3-bit soft-decision decoding is better than hard-decision decoding, roughly to the tune of 1.7 dB , and not 2 dB as commonly cited. The difference in the expected results could be attributed to the imperfect quantization of the soft outputs from the demodulator.

## Parameters

## Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder. Use the same value here and in the corresponding Convolutional Encoder block.

## Punctured code

Select this check box to specify a punctured input code. The field, Punctured code, appears.

## Puncture vector

Constant puncture pattern vector used at the transmitter (encoder). The puncture vector is a pattern of 1 s and 0 s . The 0 s indicate the punctured bits. When you select Punctured code, the Punctured vector field appears.

## Enable erasures input port

When you check this box, the decoder opens an input port labeled Era. Through this port, you can specify an erasure vector pattern of 1 s and 0 s , where the 1 s indicate the erased bits.

For these erasures in the incoming data stream, the decoder does not update the branch metric. The widths and the sample times of the erasure and the input data ports must be the same. The erasure input port can be of data type double or Boolean.

## Decision type

Specifies the use of Unquantized, Hard Decision, or Soft Decision for the branch metric calculation.

- Unquantized decision uses the Euclidean distance to calculate the branch metrics.
- Soft Decision and Hard Decision use the Hamming distance to calculate the branch metrics, where Number of soft decision bits equals 1.

## Number of soft decision bits

The number of soft decision bits to represent each input. This field is active only when Decision type is set to Soft Decision.

## Error if quantized input values are out of range

Select this check box to throw an error when quantized input values are out of range. This check box is active only when Decision type is set to Soft Decision or Hard Decision.

## Traceback depth

The number of trellis branches to construct each traceback path.

## Operation mode

Method for transitioning between successive input frames: Continuous, Terminated, and Truncated.

Note When this block outputs sequences that vary in length during simulation and you set the Operation mode to Truncated or Terminated, the block's state resets at every input time step.

Enable reset input port
When you check this box, the decoder opens an input port labeled Rst. Providing a nonzero input value to this port causes the block to set its internal memory to the initial state before processing the input data.

## Delay reset action to next time step

When you select this option, the Viterbi Decoder block resets after decoding the encoded data. This option is available only when you set Operation mode to Continuous and select Enable reset input port. You must enable this option for HDL support.

## Output data type

The output signal's data type can be double, single, boolean, int8, uint8, int16, uint16, int32, uint32, or set to 'Inherit via internal rule' or 'Smallest unsigned integer'.

When set to 'Smallest unsigned integer', the output data type is selected based on the settings used in the Hardware Implementation pane of the Configuration Parameters dialog box of the model. If ASIC/FPGA is selected in the Hardware Implementation pane, the output data type is ufix(1). For all other selections, it is an unsigned integer with the smallest specified wordlength corresponding to the char value (e.g., uint8).

When set to 'Inherit via internal rule' (the default setting), the block selects doubletyped outputs for double inputs, single-typed outputs for single inputs, and behaves similarly to the 'Smallest unsigned integer' option for all other typed inputs.

## Supported Data Types

| Port | Supported Data Types |
| :---: | :---: |
| Input | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean for Hard decision mode <br> - 8-, 16-, and 32-bit signed integers (for Hard decision and Soft decision modes) <br> - $8-, 16$-, and 32 -bit unsigned integers (for Hard decision and Soft decision modes) <br> - ufix(n), where n represents the Number of soft decision bits |
| Output | - Double-precision floating point <br> - Single-precision floating point <br> - Boolean <br> - $8-, 16$-, and 32 -bit signed integers <br> - 8-, 16-, and 32 -bit unsigned integers <br> - ufix(1) for ASIC/FPGA mode |

## More About

## Traceback Depth and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

## Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times (ConstraintLength -1) / ( 1 - coderate). The constraint length of the code, ConstraintLength, is equal to (log2(trellis.numStates) +1 ). The coderate is equal to $(K / N) \times$ (length(PuncturePattern) / sum(PuncturePattern).
$K$ is the number of input symbols, $N$ is the number of output symbols, and PuncturePattern is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate $1 / 2$ code has a traceback depth of 5(ConstraintLength - 1 ).
- A rate $2 / 3$ code has a traceback depth of 7.5 (ConstraintLength - 1).
- A rate $3 / 4$ code has a traceback depth of 10 (ConstraintLength -1 ).
- A rate $5 / 6$ code has a traceback depth of 15 (ConstraintLength -1 ).

For more information, see [7].

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using Simulink ${ }^{\circledR}$ Coder ${ }^{\mathrm{TM}}$.

## HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder ${ }^{\mathrm{TM}}$.
HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Note For decoding data encoded with truncated or terminated modes, or punctured codes, use the Viterbi Decoder block from Wireless HDL Toolbox ${ }^{\mathrm{TM}}$.

HDL Coder supports the following features of the Viterbi Decoder block:

- Non-recursive encoder/decoder with feed-forward trellis and simple shift register generation configuration
- Continuous mode
- Sample-based input
- Decoder rates from $1 / 2$ to $1 / 7$
- Constraint length from 3 to 9

When Decision type is set to Soft decision, the HDL implementation of the Viterbi Decoder block supports fixed-point inputs and output. For input, the fixed-point data type must be ufixN. $N$ is the number of soft-decision bits. Signed built-in data types (int8, int16, int32) are not supported. For output, the HDL implementation of the Viterbi Decoder block supports block-supported output data types.

When Decision type is set to Hard decision, the block supports input with data types ufix1 and Boolean. For output, the HDL implementation of the Viterbi Decoder block supports block-supported output data types. The HDL implementation of the Viterbi Decoder block does not support double and single input data types. The block does not support floating point output for fixed-point inputs.

The Viterbi Decoder block decodes every bit by tracing back through a traceback depth that you define for the block. The block implements a complete traceback for each decision bit, using registers to store the minimum state index and branch decision in the traceback decoding unit. There are two methods to optimize the traceback logic: a pipelined register-based implementation or a RAM-based architecture. See the "HDL Code Generation for Viterbi Decoder" example.

## Register-Based Traceback

You can specify that the traceback decoding unit be pipelined to improve the speed of the generated circuit. You can add pipeline registers to the traceback unit by specifying the number of traceback stages per pipeline register.

Using the TracebackStagesPerPipeline implementation parameter, you can balance the circuit performance based on system requirements. A smaller parameter value indicates the requirement to add more registers to increase the speed of the traceback circuit. Increasing the parameter value results in fewer registers along with a decrease in the circuit speed.

## RAM-Based Traceback

Instead of using registers, you can choose to use RAMs to save the survivor branch information. The coder does not support Enable reset input port when using RAM-based traceback.

1 Right-click the block and open HDL Code > HDL Block Properties. Set the Architecture property to RAM-based Traceback.
2 Double-click the block and set the Traceback depth on the Viterbi Decoder block mask.
RAM-based traceback and register-based traceback differ in the following ways:

- The RAM-based implementation traces back through one set of data to find the initial state to decode the previous set of data. The register-based implementation combines the traceback and decode operations into one step. It uses the best state found from the minimum operation as the decoding initial state.
- RAM-based implementation traces back through M samples, decodes the previous M bits in reverse order, and releases one bit in order at each clock cycle. The register-based implementation decodes one bit after a complete traceback.

Because of the differences in the two traceback algorithms, the RAM-based implementation produces different numerical results than the register-based traceback. A longer traceback depth, for example, 10 times the constraint length, is recommended in the RAM-based traceback. This depth achieves a
similar bit error rate (BER) as the register-based implementation. The size of RAM required for the implementation depends on the trellis and the traceback depth.

HDL Block Properties

| ConstrainedOutputPi <br> peline | Number of registers to place at the outputs by moving existing delays <br> within your design. Distributed pipelining does not redistribute these <br> registers. The default is 0. For more details, see <br> "ConstrainedOutputPipeline" (HDL Coder). |
| :--- | :--- |
| InputPipeline | Number of input pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "InputPipeline" (HDL <br> Coder). |
| OutputPipeline | Number of output pipeline stages to insert in the generated code. <br> Distributed pipelining and constrained output pipelining can move these <br> registers. The default is 0. For more details, see "OutputPipeline" (HDL <br> Coder). |
| TracebackStagesPerPi <br> peline | See "Register-Based Traceback" on page 5-839. |

## Restrictions

- Punctured code: Do not select this option. Punctured code requires frame-based input, which HDL Coder does not support.
- Decision type: The coder does not support the Unquantized decision type.
- Error if quantized input values are out of range: The coder does not support this option.
- Operation mode: The coder supports only the Continuous mode.
- Enable reset input port: When you enable both Enable reset input port and Delay reset action to next time step, HDL support is provided. You must select Continuous operation mode, and use register-based traceback.
- You cannot use the Viterbi Decoder block inside a Resettable Synchronous Subsystem.

## Introduced before R2006a

## Walsh Code Generator

Generate Walsh code from orthogonal set of codes

## Library

Sequence Generators sublibrary of Comm Sources

## Description

Walsh codes are defined as a set of $N$ codes, denoted $W_{\mathrm{j}}$, for $j=0,1, \ldots, N-1$, which have the following properties:

- $W_{\mathrm{j}}$ takes on the values +1 and -1 .
- $W_{j}[0]=1$ for all $j$.
- $W_{\mathrm{j}}$ has exactly $j$ zero crossings, for $j=0,1, \ldots, N-1$.
- $W_{j} W_{k}^{T}= \begin{cases}0 & j \neq k \\ N & j=k\end{cases}$
- Each code $\mathrm{W} j$ is either even or odd with respect to its midpoint.

Walsh codes are defined using a Hadamard matrix of order $N$. The Walsh Code Generator block outputs a row of the Hadamard matrix specified by the Walsh code index, which must be an integer in the range $[0, \ldots, N-1]$. If you set Walsh code index equal to an integer $j$, the output code has exactly $j$ zero crossings, for $j=0,1, \ldots, N-1$.

Note, however, that the indexing in the Walsh Code Generator block is different than the indexing in the Hadamard Code Generator block. If you set the Walsh code index in the Walsh Code Generator block and the Code index parameter in the Hadamard Code Generator block, the two blocks output different codes.

## Parameters

## Code length

Integer scalar that is a power of 2 specifying the length of the output code.

## Code index

Integer scalar in the range $[0,1, \ldots, \mathrm{~N}-1]$, where N is the Code length, specifying the number of zero crossings in the output code.

## Sample time

Output sample time, specified as -1 or a positive scalar that represents the time between each sample of the output signal. If Sample time is set to -1 , the sample time is inherited from downstream. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-842.

## Samples per frame

Samples per frame, specified as a positive integer indicating the number of samples per frame in one channel of the output data. If Samples per frame is greater than the Code length, the code is cyclically repeated. For information on the relationship between Sample time and Samples per frame, see "Sample Timing" on page 5-842.
Output data type
The output type of the block can be specified as an int8 or double. By default, the block sets this to double.

## More About

## Sample Timing

The time between output updates is equal to the product of Samples per frame and Sample time. For example, if Sample time and Samples per frame equal one, the block outputs a sample every second. If Samples per frame is increased to 10, then a 10-by-1 vector is output every 10 seconds. This ensures that the equivalent output rate is not dependent on the Samples per frame parameter.

## Compatibility Considerations

Existing models automatically update this block to current version
Behavior changed in R2020a
Starting in R2020a, Simulink no longer allows you to use the Walsh Code Generator block version available before R2015b.

Existing models automatically update to load the Walsh Code Generator block version announced in "Source blocks output frames of contiguous time samples but do not use the frame attribute" in the R2015b Release Notes. For more information on block forwarding, see "Forwarding Tables" (Simulink).

## Windowed Integrator

Integrate over time window of fixed length

```
Muindowed
Integrator
```

## Library

Comm Filters

## Description

The Windowed Integrator block creates cumulative sums of the input signal values over a sliding time window of fixed length. If the Integration period parameter is N and the input samples are denoted by $x(1), x(2), x(3), \ldots$, then the nth output sample is the sum of the $x(k)$ values for $k$ between $n-N+1$ and n . In cases where $\mathrm{n}-\mathrm{N}+1$ is less than 1 , the block uses an initial condition of 0 to represent those samples.

## Input and Output Signals

This block accepts scalar, column vector, and $M$-by- $N$ matrix input signals. The block filters an $M$-by- $N$ input matrix as follows:

- When you set the Input processing parameter to Columns as channels (frame based), the block treats each column as a separate channel. In this mode, the block creates $N$ instances of the same filter, each with its own independent state buffer. Each of the $N$ filters process $M$ input samples at every Simulink time step.
- When you set the Input processing parameter to Elements as channels (sample based), the block treats each element as a separate channel. In this mode, the block creates $M^{*} N$ instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

The output dimensions always equal those of the input signal. For information about the data types each block port supports, see the "Supported Data Type" on page 5-845 table on this page.

## Parameters

## Integration period

The length of the interval of integration, measured in samples.

## Input processing

Specify how the block processes the input signal. You can set this parameter to one of the following options:

- Columns as channels (frame based) - When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) - When you select this option, the block treats each element of the input as a separate channel.

## Rounding mode

Select the rounding mode for fixed-point operations. The block uses the Rounding mode when the result of a fixed-point calculation does not map exactly to a number representable by the data type and scaling storing the result. The filter coefficients do not obey this parameter; they always round to Nearest. For more information, see "Rounding Modes" (DSP System Toolbox) or
"Rounding Mode: Simplest" (Fixed-Point Designer).

## Saturate on integer overflow

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

## Coefficients

The block implementation uses a Direct-Form FIR filter with all tap weights set to one. The Coefficients parameter controls which data type represents the taps (i.e. ones) when the input data is a fixed-point signal.

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See "Filter Structure Diagrams" (DSP System Toolbox) for illustrations depicting the use of the coefficient data types in this block:

- When you select Same word length as input, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Specify word length, you are able to enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the coefficients, in bits. If applicable, you are able to enter separate fraction lengths for the numerator and denominator coefficients.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the coefficients. If applicable, you are able to enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the Rounding mode and the Saturate on integer overflow parameters; they are always saturated and rounded to Nearest.

## Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the product output data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the product output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

## Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Filter Structure Diagrams" (DSP System Toolbox) and "Multiplication Data Types" (DSP System Toolbox) for illustrations depicting the use of the accumulator data type in this block:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as product output, these characteristics match those of the product output.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the accumulator, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

## Output

Choose how you specify the output word length and fraction length:

- When you select Same as input, these characteristics match those of the input to the block.
- When you select Same as accumulator, these characteristics match those of the accumulator.
- When you select Binary point scaling, you are able to enter the word length and the fraction length of the output, in bits.
- When you select Slope and bias scaling, you are able to enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

## Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling tool in the Fixed-Point Tool.

## Supported Data Type

| Port | Supported Data Types |
| :---: | :---: |
| In | - Double-precision floating point <br> - Single-precision floating point <br> - Signed Fixed-point |
| Out | - Double-precision floating point <br> - Single-precision floating point <br> - Signed fixed-point |

## Examples

If Integration period is 3 and the input signal is a ramp ( $1,2,3,4, \ldots$ ), then some of the sums that form the output of this block are as follows:

- $0+0+1=1$
- $0+1+2=3$
- $1+2+3=6$
- $2+3+4=9$
- $3+4+5=12$
- $4+5+6=15$
- etc.

The zeros in the first few sums represent initial conditions. With the Input processing parameter set to Elements as channels, then the values $1,3,6, \ldots$ are successive values of the scalar output signal. With the Input processing parameter set to Columns as channels, the values 1, 3, 6,... are organized into output frames that have the same vector length as the input signal.

## Amplifier

Complex baseband model of amplifier with noise and nonlinearities
Library: RF Blockset / Idealized Baseband

## Description

The Amplifier block generates a complex baseband model of an amplifier with thermal noise. This block provides four nonlinearity models and three options to specify noise representation.

Note This block assumes a nominal impedance of 1 ohm.

## Parameters

## Main Tab

## Model - Amplifier nonlinearity model

Cubic polynomial (default)|AM/AM - AM/PM|Modified Rapp|Saleh
Specify the amplifier nonlinearity model as one of the following:

- Cubic polynomial
- AM/AM - AM/PM
- Modified Rapp
- Saleh

Linear power gain (dB) - Linear gain of amplifier
0 (default) | real scalar
Linear gain, specified as a scalar in dB .

## Type of Non-Linearity - Third - order nonlinearity type

IIP3 (default)| OIP3|IP1dB|OP1dB|IPsat |OPsat
Third order nonlinearity type, specified as IIP3, OIP3, IP1dB, OP1dB, IPsat, or OPsat.

## IIP3 - Input third-order intercept point

Inf (default) | real positive number
Input third-order intercept point, specified as a real positive number in dBm .

## Dependencies

To enable this parameter, set Model to Cubic polynomial and Type of Non-Linearity to IIP3.

## OIP3 - Output third-order intercept point

Inf (default) | real positive number
Output third-order intercept point, specified as a real positive number in dBm .

## Dependencies

To enable this parameter, set Model to Cubic polynomial and Type of Non-Linearity to OIP3.

## IP1dB - Input 1 dB compression point

Inf (default) | real positive number
Input 1 dB compression point, specified as a real positive number in dBm .

## Dependencies

To enable this parameter, set Model to Cubic polynomial and Type of Non-Linearity to IP1dB.

## OP1dB - Output 1 dB compression point

Inf (default) | real positive number
Output 1 dB compression point, specified as a real positive number in dBm .

## Dependencies

To enable this parameter, set Model to Cubic polynomial and Type of Non-Linearity to OP1dB.

## IPsat - Input saturation point

Inf (default) | real positive number
Input saturation point, specified as a real positive number in dBm .

## Dependencies

To enable this parameter, set Model to Cubic polynomial and Type of Non-Linearity to IPsat.

## OPsat - Output saturation point

Inf (default) | real positive number
Output saturation point, specified as a positive real number in dBm .

## Dependencies

To enable this parameter, set Model to Cubic polynomial and Type of Non-Linearity to OPsat.

## Simulate using - Specify type of simulation to run

Code generation (default) | Interpreted execution

- Interpreted execution - Simulate model using the MATLAB interpreter. This option shortens startup time speed, but the speed of the subsequent simulations is slower than Code generation. In this mode, you can debug the source code of the block.
- Code generation - Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.

Plot power characteristics - Plot power characteristics
button (default)

This button plots the power characteristics based on the parameters specified on the Main tab.

```
Lookup table (Pin(dBm), Pout(dBm), deg) - Stub termination
[ -25, 5, -1; -10, 20, -2; 0, 27, 5; 5, 28, 12 ] (default)| real vector
```

Table lookup entries specified as a real $M$-by-3 matrix. This table expresses the model output power dBm level in matrix column 2 and the model phase change in degrees in matrix column 3 as related to the absolute value of the input signal power of matrix column 1 for the AM/AM - AM/PM model. The column 1 input power must increase monotonically.

## Dependencies

To enable this parameter, set Model to AM/AM - AM/PM

## Output saturation level (V) - Output saturation level

1 (default) | real positive number
Voltage output saturation level, specified as a real positive number in dBm.

## Dependencies

To enable this parameter, set Model to Modified Rapp

## Magnitude smoothness factor - Magnitude smoothness factor

2 (default) | real positive number
Magnitude smoothness factor for the Modified Rapp amplifier model AM/AM calculations, specified as a positive real number.

## Dependencies

To enable this parameter, set Model to Modified Rapp

## Phase gain (rad) - Phase gain

-0.45 (default) | real scalar
Phase gain for the Modified Rapp amplifier model AM/PM calculations, specified as a real scalar in radians.

## Dependencies

To enable this parameter, set Model to Modified Rapp

## Phase saturation - Phase saturation

. 88 (default) | real positive number
Phase saturation for the Modified Rapp amplifier model AM/PM calculations, specified as a positive real number.

## Dependencies

To enable this parameter, set Model to Modified Rapp

## Phase smoothness factor - Phase smoothness factor <br> 3.43 (default) | real positive number

Phase smoothness factor for the Modified Rapp amplifier model AM/PM calculations, specified as a positive real number.

## Dependencies

To enable this parameter, set Model to Modified Rapp

## Input scaling (dB) - Scaling factor for input signal level <br> 0 (default) | nonnegative real number

Scaling factor for input signal level for the Saleh amplifier model, specified as a nonnegative real number in dB.

## Dependencies

To enable this parameter, set Model to Saleh

## AM / AM parameters [alpha beta] - AM/AM conversion parameters <br> [ 2.1587, 1.1517 ] (default)|two-element vector

AM/AM two-tuple conversion parameters for Saleh amplifier model, specified as a two-element vector of nonnegative real numbers.

## Dependencies

To enable this parameter, set Model to Saleh

## AM / PM parameters [alpha beta] - AM/PM conversion parameters <br> [ 4.0033, 9.1040 ] (default)| two-element vector

AM/PM two-tuple conversion parameters for Saleh amplifier model, specified as a two-element vector of nonnegative real numbers.

## Dependencies

To enable this parameter, set Model to Saleh

## Output scaling (dB) - Scaling factor for output signal level

0 (default) | nonnegative real number
Scaling factor for output signal level for Saleh amplifier model, specified as nonnegative real number in dB .

## Dependencies

To enable this parameter, set Model to Saleh

## Noise Tab

## Include Noise - Add noise to system

off (default) | on
Select this parameter to add system noise to the input signal. Once you select this parameter, the parameters associated with the Noise tab are displayed.

## Specify noise type - Noise representation

Noise temperature (default)|Noise figure| Noise factor
Noise descriptive type, specified as Noise temperature, Noise figure, or Noise factor.

## Noise temperature (K) - Noise temperature to model noises in amplifier 290 (default) | nonnegative real number

Noise temperature to model noise in the amplifier, specified as a nonnegative real number in degrees (K).

## Dependencies

To enable this parameter, select Include noise and set Specify noise type to Noise temperature.
Noise figure ( dB ) - Noise figure to model noise in amplifier
10 * log10( 2 ) (default)| nonnegative real number
Noise figure to model noise in the amplifier, specified as a nonnegative real number in dB .

## Dependencies

To enable this parameter, select Include noise and set Specify noise type to Noise figure.

## Noise factor - Noise factor to model noise in amplifier

2 (default) | positive integer scalar greater than or equal to 1
Noise factor to model noise in the amplifier, specified as a positive integer scalar greater than or equal to 1

## Dependencies

To enable this parameter, select Include noise and set Specify noise type to Noise factor.

## Seed source - Source of initial seed

Auto (default)|User specified
Source of initial seed used to prepare the Gaussian random number noise generator, specified as one of the following:

- Auto - When Seed source is set to Auto, seeds for each amplifier instance are generated using a random number generator. The reset method of the instance has no effect.
- User specified - When Seed source is set to User specified, the value provided in the Seed is used to initialize the random number generator and the reset method resets the random number generator using the Seed property value.

## Seed - Seed for random number generator

67987 (default) | nonnegative integer
Seed for the random number generator, specified as a nonnegative integer less than $2^{32}$. Use this value to initialize the random number generator.

## Dependencies

To enable this parameter, click Include noise check box and choose User specified in the Seed source parameter.

## Algorithms

## Model

## Cubic Polynomial

- The Cubic polynomial model uses linear power gain to determine the linear coefficient of a third-order polynomial and either IP3, P1dB, or Psat to determine the third - order coefficient of the polynomial.
- The general form of cubic nonlineaity models the AM/AM as characteristics as

$$
F_{A M / A M}(u)=c_{1} \times u+\frac{3}{4} c_{3} \times u^{3}
$$

where $\mathrm{F}_{\mathrm{AM} / \mathrm{AM}}(u)$ is the magnitude of the output signal, $u$ is the magnitude of the input signal, $c_{1}$ is the coefficient of the linear gain term, and $c_{3}$ is the coefficient of the cubic gain term.

- The results for IIP3, OIP3, PI,1dB, and Po,1dB are taken from [5] (RF Blockset).
- If "IIP3" (RF Blockset) is specified, then

$$
c_{3}=-\frac{4 c_{1}}{3 \times 10^{[(I I P 3-30) / 10]}}
$$

where IIP3 is given in dBm.

- If "OIP3" (RF Blockset) is specified, then

$$
c_{3}=-\frac{4 c_{1}^{3}}{3 \times 10^{[(O I P 3-30) / 10]}}
$$

where OIP3 is given in dBm .

- If the input 1 dB gain compression power "IP1dB" (RF Blockset) is specified, then

$$
c_{3}=-\frac{2 c_{1}\left(10^{19 / 20}-10\right)}{15 \times 10^{[(I P 1 d B-30) / 10]}}
$$

where IP1dB is given in dBm .

- If the output 1 dB gain compression power "OP1dB" (RF Blockset) is specified, then

$$
c_{3}=-\frac{2 c_{1}\left(10^{19 / 20}-10\right)}{15 \times 10^{[(O P 1 d B-30-L G d B+1) / 10]}}
$$

where OP1dB is given in dBm , and LGdB is the linear gain in dB

- If the input saturation power "IPsat" (RF Blockset) is specified, then

$$
c_{3}=-\frac{4 c_{1}}{9 \times 10^{[(I P s a t-30) / 10]}}
$$

where IPsat is given in dBm .

- If the output saturation power "OPsat" (RF Blockset) is specified, then

$$
c_{3}=-\frac{16 c_{1}^{3}}{81 \times 10^{[(O P s a t-30) / 10]}}
$$

where OPsat is given in dBm .

## AM/AM-AM/PM

The AM/AM-AM/PM model uses a lookup table to specify the amplifier power characteristics. The table returns interpolated or extrapolated values using linear interpolation. Each row in the table expresses the relationship between output power or phase change as a function of input power.

$$
u_{\text {out }}=\text { Table }_{A M / A M}(u) \times e^{\left(\left(\text {Table }_{A M / P M}(u)+\angle u\right) \times i\right)}
$$

where $u_{\text {out }}$ is the output signal and $u$ is the magnitude of input signal.

## Saleh

- The Saleh model is based on normalized transfer function. Use the input / output scaling parameters to adjust signal levels from their normalized values.
- For Saleh, the AM/AM parameters alpha $A_{A M / A M}$ and beta $a_{A M / A M}$ are used to compute the amplitude gain for an input signal using the following equation:

$$
F_{A M / A M}(u)=\frac{\text { alpha }_{A M / A M} \times|u|}{1+\operatorname{beta}_{A M / A M} \times|u|^{2}}
$$

where $|u|$ is the magnitude of the scaled signal and $u$ is calculated as:

$$
u=\text { InputScale } \times u_{\text {in }}
$$

- For Saleh, the AM/PM parameters alpha $_{\text {AM/PM }}$ and beta $_{A M / P M}$ are used to compute the phase change for an input signal using the following equation:

$$
F_{A M / P M}(u)=\frac{\operatorname{alph}_{A M / P M} \times|u|^{2}}{1+\operatorname{beta}_{A M / P M} \times|u|^{2}}+\operatorname{angle}(u)
$$

where $|u|$ is the magnitude of the scaled signal and angle is a MATLAB function that returns the phase angle of $u$.

- The scaled output signal, $u_{\text {out }}$ is calculated as:

$$
u_{\text {out }}=F_{A M / A M} \times e^{\left(F_{A M / P M} \times i\right)} \times \text { OutputScale }
$$

## Modified Rapp

- The Modified Rapp model is based on normalized transfer functions. Use the input and output scaling parameters to adjust the signal levels from their normalized values.

The AM/AM characteristics for Modified Rapp are given by:

$$
F_{A M / A M}(u)=\frac{g_{\text {lin }} \times|u|}{\left(1+\left|\frac{g_{\operatorname{lin}} \times u}{v_{\text {sat }}}\right|^{2 p}\right)^{1 / 2 p}}
$$

where $|u|$ is the magnitude of input signal,
$g_{\text {lin }}$ is $10^{(\text {Linear Gain (dB)/20) }}$, and is the amplitude gain of the amplifier, $V_{\text {sat }}$ is "Output saturation level (V)" (RF Blockset), and $p$ is "Magnitude smoothness factor" (RF Blockset).

- The AM/PM characteristics for Modified Rapp is given by

$$
F_{A M / P M}(u)=\frac{A \times u^{q}}{\left[1+\left(\frac{u}{B}\right)^{q}\right]}+\operatorname{angle}(u)
$$

where $u$ is the magnitude of input signal, $A$ is the "Phase gain (rad)" (RF Blockset), $B$ is "Phase saturation" (RF Blockset), $q$ is "Phase smoothness factor" (RF Blockset) and angle is a MATLAB function which returns phase angle of $u$.

- The output signal $u_{\text {out }}$ is calculated as:

$$
u_{\text {out }}=u_{\text {mag }} \times e^{\left(u_{\text {angle }} \times i\right)}
$$

where $u_{\text {mag }}$ is the magnitude and $u_{\text {angle }}$ is the phase of the output signal, respectively.

## Thermal Noise Simulation

According to the "Specify noise type" (RF Blockset) parameter, you can specify the amount of thermal noise in three ways,

- Noise temperature - Specifies the noise in kelvin.
- Noise factor - Specifies the noise by using the equation:

Noise factor $=1+\frac{\text { Noise temperature }}{290}$

- Noise figure - Specifies the noise in decibels relative to a noise temperature of 290 kelvin. In terms of noise factor

Noise figure $=10 \times \log$ (Noise factor)

Note Some RF Blockset ${ }^{\text {tM }}$ blocks require the sample time to perform baseband modeling calculations. To ensure accuracy in these calculations, the Input Port block, as well as the mathematical RF blocks compare the input sample time to the sample time you provide in the mask. If these times do not match, or if the input sample time is missing because the blocks are not connected, an error message appears.

## Plot power characteristics

To visualize the functionality of Plot power characteristics button, set the to the Amplifier block listed in the table.

| Model | Parameters | Power Characteristics Plot |
| :---: | :---: | :---: |
| Cubic Polynomial | Main tab: <br> - Linear power gain (dB): 7 <br> - Type of Non-linearity: IIP3 <br> - IIP3 (dBm): 33 <br> - Simulate using: Code generation <br> Noise tab: <br> - Specify noise type: Noise temperature <br> - Noise temperature: 290 <br> - Seed source: Auto |  |
| AM/AM - AM/PM | Main tab: <br> - Lookup table (Pin(dBm), Pout(dBm), deg): $[-25,5,-1 ;-10,20,-2 ;$ 0, 27, 5; 5, 28, 12] <br> - Simulate using: Code generation <br> Noise tab: <br> - Specify noise type: Noise temperature <br> - Noise temperature: 290 <br> - Seed source: User specified <br> - Seed : 67987 |  |

| Model | Parameters | Power Characteristics Plot |
| :---: | :---: | :---: |
| Modified Rapp | Main tab: <br> - Linear power gain (dB): 7 <br> - Output saturation level (V): 1 <br> - Magnitude smoothness factor: 2 <br> - Phase gain (rad): - . 45 <br> - Phase saturation: 0.88 <br> - Phase smoothness factor: 3.43 <br> - Simulate using: Code generation <br> Noise tab: <br> - Specify noise type: Noise temperature <br> - Noise temperature: 290 <br> - Seed source: User specified <br> - Seed : 67987 |  |

## Application of Nonlinearity

All four subsystems for the amplifier nonlinearity models apply a memoryless nonlinearity to the complex baseband input signal. Each model

1 Multiplies the signal by a gain factor.
2 Splits the complex signal into its magnitude and angle components.
3 Applies an AM/AM conversion to the magnitude of the signal, according to the selected nonlinearity model, to produce the magnitude of the output signal.
4 Applies an AM/PM conversion to the phase of the signal, according to the selected nonlinearity model, and adds the result to the angle of the signal to produce the angle of the output signal.
