## BER Analyzer

Analyze bit error rate (BER) performance of communications systems

## Description

The BER Analyzer app calculates BER as a function of the energy per bit to noise power spectral density ratio ( $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ ). Using this app, you can:

- Plot theoretical BER vs. $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ estimates and upper bounds.
- Plot BER vs. $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ using the semianalytic technique. The semianalytic technique estimates BER performance by using a combination of simulation and analysis. Use this technique when the system error rate is small, for example, $<10^{-6}$.
- Estimate BER performance by using MATLAB ${ }^{\circledR}$ functions or Simulink ${ }^{\circledR}$ models.

## Open the BER Analyzer App

- MATLAB Toolstrip: On the Apps tab, under Signal Processing and Communications, click the app icon.
- MATLAB command prompt: Enter bertool.

## Examples

## Theoretical Plot

Generate a theoretical estimate of BER performance for a 16-QAM link in AWGN.
Open the BER Analysis app.
bertool
Specify the $\mathbf{E}_{\mathbf{b}} / \mathbf{N}_{\mathbf{0}}$ range as 0:10.
Set Modulation type to QAM and Modulation order to 16.

| Theoretical | Semianalytic | Monte Carlo |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ range | ge: 0:10 |  | dB |  |
| Channel type: AWGN |  |  |  |  |
| Modulation type: |  | $\cdots$ |  | Demodulation type: |
| Modulati | n order: 16 | - |  | (O) Coherent Noncoherent |

Plot the BER curve by clicking Plot.

## Semianalytic Plot

Use the semianalytic technique to plot the BER for a QPSK link having rectangular pulses.
Open the BER Analysis app.
bertool
On the Semianalytic tab, set these parameters:

- Set the Modulation order to 4.
- Set the Samples per symbol parameter to 8.
- Set the Transmitted signal and Received signal parameters to rectpulse(pskmod ([0:3 $0], 4), 8)$. To use the semianalytic technique, the number of symbols must exceed $M^{L}$, where $M$ is the modulation order and $L$ is the impulse response length. The impulse response is 1 , so a minimum of five symbols is required.
- Specify the Numerator as ones (8,1)/8. These coefficients specify an ideal integrator having eight samples per symbol.

Plot the BER vs. $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ curve by clicking Plot.

## Monte Carlo Simulation

Simulate BER using a custom MATLAB function.
Open the BER Analysis app.
bertool
On the Monte Carlo tab, specify $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ range as 1:.5:6.
To plot estimated BER values, run the simulation by clicking Run.
On the Theoretical tab, specify $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ range as 1:6 and set Modulation order to 4 .
Enable convolutional coding by selecting the Convolutional check box.
Plot the upper bound of the BER curve by clicking Plot.

## Parameters

## Theoretical

$E_{b} / N_{0}$ range - Range of $E_{b} / N_{0}$ values over which the BER is evaluated 0:18 (default) | vector

Specifies the range of $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ values, in dB , over which the BER is evaluated. The values in the range vector must be real.
Example: 5:10

## Channel type - Type of channel over which the BER is evaluated <br> AWGN (default)| Rayleigh |Rician

Specifies the type of channel over which the BER is evaluated. The Rayleigh and Rician options correspond to flat fading channels.
Modulation type - Modulation type of the communication link
PSK (default) | DPSK | OQPSK | PAM \| QAM \| FSK \| MSK \| CPFSK

Specifies the modulation type of the communication link.
Modulation order - Modulation order of the communication link 2 (default) | 4 | 8 | 16 | 32 | 64

Specifies the modulation order of the communication link.

## Differential encoding - Differential encoding of the input data Off (default) | On

Specifies if the input data sequence is differentially encoded.

## Demodulation type - Demodulation type

Coherent | Noncoherent
Specifies if Coherent or Noncoherent demodulation is used. This parameter is available only when the Modulation type is FSK or MSK.

## Channel coding - Channel coding used in estimating the BER

None (default) | Convolutional | Block
Specifies the type of channel coding used to estimate the theoretical BER.

## Synchronization - Synchronization error

Perfect synchronization (default)|Normalized timing error|RMS phase noise level
Specifies the synchronization error in the demodulation process. This parameter is available only when the Modulation type is PSK and the Modulation order is 2.

- When Synchronization is Normalized timing error, specify the normalized error as a real number from 0 to 0.5.
- When Synchronization is RMS phase noise level, specify the RMS phase noise as a nonnegative real number.

Decision method - Decoding decision method
Hard (default) | Soft
Specify the method used to decode the received data. This parameter is available when either of these conditions exist:

- Channel coding is set to Convolutional
- Channel coding is set to Block and Coding Type is General

Trellis - Convolutional code trellis
poly2trellis(7,[171 133]) (default)|structure
Specify the convolutional code trellis as a structure variable. You can generate this structure by using the poly2trellis function. The parameter is available only when the Channel coding parameter is Convolutional.

## Coding type - Specify block coding type

General (default) | Hamming | Golay | Reed-Solomon
Specify the block code used in the BER evaluation.

## N - Codeword length

positive integer
Specify the codeword length as a positive integer.
K - Message length
positive integer
Specify the message length as a positive integer such that $\mathbf{K}$ is less than $\mathbf{N}$.
$d_{\text {min }}$ - Minimum code distance
positive integer
Specify the minimum distance of the ( $\mathrm{N}, \mathrm{K}$ ) block code as a positive integer. This parameter is available when the Coding type is General.

## Semianalytic

## Samples per symbol - Samples per symbol

16 (default) | positive integer
Specify the number of samples per symbol as a positive integer.

## Transmitted signal - Transmitted sample sequence

rectpulse(step(comm.BPSKModulator, [0110011110110000].'), 16) (default) | vector

Specify the transmit sequence as a real or complex column vector.
Data Types: double
Received signal - Received sample sequence
rectpulse(step (comm. BPSKModulator, $\left[\begin{array}{llllllllllllllll}0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 0\end{array}\right]$. ), 16) (default) | vector

Specify the received sequence as a real or complex column vector.
Data Types: double
Numerator - Numerator of the receive filter coefficients
ones (16, 1)/16 (default) | scalar | vector
Specify the numerator of the receive filter coefficients as a vector.

## Denominator - Denominator of the receive filter coefficients

1 (default) | scalar | vector
Specify the denominator of the receive filter coefficients as a vector.

## Monte Carlo

## Simulation MATLAB file or Simulink model - File name of the BER simulation character vector

Specify the name of the MATLAB file or Simulink model containing the simulation code.

BER variable name - Name of the variable containing the BER simulation data character vector

Specify the name of the MATLAB workspace variable that contains the BER simulation data.

## Number of errors - Number of errors measured before simulation stop 100 (default) | positive integer

Specify the number of errors that must be measured before the simulation stops. Typically, 100 measured errors are enough to produce an accurate BER estimate.

## Number of bits - Number of bits processed before simulation stop

 1e8 (default) | positive integerSpecify the number of bits that must be processed before the simulation stops. This parameter is used to prevent the simulation from running too long.

Note The Monte Carlo simulation stops when either the number of errors or number of bits threshold is reached.

## Eye Diagram Analyzer

(Removed) Visualize and measure effects of impairments

Note eyescope has been removed. Use comm. EyeDiagram instead.

## Description

The Eye Diagram Analyzer app displays and measures the effects of various impairments. Using this app, you can:

- Visualize eye diagrams.
- Measure these quantities:
- Horizontal and vertical eye openings
- Random, deterministic, total, RMS, and peak-to-peak jitter
- Rise and fall times
- Signal-to-noise ratio
- Import and compare measurement results for eye diagrams of multiple signals.

## Open the Eye Diagram Analyzer App

- MATLAB Toolstrip: On the Apps tab, under Signal Processing and Communications, click the app icon.
- MATLAB command prompt: Enter eyescope.

## Programmatic Use

eyescope calls an empty scope.
eyescope(obj) calls the eye scope and displays object obj.

## Compatibility Considerations

eyescope will be removed
Errors starting in R2020a
Eye Diagram Analyzer has been removed. Use comm. EyeDiagram instead.

## Wireless Waveform Generator

Create, impair, visualize, and export modulated waveforms

## Description

The Wireless Waveform Generator app enables you to create, impair, visualize, and export modulated waveforms.

Using the app, you can:

- Generate custom OFDM, QAM, and PSK modulated waveforms.
- Generate sine wave test waveforms.
- Generate NR test models (NR-TM) and NR uplink and downlink fixed reference channel (FRC) waveforms. This feature requires "5G Toolbox".
- Generate LTE modulated waveforms. This feature requires the "LTE Toolbox".
- Generate WLAN $\left(802.11^{\mathrm{TM}}\right)$ modulated waveforms. This feature requires the "WLAN Toolbox".
- Generate Bluetooth modulated waveforms. This feature requires the Communications Toolbox Library for the Bluetooth ${ }^{\circledR}$ Protocol. To download this library, go to Get Add-Ons (MATLAB).
- Distort the waveform by adding RF impairments, such as AWGN, phase offset, frequency offset, DC offset, IQ imbalance, and memoryless cubic nonlinearity.
- Visualize the waveform in constellation diagram, spectrum analyzer, OFDM grid, and time scope plots.
- Export the waveform to your workspace as a structure, to a . mat or a . bb file, or to a runnable MATLAB script.

Note You can use the MATLAB script to reproduce your waveform outside of the Wireless Waveform Generator app.

- Generate a waveform that you can transmit using a connected lab test instrument. The app can transmit using instruments supported by the rfsiggen function. Use of the transmit feature in the app requires "Instrument Control Toolbox".

For more information, see "Using Wireless Waveform Generator App".

## Open the Wireless Waveform Generator App

## MATLAB Toolstrip

On the Apps tab, under Signal Processing and Communications, click the app icon. MATLAB Command Prompt

At the command prompt, enter wirelessWaveformGenerator.

## Examples

## Generate OFDM Waveform

Open the Wireless Waveform Generator app and generate the default waveform by clicking Generate. The displayed waveform is an OFDM waveform with QPSK-modulated symbols.

Click Insert DC null and increase the Guard band subcarriers to [20;19]. Click Generate again. The plotted waveform changes to reflect the updated configuration.

## Generate 16-QAM Waveform with Impairments

Open the Wireless Waveform Generator app and configure a 16-QAM waveform. Specify a phase imbalance of 11.25 degrees (pi/16 radians) and an amplitude imbalance of 1.5 dB . Click Generate to generate the waveform.

Select the Filtering parameter and apply root raised cosine filtering. Click Generate again to generate a waveform using the current configuration. The plotted waveform changes to reflect the updated configuration.

## App-Based 5G NR-TM and FRC Waveform Generation

This example shows how to use the 5G Waveform Generator app to generate NR test models (NRTM) and NR uplink and downlink fixed reference channel (FRC) waveforms.

## Open 5G Waveform Generator App

On the Apps tab of the MATLAB® toolstrip, under Signal Processing and Communications, click the 5G Waveform Generator app icon. This app opens the Wireless Waveform Generator app configured for 5 G waveform generation.

## Select 5G NR Waveform

In the Waveform Type section on the app toolstrip, click the waveform you want to generate. You can select any of these waveforms.

- 5G Downlink FRC
- 5G Uplink FRC
- 5G Test Models

## Generate 5G NR Waveform

In the left pane of the app, on the Waveform tab, you can set the parameters of the selected waveform. On the app toolstrip, in the Generation section, you can add impairments and set visualization tools. To visualize the waveform, click Generate. You can export the generated waveform to the MATLAB workspace as a structure in a .mat or . bb file.

For example, this picture shows the visualization results of a downlink FRC waveform using default parameters.

## Transmit 5G NR Waveform

This feature requires "Instrument Control Toolbox". To transmit the generated waveform, on the app toolstrip, click on the Transmitter tab and set up the instruments. You can use all the instruments supported by the rfsiggen function.

## Generate LTE E-TM Test Model Waveforms

Open the Wireless Waveform Generator app and configure to generate LTE E-TM Test Model waveforms. Using this feature of the app requires the LTE Toolbox ${ }^{\mathrm{TM}}$.

In the Waveform Type section, select Test Model (E-TM) waveforms, specified in TS 36.141, Sec. 6. To display an LTE E-TM Test Model 1.1 frame with a 1.4 MHz channel bandwidth, click Generate.

Configure the app to generate an LTE E-TM Test Model 3.1b frame with a channel bandwidth of 5 MHz . To visualize the waveform, click Generate.

## Generate BLE Waveform

Open the Wireless Waveform Generator app and configure a Bluetooth low energy (BLE) waveform. To use the BLE feature, the app requires Communications Toolbox Library for the Bluetooth Protocol. In the Waveform Type section, click Bluetooth Low Energy. Change the bit source to User-defined and enter the input bits. Specify the value of Samples per symbol as 32. Click Generate to generate the BLE waveform. The plotted waveform is a BLE waveform with GMSKmodulated samples. Change the visible plots by clicking Visualize and then selecting one or more options between Constellation Diagram, Time Scope and Eye Diagram.

## Generate WLAN HE ER SU PPDU with Packet Extension

Open Wireless Waveform Generator and configure an HE extended-range (ER) SU PPDU. Using this feature of the app requires the WLAN Toolbox ${ }^{\text {rM }}$.

In the Waveform Type section, select 802.11ax. Configure the app to generate an HE ER SU PPDU with two packets, specifying a delay of 50 microseconds between packets. Specify two transmit antennas, and a nominal packet padding of eight microseconds. Click Visualize and configure to select Time Scope only. To generate the waveform, click Generate.

Functions

## algdeintrlv

Restore ordering of symbols using algebraically derived permutation table

## Syntax

```
deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h)
deintrlvd = algdeintrlv(data,num,'welch-costas',alph)
```

## Description

deintrlvd = algdeintrlv(data,num,'takeshita-costello',k,h) restores the original ordering of the elements in data using a permutation table that is algebraically derived using the Takeshita-Costello method. num is the number of elements in data if data is a vector, or the number of rows of data if data is a matrix with multiple columns. In the Takeshita-Costello method, num must be a power of 2 . The multiplicative factor, $k$, must be an odd integer less than num, and the cyclic shift, $h$, must be a nonnegative integer less than num. If data is a matrix with multiple rows and columns, the function processes the columns independently.
deintrlvd = algdeintrlv(data, num,'welch-costas',alph) uses the Welch-Costas method. In the Welch-Costas method, num+1 must be a prime number. alph is an integer between 1 and num that represents a primitive element of the finite field $\mathrm{GF}($ num +1 ).

To use this function as an inverse of the algintrlv function, use the same inputs in both functions, except for the data input. In that case, the two functions are inverses in the sense that applying algintrlv followed by algdeintrlv leaves data unchanged.

## Examples

## Interleave and Deinterleave Symbols

This example uses the Takeshita-Costello method of algintrlv and algdeintrlv.
Generate random data symbols to interleave. The number of rows of input data, num, must be a power of two.

```
num = 16;
ncols = 3;
data = rand(num,ncols)
data = 16\times3
\(0.8147 \quad 0.4218 \quad 0.2769\)
    0.9058 0.9157 0.0462
    0.1270 0.7922 0.0971
    0.9134 0.9595 0.8235
    0.6324 0.6557 0.6948
    0.0975 0.0357 0.3171
    0.2785 0.8491 0.9502
    0.5469 0.9340 0.0344
    0.9575 0.6787 0.4387
```

0.9649
0.7577
0.3816

Interleave the symbols using the Takeshita-Costello method. Set the multiplicative factor, $k$, to an odd integer less than num, and the cyclic shift, $h$, to a nonnegative integer less than num.

```
k = 3;
h = 4;
intdata = algintrlv(data,num,'takeshita-costello',k,h)
intdata = 16\times3
\begin{tabular}{lll}
0.9572 & 0.6555 & 0.1869 \\
0.2785 & 0.8491 & 0.9502 \\
0.1576 & 0.7431 & 0.7655 \\
0.0975 & 0.0357 & 0.3171 \\
0.8147 & 0.4218 & 0.2769 \\
0.1270 & 0.7922 & 0.0971 \\
0.9058 & 0.9157 & 0.0462 \\
0.9575 & 0.6787 & 0.4387 \\
0.5469 & 0.9340 & 0.0344 \\
0.1419 & 0.0318 & 0.6463
\end{tabular}
```

Deinterleave the symbols to obtain the original order.

```
deintdata = algdeintrlv(intdata,num,'takeshita-costello',k,h)
deintdata = 16×3
    0.8147 0.4218 0.2769
    0.9058 0.9157 0.0462
    0.1270 0.7922 0.0971
    0.9134 0.9595 0.8235
    0.6324 0.6557 0.6948
    0.0975 0.0357 0.3171
    0.2785 0.8491 0.9502
    0.5469 0.9340 0.0344
    0.9575 0.6787 0.4387
    0.9649 0.7577 0.3816
```

## algintrlv

Reorder symbols using algebraically derived permutation table

## Syntax

```
intrlvd = algintrlv(data,num,'takeshita-costello',k,h)
intrlvd = algintrlv(data,num,'welch-costas',alph)
```

## Description

intrlvd = algintrlv(data,num,'takeshita-costello',k,h) rearranges the elements in data using a permutation table that is algebraically derived using the Takeshita-Costello method. num is the number of elements in data if data is a vector, or the number of rows of data if data is a matrix with multiple columns. In the Takeshita-Costello method, num must be a power of 2. The multiplicative factor, $k$, must be an odd integer less than num, and the cyclic shift, $h$, must be a nonnegative integer less than num. If data is a matrix with multiple rows and columns, the function processes the columns independently.
intrlvd = algintrlv(data, num, 'welch-costas', alph) uses the Welch-Costas method. In the Welch-Costas method, num +1 must be a prime number. alph is an integer between 1 and num that represents a primitive element of the finite field $\mathrm{GF}(\mathrm{num}+1)$. This means that every nonzero element of $\mathrm{GF}($ num +1 ) can be expressed as alph raised to some integer power.

## Examples

## Reorder Symbols Using Algebraically Derived Permutation Table

This example illustrates how to use the Welch-Costas method of algebraic interleaving.
Define num such that num +1 is prime. Create data to interleave.

```
num = 10;
ncols = 3; % Number of columns of data to interleave
data = randi([0 num-1],num,ncols); % Random data to interleave
```

Find primitive polynomials of the finite field $\mathrm{GF}(\mathrm{num}+1)$. The gfprimfd function represents each primitive polynomial as a row containing the coefficients in order of ascending powers.

```
pr = gfprimfd(1,'all',num+1)
pr = 4×2
    3 1
    4 1
    5 1
    9 1
```

Notice from the output that pr has two columns and that the second column consists solely of 1s. In other words, each primitive polynomial is a monic degree-one polynomial. This is because num +1 is
prime. As a result, to find the primitive element that is a root of each primitive polynomial, find a root of the polynomial by subtracting the first column of pr from num+1 .

```
primel = (num+1)-pr(:,1) % Primitive elements of GF(num+1)
primel = 4×1
```

    8
    7
    6
    2
    Now define alph as one of the elements of primel and use algintrlv to interleave.

```
alph = primel(1);
intrlvd = algintrlv(data,num,'Welch-Costas',alph);
```

## Algorithms

- A Takeshita-Costello interleaver uses a length-num cycle vector whose nth element is $\bmod (k *(n-1) * n / 2$, num) for integers $n$ between 1 and num. The function creates a permutation vector by listing, for each element of the cycle vector in ascending order, one plus the element's successor. The interleaver's actual permutation table is the result of shifting the elements of the permutation vector left by $h$. (The function performs all computations on numbers and indices modulo num.)
- A Welch-Costas interleaver uses a permutation that maps an integer $K$ to $\bmod \left(A^{K}, n u m+1\right)-1$.

## amdemod

Amplitude demodulation

## Syntax

```
\(z=\operatorname{amdemod}(y, F c, F s)\)
z = amdemod(y,Fc,Fs,ini phase)
\(z=\operatorname{amdemod}\left(y, F c, F s, i n i \_p h a s e, c a r r a m p\right)\)
z = amdemod(y,Fc,Fs,ini_phase,carramp,num,den)
```

## Description

z = amdemod (y, Fc, Fs ) returns a demodulated signal z, given the input amplitude modulated (AM) signal $y$, where the carrier signal has frequency Fc. The carrier signal and $y$ have sampling frequency Fs. The modulated signal y has zero initial phase and zero carrier amplitude, resulting from a suppressed-carrier modulation.

Note The value of Fs must satisfy Fs $\geq 2$ Fc.
z = amdemod(y,Fc,Fs,ini_phase) specifies the initial phase of the modulated signal in radians.
z = amdemod(y,Fc,Fs,ini_phase,carramp) demodulates a signal created through transmittedcarrier modulation instead of suppressed-carrier modulation, where carramp is the carrier amplitude of the modulated signal.
z = amdemod(y,Fc,Fs,ini_phase,carramp,num,den) specifies the numerator and denominator of the lowpass Butterworth filter used in the demodulation. The numerator and denominator are generated by [num,den] = butter ( $n, F c * 2 / F s)$, where $n$ is the order of the lowpass filter.

## Examples

## Demodulate AM Signal

Set the carrier frequency to 10 kHz and sampling frequency to 80 kHz . Generate a time vector having a duration of 0.01 s .

```
fc = 10e3;
fs = 80e3;
t = (0:1/fs:0.01)';
```

Create a two-tone sinusoidal signal with frequencies 300 and 600 Hz .

```
s = sin(2*pi*300*t)+2*sin(2*pi*600*t);
```

Create a lowpass filter.
[num,den] = butter(10,fc*2/fs);

Amplitude modulate the signal s.
$y=\operatorname{ammod}(s, f c, f s) ;$
Demodulate the received signal.
$z=\operatorname{amdemod}(y, f c, f s, 0,0, n u m, d e n) ;$
Plot the original and demodulated signals.

```
plot(t,s,'c',t,z,'b--')
legend('Original Signal','Demodulated Signal')
xlabel('Time (s)')
ylabel('Amplitude')
```

The demodulated signal is nearly identical to the original signal.

## Input Arguments

## y - Amplitude modulated input signal

scalar | vector | matrix | 3-D array
Amplitude modulated input signal, specified as a numeric scalar, vector, matrix, or 3-D array. Each element of $y$ must be real.
Data Types: double

## Fc - Carrier signal frequency

positive scalar
Carrier signal frequency in hertz $(\mathrm{Hz})$, specified as a positive scalar.
Data Types: double
Fs - Sampling frequency
positive scalar
Sampling frequency of the carrier signal and input message signal in hertz (Hz), specified as a positive scalar. To avoid aliasing, the value of Fs must satisfy Fs $>2(\mathrm{Fc}+\mathrm{BW})$, where BW is the bandwidth of the original modulated signal.

Data Types: double
ini_phase - Initial phase
numeric scalar
Initial phase of the modulated signal in radians, specified as a numeric scalar.

```
Data Types: double
```

carramp - Carrier amplitude
numeric scalar

Carrier amplitude of the modulated signal, specified as a numeric scalar.
Data Types: double
num - Lowpass Butterworth filter numerator
numeric scalar
Lowpass Butterworth filter numerator, specified as a numeric scalar.
Data Types: double
den - Lowpass Butterworth filter denominator
numeric scalar
Lowpass Butterworth filter denominator, specified as a numeric scalar.
Data Types: double

## Output Arguments

## z - Amplitude demodulated output signal

scalar | vector | matrix | 3-D array
Amplitude demodulated output signal, returned as a numeric scalar, vector, matrix, or 3-D array.

## See Also

ammod \| fmdemod \| pmdemod \| ssbdemod

## Topics

"Analog Passband Modulation"

Introduced before R2006a

## ammod

Amplitude modulation

## Syntax

```
\(y=\operatorname{ammod}(x, F c, F s)\)
\(y=\operatorname{ammod}\left(x, F c, F s, i n i \_p h a s e\right)\)
\(y=\operatorname{ammod}\left(x, F c, F s, i n i \_p h a s e, c a r r a m p\right)\)
```

## Description

$y=\operatorname{ammod}(x, F c, F s)$ returns an amplitude modulated (AM) signal $y$, given the input message signal x , where the carrier signal has frequency Fc. The carrier signal and x have a sampling frequency Fs. The modulated signal has zero initial phase and zero carrier amplitude, so the result is suppressed-carrier modulation.

Note The value of Fs must satisfy Fs $\geq 2$ Fc.
$\mathrm{y}=\operatorname{ammod}(\mathrm{x}, \mathrm{Fc}, \mathrm{Fs}$, ini_phase) specifies the initial phase in the modulated signal y in radians.
$y=\operatorname{ammod}\left(x, F c, F s, i n i \_p h a s e, c a r r a m p\right)$ performs transmitted-carrier modulation instead of suppressed-carrier modulation where carramp is the carrier amplitude of the modulated signal.

## Examples

## Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz . Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz . Generate a sinusoidal signal.

```
fc = 10;
x = sin(2*pi*t);
```

Modulate x using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);
ysingle = ssbmod(x,fc,fs);
```

Create a spectrum analyzer object to plot the spectra of the two signals. Plot the spectrum of the double-sideband signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PlotAsTwoSidedSpectrum',false, ...
    'YLimits',[-60 40]);
step(sa,ydouble)
```

Plot the single-sideband spectrum.
step(sa,ysingle)

## Input Arguments

x - Input message signal
scalar | vector | matrix | 3-D array
Input message signal, specified as a scalar, vector, matrix, or a 3-D array. Each element of $x$ must be real.

Data Types: single | double

## Fc - Carrier signal frequency

positive real scalar
Carrier signal frequency in hertz (Hz), specified as a positive real scalar.
Data Types: single | double

## Fs - Sampling frequency

positive real scalar
Sampling frequency of carrier signal and input message signal in hertz (Hz), specified as a positive real scalar. To avoid aliasing, the value of Fs must satisfy Fs $>2(\mathrm{Fc}+\mathrm{BW})$, where BW is the bandwidth of $x$.

Data Types: single | double
ini_phase - Initial phase
real scalar
Initial phase of the modulated signal in radians, specified as a real scalar.
Data Types: single | double
carramp - Carrier amplitude
real scalar
Carrier amplitude of the modulated signal, specified as a real scalar.
Data Types: single | double

## Output Arguments

y - Amplitude modulated output signal
scalar | vector | matrix | 3-D array
Amplitude modulated signal, returned as a scalar, vector, matrix, or 3-D array.

## apskdemod

Amplitude phase shift keying (APSK) demodulation

## Syntax

$z=\operatorname{apskdemod}(y, M, r a d i i)$
$z=\operatorname{apskdemod}(y, M, r a d i i, p h a s e o f f s e t)$
z = apskdemod( ___ , Name,Value)

## Description

$z=\operatorname{apskdemod}(y, M$, radii) performs APSK demodulation of the input signal $y$, based on the specified number of constellation points per PSK ring, M, and the radius of each PSK ring, radii. For a description of APSK demodulation, see "APSK Hard Demodulation" on page 2-22 and "APSK Soft Demodulation" on page 2-23.

Note apskdemod specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use pskdemod.
$z=\operatorname{apskdemod}(y, M$, radii, phaseoffset) specifies an initial phase offset for each PSK ring of the APSK modulated signal.
z = apskdemod( $\qquad$ ,Name, Value) specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType', 'double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

## Demodulate 16-APSK Signal

Demodulate a 16-APSK signal that has an unequal number of constellation points on each circle. Plot the received constellation.

Define vectors for modulation order and PSK ring radii. Generate random 16-ary data symbols.

```
M = [4 12];
radii = [1 2];
modOrder = sum(M);
x = randi([0 modOrder-1],1000,1);
```

Apply APSK modulation to the data.
txSig = apskmod(x, M, radii);
Pass the modulated signal through a noisy channel.

```
snr = 20; % dB
rxSig = awgn(txSig,snr,'measured');
```

Plot the transmitted (reference) signal points and the noisy received signal points.

```
plot(rxSig,'b*')
hold on
grid
plot(txSig,'r+')
xlim([-3 3])
ylim([-3 3])
xlabel('In-Phase')
ylabel('Quadrature')
legend('Received constellation','Reference constellation')
```

Demodulate the received signal and compare to the input data.

```
z = apskdemod(rxSig,M,radii);
isequal(x,z)
ans = logical
    1
```

## Demodulate 64-APSK Custom Symbol Mapped Signal

Demodulate a 64-APSK signal with custom symbol mapping. Compute hard decision bit output and verify that the input matches the output.

Define vectors for modulation order and PSK ring radii. Generate 100 symbols of random bit input.

```
M = [8 12 16 28]; % 4-PSK circles
modOrder = sum(M);
radii = [0.5 1 1.3 2];
x = randi([0 1],100*log2(modOrder),1);
```

Create a custom symbol mapping vector of binary mapping.

```
cmap = 0:63;
```

Modulate the data and plot the constellation.

```
y = apskmod(x,M,radii,'SymbolMapping',cmap,'inputType','bit', ...
    'PlotConstellation',true);
```

64-APSK with Custom Mapping

Demodulate the received signal.
z = apskdemod(y,M,radii,'SymbolMapping',cmap,'OutputType','bit');
Verify that the demodulated signal is equal to the original data.
isequal ( $x, z$ )

```
ans = logical
    1
```

## Soft Bit Demodulate 32-APSK Signal

Demodulate a 32-APSK signal and calculate soft bits.
Define vectors for modulation order and PSK ring radii. Generate 10000 symbols of random bit data.

```
M = [16 16];
modOrder = sum(M);
radii = [0.6 1.2];
numSym = 10000;
x = randi([0 1], numSym*log2(modOrder),1);
```

Generate a reference constellation. Create a constellation diagram object.

```
refAPSK = apskmod(0:modOrder-1,M,radii);
constDiagAPSK = comm.ConstellationDiagram('ReferenceConstellation',refAPSK, ...
    'Title','Received Symbols','XLimits',[-2 2],'YLimits',[-2 2]);
```

Modulate the data.

```
txSig = apskmod(x,M,radii,'InputType','bit');
sigPow = var(txSig);
```

Pass the signal through a noisy channel.

```
snr = 15;
rxSig = awgn(txSig,snr,sigPow,'linear');
```

Plot the reference and received constellation symbols.

```
constDiagAPSK(rxSig)
```

Demodulate the signal and compute soft bits.
z = apskdemod(rxSig,M, radii,'OutputType','approxllr', ...
'NoiseVariance',sigPow/snr);

## Input Arguments

y - APSK modulated signal
scalar | vector | matrix
APSK modulated signal, specified as a complex scalar, vector, or matrix. Each column is treated as an independent channel.

Data Types: double | single
Complex Number Support: Yes
M - Constellation points per PSK ring
vector

Constellation points per PSK ring, specified as a vector with more than one element. Vector elements indicate the number of constellation points in each PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. Element values must be multiples of four and sum ( M ) must be a power of two. The modulation order is the total number of points in the signal constellation and equals the sum of the vector elements, sum(M).
Example: [4 12 16] specifies a three PSK ring constellation with a modulation order of sum $(M)=$ 32.

Data Types: double

## radii - PSK ring radii

vector
PSK ring radii, specified as a vector with the same length as M . The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The elements must be positive and arranged in increasing order.
Example: [0.5 1 2] defines constellation PSK ring radii. The inner ring has a radius of 0.5 , the second ring has a radius of 1.0, and the outer ring has a radius of 2.0.
Data Types: double
phaseoffset - PSK ring phase offsets
[pi/M(1) pi/M(2) ... pi/M(end)] (default)|scalar |vector
Phase offset of each PSK ring in radians, specified as a scalar or vector with the same length as M. The first element corresponds to the innermost circle, and so on, until the last element, that corresponds to the outermost circle. The phaseoffset can be a scalar only if all the elements of $M$ are the same value.
Example: [pi/4 pi/12 pi/16] defines three constellation PSK ring phase offsets. The inner ring has a phase offset of $\mathrm{pi} / 4$, the second ring has a phase offset of pi/12, and the outer ring has a phase offset of pi/16.
Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: y = apskdemod(x,M,radii,'OutputType','bit','OutputDataType','single');

## SymbolMapping - Symbol mapping

'gray ' | 'contourwise-gray' | integer vector
Symbol mapping, specified as the comma-separated pair consisting of SymbolMapping and one of the following:

- ' contourwise-gray' - Uses Gray mapping along the contour in phase dimension.
- 'gray ' - Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for $M$ must be equal and all the values for phaseoffset must be equal. For a description of the Gray mapping used, see [2].
- integer vector - Use custom symbol mapping. Vector must consist of sum(M) unique elements with values from 0 to (sum (M)-1). The first element corresponds to the constellation point in the
first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on $M$ and phaseOffset. When all the elements of $M$ and phaseOffset are equal, the default is 'gray'. For all other cases, the default is 'contourwisegray'.

Data Types: double | char | string

## OutputType - Output type

'integer' (default)|'bit'|'llr'|'approxllr'
Output type, specified as the comma-separated pair consisting of 'OutputType' and 'integer', 'bit', 'llr', or 'approxllr'. For a description of the returned output, see z.
Data Types: char | string

## OutputDataType - Output data type

'double' (default) |...
Output data type, specified as the comma-separated pair consisting of OutputDataType and one of the indicated data types. Acceptable values for OutputDataType depend on the OutputType value.

| OutputType Value | Acceptable OutputDataType Values |
| :--- | :--- |
| 'integer' | 'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', <br> or 'uint32' |
| 'bit' | 'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', <br> 'uint32', or 'logical' |

## Dependencies

This name-value pair argument applies only when OutputType is set to 'integer' or 'bit'.
Data Types: char | string

## NoiseVariance - Noise variance

1 (default) | positive scalar | vector of positive values
Noise variance, specified as the comma-separated pair consisting of NoiseVariance and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "APSK Soft Demodulation" on page 2-23 for algorithm selection considerations.

## Dependencies

This name-value pair argument applies only when OutputType is set to ' $l l r$ ' or 'approxllr'.
Data Types: double

## PlotConstellation - Option to plot constellation

false (default) | true
Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.

Data Types: logical

## Output Arguments

z - Demodulated signal
scalar | vector | matrix
Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of $z$ depend on the specified OutputType value.

| OutputType <br> Value | Return Value of apskdemod | Dimensions of z |
| :--- | :--- | :--- |
| 'integer' | Demodulated integer values <br> from 0 to (sum(M)-1) | z has the same dimensions as input y. |
| 'bit' | Demodulated bits | The number of rows in z is $\log _{2}($ sum(M) ) times the <br> number of rows in y. Each demodulated symbol is <br> mapped to a group of $\log _{2}($ sum $(M))$ elements in a <br> column, where the first element represents the <br> MSB and the last element represents the LSB. |
| 'llr' | Log-likelihood ratio value for <br> each bit | Approximate log-likelihood ratio <br> value for each bit |
| 'approxllr' |  |  |

## More About

## APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [1].

## APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

| Algorithm | Accuracy | Execution Speed |
| :--- | :--- | :--- |
| Exact LLR | more accurate | slower execution |
| Approximate LLR | less accurate | faster execution |

For further description of these algorithms, see "Exact LLR Algorithm" and "Approximate LLR Algorithm".

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or - Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## apskmod

Amplitude phase shift keying (APSK) modulation

## Syntax

```
y = apskmod(x,M,radii)
y = apskmod(x,M,radii,phaseoffset)
y = apskmod(
```

$\qquad$

``` ,Name, Value)
```

## Description

$y=\operatorname{apskmod}(x, M$, radii) performs APSK modulation on the input data, $x$, based on the specified number of constellation points per PSK ring, M, and the radius of each PSK ring, radii. For a description of APSK modulation, see "Algorithms" on page 2-32.

Note apskmod specifically applies to multiple ring PSK constellations. For a single ring PSK constellation, use pskmod.
$y=\operatorname{apskmod}(x, M$, radii, phaseoffset) specifies an initial phase offset for each PSK ring of the APSK modulated signal.
y = apskmod( __ ,Name,Value) specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType', 'double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

## Apply APSK Modulation

Modulate data using APSK with an unequal number of constellation points on each circle.
Define vectors for modulation order and PSK ring radii. Generate data for constellation points.

```
M = [4 8 20];
radii = [0.3 0.7 1.2];
modOrder = sum(M);
x = 0:modOrder-1;
```

Apply APSK modulation to the data.

```
y = apskmod(x,M,radii);
```

Plot the resulting constellation using a scatter plot.

```
scatterplot(y)
```

## Apply APSK Modulation with Phase Offset

Modulate a random data sequence using APSK with zero phase offset for the inner circle and pi/6 phase offset for the outer circle.

Define vectors for modulation order, PSK ring radii, and PSK ring phase offset. Generate random data.

```
M = [8 8];
modOrder = sum(M);
radii = [0.5 1];
phOff = [0 pi/6];
x = randi([0 modOrder-1],100,1);
```

Apply APSK modulation to the data.
$y=\operatorname{apskmod}(x, M$, radii, phOff);
Plot the resulting constellation using a scatter plot and observe the phase offset between the constellation circles.

```
scatterplot(y)
```

## Apply APSK Modulation Modifying Symbol Ordering

Plot APSK constellations for gray and custom symbol mappings.
Define vectors for modulation order and PSK ring radii. Generate bit data for constellation points.

```
M = [8 8];
modOrder = sum(M);
radii = [0.5 1.5];
x = 0:modOrder-1;
xBit = de2bi(x);
```

Apply APSK modulation to the data using the default phase offset. Since element values for M are equal and element values for phase offset are equal, the symbol mapping defaults to 'gray '. Binary input is used to highlight the Gray nature of the constellation mapping. Plot the constellation.

```
y = apskmod(xBit,M,radii,'PlotConstellation',true,'InputType','bit');
```

Create a custom symbol mapping vector. This custom mapping happens to be another Gray mapping. cmap $=[0 ; 1 ; 9 ; 8 ; 12 ; 13 ; 5 ; 4 ; 2 ; 3 ; 11 ; 10 ; 14 ; 15 ; 7 ; 6] ;$

Apply APSK modulation with a custom symbol mapping. Plot the constellation. Binary input is used to highlight that the custom mapping defines different Gray symbol mapping.

```
z = apskmod(xBit,M,radii,'SymbolMapping',cmap,'PlotConstellation',true,'InputType','bit');
```

## Apply APSK Modulation to Input Bits

Modulate a random bit sequence using APSK and output data type single. Pass the signal through a noisy channel and display the constellation diagram.

Define vectors for modulation order and PSK ring radii. Generate random binary data.
M = [8 12 20 24];
radii $=\left[\begin{array}{llll}0.8 & 1.2 & 2 & 2.5\end{array}\right]$
bitsPerSym = log2(sum(M));
$x=$ randi([0 1],2000*bitsPerSym,1);
Apply APSK modulation to the data and use a name-value pair to output as data type single.
y = apskmod(x, M, radii,'InputType','bit','OutputDataType','single');
Pass through an AWGN channel with a 25 dB SNR.
yrec $=$ awgn( $y, 25$, 'measured');
Plot the received constellation as a scatter plot.

```
scatterplot(yrec)
```

## Input Arguments

## x - Input signal

scalar | vector | matrix
Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers in the range [0, (sum(M)-1)].

Note To process the input signal as binary elements, set the 'InputType' name-value pair to 'bit'. For binary inputs, the number of rows must be an integer multiple of $\log _{2}(\operatorname{sum}(M))$. Groups of $\log _{2}(\operatorname{sum}(M))$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: single | double | int8|int16|int32|uint8|uint16|uint32|logical
M - Constellation points per PSK ring
vector
Constellation points per PSK ring, specified as a vector with more than one element. Each vector element indicates the number of constellation points in its corresponding PSK ring. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. Element values must be multiples of four and sum (M) must be a power of two. The
modulation order is the total number of points in the signal constellation and equals the sum of the vector elements, sum(M).

Example: [4 12 16] specifies a three PSK ring constellation with a modulation order of sum (M) = 32.

Data Types: double
radii - Radius per PSK ring
vector
Radius per PSK ring, specified as a vector with the same length as M. The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The elements must be positive and arranged in increasing order.

Example: [0.5 1 2] defines radii for three constellation PSK rings. The inner ring has a radius of 0.5 , the second ring has a radius of 1.0 , and the outer ring has a radius of 2.0 .

Data Types: double
phaseoffset - Phase offset per PSK ring
[pi/M(1) pi/M(2) ... pi/M(end)] (default)|scalar | vector
Phase offset per PSK ring in radians, specified as a scalar or vector with the same length as M . The first element corresponds to the innermost circle, and so on, until the last element, which corresponds to the outermost circle. The phaseoffset can be a scalar only if all the elements of M are the same value.

Example: [pi/4 pi/12 pi/16] defines three constellation PSK ring phase offsets. The inner ring has a phase offset of pi/4, the second ring has a phase offset of pi/12, and the outer ring has a phase offset of pi/16.
Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: y = apskmod(x,M,radii,'InputType','bit','OutputDataType','single');

## SymbolMapping - Symbol mapping

'gray' | 'contourwise-gray' |integer vector
Symbol mapping, specified as the comma-separated pair consisting of 'SymbolMapping' and one of the following:

- ' contourwise-gray' - Uses Gray mapping along the contour in the phase dimension for each PSK ring.
- 'gray ' - Uses Gray mapping along the contour in both the amplitude and phase dimensions. For Gray symbol mapping, all the values for $M$ must be equal and all the values for phaseoffset must be equal. For a description of the Gray mapping used, see [2].
- integer vector - Use custom symbol mapping. Vector must consist of sum(M) unique elements with values in the range [ 0 , (sum (M) - 1]. The first element corresponds to the constellation point in the first quadrant of the innermost circle, with subsequent elements positioned counterclockwise around the PSK rings.

The default symbol mapping depends on $M$ and phaseOffset. When all the elements of $M$ are equal and all the elements of phaseOffset are equal, the default is 'gray '. For all other cases, the default is 'contourwise-gray'.
Data Types: double |char|string

## InputType - Input type

'integer' (default)|'bit'
Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. To use 'integer', the input signal must consist of integers in the range [0, (sum(M)-1)]. To use 'bit', the input signal must contain binary values and the number of rows must be an integer multiple of $\log _{2}(\operatorname{sum}(\mathrm{M}))$.

Data Types: char \| string

## OutputDataType - Output data type

'double' (default)|'single'
Output data type, specified as the comma-separated pair consisting of 'OutputDataType' and either 'double' or 'single'.

Data Types: char | string

## PlotConstellation - Plot reference constellation <br> false (default) | true

Plot reference constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the reference constellation, set PlotConstellation to true.

Data Types: logical

## Output Arguments

## y - APSK modulated signal

scalar | vector | matrix
APSK modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of y depend on the specified 'InputType' value.

| InputType | Dimensions of $y$ |
| :--- | :--- |
| 'integer' | $y$ has the same dimensions as input $x$. |
| 'bit' | The number of rows in $y$ equals the number of rows in $x$ divided by <br> $\log _{2}(\operatorname{sum}(\mathrm{M}))$. |

## Algorithms

The function implements a pure APSK constellation.
A pure M-APSK constellation is composed of $N_{\mathrm{C}}$ concentric rings or contours, each with uniformly spaced PSK points. The M-APSK constellation set is
$\chi=\left\{\begin{array}{cc}R_{1} \exp \left(j\left(\frac{2 \Pi}{M_{1}} i+\theta_{1}\right)\right), & i=0, \ldots, M_{1}-1, \\ R_{2} \exp \left(j\left(\frac{2 \Pi}{M_{2}} i+\theta_{2}\right)\right), & i=0, \ldots, M_{2}-1, \\ \vdots & \vdots \\ R_{N_{\mathrm{C}}} \exp \left(j\left(\frac{2 \Pi}{M_{N_{\mathrm{C}}}} i+\theta_{\mathrm{NC}}\right)\right), & i=0, \ldots, M_{N_{\mathrm{C}}}-1,\end{array}\right.$
where

- The modulation order is equal to the sum of all $M_{l}$ for $l=1,2, \ldots, N_{C}$.
- $N_{\mathrm{C}}$ is the number of concentric rings. $N_{\mathrm{C}} \geq 2$.
- $M_{l}$ is the number of constellation points in the lth ring.
- $R_{l}$ is the radius of the lth ring.
- $\theta_{l}$ is the phase offset of the lth ring.
- $j=\sqrt{-1}$

## arithdeco

Decode binary code by arithmetic decoding

## Syntax

dseq = arithdeco(code,counts,len)

## Description

dseq = arithdeco(code, counts,len) decodes the binary arithmetic code in code to recover the corresponding sequence of len symbols. The input countsspecifies the statistics of the source by listing the number of times each symbol of the source alphabet occurs in a test data set. code must be an output of the arithenco function.

## Examples

## Decode Sequence Using Arithmetic Code

Using a source with a two-symbol alphabet, produce a test data set in which $99 \%$ of the symbols are 1s. Encode 1000 symbols from this source to produce a code vector with less than 1000 elements. The actual number of elements in the encoded sequence varies depending on the particular random sequence.

Specify for symbol 1 from the source alphabet to occur 99 times in the test data set.

```
counts = [99 1];
```

Generate a random sequence of length 1000.

```
len = 1000;
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the random sequence. Then, decode the encoded sequence.

```
code = arithenco(seq,counts);
dseq = arithdeco(code,counts,length(seq));
```

Verify that the decoded sequence matches the original random sequence.

```
isequal(seq,dseq)
ans = logical
    1
```

## Input Arguments

## code - Binary arithmetic code

nonnegative binary row vector

Binary arithmetic code, specified as a nonnegative binary row vector. This value must be a binary arithmetic code produced by the arithenco function.

Data Types: double
counts - Statistics of symbols
positive numeric vector
Statistics of symbols, specified as a positive numeric vector. This input specifies the number of times each symbol of the source alphabet occurs in a test data set.
Data Types: double

## len - Length of sequence

positive scalar
Length of the sequence to decode, specified as a positive scalar.
Data Types: double

## Output Arguments

## dseq - Decoded arithmetic code

positive numeric row vector
Decoded arithmetic code with a sequence of len source symbols, specified as a positive numeric row vector.

## Algorithms

The arithdeco function uses the algorithm described in [1] .

## arithenco

Encode sequence of symbols by arithmetic encoding

## Syntax

code $=$ arithenco(seq, counts)

## Description

code $=$ arithenco(seq, counts) generates the binary arithmetic code corresponding to the sequence of symbols specified in seq. The input counts specifies the statistics of the source by listing the number of times each symbol of the source alphabet occurs in a test data set.

## Examples

## Encode Data Sequence with Arithmetic Code

Using a source with a two-symbol alphabet, produce a test data set in which $99 \%$ of the symbols are 1s. Encode 1000 symbols from this source to produce a code vector with less than 1000 elements. The actual number of elements in the encoded sequence varies depending on the particular random sequence.

Specify for symbol 1 from the source alphabet to occur 99 times in the test data set.

```
counts = [99 1]
counts = 1\times2
    99 1
```

Generate a random sequence of length 1000 .

```
len = 1000;
seq = randsrc(1,len,[1 2; .99 .01]);
```

Encode the random sequence and display the encoded length.

```
code = arithenco(seq,counts);
s = size(code)
s = 1\times2
```

    157
    
## Input Arguments

## seq - Sequence of symbols

positive numeric row vector

Sequence of symbols, specified as a positive numeric row vector. This input specifies the random sequence for the function to encode.
Data Types: double
counts - Statistics of symbols
positive numeric row vector
Statistics of symbols, specified as a positive numeric row vector. This input specifies the number of times each symbol of the source alphabet occurs in a test data set.
Data Types: double

## Output Arguments

## code - Generated binary arithmetic code

nonnegative binary row vector
Generated binary arithmetic code corresponding to the sequence of source symbols, returned as a nonnegative binary row vector.

## Algorithms

The arithenco function uses the algorithm described in [1].

## awgn

Add white Gaussian noise to signal

## Syntax

```
out = awgn(in,snr)
out = awgn(in,snr,signalpower)
out = awgn(in,snr,signalpower,randobject)
out = awgn(in,snr,signalpower,seed)
out = awgn(
                ,powertype)
```

## Description

out = awgn(in, snr) adds white Gaussian noise to the vector signal in. This syntax assumes that the power of in is 0 dBW .
out = awgn(in,snr,signalpower) accepts an input signal power value in dBW. To have the function measure the power of in before adding noise, specify signalpower as 'measured'.
out $=$ awgn(in,snr,signalpower, randobject) accepts input combinations from prior syntaxes and a random number stream object to generate normal random noise samples. For information about producing repeatable noise samples, see "Tips" on page 2-43.
out = awgn(in,snr,signalpower, seed) specifies a seed value for initializing the normal random number generator that is used when adding white Gaussian noise to the input signal. For information about producing repeatable noise samples, see "Tips" on page 2-43.
out = awgn ( _ _ , powertype) specifies the signal and noise power type as 'dB' or 'linear' in addition to the input arguments in any of the previous syntaxes.

For the relationships between SNR and other measures of the relative power of the noise, such as $E_{s} / N_{0}$, and $E_{\mathrm{b}} / N_{0}$, see "AWGN Channel Noise Level".

## Examples

## Add AWGN to Sawtooth Signal

Create a sawtooth wave.

```
t = (0:0.1:10)';
x = sawtooth(t);
```

Apply white Gaussian noise and plot the results.

```
y = awgn(x,10,'measured');
plot(t,[x y])
legend('Original Signal','Signal with AWGN')
```

## General QAM Modulation in AWGN Channel

Transmit and receive data using a nonrectangular 16-ary constellation in the presence of Gaussian noise. Show the scatter plot of the noisy constellation and estimate the symbol error rate (SER) for two different signal-to-noise ratios.

Create a 16-QAM constellation based on the V. 29 standard for telephone-line modems.
$\mathrm{c}=[-5-5 i 53 i-3-3-3 i-3 i \operatorname{3-3i} 33+3 i 3 i-3+3 i-1-1 i 11 i] ;$
$M=$ length(c);
Generate random symbols.
data $=$ randi([0 M-1], 2000,1);
Modulate the data by using the genqammod function. General QAM modulation is necessary because the custom constellation is not rectangular.
modData $=$ genqammod (data, $c)$;
Pass the signal through an AWGN channel having a 20 dB signal-to-noise ratio (SNR).
rxSig = awgn(modData,20,'measured');
Display a scatter plot of the received signal and the reference constellation, c .

```
h = scatterplot(rxSig);
hold on
scatterplot(c,[],[],'r*',h)
grid
hold off
```

Scatter plot

Demodulate the received signal by using the genqamdemod function. Determine the number of symbol errors and the symbol error ratio.

```
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
numErrors = 1
```

ser $=5.0000 \mathrm{e}-04$

Repeat the transmission and demodulation process with an AWGN channel having a 10 dB SNR. Determine the symbol error rate for the reduced SNR. As expected, the performance degrades when the SNR is decreased.

```
rxSig = awgn(modData,10,'measured');
demodData = genqamdemod(rxSig,c);
[numErrors,ser] = symerr(data,demodData)
numErrors = 462
ser = 0.2310
```

## Repeatable AWGN with RandStream

Generate white Gaussian noise addition results using a RandStream object and "Class" (MATLAB).
Specify the power of X to be 0 dBW , add noise to produce an SNR of 10 dB , and utilize a local random stream.

```
S = RandStream('mt19937ar','Seed',5489);
sigin = sqrt(2)*sin(0:pi/8:6*pi);
sigoutl = awgn(sigin,10,0,S);
```

Add AWGN to sigin. Use isequal to compare sigout1 to sigout2. The outputs are not equal when the random stream was not reset.

```
sigout2 = awgn(sigin, 10,0,S);
isequal(sigout1,sigout2)
ans = logical
    0
```

Reset the random stream object, returning the object to its state prior to adding AWGN to sigout1. Add AWGN to sigin and compare sigout1 to sigout3. The outputs are equal after the random stream was reset.

```
reset(S);
sigout3 = awgn(sigin,10,0,S);
isequal(sigout1,sigout3)
ans = logical
    1
```

## Input Arguments

## in - Input signal

scalar | vector | array
Input signal, specified as a scalar, vector, or array. The power of the input signal is assumed to be 0 dBW.

Data Types: double
Complex Number Support: Yes
snr - Signal-to-noise ratio
scalar
Signal-to-noise ratio in dB , specified as a scalar.

Note When the noise is added, this function applies the same snr to all elements of the full input signal. Array input signals do not have a notion of independent channels. To consider multiple channels independently, see comm. AWGNChannel.

## Data Types: double

## signalpower - Signal power <br> scalar | 'measured '

Signal power, specified as a scalar or 'measured '.

- When signalpower is a scalar, the value is used as the signal level of in to determine the appropriate noise level based on the value of snr.
- When signalpower is 'measured ', the signal level of in is computed to determine the appropriate noise level based on the value of snr.

Note When you specify 'measured', this function computes the signal power using all elements of the full input signal. When the power is computed, array input signals do not have a notion of independent channels.

Data Types: double

## randobject - Random number stream object

RandStream object
Random number stream object, specified as a RandStream object. The state of the random stream object determines the sequence of numbers produced by the randn function. Configure the random stream object using the reset function and its properties.
wgn generates normal random noise samples using randn. The randn function uses one or more uniform values from the RandStream object to generate each normal value.

For information about producing repeatable noise samples, see "Tips" on page 2-43.

## seed - Random number generator seed

scalar
Random number generator seed value, specified as a scalar.
Data Types: double

## powertype - Signal power unit

'dB' (default) | 'linear'
Signal power unit, specified as ' dB ' or ' linear'

- When powertype is ' dB ', the $s \mathrm{nr}$ is measured in dB and signalpower is measured in dBW .
- When powertype is 'linear', the snr is measured as a ratio and signalpower is measured in watts.

For the relationships between SNR and other measures of the relative power of the noise, such as $E_{\mathrm{s}} / N_{0}$, and $E_{\mathrm{b}} / N_{0}$, see "AWGN Channel Noise Level".

## Output Arguments

## out - Output signal

scalar | vector | array

Output signal, returned as a scalar, vector, or array. The returned output signal is the input signal with white Gaussian noise added to it.

## Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
- Provide a static seed value as an input to awgn.
- Use the reset function on the randobject before passing it as an input to awgn.
- Provide randobject in a known state as an input to awgn. For more information, see RandStream.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\text {TM }}$.
Usage notes and limitations:
Code generation supported, except for syntaxes that include a RandSt ream object.

## bchdec

BCH decoder

## Syntax

```
decoded = bchdec(code,N,K)
decoded = bchdec(code,N,K,paritypos)
[decoded,cnumerr] = bchdec(
```

$\qquad$

```
[decoded,cnumerr,ccode] = bchdec(
```

$\qquad$

``` )
```

## Description

decoded $=\mathrm{bchdec}(\operatorname{code}, \mathrm{N}, \mathrm{K})$ attempts to decode the received signal in code using an (N,K) BCH decoder with the narrow-sense generator polynomial. Parity symbols are at the end and the leftmost symbol is the most significant symbol.

In the decoded Galois array, each row represents the attempt at decoding the corresponding row in code.
decoded = bchdec(code, N,K, paritypos) specifies in paritypos whether the parity symbols in code were appended or prepended to the message in the coding operation.
[decoded, cnumerr] = bchdec (__ ) returns a column vector, cnumerr, where each element is the number of corrected errors in the corresponding row of code. You can return cnumerr with either of the preceding syntaxes.
[decoded, cnumerr, ccode] = bchdec (__ ) returns ccode, the corrected version of code.

## Examples

## Results of Error Correction

BCH-decode an input that has more errors per codeword than the error correcting capability of the BCH decoder. Decode a BCH coded message with two errors per codeword using a single-error correcting BCH decoder. View the effects of the error mismatch on the output codeword.

Check the number of errors per codeword a $[63,57]$ BCH decoder is capable of correcting.
n = 63;
$\mathrm{k}=57$;
$\mathrm{t}=\mathrm{bchnumer}(\mathrm{n}, \mathrm{k})$
$\mathrm{t}=1$
The [63,57] BCH decoder is capable of correcting one error per codeword.
Create a random stream and use it to generate a GF array. Encode the message.

```
s = RandStream('swb2712','Seed',9973);
msg = gf(randi(s,[0 1],1,k));
code = bchenc(msg,n,k);
```

Add two errors per codeword and decode the errored code.

```
cnumerr2 = zeros(nchoosek(n,2),1);
nErrs = zeros(nchoosek(n,2),1);
cnumerrIdx = 1;
for idxl = 1 : n-1
    %sprintf('idx1 for 2 errors = %d', idx1)
    for idx2 = idx1+1 : n
            errors = zeros(1,n);
            errors(idx1) = 1;
            errors(idx2) = 1;
            erroredCode = code + gf(errors);
            [decoded2, cnumerr2(cnumerrIdx)] ...
            = bchdec(erroredCode,n,k);
```

Encode the decoded message. Check that the re-encoded message differs from the errored message in only one bit.

```
            if cnumerr2(cnumerrIdx) == 1
            code2 = bchenc(decoded2,n,k);
            nErrs(cnumerrIdx) = biterr(double(erroredCode.x), ...
                double(code2.x));
            end
            cnumerrIdx = cnumerrIdx + 1;
```

    end
    end

Plot the computed number of errors, based on the difference between the doubly-errored code and the re-encoded version of the initial decoding.

```
plot(nErrs)
title('Number of Actual Errors')
```

All inputs with two errors were decoded to a codeword that differs in exactly one bit from the reencoded version.

## Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).
$M=4 ;$
n = 2^M-1; $\quad$ \% Codeword length
$\mathrm{k}=5$; $\quad$ \% Message length
nwords $=10 ; \%$ Number of words to encode
Create a message.
msgTx = gf(randi([0 1], nwords,k));
Find the error-correction capability.
$\mathrm{t}=\mathrm{bchnumer}(\mathrm{n}, \mathrm{k})$
t = 3
Encode the message.
enc $=$ bchenc (msgTx, $n, k)$;

Corrupt up to $t$ bits in each codeword.
noisycode = enc + randerr(nwords,n,1:t);
Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
ans = logical
    1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, numerr. Entries of -1 correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified [ $n, k$ ] pair.

```
numerr
numerr = 10\times1
    1
    2
    -1
    2
    3
    1
    -1
    4
    2
    3
```

Two of the ten transmitted codewords were not correctly received.

## Input Arguments

## code - Encoded message

Galois array
Encoded message, specified as a Galois array of symbols over GF(2). Each N-element row of code represents a corrupted systematic codeword.

For more information, see "Creating a Galois field array".

## N - Codeword length <br> integer

Codeword length, specified as an integer of the form $N=2^{M}-1$, where $M$ is an integer from 3 to 16 . See "Tips" on page 2-49 for information about valid $N$ values, valid ( $N, K$ ) pairs, and error correcting capabilities for a given BCH code.

Example: 15 for $M=4$

## K - Message length

integer
Message length, specified as an integer. N and K must produce a narrow-sense BCH code.
Example: 5 specifies a Galois array with five elements.

## paritypos - Parity position

'end ' (default) |'beginning'
Parity position, specified as 'end ' or 'beginning '. Parity symbols are at the end or beginning of each word in the output Galois array. If paritypos is 'beginning' , then a decoding failure causes bchdec to remove $\mathrm{N}-\mathrm{K}$ symbols from the beginning rather than the end of the row.

## Output Arguments

## decoded - Decoded message

Galois array of symbols over GF(2)
Decoded message, returned as a Galois array of symbols over GF(2). Each row represents the attempt at decoding the corresponding row in code. A decoding failure occurs if bchdec detects more than $T$ errors in a row of code, where $T$ is the number of errors per codeword that the decoder is capable of correcting. When a decoding failure occurs, bchdec forms the corresponding row of decoded by removing $N-K$ symbols from the end of the row of code. For more information, see "Error Correcting Capability" on page 2-48.

## cnumerr - Number of corrected errors

column vector
Number of corrected errors in the corresponding row of code, returned as a column vector. A value of -1 in cnumer $r$ indicates a decoding failure in that row in code.

## ccode - Corrected version of code

## Galois array

Corrected version of code, returned as a Galois array. ccode has the same format as the input code. If a decoding failure occurs in a certain row of code, the corresponding row in ccode contains that row unchanged.

## More About

## Error Correcting Capability

BCH decoders correct up to a specified number of errors per codeword based on the ( $\mathrm{N}, \mathrm{K}$ ) pair used to BCH encode that message. The error correcting capability, $T$, of a given $(N, K)$ pair is returned by
bchnumerr. See "Tips" on page 2-49 for information about valid $N$ values, valid ( $\mathrm{N}, \mathrm{K}$ ) pairs, and error correcting capabilities for a given BCH code.

If the coded message contains more errors per codeword than the decoder is capable of correcting, the decoder is unlikely to decode to the correct codeword. For example, when a single-errorcorrecting BCH decoder ( $T=1$ ) is given an input with two errors per codeword, it decodes it to a valid codeword but not the correct codeword. When a double-error-correcting BCH decoder ( $T=2$ ) is given an input with three errors per codeword, the decoder sometimes decodes to an invalid codeword. The cnumerr and ccode output provide feedback to analyze the correctness of the decoded message.

## Tips

- To generate the list of valid $(N, K)$ pairs along with the corresponding values of the error-correction capability, run bchnumerr(N).
- Valid values for $N=2^{M}-1$, where $M$ is an integer from 3 through 16. The maximum allowable value of $N$ is 65,535 .

## Algorithms

bchdec uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in "References" on page 2-49.

## bchenc

BCH encoder

## Syntax

```
code = bchenc(msg,N,K)
code = bchenc(msg,N,K,paritypos)
```

## Description

code $=$ bchenc(msg, $\mathrm{N}, \mathrm{K}$ ) encodes the input message using an ( $\mathrm{N}, \mathrm{K}$ ) BCH encoder that uses a narrow-sense generator polynomial. For a description of Bose-Chaudhuri-Hocquenghem (BCH) coding, see [1].
code $=$ bchenc(msg, $N, K$, paritypos) appends or prepends the parity symbols to the encoded input message to form the output.

## Examples

## Decode Received BCH Codeword in Noisy Channel

Set the BCH parameters for a Galois array of GF(2).

```
M = 4;
n = 2^M-1; % Codeword length
k = 5; %Message length
nwords = 10; % Number of words to encode
```

Create a message.
msgTx = gf(randi([0 1], nwords,k));
Find the error-correction capability.
$\mathrm{t}=\mathrm{bchnumer}(\mathrm{n}, \mathrm{k})$
$\mathrm{t}=3$
Encode the message.
enc = bchenc(msgTx, $n, k$ );
Corrupt up to $t$ bits in each codeword.
noisycode = enc + randerr(nwords,n,1:t);
Decode the noisy code.

```
msgRx = bchdec(noisycode,n,k);
```

Validate that the message was properly decoded.

```
isequal(msgTx,msgRx)
ans = logical
    1
```

Increase the number of possible errors, and generate another noisy codeword.

```
t2 = t + 1;
noisycode2 = enc + randerr(nwords,n,1:t2);
```

Decode the new received codeword.

```
[msgRx2,numerr] = bchdec(noisycode2,n,k);
```

Determine if the message was properly decoded by examining the number of corrected errors, numerr. Entries of -1 correspond to decoding failures, which occur when the codeword has more errors than can be corrected for the specified [ $n, k$ ] pair.

```
numerr
numerr = 10\times1
    1
    2
    -1
    2
    3
    1
    -1
    4
    2
    3
```

Two of the ten transmitted codewords were not correctly received.

## Input Arguments

## msg - Message to encode

Galois array of symbols over GF(2)
Message to encode, specified as a Galois array of symbols over GF(2). Each K-element row of msg represents a message word, where the leftmost symbol is the most significant symbol.

For more information, see "Creating a Galois field array".
Example: $m s g T x=g f(\operatorname{randi}([01], 10,5))$, where msgTx is a 10 -by- 5 gf array.

## N - Codeword length

integer
Codeword length, specified as an integer of the form $N=2^{M}-1$, where $M$ is an integer from 3 through 16. For more information, see "Tips" on page 2-52.

Example: 15 for $M=4$

## K - Message length <br> integer

Message length, specified as an integer. N and K must produce a narrow-sense BCH code.
Example: 5 specifies a Galois array with five elements
paritypos - Parity position
'end ' (default)|'beginning'
Parity position, specified as 'end ' or 'beginning '. Parity symbols are at the end or beginning of each word in the output Galois array.

## Output Arguments

## code - Encoded message

Galois array
Encoded message, returned as a Galois array. Parity symbols are at the end or beginning of each word in the output Galois array. To specify the position of the parity symbols, use the paritypos argument.

## Tips

- To generate the list of valid ( $\mathrm{N}, \mathrm{K}$ ) pairs along with the corresponding values of the error-correction capability, run bchnumerr(N).
- Valid values for $N=2^{M}-1$, where $M$ is an integer from 3 through 16. The maximum allowable value of $N$ is 65,535 .

## bchgenpoly

Generator polynomial of BCH code

## Syntax

```
genpoly = bchgenpoly(n,k)
genpoly = bchgenpoly(n,k,prim_poly)
genpoly = bchgenpoly(n,k,prim_poly,outputFormat)
[genpoly,t] = bchgenpoly(...)
```

## Description

genpoly $=$ bchgenpoly $(\mathrm{n}, \mathrm{k})$ returns the narrow-sense generator polynomial of a BCH code with codeword length $n$ and message length $k$. The codeword length $n$ must have the form $2^{\mathrm{m}}-1$ for some integer $m$ between 3 and 16. The output genpoly is a Galois row vector that represents the coefficients of the generator polynomial in order of descending powers. The narrow-sense generator polynomial is LCM[m_1(x), $\left.m_{-} 2(x), \ldots, m_{-} 2 t(x)\right]$, where:

- LCM represents the least common multiple,
- m_i(x) represents the minimum polynomial corresponding to $\alpha^{\mathrm{i}}, \alpha$ is a root of the default primitive polynomial for the field $G F(n+1)$,
- and t represents the error-correcting capability of the code.

Note Although the bchgenpoly function performs intermediate computations in GF( $\mathrm{n}+1$ ), the final polynomial has binary coefficients. The output from bchgenpoly is a Galois vector in GF(2) rather than in $\mathrm{GF}(\mathrm{n}+1)$.
genpoly = bchgenpoly( $\left.n, k, p r i m \_p o l y\right)$ is the same as the syntax above, except that prim_poly specifies the primitive polynomial for $\mathrm{GF}(\mathrm{n}+1)$ that has Alpha as a root. prim_poly is either a polynomial character vector or an integer whose binary representation indicates the coefficients of the primitive polynomial in order of descending powers. To use the default primitive polynomial for GF(n+1), set prim_poly to [].
genpoly = bchgenpoly( $n, k$, prim_poly,outputFormat) is the same as the previous syntax, except that outputFormat specifies output data type. The value of outputFormat can be ' $g f$ ' or 'double' corresponding to Galois field and double data types respectively. The default value of outputFormat is ' gf '.
[genpoly,t] = bchgenpoly(...) returns $t$, the error-correction capability of the code.

## Examples

## Create a BCH Generator Polynomial

Create two BCH generator polynomials based on different primitive polynomials.
Set the codeword and message lengths, n and k .

```
n = 15;
k = 11;
```

Create the generator polynomial and return the error correction capability, t .

```
[genpoly,t] = bchgenpoly(15,11)
genpoly = GF(2) array.
Array elements =
    1 0
t = 1
```

Create a generator polynomial for a $(15,11)$ BCH code using a different primitive polynomial expressed as a character vector. Note that genpoly2 differs from genpoly, which uses the default primitive.

```
genpoly2 = bchgenpoly(15,11,'D^4 + D^3 + 1')
genpoly2 = GF(2) array.
Array elements =
    1
```

## Limitations

The maximum allowable value of n is 65535 .

## bchnumerr

Number of correctable errors for BCH code

## Syntax

$\mathrm{T}=\mathrm{bchnumerr}(\mathrm{N})$
$\mathrm{T}=\mathrm{bchnumer}(\mathrm{N}, \mathrm{K})$

## Description

$\mathrm{T}=\mathrm{bchnumer}(\mathrm{N})$ returns all the possible combinations of message length, K , and number of correctable errors, T , for a BCH code of codeword length, N .
$\mathrm{T}=\mathrm{bchnumer}(\mathrm{N}, \mathrm{K})$ returns the number of correctable errors, T , for an ( $\mathrm{N}, \mathrm{K}$ ) BCH code.

## Examples

## Determine Message Length Combinations for BCH Code

Calculate the possible message length combinations for a BCH code word length of 15.
$\mathrm{T}=\mathrm{bchnumer}(\mathrm{C} 5)$
$\mathrm{T}=3 \times 3$

| 15 | 11 | 1 |
| ---: | ---: | ---: |
| 15 | 7 | 2 |
| 15 | 5 | 3 |

## Compute the Correctable Errors for BCH Code

Calculate the number of correctable errors for BCH code 15,11
$\mathrm{T}=\operatorname{bchnumerr}(15,11)$
$\mathrm{T}=1$

## Input Arguments

## N - Codeword length

integer scalar
Codeword length, specified as an integer scalar. N must have the form $2^{\mathrm{m}}-1$ for some integer, m , between 3 and 16.

Example: 15

Data Types: double
K - Message length
integer scalar
Message length, specified as an integer scalar. N and K must produce a narrow-sense BCH code.
Example: 11
Data Types: double

## Output Arguments

## T - Number of correctable errors

scalar or matrix
Number of correctable errors, returned as a scalar or matrix value.
bchnumerr( N ) returns a matrix with three columns. The first column lists N , the second column lists K , and the third column lists T .
bchnumerr ( $\mathrm{N}, \mathrm{K}$ ) returns a scalar, which represents the number of correctable errors for the BCH code.

## berawgn

Bit error rate (BER) for uncoded AWGN channels

## Syntax

```
ber = berawgn(EbNo,'pam',M)
ber = berawgn(EbNo,'qam',M)
ber = berawgn(EbNo,'psk',M,dataenc)
ber = berawgn(EbNo,'oqpsk',dataenc)
ber = berawgn(EbNo,'dpsk',M)
ber = berawgn(EbNo,'fsk',M,coherence)
ber = berawgn(EbNo,'fsk',2,coherence,rho)
ber = berawgn(EbNo,'msk',precoding)
ber = berawgn(EbNo,'msk',precoding,coherence)
berlb = berawgn(EbNo,'cpfsk',M,modindex,kmin)
[BER,SER] = berawgn(EbNo, ...)
```

## Description

## For All Syntaxes

The berawgn function returns the BER of various modulation schemes over an additive white Gaussian noise (AWGN) channel. The first input argument, EbNo, is the ratio of bit energy to noise power spectral density, in dB . If EbNo is a vector, the output ber is a vector of the same size, whose elements correspond to the different $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ levels. The supported modulation schemes, which correspond to the second input argument to the function, are in the following table.

| Modulation Scheme | Second Input Argument |
| :--- | :--- |
| Phase shift keying (PSK) | 'psk ' |
| Offset quadrature phase shift keying (OQPSK) | 'oqpsk' |
| Differential phase shift keying (DPSK) | 'dpsk' |
| Pulse amplitude modulation (PAM) | 'pam ' |
| Quadrature amplitude modulation (QAM) | 'qam' |
| Frequency shift keying (FSK) | ' fsk ' |
| Minimum shift keying (MSK) | 'msk' |
| Continuous phase frequency shift keying (CPFSK) | 'cpfsk' |

Most syntaxes also have an M input that specifies the alphabet size for the modulation. M must have the form $2^{\mathrm{k}}$ for some positive integer k . For all cases, the function assumes the use of a Gray-coded signal constellation.

## For Specific Syntaxes

ber = berawgn(EbNo, ' pam', M ) returns the BER of uncoded PAM over an AWGN channel with coherent demodulation.
ber = berawgn(EbNo,' qam', M) returns the BER of uncoded QAM over an AWGN channel with coherent demodulation. The alphabet size, $M$, must be at least 4 . When $k=\log _{2} M$ is odd, a rectangular constellation of size $M=I \times J$ is used, where $I=2^{\frac{k-1}{2}}$ and $J=2^{\frac{k+1}{2}}$. When $k$ is even, a square constellation of size $2^{\frac{k}{2}} \times 2^{\frac{k}{2}}$ is used.
ber = berawgn(EbNo,'psk',M,dataenc) returns the BER of coherently detected uncoded PSK over an AWGN channel. dataenc is either 'diff' for differential data encoding or 'nondiff' for nondifferential data encoding. If dataenc is 'diff', M must be no greater than 4.
ber $=$ berawgn(EbNo, 'oqpsk', dataenc) returns the BER of coherently detected offset-QPSK over an uncoded AWGN channel.
ber = berawgn(EbNo,'dpsk',M) returns the BER of uncoded DPSK modulation over an AWGN channel.
ber = berawgn(EbNo,'fsk',M, coherence) returns the BER of orthogonal uncoded FSK modulation over an AWGN channel. coherence is either ' coherent ' for coherent demodulation or 'noncoherent ' for noncoherent demodulation. M must be no greater than 64 for ' noncoherent'.
ber = berawgn(EbNo,'fsk',2,coherence,rho) returns the BER for binary nonorthogonal FSK over an uncoded AWGN channel, where rho is the complex correlation coefficient. See "Nonorthogonal 2-FSK with Coherent Detection" for the definition of the complex correlation coefficient and how to compute it for nonorthogonal BFSK.
ber $=$ berawgn(EbNo, 'msk', precoding) returns the BER of coherently detected MSK modulation over an uncoded AWGN channel. Setting precoding to 'off' returns results for conventional MSK while setting precoding to ' on ' returns results for precoded MSK.
ber = berawgn(EbNo,'msk',precoding,coherence) specifies whether the detection is coherent or noncoherent.
berlb = berawgn(EbNo,'cpfsk', M, modindex,kmin) returns a lower bound on the BER of uncoded CPFSK modulation over an AWGN channel. modindex is the modulation index, a positive real number. kmin is the number of paths having the minimum distance; if this number is unknown, you can assume a value of 1 .
[BER,SER] = berawgn(EbNo, ...) returns both the BER and SER.

## Examples

## Generate Theoretical BER Data for AWGN Channels

This example shows how to generate theoretical bit error rate data for several modulation schemes assuming an AWGN channel.

Create a vector of $\mathrm{Eb} / \mathrm{No}$ values and set the modulation order, M .
EbNo = (0:10)';
M = 4;
Generate theoretical BER data for QPSK modulation by using the berawgn function.

```
berQ = berawgn(EbNo,'psk',M,'nondiff');
```

Generate equivalent data for DPSK and FSK.

```
berD = berawgn(EbNo,'dpsk',M);
berF = berawgn(EbNo,'fsk',M,'coherent');
```

Plot the results.

```
semilogy(EbNo,[berQ berD berF])
xlabel('Eb/No (dB)')
ylabel('BER')
legend('QPSK','DPSK','FSK')
grid
```

## Limitations

The numerical accuracy of this function's output is limited by approximations related to the numerical implementation of the expressions.

You can generally rely on the first couple of significant digits of the function's output.

## Alternatives

As an alternative to the berawgn function, invoke the BERTool GUI (bertool), and use the Theoretical tab.

## bercoding

Bit error rate (BER) for coded AWGN channels

## Syntax

```
berub = bercoding(EbNo,'conv',decision,coderate,dspec)
berub = bercoding(EbNo,'block','hard',n,k,dmin)
berub = bercoding(EbNo,'block','soft',n,k,dmin)
berapprox = bercoding(EbNo,'Hamming','hard',n)
berub = bercoding(EbNo,'Golay','hard',24)
berapprox = bercoding(EbNo,'RS','hard',n,k)
berapprox = bercoding(...,modulation)
```

## Description

berub = bercoding(EbNo,'conv',decision, coderate,dspec) returns an upper bound or approximation on the BER of a binary convolutional code with coherent phase shift keying (PSK) modulation over an additive white Gaussian noise (AWGN) channel. EbNo is the ratio of bit energy to noise power spectral density, in dB . If EbNo is a vector, berub is a vector of the same size, whose elements correspond to the different $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ levels. To specify hard-decision decoding, set decision to ' hard'; to specify soft-decision decoding, set decision to ' soft'. The convolutional code has code rate equal to coderate. The dspec input is a structure that contains information about the code's distance spectrum:

- dspec.dfree is the minimum free distance of the code.
- dspec.weight is the weight spectrum of the code.

To find distance spectra for some sample codes, use the distspec function or see [5] and [3].

Note The results for binary PSK and quadrature PSK modulation are the same. This function does not support M-ary PSK when M is other than 2 or 4.
berub = bercoding(EbNo,'block','hard',n,k,dmin) returns an upper bound on the BER of an $[n, k]$ binary block code with hard-decision decoding and coherent BPSK or QPSK modulation. dmin is the minimum distance of the code.
berub = bercoding(EbNo,'block','soft', n, $\mathrm{k}, \mathrm{dmin}$ ) returns an upper bound on the BER of an [ $\mathrm{n}, \mathrm{k}$ ] binary block code with soft-decision decoding and coherent BPSK or QPSK modulation. dmin is the minimum distance of the code.
berapprox = bercoding(EbNo,'Hamming','hard',n) returns an approximation of the BER of a Hamming code using hard-decision decoding and coherent BPSK modulation. (For a Hamming code, if n is known, then k can be computed directly from n .)
berub $=$ bercoding(EbNo,'Golay', 'hard', 24) returns an upper bound of the BER of a Golay code using hard-decision decoding and coherent BPSK modulation. Support for Golay currently is only for $\mathrm{n}=24$. In accordance with [3], the Golay coding upper bound assumes only the correction of

3-error patterns. Even though it is theoretically possible to correct approximately 19\% of 4-error patterns, most decoders in practice do not have this capability.
berapprox $=$ bercoding(EbNo, 'RS', 'hard', $n, k$ ) returns an approximation of the BER of $(\mathrm{n}, \mathrm{k})$ Reed-Solomon code using hard-decision decoding and coherent BPSK modulation.
berapprox $=$ bercoding(..., modulation) returns an approximation of the BER for coded AWGN channels when you specify a modulation type. See the berawgn function for a listing of the supported modulation types.

## Examples

## Upper Bound on Theoretical BER for a Block Code

Find an upper bound on the theoretical BER of a $(23,12)$ block code.
Set the example parameters.

```
n = 23; % Codeword length
k = 12; % Message length
dmin = 7; % Minimum distance
EbNo = 1:10; % Eb/No range (dB)
```

Estimate the BER.
berBlk $=$ bercoding(EbNo,'block','hard', $n, k, d m i n) ;$

Plot the estimated BER.

```
berfit(EbNo,berBlk)
```

ylabel('Bit Error Probability')
title('BER Upper Bound vs. Eb/No, with Best Curve Fit')

## Estimate Coded BER Performance of 16-QAM in AWGN

Estimate the performance of a 16-QAM channel in AWGN when encoded with a $(15,11)$ Reed-Solomon code using hard-decision decoding.

Set the input Eb/No range and determine the uncoded BER for 16-QAM.

```
ebno = (2:12)';
uncodedBER = berawgn(ebno,'qam',16);
```

Estimate the coded BER for 16-QAM channel with a $(15,11)$ Reed-Solomon code using hard decision decoding.

```
codedBER = bercoding(ebno,'RS','hard',15,11,'qam',16);
```

Plot the estimated BER curves.

```
semilogy(ebno,[uncodedBER codedBER])
grid
legend('Uncoded BER','Coded BER')
xlabel('Eb/No (dB)')
ylabel('BER')
```

## Limitations

The numerical accuracy of this function's output is limited by

- Approximations in the analysis leading to the closed-form expressions that the function uses
- Approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

## Alternatives

As an alternative to the bercoding function, invoke the BERTool GUI (bertool) and use the Theoretical tab.

## berconfint

Bit error rate (BER) and confidence interval of Monte Carlo simulation

## Syntax

```
[ber,interval] = berconfint(nerrs,ntrials)
[ber,interval] = berconfint(nerrs,ntrials,level)
```

## Description

[ber,interval] = berconfint(nerrs,ntrials) returns the error probability estimate ber and the $95 \%$ confidence interval interval for a Monte Carlo simulation of ntrials trials with nerrs errors. interval is a two-element vector that lists the endpoints of the interval. If the errors and trials are measured in bits, the error probability is the bit error rate (BER); if the errors and trials are measured in symbols, the error probability is the symbol error rate (SER).
[ber,interval] = berconfint(nerrs,ntrials,level) specifies the confidence level as a real number between 0 and 1 .

## Examples

If a simulation of a communication system results in 100 bit errors in $10^{6}$ trials, the BER (bit error rate) for that simulation is the quotient $10^{-4}$. The command below finds the $95 \%$ confidence interval for the BER of the system.

```
nerrs = 100; % Number of bit errors in simulation
ntrials = 10^6; % Number of trials in simulation
level = 0.95; % Confidence level
[ber,interval] = berconfint(nerrs,ntrials,level)
```

The output below shows that, with $95 \%$ confidence, the BER for the system is between 0.0000814 and 0.0001216 .

```
ber =
    1.0000e-004
interval =
    1.0e-003 *
        0.0814 0.1216
```

For an example that uses the output of berconfint to plot error bars on a BER plot, see "Curve Fitting An Error Rate Plot"

## berfading

Bit error rate (BER) for Rayleigh and Rician fading channels

## Syntax

```
ber = berfading(EbNo,'pam',M,divorder)
ber = berfading(EbNo,'qam',M,divorder)
ber = berfading(EbNo,'psk',M,divorder)
ber = berfading(EbNo,'depsk',M,divorder)
ber = berfading(EbNo,'oqpsk',divorder)
ber = berfading(EbNo,'dpsk',M,divorder)
ber = berfading(EbNo,'fsk',M,divorder,coherence)
ber = berfading(EbNo,'fsk',2,divorder,coherence,rho)
ber = berfading(EbNo,....,K)
ber = berfading(EbNo,'psk',2,1,K,phaserr)
[BER,SER] = berfading(EbNo, ...)
```

## Description

## For All Syntaxes

The first input argument, EbNo, is the ratio of bit energy to noise power spectral density, in dB. If EbNo is a vector, the output ber is a vector of the same size, whose elements correspond to the different $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ levels.

Most syntaxes also have an M input that specifies the alphabet size for the modulation. M must have the form $2^{\mathrm{k}}$ for some positive integer k .
berfading uses expressions that assume Gray coding. If you use binary coding, the results may differ.

For cases where diversity is used, the $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ on each diversity branch is EbNo/divorder, where divorder is the diversity order (the number of diversity branches) and is a positive integer.

## For Specific Syntaxes

ber = berfading(EbNo,'pam',M, divorder) returns the BER for PAM over an uncoded Rayleigh fading channel with coherent demodulation.
ber = berfading(EbNo,'qam',M, divorder) returns the BER for QAM over an uncoded Rayleigh fading channel with coherent demodulation. The alphabet size, $M$, must be at least 4 . When
$k=\log _{2} M$ is odd, a rectangular constellation of size $M=I \times J$ is used, where $I=2^{\frac{k-1}{2}}$ and $J=2^{\frac{k+1}{2}}$.
ber = berfading(EbNo, 'psk',M, divorder) returns the BER for coherently detected PSK over an uncoded Rayleigh fading channel.
ber = berfading(EbNo,'depsk',M,divorder) returns the BER for coherently detected PSK with differential data encoding over an uncoded Rayleigh fading channel. Only $M=2$ is currently supported.
ber = berfading(EbNo,'oqpsk', divorder) returns the BER of coherently detected offsetQPSK over an uncoded Rayleigh fading channel.
ber = berfading(EbNo, 'dpsk',M, divorder) returns the BER for DPSK over an uncoded Rayleigh fading channel. For DPSK, it is assumed that the fading is slow enough that two consecutive symbols are affected by the same fading coefficient.
ber = berfading(EbNo,'fsk',M,divorder, coherence) returns the BER for orthogonal FSK over an uncoded Rayleigh fading channel. coherence should be ' coherent' for coherent detection, or 'noncoherent' for noncoherent detection.
ber = berfading(EbNo,'fsk',2,divorder, coherence, rho) returns the BER for binary nonorthogonal FSK over an uncoded Rayleigh fading channel. rho is the complex correlation coefficient. See "Nonorthogonal 2-FSK with Coherent Detection" for the definition of the complex correlation coefficient and how to compute it for nonorthogonal BFSK.
ber $=$ berfading (EbNo, . . . K) returns the BER over an uncoded Rician fading channel, where K is the ratio of specular to diffuse energy in linear scale. For the case of ' fsk', rho must be specified before K .
ber = berfading(EbNo,'psk',2,1,K, phaserr) returns the BER of BPSK over an uncoded Rician fading channel with imperfect phase synchronization. phaserr is the standard deviation of the reference carrier phase error in radians.
[BER,SER] = berfading(EbNo, ...) returns both the BER and SER.

## Examples

## Estimate BER Performance of 16-QAM in Fading

Generate a vector of $\mathrm{Eb} /$ No values to evaluate.
EbNo = 8:2:20;
Initialize the BER results vector.
ber $=$ zeros(length(EbNo), 20);
Generate BER vs. Eb/No curves for 16-QAM in a fading channel. Vary the diversity order from 1 to 20 .

```
for L = 1:20
    ber(:,L) = berfading(EbNo,'qam',16,L);
end
```

Plot the results.

```
semilogy(EbNo,ber,'b')
text(18.5, 0.02, sprintf('L=%d',1))
text(18.5, le-11, sprintf('L=%d',20))
title('QAM over fading channel with diversity order 1 to 20')
xlabel('E b/N 0 (dB)')
```

```
ylabel('BER')
```

grid on

## Limitations

The numerical accuracy of this function's output is limited by approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

## Alternatives

As an alternative to the berfading function, invoke the BERTool GUI (bertool), and use the Theoretical tab.

## berfit

Fit curve to nonsmooth empirical bit error rate (BER) data

## Syntax

```
fitber = berfit(empEbNo,empber)
fitber = berfit(empEbNo,empber,fitEbNo)
fitber = berfit(empEbNo,empber,fitEbNo,options)
fitber = berfit(empEbNo,empber,fitEbNo,options,fittype)
[fitber,fitprops] = berfit(...)
berfit(...)
berfit(empEbNo,empber,fitEbNo,options,'all')
```

## Description

fitber $=$ berfit(empEbNo,empber) fits a curve to the empirical BER data in the vector empber and returns a vector of fitted bit error rate (BER) points. The values in empber and fitber correspond to the $E_{b} / N_{0}$ values, in dB , given by empEbNo. The vector empEbNo must be in ascending order and must have at least four elements.

Note The berfit function is intended for curve fitting or interpolation, not extrapolation. Extrapolating BER data beyond an order of magnitude below the smallest empirical BER value is inherently unreliable.
fitber $=$ berfit(empEbNo,empber,fitEbNo) fits a curve to the empirical BER data in the vector empber corresponding to the $E_{\mathrm{b}} / N_{0}$ values, in dB , given by empEbNo. The function then evaluates the curve at the $E_{\mathrm{b}} / N_{0}$ values, in dB , given by fitEbNo and returns the fitted BER points. The length of fitEbNo must equal or exceed that of empEbNo.
fitber = berfit(empEbNo,empber,fitEbNo,options) uses the structure options to override the default options used for optimization. These options are the ones used by the fminsearch function. You can create the options structure using the optimset function. Particularly relevant fields are described in the table below.

| Field | Description |
| :--- | :--- |
| options.Display | Level of display: ' off ' (default) displays no <br> output; ' 'iter ' displays output at each iteration; <br> 'final ' displays only the final output; ' notify ' <br> displays output only if the function does not <br> converge. |
| options . MaxFunEvals | Maximum number of function evaluations before <br> optimization ceases. The default is $10^{4}$. |
| options. MaxIter | Maximum number of iterations before optimization <br> ceases. The default is $10^{4}$. |

| Field | Description |
| :--- | :--- |
| options. TolFun | Termination tolerance on the closed-form function <br> used to generate the fit. The default is $10^{-4}$. |
| options. TolX | Termination tolerance on the coefficient values of <br> the closed-form function used to generate the fit. <br> The default is $10^{-4}$. |

fitber = berfit(empEbNo,empber,fitEbNo,options,fittype) specifies which closed-form function berfit uses to fit the empirical data, from the possible fits listed in "Algorithms" on page 277 below. fittype can be 'exp', 'exp+const', 'polyRatio', or 'doubleExp+const'. To avoid overriding default optimization options, use options $=$ [].
[fitber,fitprops] = berfit(...) returns the MATLAB structure fitprops, which describes the results of the curve fit. Its fields are described in the table below.

| Field | Description |
| :--- | :--- |
| fitprops.fitType | The closed-form function type used to generate <br> the fit: 'exp', 'exp+const ' ' polyRatio', or <br> 'doubleExp+const'. |
| fitprops.coeffs | The coefficients used to generate the fit. If the <br> function cannot find a valid fit, <br> fitprops. coeffs is an empty vector. |
| fitprops.sumSqErr | The sum squared error between the log of the <br> fitted BER points and the log of the empirical <br> BER points. |
| fitprops.exitState | The exit condition of berfit: ' The curve fit <br> converged to a solution. ', 'The <br> maximum number of function <br> evaluations was exceeded. ' or 'No <br> desirable fit was found '. |
| fitprops.funcCount | The number of function evaluations used in <br> minimizing the sum squared error function. |
| fitprops.iterations | The number of iterations taken in minimizing the <br> sum squared error function. This is not <br> necessarily equal to the number of function <br> evaluations. |

berfit(...) plots the empirical and fitted BER data.
berfit(empEbNo,empber,fitEbNo,options,'all') plots the empirical and fitted BER data from all the possible fits, listed in the "Algorithms" on page 2-77 below, that return a valid fit. To avoid overriding default options, use options = [].

## Note A valid fit must be

- real-valued
- monotonically decreasing
- greater than or equal to 0 and less than or equal to 1

If a fit does not confirm to this criteria, it is rejected.

## Examples

## Bit Error Rate Curve Fitting

These examples illustrate the syntax of the berfit function, but they use hard-coded or theoretical BER data for simplicity. For an example that uses empirical BER data from a simulation, see "Curve Fitting An Error Rate Plot".

## Best fit for a sample set of data

```
EbN0 = 0:13;
berdata = [.2 . 15 . 13 . 12 . 08 . 09 . 08 . 07 . 06 . 04 . 03 . 02 .01 .004];
berfit(EbN0,berdata);
```

BER vs. Eb/No with Best Curve Fit

Plot the best fit. The curve connects the points created by evaluating the fit expression at the values in EbN0. To make the curve look smoother, use a syntax like berfit(EbN0, berdata, [0:0.2:13]). This alternative syntax uses more points when plotting the curve, but it does not change the fit expression.

## Fit for a BER curve with an error floor

We generate the empirical BER array by simulating a channel with a null (ch $=[0.50 .47]$ ) with BPSK modulation and linear MMSE equalizer at the receiver. We run the berfit with the 'all' option. The
'doubleExp+const' fit does not provide a valid fit, and the 'exp' fit type does not work well for this data. The 'exp+const' and 'polyRatio' fits closely match the simulated data.

```
EbN0 = -10:3:15;
empBER = [0.3361 0.3076 0.2470 0.1878 0.1212 0.0845 0.0650 0.0540 0.0474];
figure; berfit(EbN0, empBER, [], [], 'all');
```

## Use of the options input structure as well as the fitprops output structure

The 'notify' value for the display level causes the function to produce output when one of the attempted fits does not converge. The exitState field of the output structure also indicates which fit converges and which fit does not.

```
M = 8; EbN0 = 3:10;
berdata = berfading(EbN0,'psk',M,2); % Compute theoretical BER.
noisydata = berdata.*[.93 . 92 1 .59 . 08 . 15 .01 .01];
% Say when fit fails to converge.
options = optimset('display','notify');
disp('*** Trying exponential fit.') % Poor fit
*** Trying exponential fit.
[fitber1,fitprops1] = berfit(EbN0,noisydata,EbN0,...
    options,'exp')
```

```
Exiting: Maximum number of function evaluations has been exceeded
    - increase MaxFunEvals option.
    Current function value: 2.749919
fitber1 = 1×8
    0.1247 0.0727 0.0376 0.0168 0.0064 0.0020 0.0005 0.0001
fitprops1 = struct with fields:
        fitType: 'exp'
            coeffs: [4x1 double]
        sumSqErr: 2.7499
        exitState: 'The maximum number of function evaluations has been exceeded'
        funcCount: 10001
    iterations: 6193
disp('*** Trying polynomial ratio fit.') % Good fit
*** Trying polynomial ratio fit.
[fitber2,fitprops2] = berfit(EbN0,noisydata,EbN0,...
    options,'polyRatio')
fitber2 = 1×8
\begin{tabular}{llllllll}
0.1701 & 0.0874 & 0.0407 & 0.0169 & 0.0060 & 0.0016 & 0.0003 & 0.0001
\end{tabular}
fitprops2 = struct with fields:
        fitType: 'polyRatio'
        coeffs: [6x1 double]
        sumSqErr: 2.3880
        exitState: 'The curve fit converged to a solution'
        funcCount: 554
    iterations: 331
```

## Algorithms

The berfit function fits the BER data using unconstrained nonlinear optimization via the fminsearch function. The closed-form functions that berfit considers are listed in the table below, where $x$ is the $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ in linear terms (not dB ) and $f$ is the estimated BER. These functions were empirically found to provide close fits in a wide variety of situations, including exponentially decaying BERs, linearly varying BERs, and BER curves with error rate floors.

| Value of fittype | Functional Expression |
| :--- | :--- |
| ' $\exp$ ' | $f(x)=a_{1} \exp \left[\frac{-\left(x-a_{2}\right)^{a_{3}}}{a_{4}}\right]$ |
| ' exp+const' | $f(x)=a_{1} \exp \left[\frac{-\left(x-a_{2}\right)^{a_{3}}}{a_{4}}\right]+a_{5}$ |

| Value of fittype | Functional Expression |
| :--- | :--- |
| 'polyRatio' | $f(x)=\frac{a_{1} x^{2}+a_{2} x+a_{3}}{x^{3}+a_{4} x^{2}+a_{5} x+a_{6}}$ |
| 'doubleExp+const' | $a_{1} \exp \left[\frac{-\left(x-a_{2}\right)^{a_{3}}}{a_{4}}\right]$ <br>  <br>  <br> $a_{5} \exp \left[\frac{-\left(x-a_{6}\right)^{a_{7}}}{a_{8}}\right]+a_{9}$ |

The sum squared error function that fminsearch attempts to minimize is

$$
F=\sum[\log (\text { empirical BER })-\log (\text { fitted BER })]^{2}
$$

where the fitted BER points are the values in fitber and the sum is over the $E_{b} / N_{0}$ points given in empEbNo. It is important to use the log of the BER values rather than the BER values themselves so that the high-BER regions do not dominate the objective function inappropriately.

## bersync

Bit error rate (BER) for imperfect synchronization

## Syntax

ber $=$ bersync(EbNo,timerr,'timing')
ber $=$ bersync(EbNo,phaserr,'carrier')

## Description

ber = bersync(EbNo,timerr,'timing') returns the BER of uncoded coherent binary phase shift keying (BPSK) modulation over an additive white Gaussian noise (AWGN) channel with imperfect timing. The normalized timing error is assumed to have a Gaussian distribution. EbNo is the ratio of bit energy to noise power spectral density, in dB . If EbNo is a vector, the output ber is a vector of the same size, whose elements correspond to the different $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ levels. timerr is the standard deviation of the timing error, normalized to the symbol interval. timerr must be between 0 and 0.5 .
ber = bersync(EbNo, phaserr,'carrier') returns the BER of uncoded BPSK modulation over an AWGN channel with a noisy phase reference. The phase error is assumed to have a Gaussian distribution. phaserr is the standard deviation of the error in the reference carrier phase, in radians.

## Examples

## Calculate Bit Error Rate (BER) for Imperfect Synchronization

The code below computes the BER of coherent BPSK modulation over an AWGN channel with imperfect timing. The example varies both EbNo and timerr. (When timerr assumes the final value of zero, the bersync command produces the same result as berawgn(EbNo, 'psk',2).)

```
EbNo = [4 8 12];
timerr = [0.2 0.07 0];
ber = zeros(length(timerr),length(EbNo));
for ii = 1:length(timerr)
    ber(ii,:) = bersync(EbNo,timerr(ii),'timerr');
end
```

Display result using scientific notation.

```
format short e; ber
ber = 3 3 3
    5.2073e-02 2.0536e-02 1.1160e-02
    1.8948e-02 7.9757e-04 4.9008e-06
    1.2501e-02 1.9091e-04 9.0060e-09
```

Switch back to default notation format.
format;

## Limitations

The numerical accuracy of this function's output is limited by

- Approximations in the analysis leading to the closed-form expressions that the function uses
- Approximations related to the numerical implementation of the expressions

You can generally rely on the first couple of significant digits of the function's output.

## Limitations Related to Extreme Values of Input Arguments

Inherent limitations in numerical precision force the function to assume perfect synchronization if the value of timerr or phaserr is very small. The table below indicates how the function behaves under these conditions.

| Condition | Behavior of Function |
| :--- | :--- |
| timerr < eps | bersync (EbNo, timerr,'timing') defined as <br> berawgn(EbNo,'psk', 2) |
| phaserr < eps | bersync(EbNo, phaserr, 'carrier') defined as <br> berawgn(EbNo,' $\left.p s k^{\prime}, 2\right)$ |

## Algorithms

This function uses formulas from [3].
When the last input is 'timing', the function computes

$$
\frac{1}{4 \Pi \sigma} \int_{-\infty}^{\infty} \exp \left(-\frac{\xi^{2}}{2 \sigma^{2}}\right) \int_{\sqrt{2 R}(1-2|\xi|)}^{\infty} \exp \left(-\frac{x^{2}}{2}\right) d x d \xi+\frac{1}{2 \sqrt{2 \Pi}} \int_{\sqrt{2 R}}^{\infty} \exp \left(-\frac{x^{2}}{2}\right) d x
$$

where $\sigma$ is the timerr input and $R$ is the value of EbNo converted from $d B$ to a linear scale.
When the last input is 'carrier', the function computes

$$
\frac{1}{\Pi \sigma} \int_{0}^{\infty} \exp \left(-\frac{\phi^{2}}{2 \sigma^{2}}\right) \int_{\sqrt{2 R} \cos \phi}^{\infty} \exp \left(-\frac{y^{2}}{2}\right) d y d \phi
$$

where $\sigma$ is the phaserr input and $R$ is the value of EbNo converted from $d B$ to a linear scale.

## Alternatives

As an alternative to the bersync function, invoke the BERTool GUI (bertool) and use the Theoretical tab.

## bertool

Open bit error rate analysis GUI (BERTool)

## Syntax

bertool

## Description

bertool launches the Bit Error Rate Analysis Tool (BERTool). The BERTool application enables you to analyze the bit error rate (BER) performance of communications systems. BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB functions and Simulink models or with theoretical closed-form expressions for selected types of communication systems. See "BERTool" to learn more.

Introduced before R2006a

## bi2de

Convert binary vectors to decimal numbers

## Syntax

d = bi2de(b)
$\mathrm{d}=\mathrm{bi} 2 \mathrm{de}(\mathrm{b}, \mathrm{flg})$
$\mathrm{d}=\mathrm{bi2de}(\mathrm{~b}, \mathrm{p})$
$d=\operatorname{bi2de}(b, p, f l g)$

## Description

$\mathrm{d}=\mathrm{bi2de}(\mathrm{~b})$ converts a binary row vector b to a decimal integer.
$\mathrm{d}=\mathrm{bi} 2 \mathrm{de}(\mathrm{b}, \mathrm{flg})$ converts a binary row vector to a decimal integer, where flg determines the position of the most significant digit.
$d=b i 2 d e(b, p)$ converts a base-p row vector $b$ to a decimal integer.
$d=b i 2 d e(b, p, f l g)$ converts a base-p row vector to a decimal integer, where flg determines the position of the most significant digit.

## Examples

## Convert Binary Numbers to Decimals

Generate a matrix that contains binary representations of five random numbers between 0 and 15 . Convert the binary numbers to decimal integers.

```
b = randi([0 1],5,4);
d = bi2de(b)
d = 5×1
    1
    5
    14
    1 1
    1 5
```

## Convert Binary to Decimal

This example shows how to convert binary numbers to decimal integers. It highlights the difference between right- and left- most significant digit positioning.
b1 $=\left[\begin{array}{lllll}0 & 1 & 0 & 1 & 1\end{array}\right] ;$
b2 = [1 1 1 0 ];

Convert the two binary arrays to decimal by using the bi2de function. Assign the most significant digit is the leftmost element. The output of converting b1 corresponds to $0\left(2^{4}\right)+1\left(2^{3}\right)+0\left(2^{2}\right)+1\left(2^{1}\right)+1\left(2^{0}\right)=11$, and b2 corresponds to $1\left(2^{3}\right)+1\left(2^{2}\right)+1\left(2^{1}\right)+0\left(2^{0}\right)=14$.
d1 = bi2de(b1,'left-msb')
d1 = 11
d2 = bi2de(b2,'left-msb')
d2 $=14$
Assign the most significant digit is the rightmost element. The output of converting b1 corresponds to $0\left(2^{0}\right)+1\left(2^{1}\right)+0\left(2^{2}\right)+1\left(2^{3}\right)+1\left(2^{4}\right)=26$, and b2 corresponds to $1\left(2^{0}\right)+1\left(2^{1}\right)+1\left(2^{2}\right)+0\left(2^{3}\right)=7$. d1 = bi2de(b1,'right-msb')
d1 $=26$
d2 = bi2de(b2,'right-msb')
d2 $=7$

## Convert Octal Number to Decimal

Convert an octal (base-8) number to its decimal equivalent.
Assign the most significant digit to the leftmost position. The output corresponds to
$4\left(8^{3}\right)+2\left(8^{2}\right)+7\left(8^{1}\right)+1\left(8^{0}\right)=2233$.
d = bi2de([4 27 1],8,'left-msb')
d $=2233$
Assign the most significant digit to the rightmost position. The output corresponds to $4\left(8^{0}\right)+2\left(8^{1}\right)+7\left(8^{2}\right)+1\left(8^{3}\right)=980$.
d = bi2de([4 27 1],8,'right-msb')
$d=980$

## Input Arguments

b - Binary input
row vector | matrix
Binary input, specified as a row vector or matrix.

Note b must represent an integer less than or equal to $2^{52}$.
flg - MSB flag
'right-msb' (default)|'left-msb'

MSB flag, specified as 'right-msb' or 'left-msb'.

- 'right-msb' -- Indicates the right (or last) column of the binary input, $b$, as the most significant bit (or highest-order digit).
- ' left-msb' -- Indicates the left (or first) column of the binary input, b, as the most significant bit (or highest-order digit).

## p - Base

2 (default) | positive integer scalar
Base of the input $b$, specified as an integer greater than or equal to 2 .

## Output Arguments

## d - Decimal output <br> nonnegative integer | vector

Decimal output, returned as an nonnegative integer or row vector. If $b$ is a matrix, each row represents a base-p number. In this case, the output $d$ is a column vector in which each element is the decimal representation of the corresponding row of $b$.

If the value of $d$ can be contained in the same data type as the input, it inherits the input data type. Otherwise, the output data type is chosen to be big enough to contain the decimal output.

## bin2gray

(To be removed) Convert positive integers into corresponding Gray-encoded integers

Note will be removed in a future release. Use the appropriate modulation object or function to remap constellation points instead. For more information, see "Compatibility Considerations".

## Syntax

$y=$ bin2gray ( $x$, modulation, $M$ )
[y,map] = bin2gray(x,modulation, M)

## Description

$y=$ bin2gray ( $x$, modulation,$M$ ) generates a Gray-encoded vector or matrix output $y$ with the same dimensions as its input parameter x . x can be a scalar, vector, matrix, or 3-D array. modulation is the modulation type and must be 'qam', 'pam', 'fsk', 'dpsk', or 'psk'. M is the modulation order and must be an integer power of 2 .

Note If you are converting binary-coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the 'Gray ' option, instead of bin2gray.
[ y , map] = bin2gray ( x , modulation, $M$ ) generates a Gray-encoded output y with its respective Gray-encoded constellation map, map.

You can use map output to label a Gray-encoded constellation. The map output gives the Grayencoded labels for the corresponding modulation.

## Examples

## Binary to Gray Symbol Mapping

This example shows how to use the bin2gray and gray2bin functions to map integer inputs from a natural binary order symbol mapping to a Gray-coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray-coded and binary-coded symbol mappings is shown.

## Convert Binary to Gray

Create a complete vector of 16-QAM integers.
M = 16;
$x=(0: M-1)$;
Convert the input vector from a natural binary order to a Gray-encoded vector using bin2gray.

```
[y,mapy] = bin2gray(x,'qam',M);
```

## Convert Gray to Binary

Convert the Gray-encoded symbols, y , back to a binary ordering using gray2bin.
z = gray2bin(y,'qam', M);
Verify that the original data, $x$, and the final output vector, $z$, are identical.

```
isequal(x,z)
ans = logical
    1
```

## Show Symbol Mappings

To create a constellation plot showing the different symbol mappings, use the qammod function to find the complex symbol values.

```
sym = qammod(x,M);
```

Plot the constellation symbols and label them using the Gray ( $y$ ) and binary ( $z$ ) output vectors. The binary representation of the Gray-coded symbols is shown in black while the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
scatterplot(sym,1,0,'b*');
for k = 1:16
    text(real(sym(k))-0.3,imag(sym(k))+0.3,...
        dec2base(mapy(k),2,4));
    text(real(sym(k))-0.3,imag(sym(k))-0.3,...
        dec2base(z(k),2,4),'Color',[1 0 0]);
end
axis([-4 4 -4 4])
```

## Input Arguments

x - Binary-encoded data
vector | matrix
Input binary-encoded data, specified as a vector or matrix.
Data Types: double
modulation - Modulation type
'qam'|'pam'|'fsk'|'dpsk'|'psk'
Modulation type, specified as, 'qam', 'pam', 'fsk', 'dpsk', or 'psk'
M - Modulation order
scalar
Modulation order, specified as an integer power of 2.
Data Types: double

## Output Arguments

## y - Gray-encoded data

vector | matrix

Gray-encoded data with the same size and dimensions input $x$.

## map - Map of labels

vector
Map output to label a Gray-encoded constellation, specified as a vector with a length the size of the modulation order, M. The map gives the Gray-encoded labels for the corresponding modulation.

## Compatibility Considerations

## bin2gray will be removed

Not recommended starting in R2020a
bin2gray will be removed in a future release. Use the appropriate modulation object or function instead. If your workflow uses bin2gray or gray2bin with any of the modulations schemes in this table, follow the appropriate example.

| Modulation | Old Functionality | Use This Instead |
| :---: | :---: | :---: |

Gray Encoding a Modulated Signal

Introduced before R2006a

## biterr

Number of bit errors and bit error rate (BER)

## Syntax

[number, ratio] = biterr $(x, y)$
[number, ratio] $=\operatorname{biterr}(x, y, k)$
[number, ratio] $=\operatorname{biterr}(x, y, k, f l a g)$
[number, ratio,individual] = biterr( $\qquad$ )

## Description

[number, ratio] $=$ biterr $(x, y)$ compares the unsigned binary representation of elements in $x$ to those in y . The function returns number, the number of bits that differ in the comparison, and ratio, the ratio of number to the total number of bits. The function determines the order in which it compares $x$ and $y$ based on their sizes. For more details, see Algorithms on page 2-95 section.
[number, ratio] = biterr ( $x, y, k$ ) also specifies $k$, the maximum number of bits for each element in $x$ and $y$. If the unsigned binary representation of any element in $x$ or $y$ is more than $k$ digits, the function errors.
[number, ratio] = biterr( $x, y, k, f l a g)$ specifies a flag to override default settings for how the function compares the elements and computes the outputs. For more information, see Algorithms on page 2-96 section.
[number, ratio,individual] = biterr (__ ) returns the binary comparison result of x and y as matrix individual. You can specify any of the input argument combination from the previous syntaxes.

## Examples

## Bit Error Rate Computation

Create two binary matrices.

```
x = [0 0; 0 0; 0 0; 0 0]
x = 4×2
    0}
    0
    0}
    0
y = [0 0; 0 0; 0 0; 1 1]
y = 4\times2
    0 0
```

```
0}
0
1 1
```

Determine the number of bit errors.

```
numerrs = biterr(x,y)
numerrs = 2
```

Compute the number of column-wise errors .

```
numerrs = biterr(x,y,[],'column-wise')
numerrs = 1\times2
```

    \(1 \quad 1\)
    Compute the number of row-wise errors.

```
numerrs = biterr(x,y,[],'row-wise')
numerrs = 4×1
    0
    0
    0
    2
```

Compute the number of overall errors. Behavior is the same as the default behaviour.

```
numerrs = biterr(x,y,[],'overall')
numerrs = 2
```

## Estimate Bit Error Rate for 64-QAM in AWGN

Demodulate a noisy 64-QAM signal and estimate the bit error rate (BER) for a range of Eb/No values. Compare the BER estimate to theoretical values.

Set the simulation parameters.

```
M = 64; % Modulation order
k = log2(M); % Bits per symbol
EbNoVec = (5:15)'; % Eb/No values (dB)
numSymPerFrame = 100; % Number of QAM symbols per frame
Initialize the results vector.
berEst = zeros(size(EbNoVec));
```

The main processing loop executes these steps.

- Generate binary data and convert to 64 -ary symbols.
- QAM-modulate the data symbols.
- Pass the modulated signal through an AWGN channel.
- Demodulate the received signal.
- Convert the demodulated symbols into binary data.
- Calculate the number of bit errors.

The while loop continues to process data until either 200 errors are encountered or 1 e 7 bits are transmitted.

```
for n = 1:length(EbNoVec)
    % Convert Eb/No to SNR
    snrdB = EbNoVec(n) + 10*log10(k);
    % Reset the error and bit counters
    numErrs = 0;
    numBits = 0;
    while numErrs < 200 && numBits < 1e7
        % Generate binary data and convert to symbols
        dataIn = randi([0 1],numSymPerFrame,k);
        dataSym = bi2de(dataIn);
        % QAM modulate using 'Gray' symbol mapping
        txSig = qammod(dataSym,M);
        % Pass through AWGN channel
        rxSig = awgn(txSig,snrdB,'measured');
            % Demodulate the noisy signal
            rxSym = qamdemod(rxSig,M);
            % Convert received symbols to bits
            dataOut = de2bi(rxSym,k);
            % Calculate the number of bit errors
            nErrors = biterr(dataIn,data0ut);
            % Increment the error and bit counters
            numErrs = numErrs + nErrors;
            numBits = numBits + numSymPerFrame*k;
    end
    % Estimate the BER
    berEst(n) = numErrs/numBits;
end
```

Determine the theoretical BER curve by using the berawgn function.

```
berTheory = berawgn(EbNoVec,'qam',M);
```

Plot the estimated and theoretical BER data. The estimated BER data points are well aligned with the theoretical curve.

```
semilogy(EbNoVec,berEst,'*')
hold on
semilogy(EbNoVec,berTheory)
grid
```

legend('Estimated BER','Theoretical BER')

ylabel('Bit Error Rate')

## Input Arguments

## $\mathrm{x}, \mathrm{y}$ - Inputs to be compared (as separate arguments) <br> vector | matrix

Inputs to be compared, specified as separate arguments, as a vector or matrix of nonnegative integer elements. The function converts each element of $x$ and $y$ to its unsigned binary representation for comparison.

```
Data Types: single| double| int8| int16| int32| int64|uint8|uint16|uint32|uint64|
logical
```

## k - Maximum number of bits for input elements

positive integer
Maximum number of bits for input elements of $x$ and $y$, specified as a positive integer. If the number of bits required for binary representation of any element in $x$ or $y$ is greater than $k$, the function errors.

If you do not set $k$, the function sets it as the number of bits in the binary representation of the largest element in x and y .

## Data Types: single | double

## flag - Flag to override default settings

'overall' | 'row-wise'| 'column-wise'
Flag to override default settings of the function, specified as 'overall', 'row-wise', or 'columnwise'. Flag specifies how the function compares elements in inputs $x, y$ and computes the output. For more details, see the Algorithms on page 2-96 section.
Data Types: string | char

## Output Arguments

## number - Number of bit errors

nonnegative integer | integer vector
Number of bit errors, returned as a nonnegative integer or integer vector.
Data Types: single | double
ratio - Bit error rate
scalar
Bit error rate, returned as a scalar. ratio is the number of bit errors, number, to the total number of bits used in the binary representation. The total number of bits is $k$ times the number of entries in the smaller of the inputs $\mathrm{x}, \mathrm{y}$.

## individual - Binary comparison result of each input element matrix

Binary comparison result of each input element in $x$ and $y$, returned as a matrix whose dimensions are those of the larger of $x$ and $y$. Each element specifies the number of bits by which the elements in the pair differ.
Data Types: single | double

## Algorithms

## Comparing Inputs Based on Sizes

The function uses the sizes of $x$ and $y$ to determine the order in which it compares their elements.

- If inputs are matrices of the same dimensions, then the function compares the inputs element by element. number is a nonnegative integer in this case. For example, see case (a) in the figure.
- If one input is a matrix and the other input is a column vector, then the function compares each column of the matrix element by element with the column vector. The number of rows in the matrix must be equal to the length of the column vector. In other words, if the matrix has dimensions $m$-by- $n$, then the column vector must have dimensions $m$-by- 1 . For example, see case (b) in the figure.
- If one input is a matrix and the other input is a row vector, then the function compares each row of the matrix element by element with the row vector. The number of columns in the matrix must be equal to the length of the row vector. In other words, if the matrix has dimensions $m$-by- $n$, then the row vector must have dimensions 1-by-n. For example, see case (c) in the figure.

## Comparing Inputs Based on Flag

This table describes how the output is computed based on the different values of $\mathrm{flag} . \mathrm{x}$ is considered as a matrix in this table and the size of y is varied.

| Size of $y$ | flag Value | Type of Comparison | number Value | Total Number of Bits |
| :---: | :---: | :---: | :---: | :---: |
| Matrix | 'overall' (default) | Element by element | Total number of bit errors | $k$ times the number of elements in $y$ |
|  | 'row-wise' | mth row of x to mth row of $y$ | Column vector whose elements represent the bit errors in each row | k times the number of elements in $y$ |
|  | 'column-wise' | mth column of x to $m$ th column of $y$ | Row vector whose elements represent the bit errors in each column | $k$ times the number of elements in $y$ |
| Row vector | 'overall' | $y$ to each row of $x$ | Total number of bit errors | k times the number of elements of $x$ |
|  | 'row-wise'(default) | $y$ to each row of $x$ | Column vector whose elements represent the bit errors in each row of $x$ | $k$ times the size of y |
| Column vector | 'overall' | $y$ to each column of x | Total number of bit errors | k times the number of elements of $x$ |
|  | 'column-wise' (default) | y to each column of x | Row vector whose elements represent bit errors in each column of $x$ | $k$ times the size of y |

## bsc

Binary symmetric channel

## Syntax

```
ndata = bsc(data,probability)
ndata = bsc(data,probability,streamhandle)
ndata = bsc(data,probability,seed)
[ndata,err] = bsc(
```

$\qquad$

``` )
```

## Description

ndata $=\mathrm{bsc}($ data, probability) passes the binary input signal data through a binary symmetric channel having the specified error probability. The channel introduces a bit error and processes each element of the input data independently. data must be an array of binary numbers or a Galois array in $\mathrm{GF}(2)$. probability must be a scalar from 0 to 1 .
ndata $=$ bsc(data, probability, streamhandle) accepts a random stream handle to generate uniform noise samples by using rand. Providing a random stream handle or using the reset function on the default random stream object enables you to generate repeatable noise samples. For more information, see RandStream.
ndata = bsc(data, probability, seed) accepts a seed value, for initializing the uniform random number generator, rand. If you want to generate repeatable noise samples, then either reset the random stream input before calling bsc or use the same seed input.
[ndata,err] = bsc(__ ) returns an array containing the channel errors, using any of the preceding syntaxes.

## Examples

## Add Bit Errors to Bit Stream

Using the bsc function, introduce bit errors in the bits in a random matrix with probability 0.15 .

```
z = randi([0 1],100,100); % Random matrix
nz = bsc(z,.15); % Binary symmetric channel
[numerrs, pcterrs] = biterr(z,nz) % Number and percentage of errors
numerrs = 1509
pcterrs = 0.1509
```

The output below is typical. For relatively small sets of data, the percentage of bit errors is not exactly $15 \%$ in most trials. If the size of the matrix $z$ is large, the bit error percentage will be closer to the exact probability you specify.

## Check for Errors After Decoding

Using the bsc function, introduce bit errors in the bits in a random matrix with probability 0.01 . Use Viterbi decoder to decode message data.

Define trellis for Viterbi decoder. Generate and encode message data.

```
trel = poly2trellis([4 3],[4 5 17;7 4 2]);
msg = ones(10000,1);
```

Create objects for convolutional encoder, Viterbi decoder, and error rate calculator.

```
hEnc = comm.ConvolutionalEncoder(trel);
hVitDec = comm.ViterbiDecoder(trel, 'InputFormat','hard', 'TracebackDepth',...
    2, 'TerminationMethod', 'Truncated');
hErrorCalc = comm.ErrorRate;
```

Encode the message data. Introduce bit errors. Display the total number of errors.

```
code = hEnc(msg);
[ncode,err] = bsc(code,.01);
numchanerrs = sum(sum(err))
numchanerrs = 158
```

Decode the data and check the number of errors after decoding.

```
dcode = hVitDec(ncode);
berVec = hErrorCalc(msg, dcode);
ber = berVec(1)
ber = 0.0049
numsyserrs = berVec(2)
numsyserrs = 49
```

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
Code generation supported, except for syntaxes that include a RandStream object.

## Introduced before R2006a

## cdma2000ForwardReferenceChannels

Define cdma2000 forward reference channel

## Syntax

cfg = cdma2000ForwardReferenceChannels(wv)
cfg = cdma2000ForwardReferenceChannels(wv, numchips)
cfg = cdma2000ForwardReferenceChannels(BSTM-RC, numchips, P,M)
cfg = cdma2000ForwardReferenceChannels(traffic, numchips,F-SCH-SPEC)

## Description

cfg = cdma2000ForwardReferenceChannels(wv) returns a structure, cfg, that defines the cdma $2000{ }^{\circledR}$ forward link parameters given the input waveform identifier, wv. To generate a forward link reference channel waveform, pass this structure to the cdma2000ForwardWaveformGenerator function.

For all syntaxes, cdma2000ForwardReferenceChannels creates a configuration structure that is compliant with the cdma2000 physical layer specification [1].
cfg = cdma2000ForwardReferenceChannels(wv, numchips) specifies the number of chips to generate.
cfg = cdma2000ForwardReferenceChannels(BSTM-RC, numchips,P,M) returns the data structure for the BSTM-RC waveform identifiers, given the total traffic channel power, $P$, and the number of traffic channels, M. For more information on base station testing, see Table 6.5.2-1 of [2].
cfg = cdma2000ForwardReferenceChannels(traffic,numchips,F-SCH-SPEC) returns the data structure for the specified traffic channel, traffic, and the forward supplemental channel ( F SCH ) and frame length combination, $\mathrm{F}-\mathrm{SCH}-\mathrm{SPEC}$. If omitted, $\mathrm{F}-\mathrm{SCH}-\mathrm{SPEC}$ has a default value of the lowest F-SCH data rate allowable for a 20 ms frame length, given the radio configuration specified by traffic.

## Examples

## Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, config, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
config = struct with fields:
    SpreadingRate: 'SR1'
            Diversity: 'NTD'
                        QOF: 'QOFI'
            PNOffset: 0
        LongCodeState: 0
    PowerNormalization: 'Off'
```

```
    OversamplingRatio: 4
        FilterType: 'cdma2000Long'
            InvertQ: 'Off'
    EnableModulation: 'Off'
ModulationFrequency: 0
        NumChips: 1000
            FPICH: [1x1 struct]
            FAPICH: [1x1 struct]
            FTDPICH: [1x1 struct]
        FATDPICH: [1x1 struct]
            FPCH: [1x1 struct]
            FSYNC: [1x1 struct]
            FBCCH: [1x1 struct]
            FCACH: [1x1 struct]
            FCCCH: [1x1 struct]
            FCPCCH: [1x1 struct]
            FQPCH: [1x1 struct]
                FFCH: [1x1 struct]
            FOCNS: [1x1 struct]
            FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is $14,400 \mathrm{bps}$ and the frame length is 20 ms .

```
config.FFCH
ans = struct with fields:
                        Enable: 'On'
            Power: 0
    RadioConfiguration: 'RC2'
            DataRate: 14400
        FrameLength: 20
        LongCodeMask: 0
        EnableCoding: 'On'
        DataSource: {'PN9' [1]}
            WalshCode: 7
            Enable00F: 'Off'
    PowerControlEnable: 'Off'
```

Generate the complex waveform using the corresponding waveform generator function.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

A waveform composed of the channels specified by each substructure of config is generated by cdma2000ForwardWaveformGenerator.

## Generate CDMA200 Waveform Containing Sync Channel Message

Create a reference channel, specify the sync channel message as the data source, add the SyncMessage structure to the FSYNC substructure. Generate the waveform using this reference channel configuration.

Create a reference channel for testing a base station using radio configuration 3.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3');
```

Adjust the Forward Sync Channel (F-SYNC) settings. Set a relative channel power of 0.0 dB and specify the sync channel message as the data source.

```
config.FSYNC.Power = 0.0;
config.FSYNC.DataSource = 'SyncMessage';
```

Define the sync channel message structure (for P_REV $=6$ (IS-2000-0)) and add it to the config. FSYNC substructure. Display the FSYNC structure.

```
sm = struct();
sm.P REV = 6; % Protocol Revision field
sm.MIN P REV = 6; % Minimum Protocol Revision field
sm.SID = hex2dec('14B'); % System Identifier field
sm.NID = 1; % Network Identification field
sm.PILOT_PN = 0; % Pilot PN Offset field
sm.LC_STATTE = hex2dec('20000000000'); % Long Code State field
sm.SYS_TIME = hex2dec('36AE0924C'); % System Time field
sm.LP_\overline{SEC = 0; % Leap Second field}
sm.LTM_OFF = 0; % Local Time Offset field
sm.DAYLT = 0; % Daylight Savings Time Indicator field
sm.PRAT = 0; % Paging Channel Data Rate field
sm.CDMA_FREQ = hex2dec('2F6'); % CDMA Frequency field
sm.EXT_\overline{CDMA_FREQ = hex2dec('2F6'); % Extended CDMA Frequency field}
config.FSYNC.SyncMessage = sm;
config.FSYNC
ans = struct with fields:
    Enable: 'On'
            Power: 0
    EnableCoding: 'On'
    DataSource: 'SyncMessage'
    SyncMessage: [lx1 struct]
```

Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

## Generate F-CCCH Waveform

Create a structure for a 2000-chip forward common control channel (F-CCCH). Specify a $38,400 \mathrm{bps}$ data rate, a 5 ms frame length, and an accompanying broadcast control channel ( $\mathrm{F}-\mathrm{BCCH}$ ) with a 9600 bps data rate.

```
config = cdma2000ForwardReferenceChannels('CONTROL-38400-5-9600', 2000)
config = struct with fields:
    SpreadingRate: 'SR1'
            Diversity: 'NTD'
                QOF: 'QOF1'
            PNOffset: 0
    LongCodeState: 0
```

```
PowerNormalization: 'Off'
    OversamplingRatio: 4
            FilterType: 'cdma2000Long'
            InvertQ: 'Off'
    EnableModulation: 'Off'
ModulationFrequency: 0
        NumChips: 2000
            FPICH: [1x1 struct]
            FPCH: [1x1 struct]
            FCCCH: [1x1 struct]
            FBCCH: [1x1 struct]
```

Verify that the F-CCCH and F-BCCH data rates are $38,400 \mathrm{bps}$ and 9600 bps , respectively.

```
config.FCCCH.DataRate
```

ans $=38400$
config. FBCCH.DataRate
ans $=9600$

Generate the forward link waveform.
waveform = cdma2000ForwardWaveformGenerator(config);

## Generate Waveform for Base Station Testing

Create a reference channel for testing a base station using radio configuration 3 . Specify the number of chips, the total power allocated to the individual channels, and the number of traffic channels. The FFCH substructure is a structure array whose dimensions are set by the number of traffic channels.

```
config = cdma2000ForwardReferenceChannels('BSTM-RC3',1000,-3,4)
config = struct with fields:
        SpreadingRate: 'SR1'
            Diversity: 'NTD'
                            QOF: 'QOF1'
                PNOffset: 0
        LongCodeState: 0
    PowerNormalization: 'Off'
        OversamplingRatio: 4
            FilterType: 'cdma2000Long'
            InvertQ: 'Off'
        EnableModulation: 'Off'
    ModulationFrequency: 0
            NumChips: 1000
            FPICH: [1x1 struct]
            FSYNC: [1x1 struct]
                    FPCH: [1x1 struct]
                    FFCH: [1x4 struct]
```

Verify that the length of the FFCH substructure corresponds to the number of specified traffic channels, 4.

```
length(config.FFCH)
ans = 4
```

Generate the forward link waveform.
waveform = cdma2000ForwardWaveformGenerator(config);

## Generate F-SCH Waveform

Create a traffic channel using radio configuration 7 composed of a $614,400 \mathrm{bps}$ forward supplemental channel (F-SCH) having a 20 ms frame length. Set the number of chips to 5000 .

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
    5000,'F-SCH-614400-20')
config = struct with fields:
            SpreadingRate: 'SR3'
            Diversity: 'NTD'
                            QOF: 'QOF1'
                PNOffset: 0
            LongCodeState: 0
        PowerNormalization: 'Off'
        OversamplingRatio: 4
            FilterType: 'cdma2000Long'
            InvertQ: 'Off'
        EnableModulation: 'Off'
    ModulationFrequency: 0
            NumChips: 5000
            FPICH: [1x1 struct]
            FFCH: [1x1 struct]
                    FSCH: [1x1 struct]
```

This channel uses spreading rate 3 , 'SR3' ', which has a 3.75 MHz bandwidth.
Generate the forward link waveform.

```
waveform = cdma2000ForwardWaveformGenerator(config);
```

## Input Arguments

## wv - Waveform identification

character vector
Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify wv, connect the substrings with hyphens, for example, 'CONTROL-19200-10-4800'.

| Parameter Field | Values |  |  |  | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Substring 1 | Substring 2 | Substring 3 | Substring 4 |  |
| wv | ' FPICH-ONLY' |  |  |  | Generates a waveform containing a pilot channel only. |
|  | ' CONTROL' | 9600 | 20 | $\begin{aligned} & 4800\|9600\| \\ & 19200 \end{aligned}$ | Character vector representing the forward common control channel (FCCCH) data rate in bps, the frame length in ms, and the forward broadcast control channel (F-BCCH) data rate in bps. Specify ' CONTROL-960 0-20-9600' to create a structure variable, wv, with a 9600 bps F-CCCH data rate, a 20 ms frame length, and a 9600 bps F-BCCH data rate. |
|  |  | 19200 | 10 \| 20 |  |  |
|  |  | 38400 | 5\|10|20 |  |  |
|  | 'TRAFFIC' | RC1 | $1200\|2400\|$ $4800 \mid 9600$ | N/A | Charactervectorrepresentingthe radioconfigurationand the forwardfundamentalchannel (F-FCH) data ratein bps. Specify'TRAFFIC-RC9-14400' tocreate achannel withradio |
|  |  | $\begin{array}{\|l} \hline \mathrm{RC2}\|\mathrm{RC5}\| \mathrm{RC8} \\ \mid \mathrm{RC9} \end{array}$ | $1800\|3600\|$ $7200 \mid 14400$ |  |  |

| Parameter Field | Values |  |  |  | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Substring 1 | Substring 2 | Substring 3 | Substring 4 |  |
|  |  | $\begin{aligned} & \mathrm{RC3}\|\mathrm{RC4}\| \mathrm{RC6} \\ & \mid \mathrm{RC7} \end{aligned}$ | $1500\|2700\|$ $4800 \mid 9600$ |  | configuration 9 having a 14400 bps F-FCH data rate. |
|  | 'BSTM' | RC1 \| RC2 | RC3 $\mid$ RC4 \| RC5 | RC6 | RC7 | RC8 $\mid$ RC9 | N/A | N/A | Models for testing the base station transmitter. Specify 'BSTMRC1' to create a structure for base station testing with radio configuration 1. |
|  | 'ALL' | RC1 \| RC2 | RC3 $\mid$ RC4 \| RC5 | RC6 | RC7 | RC8 $\mid$ RC9 | N/A | N/A | Returns all channels that are supported for the specified radio configuration. Specify 'ALLRC4 ' to create a structure containing all traffic channels for radio configuration 4. |

Example: 'CONTROL-9600-20-9600'
Example: 'TRAFFIC-RC9-7200'
Example: 'ALL-RC5'

## Data Types: char

## numchips - Number of chips

1000 (default) | positive integer scalar
Number of chips, specified as a positive integer.
Example: 1024
Data Types: double

## BSTM-RC - BSTM reference channel type

'BSTM-RC1'|'BSTM-RC2'|'BSTM-RC3'|'BSTM-RC4'|'BSTM-RC5'|'BSTM-RC6'|'BSTM-RC7'|'BSTM-RC8'|'BSTM-RC9'

BSTM reference channel type, specified as a character vector. For more information, see Table 6.5.2-1 of [2].

## Example: 'BSTM-RC8'

## Data Types: char

## P - Power budget allocated to traffic channels

0 (default) | real scalar
Power budget allocated to all traffic channels, specified in decibels as a real scalar.

## Example: 5

Data Types: double

## M - Number of traffic channels

6 (default) | positive integer scalar
Number of traffic channels, specified as a positive integer.
Example: 8
Data Types: double

## traffic - Traffic configuration

character vector
Traffic channel configuration, specified as a character vector. The table shows the supported traffic channel configurations.

| Radio Configuration | Traffic Channel Configuration |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

| 5 | 'TRAFFIC -RC5-1800 ${ }^{\prime}$ | $\begin{aligned} & \hline \text { 'TRAFFIC - } \\ & \text { RC5-3600 ' } \end{aligned}$ | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC5-7200 ' } \end{aligned}$ | $\begin{aligned} & \text { 'TRAFFIC- } \\ & \text { RC5-14400 ' } \end{aligned}$ |
| 6 | $\begin{aligned} & \text { 'TRAFFIC- } \\ & \text { RC6-1500' } \end{aligned}$ | $\begin{aligned} & \text { 'TRAFFIC- } \\ & \text { RC6-2700' } \end{aligned}$ | $\begin{aligned} & \text { 'TRAFFIC- } \\ & \text { RC6-4800' } \end{aligned}$ | $\begin{array}{\|l\|} \hline \text { 'TRAFFIC- } \\ \text { RC6-9600' } \end{array}$ |
| 7 | 'TRAFFIC RC7-1500' | $\begin{aligned} & \hline \text { 'TRAFFIC } \\ & \text { RC7-2700' } \end{aligned}$ | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC7-4800 ' } \end{aligned}$ | 'TRAFFIC -RC7-9600' |
| 8 | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC8-1800' } \end{aligned}$ | $\begin{aligned} & \text { 'TRAFFIC- } \\ & \text { RC8-3600' } \end{aligned}$ | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC8-7200' } \end{aligned}$ | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC8-14400 ' } \end{aligned}$ |
| 9 | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC9-1800 ' } \end{aligned}$ | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC9-3600' } \end{aligned}$ | $\begin{aligned} & \hline \text { 'TRAFFIC- } \\ & \text { RC9-7200 ' } \end{aligned}$ | $\begin{aligned} & \text { 'TRAFFIC- } \\ & \text { RC9-14400 ' } \end{aligned}$ |

Example: 'TRAFFIC-RC6-4800' is a traffic channel that uses radio configuration 6 with a 4800 bps data rate.

Data Types: char

## F-SCH-SPEC - Forward supplemental channel data rate and frame length

character vector
Forward supplemental channel data rate and frame length, specified as a character vector. The supported data rate and frame length combinations are summarized in the table.

| Radio Configuration | Frame Length |  |  |
| :---: | :---: | :---: | :---: |
|  | 20 ms | 40 ms | 80 ms |
| 3\|4|6|7 | 'F-SCH-1500-20' 'F-SCH-2700-20' 'F-SCH-4800-20' 'F-SCH-9600-20' 'F-SCH-19200-20' 'F-SCH-38400-20' 'F-SCH-76800-20' 'F-SCH-153600-20' | 'F-SCH-1350-40' 'F-SCH-2400-40' 'F-SCH-4800-40' 'F-SCH-9600-40' 'F-SCH-19200-40' 'F-SCH-38400-40' 'F-SCH-76800-40' | 'F-SCH-1200-80' 'F-SCH-2400-80' 'F-SCH-4800-80' 'F-SCH-9600-80' 'F-SCH-19200-80' 'F-SCH-38400-80' |

For more data rate information for the cdma2000 forward links, see tables 3.1.3.1.3-2 and 3.1.3.1.3-4 of [1].

Example: ' F -SCH-460800-20' is a supplemental channel with a 460,800 bps data rate and a 20 ms frame length.

Data Types: char

## Output Arguments

cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

## Top-Level Parameters and Substructures

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| SpreadingRate | 'SR1' \| 'SR3' | Spreading rate of the waveform. SR1 corresponds to a 1.2288 Mcps carrier. SR3 corresponds to a 3.6864 Mcps carrier. <br> SR3 supports direct sequence spreading only. |
| Diversity | 'NTD ' \| 'OTD ' | 'STS' | Transmit diversity type (applicable only for SR1), where NTD is no transmit diversity, OTD is orthogonal transmit diversity, and STS is space time spreading |
| Q0F | 'Q0F1 \| 'Q0F2' | 'Q0F3' | Quasi-orthogonal function type |
| PNOffset | Nonnegative scalar integer | PN offset of the base station |
| LongCodeState | Positive scalar integer | Initial long code state |
| PowerNormalization | 'Off'\|'NormalizeTo0dB' | 'NoiseFillTo0dB' | Power normalization of the waveform |
| NumChips | Positive scalar integer | Number of chips in the waveform |
| FilterType | ' cdma2000Long ' \| <br> 'cdma2000Short'\|'0ff'| <br> 'Custom' | Type of output filtering |
| CustomFilterCoeffici ents | Real vector | Custom filter coefficients, used only when the FilterType field is set to 'Custom' |
| OversamplingRatio | Positive scalar integer | Oversampling ratio at output |
| InvertQ | 'Off'\| 'On' | Negate the quadrature output |
| EnableModulation | 'Off'\| 'On' | Enable carrier modulation |
| ModulationFrequency | Nonnegative scalar integer | Carrier modulation frequency (applies when EnableModulation is ' $0 n$ ') |
| FPICH | Structure | See FPICH Substructure. Optional. |
| FAPICH | Structure | See FAPICH Substructure. Optional. |
| FTDPICH | Structure | See FTDPICH Substructure. Optional. |
| FATDPICH | Structure | See FATDPICH Substructure. Optional. |
| FSYNC | Structure | See FSYNC Substructure. Optional. |
| FPCH | Structure | See FPCH Substructure. Optional. |
| FCCCH | Structure | See FCCCH Substructure. Optional. |
| FCACH | Structure | See FCACH Substructure. Optional. |
| FQPCH | Structure | See FQPCH Substructure. Optional. |
| FCPCCH | Structure | See FCPCCH Substructure. Optional. |
| FBCCH | Structure | See FBCCH Substructure. Optional. |
| FFCH | Structure | See FFCH Substructure. Optional. |
| FDCCH | Structure | See FDCCH Substructure. Optional. |
| FSCCH | Structure | See FSCCH Substructure. Optional. |

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| FSCH | Structure | See FSCH Substructure. Optional. |
| FOCNS | Structure | See FOCNS Substructure. Optional. |

## FPICH Substructure

Include the FPICH substructure in the cfg structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On ' $\mid$ 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power $(\mathrm{dB})$ |

## FAPICH Substructure

Include the FAPICH substructure in the cfg structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' $\mid$ 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| WalshLength | $64\|128\| 256 \mid 512$ | Walsh code length |
| WalshCode | Nonnegative integer scalar, <br> such that $0 \leq$ WalshCode $\leq$ <br> WalshLength - | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |

## FTDPICH Substructure

Include the FTDPICH substructure in the cfg structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |

## FATDPICH

Include the FATDPICH substructure in the cfg structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| WalshLength | $64\|128\| 256,512$ | Walsh code length |

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| WalshCode | Nonnegative integer scalar, <br> such that $0 \leq$ WalshCode $\leq$ <br> WalshLength -1 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |

## FSYNC Substructure

Include the FSYNC substructure in the cfg structure to configure the forward sync channel (F-SYNC). The FSYNC substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| EnableCoding | 'On' \| 'Off' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN <br> Seed\}, binary vector, or <br> 'SyncMessage '. <br> Standard PN types are | Data source. Specify a standard PN sequence <br> with a random number seed, a binary vector, <br> or a 'SyncMessage ' character vector. |
| 'PN9' ' 'PN15', 'PN23', <br> 'PN9-ITU ' and 'PN11'. |  |  |
| SyncMessage | Structure | See SyncMessage Substructure. Optional. |

## SyncMessage Substructure

If the DataSource field of the FSYNC substructure is set to 'SyncMessage ', add the SyncMessage substructure to the cfg.FSYNC substructure to configure the sync channel message. The SyncMessage substructure contains these fields.

| Parameter Field | Typical Value | Description |
| :--- | :--- | :--- |
| P_REV | 6 | Protocol revision field |
| MIN_P_REV | 6 | Minimum protocol revision field |
| SID | hex2dec ( ' $14 B^{\prime}$ ' ) | System identifier field |
| NID | 1 | Network identification field |
| PILOT_PN | 0 | Pilot PN offset field |
| LC_STATE | hex2dec ( ' $20000000000^{\prime}$ ' ) | Long code state field |
| SYS_TIME | hex2dec ( '36AE0924C' ) | System time field |
| LP_SEC | 0 | Leap second field |
| LTM_OFF | 0 | Local time offset field |
| DAYLT | 0 | Daylight savings time indicator <br> field |
| PRAT | 0 | Paging channel data rate field |
| CDMA_FREQ | hex2dec ( '2F6' ) | CDMA frequency field |
| EXT_CDMA_FREQ | hex2dec ('2F6' ) | Extended CDMA frequency field |

## FPCH Substructure

Include the FPCH substructure in the cfg substructure to configure the forward paging channel (FPCH). The FPCH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | 'On'\| '0ff' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| DataRate | 4800 \| 9600 | Data rate (bps) |
| LongCodeMask | Positive scalar integer | Long code identifier |
| WalshCode | Nonnegative integer scalar, such that $0 \leq$ WalshCode $\leq$ 7 | Walsh code number |
| EnableCoding | 'On'\| '0ff' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\}, binary vector, or a paging message character vector. <br> Standard PN types are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'. <br> Paging message options include 'PagingMessagel', <br> 'PagingMessage2', and 'PagingMessage3'. | Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1. |

1 When the DataSource enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:

- 'PagingMessage1' - Streams a 7680 bit sequence ( 800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.
- 'PagingMessage2' - Streams a 2304 bit sequence ( 240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full 'PagingMessage1' content.
- 'PagingMessage3' - Streams an 864 bit sequence ( 90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.

For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2-1.

## FCCCH Substructure

Include the FCCCH substructure in the cfg structure to configure the forward common control channel (F-CCCH). The FCCCH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | 'On'\| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| DataRate | 9600\| 19200 | 38400 | Data rate (bps) |
| FrameLength | 5 \| 10 | 20 | Frame length (ms) |
| CodingType | 'conv' \| 'turbo' | Type of error correction coding |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableCoding | 'On'\| 0 '0ff' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9','PN15', 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |

## FCACH Substructure

Include the FCACH substructure in the cfg structure to configure the forward common assignment channel (F-CACH). The FCACH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | 'On'\| '0ff' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| CodingType | 'conv'\|'turbo' | Type of error correction coding |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableCoding | 'On'\| '0ff' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |

## FQPCH Substructure

Include the FQPCH substructure in the cfg structure to configure the forward quick paging channel (F-QPCH). The FQPCH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | '0n'\| '0ff' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| DataRate | 2400 \| 4800 | Data rate (bps) |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableCoding | '0n'\| '0ff' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |

## FCPCCH Substructure

Include the FCPCCH substructure in the cfg structure to configure the forward common power control channel (F-CPCCH). The FCPCCH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| WalshCode | Nonnegative integer scalar <br> such that $0 \leq$ WalshCode $\leq$ <br> 63 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableCoding | 'On' \| 'Off' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', <br> Seed\} or binary vector. <br> Standard PN sequence | Data source. Specify a standard PN sequence <br> with a random number seed or a custom <br> vector. |
| options are 'PN9', 'PN15' ' |  |  |
| 'PN23', 'PN9-ITU', and <br> 'PN11'. |  |  |

## FBCCH Substructure

Include the FBCCH substructure in the cfg structure to configure the forward broadcast control channel (F-BCCH). The FBCCH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| DataRate | 4800 \| 9600 | 19200 | Data rate (bps) |
| CodingType | 'conv ' \| 'turbo' | Type of error correction coding |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 127 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableCoding | '0n'\| 'Off' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |

## FFCH Substructure

Include the FFCH substructure in the cfg structure to configure the forward fundamental traffic channel (F-FCH). The FFCH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | 'On'\| '0ff' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| RadioConfiguratio <br> n | 'RC1' through 'RC9' | Radio configuration channel |
| DataRate | $1200\|1500\| 1800\|2400\|$ $2700\|3600\| 4800\|7200\|$ $9600 \mid 14400$ | Data rate (bps) |
| FrameLength | 5\|10|20 | Frame length (ms) |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableQOF | 'On'\| 'Off' | Enable QOF spreading |
| EnableCoding | 'On'\| 'Off' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9','PN15', 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |
| PowerControlEnabl e | 'On'\| 'Off' | Enable or disable power control subchannel |

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| PowerControlPower | Real scalar | Power control subchannel power (relative to <br> F-FCH) |
| PowerControlDataS <br> ource | Cell array: \{ 'PN Type' , RN <br> Seed\} or binary vector. | Power control subchannel data source |
|  | Standard PN sequence <br> options are 'PN9', 'PN15 ' , <br> 'PN23' ' 'PN9-ITU' , and <br> 'PN11'. |  |

## FDCCH Substructure

Include the FDCCH substructure in the cfg structure to configure the forward dedicated control channel (F-DCCH). The FDCCH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | 'On'\| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| RadioConfiguratio n | 'RC3' through 'RC9' | Radio configuration channel |
| DataRate | 9600 \| 14400 | Data rate (bps) |
| FrameLength | 5 \| 20 | Frame length (ms) |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableQOF | 'On'\| 'Off' | Enable QOF spreading |
| EnableCoding | 'On'\| '0ff' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9', 'PN15', <br> 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |

## FSCCH Substructure

Include the FSCCH substructure in the cfg structure to configure the forward supplemental code channel (F-SCCH). The FSCCH substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On ' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| RadioConfiguratio <br> $\mathbf{n}$ | 'RC1' \| 'RC2' | Radio configuration channel |

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| WalshCode | Nonnegative integer scalar <br> such that $0 \leq$ WalshCode $\leq$ <br> 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableCoding | 'On' \| 'Off' | Enable or disable channel coding |
| DataSource | Cell array: \{ 'PN Type', RN <br> Seed\} or binary vector. <br> Standard PN sequence | Data source. Specify a standard PN sequence <br> with a random number seed or a custom <br> vector. |
| options are 'PN9', 'PN15' ', |  |  |
| 'PN23', 'PN9-ITU', and |  |  |
| 'PN11'. |  |  |

## FSCH Substructure

Include the FSCH substructure in the cfg structure to configure the forward supplemental channel (F-SCH). The FSCH substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Enable | 'On'\| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| RadioConfiguratio n | 'RC3'\| 'RC6' 'RC6'| 'RC9' | Radio configuration channel |
| DataRate | $1200\|1350\| 1500\|1800\|$ $2400\|2700\| 3600\|4800\|$ $7200\|9600\| 14400 \mid 19200$ $\|28800\| 38400\|57600\|$ $76800\|115200\| 153600 \mid$ $230400 \mid 307200$ | Data rate (bps) |
| FrameLength | 20\|40|80 | Frame length (ms) |
| CodingType | 'Conv' \| 'Turbo' | Channel coding type, convolutional or turbo |
| WalshCode | Nonnegative integer scalar such that $0 \leq$ WalshCode $\leq$ 255 | Walsh code number |
| LongCodeMask | Positive scalar integer | Long code identifier |
| EnableQOF | 'On'\| '0ff' | Enable QOF spreading |
| EnableCoding | '0n'\| '0ff' | Enable or disable channel coding |
| DataSource | Cell array: \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9', 'PN15', <br> 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |

## FOCNS Substructure

Include the FOCNS substructure in the cfg structure to configure orthogonal channel noise source information. The FOCNS substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Enable or disable the channel |
| Power | Real scalar | Relative channel power (dB) |
| WalshLength | $64\|128\| 256$ | Walsh code length |
| WalshCode | Nonnegative integer scalar <br> such that $0 \leq$ WalshCode $\leq$ <br> WalshLength -1 | Walsh code number |

## cdma2000ForwardWaveformGenerator

Generate cdma2000 forward link waveform

## Syntax

[waveform1,waveform2] = cdma2000ForwardWaveformGenerator(cfg)

## Description

[waveform1,waveform2] = cdma2000ForwardWaveformGenerator(cfg) returns the cdma2000 forward link baseband primary waveform, waveform1, and the forward link diversity waveform, waveform2, as defined by the parameter definition structure, cfg.

The top-level parameters and lower-level substructures of cfg specify the waveform and channel properties the function uses to generate a cdma2000 waveform. You can generate cfg by using the cdma2000ForwardReferenceChannels function. The top-level parameters of cfg are SpreadingRate, Diversity, QOF, PNOffset, LongCodeState, PowerNormalization, CustomFilterCoefficients, OversamplingRatio, FilterType, InvertQ,
EnableModulation, ModulationFrequency, and NumChips. To enable specific channels, add their associated substructures, for example, the forward paging channel, FPCH.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the cdma2000ForwardReferenceChannels function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

## Examples

## Generate Waveform for RC2 Forward Traffic Channels

Create a parameter structure, config, for all forward traffic channels (F-FCH and F-SCCH) that are supported by radio configuration 2.

```
config = cdma2000ForwardReferenceChannels('ALL-RC2')
config = struct with fields:
        SpreadingRate: 'SR1'
            Diversity: 'NTD'
                            Q0F: 'Q0F1'
                PNOffset: 0
        LongCodeState: 0
        PowerNormalization: 'Off'
    OversamplingRatio: 4
            FilterType: 'cdma2000Long'
                InvertQ: 'Off'
    EnableModulation: 'Off'
    ModulationFrequency: 0
```

```
NumChips: 1000
        FPICH: [1x1 struct]
        FAPICH: [1x1 struct]
    FTDPICH: [1x1 struct]
FATDPICH: [1x1 struct]
            FPCH: [1x1 struct]
        FSYNC: [1x1 struct]
        FBCCH: [1x1 struct]
        FCACH: [1x1 struct]
        FCCCH: [1x1 struct]
    FCPCCH: [1x1 struct]
        FQPCH: [1x1 struct]
        FFCH: [1x1 struct]
        FOCNS: [1x1 struct]
        FSCCH: [1x1 struct]
```

Examine the fields for the Forward Fundamental Channel (F-FCH). The data rate is 14,400 bps and the frame length is 20 ms .

```
config.FFCH
ans = struct with fields:
    Enable: 'On'
    Power: 0
    RadioConfiguration: 'RC2'
            DataRate: 14400
        FrameLength: 20
        LongCodeMask: 0
        EnableCoding: 'On'
        DataSource: {'PN9' [1]}
            WalshCode: 7
            EnableQ0F: 'Off'
    PowerControlEnable: 'Off'
```

Generate the complex waveform using the corresponding waveform generator function.
waveform = cdma2000ForwardWaveformGenerator(config);
A waveform composed of the channels specified by each substructure of config is generated by cdma2000ForwardWaveformGenerator.

## Generate Forward Traffic Channel for RC4

Configure a cdma2000 forward link supporting a 307.2 kbps forward supplemental channel (F-SCH) using radio configuration 4.

```
config = cdma2000ForwardReferenceChannels('TRAFFIC-RC4-4800',5000, ...
    'F-SCH-307200-20');
```

Generate the waveform and plot its spectrum. The sample rate is equal to the product of the chip rate and the oversampling ratio. RC4 uses spreading rate 1, which is equivalent to a 1.2288 Mcps chip rate.

```
wv = cdma2000ForwardWaveformGenerator(config);
fs = 1.2288e6 * config.OversamplingRatio;
sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```

Change the filter type to 'cdma2000Short' and plot the spectrum.
config.FilterType = 'cdma2000Short';
wv = cdma2000ForwardWaveformGenerator(config);
step(sa,wv)

The ' cdma2000Short ' filter does not provide as much out-of-band attenuation as does the 'cdma2000Long ' filter.

## Generate cdma2000 Waveform with Two Forward Supplemental Channels

Create a parameter structure that specifies a forward traffic channel. Use it to generate a forward channel waveform.

Create a parameter structure specifying a traffic channel consisting of a 4800 bps fundamental channel, 5000 chips, and a 614.4 kbps supplemental channel (F-SCH) having a 20 ms frame duration.
cfg = cdma2000ForwardReferenceChannels('TRAFFIC-RC7-4800', ...
5000, 'F-SCH-614400-20') ;
Based on the first F-SCH, create a second F-SCH.
cfg(2). $\mathrm{FSCH}=\mathrm{cfg} . \mathrm{FSCH}$;
Set the data rate of the second F-SCH to 38.4 kbps. Set the frame duration to 40 ms .
cfg(2).FSCH.DataRate $=38400$;
cfg(2).FSCH.FrameLength $=40$;
cfg. FSCH

```
ans = struct with fields:
    Enable: 'On'
        Power: 0
    RadioConfiguration: 'RC7'
            DataRate: 614400
        FrameLength: 20
        LongCodeMask: 0
        EnableCoding: 'On'
            DataSource: {'PN9' [1]}
            WalshCode: 2
            EnableQOF: 'Off'
            CodingType: 'conv'
ans = struct with fields:
                            Enable: 'On'
                            Power: 0
    RadioConfiguration: 'RC7'
            DataRate: 38400
        FrameLength: 40
        LongCodeMask: 0
        EnableCoding: 'On'
            DataSource: {'PN9'
            WalshCode: 2
            EnableQOF: 'Off'
            CodingType: 'conv'

Set the Walsh code of the second F-SCH so that it is not identical to the Walsh code of the first F-SCH.
cfg(2).FSCH.WalshCode = 3;
Generate the forward link waveform.
wv = cdma2000ForwardWaveformGenerator(cfg);

\section*{Input Arguments}
cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

\section*{Top-Level Parameters and Substructures}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline SpreadingRate & 'SR1' | 'SR3' & \begin{tabular}{l} 
Spreading rate of the waveform. SR1 \\
corresponds to a 1.2288 Mcps carrier. SR3 \\
corresponds to a 3.6864 Mcps carrier. \\
SR3 supports direct sequence spreading only.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Diversity & 'NTD'| 'OTD'| 'STS' & Transmit diversity type (applicable only for SR1), where NTD is no transmit diversity, OTD is orthogonal transmit diversity, and STS is space time spreading \\
\hline QOF & 'Q0F1' | 'Q0F2' | 'Q0F3' & Quasi-orthogonal function type \\
\hline PNOffset & Nonnegative scalar integer & PN offset of the base station \\
\hline LongCodeState & Positive scalar integer & Initial long code state \\
\hline PowerNormalization &  & Power normalization of the waveform \\
\hline NumChips & Positive scalar integer & Number of chips in the waveform \\
\hline FilterType & \[
\begin{aligned}
& \text { 'cdma2000Long' | } \\
& \text { 'cdma2000Short' | } 0 \text { ff' | }
\end{aligned}
\]
'Custom' & Type of output filtering \\
\hline CustomFilterCoeffici ents & Real vector & Custom filter coefficients, used only when the FilterType field is set to 'Custom' \\
\hline OversamplingRatio & Positive scalar integer & Oversampling ratio at output \\
\hline InvertQ & '0ff'| 'On' & Negate the quadrature output \\
\hline EnableModulation & 'Off'|'On' & Enable carrier modulation \\
\hline ModulationFrequency & Nonnegative scalar integer & Carrier modulation frequency (applies when EnableModulation is ' On ') \\
\hline FPICH & Structure & See FPICH Substructure. Optional. \\
\hline FAPICH & Structure & See FAPICH Substructure. Optional. \\
\hline FTDPICH & Structure & See FTDPICH Substructure. Optional. \\
\hline FATDPICH & Structure & See FATDPICH Substructure. Optional. \\
\hline FSYNC & Structure & See FSYNC Substructure. Optional. \\
\hline FPCH & Structure & See FPCH Substructure. Optional. \\
\hline FCCCH & Structure & See FCCCH Substructure. Optional. \\
\hline FCACH & Structure & See FCACH Substructure. Optional. \\
\hline FQPCH & Structure & See FQPCH Substructure. Optional. \\
\hline FCPCCH & Structure & See FCPCCH Substructure. Optional. \\
\hline FBCCH & Structure & See FBCCH Substructure. Optional. \\
\hline FFCH & Structure & See FFCH Substructure. Optional. \\
\hline FDCCH & Structure & See FDCCH Substructure. Optional. \\
\hline FSCCH & Structure & See FSCCH Substructure. Optional. \\
\hline FSCH & Structure & See FSCH Substructure. Optional. \\
\hline FOCNS & Structure & See FOCNS Substructure. Optional. \\
\hline
\end{tabular}

\section*{FPICH Substructure}

Include the FPICH substructure in the cfg structure to configure the forward pilot channel (F-PICH). The FPICH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power \((\mathrm{dB})\) \\
\hline
\end{tabular}

\section*{FAPICH Substructure}

Include the FAPICH substructure in the cfg structure to configure the forward auxiliary pilot channel (F-APICH). The FAPICH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\mid\) 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power \((\mathrm{dB})\) \\
\hline WalshLength & \(64|128| 256 \mid 512\) & Walsh code length \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar, \\
such that \(0 \leq\) WalshCode \(\leq\) \\
WalshLength -
\end{tabular} & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline
\end{tabular}

\section*{FTDPICH Substructure}

Include the FTDPICH substructure in the cfg structure to configure the forward transmit diversity pilot Channel (F-TDPICH). The FTDPICH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline
\end{tabular}

\section*{FATDPICH}

Include the FATDPICH substructure in the cfg structure to configure the forward auxiliary transmit diversity pilot channel (F-ATDPICH). The FATDPICH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\mid\) 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline WalshLength & \(64|128| 256,512\) & Walsh code length \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar, \\
such that \(0 \leq\) WalshCode \(\leq\) \\
WalshLength -1
\end{tabular} & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline
\end{tabular}

\section*{FSYNC Substructure}

Include the FSYNC substructure in the cfg structure to configure the forward sync channel (F-SYNC). The FSYNC substructure contains these fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline EnableCoding & 'On' | 0 'ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\}, binary vector, or 'SyncMessage'. \\
Standard PN types are \\
'PN9', 'PN15', 'PN23', \\
'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed, a binary vector, or a 'SyncMessage' character vector. \\
\hline SyncMessage & Structure & See SyncMessage Substructure. Optional. \\
\hline
\end{tabular}

\section*{SyncMessage Substructure}

If the DataSource field of the FSYNC substructure is set to 'SyncMessage ', add the SyncMessage substructure to the cfg.FSYNC substructure to configure the sync channel message. The SyncMessage substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Typical Value & Description \\
\hline P_REV & 6 & Protocol revision field \\
\hline MIN_P_REV & 6 & Minimum protocol revision field \\
\hline SID & hex2dec ( ' \(14 \mathrm{~B}^{\prime}\) ' ) & System identifier field \\
\hline NID & 1 & Network identification field \\
\hline PILOT_PN & 0 & Pilot PN offset field \\
\hline LC_STATE & hex2dec ( '20000000000' ) & Long code state field \\
\hline SYS_TIME & hex2dec ( '36AE0924C' ) & System time field \\
\hline LP_SEC & 0 & Leap second field \\
\hline LTM_OFF & 0 & Local time offset field \\
\hline DAYLT & 0 & \begin{tabular}{l} 
Daylight savings time indicator \\
field
\end{tabular} \\
\hline PRAT & 0 & Paging channel data rate field \\
\hline CDMA_FREQ & hex2dec ('2F6' ) & CDMA frequency field \\
\hline EXT_CDMA_FREQ & hex2dec ('2F6' ) & Extended CDMA frequency field \\
\hline
\end{tabular}

\section*{FPCH Substructure}

Include the FPCH substructure in the cfg substructure to configure the forward paging channel (FPCH). The FPCH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(4800 \mid 9600\) & Data rate (bps) \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline WalshCode & Nonnegative integer scalar, such that \(0 \leq\) WalshCode \(\leq\) 7 & Walsh code number \\
\hline EnableCoding & 'On' \| Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\}, binary vector, or a paging message character vector. \\
Standard PN types are \\
'PN9', 'PN15','PN23', \\
'PN9-ITU', and 'PN11'. \\
Paging message options include 'PagingMessage1' \\
'PagingMessage2', and \\
'PagingMessage3'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed, a binary vector, or one of three paging messages. For a description of paging message contents see footnote 1. \\
\hline
\end{tabular}

1 When the DataSource enumeration specifies one of the paging message options, simulated paging message data is used as input to the F-PCH physical channel:
- 'PagingMessage1' - Streams a 7680 bit sequence ( 800 ms at fullrate) of paging message contents onto the channel that includes the General Page Message, the CDMA Channel List Message, the Extended System Parameter Message, the Extended Neighbor List Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a nonsequential pattern.
- 'PagingMessage2' - Streams a 2304 bit sequence ( 240 ms at fullrate) of paging message contents onto the channel that includes a truncated version of the full 'PagingMessage1' content.
- 'PagingMessage3' - Streams an 864 bit sequence ( 90 ms at fullrate) of paging message contents onto the channel that includes the Neighbor List Message, the CDMA Channel List Message, the General Page Message, the System Parameter Message, and the Access Parameter Message. The paging message repeats these messages in a sequential pattern.

For more information on the F-PCH contents, refer to 3GPP2 C.S0004, Table 3.1.2.3.1.1.2-1.

\section*{FCCCH Substructure}

Include the FCCCH substructure in the cfg structure to configure the forward common control channel (F-CCCH). The FCCCH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(9600|19200| 38400\) & Data rate \((\mathrm{bps})\) \\
\hline FrameLength & \(5|10| 20\) & Frame length \((\mathrm{ms})\) \\
\hline CodingType & 'conv ' \(\left.\right|^{\prime}\) turbo ' & Type of error correction coding \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
255
\end{tabular} & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableCoding & 'On' | 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l} 
Cell array: \{ 'PN Type' , RN \\
Seed\} or binary vector.
\end{tabular} & \begin{tabular}{l} 
Data source. Specify a standard PN sequence \\
with a random number seed or a custom \\
vector.
\end{tabular} \\
\begin{tabular}{l} 
Standard PN sequence \\
options are 'PN9', 'PN15' ' \\
'PN23', 'PN9-ITU', and \\
'PN11'.
\end{tabular} \\
\hline
\end{tabular}

\section*{FCACH Substructure}

Include the FCACH substructure in the cfg structure to configure the forward common assignment channel (F-CACH). The FCACH substructure contains these fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| 0 'ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline CodingType & 'conv'| 'turbo' & Type of error correction coding \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 255 & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableCoding & 'On' | '0ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{FQPCH Substructure}

Include the FQPCH substructure in the cfg structure to configure the forward quick paging channel (F-QPCH). The FQPCH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(2400 \mid 4800\) & Data rate (bps) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
255
\end{tabular} & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableCoding & 'On' | 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l} 
Cell array: \{ 'PN Type' , RN \\
Seed\} or binary vector.
\end{tabular} & \begin{tabular}{l} 
Data source. Specify a standard PN sequence \\
with a random number seed or a custom \\
vector.
\end{tabular} \\
\begin{tabular}{l} 
Standard PN sequence \\
options are 'PN9', 'PN15' ' \\
'PN23', 'PN9-ITU', and \\
'PN11'.
\end{tabular} \\
\hline
\end{tabular}

\section*{FCPCCH Substructure}

Include the FCPCCH substructure in the cfg structure to configure the forward common power control channel (F-CPCCH). The FCPCCH substructure contains these fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| '0ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 63 & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableCoding & 'On'| 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{FBCCH Substructure}

Include the FBCCH substructure in the cfg structure to configure the forward broadcast control channel (F-BCCH). The FBCCH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On ' \(\left.\right|^{\prime}\) Off' \(^{\prime}\) & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(4800|9600| 19200\) & Data rate (bps) \\
\hline CodingType & 'conv ' \(\left.\right|^{\prime}\) turbo ' & Type of error correction coding \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
127
\end{tabular} & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableCoding & 'On' | 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l} 
Cell array: \{ 'PN Type',\(~ R N ~\) \\
Seed\} or binary vector. \\
Data source. Specify a standard PN sequence \\
with a random number seed or a custom \\
vector.
\end{tabular} \\
\hline \begin{tabular}{l} 
Standard PN sequence \\
options are 'PN9', 'PN15' ' \\
'PN23', 'PN9-ITU' ' and \\
'PN11'.
\end{tabular} \\
\hline
\end{tabular}

\section*{FFCH Substructure}

Include the FFCH substructure in the cfg structure to configure the forward fundamental traffic channel (F-FCH). The FFCH substructure contains these fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline \begin{tabular}{l}
RadioConfiguratio \\
n
\end{tabular} & 'RC1' through 'RC9' & Radio configuration channel \\
\hline DataRate & \(1200|1500| 1800|2400|\)
\(2700|3600| 4800|7200|\)
\(9600 \mid 14400\) & Data rate (bps) \\
\hline FrameLength & 5|10|20 & Frame length (ms) \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 255 & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableQOF & 'On' | 'Off' & Enable QOF spreading \\
\hline EnableCoding & 'On'| 0 'f' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline PowerControlEnabl e & 'On' | 0 Off & Enable or disable power control subchannel \\
\hline PowerControlPower & Real scalar & Power control subchannel power (relative to F-FCH) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline \begin{tabular}{l} 
PowerControlDataS \\
ource
\end{tabular} & \begin{tabular}{l} 
Cell array: \{ 'PN Type' , RN \\
\\
Seed\} or binary vector.
\end{tabular} & Power control subchannel data source \\
& \begin{tabular}{l} 
Standard PN sequence \\
options are 'PN9', 'PN15 ' ,
\end{tabular} & \\
& 'PN23' ' 'PN9-ITU ' , and & \\
& 'PN11'. & \\
\hline
\end{tabular}

\section*{FDCCH Substructure}

Include the FDCCH substructure in the cfg structure to configure the forward dedicated control channel (F-DCCH). The FDCCH substructure contains these fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| '0ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline RadioConfiguratio n & 'RC3' through 'RC9' & Radio configuration channel \\
\hline DataRate & 9600 | 14400 & Data rate (bps) \\
\hline FrameLength & 5 | 20 & Frame length (ms) \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 255 & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableQOF & 'On'| 'Off' & Enable QOF spreading \\
\hline EnableCoding & 'On'| 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', 'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{FSCCH Substructure}

Include the FSCCH substructure in the cfg structure to configure the forward supplemental code channel (F-SCCH). The FSCCH substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On ' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline \begin{tabular}{l} 
RadioConfiguratio \\
\(\mathbf{n}\)
\end{tabular} & 'RC1' | 'RC2' & Radio configuration channel \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\

\end{tabular} & \begin{tabular}{l} 
Data source. Specify a standard PN sequence \\
with a random number seed or a custom \\
vector.
\end{tabular} \\
\hline
\end{tabular}

\section*{FSCH Substructure}

Include the FSCH substructure in the cfg structure to configure the forward supplemental channel (F-SCH). The FSCH substructure contains these fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| '0ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline RadioConfiguratio n & 'RC3' | 'RC4' | 'RC5' |
'RC6'|
'RC9' & Radio configuration channel \\
\hline DataRate & \(1200|1350| 1500|1800|\)
\(2400|2700| 3600|4800|\)
\(7200|9600| 14400 \mid 19200\)
\(|28800| 38400|57600|\)
\(76800|115200| 153600 \mid\)
\(230400 \mid 307200\) & Data rate (bps) \\
\hline FrameLength & 20|40|80 & Frame length (ms) \\
\hline CodingType & 'Conv'| 'Turbo' & Channel coding type, convolutional or turbo \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 255 & Walsh code number \\
\hline LongCodeMask & Positive scalar integer & Long code identifier \\
\hline EnableQOF & 'On'| '0ff' & Enable QOF spreading \\
\hline EnableCoding & '0n'| '0ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{FOCNS Substructure}

Include the FOCNS substructure in the cfg structure to configure orthogonal channel noise source information. The FOCNS substructure contains these fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline WalshLength & \(64|128| 256\) & Walsh code length \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
WalshLength -1
\end{tabular} & Walsh code number \\
\hline
\end{tabular}

\section*{Output Arguments}
waveform1 - Modulated baseband waveform comprising the primary physical channels
complex vector array
Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

\section*{waveform2 - Modulated baseband waveform comprising the diversity physical channels}
complex vector array
Modulated baseband waveform comprising the diversity cdma2000 physical channels, returned as a complex vector array.

cdma2000ForwardReferenceChannels | cdma2000ReverseWaveformGenerator Introduced in R2015b

\section*{cdma2000ReverseReferenceChannels}

Define cdma2000 reverse reference channel

\section*{Syntax}
cfg = cdma2000ReverseReferenceChannels(wv)
cfg = cdma2000ReverseReferenceChannels(wv, numchips)
cfg = cdma2000ReverseReferenceChannels(traffic,numchips,R-SCH-SPEC)

\section*{Description}
cfg = cdma2000ReverseReferenceChannels(wv) returns a structure, cfg, that defines the cdma2000 reverse link parameters given the input waveform identifier, wv. Pass the structure to the cdma2000ReverseWaveformGenerator function to generate a reverse link reference channel waveform.

For all syntaxes, cdma2000ReverseReferenceChannels creates a configuration structure that is compliant with the physical layer specification for cdma2000 systems described in [1].
cfg = cdma2000ReverseReferenceChannels(wv, numchips) specifies the number of chips to generate.
cfg = cdma2000ReverseReferenceChannels(traffic, numchips,R-SCH-SPEC) returns cfg for the specified traffic channel, traffic, and the reverse supplemental channel (R-SCH) and frame length combination, R-SCH-SPEC.

\section*{Examples}

\section*{Generate Reverse Common Control Channel Waveform}

Generate the structure corresponding to the reverse common control channel (R-CCCH) having a 19,200 bps data rate and 10 ms frames.
```

config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');

```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.
```

config.RCCCH
ans = struct with fields:
Enable: 'On'
Power: 0
LongCodeMask: 0
EnableCoding: 'On'
DataSource: {'PN9' [1]}
DataRate: }1920
FrameLength: 10
WalshCode: 1

```

Generate the reverse channel waveform using the corresponding waveform generator function, cdma2000ReverseWaveformGenerator.
wv = cdma2000ReverseWaveformGenerator(config);

\section*{Generate Reverse Channels for RC1 and RC6}

Create a configuration structure to generate all possible channels associated with radio configuration 1 in which the number of chips is specified as 2500.
```

config = cdma2000ReverseReferenceChannels('ALL-RC1',2500)
config = struct with fields:
RadioConfiguration: 'RC1'
PowerNormalization: 'Off'
OversamplingRatio: 4
FilterType: 'cdma2000Long'
InvertQ: 'Off'
EnableModulation: 'Off'
ModulationFrequency: 0
NumChips: 2500
RFCH: [1x1 struct]
RACH: [1x1 struct]
RSCCH: [1x1 struct]

```

The structure contains substructures corresponding to the R-FCH, R-ACH, and R-SCCH channels. Call the function again using radio configuration 6.
```

config = cdma2000ReverseReferenceChannels('ALL-RC6',2500)
config = struct with fields:
RadioConfiguration: 'RC6'
PowerNormalization: 'Off'
OversamplingRatio: 4
FilterType: 'cdma2000Long'
InvertQ: 'Off'
EnableModulation: 'Off'
ModulationFrequency: 0
NumChips: 2500
RFCH: [1\times1 struct]
RPICH: [1x1 struct]
REACH: [1x1 struct]
RCCCH: [1x1 struct]
RDCCH: [1x1 struct]
RSCH1: [1x1 struct]
RSCH2: [1x1 struct]

```

The channels supported by RC6 differ from those supported by RC1. They include R-FCH, R-PICH, REACH, R-CCCH, R-DCCH, R-SCH1, and R-SCH2.

Create the waveform corresponding to the set of RC6 channels.
wv = cdma2000ReverseWaveformGenerator(config);

\section*{Generate Reverse Supplemental Channel}

Create a configuration structure using radio configuration 3 with a reverse fundamental channel (RFCH). Specify a 2700 bps data rate and a reverse supplemental channel (R-SCH) having a 76,800 bps data rate and an 80 ms frame length.
```

config = cdma2000ReverseReferenceChannels('TRAFFIC-RC3-2700',2000, ...
'R-SCH-76800-80');

```

Verify that the R-FCH data rate is 2700 bps and the first R-SCH data rate is \(76,800 \mathrm{bps}\) with an 80 ms frame length.
```

config.RFCH.DataRate
ans = 2700
config.RSCH1.DataRate
ans = 76800
config.RSCH1.FrameLength
ans = 80

```

Generate the corresponding waveform.
wv = cdma2000ReverseWaveformGenerator(config);

\section*{Input Arguments}

\section*{wv - Waveform identification}
character vector
Waveform identification of the reference channel, specified as a character vector. The input typically identifies the channel type, radio configuration, data rate, and frame length. To specify wv, connect the substrings with hyphens, for example, 'TRAFFIC-RC2-3600'.
\begin{tabular}{|l|l|l|l|l|}
\hline Parameter Field & \multicolumn{2}{|l|}{ Values } & Description \\
\cline { 2 - 4 } & Substring 1 & Substring 2 & Substring 3 & \\
\hline WV & 'R-PICH- ONLY' & & & \(\begin{array}{l}\text { Generates a } \\
\text { waveform } \\
\text { containing a pilot } \\
\text { channel only. }\end{array}\) \\
\cline { 2 - 5 } & & 9600 & 20 & \(\begin{array}{l}\text { Character vector } \\

\hline & Substring 1 & Substring 2 & Substring 3 & \\
\hline & 'ALL' & \[
\begin{aligned}
& \text { RC1 | RC2 } \\
& \text { RC4 } \mid \text { RC3 } \\
& \text { RC3 }
\end{aligned}
\] & N/A & Returns all channels that are supported for the specified radio configuration. Specify 'ALLRC4 ' to create a structure containing all traffic channels for radio configuration 4. \\
\hline
\end{tabular}

Example: 'R-CCCH-9600-20' is a R-CCH channel having a 9600 bps data rate and a 20 ms frame length.
Example: 'R-EACH-38400-5' is a R-EACH channel having a 38,400 bps data rate and a 5 ms frame length.

\section*{Data Types: char}

\section*{numchips - Number of chips}

1000 (default) | positive integer scalar
Number of chips, specified as a positive integer.
Example: 2048

\section*{Data Types: double}

\section*{traffic - Traffic configuration}
character vector
Traffic channel configuration, specified as a character vector. The table shows the valid configurations.
\begin{tabular}{|c|c|c|c|c|}
\hline Radio & \multicolumn{4}{|l|}{Traffic Channel Configuration} \\
\hline 1 & 'TRAFFIC-
RC1-1200' & 'TRAFFIC-RC1-2400' & 'TRAFFIC -RC1-4800' & \begin{tabular}{l}
'TRAFFIC- \\
RC1-9600'
\end{tabular} \\
\hline 2 & \[
\begin{array}{|l|}

\] \\
\hline
\end{tabular}

Additional data rate information for the cdma2000 reverse links is given in Tables 2.1.3.1.3-1 and 2.1.3.1.3-2 of [1].

Example: 'R-SCH-153600-20' is an R-SCH having a 153,600 bps data rate and a 20 ms frame length.
Data Types: char

\section*{Output Arguments}
cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline RadioConfiguration & 'RC1'| 'RC2' | 'RC3' | 'RC4'
| 'RC5' | 'RC6' & Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6. \\
\hline PowerNormalization & 'Off' | 'NormalizeTo0dB' & Power normalization of the waveform \\
\hline NumChips & Positive scalar integer & Number of chips in the waveform \\
\hline OversamplingRatio & Positive scalar integer & Oversampling ratio at output \\
\hline FilterType & ' cdma2000Long ' |
'cdma2000Short' | 0 '
'Cust ' | & Type of output filtering \\
\hline CustomFilterCoeffici ents & Real vector & Custom filter coefficients used only when the FilterType field is set to 'Custom' \\
\hline InvertQ & 'Off'|'On' & Negate the quadrature output \\
\hline EnableModulation & 'Off'|'On' & Enable carrier modulation \\
\hline ModulationFrequency & Nonnegative scalar integer & Carrier modulation frequency (applies when EnableModulation is ' On ') \\
\hline RPICH & Structure & See RPICH Substructure. Optional. \\
\hline RACH & Structure & See RACH Substructure. Optional. \\
\hline REACH & Structure & See REACH Substructure. Optional. \\
\hline RCCCH & Structure & See RCCCH Substructure. Optional. \\
\hline RDCCH & Structure & See RDCCH Substructure. Optional. \\
\hline RFCH & Structure & See RFCH Substructure. Optional. \\
\hline RSCCH & Structure & See RSCCH Substructure. Optional. \\
\hline RSCH1 & Structure & See RSCH1 Substructure. Optional. \\
\hline RSCH2 & Structure & See RSCH2 Substructure. Optional. \\
\hline
\end{tabular}

\section*{RPICH Substructure}

Include the RPICH substructure in the cfg structure to configure the Reverse Pilot Channel (RPICH). The RPICH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline \begin{tabular}{l} 
PowerControlEnabl \\
e
\end{tabular} & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable power control subchannel \\
\hline PowerControlPower & Real scalar & \begin{tabular}{l} 
Power control subchannel power (relative to \\
R-PICH)
\end{tabular} \\
\hline \begin{tabular}{l} 
PowerControlDataS \\
ource
\end{tabular} & \begin{tabular}{l} 
Cell array, \{'PN Type' , RN \\
Seed\} or binary vector.
\end{tabular} & Power control subchannel data source \\
\begin{tabular}{l} 
Standard PN sequence \\
options are 'PN9', 'PN15' ' \\
'PN23', 'PN9-ITU', and \\
'PN11'.
\end{tabular} & \\
\hline
\end{tabular}

\section*{RACH Substructure}

Include the RACH substructure in the cfg structure to configure the Reverse Access Channel (RACH ). The RACH substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On'| '0ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or a binary vector. \\
Standard PN types are \\
'PN9', 'PN15', 'PN23', \\
'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a binary vector. \\
\hline
\end{tabular}

\section*{REACH Substructure}

Include the REACH substructure in the cfg structure to configure the Reverse Enhanced Access Channel (R-EACH). The REACH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(9600|19200| 38400\) & Data rate (bps) \\
\hline FrameLength & \(5|10| 20\) & Frame length (ms) \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) Wal shCode \(\leq\) \\
7
\end{tabular} & Walsh code number \\
\hline LongCodeMask & 42 -bit binary number & Long code identifier \\
\hline EnableCoding & 'On' |'Off' & Enable or disable channel coding \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or a binary vector. \\
Standard PN types are \\
'PN9','PN15','PN23', \\
'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a binary vector. \\
\hline
\end{tabular}

\section*{RCCCH Substructure}

Include the RCCCH substructure in the cfg structure to configure the Reverse Common Control Channel (R-CCCH). The RCCCH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(9600|19200| 38400\) & Data rate (bps) \\
\hline FrameLength & \(5|10| 20\) & Frame length (ms) \\
\hline CodingType & 'conv ' | 'turbo' & Type of error control coding \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
7
\end{tabular} & Walsh code number \\
\hline LongCodeMask & 42 -bit binary number & Long code identifier \\
\hline EnableCoding & 'On ' | 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l} 
Cell array: \{ 'PN Type ', RN \\
Seed\} or binary vector. \\
Standard PN sequence \\
options are 'PN9', 'PN15' ', \\
'PN23', ' PN9-ITU ', and \\
'PN11 '.
\end{tabular} & \begin{tabular}{l} 
with a random number seed or a custom \\
vector.
\end{tabular} \\
\hline
\end{tabular}

\section*{RDCCH Substructure}

Include the RDCCH substructure in the cfg structure to configure the Reverse Dedicated Control Channel (R-DCCH). The RDCCH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline FrameLength & \(5 \mid 20\) & Frame length (ms) \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
15
\end{tabular} & Walsh code number \\
\hline LongCodeMask & 42 -bit binary number & Long code identifier \\
\hline EnableCoding & 'On' | 'Off' & Enable or disable channel coding \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', 'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RFCH Substructure}

Include the RFCH substructure in the cfg structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The RFCH substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(1200|1500| 1800|2400|\)
\(2700|3600| 4800|7200|\)
\(9600 \mid 14400\) & Data rate (bps) \\
\hline FrameLength & 5 | 10 | 20 & Frame length (ms) \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) Wal shCode \(\leq\) 15 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On'| '0ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RSCCH Substructure}

Include the RSCCH substructure in the cfg structure to configure the Reverse Supplemental Code Channel (R-SCCH). The RSCCH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline LongCodeMask & 42 -bit binary number & Long code identifier \\
\hline EnableCoding & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable channel coding \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RSCH1 Substructure}

Include the RSCH1 substructure in the cfg structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The RSCH1 substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| '0ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(1200|1350| 1500|1800|\)
\(2400|2700| 3600|4800|\)
\(7200|9600| 14400 \mid 19200\)
\(|28800| 38400|57600|\)
\(76800|115200| 153600 \mid\)
\(230400|259200| 307200 \mid\)
\(460800|518400| 614400 \mid\)
1036800 & Data rate (bps) \\
\hline FrameLength & 20|40|80 & Frame length (ms) \\
\hline WalshLength & \(2 \mid 4\) & Walsh code length \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) WalshLength - 1 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On'| 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RSCH2 Substructure}

Include the RSCH2 substructure in the cfg structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The RSCH2 substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\mathrm{I}^{\prime} 0 \mathrm{ff}^{\prime}\) & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline DataRate & \(1200|1350| 1500|1800|\)
\(2400|2700| 3600|4800|\)
\(7200|9600| 14400 \mid 19200\)
\(|28800| 38400|57600|\)
\(76800|115200| 153600 \mid\)
\(230400|259200| 307200 \mid\)
\(460800|518400| 614400 \mid\)
1036800 & Data rate (bps) \\
\hline FrameLength & 20|40|80 & Frame length (ms) \\
\hline WalshLength & 4 | 8 & Walsh code length \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) WalshLength - 1 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On'| 0 Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', 'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{Introduced in R2015b}

\section*{cdma2000ReverseWaveformGenerator}

Generate cdma2000 reverse link waveform

\section*{Syntax}
waveform = cdma2000ReverseWaveformGenerator(cfg)

\section*{Description}
waveform = cdma2000ReverseWaveformGenerator(cfg) returns the cdma2000 reverse link baseband waveform, waveform as defined by the parameter configuration structure, cfg.

The top-level parameters and lower-level substructures of cfg specify the waveform and channel properties used by the function to generate a cdma2000 waveform. You can generate the input argument by using the cdma2000ReverseReferenceChannels function. The top-level parameters of cfg are RadioConfiguration, LongCodeState, PowerNormalization, OversamplingRatio, FilterType, InvertQ, EnableModulation, ModulationFrequency, and NumChips. To enable specific channels, add their associated substructures, for example, the reverse dedicated control channel, RDCCH.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all combinations of spreading rate, radio configuration, frame length, and data rate are supported. To ensure that the input argument is valid, use the cdma2000ReverseReferenceChannels function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

\section*{Examples}

\section*{Generate Reverse Common Control Channel Waveform}

Generate the structure corresponding to the reverse common control channel ( \(\mathrm{R}-\mathrm{CCCH}\) ) having a 19,200 bps data rate and 10 ms frames.
```

config = cdma2000ReverseReferenceChannels('R-CCCH-19200-10');

```

Verify that the R-CCCH substructure is configured for the correct data rate and frame duration.
```

config.RCCCH
ans = struct with fields:
Enable: 'On'
Power: 0
LongCodeMask: 0
EnableCoding: 'On'
DataSource: {'PN9' [1]}
DataRate: 19200
FrameLength: 10
WalshCode: 1

```

Generate the reverse channel waveform using the corresponding waveform generator function, cdma2000ReverseWaveformGenerator.
wv = cdma2000ReverseWaveformGenerator(config);

\section*{Generate R-SCH Channels for RC5}

Create a configuration structure for a reverse channel having an R-FCH with a 4800 bps data rate and two R-SCHs. Specify that each R-SCH have a 153,600 bps data rate using RC5.
```

config = cdma2000ReverseReferenceChannels('TRAFFIC-RC5-4800',5000, ...

```
    'R-SCH-153600-40');

Determine the sample rate. Because RC5 corresponds to SR3, the chip rate is 3.6864 Mcps. Multiply by the oversampling ratio to obtain the sample rate.
```

fs = 3.6864e6*config.OversamplingRatio;

```

Generate the reverse link waveform.
```

wv = cdma2000ReverseWaveformGenerator(config);

```

Plot the spectrum of the resultant waveform.
```

sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)

```

\section*{Generate cdma2000 Waveform with Two Reverse Supplemental Channels}

Create a parameter structure specifying a reverse traffic channel containing a pair of supplemental channels and generate the corresponding waveform.

Create a parameter structure specifying a traffic channel consisting of a \(14,400 \mathrm{bps}\) fundamental channel, 2000 chips, and a 57,600 bps supplemental channel (R-SCH) pair having a 40 ms frame duration.
cfg = cdma2000ReverseReferenceChannels('TRAFFIC-RC4-14400',2000,'F-SCH-57600-40');
Create a second R-SCH pair by copying the R-SCH fields from the existing pair.
```

cfg(2).RSCH1 = cfg.RSCH1;
cfg(2).RSCH2 = cfg.RSCH2;

```

Set the data rate of the second R-SCH pair to \(28,800 \mathrm{bps}\).
```

cfg(2).RSCH1.DataRate = 28800;
cfg(2).RSCH2.DataRate = 28800;

```

Set the Walsh codes of the second pair so that they differ from the first pair.
```

cfg(2).RSCH1.WalshCode = 4;
cfg(2).RSCH2.WalshCode = 5;

```

Verify that the data rates are set correctly and that no two supplemental channels share the same Walsh code.
```

cfg.RSCH1
ans = struct with fields:
Enable: 'On'
Power: 0
LongCodeMask: 0
EnableCoding: 'On'
DataSource: {'PN9'
DataRate: 57600
FrameLength: 40
WalshLength: 2
WalshCode: 0
ans = struct with fields:
Enable: 'On'
Power: 0
LongCodeMask: 0
EnableCoding: 'On'
DataSource: {'PN9'
DataRate: 28800
FrameLength: 40
WalshLength: 2
WalshCode: 4
cfg.RSCH2
ans = struct with fields:
Enable: 'On'
Power: 0
LongCodeMask: 0
EnableCoding: 'On'
DataSource: {'PN9'
DataRate: 57600
FrameLength: 40
WalshLength: 2
WalshCode: 1
ans = struct with fields:
Enable: 'On'
Power: 0
LongCodeMask: 0
EnableCoding: 'On'
DataSource: {'PN9'
DataRate: 28800
FrameLength: 40
WalshLength: 2
WalshCode: 5

```

Generate the reverse link waveform.
wv = cdma2000ReverseWaveformGenerator(cfg);

\section*{Input Arguments}
cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline RadioConfiguration & \[
\begin{aligned}
& \text { 'RC1' | 'RC2' | 'RC3' | 'RC4' } \\
& \text { |'RC5'|'RC6' }
\end{aligned}
\] & Radio configuration of the reverse channel. The spreading rate of the waveform is derived from the radio configuration. Spreading rate 1, SR1, corresponds to a 1.2288 Mcps carrier and is associated with RC1 through RC4. Spreading rate 3, SR3, corresponds to a 3.6864 Mcps carrier and is associated with RC5 and RC6. \\
\hline PowerNormalization & 'Off' | 'NormalizeTo0dB' & Power normalization of the waveform \\
\hline NumChips & Positive scalar integer & Number of chips in the waveform \\
\hline OversamplingRatio & Positive scalar integer & Oversampling ratio at output \\
\hline FilterType & \begin{tabular}{l}
' cdma2000Long' | \\
'cdma2000Short'|'Off'| \\
'Custom'
\end{tabular} & Type of output filtering \\
\hline CustomFilterCoeffici ents & Real vector & Custom filter coefficients used only when the FilterType field is set to 'Custom' \\
\hline InvertQ & '0ff'|'0n' & Negate the quadrature output \\
\hline EnableModulation & '0ff'|'On' & Enable carrier modulation \\
\hline ModulationFrequency & Nonnegative scalar integer & Carrier modulation frequency (applies when EnableModulation is ' On ') \\
\hline RPICH & Structure & See RPICH Substructure. Optional. \\
\hline RACH & Structure & See RACH Substructure. Optional. \\
\hline REACH & Structure & See REACH Substructure. Optional. \\
\hline RCCCH & Structure & See RCCCH Substructure. Optional. \\
\hline RDCCH & Structure & See RDCCH Substructure. Optional. \\
\hline RFCH & Structure & See RFCH Substructure. Optional. \\
\hline RSCCH & Structure & See RSCCH Substructure. Optional. \\
\hline RSCH1 & Structure & See RSCH1 Substructure. Optional. \\
\hline RSCH2 & Structure & See RSCH2 Substructure. Optional. \\
\hline
\end{tabular}

\section*{RPICH Substructure}

Include the RPICH substructure in the cfg structure to configure the Reverse Pilot Channel (RPICH). The RPICH substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' | 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline PowerControlEnabl e & 'On'| 'Off' & Enable or disable power control subchannel \\
\hline PowerControlPower & Real scalar & Power control subchannel power (relative to R-PICH) \\
\hline PowerControlDataS ource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Power control subchannel data source \\
\hline
\end{tabular}

\section*{RACH Substructure}

Include the RACH substructure in the cfg structure to configure the Reverse Access Channel (RACH ). The RACH substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & '0n' | 0 Of' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On' | 0 'f' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or a binary vector. \\
Standard PN types are 'PN9', 'PN15', 'PN23', \\
'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a binary vector. \\
\hline
\end{tabular}

\section*{REACH Substructure}

Include the REACH substructure in the cfg structure to configure the Reverse Enhanced Access Channel (R-EACH). The REACH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime} 0^{\prime} f^{\prime}\) & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power \((\mathrm{dB})\) \\
\hline DataRate & \(9600|19200| 38400\) & Data rate \((\mathrm{bps})\) \\
\hline FrameLength & \(5|10| 20\) & Frame length (ms) \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
7
\end{tabular} & Walsh code number \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline LongCodeMask & 42 -bit binary number & Long code identifier \\
\hline EnableCoding & 'On' | 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l} 
Cell array: \{ 'PN Type', \\
SN
\end{tabular} & \begin{tabular}{l} 
Data source. Specify a standard PN sequence \\
sith a random number seed or a binary \\
vector.
\end{tabular} \\
& \begin{tabular}{l} 
Standard PN types are \\
'PN9', 'PN15', 'PN23',,
\end{tabular} \\
& 'PN9-ITU ' and 'PN11'. & \\
\hline
\end{tabular}

\section*{RCCCH Substructure}

Include the RCCCH substructure in the cfg structure to configure the Reverse Common Control Channel (R-CCCH). The RCCCH substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| '0ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & 9600 | 19200 | 38400 & Data rate (bps) \\
\hline FrameLength & 5 | 10 | 20 & Frame length (ms) \\
\hline CodingType & 'conv'|'turbo' & Type of error control coding \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 7 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On'| '0ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array: \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RDCCH Substructure}

Include the RDCCH substructure in the cfg structure to configure the Reverse Dedicated Control Channel (R-DCCH). The RDCCH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\mid\) 'Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline FrameLength & \(5 \mid 20\) & Frame length (ms) \\
\hline WalshCode & \begin{tabular}{l} 
Nonnegative integer scalar \\
such that \(0 \leq\) WalshCode \(\leq\) \\
15
\end{tabular} & Walsh code number \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On' | 0 ¢f' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9', 'PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RFCH Substructure}

Include the RFCH substructure in the cfg structure to configure the Reverse Fundamental Traffic Channel (R-FCH). The RFCH substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & '0n' | 0 ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(1200|1500| 1800|2400|\)
\(2700|3600| 4800|7200|\)
\(9600 \mid 14400\) & Data rate (bps) \\
\hline FrameLength & 5 | 10 | 20 & Frame length (ms) \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) 15 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On' | 0 ff' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RSCCH Substructure}

Include the RSCCH substructure in the cfg structure to configure the Reverse Supplemental Code Channel (R-SCCH). The RSCCH substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime} O f^{\prime} '^{\prime}\) & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline LongCodeMask & 42 -bit binary number & Long code identifier \\
\hline EnableCoding & 'On' \(\left.\right|^{\prime} O f^{\prime}\) & Enable or disable channel coding \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline DataSource & \begin{tabular}{l} 
Cell array, \{ 'PN Type' ' RN \\
Seed\} or binary vector.
\end{tabular} & \begin{tabular}{l} 
Data source. Specify a standard PN sequence \\
with a random number seed or a custom \\
vector.
\end{tabular} \\
& \begin{tabular}{l} 
Standard PN sequence \\
options are 'PN9', 'PN15' ',
\end{tabular} \\
& \begin{tabular}{l} 
'PN23', 'PN9-ITU' , and \\
'PN11'.
\end{tabular} & \\
\hline
\end{tabular}

\section*{RSCH1 Substructure}

Include the RSCH1 substructure in the cfg structure to configure the Reverse Supplemental Channel 1 (R-SCH 1). The RSCH1 substructure contains the following fields.
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On'| '0ff' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline DataRate & \(1200|1350| 1500|1800|\)
\(2400|2700| 3600|4800|\)
\(7200|9600| 14400 \mid 19200\)
\(|28800| 38400|57600|\)
\(76800|115200| 153600 \mid\)
\(230400|259200| 307200 \mid\)
\(460800|518400| 614400 \mid\)
1036800 & Data rate (bps) \\
\hline FrameLength & 20|40|80 & Frame length (ms) \\
\hline WalshLength & \(2 \mid 4\) & Walsh code length \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) WalshLength - 1 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On'| 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9','PN15', \\
'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{RSCH2 Substructure}

Include the RSCH2 substructure in the cfg structure to configure the Reverse Supplemental Channel 2 (R-SCH 2). The RSCH2 substructure contains the following fields.
\begin{tabular}{|l|l|l|}
\hline Parameter Field & Values & Description \\
\hline Enable & 'On' \(\left.\right|^{\prime}\) Off' & Enable or disable the channel \\
\hline Power & Real scalar & Relative channel power (dB) \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline Parameter Field & Values & Description \\
\hline DataRate & \(1200|1350| 1500|1800|\)
\(2400|2700| 3600|4800|\)
\(7200|9600| 14400 \mid 19200\)
\(|28800| 38400|57600|\)
\(76800|115200| 153600 \mid\)
\(230400|259200| 307200 \mid\)
\(460800|518400| 614400 \mid\)
1036800 & Data rate (bps) \\
\hline FrameLength & 20|40|80 & Frame length (ms) \\
\hline WalshLength & 4 | 8 & Walsh code length \\
\hline WalshCode & Nonnegative integer scalar such that \(0 \leq\) WalshCode \(\leq\) Wal shLength - 1 & Walsh code number \\
\hline LongCodeMask & 42-bit binary number & Long code identifier \\
\hline EnableCoding & 'On' \| 'Off' & Enable or disable channel coding \\
\hline DataSource & \begin{tabular}{l}
Cell array, \{'PN Type', RN Seed\} or binary vector. \\
Standard PN sequence options are 'PN9', 'PN15', 'PN23', 'PN9-ITU', and 'PN11'.
\end{tabular} & Data source. Specify a standard PN sequence with a random number seed or a custom vector. \\
\hline
\end{tabular}

\section*{Output Arguments}

\section*{waveform - Modulated baseband waveform comprising the physical channels}
complex vector array
Modulated baseband waveform comprising the cdma2000 physical channels, returned as a complex vector array.

\section*{cma}
(To be removed) Construct constant modulus algorithm (CMA) object
\(\overline{\text { Note }}\) will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead.

\section*{Syntax}
alg = cma(stepsize)
alg = cma(stepsize,leakagefactor)

\section*{Description}

The cma function creates an adaptive algorithm object that you can use with the lineareq function or dfe function to create an equalizer object. You can then use the equalizer object with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".

Note After you use either lineareq or dfe to create a CMA equalizer object, you should initialize the equalizer object's Weights property with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and 0s elsewhere.
alg \(=\mathrm{cma}(\) stepsize) constructs an adaptive algorithm object based on the constant modulus algorithm (CMA) with a step size of stepsize.
alg = cma(stepsize,leakagefactor) sets the leakage factor of the CMA. leakagefactor must be between 0 and 1 . A value of 1 corresponds to a conventional weight update algorithm, while a value of 0 corresponds to a memoryless update algorithm.

\section*{Properties}

The table below describes the properties of the CMA adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see "Equalization".
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline AlgType & Fixed value, 'Constant Modulus ' \\
\hline StepSize & \begin{tabular}{l} 
CMA step size parameter, a nonnegative real \\
number
\end{tabular} \\
\hline LeakageFactor & \begin{tabular}{l} 
CMA leakage factor, a real number between 0 \\
and 1
\end{tabular} \\
\hline
\end{tabular}

\section*{Examples}

\section*{Configuring Linear Equalizers}

This example configures the recommended comm. LinearEqualizer System object \({ }^{\text {TM }}\) and the legacy lineareq feature with comparable settings.

\section*{Initialize Variables and Supporting Objects}
```

d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r=awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols

```

To compare the equalized output, plot the constellations using code such as:
```

% plot(yNew,'*')
% hold on
% plot(yOld,'o')
% hold off; legend('New Eq','Old Eq'); grid on

```

\section*{Use CMA Algorithm with Linear Equalizer}

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from CMA algorithm. The comm. LinearEqualizer System object \({ }^{\text {TM }}\) assumes that leakage factor is always 1.
```

eq0ld = lineareq(5,cma(0.05),pskmod(0:3,4,pi/4))
eqOld =
EqType: 'Linear Equalizer'
AlgType: 'Constant Modulus'
nWeights: 5
nSampPerSym: 1
SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071-0.7071i 0.7071 - 0.7071i]
StepSize: 0.0500
LeakageFactor: 1
Weights: [1 0 0 0 0)]
WeightInputs: [0 0 0 0 0)
ResetBeforeFiltering: 1
NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','CMA','StepSize',0.05, ...
'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
Algorithm: 'CMA'
NumTaps: 5
StepSize: 0.0500
Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
ReferenceTap: 1
InputSamplesPerSymbol: 1
AdaptWeightsSource: 'Property'
AdaptWeights: true
InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1

```

Call the equalizers.
```

y0ld = equalize(eq0ld,r);

```
yNew = eqNew(r);

\section*{Algorithms}

Referring to the schematics in "Equalization", define \(w\) as the vector of all weights \(w_{i}\) and define \(u\) as the vector of all inputs \(u_{\mathrm{i}}\). Based on the current set of weights, \(w\), this adaptive algorithm creates the new set of weights given by
(LeakageFactor) w \(+\quad\) (StepSize) \({ }^{*}\) e
where the * operator denotes the complex conjugate.

\section*{Compatibility Considerations}

\section*{cma will be removed}

Warns starting in R2020a
- cma will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead with the adaptive algorithm set to CMA.
- The comm. LinearEqualizer or comm. DecisionFeedback System objects do not have a leakage factor property. This is equivalent to setting LeakageFactor to 1 in the cma function.
- For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-156.

\section*{comm_links}

Library link information for Communications Toolbox blocks

\section*{Syntax}
```

comm links
comm_links(sys)
comm_links(sys,color)

```

\section*{Description}
comm_links returns a structure with two elements. Each element contains a cell array of strings containing names of library blocks in the current system. The blocks are grouped into two categories: obsolete and current. Blocks at all levels of the model are analyzed.
comm_links(sys) works as above on the named system sys, instead of the current system.
comm_links(sys,color) additionally colors all obsolete blocks according to the specified color. color is one of the following strings: 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

Obsolete blocks are blocks that are no longer supported. They might or might not work properly.
Current blocks are supported and represent the latest block functionality.

\section*{commscope}
(To be removed) Package of communications scope classes

Note commscope.eyediagram will be removed in a future release. Use comm. ConstellationDiagram and comm.EyeDiagram instead.

\section*{Syntax}
h = commscope.<type>(...)

\section*{Description}
h = commscope.<type>(...) returns a communications scope object h of type type.
Type help commscope to get a complete list of available types.
Each type of communications scope object is equipped with functions for simulation and visualization. Type help commscope. <type> to get the complete help on a specific communications scope object, for example help commscope.eyediagram.

\section*{Compatibility Considerations}

\section*{commscope will be removed}

Warns starting in R2017b
commscope.eyediagram will be removed in a future release. Use comm. ConstellationDiagram and comm.EyeDiagram instead.

\section*{See Also}
comm. ConstellationDiagram | comm.EyeDiagram
Introduced in R2007b

\section*{commscope.eyediagram}
(Removed) Eye diagram analysis

Note commscope.eyediagram has been removed. Use comm. EyeDiagram instead.

\section*{Syntax}
h = commscope.eyediagram
h = commscope.eyediagram(property1,value1,...)

\section*{Description}
\(\mathrm{h}=\) commscope.eyediagram constructs an eye diagram object, h , with default properties. This syntax is equivalent to:
```

H = commscope.eyediagram('SamplingFrequency', 10000, ...
'SamplesPerSymbol', 100, ...
'SymbolsPerTrace', 2, ...
'MinimumAmplitude', -1, ...
'MaximumAmplitude', 1, ...
'AmplitudeResolution', 0.0100, ...
'MeasurementDelay', 0, ...
'PlotType', '2D Color', ...
'PlotTimeOffset', 0, ...
'PlotPDFRange', [0 1], ...
'ColorScale', 'linear', ...
'RefreshPlot', 'on');

```
\(\mathrm{h}=\) commscope.eyediagram(property1, value1,...) constructs an eye diagram object, h , with properties as specified by property/value pairs.

The eye diagram object creates a series of vertical histograms from zero to \(T\) seconds, at \(T_{s}\) second intervals, where \(T\) is a multiple of the symbol duration of the input signal and \(T_{s}\) is the sampling time. A vertical histogram is defined as the histogram of the amplitude of the input signal at a given time. The histogram information is used to obtain an approximation to the probability density function (PDF) of the input amplitude distribution. The histogram data is used to generate '2D Color' plots, where the color indicates the value of the PDF, and '3D Color' plots. The '2D Line' plot is obtained by constructing an eye diagram from the last \(n\) traces stored in the object, where a trace is defined as the segment of the input signal for a \(T\) second interval.

You can change the plot type by setting the PlotType property. The following plots are examples of each type.

\section*{2D-Color Eye Diagram}

\section*{3D-Color Eye Diagram}

\section*{2D-Line Eye Diagram}

To see a detailed demonstration of this object's use, type showdemo scattereyedemo; at the command line.

\section*{Properties}

An eye diagram scope object has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline Type & \begin{tabular}{l} 
Type of scope object ( ' Eye Diagram ' ). This property is \\
not writable.
\end{tabular} \\
\hline SamplingFrequency & Sampling frequency of the input signal in hertz. \\
\hline SamplesPerSymbol & \begin{tabular}{l} 
Number of samples used to represent a symbol. An increase \\
in SamplesPerSymbol improves the resolution of an eye \\
diagram.
\end{tabular} \\
\hline SymbolRate & \begin{tabular}{l} 
The symbol rate of the input signal. This property is not \\
writable and is automatically computed based on \\
SamplingFrequency and SamplesPerSymbol.
\end{tabular} \\
\hline SymbolsPerTrace & \begin{tabular}{l} 
The number of symbols spanned on the time axis of the eye \\
diagram scope.
\end{tabular} \\
\hline MinimumAmplitude & \begin{tabular}{l} 
Minimum amplitude of the input signal. Signal values less \\
than this value are ignored both for plotting and for \\
measurement computation.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline MaximumAmplitude & \begin{tabular}{l} 
Maximum amplitude of the input signal. Signal values \\
greater than this value are ignored both for plotting and for \\
measurement computation.
\end{tabular} \\
\hline AmplitudeResolution & \begin{tabular}{l} 
The resolution of the amplitude axis. The amplitude axis is \\
created from MinimumAmplitude to MaximumAmplitude \\
with AmplitudeResolution steps.
\end{tabular} \\
\hline MeasurementDelay & \begin{tabular}{l} 
The time in seconds the scope waits before starting to \\
collect data.
\end{tabular} \\
\hline PlotType & \begin{tabular}{l} 
Type of the eye diagram plot. The choices are ' 2D Color' \\
(two dimensional eye diagram, where color intensity \\
represents the probability density function values), ' 3D \\
Color' (three dimensional eye diagram, where the z-axis \\
represents the probability density function values), and ' 2D \\
Line' (two dimensional eye diagram, where each trace is \\
represented by a line).
\end{tabular} \\
\hline Mumber0fStoredTraces & \begin{tabular}{l} 
The number of traces stored to display the eye diagram in \\
'2D Line' mode.
\end{tabular} \\
\hline PlotTime0ffset & \begin{tabular}{l} 
The plot time offset input values must reside in the closed \\
interval [-Tsym Tsym], where Tsym is the symbol duration. \\
Since the eye diagram is periodic, if the value you enter is \\
out of range, it wraps to a position on the eye diagram that \\
is within range.
\end{tabular} \\
\hline OperationMode & \begin{tabular}{l} 
The switch that controls the plot refresh style. The choices \\
are ' on' (the eye diagram plot is refreshed every time the \\
update method is called) and 'off ' the eye diagram plot \\
is not refreshed when the update method is called).
\end{tabular} \\
\hline SamplesProcessed & \begin{tabular}{l} 
All measurements are done on both the in-phase and \\
quadrature signal, unless otherwise stated. For more \\
information, see the Measurements section.
\end{tabular} \\
\hline RefreshPlot & \begin{tabular}{l} 
The range of the PDF values that will be displayed in the \\
' 2D Color ' mode. The PDF values outside the range are \\
set to a constant mask color.
\end{tabular} \\
\hline plots real signal data.
\end{tabular}

The resolution of the eye diagram in '2D Color' and '3D Color' modes can be increased by increasing SamplingFrequency, decreasing AmplitudeResolution, or both.

Changing MinimumAmplitude, MaximumAmplitude, AmplitudeResolution, SamplesPerSymbol, SymbolsPerTrace, and MeasurementDelay resets the measurements and updates the eye diagram.

\section*{Methods}

An eye diagram object is equipped with seven methods for inspection, object management, and visualization.

\section*{update}

This method updates the eye diagram object data.
update \((\mathrm{h}, \mathrm{x})\) updates the collected data of the eye diagram object h with the input x .
If the RefreshPlot property is set to ' on ' , the update method also refreshes the eye diagram figure.

The following example shows this method's use:
```

% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off')
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
'SNR', 20);
x = step(hChan,0.5*sin(2*pi*(0:1/100:10))+j*cos(2*pi*(0:1/100:10)));
% update the eyediagram
update(h, x);
% Check the number of processed samples
h.SamplesProcessed
plot

```

This method displays the eye diagram figure.
The plot method has three usage cases:
plot ( h ) plots the eye diagram for the eye diagram object h with the current colormap or the default linespec.
plot(h, cmap), when used with the plottype set to '2D Color' or '3D Color', plots the eye diagram for the object \(h\), and sets the colormap to cmap.
plot( h , linespec), when used with the plottype set to '2D Line', plots the eye diagram for the object \(h\) using linespec as the line specification. See the help for plot for valid linespecs.

The following example shows this method's use:
```

% Create an eye diagram scope object
h = commscope.eyediagram;
% Prepare a noisy sinusoid as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...

```
'SNR', 20);
\(x=\operatorname{step}\left(h C h a n, 0.5 * \sin \left(2 *\right.\right.\) pi* \(\left.^{*}(0: 1 / 100: 10)\right)+j^{*} 0.5^{*} \cos \left(2 *\right.\) pi*\(\left.\left.^{*}(0: 1 / 100: 10)\right)\right)\);
\% Update the eye diagram
update(h, x);
\% Display the eye diagram figure
plot(h)
\% Display the eye diagram figure with jet colormap
plot(h, jet(64))
\% Display 2D Line eye diagram with red dashed lines
h.PlotType = '2D Line';
plot(h, 'r--')
exportdata
This method exports the eye diagram data.
[VERHIST EYEL HORHISTX HORHISTRF] = EXPORTDATA(H) Exports the eye diagram data collected by the eyediagram object \(H\).

VERHIST is a matrix that holds the vertical histogram, which is also used to plot '2D Color' and '3D Color' eye diagrams.

EYEL is a matrix that holds the data used to plot 2D Line eye diagram. Each row of the EYEC holds one trace of the input signal.

HORHISTX is a matrix that holds the crossing point histogram data collected for the values defined by the CrossingAmplitudes property of the MeasurementSetup object. HORHISTX(i, :) represents the histogram for CrossingAmplitudes(i).

HORHISTRF is a matrix that holds the crossing point histograms for rise and fall time levels. HORHISTRF( \(\mathrm{i},:\) ) represents the histogram for AmplitudeThreshold(i).

The following example shows this method's use:
```

% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off');
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*cos(2*pi*(0:1/100:10)));
% Update the eyediagram
update(h, x);
% Export the data
[eyec eyel horhistx horhistrf] = exportdata(h);
% Plot line data
t=0:1/h.SamplingFrequency:h.SymbolsPerTrace/h.SymbolRate;
plot(t, real(eyel)); xlabel('time (s)');...
ylabel('Amplitude (AU)'); grid on;
% Plot 2D Color data
t=0:1/h.SamplingFrequency:h.SymbolsPerTrace/h.SymbolRate;
a=h.MinimumAmplitude:h.AmplitudeResolution:h.MaximumAmplitude;
imagesc(t,a,eyec); xlabel('time (s)'); ylabel('Amplitude (AU)');
reset

```

This method resets the eye diagram object.
reset (h) resets the eye diagram object \(h\). Resetting \(h\) clears all the collected data.
The following example shows this method's use:
```

% Create an eye diagram scope object
h = commscope.eyediagram('RefreshPlot', 'off');
% Prepare a noisy sinusoidal as input
hChan = comm.AWGNChannel('NoiseMethod', 'Signal to noise ratio (SNR)',...
'SNR', 20);
x = step(hChan, 0.5*sin(2*pi*(0:1/100:10))+ j*0.5*\operatorname{cos}(2*pi*(0:1/100:10)));
update(h, x); % update the eyediagram
h.SamplesProcessed % Check the number of processed samples
reset(h); % reset the object
h.SamplesProcessed % Check the number of processed samples

```

\section*{copy}

This method copies the eye diagram object.
\(h=\) copy (ref_obj) creates a new eye diagram object \(h\) and copies the properties of object \(h\) from properties of ref_obj.

The following example shows this method's use:
```

% Create an eye diagram scope object
h = commscope.eyediagram('MinimumAmplitude', -3, ...
'MaximumAmplitude', 3);
disp(h); % display object properties
h1 = copy(h)

```

\section*{disp}

This method displays properties of the eye diagram object.
disp(h) displays relevant properties of eye diagram object \(h\).
If a property is not relevant to the object's configuration, it is not displayed. For example, for a commscope. eyediagram object, the ColorScale property is not relevant when PlotType property is set to '2D Line'. In this case the ColorScale property is not displayed.

The following is an example of its use:
```

% Create an eye diagram scope object
h = commscope.eyediagram;
% Display object properties
disp(h);
h = commscope.eyediagram('PlotType', '2D Line')
close

```

This method closes the eye diagram object figure.
close (h) closes the figure of the eye diagram object \(h\).
The following example shows this method's use:
```

% Create an eye diagram scope object
h = commscope.eyediagram;

```
```

% Call the plot method to display the scope
plot(h);
% Wait for 1 seconds
pause(1)
% Close the scope
close(h)
analyze

```

This methods executes eye diagram measurements. analyze(h) executes the eye diagram measurements on the collected data of the eye diagram scope object \(h\). The results of the measurements are stored in the Measurements property of \(h\). For more information, see "Eye Diagram Analysis".

In some cases, the analyze method cannot determine a measurement value. If this problem occurs, verify that your settings for measurement setup values or the eye diagram are valid.

\section*{Measurement Setup Parameters}

A number of set-up parameters control eye diagram measurements. This section describes these setup parameters and the measurements they affect. For more information, see "Eye Diagram Analysis".

\section*{Eye Level Boundaries}

Eye Level Boundaries are defined as a percentage of the symbol duration. The analyze method calculates the eye levels by averaging the vertical histogram within a given time interval defined by the eye level boundaries. A common value you can use for NRZ signals is \(40 \%\) to \(60 \%\). For RZ signals, a narrower band of \(5 \%\) is more appropriate. The default setting for Eye level Boundaries is a 2-by-1 vector where the first element is the lower boundary and the second element is the upper boundary. When the eye level boundary changes, the object recalculates this value.

\section*{Reference Amplitude}

Reference Amplitude is the boundary value at which point the signal crosses from one signal level to another. Reference amplitude represents the decision boundary of the modulation scheme. This value is used to perform jitter measurements. The default setting for Reference Amplitude is a 2-by-1 double vector where the first element is the lower boundary and the second element is the upper boundary. Setting the reference amplitude resets the eye diagram.

The crossing instants of the input signal are detected and recorded as crossing times. A common value you can use for NRZ signals is 0 . For RZ signals, you can use the mean value of 1 and 0 levels. Reference amplitude is stored in a 2-by-N matrix, where the first row is the in-phase values and second row is the quadrature values. See Eye Crossing Time for more information.

\section*{Crossing Bandwidth}

Crossing Bandwidth is the amplitude band used to measure the crossing times of the eye diagram. Crossing Bandwidth represents a percentage of the amplitude span of the eye diagram, typically 5\%. See Eye Crossing Time for more information. The default setting for Crossing Bandwidth is 0.0500 .

\section*{Bit Error Rate Threshold}

The eye opening measurements, random, and total jitter measurements are performed at a given BER value. This BER value defines the BER threshold. A typical value is \(1 \mathrm{e}^{-12}\). The default setting for Bit

Error Threshold is \(1.0000 \mathrm{e}^{-12}\). When the bit error rate threshold changes, the object recalculates this value.

\section*{Amplitude Threshold}

The rise time of the signal is defined as the time required for the signal to travel from the lower amplitude threshold to the upper amplitude threshold. The fall time, measured from the upper amplitude threshold to the lower amplitude threshold, is defined as a percentage of the eye amplitude. The default setting is \(10 \%\) for the lower threshold and \(90 \%\) for the upper threshold. Setting the amplitude threshold resets the eye diagram. See Eye Rise Time and Eye Fall Time for more information.

\section*{Jitter Hysteresis}

You can use the JitterHysteresis property of the eye measurement setup object to remove the effect of noise from the horizontal histogram estimation. The default value for Jitter Hysteresis is zero. Setting the jitter hysteresis value resets the eye diagram.

If channel noise impairs the signal being tested, as shown in the following figure, the signal may seem like it crosses the reference amplitude level multiple times during a single 0-1 or 1-0 transition.

See the zoomed-in image for more detail.

To eliminate the effect of noise, define a hysteresis region between two threshold values: \(\mathrm{A}_{\text {ref }}+\Delta \mathrm{A}\) and \(\mathrm{A}_{\text {ref }}-\Delta \mathrm{A}\), where \(\mathrm{A}_{\text {ref }}\) is the reference amplitude value and \(\Delta \mathrm{A}\) is the jitter hysteresis value. If the signal crosses both threshold values, level crossing is declared. Then, linear interpolation calculates the crossing point in the horizontal histogram estimation.

\section*{Compatibility Considerations}

\section*{commscope. eyediagram has been removed}

Errors starting in R2020a
commscope.eyediagram has been removed. Use comm. EyeDiagram instead.

\section*{commsrc.combinedjitter}

Construct combined jitter generator object

\section*{Syntax}
combJitt = commsrc.combinedjitter
combJitt \(=\) commsrc.combinedjitter(Name, Value)

\section*{Description}
combJitt = commsrc.combinedjitter constructs a default combined jitter generator object, combJitt, with all jitter components disabled.

Use the object to generate jitter samples that include any combination of random, periodic, and Dirac components.
combJitt = commsrc.combinedjitter(Name, Value) creates a combined jitter generator object with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Namel,Value1,...,NameN,ValueN).

\section*{Properties}

A combined jitter generator object includes these properties. You can edit all properties, except those explicitly noted.
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline Type & \begin{tabular}{l} 
Type of object, Combined Jitter Generator. This \\
property is not writable.
\end{tabular} \\
\hline SamplingFrequency & \begin{tabular}{l} 
Sampling frequency of the input signal in hertz. Default \\
value 1e4.
\end{tabular} \\
\hline RandomJitter & \begin{tabular}{l} 
Variable to enable the random jitter generator. Specify as \\
either 'off' (default) or ' on '.
\end{tabular} \\
\hline RandomStd & \begin{tabular}{l} 
Standard deviation of the random jitter generator in \\
seconds. Applies when RandomJitter is ' on ' . Default \\
value 1e-4.
\end{tabular} \\
\hline PeriodicJitter & \begin{tabular}{l} 
Variable to enable the periodic jitter generator. Specify as \\
either 'off' (default) or ' on '.
\end{tabular} \\
\hline PeriodicNumber & \begin{tabular}{l} 
Number of sinusoidal components. The PeriodicNumber \\
must be a finite positive scalar integer. Applies when \\
PeriodicJitter is ' on '. Default value 1.
\end{tabular} \\
\hline PeriodicAmplitude & \begin{tabular}{l} 
Amplitude of each sinusoidal component of the periodic \\
jitter in seconds. Applies when PeriodicJitter is 'on ' . \\
Default value 5e-4.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline PeriodicFrequencyHz & \begin{tabular}{l} 
Frequency of each sinusoidal component of the periodic \\
jitter measured in Hz. Applies when PeriodicJitter is \\
'on '. Default value is 200.
\end{tabular} \\
\hline PeriodicPhase & \begin{tabular}{l} 
Phase of each sinusoidal component of the periodic jitter in \\
radians. Applies when PeriodicJitter is ' on ' . Default \\
value 0.
\end{tabular} \\
\hline DiracJitter & \begin{tabular}{l} 
Variable to enable the Dirac jitter generator. Specify as \\
either ' off ' (default) or ' on ' .
\end{tabular} \\
\hline DiracNumber & \begin{tabular}{l} 
Number of Dirac components. The Di racNumber must be a \\
finite positive scalar integer. Applies when Di racJitter is \\
' on '. Default value 2.
\end{tabular} \\
\hline DiracDelta & \begin{tabular}{l} 
Time delay of each Dirac component in seconds. Applies \\
when DiracJitter is ' on '. Default value [-5.e-4 5.e-4].
\end{tabular} \\
\hline DiracProbability & \begin{tabular}{l} 
Probability of each Dirac component represented as a \\
vector of length DiracNumber. The sum of the probabilities \\
must equal one. Applies when DiracJitter is ' on '. \\
Default value [0.5 0.5].
\end{tabular} \\
\hline
\end{tabular}

\section*{Object Functions}

A combined jitter generator object has three object functions, as described in this section.

\section*{generate}

This object function generates jitter samples based on the jitter generator object. It has one input argument, which is the number of samples in a frame. Its output is a single-column vector of length N . You can call this object function using this syntax:
\(\mathrm{x}=\) generate (combJitt, N )
where combJitt is the generator object, N is the number of output samples, and x is a real singlecolumn vector.

\section*{reset}

This object function resets the internal states of the combined jitter generator. You can call this object function using this syntax:
reset(combJitt)
where combJitt is the generator object.

\section*{disp}

Display the properties of the combined generator object, combJitt. You can call this object function using this syntax:
disp(combJitt)
where combJitt is the generator object.

\section*{Examples}

\section*{Generate Combined Random and Periodic Jitter}

Generate 500 jitter samples composed of random and periodic components.
Create a commsrc.combinedjitter object configured to apply a combination of random and periodic jitter components. Use name-value pairs to enable RandomJitter and PeriodicJitter, and to assign jitter settings. Set the standard deviation of the random jitter to \(2 \mathrm{e}-4\) seconds, the periodic jitter amplitude to \(5 \mathrm{e}-4\) seconds, and the periodic jitter frequency to 2 Hz .
```

numSamples = 500;
combJitt = commsrc.combinedjitter(...
'RandomJitter','on', ...
'RandomStd',2e-4, ...
'PeriodicJitter','on', ...
'PeriodicAmplitude',5e-4, ...
'PeriodicFrequencyHz',200)
combJitt =
Type: 'Combined Jitter Generator'
SamplingFrequency: 10000
RandomJitter: 'on'
RandomStd: 2.0000e-04
PeriodicJitter: 'on'
PeriodicNumber: 1
PeriodicAmplitude: 5.0000e-04
PeriodicFrequencyHz: 200
PeriodicPhase: 0
DiracJitter: 'off'

```

Use the generate method to create the combined jitter samples.
```

y = generate(combJitt,numSamples);
x = [0:numSamples-1];

```

Plot the jitter samples. You can see the Gaussian and periodic nature of the combined jitter.
```

plot(x/combJitt.SamplingFrequency,y)
xlabel('Time (seconds)')
ylabel('Jitter (seconds)')

```

\section*{Display commsrc.combinedjitter Object Settings}

Create a commsrc.combinedjitter object. Display the default object property values.
combJitt = commsrc.combinedjitter;
disp(combJitt)
Type: 'Combined Jitter Generator'
SamplingFrequency: 10000
RandomJitter: 'off'
PeriodicJitter: 'off'
DiracJitter: 'off'
Create a commsrc.combinedjitter object with random, periodic, and Dirac jitters enabled. Display the object property values.
```

combJitt = commsrc.combinedjitter('RandomJitter','on', ...
'PeriodicJitter','on','DiracJitter','on');
disp(combJitt)
Type: 'Combined Jitter Generator'
SamplingFrequency: 10000
RandomJitter: 'on'
RandomStd: 1.0000e-04
PeriodicJitter: 'on'

```
```

        PeriodicNumber: 1
    PeriodicAmplitude: 5.0000e-04
    PeriodicFrequencyHz: 200
PeriodicPhase: 0
DiracJitter: 'on'
DiracNumber: 2
DiracDelta: [-5.0000e-04 5.0000e-04]
DiracProbability: [0.5000 0.5000]

```

\section*{Generate Non-return-to-zero Pattern Signal}

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.
```

Fs = 10000; % Sample rate
Rs = 50; % Symbol rate (Sps)
sps = Fs/Rs; % Number of samples per symbol
Trise = 1/(5*Rs); % Rise time of the NRZ signal
Tfall = 1/(5*Rs); % Fall time of the NRZ signal
frameLen = 100; % Number of symbols in a frame
spt = 200; % Number of samples per trace on eye diagram

```

Create a pattern generator object with no jitter component assigned.
```

src = commsrc.pattern('SamplingFrequency', Fs, ...
'SamplesPerSymbol', sps, ...
'RiseTime', Trise, ...
'FallTime', Tfall)
src =
Type: 'Pattern Generator'
SamplingFrequency: 10000
SamplesPerSymbol: 200
SymbolRate: 50
PulseType: 'NRZ'
OutputLevels: [-1 1]
RiseTime: 0.0040
FallTime: 0.0040
DataPattern: 'PRBS7'
Jitter: [1x1 commsrc.combinedjitter]

```
src.Jitter
ans =
            Type: 'Combined Jitter Generator'
    SamplingFrequency: 10000
            RandomJitter: 'off'
        PeriodicJitter: 'off'
            DiracJitter: 'off'

Generate an NRZ signal and view the eye diagram of the signal.
message = generate(src,frameLen);
eyediagram(message,spt)

Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.
```

jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
src =
Type: 'Pattern Generator'
SamplingFrequency: 10000
SamplesPerSymbol: 200
SymbolRate: 50
PulseType: 'NRZ'
OutputLevels: [-1 1]
RiseTime: 0.0040
FallTime: 0.0040
DataPattern: 'PRBS7'
Jitter: [1x1 commsrc.combinedjitter]

```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.
```

reset(src);
message = generate(src, frameLen);
eyediagram(message,spt)

```

Introduced in R2015a

\section*{commsrc.pattern}

Construct pattern generator object

\section*{Syntax}
h = commsrc.pattern
h = commsrc.pattern(Name,Value)

\section*{Description}
\(\mathrm{h}=\) commsrc.pattern constructs a pattern generator object, h .
The pattern generator object produces modulated data patterns. The object can be used to inject jitter into modulated signals.
h = commsrc.pattern(Name, Value) creates a combined jitter generator object with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

A pattern generator object includes these properties. You can edit all properties, except those explicitly noted.
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline Type & \begin{tabular}{l} 
Type of pattern generator object ( ' Pattern \\
Generator ' ). This property is not writable.
\end{tabular} \\
\hline SamplingFrequency & Sampling frequency of the input signal in hertz. \\
\hline SymbolRate & \begin{tabular}{l} 
The symbol rate of the input signal. This property depends \\
upon the SamplingFequency and SamplesPerSymbol \\
properties. This property is not writable.
\end{tabular} \\
\hline SamplesPerSymbol & \begin{tabular}{l} 
The number of samples representing a symbol. \\
SamplesPerSymbol must be an integer. This property \\
affects SymbolRate.
\end{tabular} \\
\hline PulseType & \begin{tabular}{l} 
The type of pulse the object generates. Pulse types \\
available: return-to-zero ('RZ') and non-return-to-zero \\
(' 'NRZ' ). The initial condition for an ' NRZ' pulse is 0.
\end{tabular} \\
\hline OutputLevels & \begin{tabular}{l} 
Amplitude levels that correspond to the symbol indices. For \\
an ' NRZ' pulse, specify as a 1-by-2 vector. The first element \\
of the 1-by-2 vector corresponds to the 0th symbol (data bit \\
value 0). The second element corresponds to the 1st symbol \\
(data bit value 1). For an ' RZ ' pulse, specify as a scalar \\
and the value corresponds to the data bit value 1.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline DutyCycle & \begin{tabular}{l} 
The duty cycle of the pulse the object generates. Displays \\
calculated duty cycle based on pulse parameters. This \\
property is not writable.
\end{tabular} \\
\hline RiseTime & Specifies \(10 \%\) to \(90 \%\) rise time of the pulse in seconds. \\
\hline PulseDuration & \begin{tabular}{l} 
Pulse duration in seconds defined by IEEE STD 181 \\
standard. See the Return-to-Zero (RZ) Signal Conversion: \\
Ideal Pulse to STD-181 figure in the "Object Functions" on \\
page 2-181. Applies when PulseType is 'RZ' .
\end{tabular} \\
\hline FallTime & \begin{tabular}{l} 
Fall time of the pulse in seconds, specified as a percentage \\
from 10 to 90.
\end{tabular} \\
\hline DataPattern & \begin{tabular}{l} 
The bit sequence the object uses, specified as ' 'PRBS5 ' ', \\
'PRBS6 ', ..., 'PRBS15', ' PRBS23' , 'PRBS31' , and 'User \\
Defined '.
\end{tabular} \\
\hline UserDataPattern & \begin{tabular}{l} 
User-defined bit pattern consisting of a vector of ones and \\
zeroes. Applies when DataPattern is 'User Defined '
\end{tabular} \\
\hline Jitter & \begin{tabular}{l} 
Jitter characteristics, specified as a \\
commsrc. combinedjitter object. Use this property to \\
configure Random, Periodic and Dual Dirac Jitter.
\end{tabular} \\
\hline
\end{tabular}

\section*{Object Functions}

A pattern generator object has five object functions, as described in this section.

\section*{generate}

This object function outputs a frame worth of modulated and interpolated symbols. It has one input argument, which is the number of symbols in a frame. Its output is a column vector. You can call the object function using this syntax:
```

x = generate(h, N)

```
where h is the handle to the object, N is the number of output symbols, and x is a column vector whose length is N multiplied by h. SamplesPerSymbol.

\section*{reset}

This object function resets the pattern generator to its default state. The property values do not reset unless they relate to the state of the object. This object function has no input arguments.

\section*{idealtostd181}

This object function converts the ideal pulse specifications to IEEE STD-181 specifications. The ideal \(0 \%\) to \(100 \%\) span rise time ( tr ) and fall time ( tf ) are converted to \(10 \%\) to \(90 \%\) spans with a \(50 \%\) pulse width duration (pw). Call the idealtostd181 object function using this syntax:
h = idealtostd181(tr,tf, pw)
The object function sets the appropriate properties. The IEEE STD-181 Return-to-Zero (RZ) signal parameters are shown in this figure.

\section*{std181toideal}

The std181toideal object function converts the IEEE STD-181 pulse specifications, stored in the pattern generator, to ideal pulse specifications. The function converts the rise and fall times from \(10 \%-90 \%\) span to \(0 \%-100 \%\) span, and converts the \(50 \%\) pulse duration to pulse width. Call the std181toideal object function using this syntax:
[tr tf pw] = std181toideal(h)
where h is the pattern generator object handle, tr is the ideal \(0 \%-100 \%\) rise time, tf is the ideal \(0 \%-100 \%\) fall time, and pw is the ideal pulse width. The ideal pulse non-return-to-zero (NRZ) signal parameters are shown in this figure.

Use the property values for IEEE STD-181 specifications.

\section*{computedcd}

The computedcd object function computes the duty cycle distortion, \(D C D\), of the pulse defined by the pattern generator object \(h\).
\(D C D\) represents the ratio of the pulse on duration to the pulse off duration. For an NRZ pulse, on duration is the duration the pulse spends above the symbol boundary level. Off duration is the duration the pulse spends below zero. Call the computedcd object function using this syntax:
```

dcd = computedcd(h)

```

The software calculates \(D C D\) given \(t_{\mathrm{R}}, t_{\mathrm{F}}, T_{\text {sym }}\). This formula assumes that the symbol boundary level is zero.
\(T_{\mathrm{h}}=\left(A_{\mathrm{h}}-A_{\mathrm{l}}\right) * \frac{t_{R}}{A_{l}}+\left(A_{\mathrm{h}}-A_{\mathrm{l}}\right) * \frac{t_{F}}{A_{l}}+P W_{+}\)
\(T_{l}=\left(A_{\mathrm{h}}-A_{1}\right) * \frac{t_{R}}{A_{l}}+\left(A_{\mathrm{h}}-A_{1}\right) * \frac{t_{F}}{A_{l}}+P W\).
\(D C D=\frac{T_{h}}{T_{l}}\)
Where \(T_{\mathrm{h}}\) is the duration of the high signal, \(T_{1}\) is the duration of the low signal, and \(D C D\) represents the ratio of the duration of the high signal to the low signal.

\section*{Examples}

\section*{Display commsrc. pattern Object Settings}

Create a commsrc. pattern object. Display the default object property values.
```

h = commsrc.pattern;
disp(h)
Type: 'Pattern Generator'
SamplingFrequency: 10000
SamplesPerSymbol: 100
SymbolRate: 100
PulseType: 'NRZ'
OutputLevels: [-1 1]
RiseTime: 0
FallTime: 0
DataPattern: 'PRBS7'
Jitter: [1x1 commsrc.combinedjitter]

```

\section*{Generate Non-return-to-zero Pattern Signal}

Generate a binary non-return-to-zero (NRZ) signal utilizing the pattern generator object. View the NRZ signal with and without jitter applied to the signal.

Initialize system parameters.
```

Fs = 10000; % Sample rate
Rs = 50; % Symbol rate (Sps)
sps = Fs/Rs; % Number of samples per symbol
Trise = 1/(5*Rs); % Rise time of the NRZ signal
Tfall = 1/(5*Rs); % Fall time of the NRZ signal
frameLen = 100; % Number of symbols in a frame
spt = 200; % Number of samples per trace on eye diagram

```

Create a pattern generator object with no jitter component assigned.
```

src = commsrc.pattern('SamplingFrequency', Fs, ...
'SamplesPerSymbol', sps, ...
'RiseTime', Trise, ...
'FallTime', Tfall)
src =
Type: 'Pattern Generator'
SamplingFrequency: 10000
SamplesPerSymbol: 200
SymbolRate: 50
PulseType: 'NRZ'
OutputLevels: [-1 1]
RiseTime: 0.0040
FallTime: 0.0040
DataPattern: 'PRBS7'
Jitter: [1x1 commsrc.combinedjitter]
src.Jitter
ans =
Type: 'Combined Jitter Generator'
SamplingFrequency: 10000
RandomJitter: 'off'
PeriodicJitter: 'off'
DiracJitter: 'off'

```

Generate an NRZ signal and view the eye diagram of the signal.
```

message = generate(src,frameLen);
eyediagram(message,spt)

```

Add inter-symbol-interference (ISI) to an NRZ signal. ISI is modeled by two equal amplitude Dirac functions. Create a combined jitter object with Dirac jitter and assign it to the pattern generator object.
```

jitterSrc = commsrc.combinedjitter('DiracJitter','on', ...
'DiracDelta',0.05/Rs*[-1 1]);
src.Jitter = jitterSrc
src =
Type: 'Pattern Generator'
SamplingFrequency: 10000
SamplesPerSymbol: 200
SymbolRate: 50
PulseType: 'NRZ'
OutputLevels: [-1 1]
RiseTime: 0.0040
FallTime: 0.0040
DataPattern: 'PRBS7'
Jitter: [1x1 commsrc.combinedjitter]

```

Generate an NRZ signal that has jitter added to it and view the eye diagram of the signal.
```

reset(src);
message = generate(src, frameLen);
eyediagram(message,spt)

```

\section*{commsrc.pn}

Create PN sequence generator object

\section*{Syntax}
\(\mathrm{h}=\) commsrc.pn
h = commsrc.pn(property1,value1,...)

\section*{Description}
\(h=\) commsrc.pn creates a default PN sequence generator object \(h\), and is equivalent to the following:
```

H = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], ...
'InitialStates', [0 0 0 0 0 1], ...
'CurrentStates', [0 0 0 0 0 1], ...
'Mask', [0 0 0 0 0 1], ...
'NumBitsOut', 1)

```
or
\(H=\) commsrc.pn('GenPoly', \(\quad\left[\begin{array}{llllll}1 & 0 & 0 & 0 & 0 & 1\end{array}\right], \ldots\)
'InitialStates', [0 0000 1], ...
'CurrentStates', [0 0000 1], ...
'Shift', 0,
'NumBitsOut', 1)
h = commsrc.pn(propertyl, value1,...) creates a PN sequence generator object, \(h\), with properties you specify as property/value pairs.

\section*{Properties}

A PN sequence generator has the properties shown on the following table. All properties are writable except for the ones explicitly noted otherwise.
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline GenPoly & \begin{tabular}{l} 
Generator polynomial vector array of bits; must \\
be descending order
\end{tabular} \\
\hline InitialStates & \begin{tabular}{l} 
Vector array (with length of the generator \\
polynomial order) of initial shift register values \\
(in bits)
\end{tabular} \\
\hline CurrentStates & \begin{tabular}{l} 
Vector array (with length of the generator \\
polynomial order) of present shift register values \\
(in bits)
\end{tabular} \\
\hline NumBitsOut & \begin{tabular}{l} 
Number of bits to output at each generate \\
method invocation
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Property & \\
\hline Mask or Shift & to \\
& \\
& \\
\hline
\end{tabular}

\section*{Description \\ A mask vector of binary 0 and 1 values is used to specify which shift register state bits are XORed to produce the resulting output bit value. \\ Alternatively, a scalar shift value may be used to specify an equivalent shift (either a delay or advance) in the output sequence.}

The 'GenPoly ' property values specify the shift register connections. Enter these values as either a binary vector or a vector of exponents of the nonzero terms of the generator polynomial in descending order of powers. For the binary vector representation, the first and last elements of the vector must be 1. For the descending-ordered polynomial representation, the last element of the vector must be 0 . For more information and examples, see the LFSR SSRG Details section of this page.

\section*{Methods}

A PN sequence generator is equipped with the following methods.
generate
Generate [NumBitsOut x 1] PN sequence generator values
reset
Set the CurrentStates values to the InitialStates values

\section*{getshift}

Get the actual or equivalent Shift property value

\section*{getmask}

Get the actual or equivalent Mask property value

\section*{copy}

Make an independent copy of a commsrc.pn object

\section*{disp}

Display PN sequence generator object properties

\section*{Side Effects of Setting Certain Properties}

\section*{Setting the GenPoly Property}

Every time this property is set, it will reset the entire object. In addition to changing the polynomial values, 'CurrentStates', 'InitialStates', and 'Mask' will be set to their default values ('NumBitsOut' will remain the same), and no warnings will be issued.

\section*{Setting the InitialStates Property}

Every time this property is set, it will also set 'CurrentStates' to the new 'InitialStates' setting.

\section*{LFSR SSRG Details}

The generate method produces a pseudorandom noise (PN) sequence using a linear feedback shift register (LFSR). The LFSR is implemented using a simple shift register generator (SSRG, or Fibonacci) configuration, as shown below.

All \(r\) registers in the generator update their values at each time step according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2 . The shift register is described by the 'GenPoly' property (generator polynomial), which is a primitive binary polynomial in \(z, g_{r^{r}}+g_{\mathrm{r}-1} \mathrm{z}^{\mathrm{r}-1}+\mathrm{g}_{\mathrm{r}-2} \mathrm{z}^{\mathrm{r}-2}+\ldots+\mathrm{g}_{0}\). The coefficient \(\mathrm{g}_{\mathrm{k}}\) is 1 if there is a connection from the kth register, as labeled in the preceding diagram, to the adder. The leading term \(g_{r}\) and the constant term \(g_{0}\) of the 'GenPoly ' property must be 1 because the polynomial must be primitive.

You can specify the Generator polynomial parameter using either of these formats:
- A vector that lists the coefficients of the polynomial in descending order of powers. The first and last entries must be 1 . Note that the length of this vector is one more than the degree of the generator polynomial.
- A vector containing the exponents of \(z\) for the nonzero terms of the polynomial in descending order of powers. The last entry must be 0 .

For example, \(\left[\begin{array}{lllllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1\end{array}\right]\) and \(\left[\begin{array}{lll}8 & 2 & 0\end{array}\right]\) represent the same polynomial, \(p(z)=z^{8}+z^{2}+\) 1.

The Initial states parameter is a vector specifying the initial values of the registers. The Initial states parameter must satisfy these criteria:
- All elements of the Initial states vector must be binary numbers.
- The length of the Initial states vector must equal the degree of the generator polynomial.

Note At least one element of the Initial states vector must be nonzero in order for the block to generate a nonzero sequence. That is, the initial state of at least one of the registers must be nonzero.

For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of \(p(z)=z^{8}+z^{2}+1\).
\begin{tabular}{|l|l|l|}
\hline Quantity & Example 1 & Example 2 \\
\hline \begin{tabular}{l} 
Generator \\
polynomial
\end{tabular} & \(g 1=\left[\begin{array}{lllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 1\end{array}\right]\) & \(g 2=\left[\begin{array}{lllll}8 & 2 & 0\end{array}\right]\) \\
\hline \begin{tabular}{l} 
Degree of generator \\
polynomial
\end{tabular} & 8 , which is length \((g 1)-1\) & 8 \\
\hline Initial states & {\(\left[\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0\end{array}\right]\)} & {\(\left[\begin{array}{llllllll}1 & 0 & 0 & 0 & 0 & 0 & 1 & 0\end{array}\right]\)} \\
\hline
\end{tabular}

Output mask vector (or scalar shift value) shifts the starting point of the output sequence. With the default setting for this parameter, the only connection is along the arrow labeled \(m_{0}\), which corresponds to a shift of 0 . The parameter is described in greater detail below.

You can shift the starting point of the PN sequence with Output mask vector (or scalar shift value). You can specify the parameter in either of two ways:
- An integer representing the length of the shift
- A binary vector, called the mask vector, whose length is equal to the degree of the generator polynomial

The difference between the block's output when you set Output mask vector (or scalar shift value) to 0 , versus a positive integer \(d\), is shown in the following table.
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline & T = 0 & T= 1 & T= 2 & \(\ldots\) & T = d & T= d+1 \\
\hline Shift \(=0\) & \(x_{0}\) & \(x_{1}\) & \(x_{2}\) & \(\ldots\) & \(x_{d}\) & \(x_{d+1}\) \\
\hline Shift \(=\) d & \(x_{d}\) & \(x_{d+1}\) & \(x_{d+2}\) & \(\ldots\) & \(x_{2 d}\) & \(x_{2 d+1}\) \\
\hline
\end{tabular}

Alternatively, you can set Output mask vector (or scalar shift value) to a binary vector, corresponding to a polynomial in \(z, \mathrm{~m}_{\mathrm{r}-1} \mathrm{Z}^{\mathrm{r}-1}+\mathrm{m}_{\mathrm{r}-2} \mathrm{Z}^{\mathrm{r}-2}+\ldots+\mathrm{m}_{1} \mathrm{z}+\mathrm{m}_{0}\), of degree at most \(\mathrm{r}-1\). The mask vector corresponding to a shift of \(d\) is the vector that represents \(m(z)=z^{d}\) modulo \(g(z)\), where \(g(z)\) is the generator polynomial. For example, if the degree of the generator polynomial is 4 , then the mask vector corresponding to \(d=2\) is [ 01000 ], which represents the polynomial \(m(z)=z^{2}\). The preceding schematic diagram shows how Output mask vector (or scalar shift value) is implemented when you specify it as a mask vector. The default setting for Output mask vector (or scalar shift value) is 0 . You can calculate the mask vector using the Communications Toolbox function shift2mask.

\section*{Sequences of Maximum Length}

If you want to generate a sequence of the maximum possible length for a fixed degree, \(r\), of the generator polynomial, you can set Generator polynomial to a value from the following table. See Proakis, John G., Digital Communications, Third edition, New York, McGraw Hill, 1995 for more information about the shift-register configurations that these polynomials represent.
\begin{tabular}{|c|c|c|c|}
\hline r & Generator Polynomial & r & Generator Polynomial \\
\hline 2 & \(\left[\begin{array}{lll}2 & 1 & 0\end{array}\right]\) & 21 & [21 19 0] \\
\hline 3 & \(\left[\begin{array}{lll}3 & 2 & 0\end{array}\right]\) & 22 & [22 2100\(]\) \\
\hline 4 & \(\left[\begin{array}{lll}4 & 3 & 0\end{array}\right]\) & 23 & \(\left[\begin{array}{lll}23 & 18 & 0\end{array}\right]\) \\
\hline 5 & \(\left[\begin{array}{lll}5 & 3 & 0\end{array}\right]\) & 24 & \(\left[\begin{array}{lllll}24 & 23 & 22 & 17 & 0\end{array}\right]\) \\
\hline 6 & [ \(\left.\begin{array}{lll}6 & 5 & 0\end{array}\right]\) & 25 & [25 22 0]\(]\) \\
\hline 7 & [76 0] & 26 & \(\left[\begin{array}{lllll}26 & 25 & 24 & 20 & 0\end{array}\right]\) \\
\hline 8 & [8 655400 & 27 & \(\left[\begin{array}{lllll}27 & 26 & 25 & 22 & 0\end{array}\right]\) \\
\hline 9 & [9 5 0] & 28 & \(\left[\begin{array}{lll}28 & 25 & 0\end{array}\right]\) \\
\hline 10 & [10 7 0] & 29 & \(\left[\begin{array}{llll}29 & 27 & 0\end{array}\right]\) \\
\hline 11 & [1190] & 30 & \(\left[\begin{array}{llllll}30 & 29 & 28 & 7 & 0\end{array}\right]\) \\
\hline 12 & [12 118660\(]\) & 31 & \(\left[\begin{array}{lll}31 & 28 & 0\end{array}\right]\) \\
\hline 13 & \(\left[\begin{array}{lllll}13 & 12 & 10 & 9 & 0\end{array}\right]\) & 32 & [32 31301000\(]\) \\
\hline 14 & \(\left[\begin{array}{lllll}14 & 13 & 8 & 0\end{array}\right]\) & 33 & \(\left[\begin{array}{llll}33 & 20 & 0\end{array}\right]\) \\
\hline 15 &  & 34 & \(\left[\begin{array}{llllll}34 & 15 & 14 & 1 & 0\end{array}\right]\) \\
\hline 16 & \(\left[\begin{array}{lllll}16 & 15 & 13 & 4 & 0\end{array}\right]\) & 35 & \(\left[\begin{array}{lll}35 & 2 & 0\end{array}\right]\) \\
\hline 17 & [17 14 14 0] & 36 & [36 111 0] \\
\hline 18 & \(\left[\begin{array}{llll}18 & 11 & 0\end{array}\right]\) & 37 & [37 1210200 \\

\section*{Examples}

\section*{Setting Up PN Sequence Generator}

Set up a PN sequence generator. Define the polynomial in binary vector format or exponential vector format.

This figure defines a PN sequence generator with a generator polynomial \(p(z)=z^{6}+z+1\).

Define this PN sequence generator as follows:
```

h1 = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], 'Mask', [1 1 0 1 0 1]);
h2 = commsrc.pn('GenPoly', [1 0 0 0 0 1 1], 'Shift', 22);
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])
ans = 22

```

Alternatively, you can input GenPoly as the exponents of \(z\) for the nonzero terms of the polynomial in descending order of powers:

```

h =
GenPoly: [1 0 0 0 0 1 1]
InitialStates: [0 0 0 0 0 1]
CurrentStates: [0 0 0 0 0 1]
Mask: [1 1 0 1 0 1]
NumBitsOut: 1

```

\section*{General commsrc.pn Use}

Typically commsrc.pn is used to output pseudorandom data streams.
Construct a PN object.
h = commsrc.pn('Shift',0);
Output 10 PN bits.
```

set(h,'NumBitsOut',10);
generate(h)
ans = 10\times1

```
    1
```

0
0
0
0
0
1
0
0
0

```

Output 10 more PN bits.
```

generate(h)

```
ans \(=10 \times 1\)

0
1
1
0
0
0
1
0
1
0

Reset the object to the initial shift register state values.
```

reset(h);

```

Output 4 PN bits.
```

set(h,'NumBits0ut',4);
generate(h)
ans = 4×1
1
0
0
0

```

\section*{Copied commsrc.pn Object Behavior}

When a commsrc.pn object is copied, its states are also copied. Subsequent outputs from the copied object are likely to be different from the initial outputs from the original object.

Construct a PN object and output a sequence from it.
```

h = commsrc.pn('Shift', 0);
set(h, 'NumBits0ut', 5);
generate(h)

```
```

ans = 5×1
1
0
0
0
0

```

Make a copy of \(h\). Generate a sequence from the copied object. Because the copy was made after the state of \(h\) changed, the initial sequence generated by \(g\) is different from the initial sequence generated from \(h\).
\(g=\operatorname{copy}(h)\);
generate(g)
ans \(=5 \times 1\)
0
1
0
0
0

But if g is reset, it generates the same sequence that h generated.
```

reset(g);
generate(g)
ans = 5\times1
1
0
0
0
0

```

\section*{Introduced in R2009a}

\section*{commtest.ErrorRate}
(To be removed) Create error rate test console

\section*{Compatibility}
commtest.ErrorRate will be removed in a future release. Use comm. ErrorRate or bertool instead. For more information, see "Compatibility Considerations" on page 2-212.

\section*{Syntax}
h = commtest.ErrorRate
h = commtest.ErrorRate(sys)
h = commtest.ErrorRate(sys,'PropertyName',PropertyValue,...)
h = commtest.ErrorRate('PropertyName',PropertyValue,...)

\section*{Description}
\(\mathrm{h}=\) commtest.ErrorRate returns an error rate test console, h . The error rate test console runs simulations of a system under test to obtain error rates.
h = commtest.ErrorRate(sys) returns an error rate test console, error rate test console, h, with each specified property set to the \(h\), with an attached system under test, SYS.
h = commtest.ErrorRate(sys,'PropertyName',PropertyValue,....) returns an error rate test console, h, with an attached system under test, sys. Each specified property, 'PropertyName', is set to the specified value, PropertyValue.
h = commtest.ErrorRate('PropertyName',PropertyValue,...) returns an error rate test console, \(h\), with each specified property 'PropertyName', set to the specified value, PropertyValue.

\section*{Properties}

The error rate test console object has the properties in the following table. Setting any property resets the object. A property that is irrelevant is one that you can set, but its value does not affect measurements. Similarly, you cannot display irrelevant properties using the disp method. You can write to all properties, except for the ones explicitly noted otherwise.
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline Description & 'Error Rate Test Console'. Read-only. \\
\hline SystemUnderTestName & System under test name. Read-only. \\
\hline
\end{tabular}
\(\left.\begin{array}{|l|l|}\hline \text { Property } & \text { Description } \\ \hline \text { FrameLength } & \begin{array}{l}\text { Specify the length of the transmission frame at each iteration. This } \\ \text { property becomes relevant only when the system under test registers a } \\ \text { valid test input. }\end{array} \\ & \begin{array}{l}\text { If the system under test registers a NumTransmissions test input } \\ \text { and calls its getInput method, the error rate test console returns } \\ \text { the value stored in FrameLength. Using an internal data source, the } \\ \text { system under test uses this value to generate a transmission frame of } \\ \text { the specified length. }\end{array} \\ \begin{array}{ll}\text { - If the system under test registers a DiscreteRandomSource test } \\ \text { input and calls its getInput method, the test console generates and } \\ \text { returns a frame of symbols. The length of the frame of symbols } \\ \text { matches the FrameLength property. This property defaults to 500. }\end{array} \\ \hline \text { Specify how the object determines simulation points. }\end{array}\right\}\)
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline SystemResetMode & \begin{tabular}{l} 
Specify the stage of a simulation run at which the system resets. \\
- \\
Setting to Reset at new simulation point resets the system \\
under test at the beginning of a new simulation point. \\
Setting to Reset at every iteration resets the system under \\
test at every iteration.
\end{tabular} \\
\hline SimulationLimitOption & \begin{tabular}{l} 
Specify how to stop the simulation for each sweep parameter point. \\
- If set to Number of transmissions the simulation for a sweep \\
parameter point stops when the number of transmissions equals the \\
value for MaxNumTransmissions. \\
- Set TransmissionCount
\end{tabular} \\
registered test point containing the transmission count you are \\
comparing to MaxNumTransmissions.
\end{tabular}
\begin{tabular}{|c|c|}
\hline Property & Description \\
\hline MaxNumTransmissions & \begin{tabular}{l}
Specify the maximum number of transmissions the object counts before stopping the simulation for a sweep parameter point. This property becomes relevant only when SimulationLimitOption is Number of transmissions or Number of errors or transmissions. \\
- When setting SimulationLimitOption to Number of transmissions the simulation for each sweep parameter point stops when reaching the number of transmissions MaxNumTransmissions specifies. \\
- Setting SimulationLimitOption to Number of errors or transmissions stops the simulation for each sweep parameter point for one of two conditions. \\
- The simulation stops when completing the number of transmissions MaxNumTransmissions specifies. \\
- The simulation stops when obtaining the number of errors MinNumErrors specifies. \\
The TransmissionCountTestPoint property supplies the name of a registered test point containing the count transmission type. Calling the info method of the error rate test console displays the valid registered test points. If this property contains registered test points, the test console runs iterations equal to the value for MaxNumTransmissions for each sweep parameter point. If this property has no registered test parameters, the test console runs the number of iterations equal to the value for MaxNumTransmissions and stops. The value defaults to 1000 .
\end{tabular} \\
\hline MinNumErrors & \begin{tabular}{l}
Specify the minimum number of errors the object counts before stopping the simulation for a sweep parameter point. This property becomes relevant only when setting the SimulationLimitOption to Number of errors or Number of errors or transmissions. \\
- When setting SimulationLimitOption to Number of errors the simulation for each parameter point stops when reaching the number of errors you specify for the MinNumErrors property. \\
- When setting the SimulationLimitOption property to Number of errors or transmissions the simulation for each sweep parameter point stops for one of two conditions. \\
- The simulation stops when reaching the number of errors you specify for the MaxNumTransmissions property. \\
- The simulation stops when reaching the number of errors you specify for the MinNumErrors property. \\
Specify the type of errors the error count uses by setting the ErrorCountTestPoint property to the name of a registered test point containing the count. Call the info method of the error rate test console to see the valid registered test point names. This value defaults to 100 .
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline TransmissionCountTestPoint & \begin{tabular}{l} 
Specify and register a test point containing the transmission count that \\
controls the test console simulation stop mechanism. This property \\
becomes relevant only when setting SimulationLimit0ption to \\
Number of transmissions, Number of errors or \\
transmissions, or Number of errors and transmissions. In \\
this scenario, if you register a test point, and \\
TransmissionCount TestPoint equals Not set, the value of this \\
property automatically updates to that of the registered test point name. \\
Call the info method to see the valid test point names.
\end{tabular} \\
\hline ErrorCountTestPoint & \begin{tabular}{l} 
Specify and register the name of a test point containing the error count \\
that controls the simulation stop mechanism. This property is only \\
relevant when setting the SimulationLimitOption property to \\
Number of errors, Number of errors or transmissions, or
\end{tabular} \\
Number of errors and transmissions. In this scenario, if you \\
register a test point, and ErrorCountTestPoint equals Not set, the \\
value of this property automatically updates to that of the registered test \\
point name. Call the info method to see the valid test point names.
\end{tabular}

\section*{Methods}

The error rate test console object has the following methods:
run
Runs a simulation.
Runs the number of error rate simulations you specify for a system under test with a specified set of parameter values. If a Parallel Computing Toolbox \({ }^{T M}\) license is available and a parpool is open, then the object distributes the iterations among the number of workers available.

\section*{getResults}

Returns the simulation results.
\(r=\) getResults(h) returns the simulation results, \(r\), for the test console, \(h . r\) is an object of the type you specify using testconsole.Results. It contains the simulation data for all the registered test points and methods to parse the data and plot it.

\section*{info}

Returns a report of the current test console settings.
info(h) displays the current test console settings, such as registered test parameters and registered test points.

\section*{reset}

Resets the error rate test console.
reset(h) resets test parameters and test probes and then clears all simulation results of test console, \(h\).

\section*{attachSystem}

Attaches a system to test console.
attachSystem(ho,sys) attaches a valid user-defined system, sys, to the test console, h .

\section*{detachSystem}

Detaches the system from the test console.
detachSystem(h) detaches a system from the test console, h. This method also clears the registered test inputs, test parameters, test probes, and test points.

\section*{setTestParameterSweepValues}

Sets test parameter sweep values.
setTestParameterSweepValues(h,name,sweep) specifies a set of sweep values, 'sweep', for the registered test parameter, 'name', in the test console, h. You only specify sweep values for registered test parameters. sweep must have values within the specified range of the test parameter. It can be a row vector of numeric values, or a cell array of char values. Display the valid ranges using the getTestParameterValidRanges method.
setTestParameterSweepValues(h,name1,sweep1,name2,sweep2...) simultaneously specifies sweep values for multiple registered test parameters.

\section*{getTestParameterSweepValues}

Returns test parameter sweep values.
getTestParameterSweepValues(h,name) gets the sweep values currently specified for the registered test parameter, name, in the test console, h .

\section*{getTestParameterValidRanges}

Returns the test parameter valid ranges.
getTestParameterValidRanges(h,name) gets the valid ranges for a registered test parameter, name, in the test console, h .

\section*{registerTestPoint}

Registers a test point.
registerTestPoint(h, name, actprobe,expprobe) registers a new test point object, name, to the error rate test console, h. The test point must contain a pair of registered test probes, actprobe, and expprobe. actprobe contains actual data, and expprobe contains expected data. The object compares the data from these probes and obtains error rate values. The error rate calculation uses a default error rate calculator function that simply performs one-to-one comparisons of the data vectors available in the probes.
registerTestPoint(h, name, actprobe,expprobe, handle) adds the handle, handle, to a user-defined error calculation function that compares the data in the probes and then obtains error rate results.

The user-defined error calculation function must comply with the following syntax: [ecnt tent] = functionName(act, exp, udata) where
- ecnt output corresponds to the error count
- tcnt output is the number of transmissions used to obtain the error count
- act and exp correspond to actual and expected data

The error rate test console sets the inputs to the data available in the pair of test point probes, actprobe, and expprobe.
udata is a data input that the system under test passes to the test console at run time, using the setUserData method. udata contains the data necessary to compute errors, such as delays and data buffers.

The error rate test console passes the data that the system under test logs to the error calculation functions for all the registered test points. Calling the info method returns the names of the registered test points and the error rate calculator functions associated with them. It also returns the names of the registered test probes.

\section*{unregisterTestPoint}

Unregister a test point.
unregisterTestPoint(h,name) removes the test point, name, from the test console, h .

\section*{Examples}

\section*{Error Rate Simulation Sweeps}

The commtest.ErrorRate and testconsole. Results object packages will be removed in a future release. They can be used to perform parameter sweeps to analyze communication system performance. This example demonstrates a workflow that uses them and along with recommended alternate workflows.

\section*{Multiple Parameter Sweep and Parallel Run using commtest.ErrorRate}

Obtain bit error rate and symbol error rate of an M-PSK system for different modulation orders and EbNo values. System under test is commtest.MPSKSystem.
```

% Create an M-ary PSK system
systemUnderTest = commtest.MPSKSystem;
% Instantiate an Error Rate Test Console and attach the system
errorRateTester = commtest.ErrorRate(systemUnderTest);
Warning: commtest.ErrorRate will be removed in the future. Use comm.ErrorRate or bertool instead
errorRateTester.SimulationLimitOption = 'Number of errors or transmissions';
errorRateTester.MaxNumTransmissions = 1e5;
% Set sweep values for simulation test parameters
setTestParameterSweepValues(errorRateTester,'M',2.^[1 2 3 4],'EbNo',(-5:10))
% Register a test point
registerTestPoint(errorRateTester,'MPSK_BER','TxInputBits','Rx0utputBits')
% Get information about the simulation settings
info(errorRateTester)

```

## Multiple Variable Sweeps using BERTool

BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB® functions and Simulink $®$ models or with theoretical closedform expressions for selected types of communication systems. The bertool function opens the BERTool. Here BERTool is configured to call the simulation defined in the function mpsksim included below.
function [ber, numBits] = mpsksim(EbNo,minNumErrs,maxNumBits)
\% Import the Java class for BERTool, so that you will be able to stop the simulation using the import com.mathworks.toolbox.comm.BERTool;

```
frameLength = 500;
M = 16; % Can be 2, 4, 8, 16
bitsPerSymbol = log2(M);
maxNumSymbols = maxNumBits/bitsPerSymbol;
SNR = EbNo + 10*log10(bitsPerSymbol);
% Initialize variables related to exit criteria.
numBitErrors = 0;
numSymbols = 0;
while (numBitErrors < minNumErrs) || (numSymbols < maxNumSymbols)
    % Check if the user clicked the Stop button of BERTool.
    if (BERTool.getSimulationStop)
        break;
    end
    % Generate frameLength source outputs
    txMsg = randi([0 M-1],frameLength,1);
    numSymbols = numSymbols+frameLength;
    % Modulate the data
    txOutput = pskmod(txMsg,M,0,'gray');
    % Pass data through an AWGN channel with current SNR value
    chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
    % Demodulate the data
    rxOutput = pskdemod(chnlOutput,M,0,'gray');
    % Convert symbol streams to bit streams
    bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
    bTx = bTx(:);
    bRx = de2bi(rxOutput,bitsPerSymbol,'left-msb')';
    bRx = bRx(:);
    % Calculate number of bit errors
    numBitErrors = numBitErrors+sum(bTx~=bRx);
end
% Assign values to the output variables.
numBits = numSymbols*bitsPerSymbol;
ber = numBitErrors/numBits;
```

Configure BERTool as follows.

Set $\mathrm{M}=2$ in the mpsksim function and click Run. Set the BER Data Set name to ' $\mathrm{M}=2$ '.

| -) Bit Error Rate Analysis Tool |  |  |  |  |  | - |  | $\times$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  |  |  |  |  |  |  | Run | Stop |

Display the BER curve for $\mathrm{M}=2$.

Update the value for $M$ in the mpsksim function, repeating this process for $M=4,8,16$. You will see results similar to those below in the Bit Error Rate Analysis Tool window and the BER figure.

## Parallel SNR Sweep using BERTool

Using parfor, run each simulation point in parallel by configuring your simulation function similar to the mpsksim_parfor function included below. Since parfor cannot work with the Java class for BERTool, you will not be able to stop the simulation using the Stop button.

```
function [ber,numBits] = mpsksim_parfor(EbNo,minNumErrs,maxNumBits)
% Find out if there is a parallel pool and how many workers are available
if license('test','Distrib Computing_Toolbox')
    p = gcp;
    if isempty(p)
        numWorkers = 1;
```

```
    else
        numWorkers = p.NumWorkers;
    end
else
    numWorkers = 1;
end
M = 2;
bitsPerSymbol = log2(M);
maxNumSymbols = maxNumBits/bitsPerSymbol;
minNumErrorsPerWorker = minNumErrs/numWorkers;
maxNumSymbolsPerWorker = maxNumSymbols/numWorkers;
frameLength = 500;
SNR = EbNo + 10*log10(bitsPerSymbol);
% Initialize variables related to exit criteria.
numBitErrors = zeros(numWorkers,1);
numSymbols = zeros(numWorkers,1);
parfor worker = 1:numWorkers
    while (numBitErrors(worker) < minNumErrorsPerWorker) ...
            || (numSymbols(worker) < maxNumSymbolsPerWorker)
        % Generate frameLength source outputs
        txMsg = randi([0 M-1],frameLength,1);
        numSymbols(worker) = numSymbols(worker)+frameLength;
        % Modulate the data
        txOutput = pskmod(txMsg, M, 0, 'gray');
        % Pass data through an AWGN channel with current SNR value
        chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
        % Demodulate the data
        rxOutput = pskdemod(chnlOutput,M,0,'gray');
        % Convert symbol streams to bit streams
        bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
        bTx = bTx(:);
        bRx = de2bi(rx0utput,bitsPerSymbol,'left-msb')';
        bRx = bRx(:);
        % Calculate number of bit errors
        numBitErrors(worker) = numBitErrors(worker)+sum(bTx~=bRx);
    end
end
% Assign values to the output variables.
ber = sum(numBitErrors)/sum(numSymbols);
numBits = sum(numSymbols)*bitsPerSymbol;
```

## Compatibility Considerations

commtest.ErrorRate will be removed
Warns starting in R2019b
commtest.ErrorRate will be removed in a future release. Use comm. ErrorRate or bertool instead. The "Error Rate Simulation Sweeps" on page 2-201 example demonstrates alternate workflows using comm. ErrorRate and bertool.

## compand

Source code mu-law or A-law compressor or expander

## Syntax

```
out = compand(in,Mu,v)
out = compand(in,Mu,v,'mu/compressor')
out = compand(in,Mu,v,'mu/expander')
out = compand(in,A,v,'A/compressor')
out = compand(in,A,v,'A/expander')
```

## Description

out = compand(in, Mu, v) implements a $\mu$-law compressor for the input vector in. Mu specifies $\mu$, and $v$ is the input signal's maximum magnitude. out has the same dimensions and maximum magnitude as in.
out $=$ compand(in, Mu,v,'mu/compressor') is the same as the syntax above.
out = compand(in, Mu,v,'mu/expander') implements a $\mu$-law expander for the input vector in. Mu specifies $\mu$ and $v$ is the input signal's maximum magnitude. out has the same dimensions and maximum magnitude as in.
out = compand(in, $\mathrm{A}, \mathrm{v}$, 'A/compressor') implements an A-law compressor for the input vector in. The scalar $A$ is the A-law parameter, and $v$ is the input signal's maximum magnitude. out is a vector of the same length and maximum magnitude as in.
out = compand(in, $\mathrm{A}, \mathrm{v}$, 'A/expander') implements an A-law expander for the input vector in. The scalar $A$ is the $A$-law parameter, and $v$ is the input signal's maximum magnitude. out is a vector of the same length and maximum magnitude as in.

Note The prevailing parameters used in practice are $\mu=255$ and $\mathrm{A}=87.6$.

## Examples

## $\mu$-Law Compression and Expansion

Generate a data sequence.
data $=2: 2: 12 ;$
Compress the input sequence using an $\mu$-law compander. The typical value for $\mu$ is 255 . The data ranges between 8.1 and 12 instead of between 2 and 12 .

```
compressed = compand(data,255,max(data),'mu/compressor')
compressed = 1×6
```

8.1644
9.6394
10.5084
11.1268
11.6071
12.0000

Expand the compressed signal. The expanded sequence is nearly identical to the original.
expanded $=$ compand(compressed, $255, \max (d a t a), ' m u / e x p a n d e r ')$
expanded $=1 \times 6$
2.0000
4.0000
6.0000
$8.0000 \quad 10.0000$
12.0000

## A-Law Compression and Expansion

Generate a data sequence.

```
data = 1:5;
```

Compress the input sequence using an A-law compander. The typical value for A is 87.5. The data ranges between 3.5 and 5 instead of between 1 and 5 .

```
compressed = compand(data,87.6,max(data),'a/compressor')
compressed = 1\times5
```

3.5296
4.1629
4.5333
4.7961
5.0000

Expand the compressed signal. The expanded sequence is nearly identical to the original.

```
expanded = compand(compressed,87.6,max(data),'a/expander')
expanded = 1\times5
\(1.0000 \quad 2.0000 \quad 3.0000 \quad 4.0000 \quad 5.0000\)
```

## Algorithms

For a given signal $x$, the output of the $\mu$-law compressor is

$$
y=\frac{V \log (1+\mu|x| / V)}{\log (1+\mu)} \operatorname{sgn}(x)
$$

where $V$ is the maximum value of the signal $x, \mu$ is the $\mu$-law parameter of the compander, log is the natural logarithm, and sgn is the signum function (sign in MATLAB).

The output of the A-law compressor is

$$
y=\left\{\begin{array}{cc}
\frac{A|x|}{1+\log A} \operatorname{sgn}(x) & \text { for } 0 \leq|x| \leq \frac{V}{A} \\
\frac{V(1+\log (A|x| / V))}{1+\log A} \operatorname{sgn}(x) & \text { for } \frac{V}{A}<|x| \leq V
\end{array}\right.
$$

where $A$ is the A-law parameter of the compander and the other elements are as in the $\mu$-law case.

## convdeintrlv

Restore ordering of symbols using shift registers

## Syntax

deintrlved $=$ convdeintrlv(data, nrows,slope)
[deintrlved,state] = convdeintrlv(data,nrows,slope)
[deintrlved,state] = convdeintrlv(data, nrows,slope,init_state)

## Description

deintrlved = convdeintrlv(data, nrows,slope) restores the ordering of elements in data by using a set of nrows internal shift registers. The delay value of the kth shift register is (nrows k) slope, where $\mathrm{k}=1,2,3, \ldots$, nrows. Before the function begins to process data, it initializes all shift registers with zeros. If data is a matrix with multiple rows and columns, the function processes the columns independently.
[deintrlved,state] = convdeintrlv(data,nrows,slope) returns a structure that holds the final state of the shift registers. state.value stores any unshifted symbols. state.index is the index of the next register to be shifted.
[deintrlved,state] = convdeintrlv(data, nrows,slope,init_state) initializes the shift registers with the symbols contained in init_state. value and directs the first input symbol to the shift register referenced by init_state.index. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding interleaver.

## Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the convintrlv function, use the same nrows and slope inputs in both functions. In that case, the two functions are inverses in the sense that applying convintrlv followed by convdeintrlv leaves data unchanged, after you take their combined delay of nrows*(nrows-1)*slope into account. To learn more about delays of convolutional interleavers, see "Delays of Convolutional Interleavers".

## Examples

The example in "Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB" uses convdeintrlv and illustrates how you can handle the delay of the interleaver/deinterleaver pair when recovering data.

The example on the reference page for muxdeintrlv illustrates how to use the state output and init_state input with that function; the process is analogous for this function.

## convenc

Convolutionally encode binary message

## Syntax

```
codedout = convenc(msg,trellis)
codedout = convenc(msg,trellis,puncpat)
codedout = convenc(
```

$\qquad$

``` ,istate)
[codedout,fstate] = convenc(___)
```

## Description

codedout $=$ convenc(msg,trellis) encodes the input binary message by using a convolutional encoder represented by a trellis structure. For details about trellis structures in MATLAB, see "Trellis Description of a Convolutional Code". The input message contains one or more symbols, each of which consists of log2(trellis.numInputSymbols) bits. The coded output, codedout, contains one or more symbols, each of which consists of log2(trellis.num0utputSymbols) bits.
codedout $=$ convenc(msg,trellis, puncpat)specifies a puncture pattern, puncpat, to enable higher rate encoding than unpunctured coding.

For some commonly used puncture patterns for specific rates and polynomials, see the last three references.
codedout $=$ convenc ( _ _ ,istate) enables the encoder registers to start at a state specified by istate. Specify istate as the last input parameter preceded by any of the input argument combinations in the previous syntaxes.
[codedout,fstate] = convenc (__ ) also returns the final state of the encoder. When calling convenc iteratively, fstate is typically used to set istate for subsequent calls to the convenc function.

## Examples

## Create Convolutional Codes

Create convolutional codes by using a trellis structure. You can define the trellis by using the poly2trellis function or by manually specifying the trellis structure. The example shows both methods.

## Define trellis by using poly2trellis function

Define the trellis structure to be used to configure the encoder by using the poly2trellis function.

```
trellis_a = poly2trellis([5 4],[23 35 0; 0 5 13])
trellis_a = struct with fields:
    numInputSymbols: 4
    numOutputSymbols: 8
```

```
    numStates: 128
nextStates: [128x4 double]
    outputs: [128\times4 double]
```

Use the trellis structure to configure the convenc function. Encode five two-bit symbols for a K/N rate $2 / 3$ convolutional code by using the convenc function.

```
K = log2(trellis_a.numInputSymbols) % Number of input bit streams
K = 2
N = log2(trellis_a.numOutputSymbols) % Number of output bit streams
N = 3
numReg = log2(trellis_a.numStates) % Number of coder registers
numReg = 7
numSymPerFrame = 5; % Number of symbols per frame
data = randi([0 1],K*numSymPerFrame,1);
[code_a,fstate_a] = convenc(data,trellis_a);
```

Verify that the encoded output is 15 bits, which is $3 / 2(\mathrm{~N} / \mathrm{K})$ times the length of the input sequence, data.

```
code_a'
ans = 1 1 15
```

| 1 | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

length(data)
ans $=10$
length(code_a)
ans $=15$

## Define trellis manually

Manually define a trellis structure for a $\mathrm{K} / \mathrm{N}$ rate $1 / 2$ convolutional code.

```
trellis_b = struct('numInputSymbols',2,'num0utputSymbols',4, ...
'numStates',4,'nextStates',[0 2;0 2;1 3;1 3], ...
'outputs',[0 3;1 2;3 0;2 1])
trellis_b = struct with fields:
    numInputSymbols: 2
    numOutputSymbols: 4
            numStates: 4
            nextStates: [4\times2 double]
            outputs: [4\times2 double]
```

Use the trellis structure to configure the convenc function when encoding 10 one-bit symbols.

```
K = log2(trellis_b.numInputSymbols) % Number of input bit streams
```

```
K = 1
N = log2(trellis_b.numOutputSymbols) % Number of output bit streams
N = 2
numReg = log2(trellis_b.numStates) % Number of coder registers
numReg = 2
numSymPerFrame = 10; % Number of symbols per frame
data = randi([0 1],K*numSymPerFrame,1);
code_b = convenc(data,trellis_b);
```

Verify that the encoded output is 20 bits, which is $2 / 1(\mathrm{~N} / \mathrm{K})$ times the length of the input sequence, data.
code_b'
ans $=1 \times 20$
$\begin{array}{llllllllllllllll}0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 1 & 1\end{array}$
length(data)
ans $=10$
length(code_b)
ans $=20$

## Adjust Convolutional Encoding Code Rate by Using Puncturing

Use puncturing to adjust the $\mathrm{K} / \mathrm{N}$ code rate of the convolutional encoder from $1 / 2$ to $3 / 4$.
Initialize parameters for the encoding operation.

```
trellis = poly2trellis(7,[171 133])
trellis = struct with fields:
    numInputSymbols: 2
    numOutputSymbols: 4
        numStates: 64
        nextStates: [64x2 double]
            outputs: [64\times2 double]
puncpat = [1;1;0];
```

Calculate the unpunctured and punctured code rates.
K = log2(trellis.numInputSymbols); \% Number of input streams
$\mathrm{N}=\log 2(t r e l l i s . n u m 0 u t p u t S y m b o l s) ;$ \% Number of output streams
unpunc_coderate $=\mathrm{K} / \mathrm{N}$; \% Unpunctured code rate punc_coderate $=(K / N) *$ length (puncpat)/sum(puncpat); \% Punctured code rate fprintf('K is \%d and $N$ is \%d. The unpunctured code rate is $\% 3.2 f$ and the punctured code rate is

K is 1 and N is 2. The unpunctured code rate is 0.50 and the punctured code rate is 0.75 .

Convolutionally encode an all 1 s three-bit message without puncturing applied to the coded output. Then, convolutionally encode the same message with puncturing.

```
msg = ones(length(puncpat),1);
unpuncturedcode = convenc(msg,trellis);
puncturedcode = convenc(msg,trellis,puncpat);
```

```
msg'
```

msg'
ans = 1\times3
1 1 1 1
unpuncturedcode'
ans = 1\times6
1 1 1 0 0 1 1 1 1 0
puncpat'
ans = 1\times3
1 1 0
puncturedcode'
ans = 1\times4
1 1 1 1 1

```

Show the message, the unpunctured code, the punctured code, and the puncture pattern.

Without puncturing, the configured convolutional encoding inputs three message bits and outputs six coded bits. Confirm the resulting code rate matches the expected code rate of \(1 / 2\).
length(msg)/length(unpuncturedcode)
ans \(=0.5000\)
With puncturing, bits in positions 1 and 2 of the input message are transmitted, while the bit in position 3 is removed. For every three bits of input, the punctured code generates four bits of output. Confirm the resulting code rate matches the expected code rate of \(3 / 4\).
```

length(msg)/length(puncturedcode)
ans = 0.7500

```

\section*{Use Trellis Structure for Rate 1/2 Feedforward Convolutional Encoder}

Use a trellis structure to configure the rate \(1 / 2\) feedforward convolutional code in this diagram.

Create a trellis structure, setting the constraint length to 3 and specifying the code generator as a cell array of polynomial character vectors.
```

trellis = poly2trellis(3,{'1 + x^2','1 + x + x^2'})
trellis = struct with fields:
numInputSymbols: 2
numOutputSymbols: 4
numStates: 4
nextStates: [4\times2 double]
outputs: [4\times2 double]

```

Generate random binary data. Convolutionally encode the data, by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.
```

data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34;
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');

```

Verify the decoded data has zero bit errors.
```

biterr(data,decodedData)
ans = 0

```

\section*{Use Trellis Structure for Rate 1/2 Feedback Convolutional Encoder}

Create a trellis structure to represent the rate \(1 / 2\) systematic convolutional encoder with feedback shown in this diagram.

This encoder has 5 for its constraint length, [37 33] as its generator polynomial matrix, and 37 for its feedback connection polynomial.

The first generator polynomial is octal 37. The second generator polynomial is octal 33. The feedback polynomial is octal 37. The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits.

The binary vector [1: 1011111 ] represents octal 37 and corresponds to the upper row of binary digits in the diagram. The binary vector [1 1011 1] represents octal 33 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram. The initial 1 corresponds to the input bit.

Convert the polynomial to a trellis structure by using the poly2trellis function. When used with a feedback polynomial, poly2trellis makes a feedback connection to the input of the trellis.
```

trellis = poly2trellis(5,[37 33],37)
trellis = struct with fields:
numInputSymbols: 2
numOutputSymbols: 4
numStates: 16
nextStates: [16x2 double]
outputs: [16x2 double]

```

Generate random binary data. Convolutionally encode the data by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.
```

data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34; % Traceback depth for Viterbi decoder
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');

```

Verify the decoded data has zero bit errors.
```

biterr(data,decodedData)

```
ans \(=0\)

\section*{Compare Full Message to Piecewise Message Convolutional Encoding}

Compare the convolutional encoding of a full message to the convolutional encoding of a message in two segments.

This diagram shows a rate \(2 / 3\) encoder with two input streams, three output streams, and seven shift registers.

Define the trellis structure in the diagram by using the poly2trellis function. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4 . The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.
```

trellis = poly2trellis([5 4],[23 35 0; 0 5 13]);

```

Inspect the coder configuration.
```

K = log2(trellis.numInputSymbols) % Number of input bit streams
K = 2
N = log2(trellis.numOutputSymbols) % Number of output bit streams
N = 3
coderate = K/N
coderate = 0.6667
numReg = log2(trellis.numStates) % Number of coder registers
numReg = 7

```

Define a message with five two-bit input symbols.
```

numSymPerFrame = 5;% Number of symbols per frame
msg = randi([0 1],K*numSymPerFrame,1);

```

Encode the full message by using the trellis to configure the convenc function.
[code_a,fstate_a] = convenc(msg,trellis);

Apply piecewise message encoding by using the same trellis structure. Use the final and initial state arguments when using the convenc function. For piecewise message encoding, message segments must be a multiple of the number of bits in an input symbol.

Encode part of the message, recording the final state for later use.
[code_al,fstate_al] = convenc(msg(1:6),trellis);
Encode the rest of the message, using the final state, fstate_al, as the initial state input argument.
[code_a2,fstate_a2] = convenc(msg(7:end),trellis,fstate_a1);
Verify that the full coded message, code_a, matches the concatenated piecewise coded message, [code_a1; code_a2].
isequal(code_a,[code_a1; code_a2])
ans = logical
1

Verify that the final state, fstate_a, of the encoder after the full message encoding matches the final state, fstate_a2, of the encoder after piecewise message encoding.
isequal(fstate_a,fstate_a2)
ans = logical
1

\section*{Input Arguments}

\section*{msg - Binary message}
vector of binary values
Binary message, specified as a vector of binary values. msg must contain one or more symbols. Each symbol must consist of log2(trellis.numInputSymbols) bits.

Example: [ \(\left.\begin{array}{llllllll}1 & 1 & 0 & 1 & 0 & 0 & 1 & 1\end{array}\right]\) specifies the message as a binary row vector with eight elements. Data Types: double | logical

\section*{trellis - Trellis description}
structure
Trellis description, specified as a structure with these fields for a rate \(K / N\) code. \(K\) represents the number of input bit streams, and \(N\) represents the number of output bit streams. You can either use the poly2trellis function to create the trellis structure or create it manually. For more about this structure, see "Trellis Description of a Convolutional Code" and the istrellis function.

\section*{Trellis Structure Fields for Rate K/N Code}
numInputSymbols - Number of input symbols
integer
Number of input symbols, specified as an integer with a value of \(2^{K}\). This value represents the number of symbols input to the encoder.

Data Types: double
numOutputSymbols - Number of output symbols
integer
Number of output symbols, specified as an integer with a value of \(2^{N}\). This value represents the number of symbols output from the encoder.
Data Types: double
numStates - Number of states
integer
Number of states in the encoder, specified as an integer. numStates must be a power of 2 .
Data Types: double
nextStates - Next states
matrix of integer values
Next states for all combinations of current states and current inputs, specified as a numStates-by- \(2^{N}\) matrix of integer values.
Data Types: double

\section*{outputs - Outputs}
matrix of integer values
Outputs for all combinations of current states and current inputs, specified as a numStates-by-2 \({ }^{N}\) matrix of integer values. The elements of this matrix must be octal numbers.
Data Types: double
puncpat - Puncture pattern
vector of binary values
Puncture pattern, specified as a vector of binary values. Indicate punctured bits with 0 s and unpunctured bits with 1s. The length of the puncpat vector must be an integer divisor of the input message vector length, length(msg).

Data Types: double

\section*{istate - Initial state}
integer scalar
Initial state used for the encoder registers, specified as an integer scalar in the range [0, (trellis.numStates-1)].
Data Types: double

\section*{Output Arguments}
codedout - Convolutionally encoded message
vector of binary values

Convolutionally encoded message, returned as a vector of binary values. This output vector has the same data type and orientation as input msg. Each symbol in codedout consists of \(\log 2(t r e l l i s . n u m O u t p u t S y m b o l s)\) bits.

\section*{Data Types: double | logical}
fstate - Final state
integer scalar
Final state of the encoder registers, returned as an integer scalar. When calling convenc iteratively, such as in a loop, fstate is typically used to set istate for subsequent calls to the convenc function.

Data Types: double

\section*{More About}

\section*{Convolutional Coding}

Convolutional coding is an error-control coding that has memory. Specifically, the computations and coded output depend on the current set of input symbols and on a number of previous input symbols that varies depending on the trellis configuration. A convolutional encoder accepts a fixed number of message symbols and produces a fixed number of code symbols.

Using a trellis structure that defines a set of generator polynomials, you can model nonsystematic, systematic feedforward, or systematic feedback convolutional codes. Examples on this page demonstrate various convolutional code architectures. For more information, see "Convolutional Codes".

To decode the convolutionally coded output, you can use:
- The vitdec function or comm.ViterbiDecoder System object \({ }^{\text {TM }}\) - Uses the Viterbi algorithm with hard-decision and soft-decision decoding
- The comm. APPDecoder System object - Uses an a posteriori probability decoder for the soft output decoding of convolutional codes

\section*{convintrlv}

Permute symbols using shift registers

\section*{Syntax}
intrlved = convintrlv(data, nrows,slope)
[intrlved,state] = convintrlv(data, nrows,slope)
[intrlved,state] = convintrlv(data, nrows,slope,init_state)

\section*{Description}
intrlved = convintrlv(data, nrows, slope) permutes the elements in data by using a set of nrows internal shift registers. The delay value of the kth shift register is ( \(\mathrm{k}-1\) ) *slope, where \(\mathrm{k}=1\), \(2,3, \ldots\) nrows. Before the function begins to process data, it initializes all shift registers with zeros. If data is a matrix with multiple rows and columns, the function processes the columns independently.
[intrlved,state] = convintrlv(data, nrows, slope) returns a structure that holds the final state of the shift registers. state.value stores any unshifted symbols. state.index is the index of the next register to be shifted.
[intrlved,state] = convintrlv(data, nrows,slope,init_state) initializes the shift registers with the symbols contained in init_state.value and directs the first input symbol to the shift register referenced by init_state.index. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

\section*{Examples}

The example below shows that convintrlv is a special case of the more general function muxintrlv. Both functions yield the same numerical results.
```

x = randi([0 1],100,1); % Original data
nrows = 5; % Use 5 shift registers
slope = 3; % Delays are 0, 3, 6, 9, and 12.
y = convintrlv(x,nrows,slope); % Interleaving using convintrlv.
delay = [0:3:12]; % Another way to express set of delays
y1 = muxintrlv(x,delay); % Interleave using muxintrlv.
isequal(y,y1)

```

The output below shows that \(y\), obtained using convintrlv, and \(y 1\), obtained using muxintrlv, are the same.
```

ans =

```

1
Another example using this function is in "Effect of Delays on Recovery of Convolutionally Interleaved Data Using MATLAB".

The example on the muxdeintrlv reference page illustrates how to use the state output and init_state input with that function; the process is analogous for this function.

\section*{convmtx}

Convolution matrix of Galois field vector

\section*{Syntax}
\(\mathrm{A}=\operatorname{convmtx}(\mathrm{c}, \mathrm{n})\)

\section*{Description}

A convolution matrix is a matrix, formed from a vector, whose inner product with another vector is the convolution of the two vectors.
\(\mathrm{A}=\) convmtx \((\mathrm{c}, \mathrm{n})\) returns a convolution matrix for the Galois vector c . The output A is a Galois array that represents convolution with \(c\) in the sense that conv( \(c, x\) ) equals
- \(A^{*} x\), if \(c\) is a column vector and \(x\) is any Galois column vector of length \(n\). In this case, \(A\) has \(n\) columns and \(\mathrm{m}+\mathrm{n}-1\) rows.
- \(\quad \mathrm{x}^{*} \mathrm{~A}\), if c is a row vector and x is any Galois row vector of length n . In this case, A has n rows and m+n-1 columns.

\section*{Examples}

The code below illustrates the equivalence between using the conv function and multiplying by the output of convmtx.
```

m = 4;
c = gf([1; 9; 3],m); % Column vector
n = 6;
x = gf(randi([0 2^m-1],n,1),m);
ck1 = isequal(conv(c,x), convmtx(c,n)*x) % True
ck2 = isequal(conv(c', ('), ('**onvmtx(c',n)) % True

```

The output is
```

ck1 =

```

1
ck2 =
1

\section*{cosets}

Produce cyclotomic cosets for Galois field

\section*{Syntax}
```

cst = cosets(m)

```

\section*{Description}
cst \(=\) cosets \((m)\) produces cyclotomic cosets mod \(2^{\wedge} m-1\). Each element of the cell array cst is a Galois array that represents one cyclotomic coset.

A cyclotomic coset is a set of elements that share the same minimal polynomial. Together, the cyclotomic cosets mod \(2^{\wedge} \mathrm{m}-1\) form a partition of the group of nonzero elements of \(\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)\). For more details on cyclotomic cosets, see the works listed in "References" on page 2-235.

\section*{Examples}

The commands below find and display the cyclotomic cosets for GF(8). As an example of interpreting the results, \(\mathrm{c}\{2\}\) indicates that \(\mathrm{A}, \mathrm{A}^{2}\), and \(\mathrm{A}^{2}+\mathrm{A}\) share the same minimal polynomial, where A is a primitive element for \(\mathrm{GF}(8)\).
\(\mathrm{c}=\operatorname{cosets}(3)\);
c\{1\}'
c \(\{2\}^{\prime}\)
c\{3\}'
The output is below.
```

ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
1
ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
2 4 6
ans = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
3

```

\section*{crc.detector}

Construct CRC detector object

\section*{Syntax}
```

h= crc.detector(polynomial)
h= crc.detector(generatorObj)
h= crc.detector('Polynomial', polynomial, 'param1', val1, etc.)
h= crc.detector

```

\section*{Description}
\(\mathrm{h}=\mathrm{crc}\).detector(polynomial) constructs a CRC detector object H defined by the generator polynomial POLYNOMIAL
\(\mathrm{h}=\mathrm{crc}\).detector(generatorObj) constructs a CRC detector object H defined by the parameters found in the CRC generator object GENERATOROBJ
h= crc.detector('property1', val1, ...) constructs a CRC detector object H with properties as specified by PROPERTY/VALUE pairs.
\(\mathrm{h}=\mathrm{crc}\).detector constructs a CRC detector object H with default properties. It constructs a CRCCCITT detector, and is equivalent to:
\(\mathrm{h}=\)
crc. detector('Polynomial','0x1021','InitialState','0xFFFF','ReflectInput',fal se,'ReflectRemainder',false,'FinalXOR','0x0000')

\section*{Properties}

The following table describes the properties of a CRC detector object. All properties are writable, except Type.
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline Type & Specifies the object as a 'CRC Detector'. \\
\hline Polynomial & \begin{tabular}{l} 
The generator polynomial that defines \\
connections for a linear feedback shift register. \\
This property can be specified as a binary vector \\
representing descending powers of the \\
polynomial. In this case, the leading '1' of the \\
polynomial must be included. It can also be \\
specified as a string, prefaced by '0x', that is a \\
hexadecimal representation of the descending \\
powers of the polynomial. In this case, the \\
leading '1' of the polynomial is omitted.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Property & Description \\
\hline InitialState & \begin{tabular}{l} 
The initial contents of the shift register. This \\
property can be specified as a binary scalar, a \\
binary vector, or as a string, prefaced by '0x', that \\
is a hexadecimal representation of the binary \\
vector. As a binary vector, its length must be one \\
less than the length of the binary vector \\
representation of the Polynomial.
\end{tabular} \\
\hline ReflectInput & \begin{tabular}{l} 
A Boolean quantity that specifies whether the \\
input data should be flipped on a bytewise basis \\
prior to entering the shift register.
\end{tabular} \\
\hline ReflectRemainder & \begin{tabular}{l} 
A Boolean quantity that specifies whether the \\
binary output CRC checksum should be flipped \\
around its center after the input data is \\
completely through the shift register.
\end{tabular} \\
\hline FinalXOR & \begin{tabular}{l} 
The value with which the CRC checksum is to be \\
XORed just prior to detecting the input data. This \\
property can be specified as a binary scalar, a
\end{tabular} \\
binary vector or as a string, prefaced by '0x', that \\
is a hexadecimal representation of the binary \\
vector. As a binary vector, its length must be one \\
less than the length of the binary vector \\
representation of the Polynomial.
\end{tabular}

A detect method is used with the object to detect errors in digital transmission.

\section*{CRC Generation Algorithm}

For information pertaining to the CRC generation algorithm, see "Cyclic Redundancy Check Codes".

\section*{Detector Method}
[OUTDATA ERROR] = DETECT( H , INDATA) detects transmission errors in the encoded input message INDATA by regenerating a CRC checksum using the CRC detector object H. The detector then compares the regenerated checksum with the checksum appended to INDATA. The binaryvalued INDATA can be either a column vector or a matrix. If it is a matrix, each column is considered to be a separate channel. OUTDATA is identical to the input message INDATA, except that it has the CRC checksum stripped off. ERROR is a 1 xC logical vector indicating if the encoded message INDATA has errors, where C is the number of channels in INDATA. An ERROR value of 0 indicates no errors, and a value of 1 indicates errors.

\section*{Examples}

The following three examples demonstrate the use of constructing an object. The fourth example demonstrates use of the detect method.
```

% Construct a CRC detector with a polynomial
% defined by x^4+\mp@subsup{x}{}{\wedge}3+\mp@subsup{x}{}{\wedge}2+x+1:
h = crc.detector([1 1 1 1 1])

```

This example generates the following output:
```

h =
Type: CRC Detector
Polynomial: 0xF
InitialState: 0x0 ReflectInput: false
ReflectRemainder: false
FinalXOR: 0x0
% Construct a CRC detector with a polynomial
% defined by x^3+x+1, with
% zero initial states, and with an all-ones
% final XOR value:
h = crc.detector('Polynomial', [1 0 1 1], ...
'InitialState', [0 0 0], 'FinalXOR', [1 1 1])

```

This example generates the following output:
```

h =
Type: CRC Detector
Polynomial: [1 0 1 1]
InitialState: [0 0 0]
ReflectInput: false
ReflectRemainder: false
FinalXOR: [ll 1 1]
% Construct a CRC detector with a polynomial
% defined by x^4+\mp@subsup{x}{}{\wedge}3+\mp@subsup{x}{}{\wedge}2+x+1,
% all-ones initial states, reflected input, and all-zeros
% final XOR value:
h = crc.detector('Polynomial', '0xF', 'InitialState', ...
'0xF', 'ReflectInput', true, 'FinalXOR', '0x0')

```

This example generates the following output:
```

h =
Type: CRC Detector
Polynomial: 0xF
InitialState: 0xF
ReflectInput: true
ReflectRemainder: false
FinalXOR: 0x0
% Create a CRC-16 CRC generator, then use it to generate
% a checksum for the
% binary vector represented by the
% ASCII sequence '123456789'.
% Introduce an error, then detect it
% using a CRC-16 CRC detector.
gen = crc.generator('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
det = crc.detector('Polynomial', '0x8005', 'ReflectInput', ...
true, 'ReflectRemainder', true);
% The message below is an ASCII representation
% of the digits 1-9
msg = reshape(de2bi(49:57, 8, 'left-msb')', 72, 1);
encoded = generate(gen, msg);

```
```

encoded(1) = ~encoded(1);
% Introduce an error
[outdata error] = detect(det, encoded);
noErrors = isequal(msg, outdata)
error
% Detect the error
% Should be 0
% Should be 1

```

This example generates the following output:
noErrors =
0
error =
1

\section*{CRC Generation Algorithm}

For information pertaining to the CRC generation algorithm, refer to the "CRC Non-Direct Algorithm" section of the Communications Toolbox User's Guide.

\section*{Generator Method}
encoded \(=\) generate \((\mathrm{h}, \mathrm{msg})\) generates a CRC checksum for an input message using the CRC generator object H. It appends the checksum to the end of MSG. The binary-valued MSG can be either a column vector or a matrix. If it is a matrix, then each column is considered to be a separate channel.

\section*{Usage Example}

The following examples demonstrate the use of this object.
```

% Construct a CRC generator with a polynomial defined
% by x^4+x^3+x^2++x+1:
h = crc.generator([[1 1 1 1 1 1])
% Construct a CRC generator with a polynomial defined
% by x^4+\mp@subsup{x}{}{\wedge}3+\mp@subsup{x}{}{\wedge}2+x+1, all-ones initial states, reflected
% input, and all-zeros final XOR value:
h = crc.generator('Polynomial', '0xF', 'InitialState', ...
'0xF', 'ReflectInput', true, 'FinalXOR', '0x0')
% Create a CRC-16 CRC generator, then use it to generate
% a checksum for the
% binary vector represented by the ASCII sequence '123456789'.

```
```

gen = crc.generator('Polynomial', '0x8005', ..
'ReflectInput', true, 'ReflectRemainder', true);
% The message below is an ASCII representation of ...
% the digits 1-9
msg = reshape(de2bi(49:57, 8, 'left-msb')', 72, 1);
encoded = generate(gen, msg);
% Construct a CRC generator with a polynomial defined
% by x^3+x+1, with zero initial states,
% and with an all-ones final XOR value:
h = crc.generator('Polynomial', [1 0 1 1], ...

\section*{cyclgen}

Produce parity-check and generator matrices for cyclic code

\section*{Syntax}
\(h=\operatorname{cyclgen}(\mathrm{n}, \mathrm{pol})\)
\(\mathrm{h}=\operatorname{cyclgen}(\mathrm{n}, \mathrm{pol}, o p t)\)
[h,g] = cyclgen(...)
[h,g,k] = cyclgen(...)

\section*{Description}

For all syntaxes, the codeword length is \(n\) and the message length is \(k\). A polynomial can generate a cyclic code with codeword length \(n\) and message length \(k\) if and only if the polynomial is a degree-( \(n\) k) divisor of \(x^{\wedge} n-1\). (Over the binary field GF(2), \(x^{\wedge} n-1\) is the same as \(x^{\wedge} n+1\).) This implies that \(k\) equals \(n\) minus the degree of the generator polynomial.
\(\mathrm{h}=\operatorname{cyclgen}(\mathrm{n}, \mathrm{pol})\) produces an ( \(\mathrm{n}-\mathrm{k}\) )-by-n parity-check matrix for a systematic binary cyclic code having codeword length n . The row vector pol gives the binary coefficients, in order of ascending powers, of the degree-(n-k) generator polynomial. Alternatively, you can specify pol as a polynomial character vector. For more information, see "Character Representation of Polynomials".
\(\mathrm{h}=\mathrm{cyclgen}(\mathrm{n}, \mathrm{pol}, \mathrm{opt})\) is the same as the syntax above, except that the argument opt determines whether the matrix should be associated with a systematic or nonsystematic code. The values for opt are 'system' and 'nonsys'.
\([h, g]=\operatorname{cyclgen}(\ldots)\) is the same as \(h=\operatorname{cyclgen}(\ldots)\), except that it also produces the \(k\)-byn generator matrix g that corresponds to the parity-check matrix h .
\([h, g, k]=\operatorname{cyclgen}(\ldots)\) is the same as \([h, g]=\operatorname{cyclgen}(\ldots)\), except that it also returns the message length \(k\).

\section*{Examples}

\section*{Parity Check and Generator Matrices for Binary Cyclic Codes}

Create parity check and generator matrices for a binary cyclic code having codeword length 7 and message length 4.

Create the generator polynomial using cyclpoly.
pol \(=\operatorname{cyclpoly}(7,4)\);
Create the parity check and generator matrices. The parity check matrix parmat has a 3-by-3 identity matrix embedded in its leftmost columns.
```

[parmat,genmat,k] = cyclgen(7,pol)
parmat = 3\times7

```
\begin{tabular}{rrrrrrr}
1 & 0 & 0 & 1 & 1 & 1 & 0 \\
0 & 1 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 1 & 1 & 1 & 0 & 1 \\
& & & & & & \\
genmat \(=4 \times 7\) & & & & & \\
& & & & & & \\
1 & 0 & 1 & 1 & 0 & 0 & 0 \\
1 & 1 & 1 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 1 & 0 \\
& 1 & 0 & 0 & 0 & 1 \\
\(\mathrm{k}=4\)
\end{tabular}

Create a parity check matrix in which the code is not systematic. The matrix parmatn does not have an embedded 3-by-3 identity matrix.
```

parmatn = cyclgen(7,pol,'nonsys')
parmatn = 3×7

```
\begin{tabular}{lllllll}
1 & 1 & 1 & 0 & 1 & 0 & 0 \\
0 & 1 & 1 & 1 & 0 & 1 & 0 \\
0 & 0 & 1 & 1 & 1 & 0 & 1
\end{tabular}

Create the parity check and generator matrices for a \((7,3)\) binary cyclic code. As this is a systematic code, there is a 4 -by-4 identity matrix in the leftmost columns of parmat2.
```

parmat2 = cyclgen(7,'1 + x^2 + x^3 + x^4')
parmat2 = 4×7

| 1 | 0 | 0 | 0 | 1 | 1 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 0 | 0 | 1 | 1 |

Introduced before R2006a

\section*{cyclpoly}

Produce generator polynomials for cyclic code

\section*{Syntax}
```

pol = cyclpoly(n,k)
pol = cyclpoly(n,k,opt)

```

\section*{Description}

For all syntaxes, a polynomial is represented as a row containing the coefficients in order of ascending powers.
pol \(=\operatorname{cyclpoly}(\mathrm{n}, \mathrm{k})\) returns the row vector representing one nontrivial generator polynomial for a cyclic code having codeword length \(n\) and message length \(k\).
pol = cyclpoly( \(\mathrm{n}, \mathrm{k}, o p t\) ) searches for one or more nontrivial generator polynomials for cyclic codes having codeword length \(n\) and message length \(k\). The output pol depends on the argument opt as shown in the table below.
\begin{tabular}{|l|l|l|}
\hline opt & Significance of pol & Format of pol \\
\hline 'min' & \begin{tabular}{l} 
One generator polynomial \\
having the smallest possible \\
weight
\end{tabular} & \begin{tabular}{l} 
Row vector representing the \\
polynomial
\end{tabular} \\
\hline 'max' & \begin{tabular}{l} 
One generator polynomial \\
having the greatest possible \\
weight
\end{tabular} & \begin{tabular}{l} 
Row vector representing the \\
polynomial
\end{tabular} \\
\hline 'all' & All generator polynomials & \begin{tabular}{l} 
Matrix, each row of which \\
represents one such polynomial
\end{tabular} \\
\hline a positive integer, \(L\) & \begin{tabular}{l} 
All generator polynomials \\
having weight \(L\)
\end{tabular} & \begin{tabular}{l} 
Matrix, each row of which \\
represents one such polynomial
\end{tabular} \\
\hline
\end{tabular}

The weight of a binary polynomial is the number of nonzero terms it has. If no generator polynomial satisfies the given conditions, the output pol is empty and a warning message is displayed.

\section*{Examples}

\section*{Cyclic Code Generator Polynomials}

Create [15,4] cyclic code generator polynomials.
Use the input 'all' to show all possible generator polynomials for a [15,4] cyclic code. Use the input 'max' to show that \(1+x+x^{2}+x^{3}+x^{5}+x^{7}+x^{8}+x^{11}\) is one such polynomial that has the largest number of nonzero terms.
```

c1 = cyclpoly(15,4,'all')
c1 = 3\times12

```
```

        1
        1
        1
    c2 = cyclpoly(15,4,'max')
c2 = 1\times12

| 1 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

```

This command shows that no generator polynomial for a [15,4] cyclic code has exactly three nonzero terms.
c3 \(=\) cyclpoly (15,4,3)
Warning: No cyclic generator polynomial satisfies the given constraints.
c3 =
[]

\section*{Algorithms}

If opt is 'min', 'max', or omitted, polynomials are constructed by converting decimal integers to base \(p\). Based on the decimal ordering, gfprimfd returns the first polynomial it finds that satisfies the appropriate conditions. This algorithm is similar to the one used in gfprimfd.

\section*{de2bi}

Convert decimal numbers to binary vectors

\section*{Syntax}
```

b = de2bi(d)
$b=\operatorname{de2bi}(d, n)$
$b=\operatorname{de2bi}(d, n, p)$
b = de2bi(d, [], p)
b $=$ de2bi(d,

```
\(\qquad\)
``` ,flg)
```

## Description

$b=d e 2 b i(d)$ converts a nonnegative decimal integer $d$ to a binary row vector. If $d$ is a vector, the output b is a matrix in which each row is the binary form of the corresponding element in d .
$\mathrm{b}=\mathrm{de} 2 \mathrm{bi}(\mathrm{d}, \mathrm{n})$ has an output with n columns.
$b=d e 2 b i(d, n, p)$ converts a nonnegative decimal integer $d$ to a base-p row vector.
b = de2bi(d, [],p) specifies the base, p.
b = de2bi(d
$, f l g)$ uses $f l g$ to determine whether the first column of $b$ contains the lowestorder or highest-order digits.

## Examples

## Convert Decimals to Binary Numbers

Convert decimals 1 through 10 into their equivalent binary representations.

```
d = (1:10)';
b = de2bi(d);
[d b]
ans = 10\times5
\begin{tabular}{rllll}
1 & 1 & 0 & 0 & 0 \\
2 & 0 & 1 & 0 & 0 \\
3 & 1 & 1 & 0 & 0 \\
4 & 0 & 0 & 1 & 0 \\
5 & 1 & 0 & 1 & 0 \\
6 & 0 & 1 & 1 & 0 \\
7 & 1 & 1 & 1 & 0 \\
8 & 0 & 0 & 0 & 1 \\
9 & 1 & 0 & 0 & 1 \\
10 & 0 & 1 & 0 & 1
\end{tabular}
```

Convert 3 and 9 to binary numbers. Each value is represented by a four-element row.
b = de2bi([3 9])
b $=2 \times 4$
$\begin{array}{llll}1 & 1 & 0 & 0\end{array}$
$\begin{array}{llll}1 & 0 & 0 & 1\end{array}$

Repeat the conversion with the number of columns set to 5 . The output is now padded with zeros in the fifth column.

```
bb = de2bi([3 9],5)
bb = 2\times5
```

    \(\begin{array}{lllll}1 & 1 & 0 & 0 & 0\end{array}\)
    
## Convert Decimals to Base-3 Numbers

Convert the decimals 1 through 6 to their base-3 equivalents. Set the leftmost bit as the most significant digit.

```
d = (1:6)';
t = de2bi(d,[],3,'left-msb');
[d t]
ans = 6×3
\begin{tabular}{lll}
1 & 0 & 1 \\
2 & 0 & 2 \\
3 & 1 & 0 \\
4 & 1 & 1 \\
5 & 1 & 2 \\
6 & 2 & 0
\end{tabular}
```

## Convert Decimal to Binary

This example shows how to convert decimals to binary numbers in their base-2 equivalents.

```
d_array = [1 2 3 4];
```

Convert the decimal array to binary by using the de2bi function. Specify that the most significant digit is the leftmost element and set the number of desired columns to 5 . The output becomes a 4 -by-5 matrix where each row corresponds to a decimal value from the input. Because the largest decimal value in d array can be expressed in 3 columns, the de2bi pads the matrix with two extra zero columns at the specified most-significant bit side. If you specify too few columns, the conversion will fail.

```
b array = de2bi(d array,5,'left-msb')
```

b_array $=4 \times 5$

| 0 | 0 | 0 | 0 | 1 |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 1 | 1 |
| 0 | 0 | 1 | 0 | 0 |

b_array = de2bi(d_array,5,'right-msb')
b_array $=4 \times 5$

| 1 | 0 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 0 | 0 |
| 1 | 1 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 | 0 |

If you do not specify a number of columns, the number of columns is exactly what is needed to express the largest decimal of the input.
b_array = de2bi(d_array,'left-msb')
b_array $=4 \times 3$

| 0 | 0 | 1 |
| :--- | :--- | :--- |
| 0 | 1 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 0 |

The output rows for specifying a leftmost-significant bit correspond to:

$$
\begin{aligned}
& 1=0\left(2^{2}\right)+0\left(2^{1}\right)+1\left(2^{0}\right) \\
& 2=0\left(2^{2}\right)+1\left(2^{1}\right)+0\left(2^{0}\right) \\
& 3=0\left(2^{2}\right)+1\left(2^{1}\right)+1\left(2^{0}\right) \\
& 4=1\left(2^{2}\right)+0\left(2^{1}\right)+0\left(2^{0}\right) \\
& \text { b_array = de2bi(d_array,'right-msb') } \\
& \text { b_array }=4 \times 3
\end{aligned}
$$

The output rows for specifying a rightmost-significant bit correspond to:

$$
\begin{aligned}
& 1=1\left(2^{0}\right)+0\left(2^{1}\right)+0\left(2^{2}\right) \\
& 2=0\left(2^{0}\right)+1\left(2^{1}\right)+0\left(2^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& 3=1\left(2^{0}\right)+1\left(2^{1}\right)+0\left(2^{2}\right) \\
& 4=0\left(2^{0}\right)+0\left(2^{1}\right)+1\left(2^{2}\right)
\end{aligned}
$$

## Input Arguments

## d - Decimal input

nonnegative integer | vector | matrix
Decimal input, specified as a nonnegative integer, vector, or matrix. If $d$ is a matrix, it is treated like the column vector d (: ).

Note To ensure an accurate conversion, d must be less than or equal to $2^{52}$.

## n - Number of output columns

positive integer scalar
The number of output columns specified as a positive scalar. If necessary, the binary representation of d is padded with extra zeros.
p-Base
2 (default) | positive integer scalar
Base of the output $b$, specified as an integer greater than or equal to 2 .

- If d is a vector, the output b is a matrix in which each row is the base-p form of the corresponding element in d .
- If $d$ is a matrix, de2bi treats it like the vector $d(:)$.

## flg - MSB flag

'right-msb' (default)|'left-msb'
MSB flag, specified as 'right-msb' or 'left-msb'.

- 'right-msb' -- Indicates the right (or last) column of the binary output, $b$, as the most significant bit (or highest-order digit).
- 'left-msb' -- Indicates the left (or first) column of the binary output, $b$, as the most significant bit (or highest-order digit).

## Output Arguments

## b - Binary output

vector | matrix
Binary representation of d, returned as a row vector or matrix. The output is of the same data type as the input.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## decode

Block decoder

## Syntax

```
msg = decode(code,n,k,'hamming/fmt',prim_poly)
msg = decode(code,n,k,'linear/fmt',genmat,trt)
msg = decode(code,n,k,'cyclic/fmt',genpoly,trt)
msg = decode(code,n,k)
[msg,err] = decode(...)
[msg,err,ccode] = decode(...)
[msg,err,ccode,cerr] = decode(...)
```

## Optional Inputs

| Input | Default Value |
| :--- | :--- |
| fmt | binary |
| prim_poly | gfprimdf(m) where $\mathrm{n}=2^{\wedge} \mathrm{m}-1$ |
| genpoly | cyclpoly $(\mathrm{n}, \mathrm{k})$ |
| trt | Uses syndtable to create the syndrome <br> decoding table associated with the method's <br> parity-check matrix |

## Description

## For All Syntaxes

The decode function aims to recover messages that were encoded using an error-correction coding technique. The technique and the defining parameters must match those that were used to encode the original signal.

The encode reference page explains the meanings of $n$ and $k$, the possible values of $f m t$, and the possible formats for code and msg. You should be familiar with the conventions described there before reading the rest of this section. Using the decode function with an input argument code that was not created by the encode function might cause errors.

## For Specific Syntaxes

msg = decode(code, $\mathrm{n}, \mathrm{k}$, 'hamming/fmt', prim_poly) decodes code using the Hamming method. For this syntax, $n$ must have the form $2^{\mathrm{m}}-1$ for some integer $m$ greater than or equal to 3 , and $k$ must equal $n-m$. prim_poly is a polynomial character vector or a row vector that gives the binary coefficients, in order of ascending powers, of the primitive polynomial for $\mathrm{GF}\left(2^{\mathrm{m}}\right)$ that is used in the encoding process. The default value of prim_poly is $\operatorname{gfprimdf}(\mathrm{m})$. The decoding table that the function uses to correct a single error in each codeword is syndtable(hammgen $(\mathrm{m})$ ).
msg = decode(code, $\mathrm{n}, \mathrm{k}$, ' linear/fmt', genmat, trt) decodes code, which is a linear block code determined by the $k$-by-n generator matrix genmat. genmat is required as input. decode tries to correct errors using the decoding table trt, where trt is a $2^{\wedge}(n-k)$-by-n matrix.
$m s g=$ decode(code, $n, k$, cyclic/fmt',genpoly,trt) decodes the cyclic code code and tries to correct errors using the decoding table trt, where trt is a $2^{\wedge}(n-k)$-by-n matrix. genpoly is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of the binary generator polynomial of the code. The default value of genpoly is cyclpoly ( $n, k$ ). By definition, the generator polynomial for an $[n, k]$ cyclic code must have degree $n-k$ and must divide $\mathrm{x}^{\mathrm{n}}-1$.
$m s g=$ decode (code $, n, k)$ is the same as $m s g=$ decode(code, $n, k$, 'hamming/binary').
[msg,err] = decode(...) returns a column vector err that gives information about error correction. If the code is a convolutional code, err contains the metric calculations used in the decoding decision process. For other types of codes, a nonnegative integer in the rth row of err indicates the number of errors corrected in the rth message word; a negative integer indicates that there are more errors in the rth word than can be corrected.
[msg,err,ccode] $=$ decode(...) returns the corrected code in ccode.
[msg,err,ccode, cerr] = decode(...) returns a column vector cerr whose meaning depends on the format of code:

- If code is a binary vector, a nonnegative integer in the rth row of vec2matcerr indicates the number of errors corrected in the rth codeword; a negative integer indicates that there are more errors in the rth codeword than can be corrected.
- If code is not a binary vector, cerr = err.

## Examples

## Encode and Decode Message with Hamming Code

Set the values of the codeword length and message length.
n = 15; \% Codeword length
k = 11; \% Message length
Create a random binary message with length equal to the message length.
data $=$ randi([0 1],k,1);
Encode the message.
encData $=$ encode(data, $n, k, ' h a m m i n g / b i n a r y ') ;$
Corrupt the encoded message sequence by introducing an error in the fourth bit.
encData(4) = ~encData(4);
Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
numerr = biterr(data,decData)
numerr = 0
```

## Algorithms

Depending on the decoding method, decode relies on such lower-level functions as hammgen, syndtable, and cyclgen.

## deintrlv

Restore ordering of symbols

## Syntax

```
deintrlvd = deintrlv(data,elements)
```

## Description

deintrlvd = deintrlv(data,elements) restores the original ordering of the elements of data by acting as an inverse of intrlv. If data is a length-N vector or an N-row matrix, elements is a length- N vector that permutes the integers from 1 to N . To use this function as an inverse of the intrlv function, use the same elements input in both functions. In that case, the two functions are inverses in the sense that applying intrlv followed by deintrlv leaves data unchanged.

## Examples

The code below illustrates the inverse relationship between intrlv and deintrlv.

```
p = randperm(10); % Permutation vector
a = intrlv(10:10:100,p); % Rearrange [10 20 30 ... 100].
b = deintrlv(a,p) % Deinterleave a to restore ordering.
```

The output is
b =

| 10 | 20 | 30 | 40 | 50 | 60 | 70 | 80 | 90 | 100 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.

## dfe

(To be removed) Construct decision-feedback equalizer object

Note will be removed in a future release. Use comm. DecisionFeedback instead.

## Syntax

```
eqobj = dfe(nfwdweights,nfbkweights,alg)
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst)
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst,nsamp)
```

## Description

The dfe function creates an equalizer object that you can use with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
eqobj = dfe(nfwdweights,nfbkweights,alg) constructs a decision feedback equalizer object. The equalizer's feedforward and feedback filters have nfwdweights and nfbkweights symbolspaced complex weights, respectively, which are initially all zeros. alg describes the adaptive algorithm that the equalizer uses; you should create alg using any of these functions: lms, signlms, normlms, varlms, rls, or cma. The signal constellation of the desired output is [-1 1], which corresponds to binary phase shift keying (BPSK).
eqobj = dfe(nfwdweights,nfbkweights,alg,sigconst) specifies the signal constellation vector of the desired output.
eqobj = dfe(nfwdweights,nfbkweights,alg, sigconst,nsamp) constructs a DFE with a fractionally spaced forward filter. The forward filter has nfwdweights complex weights spaced at T/ nsamp, where T is the symbol period and nsamp is a positive integer. nsamp $=1$ corresponds to a symbol-spaced forward filter.

## Properties

The table below describes the properties of the decision feedback equalizer object. To learn how to view or change the values of a decision feedback equalizer object, see "Equalization".

Note To initialize or reset the equalizer object eqobj, enter reset (eqobj).

| Property | Description |
| :--- | :--- |
| EqType | Fixed value, ' Decision Feedback <br> Equalizer' |
| AlgType | Name of the adaptive algorithm represented by <br> alg |

| Property | Description |
| :--- | :--- |
| nWeights | Number of weights in the forward filter and the <br> feedback filter, in the format [nfwdweights, <br> nfbkweights]. The number of weights in the <br> forward filter must be at least 1. |
| nSampPerSym | Number of input samples per symbol (equivalent <br> to nsamp input argument). This value relates to <br> both the equalizer structure (see the use of K in <br> "Equalization") and an assumption about the <br> signal to be equalized. |
| RefTap (except for CMA equalizers) | Reference tap index, between 1 and <br> nfwdweights. Setting this to a value greater <br> than 1 effectively delays the reference signal with <br> respect to the equalizer's input signal. |
| SigConst | Signal constellation, a vector whose length is <br> typically a power of 2. |
| Weights | Vector that concatenates the complex coefficients <br> from the forward filter and the feedback filter. |
| This is the set of wi values in the schematic in |  |
| "Equalization". |  |

## Relationships Among Properties

If you change nWeights, MATLAB maintains consistency in the equalizer object by adjusting the values of the properties listed below.

| Property | Adjusted Value |
| :--- | :--- |
| Weights | zeros(1, sum (nWeights) ) |
| WeightInputs | zeros(1, sum (nWeights)) |
| StepSize (Variable-step-size LMS <br> equalizers) | InitStep*ones(1,sum(nWeights)) |
| InvCorrMatrix (RLS equalizers) | InvCorrInit*eye(sum(nWeights)) |

## Examples

## Configuring Decision Feedback Equalizers

This example configures the recommended comm. DecisionFeedback System object ${ }^{\text {TM }}$ and the legacy dfe feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1)
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol' ,4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ..
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(y0ld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

## Use LMS Algorithm with Decision Feedback Equalizer

Configure dfe and comm.DecisionFeedback objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. DecisionFeedback System object ${ }^{\mathrm{TM}}$ assumes that leakage factor is always 1 .

```
eq0ld = dfe(5,3,lms(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Decision Feedback Equalizer'
    AlgType: 'LMS'
    nWeights: [5 3]
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0) ]
    WeightInputs: [0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.DecisionFeedback('NumForwardTaps',5,'NumFeedbackTaps',3, ...
            Algorithm','LMS','StepSize',0.05, ...
            Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.DecisionFeedback with properties:
    Algorithm: 'LMS'
    NumForwardTaps: 5
    NumFeedbackTaps: 3
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071-0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.

```
y0ld = equalize(eq0ld,r,x(1:100));
yNew = eqNew(r,x(1:100));
```

## Use RLS Algorithm with Decision Feedback Equalizer

Configure dfe and comm.DecisionFeedback objects with comparable settings.

```
eq0ld = dfe(5,3,rls(0.95),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Decision Feedback Equalizer'
    AlgType: 'RLS'
    nWeights: [5 3]
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    Forget Factor: 0.9500
    InvCorrInit: 0.1000
    InvCorrMatrix: [8\times8 double]
    Weights: [0 0 0 0 0 0 0 0]
    WeightInputs: [0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.DecisionFeedback('NumForwardTaps',5,'NumFeedbackTaps',3,'Algorithm','RLS', ...
        'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.DecisionFeedback with properties:
    Algorithm: 'RLS'
    NumForwardTaps: 5
    NumFeedbackTaps: 3
    ForgettingFactor: 0.9500
    InitialInverseCorrelationMatrix: 0.1000
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071-0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. DecisionFeedback object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Configure dfe and comm. DecisionFeedback objects with comparable settings. For the comm. DecisionFeedback object, set the initial inverse correlation matrix to eye(5)*0.2.

```
eqOld = dfe(5,3,rls(0.95),pskmod(0:3,4,pi/4))
```

eq0ld =
EqType: 'Decision Feedback Equalizer'
AlgType: 'RLS'
nWeights: [5 3]
nSampPerSym: 1
RefTap: 1
SigConst: [0.7071 + 0.7071i-0.7071 + 0.7071i-0.7071 - 0.7071i 0.7071-0.7071i]
ForgetFactor: 0.9500
InvCorrInit: 0.1000
InvCorrMatrix: [8×8 double]
Weights: [0 00000000$]$

```
    WeightInputs: [0 0 0 0 0 0 0 0]
```

    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
    eqNew $=$ comm. DecisionFeedback('NumForwardTaps',5,'NumFeedbackTaps',3,'Algorithm', 'RLS', ...
'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4), 'ReferenceTap',1, ..
'InitialInverseCorrelationMatrix', eye(5)*0.2)
eqNew $=$ comm. DecisionFeedback with properties:
Algorithm: 'RLS'
NumForwardTaps: 5
NumFeedbackTaps: 3
ForgettingFactor: 0.9500
InitialInverseCorrelationMatrix: [8×8 double]
Constellation: $[0.7071+0.7071 i-0.7071+0.7071 i-0.7071-0.7071 i \operatorname{0.7071-0.7071i]}$
ReferenceTap: 1
InputDelay: 0
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
AdaptAfterTraining: true
InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. DecisionFeedback object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

## Use Decision Feedback Equalizers Considering Signal Delays

Configure dfe and comm.DecisionFeedback objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the dfe to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eq0ld = dfe(filterDelay*sps+4,6,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eqOld =
    EqType: 'Decision Feedback Equalizer'
    AlgType: 'LMS'
    nWeights: [16 6]
    nSampPerSym: 2
    RefTap: }1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 | |
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.DecisionFeedback('NumForwardTaps',filterDelay*sps+4, ...
            'NumFeedbackTaps',6,'Algorithm','LMS','StepSize',0.01, ...
            'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
            ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.DecisionFeedback with properties:
    Algorithm: 'LMS'
    NumForwardTaps: 16
    NumFeedbackTaps: 6
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
```

InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1
Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. DecisionFeedback object.

```
yOld1 = equalize(eqOld,r,x(1:100));
y0ld2 = equalize(eqOld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the comm. DecisionFeedback object, InputDelay is used to synchronize with the delayed signal. NumForwardTaps, NumFeedbackTaps, and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.DecisionFeedback('NumForwardTaps',11,'NumFeedbackTaps',4, ...
    Algorithm','LMS','StepSize',0.01,
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    ReferenceTap',6,'InputDelay',filterDelay*sps)
eqNew = comm.DecisionFeedback with properties:
    Algorithm: 'LMS'
    NumForwardTaps: 11
    NumFeedbackTaps: 4
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: 12
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

## Compatibility Considerations

## dfe will be removed

Warns starting in R2020a
dfe will be removed in a future release. Use comm. DecisionFeedback instead. For examples comparing setup of comm. DecisionFeedback to dfe, see "Configuring Decision Feedback Equalizers" on page 2-258.

## dftmtx

Discrete Fourier transform matrix in Galois field

## Syntax

```
dm = dftmtx(alph)
```

## Description

$\mathrm{dm}=\mathrm{dftmtx}(\mathrm{alph})$ returns a Galois array that represents the discrete Fourier transform operation on a Galois vector, with respect to the Galois scalar alph. The element alph is a primitive nth root of unity in the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)=\mathrm{GF}(\mathrm{n}+1)$; that is, n must be the smallest positive value of k for which alph^k equals 1. The discrete Fourier transform has size $n$ and $d m$ is an $n-b y-n$ array. The array dm represents the transform in the sense that dm times any length-n Galois column vector yields the transform of that vector.

Note The inverse discrete Fourier transform matrix is dftmtx(1/alph).

## Examples

The example below illustrates the discrete Fourier transform and its inverse, with respect to the element $\mathrm{gf}(3,4)$. The example examines the first n powers of that element to make sure that only the nth power equals one. Afterward, the example transforms a random Galois vector, undoes the transform, and checks the result.

```
m = 4;
n= 2^m-1;
a = 3;
alph = gf(a,m);
mp = minpol(alph);
if (mp(1)==1 && isprimitive(mp)) % Check that alph has order n.
    disp('alph is a primitive nth root of unity.')
    dm = dftmtx(alph);
    idm = dftmtx(1/alph);
    x = gf(randi([0 2^m-1],n,1),m);
    y = dm*x; % Transform x.
    z = idm*y; % Recover x.
    ck = isequal(x,z)
end
```

The output is

```
alph is a primitive nth root of unity.
```

ck =

## Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, alph must be a primitive nth root of unity in the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, where m is an integer between 1 and 8.

## Algorithms

The element $d m(a, b)$ equals $a l p h^{\wedge}((a-1) *(b-1))$.

## distspec

Compute distance spectrum of convolutional code

## Syntax

spect $=$ distspec(trellis, $n$ )
spect = distspec(trellis)

## Description

spect $=$ distspec (trellis, n ) computes the free distance and the first n components of the weight and distance spectra of a linear convolutional code. Because convolutional codes do not have block boundaries, the weight spectrum and distance spectrum are semi-infinite and are most often approximated by the first few components. The input trellis is a valid MATLAB trellis structure, as described in "Trellis Description of a Convolutional Code". The output, spect, is a structure with these fields:

| Field | Meaning |
| :--- | :--- |
| spect.dfree | Free distance of the code. This is the minimum <br> number of errors in the encoded sequence <br> required to create an error event. |
| spect. weight | A length-n vector that lists the total number of <br> information bit errors in the error events <br> enumerated in spect. event. |
| spect.event | A length-n vector that lists the number of error <br> events for each distance between spect. dfree <br> and spect.dfree+n-1. The vector represents <br> the first $n$ components of the distance spectrum. |

spect $=$ distspec(trellis) is the same as spect $=$ distspec(trellis,1).

## Examples

The example below performs these tasks:

- Computes the distance spectrum for the rate $2 / 3$ convolutional code that is depicted on the reference page for the poly2trellis function
- Uses the output of distspec as an input to the bercoding function, to find a theoretical upper bound on the bit error rate for a system that uses this code with coherent BPSK modulation
- Plots the upper bound using the berfit function

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
spect = distspec(trellis,4)
berub = bercoding(1:10,'conv','hard',2/3,spect); % BER bound
berfit(1:10,berub); ylabel('Upper Bound on BER'); % Plot.
```

The output and plot are below.

```
trellis =
    numInputSymbols: 4
    numOutputSymbols: 8
        numStates: 128
        nextStates: [128x4 double]
                outputs: [128\times4 double]
```

spect $=$
dfree: 5
weight: [1 628 142]
event: [11 2 8 25]

## Algorithms

The function uses a tree search algorithm implemented with a stack, as described in [2].

## doppler

Construct Doppler spectrum structure

## Syntax

s = doppler(specType)
s = doppler(specType, fieldValue)
s = doppler('BiGaussian', Name,Value)

## Description

s = doppler(specType) constructs a Doppler spectrum structure of type specType for use with a fading channel System object. The returned structure, $s$, has default values for its dependent fields.
s = doppler(specType, fieldValue) constructs a Doppler spectrum structure of type specType for use with a fading channel System object. The returned structure, s, has its dependent field specified to fieldValue.
s = doppler('BiGaussian', Name,Value) constructs a BiGaussian Doppler spectrum structure for use with a fading channel System object. The returned structure, s, has dependent fields specified by Name, Value pair arguments.

## Examples

## Construct a Flat Doppler Spectrum Structure

Construct a flat Doppler structure variable for use with channel objects such as comm. RayleighChannel.

Invoke the doppler function to create a flat Doppler structure variable.

```
s = doppler('Flat')
s = struct with fields:
    SpectrumType: 'Flat'
```

## Create a Bell Doppler Structure Variable

Use the doppler function to create a Doppler structure variable having the Bell spectrum.

```
s = doppler('Bell')
s = struct with fields:
    SpectrumType: 'Bell'
        Coefficient: 9
```

## Construct a Rounded Doppler Spectrum Structure with Specified Polynomial

Specify the coefficients of the Doppler spectrum structure variable.
Construct a Rounded Doppler spectrum structure with coefficients a0, a2, and a4 set to 2, 6, and 1, respectively.

```
s = doppler('Rounded', [2, 6, 1])
s = struct with fields:
    SpectrumType: 'Rounded'
        Polynomial: [2 6 1]
```

## Construct a BiGaussian Doppler Spectrum Structure with Specified Field Values

Use the doppler function to create a Doppler spectrum structure with the parameters specified for a BiGaussian spectrum.

```
s = doppler('BiGaussian','NormalizedCenterFrequencies', ...
    [.1 .85],'PowerGains',[1 2])
s = struct with fields:
            SpectrumType: 'BiGaussian'
    NormalizedStandardDeviations: [0.7071 0.7071]
        NormalizedCenterFrequencies: [0.1000 0.8500]
            PowerGains: [1 2]
```

The NormalizedStandardDeviations field is set to the default value. The NormalizedCenterFrequencies, and PowerGains fields are set to the values specified from the input arguments.

## Input Arguments

specType - Spectrum type of Doppler spectrum structure for use with fading channel System object

```
'Jakes'|'Flat'|'Rounded'|'Bell'|'Asymmetric Jakes'|'Restricted Jakes'|
'Gaussian'|'BiGaussian'
```

The spectrum type of a Doppler spectrum structure for use with a fading channel System object. Specify this value as a character vector.

The analytical expression for each Doppler spectrum type is described in the "Algorithms" on page 2270 section.

Data Types: char
fieldValue - Value of dependent field of Doppler spectrum structure
scalar | vector

The value of the dependent field of the Doppler spectrum structure, specified as a scalar or vector of built-in data type. If you do not specify fieldValue, the dependent fields of the spectrum type use the default values.

| Spectrum Type | Dependent Field | Description | Default Value |
| :---: | :---: | :---: | :---: |
| "Jakes" on page 2-271 | - | - | - |
| "Flat" on page 2-271 | - | - | - |
| "Rounded" on page 2271 | Polynomial | 1-by-3 vector of real finite values, representing the polynomial coefficients, a0, a2 and a4 | [1 1 -1.72 0.785$]$ |
| "Bell" on page 2-271 | Coefficient | Nonnegative, finite, real scalar representing the Bell spectrum coefficient | 9 |
| "Asymmetric Jakes" on page 2-271 | NormalizedFrequenc yInterval | 1-by-2 vector of real values between -1 and 1, inclusive, representing the minimum and maximum normalized Doppler shifts | [01] |
| "Restricted Jakes" on page 2-272 | NormalizedFrequenc yInterval | 1-by-2 vector of real values between 0 and 1 , inclusive, representing the minimum and maximum normalized Doppler shifts | [01] |
| "Gaussian" on page 2272 | NormalizedStandard Deviation | Normalized standard deviation of the Gaussian Doppler spectrum, specified as a positive, finite, real scalar | 0.7071 |
| "BiGaussian" on page 2272 | NormalizedStandard Deviations | Normalized standard deviations of the BiGaussian Doppler spectrum, specified as a positive, finite, real 1-by-2 vector | [0.7071 0.7071] |
|  | NormalizedCenterFr eqencies | Normalized center frequencies of the BiGaussian Doppler spectrum specified as a real 1-by-2 vector whose elements fall between 1 and 1 | [0 0] |

| Spectrum Type | Dependent Field | Description | Default Value |
| :--- | :--- | :--- | :--- |
|  | PowerGains | Linear power gains of <br> the BiGaussian Doppler <br> spectrum specified as a <br> real nonnegative 1-by-2 <br> vector | $\left[\begin{array}{ll}0.5 \quad 0.5\end{array}\right]$ |

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: s=doppler('BiGaussian', 'NormalizedStandardDeviations', [. 8 .75],
'NormalizedCenterFrequencies', [-. 8 0], 'PowerGains', [.6 .6])
NormalizedStandardDeviations - Normalized standard deviations of first and second Gaussian functions
[1/sqrt(2) 1/sqrt(2)] (default) | 1-by-2 positive numeric vector
The normalized standard deviation of the first and second Gaussian functions. You can specify this value as a 1-by-2 positive numeric vector, of built-in data types.

When you do not specify this dependent field, the default value is [1/sqrt(2) $1 /$ sqrt(2)].
Data Types: double

## NormalizedCenterFrequencies - Normalized center frequencies of first and second Gaussian functions

[0 0] (default) | 1-by-2 numeric vector
The normalized center frequencies of the first and second Gaussian functions. You can specify this value as a 1 -by- 2 numeric vector of real values between -1 and 1 , of built-in data types.

When you do not specify this dependent field, the default value is [0 0].
Data Types: double

## PowerGains - Power gains of first and second Gaussian functions

[0.5 0.5] (default) | 1 -by-2 numeric vector
The power gains of the first and second Gaussian functions. You can specify this value as a 1-by-2 nonnegative numeric vector of built-in data types.

When you do not specify this dependent field, the default value is [0.5 0.5].
Data Types: double

## Algorithms

The following algorithms represent the analytical expressions for each Doppler spectrum type. In each case, $f_{d}$ denotes the maximum Doppler shift (MaximumDopplerShift property) of the associated fading channel System object.

## Jakes

The theoretical Jakes Doppler spectrum, $S(f)$ has the analytic formula

$$
S(f)=\frac{1}{\pi f_{d} \sqrt{1-\left(f / f_{d}\right)^{2}}},|f| \leq f_{d}
$$

## Flat

The theoretical Flat Doppler spectrum, $S(f)$ has the analytic formula

$$
S(f)=\frac{1}{2 f_{d}},|f| \leq f_{d}
$$

## Rounded

The theoretical Rounded Doppler spectrum, $S(f)$ has the analytic formula

$$
S(f)=C_{r}\left[a_{0}+a_{2}\left(\frac{f}{f_{d}}\right)^{2}+a_{4}\left(\frac{f}{f_{d}}\right)^{4}\right],|f| \leq f_{d}
$$

where

$$
C_{r}=\frac{1}{2 f_{d}\left[a_{0}+\frac{a_{2}}{3}+\frac{a_{4}}{5}\right]}
$$

and you can specify $\left[\begin{array}{lll}a_{0} & a_{2}, & a_{4}\end{array}\right]$ in the dependent field, polynomial.

## Bell

The theoretical Bell Doppler spectrum, $S(f)$ has the analytic formula

$$
\begin{aligned}
& S(f)=\frac{C_{b}}{1+A\left(\frac{f}{f_{d}}\right)^{2}} \\
& |f| \leq f_{d}
\end{aligned}
$$

where

$$
C_{b}=\frac{\sqrt{A}}{\Pi f_{d}}
$$

You can specify $A$ in the dependent field, coefficient.

## Asymmetric Jakes

The theoretical Asymmetric Jakes Doppler spectrum, $S(f)$ has the analytic formula

$$
\begin{gathered}
S(f)=\frac{A_{a}}{\pi f_{d} \sqrt{1-\left(f / f_{d}\right)^{2}}},-f_{d} \leq f_{\min } \leq f \leq f_{\max } \leq f_{d} \\
A_{a}=\frac{1}{\frac{1}{\pi}\left[\sin ^{-1}\left(\frac{f_{\max }}{f_{d}}\right)-\sin ^{-1}\left(\frac{f_{\min }}{f_{d}}\right)\right]}
\end{gathered}
$$

where you can specify $f_{\min } / f_{d}$ and $f_{\max } / f_{d}$ in the dependent field, NormalizedFrequencyInterval.

## Restricted Jakes

The theoretical Restricted Jakes Doppler spectrum, $S(f)$ has the analytic formula

$$
S(f)=\frac{A_{r}}{\pi f_{d} \sqrt{1-\left(f / f_{d}\right)^{2}}}, 0 \leq f_{\min } \leq|f| \leq f_{\max } \leq f_{d}
$$

where

$$
A_{r}=\frac{1}{\frac{2}{\Pi}\left[\sin ^{-1}\left(\frac{f_{\max }}{f_{d}}\right)-\sin ^{-1}\left(\frac{f_{\min }}{f_{d}}\right)\right]}
$$

where you can specify $f_{\min } / f_{d}$ and $f_{\max } / f_{d}$ in the dependent field, NormalizedFrequencyInterval.

## Gaussian

The theoretical Gaussian Doppler spectrum, $S(f)$ has the analytic formula

$$
S_{G}(f)=\frac{1}{\sqrt{2 \Pi \sigma_{G}^{2}}} \exp \left(-\frac{f^{2}}{2 \sigma_{G}^{2}}\right)
$$

You can specify $\sigma_{G} / f_{d}$ in the dependent field, NormalizedStandardDeviation.

## BiGaussian

The theoretical BiGaussian Doppler spectrum, $S(f)$ has the analytic formula

$$
S_{G}(f)=A_{G}\left[\frac{C_{G 1}}{\sqrt{2 \Pi \sigma_{G 1}^{2}}} \exp \left(-\frac{\left(f-f_{G 1}\right)^{2}}{2 \sigma_{G 1}^{2}}\right)+\frac{C_{G 2}}{\sqrt{2 \pi \sigma_{G 2}^{2}}} \exp \left(-\frac{\left(f-f_{G 2}\right)^{2}}{2 \sigma_{G 2}^{2}}\right)\right]
$$

where $A_{G}=\frac{1}{C_{G 1}+C_{G 2}}$ is a normalization coefficient.
You can specify $\sigma_{G 1} / f_{d}$ and $\sigma_{G 2} / f_{d}$ in the NormalizedStandardDeviations dependent field.
You can specify $f_{G 1} / f_{d}$ and $f_{G 2} / f_{d}$ in the NormalizedCenterFrequencies dependent field.
$C_{G 1}$ and $C_{G 2}$ are power gains that you can specify in the PowerGains dependent field.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
All inputs must be constants. Expressions or variables are allowed if their values do not change.

## doppler.ajakes

(To be removed) Construct asymmetrical Doppler spectrum object

Note doppler. ajakes will be removed in a future release. Use doppler('Asymmetric Jakes', ...) instead.

## Syntax

dop = doppler.ajakes(freqminmaxajakes)
dop = doppler.ajakes

## Description

The doppler. ajakes function creates an asymmetrical Jakes (AJakes) Doppler spectrum object. This object is to be used for the DopplerSpectrum property of a channel object created with the rayleighchan or the ricianchan functions.
dop = doppler.ajakes(freqminmaxajakes), where freqminmaxajakes is a row vector of two finite real numbers between -1 and 1, creates a Jakes Doppler spectrum that is nonzero only for normalized (by the maximum Doppler shift $f_{d}$, in Hz) frequencies $f_{\text {norm }}$ such that
$-1 \leq f_{\min , \text { norm }} \leq f_{\text {norm }} \leq f_{\text {max, }}$ norm $\leq 1$, where $f_{\text {min, norm }}$ is given by freqminmaxajakes ( 1 ) and $f_{\text {max, norm }}$ is given by freqminmaxajakes (2). The maximum Doppler shift $f_{d}$ is specified by the MaxDopplerShift property of the channel object. Analytically: $f_{\min , n o r m}=f_{\min } / f_{d}$ and $f_{\text {max }, ~ n o r m ~}=f_{\max } / f_{d}$, where $f_{\text {min }}$ is the minimum Doppler shift (in hertz) and $f_{\max }$ is the maximum Doppler shift (in hertz).

When dop is used as the DopplerSpectrum property of a channel object, space
freqminmaxajakes(1) and freqminmaxajakes (2) by more than $1 / 50$. Assigning a smaller spacing results in freqminmaxarjakes being reset to the default value of [01].
dop = doppler.ajakes creates an asymmetrical Doppler spectrum object with a default freqminmaxajakes = [0 1]. This syntax is equivalent to constructing a Jakes Doppler spectrum that is nonzero only for positive frequencies.

## Properties

The AJakes Doppler spectrum object contains the following properties.

| Property | Description |
| :--- | :--- |
| SpectrumType | Fixed value, 'AJakes ' |
| FreqMinMaxAJakes | Vector of minimum and maximum normalized <br> Doppler shifts, two real finite numbers between <br> -1 and 1 |

## Theory and Applications

The Jakes power spectrum is based on the assumption that the angles of arrival at the mobile receiver are uniformly distributed [1]: the spectrum then covers the frequency range from $-f_{d}$ to $f_{d}, f_{d}$ being the maximum Doppler shift. When the angles of arrival are not uniformly distributed, then the Jakes power spectrum does not cover the full Doppler bandwidth from $-f_{d}$ to $f_{d}$. The AJakes Doppler spectrum object covers the case of a power spectrum that is nonzero only for frequencies $f$ such that $-f_{d} \leq f_{\min } \leq f \leq f_{\max } \leq f_{d}$. It is an asymmetrical spectrum in the general case, but becomes a symmetrical spectrum if $f_{\text {min }}=-f_{\text {max }}$.

The normalized AJakes Doppler power spectrum is given analytically by:

$$
\begin{gathered}
S(f)=\frac{A_{a}}{\Pi f_{d} \sqrt{1-\left(f / f_{d}\right)^{2}}}, \quad-f_{d} \leq f_{\min } \leq f \leq f_{\max } \leq f_{d} \\
A_{a}=\frac{1}{\frac{1}{\Pi}\left[\sin ^{-1}\left(\frac{f_{\max }}{f_{d}}\right)-\sin ^{-1}\left(\frac{f_{\min }}{f_{d}}\right)\right]}
\end{gathered}
$$

where $f_{\min }$ and $f_{\max }$ denote the minimum and maximum frequencies where the spectrum is nonzero. You can determine these values from the probability density function of the angles of arrival.

## Examples

The following MATLAB code first creates a Rayleigh channel object with a maximum Doppler shift of $f_{d}=10 \mathrm{~Hz}$. It then creates an AJakes Doppler object with minimum normalized Doppler shift $f_{\min , \text { norm }}=-0.2$ and maximum normalized Doppler shift $f_{\text {max, }}$ norm $=0.05$. The Doppler object is then assigned to the DopplerSpectrum property of the channel object. The channel then has a Doppler spectrum that is nonzero for frequencies $f$ such that $-f_{d} \leq f_{\min } \leq f \leq f_{\max } \leq f_{d}$, where $f_{\text {min }}=f_{\text {min, norm }} \times f_{d}=-2 \mathrm{~Hz}$ and $f_{\text {max }}=f_{\text {max, norm }} \times f_{d}=0.5 \mathrm{~Hz}$.

```
chan = rayleighchan(1/1000, 10);
```

dop_ajakes = doppler.ajakes([-0.2 0.05]);
chan.DopplerSpectrum = dop_ajakes;
chan.DopplerSpectrum
This code returns:
SpectrumType: 'AJakes'
FreqMinMaxAJakes: [-0.2000 0.0500]

## doppler.bell

(To be removed) Construct bell-shaped Doppler spectrum object

Note doppler.ajakes will be removed in a future release. Use doppler('Bell' , ....) instead.

## Syntax

doppler.bell
doppler.bell(coeffbell)

## Description

doppler.bell creates a bell Doppler spectrum object. You can use this object with the DopplerSpectrum property of any channel object created with either the rayleighchan function, the ricianchan function, or comm. MIMOChannel System object.
dop $=$ doppler.bell creates a bell Doppler spectrum object with default coefficient.
dop $=$ doppler.bell (coeffbell) creates a bell Doppler spectrum object with coefficient given by coeffbell, where coeffbell is a positive, finite, real scalar.

## Properties

The bell Doppler spectrum object has the following properties.

| Property | Description |
| :--- | :--- |
| SpectrumType | Fixed value, 'Bell' |
| CoeffBell | Bell spectrum coefficient, positive real finite <br> scalar. |

## Theory and Applications

A bell spectrum was proposed in [1] for the Doppler spectrum of indoor MIMO channels, for 802.11n channel modeling.

The normalized bell Doppler spectrum is given analytically by:

$$
S(f)=\frac{C_{b}}{1+A\left(\frac{f}{f_{d}}\right)^{2}}
$$

where

$$
|f| \leq f_{d}
$$

and

$$
C_{b}=\frac{\sqrt{A}}{\Pi f_{d}}
$$

$f_{d}$ represents the maximum Doppler shift specified for the channel object, and $A$ represents a positive real finite scalar (CoeffBell). The indoor MIMO channel model of IEEE 802.11n [1] uses the following parameter: $A=9$. Since the channel is modeled as Rician fading with a fixed line-of-sight (LOS) component, a Dirac delta is also present in the Doppler spectrum at $f=0$.

## Examples

Construct a bell Doppler spectrum object with a coefficient of 8.5. Assign it to a Rayleigh channel object with one path.

```
dop = doppler.bell(8.5);
chan = rayleighchan(1e-5, 10);
chan.DopplerSpectrum = dop;
```

## doppler.bigaussian

(To be removed) Construct bi-Gaussian Doppler spectrum object

Note doppler. bigaussian will be removed in a future release. Use doppler('BiGaussian', ...) instead.

## Syntax

```
dop = doppler.bigaussian(property1,value1,...)
```

dop = doppler.bigaussian

## Description

The doppler.bigaussian function creates a bi-Gaussian Doppler spectrum object to be used for the DopplerSpectrum property of a channel object (created with either the rayleighchan function or the ricianchan function).
dop $=$ doppler.bigaussian(property1,value1,...) creates a bi-Gaussian Doppler spectrum object with properties as specified by the property/value pairs. If you do not specify a value for a property, the property is assigned a default value.
dop = doppler.bigaussian creates a bi-Gaussian Doppler spectrum object with default properties. The constructed Doppler spectrum object is equivalent to a single Gaussian Doppler spectrum centered at zero frequency. The equivalent command with property/value pairs is:

```
dop = doppler.bigaussian('SigmaGaussian1', 1/sqrt(2), ...
    'SigmaGaussian2', 1/sqrt(2), ...
    'CenterFreqGaussian1', 0, ...
    'CenterFreqGaussian2', 0, ...
    'GainGaussian1', 0.5, ...
    'GainGaussian2', 0.5)
```

## Properties

The bi-Gaussian Doppler spectrum object contains the following properties.

| Property | Description |
| :--- | :--- |
| SpectrumType | Fixed value, ' BiGaussian ' |
| SigmaGaussian1 | Normalized standard deviation of first Gaussian <br> function (real positive finite scalar value) |
| SigmaGaussian2 | Normalized standard deviation of second <br> Gaussian function (real positive finite scalar <br> value) |
| CenterFreqGaussian1 | Normalized center frequency of first Gaussian <br> function (real scalar value between -1 and 1) |

| Property | Description |
| :--- | :--- |
| CenterFreqGaussian2 | Normalized center frequency of second Gaussian <br> function (real scalar value between -1 and 1) |
| GainGaussian1 | Power gain of first Gaussian function (linear <br> scale, real nonnegative finite scalar value) |
| GainGaussian2 | Power gain of second Gaussian function (linear <br> scale, real nonnegative finite scalar value) |

All properties are writable except for the SpectrumType property.
The properties SigmaGaussian1, SigmaGaussian2, GainGaussian1, and GainGaussian2 are normalized by the MaxDopplerShift property of the associated channel object.

Analytically, the normalized standard deviations of the first and second Gaussian functions are determined as $\sigma_{G 1, \text { norm }}=\sigma_{G 1} / f_{d}$ and $\sigma_{G 2, \text { norm }}=\sigma_{G 2} / f_{d}$, respectively, where $\sigma_{G 1}$ and $\sigma_{G 2}$ are the standard deviations of the first and second Gaussian functions, and $f_{d}$ is the maximum Doppler shift, in hertz. Similarly, the normalized center frequencies of the first and second Gaussian functions are determined as $f_{G 1, \text { norm }}=f_{G 1} / f_{d}$ and $f_{G 2, \text { norm }}=f_{G 2} / f_{d}$, respectively, where $f_{G 1}$ and $f_{G 2}$ are the center frequencies of the first and second Gaussian functions. The properties GainGaussian1 and GainGaussian2 correspond to the power gains $C_{G 1}$ and $C_{G 2}$, respectively, of the two Gaussian functions.

## Theory and Applications

The bi-Gaussian power spectrum consists of two frequency-shifted Gaussian spectra. The COST207 channel models ([1], [2], [3]) specify two distinct bi-Gaussian Doppler spectra, GAUS1 and GAUS2, to be used in modeling long echos for urban and hilly terrain profiles.

The normalized bi-Gaussian Doppler spectrum is given analytically by:

$$
S_{G}(f)=A_{G}\left[\frac{C_{G 1}}{\sqrt{2 \Pi \sigma_{G 1}^{2}}} \exp \left(-\frac{\left(f-f_{G 1}\right)^{2}}{2 \sigma_{G 1}^{2}}\right)+\frac{C_{G 2}}{\sqrt{2 \Pi \sigma_{G 2}^{2}}} \exp \left(-\frac{\left(f-f_{G 2}\right)^{2}}{2 \sigma_{G 2}^{2}}\right)\right]
$$

where $\sigma_{G 1}$ and $\sigma_{G 2}$ are standard deviations, $f_{G 1}$ and $f_{G 2}$ are center frequencies, $C_{G 1}$ and $C_{G 2}$ are power gains, and $A_{G}=\frac{1}{C_{G 1}+C_{G 2}}$ is a normalization coefficient.

If either $f_{G 1}=0$ or $f_{G 2}=0$, a frequency-shifted Gaussian Doppler spectrum is obtained.

## Examples

The following MATLAB code first creates a bi-Gaussian Doppler spectrum object with the same parameters as that of a COST 207 GAUS2 Doppler spectrum. It then creates a Rayleigh channel object with a maximum Doppler shift of $f_{d}=30$ and assigns the constructed Doppler spectrum object to its DopplerSpectrum property.

```
dop_bigaussian = doppler.bigaussian('SigmaGaussian1', 0.1, ...
    `'SigmaGaussian2', 0.15, 'CenterFreqGaussian1', 0.7, ...
    'CenterFreqGaussian2', -0.4, 'GainGaussian1', 1, ...
    'GainGaussian2', 1/10^1.5)
```

chan $=$ rayleighchan(1e-3, 30);
chan. DopplerSpectrum = dop_bigaussian;

## doppler.flat

(To be removed) Construct flat Doppler spectrum object

Note doppler.flat will be removed in a future release. Use doppler('Flat ') instead.

## Syntax

dop $=$ doppler.flat

## Description

dop $=$ doppler.flat creates a flat Doppler spectrum object that is to be used for the DopplerSpectrum property of a channel object (created with either the rayleighchan or the ricianchan function). The maximum Doppler shift of the flat Doppler spectrum object is specified by the MaxDopplerShift property of the channel object.

## Properties

The flat Doppler spectrum object contains only one property, SpectrumType, which is read-only and has a fixed value of 'Flat'.

## Theory and Applications

In a 3-D isotropic scattering environment, where the angles of arrival are uniformly distributed in the azimuth and elevation planes, the Doppler spectrum is found theoretically to be flat [2]. A flat Doppler spectrum is also specified in some cases of the ANSI J-STD-008 reference channel models for PCS, for both outdoor (pedestrian) and indoor (commercial) [1] applications.

The normalized flat Doppler power spectrum is given analytically by:

$$
S(f)=\frac{1}{2 f_{d}},|f| \leq f_{d}
$$

where $f_{d}$ is the maximum Doppler frequency.

"Fading Channels"

## Introduced in R2007a

## doppler.gaussian

(To be removed) Construct Gaussian Doppler spectrum object

Note doppler.gaussian will be removed in a future release. Use doppler ('Gaussian', ....) instead.

## Syntax

```
dop = doppler.gaussian
dop = doppler.gaussian(sigmagaussian)
```

## Description

The doppler.gaussian function creates a Gaussian Doppler spectrum object that is to be used for the DopplerSpectrum property of a channel object (created with either the rayleighchan or the ricianchan function).
dop = doppler.gaussian creates a Gaussian Doppler spectrum object with a default standard deviation (normalized by the maximum Doppler shift $f_{d}$, in Hz ) $\sigma_{G, \text { norm }}=1 / \sqrt{2}$. The maximum Doppler shift $f_{d}$ is specified by the MaxDopplerShift property of the channel object. Analytically, $\sigma_{G, \text { norm }}=\sigma_{G} / f_{d}=1 / \sqrt{2}$, where $\sigma_{G}$ is the standard deviation of the Gaussian Doppler spectrum.
dop = doppler.gaussian(sigmagaussian) creates a Gaussian Doppler spectrum object with a normalized $f_{d}$ (by the maximum Doppler shift $f_{d}$, in Hz ) $\sigma_{G, \text { norm }}$ of value sigmagaussian.

## Properties

The Gaussian Doppler spectrum object contains the following properties.

| Property | Description |
| :--- | :--- |
| SpectrumType | Fixed value, 'Gaussian ' |
| SigmaGaussian | Normalized standard deviation of the Gaussian <br> Doppler spectrum (a real positive number) |

## Theory and Applications

The Gaussian power spectrum is considered to be a good model for multipath components with long delays in UHF communications [3]. It is also proposed as a model for the aeronautical channel [2]. A Gaussian Doppler spectrum is also specified in some cases of the ANSI J-STD-008 reference channel models for PCS applications, for both outdoor (wireless loop) and indoor (residential, office) [1]. The normalized Gaussian Doppler power spectrum is given analytically by:

$$
S_{G}(f)=\frac{1}{\sqrt{2 \Pi \sigma_{G}^{2}}} \exp \left(-\frac{f^{2}}{2 \sigma_{G}^{2}}\right)
$$

An alternate representation is [4]:

$$
S_{G}(f)=\frac{1}{f_{c}} \sqrt{\frac{\ln 2}{\Pi}} \exp \left(-(\ln 2)\left(\frac{f}{f_{c}}\right)^{2}\right)
$$

where $f_{C}=\sigma_{G} \sqrt{2 \ln 2}$ is the 3 dB cutoff frequency. If you set $f_{C}=f_{d} \sqrt{\ln 2}$, where $f_{d}$ is the maximum Doppler shift, or equivalently $\sigma_{G}=f_{d} / \sqrt{2}$, the Doppler spread of the Gaussian power spectrum becomes equal to the Doppler spread of the Jakes power spectrum, where Doppler spread is defined as:

$$
\sigma_{D}=\sqrt{\frac{\int_{-\infty}^{\infty} f^{2} S(f) d f}{\int_{-\infty}^{\infty} S(f) d f}}
$$

## Examples

The following code creates a Rayleigh channel object with a maximum Doppler shift of $f_{d}=10$. It then creates a Gaussian Doppler spectrum object with a normalized standard deviation of $\sigma_{G, \text { norm }}=0.5$, and assigns it to the DopplerSpectrum property of the channel object.
chan $=$ rayleighchan(1/1000,10);
dop_gaussian = doppler.gaussian(0.5);
chan. DopplerSpectrum = dop_gaussian;

## doppler.jakes

(To be removed) Construct Jakes Doppler spectrum object

Note doppler. jakes will be removed in a future release. Use doppler('Jakes ' ) instead.

## Syntax

## Description

dop = doppler.jakes creates a Jakes Doppler spectrum object that is to be used for the DopplerSpectrum property of a channel object (created with either the rayleighchan or the ricianchan function). The maximum Doppler shift of the Jakes Doppler spectrum object is specified by the MaxDopplerShift property of the channel object. By default, channel objects are created with a Jakes Doppler spectrum.

## Properties

The Jakes Doppler spectrum object contains only one property, SpectrumType, which is read-only and has a fixed value of 'Jakes'.

## Theory and Applications

The Jakes Doppler power spectrum model is actually due to Gans [2], who analyzed the Clarke-Gilbert model ([1], [3], and [5]). The Clarke-Gilbert model is also called the classical model.

The Jakes Doppler power spectrum applies to a mobile receiver. It derives from the following assumptions [6]:

- The radio waves propagate horizontally.
- At the mobile receiver, the angles of arrival of the radio waves are uniformly distributed over [ $-\Pi, \Pi]$.
- At the mobile receiver, the antenna is omnidirectional (i.e., the antenna pattern is circularsymmetrical).

The normalized Jakes Doppler power spectrum is given analytically by:

$$
S(f)=\frac{1}{\Pi f_{d} \sqrt{1-\left(f / f_{d}\right)^{2}}},|f| \leq f_{d}
$$

where $f_{d}$ is the maximum Doppler frequency.

## Examples

Create a Rayleigh channel object with a maximum Doppler shift of $\mathrm{fd}=10$ Hertz. Then, create a Jakes Doppler spectrum object and assigns it to the DopplerSpectrum property of the channel object.

```
chan = rayleighchan(1/1000,10);
```

dop_gaussian = doppler.jakes;
chan. DopplerSpectrum = dop_gaussian

## doppler.rjakes

(To be removed) Construct restricted Jakes Doppler spectrum object

Note doppler. rjakes will be removed in a future release. Use doppler('Restricted Jakes', ...) instead.

## Syntax

dop = doppler.rjakes
dop $=$ doppler.rjakes(freqminmaxrjakes)

## Description

The doppler. rjakes function creates a restricted Jakes (RJakes) Doppler spectrum object that is used for the DopplerSpectrum property of a channel object (created with either the rayleighchan or the ricianchan function).
dop = doppler.rjakes creates a Doppler spectrum object equivalent to the Jakes Doppler spectrum. The maximum Doppler shift of the RJakes Doppler spectrum object is specified by the MaxDopplerShift property of the channel object.
dop = doppler.rjakes(freqminmaxrjakes), where freqminmaxrjakes is a row vector of two finite real numbers between 0 and 1, creates a Jakes Doppler spectrum. This spectrum is nonzero only for normalized frequencies (by the maximum Doppler shift, $f_{d}$, in Hertz), $f_{\text {norm }}$, such that $0 \leq f_{\min , \text { norm }} \leq\left|f_{\text {norm }}\right| \leq f_{\text {max, norm }} \leq 1$, where $f_{\min , \text { norm }}$ is given by freqminmaxrjakes(1) and $f_{\text {max }, \text { norm }}$ is given by freqminmaxrjakes(2). The maximum Doppler shift $f_{d}$ is specified by the MaxDopplerShift property of the channel object. Analytically, $f_{\min , n o r m}=f_{\min } / f_{d}$ and $f_{\text {max }}$ norm $=f_{\max } / f_{d}$, where $f_{\min }$ is the minimum Doppler shift (in Hertz) and $f_{\max }$ is the maximum Doppler shift (in Hertz).

When dop is used as the DopplerSpectrum property of a channel object, freqminmaxrjakes (1) and freqminmaxrjakes (2) should be spaced by more than $1 / 50$. Assigning a smaller spacing results in freqminmaxrjakes being reset to the default value of [ 011 ].

## Properties

The RJakes Doppler spectrum object contains the following properties.

| Property | Description |
| :--- | :--- |
| SpectrumType | Fixed value, 'RJakes ' |
| FreqMinMaxRJakes | Vector of minimum and maximum normalized <br> Doppler shifts (two real finite numbers between 0 <br> and 1) |

## Theory and Applications

The Jakes power spectrum is based on the assumption that the angles of arrival at the mobile receiver are uniformly distributed [1], where the spectrum covers the frequency range from $-f_{d}$ to $f_{d}, f_{d}$ being the maximum Doppler shift. When the angles of arrival are not uniformly distributed, the Jakes power spectrum does not cover the full Doppler bandwidth from $-f_{d}$ to $f_{d}$. This exception also applies to the case where the antenna pattern is directional. This type of spectrum is known as restricted Jakes [3]. The RJakes Doppler spectrum object covers only the case of a symmetrical power spectrum, which is nonzero only for frequencies $f$ such that $0 \leq f_{\min } \leq|f| \leq f_{\max } \leq f_{d}$.

The normalized RJakes Doppler power spectrum is given analytically by:

$$
S(f)=\frac{A_{r}}{\pi f_{d} \sqrt{1-\left(f / f_{d}\right)^{2}}}, 0 \leq f_{\min } \leq|f| \leq f_{\max } \leq f_{d}
$$

where

$$
A_{r}=\frac{1}{\frac{2}{\Pi}\left[\sin ^{-1}\left(\frac{f_{\max }}{f_{d}}\right)-\sin ^{-1}\left(\frac{f_{\min }}{f_{d}}\right)\right]}
$$

$f_{\min }$ and $f_{\max }$ denote the minimum and maximum frequencies where the spectrum is nonzero. They can be determined from the probability density function of the angles of arrival.

## Examples

The following code first creates a Rayleigh channel object with a maximum Doppler shift of $f_{d}=10$. It then creates an RJakes Doppler object with minimum normalized Doppler shift $f_{\min , \text { norm }}=0.14$ and maximum normalized Doppler shift $f_{\text {max, norm }}=0.9$.

The Doppler object is assigned to the DopplerSpectrum property of the channel object. The channel then has a Doppler spectrum that is nonzero for frequencies $f$ such that $0 \leq f_{\min } \leq|f| \leq f_{\max } \leq f_{d}$, where $f_{\min }=f_{\min , \text { norm }} \times f_{d}=1.4 \mathrm{~Hz}$ and $f_{\max }=f_{\text {max }, \text { norm }} \times f_{d}=9 \mathrm{~Hz}$.

```
chan = rayleighchan(1/1000, 10);
```

dop_rjakes = doppler.rjakes([0.14 0.9]);
chañ. DopplerSpectrum = dop_rjakes;
chan. DopplerSpectrum
The output is:
SpectrumType: 'RJakes'
FreqMinMaxRJakes: [0.1400 0.9000]

## doppler.rounded

(To be removed) Construct rounded Doppler spectrum object

Note doppler. rounded will be removed in a future release. Use doppler('Rounded' , ...) instead.

## Syntax

dop = doppler.rounded
dop $=$ doppler. rounded(coeffrounded)

## Description

The doppler. rounded function creates a rounded Doppler spectrum object that is used for the DopplerSpectrum property of a channel object (created with either the rayleighchan or the ricianchan function).
dop $=$ doppler. rounded creates a rounded Doppler spectrum object with default polynomial coefficients $a_{0}=1, a_{2}=-1.72, a_{4}=0.785$ (see "Theory and Applications" on page 2-291 for the meaning of these coefficients). The maximum Doppler shift $f_{d}$ (in Hertz) is specified by the MaxDopplerShift property of the channel object.
dop = doppler.rounded(coeffrounded), where coeffrounded is a row vector of three finite real numbers, creates a rounded Doppler spectrum object with polynomial coefficients, $a_{0}, a_{2}, a_{4}$, given by coeffrounded (1), coeffrounded(2), and coeffrounded(3), respectively.

## Properties

The rounded Doppler spectrum object contains the following properties.

| Property | Description |
| :--- | :--- |
| SpectrumType | Fixed value, 'Rounded ' |
| CoeffRounded | Vector of three polynomial coefficients (real finite <br> numbers) |

## Theory and Applications

A rounded spectrum is proposed as an approximation to the measured Doppler spectrum of the scatter component of fixed wireless channels at 2.5 GHz [1]. However, the shape of the spectrum is influenced by the center carrier frequency.

The normalized rounded Doppler spectrum is given analytically by a polynomial in $f$ of order four, where only the even powers of $f$ are retained:

$$
S(f)=C_{r}\left[a_{0}+a_{2}\left(\frac{f}{f_{d}}\right)^{2}+a_{4}\left(\frac{f}{f_{d}}\right)^{4}\right],|f| \leq f_{d}
$$

where

$$
C_{r}=\frac{1}{2 f_{d}\left[a_{0}+\frac{a_{2}}{3}+\frac{a_{4}}{5}\right]}
$$

$f_{d}$ is the maximum Doppler shift, and $a_{0}, a_{2}, a_{4}$ are real finite coefficients. The fixed wireless channel model of IEEE 802.16 [1] uses the following parameters: $a_{0}=1, a_{2}=-1.72$, and $a_{4}=0.785$.
Because the channel is modeled as Rician fading with a fixed line-of-sight (LOS) component, a Dirac delta is also present in the Doppler spectrum at $f=0$.

## Examples

The following code creates a Rician channel object with a maximum Doppler shift of $f_{d}=10$. It then creates a rounded Doppler spectrum object with polynomial coefficients $a_{0}=1.0, a_{2}=-0.5$, $a_{4}=1.5$, and assigns it to the DopplerSpectrum property of the channel object.

```
chan = ricianchan(1/1000,10,1);
```

dop_rounded = doppler. rounded([1.0-0.5 1.5]);
chan.DopplerSpectrum = dop_rounded;

## dpcmdeco

Decode using differential pulse code modulation

## Syntax

sig = dpcmdeco(indx, codebook, predictor)
[sig,quanterror] = dpcmdeco(indx,codebook, predictor)

## Description

sig = dpcmdeco(indx, codebook, predictor) implements differential pulse code demodulation to decode the vector indx. The vector codebook represents the predictive-error quantization codebook. The vector predictor specifies the predictive transfer function. If the transfer function has predictive order M, predictor has length $\mathrm{M}+1$ and an initial entry of 0 . To decode correctly, use the same codebook and predictor in dpcmenco and dpcmdeco.

See "Represent Partitions", "Represent Codebooks", or the quantiz reference page, for a description of the formats of partition and codebook.
[sig,quanterror] = dpcmdeco(indx,codebook,predictor) is the same as the syntax above, except that the vector quanterror is the quantization of the predictive error based on the quantization parameters. quanterror is the same size as sig.

Note You can estimate the input parameters codebook, partition, and predictor using the function dpcmopt.

## Examples

See "Example: DPCM Encoding and Decoding" and "Example: Comparing Optimized and Nonoptimized DPCM Parameters" for examples that use dpcmdeco.

## References

## dpcmenco

Encode using differential pulse code modulation

## Syntax

indx = dpcmenco(sig, codebook,partition, predictor)
[indx,quants] = dpcmenco(sig, codebook, partition, predictor)

## Description

indx = dpcmenco(sig, codebook, partition, predictor) implements differential pulse code modulation to encode the vector sig. partition is a vector whose entries give the endpoints of the partition intervals. codebook, a vector whose length exceeds the length of partition by one, prescribes a value for each partition in the quantization. predictor specifies the predictive transfer function. If the transfer function has predictive order M, predictor has length M+1 and an initial entry of 0 . The output vector indx is the quantization index.

See "Differential Pulse Code Modulation" for more about the format of predictor. See "Represent Partitions", "Represent Partitions", or the reference page for quantiz in this chapter, for a description of the formats of partition and codebook.
[indx,quants] = dpcmenco(sig, codebook, partition, predictor) is the same as the syntax above, except that quants contains the quantization of sig based on the quantization parameters. quants is a vector of the same size as sig.

Note If predictor is an order-one transfer function, the modulation is called a delta modulation.

## Examples

See "Example: DPCM Encoding and Decoding" and "Example: Comparing Optimized and Nonoptimized DPCM Parameters" for examples that use dpcmenco.

## References

## Topics

"Differential Pulse Code Modulation"

Introduced before R2006a

## dpcmopt

Optimize differential pulse code modulation parameters

## Syntax

predictor = dpcmopt(training_set,ord)
[predictor,codebook, partition] = dpcmopt(training_set,ord,len)
[predictor,codebook, partition] = dpcmopt(training_set,ord,ini_cb)

## Description

predictor = dpcmopt(training_set,ord) returns a vector representing a predictive transfer function of order ord that is appropriate for the training data in the vector training_set.
predictor is a row vector of length ord +1 . See "Represent Predictors" for more about its format.

Note dpcmopt optimizes for the data in training_set. For best results, training_set should be similar to the data that you plan to quantize.
[predictor,codebook,partition] = dpcmopt(training_set,ord,len) is the same as the syntax above, except that it also returns corresponding optimized codebook and partition vectors codebook and partition. len is an integer that prescribes the length of codebook. partition is a vector of length len-1. See "Represent Partitions", "Represent Codebooks", or the reference page for quantiz in this chapter, for a description of the formats of partition and codebook.
[predictor,codebook,partition] = dpcmopt(training_set,ord,ini_cb) is the same as the first syntax, except that it also returns corresponding optimized codebook and partition vectors codebook and partition. ini_cb, a vector of length at least 2 , is the initial guess of the codebook values. The output codebook is a vector of the same length as ini_cb. The output partition is a vector whose length is one less than the length of codebook.

## Examples

See "Example: Comparing Optimized and Nonoptimized DPCM Parameters" for an example that uses dpcmopt.

## dpskdemod

Differential phase shift keying demodulation

## Syntax

```
z = dpskdemod(y, M)
z = dpskdemod(y,M,phaserot)
\(z=\operatorname{dpskdemod}(y, M\), phaserot, symorder)
```

## Description

$z=d p s k d e m o d(y, M)$ demodulates the complex envelope, $y$, of a DPSK-modulated signal having modulation order M .
$z=d p s k d e m o d(y, M$, phaserot $)$ specifies the phase rotation of the DPSK modulation.
z = dpskdemod(y,M, phaserot,symorder) also specifies the symbol order.

## Examples

## DPSK Demodulation

Demodulate DPSK data in a communication channel in which a phase shift is introduced.
Generate a 4 -ary data vector and modulate it using DPSK.

```
M = 4; % Alphabet size
dataIn = randi([0 M-1],1000,1); % Random message
txSig = dpskmod(dataIn,M); % Modulate
```

Apply the random phase shift resulting from the transmission process.

```
rxSig = txSig*exp(2i*pi*rand());
```

Demodulate the received signal.

```
dataOut = dpskdemod(rxSig,M);
```

The modulator and demodulator have the same initial condition. However, only the received signal experiences a phase shift. As a result, the first demodulated symbol is likely to be in error. Therefore, you should always discard the first symbol when using DPSK.

Find the number of symbol errors.

```
errs = symerr(dataIn,data0ut)
errs = 1
```

One symbol is in error. Repeat the error calculation after discarding the first symbol.

```
errs = symerr(dataIn(2:end),dataIn(2:end))
```

```
errs = 0
```

## Input Arguments

## y - DPSK-modulated input signal

vector | matrix
DPSK-modulated input signal, specified as a real or complex vector or matrix. If y is a matrix, the function processes the columns independently.

Data Types: double
Complex Number Support: Yes

## M - Modulation order

integer power of two
Modulation order, specified as an integer power of two.
Example: 2 | 4 | 16
Data Types: double
phaserot - Phase rotation
0 (default) | scalar | [ ]
Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of phaserot and the phase generated by the differential modulation.

If you specify phaserot as empty, then dspkdemod uses a phase rotation of 0 degrees.
Example: pi/4
Data Types: double

## symorder - Symbol order

'bin' (default)|'gray'
Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

## Output Arguments

## z - DPSK-demodulated output signal

vector | matrix
DPSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal $y$.

Note The differential algorithm used in this function compares two successive elements of a modulated signal. To determine the first element of vector $z$, or the first row of matrix $z$, the function uses an initial phase rotation of 0 .

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## See Also

"Phase Modulation"

Introduced before R2006a

## dpskmod

Differential phase shift keying modulation

## Syntax

$y=d p s k m o d(x, M)$
$y=d p s k m o d(x, M$, phaserot $)$
$\mathrm{y}=\mathrm{dpskmod}(\mathrm{x}, \mathrm{M}$, phaserot, symorder)

## Description

$\mathrm{y}=\mathrm{dpskmod}(\mathrm{x}, \mathrm{M})$ modulates the input signal using differential phase shift keying (DPSK) with modulation order M .
$y=d p s k m o d(x, M, p h a s e r o t)$ specifies the phase rotation of the DPSK modulation.
$y=d p s k m o d(x, M, p h a s e r o t, s y m o r d e r)$ also specifies the symbol order.

## Examples

## View Signal Trajectory of DPSK-Modulated Signal

Plot the output of the dspkmod function to view the possible transitions between DPSK symbols.
Set the modulation order to 4 to model DQPSK modulation.
M = 4;
Generate a sequence of 4-ary random symbols.
$x=$ randi([0 M-1],500,1);
Apply DQPSK modulation to the input symbols.
y = dpskmod(x,M,pi/8);
Specify a constellation diagram object to display a signal trajectory diagram and without displaying the corresponding reference constellation. Display the trajectory.

```
cd = comm.ConstellationDiagram('ShowTrajectory',true,'ShowReferenceConstellation',false);
cd(y)
```

## Input Arguments

## x - Input signal

vector | matrix
Input signal, specified as a vector or matrix of positive integers. The elements of $x$ must have values in the range of $[0, M-1]$.

Data Types: double

## M - Modulation order

integer power of two
Modulation order, specified as an integer power of two.
Example: 2 | 4 | 16
Data Types: double

## phaserot - Phase rotation

0 (default) | scalar | [ ]
Phase rotation of the DPSK modulation, specified in radians as a real scalar. The total phase shift per symbol is the sum of phaserot and the phase generated by the differential modulation.

If you specify phaserot as empty, then dpskmod uses a phase rotation of 0 degrees.
Example: pi/4
Data Types: double
symorder - Symbol order
'bin' (default)|'gray'
Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.

- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

## Output Arguments

## y - DPSK-modulated output signal

vector | matrix
Complex baseband representation of a DPSK-modulated output signal, returned as vector or matrix of complex values. The columns represent independent channels.

Note An initial phase rotation of 0 is used in determining the first element of the output $y$ (or the first row of $y$ if it is a matrix with multiple rows), because two successive elements are required for a differential algorithm.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\mathrm{Tm}}$.

## Topics

"Phase Modulation"

Introduced before R2006a

## dvbs2Idpc

Low-density parity-check (LDPC) codes from DVB-S. 2 standard

## Syntax

$H=d v b s 2 l d p c(r)$
H = dvbs2ldpc(r,outputFormat)

## Description

$H=\operatorname{dvbs} 2 l d p c(r)$ returns the parity-check matrix $H$ of the LDPC code with code rate $r$ from the Digital Video Broadcasting standard DVB-S.2. The block length of the code is 64,800 .
$H=d v b s 2 l d p c(r$, outputFormat $)$ specifies the format for the output parity-check matrix.

## Examples

## Create LDPC Code Parity-Check Matrix from DVB-S. 2 Standard

Create an LDPC parity check matrix for a code rate of $3 / 5$ from the DVB-S. 2 standard.
p = dvbs2ldpc(3/5);
Create an LDPC encoder object from the parity-check matrix p .
enc = comm.LDPCEncoder(p);
The parity-check matrix has dimensions of ( $N-K$ )-by- $N$. Calculate the length of the input message.
msgLength $=\operatorname{size}(\mathrm{p}, 2)-\operatorname{size}(\mathrm{p}, 1)$
msgLength $=38880$

## Input Arguments

## r-Code rate

$1 / 4|1 / 3| 2 / 5|1 / 2| . .$.
Code rate, specified as $1 / 4,1 / 3,2 / 5,1 / 2,3 / 5,2 / 3,3 / 4,4 / 5,5 / 6,8 / 9$, or $9 / 10$.
Data Types: double

## outputFormat - Output format

'sparse'|'indices'
Output format for parity-check matrix H, specified as 'sparse' or 'indices'.
If you set this value to 'sparse', H is a sparse logical matrix. If you set this value to 'indices ', H is a two-column matrix that defines the row and column indices of the 1 s in H .

## Data Types: char|string

## Output Arguments

## H - Parity-check matrix

## numeric matrix

Parity-check matrix, returned as a numeric matrix.
The default parity-check matrix of size 32,400-by-64,800 corresponds to an irregular LDPC code with the structure shown in this table.

| Row | Number of 1s per Row |
| :--- | :--- |
| 1 | 6 |
| 2 to 32400 | 7 |

| Column | Number of 1s per Column |
| :--- | :--- |
| 1 to 12960 | 8 |
| $12961-32400$ | 3 |

Columns from 32,401 to 64,800 form a lower triangular matrix. Only the elements on the main diagonal of the matrix and the subdiagonal immediately below the main diagonal are 1s. This LDPC code is used in conjunction with a BCH code in the DVB-S. 2 standard to achieve a packet error rate below $10^{-7}$ at about 0.7 dB to 1 dB from the Shannon limit.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
All inputs must be constants. Expressions or variables are allowed if their values do not change.

Introduced in R2007a

## dvbsapskdemod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) demodulation

## Syntax

```
z = dvbsapskdemod(y,M,stdSuffix)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF)
z = dvbsapskdemod(y,M,stdSuffix,codeIDF,frameLength)
z = dvbsapskdemod(
```

$\qquad$

``` ,Name, Value)
```

## Description

$z=d v b s a p s k d e m o d(y, M, s t d S u f f i x)$ demodulates an APSK input signal, $y$, that was modulated in accordance with the digital video broadcast (DVB) standard identified by stdSuffix and the modulation order, M. For a description of DVB-compliant APSK demodulation, see "DVB Compliant APSK Hard Demodulation" on page 2-310 and "DVB Compliant APSK Soft Demodulation" on page 2310.
z = dvbsapskdemod(y, M, stdSuffix, codeIDF) specifies code identifier codeIDF, to use when selecting the demodulation parameters.
$z=d v b s a p s k d e m o d(y, M, s t d S u f f i x$, codeIDF,frameLength) specifies codeIDF and frameLength to use when selecting the demodulation parameters.
z = dvbsapskdemod( $\qquad$ , Name, Value) specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType', 'double' specifies the desired output data type. Specify name-value pair arguments after all other input arguments.

## Examples

## Demodulate DVB-S2X Specific 64-APSK Signal

Demodulate a 64 -APSK signal that was modulated as specified in DVB-S2X. Compute hard decision integer output and verify that the output matches the input.

Set the modulation order and standard suffix. Generate random data.

```
M = 64;
std = 's2x';
x = randi([0 M-1],1000,1);
```

Modulate the data.
y = dvbsapskmod(x,M,std);
Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std);
isequal(z,x)
```

```
ans = logical
```

    1
    
## Demodulate DVB-S2 Specific 32-APSK Signal

Demodulate a 32-APSK signal that was modulated as specified in DVB-S2. Compute hard decision bit output and verify that the output matches the input.

Set the modulation order, standard suffix, and code identifier. Generate random bit data.

```
M = 32;
std = 's2';
codeIDF = '4/5';
numBitsPerSym = log2(M);
x = randi([0 1],100*numBitsPerSym,1,'uint32');
```

Modulate the data. Use a name-value pair to specify bit input data.
y = dvbsapskmod(x,M,std,codeIDF,'InputType','bit');
Demodulate the received signal. Compare the demodulated data to the original data.

```
z = dvbsapskdemod(y,M,std,'4/5','OutputType','bit', ...
    'OutputDataType','uint32');
isequal(z,x)
ans = logical
    1
```

## Soft Bit Demodulate DVB-SH Specific 16-APSK Signal

Demodulate a DVB-SH compliant 16-APSK signal and calculate soft bits.
Set the modulation order and generate a random bit sequence.

```
M = 16;
std = 'sh';
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1],numSym*numBitsPerSym,1);
```

Modulate the data. Use a name-value pair to specify bit input data.

```
txSig = dvbsapskmod(x,M,std,'InputType','bit');
```

Pass the modulated signal through a noisy channel.

```
rxSig = awgn(txSig,10,'measured');
```

View the constellation of the received signal using a scatter plot.

```
scatterplot(rxSig)
```

DVB-SH compliant constellations have unit average power. Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = dvbsapskdemod(rxSig,M,std,'OutputType','approxllr', ...
```

    'NoiseVariance',0.1);
    
## Input Arguments

## y - APSK modulated signal

scalar | vector | matrix
APSK modulated signal, specified as a complex scalar, vector, or matrix. When y is a matrix, each column is treated as an independent channel.
y must be modulated in accordance with Digital Video Broadcasting (DVB) - Satellite Communications standard DVB-S2, DVB-S2X or DVB-SH. For more information, see [1], [2], and [3].
Data Types: single | double
Complex Number Support: Yes
Complex Number Support: Yes

## M - Modulation order

integer
Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

## Data Types: double

## stdSuffix - Standard suffix <br> 's2'|'s2x'|'s2h'

Standard suffix for DVBS modulation variant, specified as 's2', 's2x', or 's2h'.
Data Types: char|string
codeIDF - Code identifier
char \| string
Code identifier, specified as a character vector or string. This table lists the acceptable codeIDF values.

| Constellation Order (M) | Applicable Standard (stdSuffix) | Acceptable Code Identifier (CodeIDF) Values |
| :---: | :---: | :---: |
| 16 | 's2' or 's2x' | $\begin{aligned} & \text { '2/3', '3/4','4/5', '5/6', } \\ & \text { '8/9', '9/10' } \end{aligned}$ |
| 16 | 's2x' | '26/45','3/5','28/45', '23/36', '25/36','13/18', '7/9','77/90','100/180', '96/180','90/180', '18/30', '20/30' '3/4' |
| 32 | 's2' or 's2x' | $\begin{aligned} & \text { '3/4', '4/5', '5/6', '8/9', } \\ & \text { '9/10' } \end{aligned}$ |
| 32 | 's2x' | $\begin{aligned} & \text { '32/45', '11/15', '7/9', } \\ & \text { '2/3' } \end{aligned}$ |
| 64 | 's2x' | $\begin{aligned} & \text { '11/15','7/9','4/5', } \\ & \text { '5/6', '128/180' } \end{aligned}$ |
| 128 | 's2x' | '3/4', '7/9' |
| 256 | 's2x' | '32/45', '3/4', '116/180' '20/30', '124/180', '22/30' |

For more information, refer to Tables 9 and 10 in the DVB-S2 standard [1] and Table 17a in the DVBS2X standard [2].

## Dependencies

This input argument applies only when stdSuffix is set to 's2' or 's $2 x^{\prime}$ '.
Data Types: char | string

## frameLength - Frame length

'normal' (default)|'short'
Frame length, specified as 'normal' or 'short'. The function usesframeLength and codeIDF to select the modulation parameters.

## Dependencies

This input argument applies only when stdSuffix is set to 's2' or 's $2 x^{\prime}$ '.
Data Types: char | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: y =
dvbsapskdemod(x,M,stdSuffix,'InputType','bit','OutputDataType','single');

## OutputType - Output type

'integer' (default)|'bit'|'llr'|'approxllr'
Output type, specified as the comma-separated pair consisting of OutputType and 'integer', 'bit', 'llr', or 'approxllr'. For a description of returned output, see z.
Data Types: char \| string

## OutputDataType - Output data type

'double' (default)|...
Output data type, specified as the comma-separated pair consisting of OutputDataType and one of the indicated data types. Acceptable values for OutputDataType depend on the OutputType value.

| OutputType Value | Acceptable OutputDataType Values |
| :--- | :--- |
| 'integer' | 'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', <br> or 'uint32' |
| 'bit' | 'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', <br>  $\mathbf{~ u i n t 3 2 ' , ~ o r ~ ' l o g i c a l ' ~}$ |

## Dependencies

This name-value pair argument applies only when OutputType is set to 'integer' or 'bit'.
Data Types: char | string

## UnitAveragePower - Unit average power flag

false (default) | true
Unit average power flag, specified as the comma-separated pair consisting of UnitAveragePower and a logical scalar. When this flag is true, the function scales the constellation to an average power of 1 watt referenced to 1 ohm . When this flag is false, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

Note When stdSuffix is set to 'sh', the constellation always has unit average power.

## Dependencies

This name-value pair argument applies only when stdSuffix is set to 's2' or 's2x'.
Data Types: logical

## NoiseVariance - Noise variance

1 (default) | positive scalar | vector of positive values

Noise variance, specified as the comma-separated pair consisting of NoiseVariance and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "DVB Compliant APSK Soft Demodulation" on page 2-310 for algorithm selection considerations.

## Dependencies

This name-value pair argument applies only when OutputType is set to ' $l l r$ ' or 'approxllr'.
Data Types: double

## PlotConstellation - Option to plot constellation

false (default) | true
Option to plot constellation, specified as the comma-separated pair consisting of
'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.
Data Types: logical

## Output Arguments

## z - Demodulated signal

scalar | vector | matrix
Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of the output vary depending on the specified OutputType value.

| OutputType <br> Value | Return Value of <br> dvbsapskdemod | Dimensions of z |
| :--- | :--- | :--- |
| 'integer' | Demodulated integer values <br> from 0 to (M - 1) | z has the same dimensions as input y. |
| 'bit' | Demodulated bits | The number of rows in z is $\log _{2}($ sum(M) ) times the <br> number of rows in y. Each demodulated symbol is <br> mapped to a group of $\log _{2}($ sum $(M))$ elements in a <br> column, where the first element represents the <br> MSB and the last element represents the LSB. |
| 'llr' | Log-likelihood ratio value for <br> each bit | Approximate log-likelihood ratio <br> value for each bit |
| 'approxllr' |  |  |

## More About

## DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

## DVB Compliant APSK Hard Demodulation

The hard demodulation algorithm applies amplitude phase decoding as described in [4].

## DVB Compliant APSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

| Algorithm | Accuracy | Execution Speed |
| :--- | :--- | :--- |
| Exact LLR | more accurate | slower execution |
| Approximate LLR | less accurate | faster execution |

For further description of these algorithms, see "Exact LLR Algorithm" and "Approximate LLR Algorithm".

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or - Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## dvbsapskmod

DVB-S2/S2X/SH standard-specific amplitude phase shift keying (APSK) modulation

## Syntax

```
y = dvbsapskmod(x,M,stdSuffix)
y = dvbsapskmod(x,M,stdSuffix, codeIDF)
y = dvbsapskmod(x,M,stdSuffix, codeIDF,frameLength)
y = dvbsapskmod( __, ,Name,Value)
```

## Description

$y=d v b s a p s k m o d(x, M$, stdSuffix) performs APSK modulation on the input signal, $x$, in accordance with the digital video broadcast (DVB) standard identified by stdSuffix and the modulation order, M .
$y=d v b s a p s k m o d(x, M, s t d S u f f i x$, codeIDF) specifies the code identifier, codeIDF, to use when selecting the modulation parameters.
y = dvbsapskmod(x,M,stdSuffix,codeIDF,frameLength) specifies codeIDF and frameLength to use when selecting the modulation parameters.
$y=d v b s a p s k m o d(\ldots$, , Name, Value) specifies options using one or more name-value pair arguments using any of the previous syntaxes. For example, 'OutputDataType','double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

## Apply DVB-S2X 32-APSK Modulation to Data

Modulate data using the DVB-S2X standard specified 32-APSK modulation scheme. Display the result in a scatter plot.

Set the modulation order and the suffix identifying the DVB-S2X standard. Create a data vector with all possible symbols.

```
M = 32;
stdSuffix = 's2x';
x = (0:M-1);
```

Modulate the data.

```
y = dvbsapskmod(x,M,stdSuffix);
```

Display the constellation using a scatter plot.

```
scatterplot(y)
```

## Apply DVB-S2X 64-APSK Modulation Specifying Code Identifier

Modulate data using 64-APSK as specified in DVB-S2X standard. Plot constellation for different code identifiers.

Set the modulation order and standard suffix. Generate 1000 symbols of random data in one channel.
$M=64 ;$
std = 's2x';
$x=\operatorname{randi}([0 \mathrm{M}-1], 1000,1)$;
Modulate the data according to the 64-APSK constellation for the code identifier 7/9 and plot the reference constellation.
y1 = dvbsapskmod(x,M,std,'7/9','PlotConstellation',true);

DVB-S2x 64(8+16+20+20)-APSK with Code Rate 7/9, UnitAveragePower=false

Modulate setting the code identifier to 132/180 and observe the constellation structure differences.
y2 = dvbsapskmod(x,M,std,'132/180','PlotConstellation',true);

## Apply DVB-S2 16-APSK Modulation Change Frame Length

Modulate data using 16-APSK as specified in DVB-S2 standard for normal and short frame lengths. Compute the output signal power.

Set the modulation order and the standard suffix. Generate random bit data for 1000 symbols in one channel.

M = 16;
std = 's2';
$\mathrm{x}=\mathrm{randi}([0 \mathrm{1}], 1000 * \log 2(\mathrm{M}), 1)$;
Set the input type to bit and modulate the data according to the 16-APSK constellation for code identifier $2 / 3$. Use the default normal frame length.
y1 = dvbsapskmod(x,M,std,'2/3','InputType','bit');
Modulate the data using different settings, set the code-identifier to $8 / 9$ and use a short frame length.
y2 = dvbsapskmod(x,M,std,'8/9','short','InputType','bit');
The average power of the modulated signal changes based on the code identifier. Compute the average power of the modulated signals.
ylavgPow $=$ mean (abs(y1).^2)

```
ylavgPow = 0.7590
y2avgPow = mean(abs(y2).^2)
y2avgPow = 0.7716
```

## Normalize 16-APSK Modulated DVB Signals by Average Power

Modulate data applying 16-APSK as specified in the DVB-SH and DVB-S2 standards. Normalize the modulator output so that it has an average signal power of 1 W .

Set the modulation order and generate all possible symbols.
$M=16 ;$
$x=0: M-1$;
Modulate the data applying 16-APSK as specified in DVB-SH. Use a name-value pair to specify single data type output.

```
y1 = dvbsapskmod(x,M,'sh','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use a name-value pair to specify single data type output.

```
y2 = dvbsapskmod(x,M,'s2','OutputDataType','single');
```

Modulate the data applying 16-APSK as specified in DVB-S2. Use name-value pairs to set unit average power to true and to specify single data type output.

```
y3 = dvbsapskmod(x,M,'s2','UnitAveragePower',true,'OutputDataType','single');
```

Check which signals have unit average power.

```
ylavgPow = mean(abs(y1).^2)
ylavgPow = single
    1
y2avgPow = mean(abs(y2).^2)
y2avgPow = single
    0.7752
y3avgPow = mean(abs(y3).^2)
y3avgPow = single
    1.0000
```

## Input Arguments

Input signal, specified as a scalar, vector, or matrix. The elements of $x$ must be binary values or integers that range from 0 to $(M-1)$, where $M$ is the modulation order.

Note To process the input signal as binary elements, set 'InputType' value to 'bit'. For binary inputs, the number of rows must be an integer multiple of $\log _{2}(\mathrm{M})$. A group of $\log _{2}(\mathrm{M})$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: double | single | int8|int16| int32 | uint8|uint16|uint32|logical

## M - Modulation order

integer
Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.
Data Types: double

## stdSuffix - Standard suffix

```
's2'|'s2x'|'sh'
```

Standard suffix for DVBS modulation variant, specified as 's2', 's2x', or 'sh'.

## Data Types: char | string

## codeIDF - Code identifier

char \| string
Code identifier, specified as a character vector or string. This table lists the acceptable codeIDF values.

| Constellation Order (M) | Applicable Standard (stdSuffix) | Acceptable Code Identifier (CodeIDF) Values |
| :---: | :---: | :---: |
| 16 | 's2' or 's2x' | '2/3', '3/4', '4/5', '5/6', '8/9', '9/10' $' 26 / 45 ' ~$ |
| 16 | 's2x' | '26/45', '3/5','28/45', <br> '23/36', '25/36','13/18', <br> '7/9','77/90','100/180', <br> '96/180','90/180', <br> '18/30', $20 / 30^{\prime}$ |
| 32 | 's2' or 's2x' | $\begin{aligned} & \text { '3/4', '4/5', '5/6', '8/9' } \\ & \text { '9/10' } \end{aligned}$ |
| 32 | 's2x' | $\begin{aligned} & \text { '32/45', '11/15', '7/9', } \\ & \text { '2/3' } \end{aligned}$ |
| 64 | 's2x' | $\begin{aligned} & \text { '11/15','7/9','4/5', } \\ & \text { '5/6', '128/180' } \end{aligned}$ |
| 128 | 's2x' | '3/4', '7/9' |
| 256 | 's2x' | $\begin{aligned} & \hline \text { '32/45', '3/4', '116/180', } \\ & \text { '20/30', '124/180', '22/30' } \end{aligned}$ |

For more information, refer to Tables 9 and 10 in the DVB-S2 standard, [1], and Table 17a in the DVBS2X standard, [2].

## Dependencies

This input argument applies only when stdSuffix is set to 's2' or 's $2 x^{\prime}$ '.
Data Types: char | string

```
frameLength - Frame length
'normal' (default)|'short'
```

Frame length, specified as 'normal' or 'short'. frameLength and codeIDF are used to determine the modulation parameters.

## Dependencies

This input argument applies only when stdSuffix is set to 's2' or 's2x'.
Data Types: char | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: y = dvbsapskmod(x,M,std,'InputType','bit','OutputDataType','single');

## InputType - Input type

'integer' (default)|'bit'
Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. To use 'integer', the input signal must consist of integer values from 0 to ( $\mathrm{M}-1$ ). To use 'bit ', the input signal must contain binary values and the number of rows must be an integer multiple of $\log _{2}(\mathrm{M})$.

## Data Types: char | string

## UnitAveragePower - Unit average power flag <br> false (default) | true

Unit average power flag, specified as the comma-separated pair consisting of 'UnitAveragePower' and a logical scalar. When this flag is true, the function scales the constellation to an average power of 1 watt referenced to 1 ohm . When this flag is false, the function scales the constellation based on specifications in the relevant standard, as described in [1] and [2].

Note When stdSuffix is set to 'sh', the constellation always has unit average power.

## Dependencies

This name-value pair argument applies only when stdSuffix is set to 's2' or 's2x'.

```
Data Types: logical
```

## OutputDataType - Output data type

'double' (default)|'single'

Output data type, specified as the comma-separated pair consisting of 'OutputDataType' and either 'double' or 'single'.
Data Types: char | string

## PlotConstellation - Option to plot constellation <br> false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.
Data Types: logical

## Output Arguments

y - Modulated signal
scalar | vector | matrix
Modulated signal, returned as a complex scalar, vector, or matrix. The dimensions of $y$ depend on the specified 'InputType' value.

| 'InputType' Value | Dimensions of $y$ |
| :--- | :--- |
| 'integer' | y has the same dimensions as input x. |
| 'bit' | The number of rows in y equals the number of rows in x divided by $\log _{2}(\mathrm{M})$. |

Data Types: double | single

## More About

## DVB-S2/S2X/SH

Digital video broadcasting (DVB) standards specify S2, S2X, and SH standard-specific amplitude phase shift keying (APSK) modulation. For further information on the DVB-S2/S2X/SH standards, see specified in [1], [2], and [3], respectively.

## encode

Block encoder

## Syntax

```
code = encode(msg,n,k)
code = encode(msg,n,k,codingMethod,prim_poly)
code = encode(msg,n,k,codingMethod,genmat)
code = encode(msg,n,k,codingMethod,genpoly)
[code,added] = encode(
```

$\qquad$

``` )
```

## Description

code $=$ encode(msg, $\mathrm{n}, \mathrm{k}$ ) encodes message, msg, using the Hamming encoding method with codeword length, $n$, and message length, $k$. The value of $n$ must be calculated for an integer, $m$, such that $m \geq 2$. The values of n and k are calculated as $2^{m}-1$ and $\mathrm{n}-m$, respectively.
code $=$ encode(msg, $n, k$, codingMethod,prim_poly) encodes msg using codingMethod as the Hamming encoding method, and prim_poly as the primitive polynomial. The value of n must be calculated for an integer, $\mathrm{m} \geq 2$.
code $=$ encode(msg, $n, k$, codingMethod, genmat) encodes msg using codingMethod as the linear block encoding method and genmat as the generator matrix. The value of n must be calculated for an integer, $\mathrm{m} \geq 2$.
code $=$ encode(msg, $n, k$, codingMethod, genpoly) encodes msg using codingMethod as the systematic cyclic code and genpoly, as the generator polynomial. The value of $n$ must be calculated for an integer, $\mathrm{m} \geq 2$.
[code, added] = encode ( __ ) returns the additional variable added. added denotes the number of zeros appended at the end of the message matrix before encoding. You can specify any of the input argument combinations from the previous syntaxes.

## Examples

## Encode and Decode Message with Hamming Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 11; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Encode the message.
encData $=$ encode(data, $n, k$,'hamming/binary');

Corrupt the encoded message sequence by introducing an error in the fourth bit.
encData(4) $=$ ~encData(4);
Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'hamming/binary');
numerr = biterr(data,decData)
numerr = 0
```

## Encode and Decode Message with Linear Block Code

Set the values of codeword length and message length.

```
n = 7; % Codeword length
k = 3; % Message length
```

Create a random binary message with length equal to the message length.

```
data = randi([0 1],k,1);
```

Create a cyclic generator polynomial. Then, create a parity-check matrix and convert it into a generator matrix.

```
pol = cyclpoly(n,k);
parmat = cyclgen(n,pol);
genmat = gen2par(parmat);
```

Encode the message sequence by using the generator matrix.

```
encData = encode(data,n,k,'linear/binary',genmat);
```

Corrupt the encoded message sequence by introducing an error in the third bit.

```
encData(3) = ~encData(3);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'linear/binary',genmat);
Single-error patterns loaded in decoding table. }8\mathrm{ rows remaining.
2-error patterns loaded. 1 rows remaining.
3-error patterns loaded. 0 rows remaining.
numerr = biterr(data,decData)
numerr = 0
```

## Encode and Decode Message with Cyclic Block Code

Set the values of the codeword length and message length.

```
n = 15; % Codeword length
k = 5; % Message length
```

Create a random binary message with length equal to the message length.
data $=$ randi([0 1],k,1);
Create a generator polynomial for a cyclic code. Create a parity-check matrix by using the generator polynomial.

```
genpoly = cyclpoly(n,k);
parmat = cyclgen(n,genpoly);
```

Create a syndrome decoding table by using the parity-check matrix.

```
trt = syndtable(parmat);
Single-error patterns loaded in decoding table. }1008\mathrm{ rows remaining.
2-error patterns loaded. }918\mathrm{ rows remaining.
3-error patterns loaded. }648\mathrm{ rows remaining.
4-error patterns loaded. }243\mathrm{ rows remaining.
5-error patterns loaded. 0 rows remaining.
```

Encode the data by using the generator polynomial.

```
encData = encode(data,n,k,'cyclic/binary',genpoly);
```

Corrupt the encoded message sequence by introducing errors in the first, second, fourth and seventh bits.

```
encData(1) = ~encData(1);
encData(2) = ~encData(2);
encData(4) = ~encData(4);
```

Decode the corrupted sequence. Observe that the decoder has correctly recovered the message.

```
decData = decode(encData,n,k,'cyclic/binary',genpoly,trt);
numerr = biterr(data,decData)
numerr = 0
```

## Input Arguments

## msg - Input messages

binary column or row vector | binary matrix with k columns | column or row vector of integers in the range [0, $2^{\mathrm{k}}-1$ ]

Input messages, specified as one of these options:

- Binary column or row vector with k columns
- Binary matrix with k columns
- Column or row vector of $k$ columns and having integers in the range $\left[0,2^{\mathrm{k}}-1\right]$

Example: msg =[[0110, 0101 , 10011$]$ specifies a binary row vector for $k=4$.
Example: msg =[0 1 1 0; 0101 ; 1001$]$ specifies a binary matrix for $\mathrm{k}=4$.
Example: $\mathrm{msg}=[6,10,9]$ specifies a row vector of integers for $\mathrm{k}=4$.
Data Types: double
n - Codeword length
positive integer
Codeword length, specified as a positive integer. The function calculates this value as $2^{\wedge} m-1$, where $m$ must be greater than or equal to 2 .
Data Types: double
k - Message length
positive integer
Message length, specified as a positive integer. The function calculates this value as n-m, where $m$ must be greater than or equal to 2 .
Data Types: double
codingMethod - Error coding method and format
'hamming/binary' (default)|'hamming/decimal'|'linear/binary'|...
Error coding method and format, specified as one of these:

- 'hamming/binary'
- 'hamming/decimal'
- 'linear/binary'
- 'linear/decimal'
- 'cyclic/binary'
- 'cyclic/decimal'

Data Types: char|string
prim_poly - Primitive polynomial
gfprimdf( $n-k$ ) (default) | binary row vector | character vector \| string scalar | positive integer
Primitive polynomial, specified as one of these options:

- Binary row vector - This vector gives coefficients of prim_poly in the order of ascending powers.
- Character vector or a string scalar - This value defines prim_poly in textual representation. For more information, see polynomial character vector.
- Positive integer - This value defines prim_poly in the range $\left[2^{m}+1,2^{m+1}-1\right]$.

For more information about default primitive polynomials, see "Default Primitive Polynomials" on page 2-388. For more information about the representation of primitive polynomials, see "Primitive Polynomials and Element Representations".
Data Types: double | char | string

## genmat - Generator matrix

k-by-n numeric matrix
Generator matrix, specified as a k-by-n numeric matrix.
Data Types: double

## genpoly - Generator polynomial

cyclpoly ( $n-k$ ) (default) | binary row vector | character vector $\mid$ string scalar
Generator polynomial, specified as a polynomial character vector or a row vector that gives the coefficients in order of ascending powers of the binary generator polynomial. The value of genpoly for an [ $\mathrm{n}, \mathrm{k}$ ] cyclic code must have degree $\mathrm{n}-\mathrm{k}$ and divide $x^{\mathrm{n}}-1$, where $x$ is an identifier.
Data Types: char | string

## Output Arguments

## code - Output code

binary column or row vector | binary matrix with $n$ columns | column or row vector of integers in the range $\left[0,2^{\mathrm{n}}-1\right]$.

Output code, returned as one of the options in this table. The value and dimension of code depends on the value and dimension of the "msg" on page 2-0 and the input message format according to this table:

| msg Value | Input Message Format | code Value |
| :--- | :--- | :--- |
| Binary column or row vector | binary | Binary column or row vector |
| Binary matrix with k columns | binary | Binary matrix with n columns |
| Column or row vector of <br> integers in the range $\left[0,2^{\mathrm{k}}-1\right]$ | decimal | Column or row vector of integers <br> in the range $\left[0,2^{\mathrm{n}}-1\right]$ |

## added - Additional variable

nonnegative integer
Additional variable, returned as the number of zeros that were appended at the end of the message matrix before encoding for the matrix to have the appropriate size. The size of the message matrix depends on the $\mathrm{n}, \mathrm{k}$, and msg and the encoding method.

## Algorithms

Depending on the error-correction coding method, the encode function relies on lower-level functions such as hammgen and cyclgen.

Introduced before R2006a

## equalize

(To be removed) Equalize signal using equalizer object

Note will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead.

## Syntax

$y=$ equalize (eqobj, $x$ )
$y=$ equalize(eqobj, x,trainsig)
[y,yd] = equalize(...)
[y,yd,e] = equalize(...)

## Description

$y=$ equalize(eqobj, $x$ ) processes the baseband signal vector $x$ with equalizer object eqobj and returns the equalized signal vector $y$. At the end of the process, eqobj contains updated state information such as equalizer weight values and input buffer values. To construct eqobj, use the lineareq or dfe function. The equalize function assumes that the signal $x$ is sampled at nsamp samples per symbol, where nsamp is the value of the nSampPerSym property of eqobj. For adaptive algorithms other than CMA, the equalizer adapts in decision-directed mode using a detector specified by the SigConst property of eqobj. The delay of the equalizer is (eqobj.RefTap-1)/ eqobj.nSampPerSym.

Note that (eqobj.RefTap-1) must be an integer multiple of nSampPerSym. For a fractionallyspaced equalizer, the taps are spaced at fractions of a symbol period. The reference tap pertains to training symbols, and thus, must coincide with a whole number of symbols (i.e., an integer number of samples per symbol). eqobj.RefTap=1 corresponds to the first symbol, eqobj.RefTap=nSampPerSym+1 to the second, and so on. Therefore (eqobj.RefTap-1) must be an integer multiple of nSampPerSym.

If eqobj.ResetBeforeFiltering is 0 , equalize uses the existing state information in eqobj when starting the equalization operation. As a result, equalize (eqobj, [ $x 1 \times 2$ ]) is equivalent to [equalize(eqobj,x1) equalize(eqobj, x2)]. To reset eqobj manually, apply the reset function to eqobj.

If eqobj.ResetBeforeFiltering is 1, equalize resets eqobj before starting the equalization operation, overwriting any previous state information in eqobj.
$y=$ equalize (eqobj, x, trainsig) initially uses a training sequence to adapt the equalizer. After processing the training sequence, the equalizer adapts in decision-directed mode. The vector length of trainsig must be less than or equal to length (x) - (eqobj.RefTap-1)/eqobj.nSampPerSym.
[ $y, y d]=$ equalize(...) returns the vector yd of detected data symbols.
[ $y, y d, e]=$ equalize(...) returns the result of the error calculation. For adaptive algorithms other than CMA, e is the vector of errors between $y$ and the reference signal, where the reference signal consists of the training sequence or detected symbols.

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
        InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ..
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:
\% plot(yNew,'*')
\% hold on
\% plot(yold, 'o')
\% hold off; legend('New Eq','Old Eq'); grid on

## Use LMS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS'
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0)]
    WeightInputs: [0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.

```
y0ld = equalize(eq0ld,r,x(1:100));
yNew = eqNew(r,x(1:100));
```

## Use RLS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings.

```
eq0ld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'RLS'
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    InvCorrInit: 0.1000
    InvCorrMatrix: [5*5 double]
    Weights: [0 0 0 0 0)
    WeightInputs: [0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ..
        ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'RLS'
    NumTaps: 5
    ForgettingFactor: 0.9500
    InitialInverseCorrelationMatrix: 0.1000
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm.LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
```

$y 0 l d 2=$ equalize(eq0ld, $r, x(1: 100))$;
$y N e w 1=\operatorname{eqNew}(r, x(1: 100))$;
reset (eqNew)
yNew2 $=\operatorname{eqNew}(r, x(1: 100))$;

Configure lineareq and comm.LinearEqualizer objects with comparable settings. For the comm. LinearEqualizer object, set the initial inverse correlation matrix to eye(5)*0.2.

```
eq0ld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

eqOld =
EqType: 'Linear Equalizer'
AlgType: 'RLS
nWeights: 5
nSampPerSym: 1
RefTap: 1
SigConst: $[0.7071+0.7071 i-0.7071+0.7071 i-0.7071-0.7071 i \operatorname{0.7071-0.7071i]}$
InvCorrInit: 0.1000
InvCorrMatrix: [5×5 double]
Weights: [0 0 0 0 0]
WeightInputs: [0 0 0 0 0)
ResetBeforeFiltering: 1
NumSamplesProcessed: 0

```
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
    ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1, ...
    'InitialInverseCorrelationMatrix',eye(5)*0.2)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'RLS'
    NumTaps: 5
    ForgettingFactor: 0.9500
    InitialInverseCorrelationMatrix: [5\times5 double]
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

## Use CMA Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\text {TM }}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,cma(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'Constant Modulus'
    nWeights: 5
    nSampPerSym: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [1 0 0 0 0]
    WeightInputs: [0 0 0 0 0)]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','CMA','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap', 1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputSamplesPerSymbol: 1
    AdaptWeightsSource: 'Property'
    AdaptWeights: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.
y0ld = equalize(eqOld,r);
yNew = eqNew(r);

## Use Linear Equalizers Considering Signal Delays

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the lineareq to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eq0ld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 16
    nSampPerSym: 2
    RefTap: 13
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0] ]
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
        'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
        'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 16
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the comm. LinearEqualizer object, InputDelay is used to synchronize with the delayed signal. NumTaps and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 11
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: 12
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

yNew1 = eqNew(r2,x(1:100));
reset (eqNew)
$y N e w 2=\operatorname{eqNew}(r 2, x(1: 100))$;

## Compatibility Considerations

equalize will be removed
Warns starting in R2020a
equalize will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead. For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-327.

## evdoForwardReferenceChannels

Define 1xEV-DO forward reference channel

## Syntax

cfg = evdoForwardReferenceChannels(wv)
cfg = evdoForwardReferenceChannels(wv, numpackets)

## Description

cfg = evdoForwardReferenceChannels(wv) returns a structure, cfg, that defines 1xEV-DO forward link parameters given the input waveform identifier, wv. Pass this structure to the evdoForwardWaveformGenerator function to generate a forward link reference channel waveform.

For all syntaxes, evdoForwardReferenceChannels creates a configuration structure that is compliant with the cdma2000 high data rate packet specification, [1].
cfg = evdoForwardReferenceChannels(wv, numpackets) specifies the number of packets to be generated.

## Examples

## Generate 1xEV-DO Release 0 Forward Link Waveform

Create a configuration structure for a Release 0 channel having a 921.6 kbps data rate and transmitted over two slots.

```
config = evdoForwardReferenceChannels('Rel0-921600-2');
```

Display the number of slots and the data rate.

```
config.PacketSequence
ans = struct with fields:
    MACIndex: 0
    DataRate: 921600
    NumSlots: 2
```

Generate the complex waveform using the associated waveform generator function, evdoForwardWaveformGenerator.
wv = evdoForwardWaveformGenerator(config);

## Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.
config. PacketSequence

```
ans=1\times3 struct array with fields:
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.

```
config.PacketSequence(1)
ans = struct with fields:
    MACIndex: 0
    PacketSize: 1024
        NumSlots: 2
    PreambleLength: 64
```

Generate the waveform.
wv = evdoForwardWaveformGenerator(config);

## Input Arguments

## wv - Waveform identification

character vector
Waveform identification of the reference channel, specified as a character vector.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| wv |  | Character vector representing the 1xEVDO Release 0 reference channel with data rate in bps and number of slots. For example, you can specify <br> 'Rel0-153600-4' to create a structure that represents a reference channel with a $153,600 \mathrm{bps}$ data rate and uses four slots. |

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
|  |  | Character vector representing the 1xEVDO Revision A reference channel with the packet size in bits, the number of slots, and the preamble length in chips. For example, you can specify <br> 'RevA-256-1-64' to create a reference channel having a 256-bit packet, transmitted in one slot, with a 64-bit preamble length. |

Example: 'Rel0-614400-2'
Example: 'RevA-4096-2-64'

## Data Types: char

numpackets - Number of packets
1 (default) | positive integer scalar
Number of packets, specified as a positive integer.
Example: 4
Data Types: double

## Output Arguments

cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Release | 'Release0' \| 'RevisionA' | 1xEV-DO |
| PNOffset | Nonnegative scalar integer [0, 511] | PN offset of the base station |
| IdleSlotsWithControl | '0ff'\|'On' | Include idle slots with control channels |
| EnableControl | '0ff'\|'0n' | Enable control signaling |
| NumChips | Positive scalar integer | Number of chips in the waveform |
| OversamplingRatio | Positive scalar integer [1, 8] | Oversampling ratio at output |
| FilterType | ' cdma2000Long' \| 'cdma2000short | 'Custom ' $\mid$ 'Off' | Select filter type or disable filtering |
| CustomFilterCoeffici ents | Real vector | Custom filter coefficients (applies when the FilterType field is set to 'Custom') |
| InvertQ | '0ff'\| ${ }^{\prime}$ On' | Negate the quadrature output |
| EnableModulation | '0ff'\|'On' | Enable carrier modulation |
| ModulationFrequency | Nonnegative scalar integer | Carrier modulation frequency (applies when EnableModulation is ' On ') |
| PacketSequence | Structure | See PacketSequence substructure. |
| PacketDataSources | Structure | See PacketDataSources substructure. |

PacketSequence Substructure
Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| MACIndex | Positive scalar integer | MAC index associated with the packet |
| Release 0 |  |  |
| DataRate | $38400\|76800\| 153600 \mid$ <br> $307200\|614400\| 921600 \mid$ <br> $1228800\|1843200\|$ <br> 2457600 | Data rate (bps) |
| NumSlots | Positive scalar integer |  |
| Revision A |  |  |
| PacketSize | $128\|256\| 512\|1024\| 2048$ <br> $\|3072\| 4096 \mid 5120$ | Packet size (bits) |
| NumSlots | $1\|2\| 4\|8\| 16$ | Number of slots |
| PreambleLength | $64\|128\| 256\|512\| 1024$ | Preamble length (chips) |

## PacketDataSources Substructure

Include a PacketDataSources substructure in the cfg structure to define a set of matching data sources for each MAC index. The PacketDataSources substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| MACIndex | Positive scalar integer | MAC index associated with the packet |
| DataSource | Cell array, \{ ' PN Type ', RN <br> Seed\} or binary vector. | Data source. Specify a standard PN <br> sequence with a random number seed or a <br> custom vector. |
| Standard PN sequence <br> options are 'PN9' ' 'PN15' ' <br> 'PN23' , 'PN9-ITU' , and <br> 'PN11 '. |  |  |
| EnableCoding | 'Off' ' 'On' | Enable error correction coding |

## evdoForwardWaveformGenerator

Generate 1xEV-DO forward link waveform

## Syntax

waveform = evdoForwardWaveformGenerator(cfg)

## Description

waveform = evdoForwardWaveformGenerator(cfg) returns the 1xEV-DO forward link waveform as defined by the parameter configuration structure, cfg.

The top-level parameters and lower-level substructures of cfg specify the waveform and channel properties the function uses to generate a 1xEV-DO waveform. You can generate cfg by using the evdoForwardReferenceChannels function.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the evdoForwardReferenceChannels function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

## Examples

## Generate 1xEV-DO Revision A Forward Link Waveform

Create a structure to transmit a Revision A 1xEV-DO channel consisting of three 1024-bit packets transmitted over 2 slots with a 64-bit preamble length.

```
config = evdoForwardReferenceChannels('RevA-1024-2-64',3);
```

Verify that the function created a 1-by-3 structure array. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
ans=1\times3 struct array with fields:
    MACIndex
    PacketSize
    NumSlots
    PreambleLength
```

Examine the first structure element to verify the packet size, number of slots, and preamble length match what you specified in the function call.
config. PacketSequence(1)
ans $=$ struct with fields:
MACIndex: 0

```
    PacketSize: 1024
        NumSlots: 2
PreambleLength: 64
```

Generate the waveform.
wv = evdoForwardWaveformGenerator(config);

## Generate 1xEV-DO Forward Link Waveform with Custom Filter

Create a structure to generate two packets of a 1.8 Mbps Release 0 channel.
config = evdoForwardReferenceChannels('Rel0-1843200-1',2);
Calculate the sample rate of the waveform.
fs $=1.2288 e 6$ * config.OversamplingRatio;
Disable the internal filter of the evdoForwardWaveformGenerator function. Generate the 1xEV-DO waveform. Plot the spectrum of the waveform.

```
config.FilterType = 'off';
wv = evdoForwardWaveformGenerator(config);
sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```

Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB .

```
d = designfilt('lowpassfir', ...
    'PassbandFrequency',500e3, ...
    'StopbandFrequency',750e3, ...
    'StopbandAttenuation',60, ...
    SampleRate',fs);
```

Change the filter type to 'Custom' and specify the coefficients from the digital filter, d.
config.FilterType = 'Custom';
config.CustomFilterCoefficients = d.Coefficients;
Generate the waveform using the custom filter coefficients.
wV = evdoForwardWaveformGenerator(config);
Plot the spectrum of the filtered 1xEV-DO waveform.
step(sa,wv)

The filter attenuates the waveform by 60 dB for frequencies outside of $\pm 750 \mathrm{kHz}$.

## Input Arguments

cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

| Parameter Field | Values | Description |
| :--- | :--- | :--- |

## PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| MACIndex | Positive scalar integer | MAC index associated with the packet |
| Release 0 |  |  |
| DataRate | $38400\|76800\| 153600 \mid$ <br> $307200\|614400\| 921600 \mid$ <br> $1228800\|1843200\|$ <br> 2457600 | Data rate (bps) |
|  | Positive scalar integer |  |
| NumSlots | Revision A |  |
| Number of slots |  |  |
| PacketSize | $128\|256\| 512\|1024\| 2048$ <br> $\|3072\| 4096 \mid 5120$ | Packet size (bits) |
| NumSlots | $1\|2\| 4\|8\| 16$ | Number of slots |
| PreambleLength | $64\|128\| 256\|512\| 1024$ | Preamble length (chips) |

## PacketDataSources Substructure

Include a PacketDataSources substructure in the cfg structure to define a set of matching data sources for each MAC index. The PacketDataSources substructure contains these fields.

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| MACIndex | Positive scalar integer | MAC index associated with the packet |
| DataSource | Cell array, \{ 'PN Type ', RN <br> Seed\} or binary vector. | Data source. Specify a standard PN <br> sequence with a random number seed or a <br> custom vector. |
|  | Standard PN sequence <br> options are 'PN9', 'PN15' ', |  |
|  | 'PN23' ' 'PN9-ITU' ' and <br> 'PN11'. |  |

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| EnableCoding | 'Off' $\mathrm{I}^{\prime}$ On' | Enable error correction coding |

## Output Arguments

waveform - Modulated baseband waveform comprising the primary physical channels complex vector array

Modulated baseband waveform comprising the primary cdma2000 physical channels, returned as a complex vector array.

## evdoReverseReferenceChannels

Define 1xEV-DO reverse reference channel

## Syntax

cfg = evdoReverseReferenceChannels(wv)
cfg = evdoReverseReferenceChannels(wv, numpackets)

## Description

cfg = evdoReverseReferenceChannels(wv) returns a structure, cfg, that defines 1xEV-DO reverse link parameters given the input waveform identifier, wv. Pass this structure to the evdoReverseWaveformGenerator function to generate a reverse link reference channel waveform.

For all syntaxes, evdoReverseReferenceChannels creates a structure that is compliant with the cdma2000 high data rate packet specification,[1].
cfg = evdoReverseReferenceChannels(wv, numpackets) specifies the number of packets to be generated.

## Examples

## Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Re\0-19200');
```

Verify that the packet has a data rate of 19.2 kbps.
config.PacketSequence.DataRate
ans $=19200$
Generate the complex waveform.
wv = evdoReverseWaveformGenerator(config);

## Generate 1xEV-DO Revision A Reverse Link Waveform

Create a structure for a Revision A 1xEV-DO channel having 2048-bit packets, transmitted in 12 slots. Specify that five packets are transmitted.

```
config = evdoReverseReferenceChannels('RevA-2048-12',5);
```

Verify that a 1-by-5 structure array is created. Each element in the structure array corresponds to a data packet.

```
config.PacketSequence
```

```
ans=1\times5 struct array with fields:
    Power
    DataSource
    EnableCoding
    PayloadSize
    NumSlots
    DataRate
```

Examine the first structure element to verify the packet size and the number of slots are as specified in the function call.

```
config.PacketSequence(1)
ans = struct with fields:
            Power: 0
    DataSource: {'PN9' [1]}
    EnableCoding: 'On'
    PayloadSize: 2048
        NumSlots: 12
        DataRate: 102400
```

Generate the waveform.
wv = evdoReverseWaveformGenerator(config);

## Input Arguments

wv - Waveform identification
character vector
Waveform identification of the reference channel, specified as a character vector.

| Parameter <br> Field | Values | Description |
| :--- | :--- | :--- |
| wv | 'Rel0-9600' <br> 'Rel0-19200' <br> 'Rel0-38400 ' <br> 'Rel0-76800 ' <br> 'Rel0-153600 ' | Character vector representing the 1xEV-DO <br> Release 0 data rate in bps. For example, you can <br> specify ' Rel0-153600 ' to create a structure <br> corresponding to a Release 0 reference channel <br> having a 153,600 bps data rate. |
|  |  |  |

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
|  |  | Character vector representing the 1xEV-DO Revision A packet size in bits and the number of slots. For example, you can specify 'RevA-256-4' to create a structure corresponding to a Revision A reference channel having 256 -bit packets and transmitted in four slots. |

Example: 'Rel0-38400'
Example: 'RevA-3072-12'
Data Types: char
numpackets - Number of packets
1 (default) | positive integer scalar
Number of packets, specified as a positive integer.
Example: 2
Data Types: double

## Output Arguments

cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Release | 'Release0' \| 'RevisionA' | 1xEV-DO applicable standard |
| LongCodeMaskI | 42-bit binary number | Long code identifier for in-phase channel |
| LongCodeMaskQ | 42-bit binary number | Long code identifier for quadrature channel |
| NumChips | Positive scalar integer | Number of chips in the waveform |
| OversamplingRatio | Positive scalar integer | Oversampling ratio at output |
| FilterType | 'cdma2000Long ' \| 'cdma2000Short | 'Custom' | 'Off' | Specify the filter type or disable filtering |
| CustomFilterCoeffici ents | Real vector | Custom filter coefficients (applies when FilterType is set to 'Custom') |
| InvertQ | '0ff'\| ${ }^{\prime}$ On' | Negate the quadrature output |
| EnableModulation | '0ff'\| 'On' | Enable carrier modulation |
| ModulationFrequency | Nonnegative scalar integer | Carrier modulation frequency (applies when EnableModulation is ' $O n^{\prime}$ ) |
| ACKChannel | Structure | See ACKChannel substructure. |
| PilotChannel | Structure | See PilotChannel substructure. |
| AuxPilotChannel | Not present or structure | See AuxPilotChannel substructure. |
| PacketSequence | Structure | See PacketSequence substructure. |

## ACKChannel Substructure

Include the ACKChannel substructure in the cfg structure to specify the acknowledgment channel. The ACKChannel substructure contains these fields.

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' I 'Off' | Character vector to enable or <br> disable the channel |
| Power | Real scalar | Channel power (dBW) |
| DataSource | Cell array, \{'PN Type' , RN <br> Seed\} or binary vector. <br> Standard PN sequence options <br> are 'PN9', 'PN15', 'PN23', <br> 'PN9-ITU ' and 'PN11'. | Data source. Specify a standard <br> PN sequence with a random <br> number seed or a custom vector. |

## PilotChannel Substructure

Include the PilotChannel substructure in the cfg structure to specify the pilot channel. The PilotChannel substructure contains these fields.

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On ' \| 'Off' | Character vector to enable or <br> disable the channel |
| Power | Real scalar | Channel power (dBW) |
| DataSource | Cell array, \{'PN Type' , RN <br> Seed\} or binary vector. <br> Standard PN sequence options <br> are 'PN9' ' 'PN15', 'PN23', <br> 'PN9-ITU' and 'PN11'. | Data source. Specify a standard <br> PN sequence with a random <br> number seed or a custom vector. |
| EnableCoding | 'On' \| 'Off' | Enable channel coding |

## AuxPilotChannel Substructure

Include the AuxPilotChannel substructure in the cfg structure to specify the auxiliary pilot channel, which is available only for Revision A. The AuxPilotChannel substructure contains these fields.

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \\| 'Off' | Character vector to enable or <br> disable the channel |
| Power | Real scalar | Channel power (dBW) |
| DataSource | Cell array, \{'PN Type' , RN <br> Seed\} or binary vector. <br> Standard PN sequence options <br> are 'PN9' ' 'PN15', 'PN23', <br> 'PN9-ITU' and 'PN11'. | Data source. Specify a standard <br> PN sequence with a random <br> number seed or a custom vector. |
| EnableCoding | 'On' \| 'Off' | Enable channel coding |

## PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Power | Real scalar | MAC index associated with the packet |
| EnableCoding | '0ff' \| 'On' | Enable error correction coding |
| DataSource | Cell array, \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9','PN15', 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |
| Release 0 |  |  |
| DataRate | $9600\|19200\| 38400 \mid$ $76800 \mid 153600$ | Data rate (bps) |
| Revision A |  |  |
| PacketSize | $128\|256\| 512\|768\| 1024 \mid$ $1536\|2048\| 3072\|4096\|$ $6144\|8192\| 12288$ | Packet size (bits) |
| NumSlots | 4\|8|12|16 | Number of slots |

evdoForwardReferenceChannels | evdoReverseWaveformGenerator

## Introduced in R2015b

## evdoReverseWaveformGenerator

Generate 1xEV-DO reverse link waveform

## Syntax

waveform = evdoReverseWaveformGenerator(cfg)

## Description

waveform = evdoReverseWaveformGenerator(cfg) returns the 1xEV-DO reverse link waveform as defined by the parameter configuration structure, cfg.

The top-level parameters and lower-level substructures of cfg specify the waveform and channel properties used by the function to generate a 1xEV-DO waveform. You can generate cfg by using the evdoReverseReferenceChannels function.

Note The tables herein list the allowable values for the top-level parameters and substructure fields. However, not all parameter combinations are supported. To ensure that the input argument is valid, use the evdoReverseReferenceChannels function. If you input the structure fields manually, consult [1] to ensure that the input parameter combinations are permitted.

## Examples

## Generate 1xEV-DO Reverse Channel Waveform

Create a structure to generate a Release 0, 1xEV-DO waveform having a 19.2 kbps data rate.

```
config = evdoReverseReferenceChannels('Rel0-19200');
```

Verify that the packet has a data rate of 19.2 kbps.

```
config.PacketSequence.DataRate
```

```
ans = 19200
```

Generate the complex waveform.
wv = evdoReverseWaveformGenerator(config);

## Generate 1xEV-DO Reverse Link Waveform with Custom Filter

Create a structure to generate four packets of a Revision A channel having 768-bit packets transmitted over eight slots.

```
config = evdoReverseReferenceChannels('RevA-768-8',4);
```

Calculate the sample rate of the waveform.
fs = 1.2288e6 * config.OversamplingRatio;
Disable the internal filter of the evdoReverseWaveformGenerator. Generate the 1xEV-DO waveform. Plot the spectrum of the waveform.

```
config.FilterType = 'off';
wv = evdoReverseWaveformGenerator(config);
sa = dsp.SpectrumAnalyzer('SampleRate',fs);
step(sa,wv)
```

Create a lowpass FIR filter with a 500 kHz passband, a 750 kHz stopband, and a stopband attenuation of 60 dB .
d = designfilt('lowpassfir', ...
'PassbandFrequency',500e3, ...
'StopbandFrequency',750e3, ...
'StopbandAttenuation',60, ...
'SampleRate',fs);
Change the filter type to 'Custom' and specify the coefficients from the digital filter, d .
config.FilterType = 'Custom';
config.CustomFilterCoefficients = d.Coefficients;
Generate the waveform using the custom filter coefficients.
wv = evdoReverseWaveformGenerator(config);
Plot the spectrum of the filtered 1xEV-DO waveform.
step(sa,wv)

The filter attenuates the waveform by 60 dB for frequencies outside of $\pm 750 \mathrm{kHz}$.

## Input Arguments

cfg - Configuration of the parameters and channels used by the waveform generator structure

Configuration of the parameters and channels used by the waveform generator. The configuration structure is defined in these tables.

Top-Level Parameters and Substructures

| Parameter Field | Values | Description |
| :--- | :--- | :--- |
| Release | 'Release0 ' \| 'RevisionA' | 1xEV-DO applicable standard |
| LongCodeMaskI | 42 -bit binary number | Long code identifier for in-phase channel |
| LongCodeMaskQ | 42 -bit binary number | Long code identifier for quadrature channel |

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| NumChips | Positive scalar integer | Number of chips in the waveform |
| OversamplingRatio | Positive scalar integer | Oversampling ratio at output |
| FilterType | 'cdma2000Long ' \| ' cdma2000Short | 'Custom ' | 'Off' | Specify the filter type or disable filtering |
| CustomFilterCoeffici ents | Real vector | Custom filter coefficients (applies when FilterType is set to 'Custom') |
| InvertQ | '0ff'\| ${ }^{\prime}$ On' | Negate the quadrature output |
| EnableModulation | 'Off'\|'On' | Enable carrier modulation |
| ModulationFrequency | Nonnegative scalar integer | Carrier modulation frequency (applies when EnableModulation is ' $0 n$ ') |
| ACKChannel | Structure | See ACKChannel substructure. |
| PilotChannel | Structure | See PilotChannel substructure. |
| AuxPilotChannel | Not present or structure | See AuxPilotChannel substructure. |
| PacketSequence | Structure | See PacketSequence substructure. |

## ACKChannel Substructure

Include the ACKChannel substructure in the cfg structure to specify the acknowledgment channel. The ACKChannel substructure contains these fields.

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' I 'Off' | Character vector to enable or <br> disable the channel |
| Power | Real scalar | Channel power (dBW) |
| DataSource | Cell array, \{ 'PN Type' , RN <br> Seed\} or binary vector. <br> Standard PN sequence options <br> are 'PN9' , 'PN15', 'PN23', <br> 'PN9-ITU ' and 'PN11'. | Data source. Specify a standard <br> PN sequence with a random <br> number seed or a custom vector. |

## PilotChannel Substructure

Include the PilotChannel substructure in the cfg structure to specify the pilot channel. The PilotChannel substructure contains these fields.

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' $\mathrm{I}^{\prime}$ Off' | Character vector to enable or <br> disable the channel |
| Power | Real scalar | Channel power (dBW) |

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| DataSource | Cell array, \{'PN Type' , RN <br> Seed\} or binary vector. <br> Standard PN sequence options <br> are 'PN9', 'PN15', 'PN23', <br> 'PN9-ITU', and 'PN11'. | Data source. Specify a standard <br> PN sequence with a random <br> number seed or a custom vector. |
| EnableCoding | 'On' $\mid$ 'Off' | Enable channel coding |

## AuxPilotChannel Substructure

Include the AuxPilotChannel substructure in the cfg structure to specify the auxiliary pilot channel, which is available only for Revision A. The AuxPilotChannel substructure contains these fields.

| Parameter Fields | Values | Description |
| :--- | :--- | :--- |
| Enable | 'On' \| 'Off' | Character vector to enable or <br> disable the channel |
| Power | Real scalar | Channel power (dBW) |
| DataSource | Cell array, \{'PN Type', RN <br> Seed\} or binary vector. <br> Standard PN sequence options <br> are 'PN9' ' PN15', 'PN23', | Data source. Specify a standard <br> PN sequence with a random <br> number seed or a custom vector. |
| 'PN9-ITU', and 'PN11'. |  |  |

## PacketSequence Substructure

Include the PacketSequence substructure in the cfg structure to define a sequence of data packets for consecutive transmission. The PacketSequence substructure contains these fields.

| Parameter Field | Values | Description |
| :---: | :---: | :---: |
| Power | Real scalar | MAC index associated with the packet |
| EnableCoding | '0ff'\|'On' | Enable error correction coding |
| DataSource | Cell array, \{'PN Type', RN Seed\} or binary vector. <br> Standard PN sequence options are 'PN9','PN15', <br> 'PN23', 'PN9-ITU', and 'PN11'. | Data source. Specify a standard PN sequence with a random number seed or a custom vector. |
| Release 0 |  |  |
| DataRate | $\begin{aligned} & 9600\|19200\| 38400 \mid \\ & 76800 \mid 153600 \end{aligned}$ | Data rate (bps) |
| Revision A |  |  |

| Parameter Field | Values | Description |
| :---: | :--- | :--- |
| PacketSize | $128\|256\| 512\|768\| 1024 \mid$ | Packet size (bits) |
|  | $1536\|2048\| 3072\|4096\|$ |  |
|  | $6144\|8192\| 12288$ |  |
| NumSlots | $4\|8\| 12 \mid 16$ | Number of slots |

## Output Arguments

waveform - Modulated baseband waveform comprising the physical channels
complex vector array
Modulated baseband waveform comprising the 1xEV-DO physical channels, returned as a complex vector array.

## References

## eyediagram

Generate eye diagram

## Syntax

```
eyediagram(x,n)
eyediagram(x,n,period)
eyediagram(x,n,period,offset)
eyediagram(x,n,period,offset,plotstring)
eyediagram(x,n,period,offset,plotstring,h)
h = eyediagram(
```

$\qquad$

``` )
```

## Description

eyediagram ( $\mathrm{x}, \mathrm{n}$ ) generates an eye diagram for signal x , plotting n samples in each trace. The labels on the horizontal axis of the diagram range between $-1 / 2$ and $1 / 2$. The function assumes that the first value of the signal and every nth value thereafter, occur at integer times.
eyediagram ( $x, n$, period) sets the labels on the horizontal axis to the range between -period/2 to period/2.
eyediagram( $x, n$, period, offset) specifies the offset for the eye diagram. The function assumes that the (offset +1 )th value of the signal and every nth value thereafter, occur at times that are integer multiples of period.
eyediagram( $x, n$, period, offset, plotstring) specifies plot attributes for the eye diagram.
eyediagram( $x, n$, period, offset, plotstring, $h$ ) generates the eye diagram in an existing figure whose handle is $h$.

Note Use of hold on to plot multiple signals in the same figure is not supported.
$\mathrm{h}=$ eyediagram (__ ) returns the handle to the figure that contains the eye diagram. You can specify any of the input argument combinations from the previous syntaxes.

## Examples

## Generate Eye Diagram of Filtered QPSK Signal

Generate an eyediagram of a filtered QPSK signal.
Generate random symbols. Apply QPSK modulation to get a modulated signal.

```
data = randi([0 3],1000,1);
modSig = pskmod(data,4,pi/4);
```

Specify the number of output samples per symbol parameter. Create a transmit filter object, txfilter.

```
sps=4;
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps);
```

Filter the modulated signal modSig.

```
txSig = txfilter(modSig);
```

Display the eye diagram.
eyediagram(txSig,2*sps)

## Input Arguments

## x - Input signal

numeric vector | numeric matrix
Input signal, specified as a numeric vector or numeric matrix.

The interpretation of $x$ and the number of plots depend on the shape and complexity of $x$.

- If $x$ is a real-valued two-column matrix, the function interprets the first column as in-phase components and the second column as quadrature components. The two components appear in different subplots of a single figure window.
- If $x$ is a complex-valued vector, the function interprets the real part as in-phase components and the imaginary part as quadrature components. The two components appear in different subplots of a single figure window.
- If x is a real-valued vector, the function interprets the vector as a real signal. The figure window contains a single plot.

Data Types: double
Complex Number Support: Yes
n - Number of samples per trace
integer greater than 1
Number of samples per trace, specified as a integer greater than 1.
Data Types: double

## period - Trace period

1 (default) | positive scalar
Trace period, specified as a positive scalar. The labels on the horizontal axis of the eye diagram range between -period/2 to period/2.

## Data Types: double

## offset - Offset value

0 (default) | integer in the range from 0 to ( $\mathrm{n}-1$ )
Offset value, specified as an integer in the range 0 to ( $\mathrm{n}-1$ ). The function assumes that the (offset + 1)th value of the signal and every nth value thereafter, occur at times that are integer multiples of the input period.

## Data Types: double

## plotstring - Plot attributes

'b-' (default) | character vector | string scalar
Plot attributes, specified as a character vector or string scalar containing symbols.
This argument sets the plotting symbol, line type, and color for the eye diagram. The format and meaning of the symbols are the same as in the plot function. For example, the default value 'b-' produces a solid blue line.
Data Types: char \| string

## h - Figure handle

Figure object
Figure handle to an existing figure that contains an eye diagram, specified as a Figure object. h must be a handle to a figure that the eyediagram function previously generated.

## Output Arguments

h - Figure handle
Figure object
Figure handle, returned as a Figure object. To modify properties of this object, see Figure Properties.

Introduced before R2006a

## EyeScope

(Removed) Launch eye diagram scope for eye diagram object H

Note eyescope has been removed. Use comm.EyeDiagram instead.

## Syntax

eyescope
eyescope(h)

## Description

Eye Diagram Scope is a graphical user interface (GUI) that enables you to visualize and measure the effects that various impairments, such as noise, jitter, and filtering, have on a modulated signal. The scope performs a probability density function (pdf) analysis on the signal to illustrate its trajectory in time, and to calculate such quantities as eye SNR, RMS jitter, rise time, and fall time. The scope also enables you to import and compare measurement results for eye diagrams of multiple signals.

There are two ways to call EyeScope:

- eyescope calls an empty scope
- eyescope(h) calls the scope and displays object h

Note You can call EyeScope with an eye diagram object as the input argument. EyeScope uses the inputname function to resolve the caller's work space name for the argument. If the inputname function cannot resolve the caller's work space name, then EyeScope uses a default name. To learn about the cases when EyeScope cannot determine the work space name, type help inputname at the MATLAB command line.

## Compatibility Considerations

## EyeScope has been removed

Errors starting in R2020a
EyeScope has been removed. Use comm. EyeDiagram instead.

## fft

Discrete Fourier transform

## Syntax

fft(x)

## Description

$\mathrm{fft}(\mathrm{x})$ is the discrete Fourier transform (DFT) of the Galois vector x . If x is in the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, the length of x must be $2^{\mathrm{m}}-1$.

## Examples

## Discrete Fourier Transform of Galois Vector

Set the order of the Galois field. Because x is in the Galois field $\left(2^{4}\right)$, the length of x must be $2^{m}-1$.
$\mathrm{m}=4$;
$\mathrm{n}=2^{\wedge} \mathrm{m}-1$;
Generate a random GF vector.
$x=\mathrm{gf}($ randi([0 2^m-1],n,1),m);
Perform the Fourier transform.
$y=f f t(x)$;
Invert the transform.
$z=i f f t(y) ;$
Confirm that the inverse transform $\mathrm{z}=\mathrm{x}$.
isequal(z,x)
ans = logical
1

## Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, x must be in the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, where m is an integer between 1 and 8 .

## Algorithms

If $x$ is a column vector, $f f t$ applies dftmtx to the primitive element of the Galois field and multiplies the resulting matrix by $x$.

## filter (channel)

(To be removed) Filter signal with channel object

Note This function will be removed in a future release. Use function associated with comm.RicianChannel or comm. RayleighChannel instead.

## Syntax

$y=$ filter (chan, $x$ )

## Description

$y=$ filter (chan, $x$ ) processes the baseband signal vector $x$ with the channel object chan. The result is the signal vector $y$. The final state of the channel is stored in chan. You can construct chan using either rayleighchan or ricianchan. The filter function assumes $x$ is sampled at frequency $1 / t s$, where ts equals the InputSamplePeriod property of chan.

If chan. ResetBeforeFiltering is 0 , filter uses the existing state information in chan when starting the filtering operation. As a result, filter(chan, $[x 1 \times 2]$ ) is equivalent to [filter(chan, x1) filter(chan, x2)]. To reset chan manually, apply the reset function to chan.

If chan.ResetBeforeFiltering is 1 , filter resets chan before starting the filtering operation, overwriting any previous state information in chan.

## filter (Galois field)

1-D digital filter over Galois field

## Syntax

y = filter(b,a,x)
[y,zf] = filter(b,a,x)

## Description

$y=$ filter $(b, a, x)$ filters the data in the vector $x$ with the filter described by numerator coefficient vector $b$ and denominator coefficient vector $a$. The vectors $b, a$, and $x$ must be Galois vectors in the same field. If $a(1)$ is not equal to 1 , filter normalizes the filter coefficients by $a(1)$. As a result, a(1) must be nonzero.

The filter is a Direct Form II Transposed implementation of the standard difference equation shown here:

```
a(1)*y(n) = b(1)*x(n) + b(2)*x(n-1) + ... + b(nb+1)*x(n-nb) ...
    - a(2)*y(n-1) - ... - a(na+1)*y(n-na)
```

$[y, z f]=$ filter $(b, a, x)$ returns the final conditions of the filter delays in the Galois vector $z f$. The length of the vector $z f$ is $\max (\operatorname{size}(a), \operatorname{size}(b))-1$.

## Examples

## Filter a Galois Field

When using the Galois 1-D digital filter function, the data is normalized by the first element of the denominator coefficient vector.

```
a = gf([2 3 5 7],3);
b = gf([1 3],3);
x = gf(randi([0,7],10,1),3);
filt_x = filter(b,a,x)
filt_x = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
    6
    6
    3
    4
    7
    4
    2
    2
    0
    5
```

The first coefficient of the denominator coefficient vector, $\mathrm{a}(1)=2$. To confirm the function normalizes the data, manually normalize the filtered data. Use isequal to compare the outputs, we see they are equal.

```
filt_x2 = a(1) * filter(b/a(1),a,x)
filt_x2 = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
    6
    6
    3
    4
    7
    4
    2
    2
    0
    5

## fmdemod

Frequency demodulation

## Syntax

```
z = fmdemod(y,Fc,Fs,freqdev)
z = fmdemod(y,Fc,Fs,freqdev,ini_phase)
```

## Description

$z=f m d e m o d(y, F c, F s, f r e q d e v)$ returns a demodulated signal $z$, given the input frequency modulated (FM) signal $y$, where the carrier signal has frequency Fc and sampling rate Fs. freqdev is the frequency deviation of the modulated signal.

## Note

- The value of Fs must satisfy $\mathrm{Fs} \geq 2 \mathrm{Fc}$.
- The value of freqdev must satisfy freqdev < Fc.
$z=f m d e m o d\left(y, F c, F s, f r e q d e v, i n i \_p h a s e\right)$ specifies the initial phase of the modulated signal in radians.

## Examples

## FM Modulate and Demodulate Sinusoidal Signal

Set the sampling frequency to 1 kHz and carrier frequency to 200 Hz . Generate a time vector having a duration of 0.2 s .

```
fs = 1000;
fc = 200;
t = (0:1/fs:0.2)';
```

Create two-tone sinusoidal signal with frequencies 30 and 60 Hz .

```
x = sin(2*pi*30*t)+2*sin(2*pi*60*t);
```

Set the frequency deviation to 50 Hz .

```
fDev = 50;
```

Frequency modulate $x$.
$y=f m m o d(x, f c, f s, f D e v) ;$
Demodulate z.
$z=f m d e m o d(y, f c, f s, f D e v) ;$

Plot the original and demodulated signals.

```
plot(t,x,'c',t,z,'b--');
xlabel('Time (s)')
ylabel('Amplitude')
legend('Original Signal','Demodulated Signal')
```

The demodulated signal closely approximates the original.

## Input Arguments

y - Frequency modulated input signal
scalar | vector | matrix | 3-D array
Frequency modulated input signal, specified as a numeric scalar, vector, matrix, or 3-D array. Each element of $y$ must be real.

Data Types: double

## Fc - Carrier frequency

positive real scalar
Carrier frequency in hertz (Hz), specified as a positive real scalar.
Data Types: double

## Fs - Sampling rate

positive scalar
Sampling rate in hertz (Hz), specified as a positive scalar.
Data Types: double

## freqdev - Frequency deviation

positive scalar
Frequency deviation of the modulated signal in hertz (Hz), specified as a positive scalar.
Data Types: double

## ini_phase - Initial phase

numeric scalar
Initial phase of the modulated signal in radians, specified as a numeric scalar.
Data Types: double

## Output Arguments

## z - Frequency demodulated output signal

scalar | vector | matrix | 3-D array
Frequency demodulated signal, returned as a scalar, vector, matrix, or 3-D array.

## fskdemod

Frequency shift keying demodulation

## Syntax

z = fskdemod(y, M,freq_sep,nsamp)
z = fskdemod(y, M,freq_sep,nsamp,Fs)
z = fskdemod(y,M,freq_sep,nsamp,Fs,symbol_order)

## Description

$z=f s k d e m o d\left(y, M, f r e q \_s e p, n s a m p\right)$ noncoherently demodulates the complex envelope $y$ of a signal using the frequency shift key method. $M$ is the alphabet size and must be an integer power of 2. freq_sep is the frequency separation between successive frequencies in Hz . nsamp is the required number of samples per symbol and must be a positive integer greater than 1 . The sampling frequency is 1 Hz . If y is a matrix with multiple rows and columns, the function processes the columns independently.
z = fskdemod(y, M, freq_sep, nsamp,Fs) specifies the sampling frequency in Hz .
$z=$ fskdemod (y, M,freq_sep,nsamp,Fs,symbol_order) specifies how the function assigns binary words to corresponding integers. If symbol_order is set to 'bin' (default), the function uses a natural binary-coded ordering. If symbol_order is set to 'gray', it uses a Gray-coded ordering.

## Examples

## Modulation and Demodulation of an FSK Signal in AWGN

Pass an FSK signal through an AWGN channel and estimate the resulting bit error rate (BER). Compare the estimated BER to the theoretical value.

Set the simulation parameters.

```
M = 2; % Modulation order
k = log2(M); % Bits per symbol
EbNo = 5; % Eb/No (dB)
Fs = 16; % Sample rate (Hz)
nsamp = 8; % Number of samples per symbol
freqsep = 10; % Frequency separation (Hz)
```

Generate random data symbols.
data $=$ randi([0 M-1],5000,1);
Apply FSK modulation.
txsig = fskmod(data, M,freqsep,nsamp,Fs);
Pass the signal through an AWGN channel

```
rxSig = awgn(txsig,EbNo+10*log10(k)-10*log10(nsamp),...
    'measured',[],'dB');
```

Demodulate the received signal.

```
dataOut = fskdemod(rxSig,M,freqsep,nsamp,Fs);
```

Calculate the bit error rate.

```
[num,BER] = biterr(data,dataOut);
```

Determine the theoretical BER and compare it to the estimated BER. Your BER value might vary because the example uses random numbers.

```
BER_theory = berawgn(EbNo,'fsk',M,'noncoherent');
```

[BE $\bar{R}$ BER_theory]
ans $=1 \times 2$
0.09580 .1029

## fskmod

Frequency shift keying modulation

## Syntax

```
y = fskmod(x,M,freq_sep,nsamp)
y = fskmod(x,M,freq_sep,nsamp,Fs)
y = fskmod(x,M,freq_sep,nsamp,Fs,phase_cont)
y = FSKMOD(x,M,freq_sep,nsamp,Fs,phase_cont,symbol_order)
```

## Description

$y=$ fskmod (x,M,freq_sep, nsamp) outputs the complex envelope $y$ of the modulation of the message signal x using frequency shift keying modulation. M is the alphabet size and must be an integer power of 2 . The message signal must consist of integers between 0 and $\mathrm{M}-1$. freq_sep is the desired separation between successive frequencies in Hz. nsamp denotes the number of samples per symbol in y and must be a positive integer greater than 1 . The sampling rate of y is 1 Hz . By the Nyquist sampling theorem, freq_sep and $M$ must satisfy ( $\mathrm{M}-1$ ) $\mathrm{f}_{\mathrm{f}}$ req_sep <= 1 . If x is a matrix with multiple rows and columns, the function processes the columns independently.
$y=$ fskmod(x,M,freq_sep,nsamp,Fs) specifies the sampling rate of $y$ in Hz. Because the Nyquist sampling theorem implies that the maximum frequency must be no larger than Fs/2, the inputs must satisfy (M-1)*freq_sep <= Fs.
$y=f s k m o d\left(x, M, f r e q \_s e p, n s a m p, F s\right.$, phase_cont) specifies the phase continuity. Set phase cont to 'cont' to force phase continuity across symbol boundaries in $y$, or 'discont' to avoid forcing phase continuity. The default is 'cont'.
y = FSKMOD (x,M,freq_sep,nsamp,Fs,phase_cont,symbol_order) specifies how the function assigns binary words to corresponding integers. If symbol_order is set to 'bin' (default), the function uses a natural binary-coded ordering. If symbol_order is set to 'gray', it uses a Graycoded ordering.

## Examples

## FSK Signal Spectrum Plot

Generate an FSK modulated signal and display its spectral characteristics.
Set the function parameters.

```
M = 4; % Modulation order
freqsep = 8; % Frequency separation (Hz)
nsamp = 8; % Number of samples per symbol
Fs = 32; % Sample rate (Hz)
```

Generate random M-ary symbols.

```
x = randi([0 M-1],1000,1);
```

Apply FSK modulation.
$y=$ fskmod $(x, M, f r e q s e p, n s a m p, F s) ;$
Create a spectrum analyzer System object? and use its step method to display a plot of the signal spectrum.
h = dsp.SpectrumAnalyzer('SampleRate',Fs);
step(h,y)

## gen2par

Convert between parity-check and generator matrices

## Syntax

parmat = gen2par(genmat)
genmat = gen2par(parmat)

## Description

parmat $=$ gen2par(genmat) converts the standard-form binary generator matrix genmat into the corresponding parity-check matrix parmat.
genmat = gen2par(parmat) converts the standard-form binary parity-check matrix parmat into the corresponding generator matrix genmat.

The standard forms of the generator and parity-check matrices for an $[\mathrm{n}, \mathrm{k}]$ binary linear block code are shown in the table below

| Type of Matrix | Standard Form | Dimensions |
| :--- | :--- | :--- |
| Generator | $\left[\mathrm{I}_{\mathrm{k}} \mathrm{P}\right]$ or $\left[\mathrm{P}_{\mathrm{k}}\right]$ | k -by-n |
| Parity-check | $\left[-\mathrm{P}^{\prime} \mathrm{I}_{\mathrm{n}-\mathrm{k}}\right]$ or $\left[\mathrm{I}_{\mathrm{n}-\mathrm{k}}-\mathrm{P}^{\prime}\right]$ | $(\mathrm{n}-\mathrm{k})$-by-n |

where $\mathrm{I}_{\mathrm{k}}$ is the identity matrix of size k and the ' symbol indicates matrix transpose. Two standard forms are listed for each type, because different authors use different conventions. For binary codes, the minus signs in the parity-check form listed above are irrelevant; that is, $-1=1$ in the binary field.

## Examples

## Convert Parity-Check Matrix for a Hamming Code to Generator Matrix

Convert the parity-check matrix for a Hamming code into the corresponding generator matrix and back again.

Create the parity-check matrix.

```
parmat = hammgen(3)
parmat = 3\times7
\begin{tabular}{lllllll}
1 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 1 & 0 & 1 & 1 & 1 & 0 \\
0 & 0 & 1 & 0 & 1 & 1 & 1
\end{tabular}
```

Convert the parity-check matrix into the corresponding generator matrix.
genmat $=$ gen2par(parmat)
genmat $=4 \times 7$

| 1 | 1 | 0 | 1 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 1 | 0 | 1 | 0 | 0 |
| 1 | 1 | 1 | 0 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 | 0 | 0 | 1 |

Convert the generator matrix back again. The output, parmat2, should be the same as the original matrix, parmat.
parmat2 = gen2par(genmat)
parmat2 $=3 \times 7$

| 1 | 0 | 0 | 1 | 0 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 1 | 1 | 1 | 0 |
| 0 | 0 | 1 | 0 | 1 | 1 | 1 |

## genqamdemod

General quadrature amplitude demodulation

## Syntax

$z=$ genqamdemod $(y$, const $)$

## Description

$z=$ genqamdemod( $y$, const) demodulates the complex envelope, $y$, of a quadrature amplitude modulated signal using the signal mapping specified in const.

## Examples

## General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];
quadr = [0 1 1 -1 2 -2 1 -1 0];
inphase = [inphase;-inphase]; inphase = inphase(:);
quadr = [quadr;quadr]; quadr = quadr(:);
const = inphase + li*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```

Generate input data symbols. Modulate the symbols using this constellation.
$x=[38107] ;$
$y=$ genqammod $(x$, const) ;
Demodulate the modulated signal, y .
$z=$ genqamdemod (y, const);
Plot the modulated signal in same figure.
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');

Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
numErrs = 0
```

## Input Arguments

y - Complex envelope
scalar | vector | matrix | 3-D array
Complex envelope, specified as a scalar, vector, matrix, or 3-D array of numeric values. If y is a matrix with multiple rows, the function processes the rows independently.

## const - Signal mapping

complex vector
Signal mapping, specified as a complex vector.
Data Types: double | single

## Output Arguments

z - Message signal
scalar | vector | matrix | 3-D array

Message signal, returned as a scalar, vector, matrix, or 3-D array of numeric values. The message signal consists of integers between 0 and length(const)-1. The datatype of $z$ is the same as the data type of input $x$.
Data Types: double | single

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.

## genqammod

General quadrature amplitude modulation (QAM)

## Syntax

$y=\operatorname{genqammod}(x$, const)

## Description

$y=$ genqammod( $x$, const) returns the complex envelop of the QAM for message signal $x$. Input const specifies the signal mapping for the modulation.

## Examples

## General QAM Modulation and Demodulation

Create the points that describe a hexagonal constellation.

```
inphase = [1/2 1 1 1/2 1/2 2 2 5/2];
quadr = [0 1 -1 2 -2 1 -1 0];
inphase = [inphase;-inphase]; inphase = inphase(:);
quadr = [quadr;quadr]; quadr = quadr(:);
const = inphase + li*quadr;
```

Plot the constellation.

```
h = scatterplot(const);
```

Generate input data symbols. Modulate the symbols using this constellation.
$x=[38107] ;$
$y=$ genqammod $(x$, const $)$;
Demodulate the modulated signal, y .
$z=$ genqamdemod (y, const);
Plot the modulated signal in same figure.
hold on;
scatterplot(y,1,0,'ro',h);
legend('Constellation','Modulated signal');

Determine the number of symbol errors between the demodulated data to the original sequence.

```
numErrs = symerr(x,z)
numErrs = 0
```

## Input Arguments

x - Message signal
scalar | vector | matrix | 3-D array
Message signal, specified as a scalar, vector, matrix, or 3-D array of numeric values. The message signal must consist of integers from 0 and length(const)-1. If $x$ is a matrix with multiple rows, the function processes the columns independently.
Data Types: double | single | fi |int8|int16|uint8|uint16

## const - Signal mapping

complex vector
Signal mapping, specified as a complex vector.
Data Types: double | single | fi |int8|int16|uint8|uint16

## Output Arguments

y - Complex envelope
scalar | vector | matrix | 3-D array
Complex envelope, returned as a scalar, vector, matrix, or 3-D array of numeric values. The length of $y$ is the same as the length of input $x$.
Data Types: double | single |fi|int8|int16|uint8|uint16

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.

## gf

Galois field array

## Syntax

$x_{\text {_ }} \mathrm{gf}=\mathrm{gf}(\mathrm{x})$
$x^{-} \quad g f=g f(x, m)$
$x \_g f=g f\left(x, m, p r i m \_p o l y\right)$

## Description

$x \_g f=g f(x)$ creates a Galois field (GF) array, GF(2), from matrix $x$.
$x \_g f=g f(x, m)$ creates a Galois field array from matrix $x$. The Galois field has $2^{m}$ elements, where $m$ is an integer from 1 through 16.
$x \_g f=g f\left(x, m, p r i m \_p o l y\right)$ creates a Galois field array from matrix $x$ by using the primitive polynomial prim_poly.

## Examples

## Create GF(2) Array from Specified Matrix

Specify a matrix of 0 s and 1 s .
x = [0 1 1; 0 1 0; 1 1 1];
Create a GF(2) array from $x$.
$x_{-} g f=g f(x)$
x_gf = GF(2) array.
Array elements =

| 1 | 1 |
| :--- | :--- |
| 1 | 0 |
| 1 | 1 |

## Create Sequence of GF(16) Elements

Set the order of the Galois field to 16 , where the order equals $2^{m}$. Specify a matrix of elements that range from 0 to $2^{m}-1$. Create the Galois field array.

```
m = 4;
x = [3 2 9; 1 2 1];
y = gf(x,m)
```

```
y = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)
Array elements =
    3 2 
    1 2 1
```

## Create GF Sequence with Specified Primitive Polynomial

Create a sequence of integers. Create a Galois field array in $\operatorname{GF}\left(2^{5}\right)$.

```
x = [17 8 11 27];
y = gf(x,5)
```

$y=G F\left(2^{\wedge} 5\right)$ array. Primitive polynomial = D^5+D^2+1 (37 decimal)
Array elements =
$\begin{array}{llll}17 & 8 & 11 & 27\end{array}$

Determine all possible primitive polynomials for $\operatorname{GF}\left(2^{5}\right)$.

```
pp = primpoly(5,'all')
```

Primitive polynomial(s) =
$D^{\wedge} 5+D^{\wedge} 2+1$
D^5+D^3+1
D^5+D^3+D^2+D^1+1
$D^{\wedge} 5+D^{\wedge} 4+D^{\wedge} 2+D^{\wedge} 1+1$
$D^{\wedge} 5+D^{\wedge} 4+D^{\wedge} 3+D^{\wedge} 1+1$
$D^{\wedge} 5+D^{\wedge} 4+D^{\wedge} 3+D^{\wedge} 2+1$
$\mathrm{pp}=6 \times 1$
37
41
47
55
59
61

Create a Galois field array using the primitive polynomial that has a decimal equivalent of 59.

```
z = gf(x,5,'D5+D4+D3+D+1')
```

$z=G F\left(2^{\wedge} 5\right)$ array. Primitive polynomial = D^5+D^4+D^3+D+1 (59 decimal)
Array elements =
$\begin{array}{llll}17 & 8 & 11 & 27\end{array}$

## Input Arguments

## x - Input matrix

matrix with all values greater than or equal to zero
Input matrix, specified as a matrix with values greater than or equal to zero. The function uses this value to create a GF array.

- If you do not specify the prim_poly input argument, each element of $x$ must be an integer in the range $\left[0,2^{\mathrm{m}}-1\right]$.
- If you specify prim_poly input argument, each element of $x$ must be 0 or 1 .

Data Types: double

## m - Order of primitive polynomial

positive integer
Order of primitive polynomial, specified as a postive integer from 1 through 16. The function uses this value to calculate the distinct number of elements in the GF.

Data Types: double
prim_poly - Primitive polynomial
primitive polynomial in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$ (default) | binary row vector | character vector | string scalar | positive integer

Primitive polynomial, specified as one of these options:

- Binary row vector - This vector specifies coefficients of prim_poly in the order of ascending powers.
- Character vector or a string scalar - This value defines prim_poly in a textual representation. For more details, refer polynomial character vector.
- Positive integer - This value defines prim_poly in the range $\left[\left(2^{\mathrm{m}}+1\right),\left(2^{\mathrm{m}+1}-1\right)\right]$.

If prim_poly is not specified, see "Default Primitive Polynomials" on page 2-388 for the list of default primitive polynomial used for each Galois field array GF( $2^{\mathrm{m}}$ ).
Data Types: double | char| string

## Output Arguments

## x_gf - Galois field array

variable that MATLAB recognizes as a Galois field array
Galois field array, returned as a variable that MATLAB recognizes as a Galois field array, rather than an array of integers. As a result, when you manipulate the variable, MATLAB works within the Galois field the variable specifies. For example, if you apply the $\log$ function to a Galois array, MATLAB computes the logarithm in the Galois field for that Galois array and not in the field of real or complex numbers.

## More About

## Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array $\mathrm{GF}\left(2^{\mathrm{m}}\right)$. To use a different primitive polynomial, specify prim_poly as an input argument. prim_poly must be in the range $\left[\left(2^{m}+1\right),\left(2^{m+1}-1\right)\right]$ and must indicate an irreducible polynomial. For more information, see "Primitive Polynomials and Element Representations".

| Value of $\mathbf{m}$ | Default Primitive Polynomial | Integer Representation |
| :--- | :--- | :--- |
| 1 | $D+1$ | 3 |
| 2 | $D^{2}+D+1$ | 7 |
| 3 | $D^{3}+D+1$ | 11 |
| 4 | $D^{4}+D+1$ | 19 |
| 5 | $D^{5}+D^{2}+1$ | 37 |
| 6 | $D^{6}+D+1$ | 67 |
| 7 | $D^{7}+D^{3}+1$ | 137 |
| 8 | $D^{8}+D^{4}+D^{3}+D^{2}+1$ | 285 |
| 9 | $D^{9}+D^{4}+1$ | 529 |
| 10 | $D^{10}+D^{3}+1$ | 1033 |
| 11 | $D^{11}+D^{2}+1$ | 2053 |
| 12 | $D^{12}+D^{6}+D^{4}+D+1$ | 4179 |
| 13 | $D^{13}+D^{4}+D^{3}+D+1$ | 8219 |
| 14 | $D^{14}+D^{10}+D^{6}+D+1$ | 17475 |
| 15 | $D^{15}+D+1$ | 32771 |
| 16 | $D^{16}+D^{12}+D^{3}+D+1$ | 69643 |

## Galois Computations

This table lists the operations supported for Galois field arrays.

| Operation | Description |
| :--- | :--- |
| +- | Addition and subtraction of Galois arrays |
| $* / \backslash$ | Matrix multiplication and division of Galois arrays |
| $\cdot * . / . \backslash$ | Elementwise multiplication and division of Galois <br> arrays |
| $\wedge$ | Matrix exponentiation of Galois array |
| $\wedge^{\wedge}$ | Elementwise exponentiation of Galois array |
| $\ddots^{\prime}$ | Transpose of Galois array |
| $==, \sim=$ | Relational operators for Galois arrays |
| all | True if all elements of a Galois vector are nonzero |
| any | True if any element of a Galois vector is nonzero |

| Operation | Description |
| :--- | :--- |
| conv | Convolution of Galois vectors |
| convmtx | Convolution matrix of Galois field vector |
| deconv | Deconvolution and polynomial division |
| det | Determinant of square Galois matrix |
| dftmtx | Discrete Fourier transform matrix in a Galois field |
| diag | Diagonal Galois matrices and diagonals of a <br> Galois matrix |
| fft | Discrete Fourier transform |
| filter (gf) | One-dimensional digital filter over a Galois field |
| ifft | Inverse discrete Fourier transform |
| inv | Inverse of Galois matrix |
| length | Length of Galois vector |
| log | Logarithm in a Galois field |
| lu | Lower-Upper triangular factorization of Galois <br> array |
| minpol | Find the minimal polynomial for a Galois element |
| mldivide | Matrix left division $\backslash$ of Galois arrays |
| polyval | Evaluate polynomial in Galois field |
| rank | Rank of a Galois array |
| reshape | Reshape Galois array |
| roots | Find polynomial roots across a Galois field |
| size | Size of Galois array |
| tril | Extract lower triangular part of Galois array |
| triu | Extract upper triangular part of Galois array |

"ElGamal Public Key Cryptosystem"

## Introduced before R2006a

## gfadd

Add polynomials over Galois field

## Syntax

$c=\operatorname{gfadd}(\mathrm{a}, \mathrm{b})$
$c=$ gfadd $(a, b, p)$
$c=$ gfadd $(a, b, p, l e n)$
$c=\operatorname{gfadd}(a, b, f i e l d)$

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$ where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, apply the + operator to Galois arrays of equal size. For details, see "Example: Addition and Subtraction".
$\mathrm{c}=\mathrm{gfadd}(\mathrm{a}, \mathrm{b})$ adds two $\mathrm{GF}(2)$ polynomials, a and b , which can be either polynomial character vectors or numeric vectors. If $a$ and $b$ are vectors of the same orientation but different lengths, then the shorter vector is zero-padded. If $a$ and $b$ are matrices they must be of the same size.
$c=\operatorname{gfadd}(a, b, p)$ adds two $G F(p)$ polynomials, where $p$ is a prime number. $a, b$, and $c$ are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and $p$-1. If $a$ and $b$ are matrices of the same size, the function treats each row independently.
$c=\operatorname{gfadd}(a, b, p, l e n)$ adds row vectors $a$ and $b$ as in the previous syntax, except that it returns a row vector of length len. The output c is a truncated or extended representation of the sum. If the row vector corresponding to the sum has fewer than len entries (including zeros), extra zeros are added at the end; if it has more than len entries, entries from the end are removed.
$c=\operatorname{gfadd}(a, b, f i e l d)$ adds two $G F\left(p^{m}\right)$ elements, where $m$ is a positive integer. $a$ and $b$ are the exponential format of the two elements, relative to some primitive element of $G F\left(p^{m}\right)$. field is the matrix listing all elements of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, arranged relative to the same primitive element. c is the exponential format of the sum, relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats. If $a$ and $b$ are matrices of the same size, the function treats each element independently.

## Examples

## Add Two GF Arrays

Sum $2+3 x+x^{2}$ and $4+2 x+3 x^{2}$ over GF(5).

```
x = gfadd([2 3 1],[4 2 3],5)
x = 1\times3
```

104

Add the two polynomials and display the first two elements.

```
y = gfadd([[2 3 1],[[4 2 3],5,2)
y = 1\times2
    1 0
```

For prime number $p$ and exponent $m$, create a matrix listing all elements of $G F\left(p^{\wedge} m\right)$ given primitive polynomial $2+2 x+x^{2}$.
p = 3;
$\mathrm{m}=2$;
primpoly = [2 2 1];
field $=$ gftuple((-1: $\left.p^{\wedge} m-2\right)^{\prime}$, primpoly, $\left.p\right)$;
Sum $A^{2}$ and $A^{4}$. The result is $A$.
$g=\operatorname{gfadd}(2,4, f i e l d)$
$g=1$

## Topics

"Arithmetic in Galois Fields"

Introduced before R2006a

## gfconv

Multiply polynomials over Galois field

## Syntax

$c=\operatorname{gfconv}(a, b)$
$c=\operatorname{gfconv}(a, b, p)$
$c=g f c o n v(a, b, f i e l d)$
$c=$ gfconv(polys)
$c=$ gfconv(polys,p)
c = gfconv(polys,field)

## Description

$c=g f c o n v(a, b)$ returns a row vector that specifies the $\mathrm{GF}(2)$ polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of $\mathrm{GF}(2)$ polynomials $a$ and $b$. The polynomial degree of the resulting $\mathrm{GF}(2)$ polynomial cequals the degree of a plus the degree of b.

For additional information, see "Tips" on page 2-396.
$c=\operatorname{gfconv}(a, b, p)$ multiplies two $G F(p)$ polynomials, where $p$ is a prime number. $a, b$, and $c$ are in the same Galois field. $a, b$, and $c$ are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [ $0, \mathrm{p}-1$ ].
$\mathrm{c}=\mathrm{gfconv}\left(\mathrm{a}, \mathrm{b}\right.$, field) multiplies two $\mathrm{GF}\left(p^{m}\right)$ polynomials, where field is a matrix containing the $m$-tuple of all elements in $\operatorname{GF}\left(p^{m}\right) . p$ is a prime number, and $m$ is a positive integer. $\mathrm{a}, \mathrm{b}$, and c are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically $[-I n f, 0,1,2, \ldots]$. The elements in exponential format represent the field elements [ $0,1, \alpha, \alpha^{2}, \ldots$. relative to some primitive element $\alpha$ of $\operatorname{GF}\left(p^{m}\right)$.
$\mathrm{c}=\mathrm{gfconv}($ polys $)$ returns a row vector that specifies the GF(2) polynomial coefficients in order of ascending powers. The returned vector results from the multiplication of the GF(2) polynomials specified in polys. The polynomial degree of the resulting GF(2) polynomial c equals the sum of the degrees of the polynomials contained in polys. Use this syntax when polys specifies polynomials as a cell array of character vectors or as a string array.
$\mathrm{c}=\mathrm{gfconv}($ polys, p ) multiplies the $\mathrm{GF}(\mathrm{p})$ polynomials specified in polys, where p is a prime number. polys and c are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [ $0, p-1$ ]. $a, b$, and $c$ are in the same Galois field.
$c=$ gfconv(polys,field) multiplies the $\operatorname{GF}\left(p^{m}\right)$ polynomials in polys, where field is a matrix containing the $m$-tuple of all elements in $\operatorname{GF}\left(p^{m}\right)$. $p$ is a prime number, and $m$ is a positive integer. a, b, and c are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, $0,1,2, \ldots]$. The elements in exponential format represent the field elements [ $0,1, \alpha, \alpha^{2}, \ldots$ ] relative to some primitive element $\alpha$ of $\operatorname{GF}\left(p^{m}\right)$.

## Examples

## Multiply GF(2) Polynomials

Multiply $1+2 x+3 x^{2}+4 x^{3}$ and $1+x$ three times. Represent the polynomials as row vectors, character vectors, and strings.

```
c_rv = gfconv([[1 1 0 1],[[1 1])
c_rv = 1\times5
    1 
c_cv = gfconv('1 + x + x^3','1 + x')
c cV = 1\times5
    1 0
c_s = gfconv("1 + x + x^3","1 + x")
C_s = 1\times5
    1 
```

The results corresponds to $1+x^{2}+x^{3}+x^{4}$.

## Multiply Polynomials Over GF(3)

Multiply $1+x+x^{4}$ and $x+x^{2}$ over the Galois field GF(3).

gfc $=1 \times 7$
$\begin{array}{lllllll}0 & 1 & 2 & 1 & 0 & 1 & 1\end{array}$

The result corresponds to $x+2 x^{2}+x^{3}+x^{5}+x^{6}$.

## Multiply Polynomials Over GF(2^4) Using Field Input

Multiply $1+2 x+3 x^{2}+4 x^{3}+5 x^{4}$ and $1+x$ in the Galois field $\operatorname{GF}\left(2^{4}\right)$.
field = gftuple([-1:2^4-2]',4,2);
$\mathrm{c}=\mathrm{gfconv}\left({ }^{\prime} 1+2 x+3 x^{\wedge} 2+4 x^{\wedge} 3+5 x^{\wedge} 4 ', ' 1+x^{\prime}, f i e l d\right)$
c $=1 \times 6$

```
2 
```

Use the gfpretty function to display the result in polynomial form.
gfpretty(c)

$$
2+6 x+7 x^{2}+8 x^{3}+9 x^{4}+6 x^{5}
$$

## Multiply GF(2) Polynomials Specified As Cell Array

Create a cell array containing three polynomials that result in the DVB-S2 generator polynomial for $t=3$ when multiplied together.

```
polyCell = {'1 + x + x3 + x5 + x14', ...
    '1 + x6 + x8 + x11 + x14','1 + x + x2 + x6 + x9 + x10 + x14'};
gp = gfconv(polyCell); % DVB-S2 for t=3
```

Use the gfpretty function to display the result in polynomial form.

```
gfpretty(gp)
```

$1+x^{4}+x^{6}+x^{8}+x^{10}+x^{11}+x^{13}+x^{16}+x^{17}+x^{20}+x^{24}+x^{25}+x^{26}+x^{27}$
$+x^{30}+x^{31}+x^{32}+x^{33}+x^{34}+x^{35}+x^{36}+x^{37}+x^{38}+x^{39}+x^{42}$

## Multiply Polynomials Expressed As Strings in GF(2^4) Using Field Input

Multiply $1+2 x+3 x^{2}+4 x^{3}+5 x^{4}, 1+x$, and $1+x^{3}$ in the Galois field $\operatorname{GF}\left(2^{4}\right)$.

```
field = gftuple((-1:2^4-2)', 4, 2);
c = gfconv(["1 + 2x + 3x^2 + 4x^3 + 5x^4","1 + x","1 + x3"],field)
c = 1\times9
    4
```

Use the gfpretty function to display the result in polynomial form.
gfpretty(c)

$$
4+13 x+14 x^{2}+9 x^{3}+2 x^{4}+x^{5}+7 x^{6}+8 x^{7}+8 x^{8}
$$

## Input Arguments

## a - Galois field polynomial

row vector | character vector | string
Galois field polynomial, specified as a row vector, character vector, or string. a can be either a "Character Representation of Polynomials" or numeric vector.
a and b must both be $\mathrm{GF}(p)$ polynomials or $\mathrm{GF}\left(p^{m}\right)$ polynomials, where $p$ is prime. The value of $p$ is as specified when included, 2 when omitted, or implied when field is specified.
Example: [llll $\left.\begin{array}{llll}2 & 3 & 4\end{array}\right]$ is the polynomial $1+2 x+3 x^{2}+4 x^{3}$ in $G F(5)$ expressed as a row vector.
Data Types: double | char | string
b - Galois field polynomial
row vector | character vector | string
Galois field polynomial, specified as a row vector, character vector, or string. b can be either a "Character Representation of Polynomials" or numeric vector.
a and b must both be $\mathrm{GF}(p)$ polynomials or $\mathrm{GF}\left(p^{m}\right)$ polynomials, where $p$ is prime. The value of $p$ is as specified when included, 2 when omitted, or implied when field is specified.
Example: ' $1+x$ ' is a polynomial in $\mathrm{GF}\left(2^{4}\right)$ expressed as a character vector.
Data Types: double | char | string
p - Prime number
2 (default) | prime number
Prime number, specified as a prime number.
Data Types: double

## field - m-tuple of all elements in GF( $\boldsymbol{p}^{m}$ )

matrix
m-tuple of all elements in $\operatorname{GF}\left(p^{m}\right)$, specified as a matrix. field is the matrix listing all elements of $\mathrm{GF}\left(p^{m}\right)$, arranged relative to the same primitive element. To generate the $m$-tuple of all elements in $\mathrm{GF}\left(p^{m}\right)$, use

```
field =gftuple([-1:p^m-2]',m,p)
```

The coefficients, specified in exponential format, represent the field elements in $\mathrm{GF}\left(p^{m}\right)$. For an explanation of these formats, see "Representing Elements of Galois Fields".
Data Types: double

## polys - Galois field polynomial list

cell array of character vectors | string array
Galois field polynomial list, specified as a cell array of character vectors or a string array.
Example: ["1+x+x3+x5+x14", "1+x6+x8+x11+x14"] is a string array of polynomials.
Data Types: cell | string

## Output Arguments

## c - Galois field polynomial

row vector
Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. The polynomial degree of the resulting $\mathrm{GF}\left(p^{m}\right)$ polynomial c equals the sum of the degrees of the input polynomials. c is in the same Galois field as the input polynomials.

## Tips

- The gfconv function performs computations in $\mathrm{GF}\left(p^{m}\right)$, where $p$ is prime, and $m$ is a positive integer. It multiplies polynomials over a Galois field. To work in $\mathrm{GF}\left(2^{m}\right)$, you can also use the conv function of the gf object with Galois arrays. For details, see "Multiplication and Division of Polynomials".
- To multiply elements of a Galois field, use gfmul instead of gfconv. Algebraically, multiplying polynomials over a Galois field is equivalent to convolving vectors containing the coefficients of the polynomials. This convolution operation uses arithmetic over the same Galois field.

## Introduced before R2006a

## gfcosets

Produce cyclotomic cosets for Galois field

## Syntax

$c=g f \operatorname{cosets}(m)$
c = gfcosets(m, p )

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the cosets function.
$c=g f \operatorname{cosets}(m)$ produces cyclotomic cosets $\bmod \left(2^{m}-1\right)$. Each row of the output GFCS contains one cyclotomic coset.
$c=g f \operatorname{cosets}(m, p)$ produces the cyclotomic cosets for $G F\left(p^{\wedge} m\right)$, where $m$ is a positive integer and $p$ is a prime number.

The output matrix c is structured so that each row represents one coset. The row represents the coset by giving the exponential format of the elements of the coset, relative to the default primitive polynomial for the field. For a description of exponential formats, see "Representing Elements of Galois Fields".

The first column contains the coset leaders. Because the lengths of cosets might vary, entries of NaN are used to fill the extra spaces when necessary to make c rectangular.

A cyclotomic coset is a set of elements that all satisfy the same minimal polynomial. For more details on cyclotomic cosets, see the works listed in "References" on page 2-398.

## Examples

The command below finds the cyclotomic cosets for $\mathrm{GF}(9)$.

```
c = gfcosets(2,3)
```

The output is
c =

| 0 | NaN |
| :--- | ---: |
| 1 | 3 |
| 2 | 6 |
| 4 | NaN |
| 5 | 7 |

The gfminpol function can check that the elements of, for example, the third row of c indeed belong in the same coset.

```
m = [gfminpol(2,2,3); gfminpol(6,2,3)] % Rows are identical.
```

The output is
m =

| 1 | 0 | 1 |
| :--- | :--- | :--- |
| 1 | 0 | 1 |

## gfdeconv

Divide polynomials over Galois field

## Syntax

$[q, r]=\operatorname{gfdeconv}(b, a)$
$[q, r]=\operatorname{gfdeconv}(b, a, p)$
$[q, r]=\operatorname{gfdeconv}(b, a, f i e l d)$

## Description

$[q, r]=\operatorname{gfdeconv}(b, a)$ returns the quotient $q$ and remainder $r$ as row vectors that specify $G F(2)$ polynomial coefficients in order of ascending powers. The returned vectors result from the division $b$ by a. a, b, and q are in GF(2).

For additional information, see "Tips" on page 2-402.
$[q, r]=\operatorname{gfdeconv}(b, a, p)$ divides two $G F(p)$ polynomials, where $p$ is a prime number. $b, a$, and $q$ are in the same Galois field. $b, a, q$, and $r$ are polynomials with coefficients in order of ascending powers. Each coefficient is in the range [0, p-1].
[ $q, r$ ] = gfdeconv(b,a,field) divides two $G F\left(p^{m}\right)$ polynomials, where field is a matrix containing the $m$-tuple of all elements in $\operatorname{GF}\left(p^{m}\right)$. $p$ is a prime number, and $m$ is a positive integer. b , a, and $q$ are in the same Galois field.

In this syntax, each coefficient is specified in exponential format, specifically [-Inf, $0,1,2, \ldots]$. The elements in exponential format represent the field elements [ $0,1, \alpha, \alpha^{2}, \ldots$. relative to some primitive element $\alpha$ of $\mathrm{GF}\left(p^{m}\right)$.

## Examples

## Divide Polynomials in GF(3)

Divide $x+x^{3}+x^{4}$ by $1+x$ in the Galois field GF(3) three times. Represent the polynomials as row vectors, character vectors, and strings.
$\mathrm{p}=3 ;$
Represent the polynomials using row vectors and divide them in GF(3).

```
b = [0 0 1 0 1 1];
a = [1 1];
[q_rv,r_rv] = gfdeconv(b,a,p)
q_rv = 1\times4
    1 0 0 1
r_rv = 2
```

To confirm the output, compare the original Galois field polynomials to the result of adding the remainder to the product of the quotient and the divisor.

```
bnew = gfadd(gfconv(q_rv,a,p),r_rv,p);
isequal(b,bnew)
ans = logical
    1
```

Represent the polynomials using character vectors and divide them in GF(3).

```
b = 'x + x^3 + x^4';
a = '1 + x';
[q_cv,r_cv] = gfdeconv(b,a,p)
q_cv = 1\times4
    1 0 0 1
rcv = 2
```

Represent the polynomials using strings and divide them in GF(3).

```
b = "x + x^3 + x^4";
a = "1 + x";
[q_s,r_s] = gfdeconv(b,a,p)
q_s = 1\times4
    1 0 0 1
r_s = 2
```

Use the gfpretty function to display the result without the remainder in polynomial form.
gfpretty(q_s)

$$
1+x^{3}
$$

## Check for Irreducibility and Primitiveness Over GF( $\mathbf{3}^{\wedge} \mathbf{k}$ )

In the Galois field $\mathrm{GF}(3)$, output polynomials of the form $x^{k}-1$ for $k$ in the range $[2,8]$ that are evenly divisible by $1+x^{2}$. An irreducible polynomial over $\mathrm{GF}(\mathrm{p})$ of degree at least 2 is primitive if and only if it does not divide $-1+x^{k}$ evenly for any positive integer $k$ less than $p^{m}-1$. For more information, see the gfprimck function.

The irreducibility of $1+x^{2}$ over $\mathrm{GF}(3)$, along with the polynomials that are output, indicates that $1+x^{2}$ is not primitive for $\mathrm{GF}\left(3^{2}\right)$.
$\mathrm{p}=3 ; \mathrm{m}=2 ;$
$a=\left[\begin{array}{lll}1 & 0 & 1\end{array}\right] ; \% 1+x^{\wedge} 2$

```
for ii = 2:p^m-1
    b = gfrepcov(ii); % x^ii
    b(1) = p-1; % - 1+x^ii
    [quot,remd] = gfdeconv(b,a,p);
    % Display -1+x^ii if a divides it evenly.
    if remd==0
        multiple{ii}=b;
        gfpretty(b)
    end
end
```

```
    4
2 + X
    8
2 + X
```

## Input Arguments

## b - Galois field polynomial

row vector | character vector | string
Galois field polynomial, specified as a row vector, character vector, or string. b can be either a "Character Representation of Polynomials" or numeric vector.
a and b must both be $\mathrm{GF}(p)$ polynomials or $\mathrm{GF}\left(p^{m}\right)$ polynomials, where $p$ is prime. The value of $p$ is as specified when included, 2 when omitted, or implied when field is specified.
Example: ' $1+\mathrm{x}$ ' is a polynomial in $\mathrm{GF}\left(2^{4}\right)$ expressed as a character vector.
Data Types: double | char | string
a - Galois field polynomial
row vector | character vector | string
Galois field polynomial, specified as a row vector, character vector, or string. a can be either a "Character Representation of Polynomials" or numeric vector.
a and b must both be $\mathrm{GF}(p)$ polynomials or $\mathrm{GF}\left(p^{m}\right)$ polynomials, where $p$ is prime. The value of $p$ is as specified when included, 2 when omitted, or implied when field is specified.
Example: $\left[\begin{array}{llll}1 & 2 & 3 & 4\end{array}\right]$ is the polynomial $1+2 x+3 x^{2}+4 x^{3}$ in $G F(5)$ expressed as a row vector.
Data Types: double | char | string
p - Prime number
2 (default) | prime number
Prime number, specified as a prime number.
Data Types: double

## field - m-tuple of all elements in GF ( $\boldsymbol{p}^{m}$ )

matrix
m-tuple of all elements in $\operatorname{GF}\left(p^{m}\right)$, specified as a matrix. field is the matrix listing all elements of $\mathrm{GF}\left(p^{m}\right)$, arranged relative to the same primitive element. To generate the $m$-tuple of all elements in GF $\left(p^{m}\right)$, use
field =gftuple([-1:p^m-2]',m,p)
The coefficients, specified in exponential format, represent the field elements in $\mathrm{GF}\left(p^{m}\right)$. For an explanation of these formats, see "Representing Elements of Galois Fields".
Data Types: double

## Output Arguments

## q - Galois field polynomial

row vector
Galois field polynomial, returned as a row vector of the polynomial coefficients in order of ascending powers. $q$ is the quotient from the division of $b$ by $a$ and is in the same Galois field as the input polynomials.
$r$ - Division remainder
scalar | row vector
Division remainder, returned as a scalar or a row vector of the polynomial coefficients in order of ascending powers. $r$ is the remainder resulting from the division of $b$ by $a$.

## Tips

- The gfdeconv function performs computations in $\mathrm{GF}\left(p^{m}\right)$, where $p$ is prime, and $m$ is a positive integer. It divides polynomials over a Galois field. To work in GF( $2^{m}$ ), use the deconv function of the gf object with Galois arrays. For details, see "Multiplication and Division of Polynomials".
- To divide elements of a Galois field, you can also use gfdiv instead of gfdeconv. Algebraically, dividing polynomials over a Galois field is equivalent to deconvolving vectors containing the coefficients of the polynomials. This deconvolution operation uses arithmetic over the same Galois field.

Introduced before R2006a

## gfdiv

Divide elements of Galois field

## Syntax

```
quot = gfdiv(b,a)
quot = gfdiv(b,a,p)
quot = gfdiv(b,a,field)
```

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, apply the ./ operator to Galois arrays. For details, see "Example: Division".

The gfdiv function divides elements of a Galois field. (To divide polynomials over a Galois field, use gfdeconv instead.)
quot $=\operatorname{gfdiv}(b, a)$ divides $b$ by $a$ in GF(2) element-by-element. $a$ and $b$ are scalars, vectors or matrices of the same size. Each entry in $a$ and $b$ represents an element of GF(2). The entries of $a$ and b are either 0 or 1 .
quot $=\operatorname{gfdiv}(\mathrm{b}, \mathrm{a}, \mathrm{p})$ divides b by a in $\mathrm{GF}(\mathrm{p})$ and returns the quotient. p is a prime number. If a and $b$ are matrices of the same size, the function treats each element independently. All entries of $b$, a , and quot are between 0 and $\mathrm{p}-1$.
quot $=\operatorname{gfdiv}(b, a, f i e l d)$ divides $b$ by $a \operatorname{in} G F\left(p^{m}\right)$ and returns the quotient. $p$ is a prime number and $m$ is a positive integer. If $a$ and $b$ are matrices of the same size, then the function treats each element independently. All entries of $b, a$, and quot are the exponential formats of elements of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$ relative to some primitive element of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$. field is the matrix listing all elements of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, arranged relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats.

In all cases, an attempt to divide by the zero element of the field results in a "quotient" of NaN.

## Examples

The code below displays lists of multiplicative inverses in $\mathrm{GF}(5)$ and $\mathrm{GF}(25)$. It uses column vectors as inputs to gfdiv.

```
% Find inverses of nonzero elements of GF(5).
p = 5;
b = ones(p-1,1);
a = [1:p-1]';
quot1 = gfdiv(b,a,p);
disp('Inverses in GF(5):')
disp('element inverse')
disp([a, quot1])
% Find inverses of nonzero elements of GF(25).
```

```
m = 2;
field = gftuple([-1:p^m-2]',m,p);
b = zeros(p^m-1,1); % Numerator is zero since 1 = alpha^0.
a = [0:p^m-2]';
quot2 = gfdiv(b,a,field);
disp('Inverses in GF(25), expressed in EXPONENTIAL FORMAT with')
disp('respect to a root of the default primitive polynomial:')
disp('element inverse')
disp([a, quot2])
```

## gffilter (prime Galois field)

Filter data using polynomials over prime Galois field

## Syntax

```
y = gffilter(b,a,x)
y = gffilter(b,a,x,p)
```

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the filter function with Galois arrays. For details, see "Filtering".
$y=$ gffilter $(b, a, x)$ filters the data in vector $x$ with the filter described by vectors $b$ and $a$. The vectors $b$, a and $x$ must be in GF(2), that is, be binary and $y$ is also in GF(2).
$y=g f f i l t e r(b, a, x, p)$ filters the data $x$ using the filter described by vectors $a$ and $b . y$ is the filtered data in $\mathrm{GF}(\mathrm{p})$. p is a prime number, and all entries of a and b are between 0 and $\mathrm{p}-1$.

By definition of the filter, $y$ solves the difference equation

$$
\begin{aligned}
& a(1) y(n)=b(1) x(n)+b(2) x(n-1)+b(3) x(n-2)+\ldots+b(B+1) x(n-B) \\
&-a(2) y(n-1)-a(3) y(n-2)-\ldots-a(A+1) y(n-A)
\end{aligned}
$$

where

- $\mathrm{A}+1$ is the length of the vector a
- $\mathrm{B}+1$ is the length of the vector b
- $n$ varies between 1 and the length of the vector $x$.

The vector a represents the degree- $\mathrm{n}_{\mathrm{a}}$ polynomial
$a(1)+a(2) x+a(3) x^{\wedge} 2+\ldots+a(A+1) x^{\wedge} A$

## Examples

The impulse response of a particular filter is given in the code and diagram below.

```
b = [1 0 0 0 1 0 1 0 1];
a = [1 0 1 1];
y = gffilter(b,a,[1,zeros(1,19)]);
stem(y);
axis([0 20 -. 1 1.1])
```

## See Also

## gflineq

Find particular solution of $\mathrm{Ax}=\mathrm{b}$ over prime Galois field

## Syntax

$x=g f l i n e q(A, b)$
$x=g f l i n e q(A, b, p)$
[x,vld] = gflineq(...)

## Description

Note This function performs computations in $\mathrm{GF}(\mathrm{p})$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, apply the $\backslash$ or / operator to Galois arrays. For details, see "Solving Linear Equations".
$x=g f l$ ineq $(A, b)$ outputs a particular solution of the linear equation $A x=b$ in $G F(2)$. The elements in $\mathrm{a}, \mathrm{b}$ and x are either 0 or 1 . If the equation has no solution, then x is empty.
$x=\operatorname{gflineq}(A, b, p)$ returns a particular solution of the linear equation $A x=b$ over $G F(p)$, where $p$ is a prime number. If $A$ is a $k$-by-n matrix and $b$ is a vector of length $k, x$ is a vector of length $n$. Each entry of $A, x$, and $b$ is an integer between 0 and $p-1$. If no solution exists, $x$ is empty.
$[x, v l d]=g f l i n e q(\ldots)$ returns a flag $v l d$ that indicates the existence of a solution. If $v l d=1$, the solution $x$ exists and is valid; if $v l d=0$, no solution exists.

## Examples

The code below produces some valid solutions of a linear equation over $\mathrm{GF}(3)$.

```
A = [ll 0 1;
    1 1 0;
    1 1 2];
% An example in which the solutions are valid
[x,vld] = gflineq(A,[1;0;0],3)
```

The output is below.

```
x =
    2
    1
    0
vld =
```

    1
    By contrast, the command below finds that the linear equation has no solutions.

```
[x2,vld2] = gflineq(zeros(3,3),[2;0;0],3)
```

The output is below.
This linear equation has no solution.
x2 $=$
[]
vld2 =
0

## Algorithms

gflineq uses Gaussian elimination.

## gfminpol

Find minimal polynomial of Galois field element

## Syntax

```
pol = gfminpol(k,m)
pol = gfminpol(k,m,p)
pol = gfminpol(k,prim_poly,p)
```

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the minpol function with Galois arrays. For details, see "Minimal Polynomials".
pol = gfminpol ( $\mathrm{k}, \mathrm{m}$ ) produces a minimal polynomial for each entry in $\mathrm{k} . \mathrm{k}$ must be either a scalar or a column vector. Each entry in k represents an element of $\mathrm{GF}\left(2^{m}\right)$ in exponential format. That is, k represents alpha^ $k$, where alpha is a primitive element in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$. The $i$ th row of pol represents the minimal polynomial of $k(i)$. The coefficients of the minimal polynomial are in the base field $\mathrm{GF}(2)$ and listed in order of ascending exponents.
pol = gfminpol ( $k, m, p$ ) finds the minimal polynomial of $A^{k}$ over $G F(p)$, where $p$ is a prime number, $m$ is an integer greater than 1 , and $A$ is a root of the default primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$. The format of the output is as follows:

- If k is a nonnegative integer, pol is a row vector that gives the coefficients of the minimal polynomial in order of ascending powers.
- If k is a vector of length len all of whose entries are nonnegative integers, pol is a matrix having len rows; the rth row of pol gives the coefficients of the minimal polynomial of $\mathrm{A}^{\mathrm{k}(\mathrm{r})}$ in order of ascending powers.
pol $=$ gfminpol ( k, prim_poly, p ) is the same as the first syntax listed, except that A is a root of the primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$ specified by prim_poly. prim_poly is a polynomial character vector or a row vector that gives the coefficients of the degree-m primitive polynomial in order of ascending powers.

## Examples

The syntax $\mathrm{gfminpol}(\mathrm{k}, \mathrm{m}, \mathrm{p})$ is used in the sample code in "Characterization of Polynomials".

## See Also <br> gfcosets|gfprimdf|gfroots

## Introduced before R2006a

## gfmul

Multiply elements of Galois field

## Syntax

$c=\operatorname{gfmul}(a, b, p)$
$c=\operatorname{gfmul}(a, b, f i e l d)$

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$ where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, apply the . * operator to Galois arrays. For details, see "Example: Multiplication".

The gfmul function multiplies elements of a Galois field. (To multiply polynomials over a Galois field, use gfconv instead.)
$c=\operatorname{gfmul}(a, b, p)$ multiplies $a$ and $b$ in $G F(p)$. Each entry of $a$ and $b$ is between 0 and $p-1 . p$ is $a$ prime number. If $a$ and $b$ are matrices of the same size, the function treats each element independently.
$c=\operatorname{gfmul}(a, b, f i e l d)$ multiplies $a$ and $b$ in $G F\left(p^{m}\right)$, where $p$ is a prime number and $m$ is $a$ positive integer. $a$ and $b$ represent elements of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$ in exponential format relative to some primitive element of $G F\left(p^{m}\right)$. field is the matrix listing all elements of $G F\left(p^{m}\right)$, arranged relative to the same primitive element. c is the exponential format of the product, relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats. If $a \operatorname{and} b$ are matrices of the same size, the function treats each element independently.

## Examples

"Arithmetic in Galois Fields" contains examples. Also, the code below shows that

$$
A^{2} \cdot A^{4}=A^{6}
$$

where $A$ is a root of the primitive polynomial $2+2 \mathrm{x}+\mathrm{x}^{2}$ for $\mathrm{GF}(9)$.

```
p = 3; m = 2;
prim_poly = [2 2 1];
field = gftuple([-1:p^m-2]',prim_poly,p);
a = gfmul(2,4,field)
```

The output is
a $=$
6

Introduced before R2006a

## gfpretty

Polynomial in traditional format

## Syntax

gfpretty(a)
gfpretty (a,st)
gfpretty (a,st, n)

## Description

gfpretty (a) displays a polynomial in a traditional format, using $X$ as the variable and the entries of the row vector a as the coefficients in order of ascending powers. The polynomial is displayed in order of ascending powers. Terms having a zero coefficient are not displayed.
gfpretty ( $a, s t$ ) is the same as the first syntax listed, except that the content of st is used as the variable instead of $X$.
gfpretty ( $a, s t, n$ ) is the same as the first syntax listed, except that the content of st is used as the variable instead of $X$, and each line of the display has width $n$ instead of the default value of 79 .

Note For all syntaxes: If you do not use a fixed-width font, the spacing in the display might not look correct.

## Examples

Display statements about the elements of $\mathrm{GF}(81)$.

```
p = 3; m = 4;
ii = randi([1,p^m-2],1,1); % Random exponent for prim element
primpolys = gfprimfd(m,'all',p);
[rows, cols] = size(primpolys);
jj = randi([1,rows],1,1); % Random primitive polynomial
disp('If A is a root of the primitive polynomial')
gfpretty(primpolys(jj,:)) % Polynomial in X
disp('then the element')
gfpretty([zeros(1,ii),1],'A') % The polynomial A^ii
disp('can also be expressed as')
gfpretty(gftuple(ii,m,p),'A') % Polynomial in A
```

Below is a sample of the output.
If $A$ is a root of the primitive polynomial

$$
2+2 x^{3}+x^{4}
$$

then the element

A
can also be expressed as

$$
2+A^{2}+A^{3}
$$

## See Also

gfprimdf|gftuple
Introduced before R2006a

## gfprimck

Check whether polynomial over Galois field is primitive

## Syntax

ck = gfprimck(a)
ck = gfprimck(a,p)

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. If you are working in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the isprimitive function. For details, see Finding Primitive Polynomials in "Primitive Polynomials and Element Representations".
$\mathrm{ck}=\mathrm{gfprimck}(\mathrm{a})$ checks whether the degree-m GF(2) polynomial a is a primitive polynomial for $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, where $\mathrm{m}=$ length(a) -1 . The output ck is as follows:

-     - 1 if a is not an irreducible polynomial
- 0 if a is irreducible but not a primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$
- 1 if a is a primitive polynomial for $\operatorname{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$
$\mathrm{ck}=\operatorname{gfprimck}(\mathrm{a}, \mathrm{p})$ checks whether the degree-m $\mathrm{GF}(\mathrm{P})$ polynomial a is a primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$. p is a prime number.
a is either a polynomial character vector or a row vector representing the polynomial by listing its coefficients in ascending order. For example, in $G F(5), ' 4+3 x+2 x^{\wedge} 3 '$ and [ 4 3 302 2 are equivalent.

This function considers the zero polynomial to be "not irreducible" and considers all polynomials of degree zero or one to be primitive.

## Examples

"Characterization of Polynomials" contains examples.

## Algorithms

An irreducible polynomial over $\mathrm{GF}(\mathrm{p})$ of degree at least 2 is primitive if and only if it does not divide $-1+\mathrm{x}^{\mathrm{k}}$ for any positive integer k smaller than $\mathrm{p}^{\mathrm{m}}-1$.

## gfprimdf

Provide default primitive polynomials for Galois field

## Syntax

```
pol = gfprimdf(m)
pol = gfprimdf(m,p)
```

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the primpoly function. For details, see Finding Primitive Polynomials in "Primitive Polynomials and Element Representations".
pol = gfprimdf(m) outputs the default primitive polynomial pol in GF( $2^{m}$ ).
pol $=\mathrm{gfprimdf}(\mathrm{m}, \mathrm{p})$ returns the row vector that gives the coefficients, in order of ascending powers, of the default primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$. m is a positive integer and p is a prime number.

## Examples

The command below shows that $2+\mathrm{x}+\mathrm{x}^{2}$ is the default primitive polynomial for $\mathrm{GF}\left(5^{2}\right)$.

```
pol = gfprimdf(2,5)
pol =
```

    \(\begin{array}{lll}2 & 1 & 1\end{array}\)
    The code below displays the default primitive polynomial for each of the fields $\mathrm{GF}\left(3^{\mathrm{m}}\right)$, where m ranges between 3 and 5 .

```
for m = 3:5
    gfpretty(gfprimdf(m,3))
end
```

The output is below.

$$
\begin{aligned}
& 1+2 x+x^{3} \\
& 2+x+x^{4} \\
& 1+2 x+x^{5}
\end{aligned}
$$

## gfprimfd

Find primitive polynomials for Galois field

## Syntax

pol $=\operatorname{gfprimfd}(m, o p t, p)$

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the primpoly function. For details, see Finding Primitive Polynomials in "Primitive Polynomials and Element Representations".

- If $\mathrm{m}=1, \mathrm{pol}=\left[\begin{array}{ll}1 & 1\end{array}\right]$.
- A polynomial is represented as a row containing the coefficients in order of ascending powers.
$\mathrm{pol}=\mathrm{gfprimfd}(\mathrm{m}, o p t, \mathrm{p})$ searches for one or more primitive polynomials for $\mathrm{GF}\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$, where p is a prime number and $m$ is a positive integer. If $m=1, p o l=[11]$. If $m>1$, the output pol depends on the argument opt as shown in the table below. Each polynomial is represented in pol as a row containing the coefficients in order of ascending powers.

| opt | Significance of pol | Format of pol |
| :--- | :--- | :--- |
| 'min' | One primitive polynomial for <br> GF $\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$ having the smallest <br> possible number of nonzero <br> terms | The row vector representing the <br> polynomial |
| 'max' | One primitive polynomial for <br> GF $\left.\mathrm{p}^{\wedge} \mathrm{m}\right)$ having the greatest <br> possible number of nonzero <br> terms | The row vector representing the <br> polynomial |
| 'all' | All primitive polynomials for <br> GF $\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$ | A matrix, each row of which <br> represents one such polynomial |
| A positive integer | All primitive polynomials for <br> GF $\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$ that have opt nonzero <br> terms | A matrix, each row of which <br> represents one such polynomial |

## Examples

The code below seeks primitive polynomials for $\mathrm{GF}(81)$ having various other properties. Notice that fourterms is empty because no primitive polynomial for GF(81) has exactly four nonzero terms. Also notice that fewterms represents a single polynomial having three terms, while threeterms represents all of the three-term primitive polynomials for $\mathrm{GF}(81)$.

```
p = 3; m = 4; % Work in GF(81).
fewterms = gfprimfd(m,'min',p)
```

```
threeterms = gfprimfd(m,3,p)
fourterms = gfprimfd(m,4,p)
```

The output is below.

```
fewterms =
    2 1 1 0 0 0
threeterms =
\begin{tabular}{lllll}
2 & 1 & 0 & 0 & 1 \\
2 & 2 & 0 & 0 & 1 \\
2 & 0 & 0 & 1 & 1 \\
2 & 0 & 0 & 2 & 1
\end{tabular}
No primitive polynomial satisfies the given constraints.
fourterms =
```

    []
    
## Algorithms

gfprimfd tests for primitivity using gfprimck. If opt is 'min', 'max', or omitted, polynomials are constructed by converting decimal integers to base $p$. Based on the decimal ordering, gfprimfd returns the first polynomial it finds that satisfies the appropriate conditions.

## gfrank

Compute rank of matrix over Galois field

## Syntax

$r k=\operatorname{gfrank}(A, p)$

## Description

Note This function performs computations in GF(p) where p is prime. If you are working in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the rank function with Galois arrays. For details, see "Computing Ranks".
$r k=\operatorname{gfrank}(A, p)$ calculates the rank of the matrix $A$ in $G F(p)$, where $p$ is a prime number.

## Examples

In the code below, gfrank says that the matrix A has less than full rank. This conclusion makes sense because the determinant of $A$ is zero $\bmod p$.

```
A = [1 0 1;
    2 1 0;
    0 1 1];
p = 3;
det_a = det(A); % Ordinary determinant of A
detmodp = rem(det(A),p); % Determinant mod p
rankp = gfrank(A,p);
disp(['Determinant = ',num2str(det_a)])
disp(['Determinant mod p is ',num2str(detmodp)])
disp(['Rank over GF(p) is ',num2str(rankp)])
```

The output is below.
Determinant = 3
Determinant mod p is 0
Rank over GF(p) is 2

## Algorithms

gfrank uses an algorithm similar to Gaussian elimination.
Introduced before R2006a

## gfrepcov

Convert one binary polynomial representation to another

## Syntax

polystandard = gfrepcov(poly2)

## Description

Two logical ways to represent polynomials over $\mathrm{GF}(2)$ are listed below.
1 [A_0 A_1 A_2 ... A_(m-1)] represents the polynomial
$\mathrm{A}_{-} 0+\mathrm{A}_{-} 1 x+\mathrm{A}_{-} 2 x^{2}+\cdots+\mathrm{A}_{-}(\mathrm{m}-1) \mathrm{x}^{\mathrm{m}-1}$
Each entry $A \_k$ is either one or zero.
2 [A_0 A_1 A_2 ... A_(m-1)] represents the polynomial
$x^{\mathrm{A}}-0+x^{\mathrm{A}}-1+x^{\mathrm{A}}{ }^{2} 2+\cdots+x^{\mathrm{A}}(\mathrm{m}-1)$
Each entry $A_{-} k$ is a nonnegative integer. All entries must be distinct.
Format $\mathbf{1}$ is the standard form used by the Galois field functions in this toolbox, but there are some cases in which format $\mathbf{2}$ is more convenient.
polystandard = gfrepcov(poly2) converts from the second format to the first, for polynomials of degree at least 2. poly2 and polystandard are row vectors. The entries of poly2 are distinct integers, and at least one entry must exceed 1 . Each entry of polystandard is either 0 or 1.

## Examples

The command below converts the representation format of the polynomial $1+x^{2}+x^{5}$.

```
polystandard = gfrepcov([0 2 5])
polystandard =
```

$\begin{array}{llllll}1 & 0 & 1 & 0 & 0 & 1\end{array}$

## gfroots

Find roots of polynomial over prime Galois field

## Syntax

```
rt = gfroots(f,m,p)
rt = gfroots(f,prim_poly,p)
[rt,rt_tuple] = gfroots(...)
[rt,rt_tuple,field] = gfroots(...)
```

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, use the roots function with Galois arrays. For details, see "Roots of Polynomials".

For all syntaxes, f is a polynomial character vector or a row vector that gives the coefficients, in order of ascending powers, of a degree-d polynomial.

Note gfroots lists each root exactly once, ignoring multiplicities of roots.
$r t=g f r o o t s(f, m, p)$ finds roots in $G F\left(p^{\wedge} m\right)$ of the polynomial that $f$ represents. $r t$ is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the default primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$.
$r t=g f r o o t s\left(f, p r i m \_p o l y, p\right)$ finds roots in GF(pm) of the polynomial that $f$ represents. $r$ t is a column vector each of whose entries is the exponential format of a root. The exponential format is relative to a root of the degree-m primitive polynomial for $\mathrm{GF}\left(\mathrm{p}^{m}\right)$ that prim_poly represents.
[rt,rt_tuple] = gfroots(...) returns an additional matrix rt_tuple, whose kth row is the polynomial format of the root $r t(k)$. The polynomial and exponential formats are both relative to the same primitive element.
[rt,rt_tuple,field] = gfroots(...) returns additional matrices rt_tuple and field. $r t$ tuple is described in the preceding paragraph. field gives the list of elements of the extension field. The list of elements, the polynomial format, and the exponential format are all relative to the same primitive element.

Note For a description of the various formats that gfroots uses, see "Representing Elements of Galois Fields".

## Examples

"Roots of Polynomials" contains a description and example of the use of gfroots.
The code below finds the polynomial format of the roots of the primitive polynomial $2+x^{3}+x^{4}$ for GF(81). It then displays the roots in traditional form as polynomials in alph. (The output is omitted
here.) Because prim_poly is both the primitive polynomial and the polynomial whose roots are sought, alph itself is a root.

```
p = 3; m = 4;
prim_poly = [2 0 0 1 1]; % A primitive polynomial for GF(81)
f = prim_poly; % Find roots of the primitive polynomial.
[rt,rt_tuple] = gfroots(f,prim_poly,p);
% Display roots as polynomials in alpha.
for ii = 1:length(rt_tuple)
    gfpretty(rt_tuple(ii,:),'alpha')
end
```

## See Also

gfprimdf
Introduced before R2006a

## gfsub

Subtract polynomials over Galois field

## Syntax

```
c = gfsub(a,b,p)
c = gfsub(a,b,p,len)
c = gfsub(a,b,field)
```

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To work in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, apply the - operator to Galois arrays of equal size. For details, see "Example: Addition and Subtraction".
$c=\operatorname{gfsub}(a, b, p)$ calculates a minus $b$, where $a$ and $b$ represent polynomials over $G F(p)$ and $p$ is a prime number. $a, b$, and $c$ are row vectors that give the coefficients of the corresponding polynomials in order of ascending powers. Each coefficient is between 0 and $p-1$. If $a$ and $b$ are matrices of the same size, the function treats each row independently. Alternatively, $a$ and $b$ can be represented as polynomial character vectors.
$c=g f s u b(a, b, p, l e n)$ subtracts row vectors as in the syntax above, except that it returns a row vector of length len. The output c is a truncated or extended representation of the answer. If the row vector corresponding to the answer has fewer than len entries (including zeros), extra zeros are added at the end; if it has more than len entries, entries from the end are removed.
$c=g f s u b(a, b, f i e l d)$ calculates $a$ minus $b$, where $a$ and $b$ are the exponential format of two elements of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, relative to some primitive element of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$. p is a prime number and m is a positive integer. field is the matrix listing all elements of $\operatorname{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, arranged relative to the same primitive element. c is the exponential format of the answer, relative to the same primitive element. See "Representing Elements of Galois Fields" for an explanation of these formats. If $a$ and $b$ are matrices of the same size, the function treats each element independently.

## Examples

## Subtract Two GF Arrays

Calculate $\left(2+3 x+x^{2}\right)-\left(4+2 x+3 x^{2}\right)$ over GF(5).

```
x = gfsub([[2 3 1],[[4 2 3],5)
x = 1×3
    3 1 3
```

Subtract the two polynomials and display the first two elements.

```
y = gfsub([2 3 1],[4 2 3],5,2)
```

$$
y=1 \times 2
$$

31

For prime number p and exponent m , create a matrix listing all elements of $\mathrm{GF}\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$ given primitive polynomial $2+2 x+x^{2}$.
p = 3;
m = 2;
primpoly = [2 2 1];
field $=$ gftuple((-1: $\left.p^{\wedge} m-2\right)^{\prime}$, primpoly, $\left.p\right)$;
Subtract $A^{4}$ from $A^{2}$. The result is $A^{7}$.
$\mathrm{g}=\mathrm{gfsub}(2,4, f i e l d)$
$\mathrm{g}=7$

## See Also

gfadd | gfconv | gfdeconv | gfdiv | gfmul | gftuple Introduced before R2006a

## gftable

Generate file to accelerate Galois field computations

## Syntax

gftable(m,prim_poly);

## Description

gftable(m,prim_poly) generates a file that can help accelerate computations in the field $\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)$ as described by the nondefault primitive polynomial prim_poly, which can be either a polynomial character vector or an integer. prim_poly represents a primitive polynomial for $\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)$, where $1<m<16$, using the format described in "Primitive Polynomials and Element Representations". The function places the file, called userGftable.mat, in your current working folder. If necessary, the function overwrites any writable existing version of the file.

Note If prim_poly is the default primitive polynomial for $\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)$ listed in the table on the gf reference page, this function has no effect. A MAT-file in your MATLAB installation already includes information that facilitates computations with respect to the default primitive polynomial.

## Examples

In the example below, you expect $t 3$ to be similar to $t 1$ and to be significantly smaller than $t 2$, assuming that you do not already have a userGftable. mat file that includes the (m, prim_poly) pair $(8,501)$. Notice that before executing the gftable command, MATLAB displays a warning and that after executing gftable, there is no warning. By executing the gftable command you save the GF table for faster calculations.

```
% Sample code to check how much gftable improves speed.
tic; a = gf(repmat([0:2^8-1],1000,1),8); b = a.^100; t1 = toc;
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t2 = toc;
gftable(8,501); % Include this primitive polynomial in the file.
tic; a = gf(repmat([0:2^8-1],1000,1),8,501); b = a.^100; t3 = toc;
```

## See Also

## gftrunc

Minimize length of polynomial representation

## Syntax

$\mathrm{c}=\mathrm{gftrunc}(\mathrm{a})$

## Description

$c=$ gftrunc (a) truncates a row vector, $a$, that gives the coefficients of a $G F(p)$ polynomial in order of ascending powers. If $a(k)=0$ whenever $k>d+1$, the polynomial has degree $d$. The row vector C omits these high-order zeros and thus has length $\mathrm{d}+1$.

## Examples

In the code below, zeros are removed from the end, but not from the beginning or middle, of the rowvector representation of $x^{2}+2 x^{3}+3 x^{4}+4 x^{7}+5 x^{8}$.
$c=\operatorname{gftrunc}\left(\left[\begin{array}{lllllllll}0 & 0 & 1 & 2 & 3 & 0 & 0 & 4 & 0\end{array}\right]\right.$
c =
$\begin{array}{lllllllll}0 & 0 & 1 & 2 & 3 & 0 & 0 & 4 & 5\end{array}$

Introduced before R2006a

## gftuple

Simplify or convert Galois field element formatting

## Syntax

tp = gftuple(a,m)
tp = gftuple(a, prim_poly)
tp $=$ gftuple $(a, m, p)$
tp = gftuple(a, prim_poly,p)
tp = gftuple(a,prim_poly,p,prim_ck)
[tp,expform] = gftuple(...)

## Description

Note This function performs computations in $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$, where p is prime. To perform equivalent computations in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, apply the.$^{\wedge}$ operator and the log function to Galois arrays. For more information, see "Example: Exponentiation" and "Example: Elementwise Logarithm".

## For All Syntaxes

gftuple serves to simplify the polynomial or exponential format of Galois field elements, or to convert from one format to another. For an explanation of the formats that gftuple uses, see "Representing Elements of Galois Fields".

In this discussion, the format of an element of $\mathrm{GF}\left(\mathrm{p}^{\mathrm{m}}\right)$ is called "simplest" if all exponents of the primitive element are

- Between 0 and m-1 for the polynomial format
- Either - Inf, or between 0 and $\mathrm{p}^{\mathrm{m}-2}$, for the exponential format

For all syntaxes, a is a matrix, each row of which represents an element of a Galois field. The format of a determines how MATLAB interprets it:

- If a is a column of integers, MATLAB interprets each row as an exponential format of an element. Negative integers are equivalent to - Inf in that they all represent the zero element of the field.
- If a has more than one column, MATLAB interprets each row as a polynomial format of an element. (Each entry of a must be an integer between 0 and p-1.)

The exponential or polynomial formats mentioned above are all relative to a primitive element specified by the second input argument. The second argument is described below.

## For Specific Syntaxes

$t p=g f t u p l e(a, m)$ returns the simplest polynomial format of the elements that a represents, where the kth row of $t p$ corresponds to the kth row of a. The formats are relative to a root of the default primitive polynomial for $\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)$, where m is a positive integer.
tp $=$ gftuple(a, prim_poly) is the same as the syntax above, except that prim_poly is a polynomial character vector or a row vector that lists the coefficients of a degree $m$ primitive polynomial for $\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)$ in order of ascending exponents.
$t p=g f t u p l e(a, m, p)$ is the same as $t p=g f t u p l e(a, m)$ except that 2 is replaced by a prime number $p$.
tp = gftuple(a,prim_poly,p) is the same as tp = gftuple(a,prim_poly) except that 2 is replaced by a prime number $p$.
tp = gftuple(a,prim_poly,p,prim_ck) is the same as tp = gftuple(a,prim_poly,p) except that gftuple checks whether prim_poly represents a polynomial that is indeed primitive. If not, then gftuple generates an error and tp is not returned. The input argument prim_ck can be any number or character vector; only its existence matters.
[tp,expform] = gftuple(...) returns the additional matrix expform. The kth row of expform is the simplest exponential format of the element that the kth row of a represents. All other features are as described in earlier parts of this "Description" section, depending on the input arguments.

## Examples

- "List of All Elements of a Galois Field" (end of section)
- "Converting to Simplest Polynomial Format"

As another example, the gftuple command below generates a list of elements of $\mathrm{GF}\left(\mathrm{p}^{\wedge} \mathrm{m}\right)$, arranged relative to a root of the default primitive polynomial. Some functions in this toolbox use such a list as an input argument.

```
p = 5; % Or any prime number
m = 4; % Or any positive integer
field = gftuple([-1:p^m-2]',m,p);
```

Finally, the two commands below illustrate the influence of the shape of the input matrix. In the first command, a column vector is treated as a sequence of elements expressed in exponential format. In the second command, a row vector is treated as a single element expressed in polynomial format.

```
tp1 = gftuple([0; 1],3,3)
tp2 = gftuple([0, 0, 0, 1],3,3)
```

The output is below.

```
tp1 =
    1 0 0
    0
tp2 =
    2 1 0
```

The outputs reflect that, according to the default primitive polynomial for $\mathrm{GF}\left(3^{3}\right)$, the relations below are true.

$$
\begin{aligned}
& \alpha^{0}=1+0 \alpha+0 \alpha^{2} \\
& \alpha^{1}=0+1 \alpha+0 \alpha^{2} \\
& 0+0 \alpha+0 \alpha^{2}+\alpha^{3}=2+\alpha+0 \alpha^{2}
\end{aligned}
$$

## Algorithms

gftuple uses recursive callbacks to determine the exponential format.

## gfweight

Calculate minimum distance of linear block code

## Syntax

```
wt = gfweight(genmat)
wt = gfweight(genmat,'gen')
wt = gfweight(parmat,'par')
wt = gfweight(genpoly,n)
```

## Description

The minimum distance, or minimum weight, of a linear block code is defined as the smallest positive number of nonzero entries in any n-tuple that is a codeword.
wt = gfweight(genmat) returns the minimum distance of the linear block code whose generator matrix is genmat.
wt = gfweight(genmat,'gen') returns the minimum distance of the linear block code whose generator matrix is genmat.
wt = gfweight(parmat,'par') returns the minimum distance of the linear block code whose parity-check matrix is parmat.
wt = gfweight (genpoly,n) returns the minimum distance of the cyclic code whose codeword length is n and whose generator polynomial is represented by genpoly. genpoly is a polynomial character vector or a row vector that gives the coefficients of the generator polynomial in order of ascending powers.

## Examples

## Calculate Minimum Distance of Linear Block Code

Calculate the minimum distance of a cyclic code using several methods.
Create the generate polynomial for a $(7,4)$ cyclic code.
n = 7;
genpoly $=\operatorname{cyclpoly}(\mathrm{n}, 4)$;
Calculate the minimum distance for the cyclic code using:
1 Generator polynomial genmat
2 Parity check matrix parmat
3 Generator polynomial genpoly
4 Generator polynomial specified as a character vector
[parmat, genmat] = cyclgen(n,genpoly);
wts = [gfweight(genmat,'gen') gfweight(parmat,'par'),... gfweight(genpoly,n) gfweight('1+x2+x3',n)]
wts $=1 \times 4$
$\begin{array}{llll}3 & 3 & 3\end{array}$

## gray2bin

(To be removed) Convert Gray-encoded positive integers to corresponding Gray-decoded integers

Note will be removed in a future release. Use the appropriate modulation object or function to remap constellation points instead. For more information, see "Compatibility Considerations".

## Syntax

```
y = gray2bin(x,modulation,M)
[y,map] = gray2bin(x,modulation,M)
```

## Description

$y=$ gray2bin( $x$, modulation,$M$ ) generates a Gray-decoded output vector or matrix $y$ with the same dimensions as its input parameter x . x can be a scalar, vector, matrix, or 3-D array. modulation is the modulation type and must be 'qam', 'pam', 'fsk', 'dpsk', or 'psk'. M is the modulation order and must be an integer power of 2 .
[y,map] = gray2bin(x,modulation, M) generates a Gray-decoded output y with its respective Gray-encoded constellation map, map.

You can use map output to label a Gray-encoded constellation. The map output gives the Grayencoded labels for the corresponding modulation. See "Binary to Gray Symbol Mapping" on page 2433 example.

Note If you are converting binary coded data to Gray-coded data and modulating the result immediately afterwards, you should use the appropriate modulation object or function with the 'Gray ' symbol ordering option, instead of gray2bin.

## Examples

## Binary to Gray Symbol Mapping

This example shows how to use the bin2gray and gray2bin functions to map integer inputs from a natural binary order symbol mapping to a Gray-coded signal constellation and vice versa, assuming 16-QAM modulation. In addition, a visual representation of the difference between Gray-coded and binary-coded symbol mappings is shown.

## Convert Binary to Gray

Create a complete vector of 16-QAM integers.
M = 16;
$x=(0: M-1)$;
Convert the input vector from a natural binary order to a Gray-encoded vector using bin2gray.
[y,mapy] = bin2gray(x,'qam', M) ;
Convert Gray to Binary
Convert the Gray-encoded symbols, $y$, back to a binary ordering using gray2bin.
$z=g r a y 2 b i n(y, ' q a m ', M) ;$
Verify that the original data, $x$, and the final output vector, $z$, are identical.

```
isequal(x,z)
ans = logical
    1
```

## Show Symbol Mappings

To create a constellation plot showing the different symbol mappings, use the qammod function to find the complex symbol values.

```
sym = qammod(x,M);
```

Plot the constellation symbols and label them using the Gray (y) and binary (z) output vectors. The binary representation of the Gray-coded symbols is shown in black while the binary representation of the naturally ordered symbols is shown in red. Set the axes scaling so that all points are displayed.

```
scatterplot(sym,1,0,'b*');
for k = 1:16
    text(real(sym(k))-0.3,imag(sym(k))+0.3,...
        dec2base(mapy(k),2,4));
    text(real(sym(k))-0.3,imag(sym(k))-0.3,...
        dec2base(z(k),2,4),'Color',[1 0 0]);
end
axis([-4 4 -4 4])
```

## Input Arguments

x - Gray-encoded data
vector | matrix
Gray-encoded input data, specified as a vector or matrix.
Data Types: double
modulation - Modulation type
'qam'|'pam'|'fsk'|'dpsk'|'psk'
Modulation type, specified as, 'qam', 'pam', 'fsk', 'dpsk', or 'psk'
M - Modulation order
scalar
Modulation order, specified as an integer power of 2.
Data Types: double

## Output Arguments

y - Gray-decoded data
vector | matrix

Gray－decoded data with the same size and dimensions input $x$ ．

## map－Map of labels

vector
Map output to label a Gray－encoded constellation，specified as a vector with a length the size of the modulation order，M．The map gives the Gray－encoded labels for the corresponding modulation．

## Compatibility Considerations

## gray2bin will be removed

Not recommended starting in R2020a
gray2bin will be removed in a future release．Use the appropriate modulation object or function instead．If your workflow uses bin2gray or gray2bin with any of the modulations schemes in this table，follow the appropriate example．

| Modulation | Old Functionality | Use This Instead |
| :---: | :---: | :---: |

# gsmCheckTimeMask 

Inspect GSM burst against time mask

## Syntax

```
gsmCheckTimeMask(gsmCfg)
gsmCheckTimeMask(gsmCfg,tn)
pf = gsmCheckTimeMask(gsmCfg)
pf = gsmCheckTimeMask(gsmCfg,tn)
```

## Description

gsmCheckTimeMask(gsmCfg) plots the burst for the first time slot and the upper and lower time masks for the input GSM configuration object. The RiseTime, RiseDelay, FallTime, and FallDelay properties of the configuration object define the power level versus time characteristics. For more information, see "Time Mask" on page 2-452.
gsmCheckTimeMask(gsmCfg,tn) plots the burst for the specified time slot, tn.
pf = gsmCheckTimeMask(gsmCfg) returns a pass or fail result for the specified configuration object indicating compliance of the burst in the first time slot with the time mask defined in the GSM standard. For more information, see "Time Mask" on page 2-452.
pf = gsmCheckTimeMask(gsmCfg,tn) returns a pass or fail result indicating compliance of the burst in the specified time slot, tn.

## Examples

## Check GSM Burst Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the first time slot against the time mask specified by the GSM standard.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig;
```

Use the gsmCheckTimeMask function to view the time mask and verify that the configured rise and fall characteristics of the burst comply with the time mask specified in the GSM standard. Plot the GSM burst and time mask. When no time slot number is provided, the gsmCheckTimeMask function shows the first time slot, $\mathrm{TN}=0$.

```
pf = gsmCheckTimeMask(cfggsmul);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
```

Time mask test passed.
gsmCheckTimeMask(cfggsmul);

Adjust the rise time of the GSM uplink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.RiseTime = 5
cfggsmul =
    gsmUplinkConfig with properties:
                            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
            TSC: [0 1 1 2 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 5
            RiseDelay: 0
            FallTime: 2
            FallDelay: 0
```

Use the gsmCheckTimeMask function to inspect the time mask of cfggsmul. The pass or fail result shows that the cfggsmul configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul);
if pf
```

```
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
Time mask test failed.
gsmCheckTimeMask(cfggsmul);
```

## Check GSM Burst in Specified Time Slot Against Time Mask

Create a GSM uplink TDMA frame configuration object with default settings. The GSM TDMA frame has eight time slots. Check the burst in the specified time slot against the time mask specified by the GSM standard.

Create a GSM downlink TDMA frame configuration object with default settings.
cfggsmul = gsmDownlinkConfig;
Use the gsmCheckTimeMask function to view the time mask and verify that the configured rise and fall characteristics of the burst in the specified time slot comply with the time mask specified by the GSM standard. Plot the GSM burst and time mask.

```
tn = 6; % Time slot number 6
pf = gsmCheckTimeMask(cfggsmul,tn);
```

```
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
Time mask test passed.
gsmCheckTimeMask(cfggsmul,tn);
```

Adjust the fall delay of the GSM downlink TDMA frame configuration object, specifying a value that causes a time mask failure.

```
cfggsmul.FallDelay = 4
cfggsmul =
    gsmDownlinkConfig with properties:
            BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
            TSC: [0 1 2 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
            RiseDelay: 0
            FallTime: 2
            FallDelay: 4
```

Use the gsmCheckTimeMask function to inspect the time mask of cfggsmul. The pass or fail result shows that the cfggsmul configuration now fails the time mask and the plot shows the upper time mask fails.

```
pf = gsmCheckTimeMask(cfggsmul,tn);
if pf
    disp('Time mask test passed.')
else
    disp('Time mask test failed.')
end
Time mask test failed.
```

gsmCheckTimeMask(cfggsmul,tn);

## Check Time Mask for GSM Bursts

Create GSM downlink and uplink TDMA frame configuration objects that use the various burst types available.

- Normal bursts and bursts with no data are valid for downlink and uplink frames.
- Frequency correction, synchronization, and dummy bursts are valid in downlink frames only.
- Access bursts are valid in uplink frames only.

View time masks for the different burst types against the time mask specified by the GSM standard for the downlink and uplink frames.

Create a GSM downlink TDMA frame configuration object that configures the times slot bursts as [NB FB SB Dummy Off Off Off Off].

```
cfggsmdl = gsmDownlinkConfig('BurstType',["NB" "FB" "SB" "Dummy" "Off" "Off" "Off" "Off"])
cfggsmdl =
    gsmDownlinkConfig with properties:
        BurstType: [NB FB SB Dummy Off Off Off Off]
        SamplesPerSymbol: 16
            TSC: [[0 1 1 2 3 3 4 5 6 7]
            Attenuation: [0 0 0 0 0 0 0 0]
                    RiseTime: 2
                    RiseDelay: 0
                    FallTime: 2
            FallDelay: 0
```

Use the gsmCheckTimeMask function to view the time mask for the different time slot burst types. For downlink GSM TDMA frames the same time mask limits applies for all burst types.

```
for tn = 0:4
    [dlbt,dlbtVal] = enumeration(cfggsmdl.BurstType);
    dlBurstInfo = ['Downlink (TN=',num2str(tn),'), BurstType: ',dlbtVal{tn+1}];
    disp(dlBurstInfo)
    gsmCheckTimeMask(cfggsmdl,tn);
end
Downlink (TN=0), BurstType: NB
```

Downlink (TN=1), BurstType: FB

Downlink (TN=2), BurstType: SB

Create a GSM uplink TDMA frame configuration object that configures the times slot bursts as [NB AB Off Off Off Off Off Off].

```
cfggsmul = gsmUplinkConfig('BurstType',["NB" "AB" "Off" "Off" "Off" "Off" "Off" "Off"])
cfggsmul =
    gsmUplinkConfig with properties:
```

```
            BurstType: [NB AB Off Off Off Off Off Off]
```

            BurstType: [NB AB Off Off Off Off Off Off]
        SamplesPerSymbol: 16
        SamplesPerSymbol: 16
            TSC: [0 1 2 3 4 5 6 7]
            TSC: [0 1 2 3 4 5 6 7]
                Attenuation: [0 0 0 0 0 0 0 0]
                Attenuation: [0 0 0 0 0 0 0 0]
            RiseTime: 2
            RiseTime: 2
                RiseDelay: 0
                RiseDelay: 0
            FallTime: 2
            FallTime: 2
            FallDelay: 0
    ```
            FallDelay: 0
```

Use the gsmCheckTimeMask function to view the time masks for the different time slot burst types. For uplink GSM TDMA frames the access burst has a shorter time mask than the normal burst or no data burst.

```
for tn = 0:2
    [ulbt,ulbtVal] = enumeration(cfggsmul.BurstType);
    ulBurstInfo = ['Uplink (TN=',num2str(tn),'), BurstType: ',ulbtVal{tn+1}];
    disp(ulBurstInfo)
    gsmCheckTimeMask(cfggsmul,tn);
end
```

Uplink (TN=0), BurstType: NB

Uplink (TN=1), BurstType: AB

Uplink (TN=2), BurstType: Off

## Input Arguments

gsmCfg - GSM configuration
gsmUplinkConfig object|gsmDownlinkConfig object
GSM configuration, specified as a gsmUplinkConfig or gsmDownlinkConfig object.
tn - Time slot number
0 (default) | integer in the range [0, 7]
Time slot number, specified as an integer in the range [0, 7].
Data Types: double

## Output Arguments

pf - Pass or fail result
0 | 1
Pass or fail result, returned as:

- 1 if the time mask passes
- 0 if the time mask fails

For more information, see "Time Mask" on page 2-452.

## More About

## Time Mask

The time mask defines the allowable transmitted power level versus time for time slot bursts in a GSM TDMA frame. This figure, from Annex B of TS 45.005, shows the upper and lower power limits for the time mask of a burst.

## gsmFrame

Create GSM waveform

## Syntax

gsmWaveform = gsmFrame(gsmCfg)
gsmWaveform $=$ gsmFrame(gsmCfg, numFrames)

## Description

gsmWaveform $=$ gsmFrame ( $g s m C f g$ ) creates a GSM waveform with one TDMA frame based on the input GSM configuration object. The encrypted bit field of the transmission data bursts is filled with random data. For more information, see "GSM Frames, Time Slots, and Bursts" on page 2-460.
gsmWaveform = gsmFrame(gsmCfg, numFrames) creates a GSM waveform, with numFrames identically configured TDMA frames. In each frame, the encrypted bit field of the transmission data bursts is filled with random data. For more information, see "GSM Frames, Time Slots, and Bursts" on page 2-460.

## Examples

## Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
cfggsmul =
    gsmUplinkConfig with properties:
\begin{tabular}{rllllllll} 
BurstType: & {\([N B\)} & & \(N B\) & & \(N B\) & \(N B\) & \(N B\) & \(N B\)
\end{tabular}\(N\) NB NB]
```

Display information about the configured gsmUplinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
```

SampleRate: 4.3333e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156. 2500
NumBurstsPerFrame: 8
BurstLengthInSamples: 2500
FrameLengthInSamples: 20000

Rs = wfInfo.SampleRate;
Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform.
waveform = gsmFrame(cfggsmul);
$\mathrm{t}=(0:$ length(waveform)-1)/Rs*1e3;
subplot (2,1,1)
plot(t,abs(waveform))
grid on
axis([0 50 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot (2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')

## Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])
cfggsmul =
    gsmUplinkConfig with properties:
```

Display information about the configured gsmUplinkConfig object by using the gsmInfo function. Assign the frame length in samples to a variable, spf, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
spf = wfInfo.FrameLengthInSamples;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);
t = 8*(0:length(waveform)-1)/spf;
numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
```

```
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```

## Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl =
    gsmDownlinkConfig with properties:
        BurstType: [NB NB NB NB NB NB NB NB]
        SamplesPerSymbol: 16
            TSC: [0 1 1 2 3 4 4 5 6 7]
```

```
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
        FallTime: 2
    FallDelay: 0
```

Display information about the configured gsmDownlinkConfig object by using the gsmInfo function. Assign the sample rate to a variable, Rs, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
```

$\mathrm{t}=(0:$ length(waveform)-1)/Rs*1e3;
subplot $(2,1,1)$
plot(t,abs(waveform))
grid on
axis([0 50 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot $(2,1,2)$
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')

## Input Arguments

gsmCfg - GSM configuration
gsmUplinkConfig object | gsmDownlinkConfig object
GSM configuration, specified as a gsmUplinkConfig or gsmDownlinkConfig object.
numFrames - Number of TDMA frames
16 (default) | positive integer
Number of TDMA frames in the waveform, specified as a positive integer.
Data Types: double

## Output Arguments

## gsmWaveform - Output time-domain waveform

complex-valued column vector
Output time-domain waveform, returned as a complex-valued column vector of length $N_{\mathrm{s}}$, where $N_{\mathrm{s}}$ represents the number of time-domain samples. The function generates this waveform in the form of complex in-phase quadrature (IQ) samples.

## More About

## GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25 -symbol duration when using the normal symbol period, which is a time interval of $15 / 26 \mathrm{~ms}$ or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number ( BN ). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

| Burst Type | Description | Link Direction | Useful Duration |
| :--- | :--- | :--- | :--- |
| NB | Normal burst | Uplink/Downlink | 147 |
| FB | Frequency correction <br> burst | Downlink | 147 |
| SB | Synchronization burst | Downlink | 147 |
| Dummy | Dummy burst | Downlink | 147 |
| AB | Access burst | Uplink | 87 |
| Off | No burst sent | Uplink/Downlink | 0 |

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending
half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing $1 / 2$ bit difference between the useful and active parts of the burst.

For more information, see "GSM TDMA Frame Parameterization for Waveform Generation".

## Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

| Training Sequence Code (TSC) | Training Sequence Bits (BN61, BN62, ..., <br> BN86) |
| :--- | :--- |
| 0 | $(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)$ |
| 1 | $(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)$ |
| 2 | $(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)$ |
| 3 | $(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)$ |
| 4 | $(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)$ |
| 5 | $(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)$ |
| 6 | $(1,0,1,0,0,1,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)$ |
| 7 | $(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,0)$ |

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## gsmInfo

View GSM waveform information

## Syntax

infostruct= gsmInfo(gsmCfg)

## Description

infostruct= gsmInfo(gsmCfg) returns a structure containing characteristic waveform information for the input GSM configuration object.

## Examples

## View GSM Configuration Object Information

View information from downlink and uplink GSM configuration objects.
Create a GSM downlink configuration object with default settings and use gsmInfo to view the waveform information structure.

```
cfgDL = gsmDownlinkConfig;
infostructDL = gsmInfo(cfgDL)
infostructDL = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

Create a GSM uplink configuration object with default settings and use gsmInfo to view the waveform information structure.

```
cfgUL = gsmUplinkConfig;
infostructUL = gsmInfo(cfgUL)
infostructUL = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

## Create GSM Uplink Waveform Containing Five TDMA Frames

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing five TDMA frames. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about $30.46 \times 10 \mathrm{e}-3 \mathrm{~ms}$. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 3 dB of attenuation in the last time slot to help identify the end of each frame.

```
cfggsmul = gsmUplinkConfig('Attenuation',[0 0 0 0 0 0 0 3])
cfggsmul =
    gsmUplinkConfig with properties:
\begin{tabular}{rllllllll} 
BurstType: & {\([N B\)} & & \(N B\) & & \(N B\) & \(N B\) & \(N B\) & \(N B\)
\end{tabular} NB NB]
```

Display information about the configured gsmUplinkConfig object by using the gsmInfo function. Assign the frame length in samples to a variable, spf, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)
wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
        NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
spf = wfInfo.FrameLengthInSamples;
```

Create the GSM waveform by using the gsmFrame function, and then plot the GSM waveform. The last time slot of each frame is 3 dB less than the other time slots in that frame.

```
numFrames = 5;
waveform = gsmFrame(cfggsmul,numFrames);
t = 8*(0:length(waveform)-1)/spf;
numTS = 8*numFrames;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 numTS 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time Slots')
ylabel('Amplitude')
subplot(2,1,2)
```

```
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time Slots')
ylabel('Phase (rad)')
```

## Input Arguments

gsmCfg - GSM configuration
gsmUplinkConfig object|gsmDownlinkConfig object
GSM configuration, specified as a gsmUplinkConfig or gsmDownlinkConfig object.

## Output Arguments

## infostruct - Structure containing object information

struct
Structure containing these fields with information about the characteristic GSM waveform based on the input configuration object.

## SymbolRate - GSM symbol rate

positive integer
GSM symbol rate in symbols per second, returned as a positive integer.

## SampleRate - GSM sample rate <br> positive integer

GSM sample rate in samples per second, returned as a positive integer.
BandwidthTimeProduct - Product of bandwidth and symbol time of Gaussian pulse positive integer

Product of bandwidth and symbol time of Gaussian pulse for the GMSK modulator, returned as a positive integer.

## BurstLengthInSymbols - GSM burst length

positive scalar
GSM burst length in symbols, returned as a positive scalar.
NumBurstsPerFrame - Number of bursts in GSM TDMA frame
positive integer
Number of bursts in a GSM TDMA frame, returned as a positive integer.

## BurstLengthInSamples - GSM burst length

positive integer
GSM burst length in samples, returned as a positive integer.
FrameLengthInSamples - GSM frame length
positive integer
GSM frame length in samples, returned as a positive integer.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.

## hammgen

Parity-check and generator matrices for Hamming code

## Syntax

$\mathrm{h}=$ hammgen $(\mathrm{m})$
$h=\operatorname{hammgen}(\mathrm{m}$, poly)
$[\mathrm{h}, \mathrm{g}]=$ hammgen $($ $\qquad$
$[\mathrm{h}, \mathrm{g}, \mathrm{n}, \mathrm{k}]=$ hammgen $($ $\qquad$ )

## Description

$\mathrm{h}=$ hammgen $(\mathrm{m})$ returns an $m$-by-n parity-check matrix, h , for a Hamming code of codeword length $n=2^{m}-1$. The message length of the Hamming code is $n-m$. The binary primitive polynomial that the function uses to create the Hamming code is the default primitive polynomial in GF( $\left.2^{\wedge} m\right)$. For more details of this default polynomial, see the gfprimdf function.
$h=$ hammgen ( $m$, poly) specifies poly, a binary primitive polynomial for $\mathrm{GF}\left(2^{\mathrm{m}}\right)$. The function uses poly to create the Hamming code.
[h,g] = hammgen( $\qquad$ ) additionally returns a $k$-by-n generator matrix, $g$, that corresponds to the parity-check matrix $h$. Specify any of the input argument combinations from the previous syntaxes.
$[h, g, n, k]=$ hammgen (__ ) also returns $n$, the codeword length and $k$, the message length, for the Hamming code.

## Examples

## Generate Hamming Code Parity-Check Matrix Using Default Primitive Polynomial

Generate a parity-check matrix, $h$, for a Hamming code of codeword length 7. The function uses the default primitive polynomial in GF(8) to create the Hamming code.

```
h = hammgen(3)
h = 3\times7
\begin{tabular}{lllllll}
1 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 1 & 0 & 1 & 1 & 1 & 0 \\
0 & 0 & 1 & 0 & 1 & 1 & 1
\end{tabular}
```

## Generate Hamming Code Parity-Check Matrix from Primitive Polynomials

Generate the parity-check matrices for the Hamming code of codeword length 15, specifying the primitive polynomials $1+D+D^{4}$ and $1+D^{3}+D^{4}$ in $\mathrm{GF}(16)$.

```
h1 = hammgen(4,'1+D+D^4')
h1 = 4×15
\begin{tabular}{lllllllllllllll}
1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 \\

0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 \\
0 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 \\
1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 1
\end{tabular}
```

Verify that the two resulting matrices differ.

```
isequal(h1,h2)
ans = logical
    0
```

## Generate Hamming Code Parity-Check and Generator Matrices

Generate the parity-check matrix, h and the generator matrix, g for the Hamming code of codeword length 7. Also return the codeword length, $n$, and the message length, $k$ for the Hamming code. The function uses the default primitive polynomial in $\mathrm{GF}(8)$ to create the Hamming code.

```
[h,g,n,k] = hammgen(3)
h = 3\times7
\begin{tabular}{lllllll}
1 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 1 & 0 & 1 & 1 & 1 & 0 \\
0 & 0 & 1 & 0 & 1 & 1 & 1
\end{tabular}
g = 4×7
\begin{tabular}{lllllll}
1 & 1 & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 1 & 0 & 0 \\
1 & 1 & 1 & 0 & 0 & 1 & 0 \\
1 & 0 & 1 & 0 & 0 & 0 & 1
\end{tabular}
n = 7
k = 4
```

## Input Arguments

m - Number of rows in parity-check matrix
integer greater than or equal to two
Number of rows in parity-check matrix, specified as an integer greater than or equal to two. The function uses this value to calculate the codeword length and the message length of the Hamming code.
Data Types: double
poly - Binary primitive polynomial in GF(2 ${ }^{m}$ )
binary row vector | character vector | string scalar
Binary primitive polynomial in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, specified as one of these values:

- Binary row vector of the polynomial coefficients in order of ascending powers
- Character vector
- String scalar

If poly is specified as a non-primitive polynomial, then the function hammgen displays an error.
Data Types: double | char | string

## Output Arguments

## h - Parity-check matrix for Hamming code <br> m-by-n matrix of binary values

Parity-check matrix for Hamming code, returned as an m-by-n matrix of binary values for the Hamming code.
Data Types: single | double

## g - Generator matrix for Hamming code

k -by-n matrix of binary values
Generator matrix for Hamming code, returned as a k-by-n matrix of binary values corresponding to the parity-check matrix $h$.
Data Types: single | double
n - Codeword length of Hamming code
positive integer
Codeword length of Hamming code, returned as a positive integer. This value is calculated as $2^{\mathrm{m}}-1$.
Data Types: single | double
k - Message length of Hamming code
positive integer
Message length of Hamming code, returned as a positive integer. This value is calculated as $n-m$.
Data Types: single | double

## Algorithms

hammgen uses the function gftuple to create the parity-check matrix by converting each element in the Galois field (GF) to its polynomial representation. Unlike gftuple, which performs computations in $\mathrm{GF}\left(2^{\mathrm{m}}\right)$ and processes one m -tuple at a time, the hammgen function generates the entire sequence from 0 to $2^{m}-1$. The computation algorithm uses all previously computed values to generate the computation result. If the value of $m$ is less than 25 and the primitive polynomial is the default primitive polynomial for $G F\left(2^{m}\right)$, the syntax hammgen ( m ) might be faster than the syntax hammgen (m, poly).

## hank2sys

Convert Hankel matrix to linear system model

## Syntax

[num,den] = hank2sys(h,ini,tol)
[num,den,sv] = hank2sys(h,ini,tol)
[a,b,c,d] = hank2sys(h,ini,tol)
[a,b,c,d,sv] = hank2sys(h,ini,tol)

## Description

[num, den] = hank2sys(h,ini, tol) converts a Hankel matrix $h$ to a linear system transfer function with numerator num and denominator den. The vectors num and den list the coefficients of their respective polynomials in ascending order of powers of $\mathrm{z}^{-1}$. The argument ini is the system impulse at time zero. If tol $>1$, tol is the order of the conversion. If tol $<1$, tol is the tolerance in selecting the conversion order based on the singular values. If you omit tol, its default value is 0.01 . This conversion uses the singular value decomposition method.
[num, den, sv] = hank2sys(h,ini, tol) returns a vector sv that lists the singular values of $h$.
$[\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}]=$ hank2sys(h,ini,tol) converts a Hankel matrix h to a corresponding linear system state-space model. a, b, c, and d are matrices. The input parameters are the same as in the first syntax above.
[a,b,c,d,sv] = hank2sys(h,ini,tol) is the same as the syntax above, except that sv is a vector that lists the singular values of $h$.

## Examples

```
h = hankel([1 0 1]);
[num,den,sv] = hank2sys(h,0,.01)
```

The output is
num $=$
0
1.0000
0.0000
1.0000
den $=$
$1.0000 \quad 0.0000 \quad 0.0000 \quad 0.0000$
sv =
1.6180
1.0000
0.6180

## heldeintrlv

Restore ordering of symbols permuted using helintrlv

## Syntax

[deintrlved,state] = heldeintrlv(data, col, ngrp,stp)
[deintrlved,state] = heldeintrlv(data, col, ngrp,stp,init_state)
deintrlved = heldeintrlv(data,col,ngrp,stp,init_state)

## Description

[deintrlved,state] = heldeintrlv(data,col, ngrp,stp) restores the ordering of symbols in data by placing them in an array row by row and then selecting groups in a helical fashion to place in the output, deintrlved. data must have col*ngrp elements. If data is a matrix with multiple rows and columns, it must have col*ngrp rows, and the function processes the columns independently. state is a structure that holds the final state of the array. state.value stores input symbols that remain in the col columns of the array and do not appear in the output.

The function uses the array internally for its computations. The array has unlimited rows indexed by $1,2,3, \ldots$, and col columns. The function initializes the top of the array with zeros. It then places col*ngrp symbols from the input into the next ngrp rows of the array. The function places symbols from the array in the output, intrlved, placing ngrp symbols at a time; the kth group of ngrp symbols comes from the kth column of the array, starting from row $1+(\mathrm{k}-1) *$ stp. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.
[deintrlved,state] = heldeintrlv(data,col,ngrp,stp,init_state) initializes the array with the symbols contained in init_state.value instead of zeros. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding interleaver. In this syntax, some output symbols are default values of 0 , some are input symbols from data, and some are initialization values from init_state.value.
deintrlved = heldeintrlv(data, col, ngrp, stp,init_state) is the same as the syntax above, except that it does not record the deinterleaver's final state. This syntax is appropriate for the last in a series of calls to this function. However, if you plan to call this function again to continue the deinterleaving process, the syntax above is more appropriate.

## Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the helintrlv function, use the same col, ngrp, and stp inputs in both functions. In that case, the two functions are inverses in the sense that applying helintrlv followed by heldeintrlv leaves data unchanged, after you take their combined delay of col*ngrp*ceil(stp* (col-1)/ngrp) into account. To learn more about delays of convolutional interleavers, see "Delays of Convolutional Interleavers".

Note Because the delay is an integer multiple of the number of symbols in data, you must use heldeintrlv at least twice (possibly more times, depending on the actual delay value) before the function returns results that represent more than just the delay.

## Examples

Recover interleaved data, taking into account the delay of the interleaver-deinterleaver pair.

```
col = 4; ngrp = 3; stp = 2; % Helical interleaver parameters
% Compute the delay of interleaver-deinterleaver pair.
delayval = col * ngrp * ceil(stp * (col-1)/ngrp);
len = col*ngrp; % Process this many symbols at one time.
data = randi([0 9],len,1); % Random symbols
data_padded = [data; zeros(delayval,1)]; % Pad with zeros.
% Interleave zero-padded data.
[i1,istate] = helintrlv(data_padded(1:len),col,ngrp,stp);
[i2,istate] = helintrlv(data_padded(len+1:2*len),col,ngrp, ...
    stp,istate);
i3 = helintrlv(data_padded(2*len+1:end),col,ngrp,stp,istate);
% Deinterleave.
[d1,dstate] = heldeintrlv(i1,col,ngrp,stp);
[d2,dstate] = heldeintrlv(i2,col,ngrp,stp,dstate);
d3 = heldeintrlv(i3,col,ngrp,stp,dstate);
% Check the results.
d0 = [d1; d2; d3]; % All the deinterleaved data
d0_trunc = d0(delayval+1:end); % Remove the delay.
ser = symerr(data,d0_trunc)
```

The output below shows that no symbol errors occurred.
ser $=$
0

## helintrlv

Permute symbols using helical array

## Syntax

intrlved $=$ helintrlv(data, col, ngrp,stp)
[intrlved,state] = helintrlv(data, col, ngrp,stp)
[intrlved,state] = helintrlv(data, col, ngrp,stp,init_state)

## Description

intrlved $=$ helintrlv(data,col, ngrp, stp) permutes the symbols in data by placing them in an unlimited-row array in helical fashion and then placing rows of the array in the output, intrlved. data must have col*ngrp elements. If data is a matrix with multiple rows and columns, it must have $c o l * n g r p$ rows, and the function processes the columns independently.

The function uses the array internally for its computations. The array has unlimited rows indexed by $1,2,3, \ldots$, and col columns. The function partitions col*ngrp symbols from the input into consecutive groups of ngrp symbols. The function places the kth group in the array along column k , starting from row $1+(\mathrm{k}-1)^{*}$ stp. Positions in the array that do not contain input symbols have default values of 0 . The function places col*ngrp symbols from the array in the output, intrlved, by reading the first ngrp rows sequentially. Some output symbols are default values of 0 rather than input symbols; similarly, some input symbols are left in the array and do not appear in the output.
[intrlved,state] = helintrlv(data, col, ngrp, stp) returns a structure that holds the final state of the array. state. value stores input symbols that remain in the col columns of the array and do not appear in the output.
[intrlved,state] = helintrlv(data, col, ngrp,stp,init_state) initializes the array with the symbols contained in init_state.value. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding deinterleaver. In this syntax, some output symbols are default values of 0 , some are input symbols from data, and some are initialization values from init_state. value.

## Examples

The example below rearranges the integers from 1 to 24 .

```
% Interleave some symbols. Record final state of array.
[i1,state] = helintrlv([1:12]',3,4,1);
% Interleave more symbols, remembering the symbols that
% were left in the array from the earlier command.
i2 = helintrlv([13:24]',3,4,1,state);
disp('Interleaved data:')
disp([i1,i2]')
disp('Values left in array after first interleaving operation:')
state.value{:}
```

During the successive calls to helintrlv, it internally creates the three-column arrays

```
[1 1 0 0;
    2 5 0;
    3 6 9;
4 10;
0 8 11;
0 0 12]
and
[13 8 11;
14 17 12;
15 18 21;
16 19 22;
    0 20 23;
    0 0 24]
```

In the second array shown above, the 8,11 , and 12 are values left in the array from the previous call to the function. Specifying the init state input in the second call to the function causes it to use those values rather than the default values of 0 .

The output from this example is below. (The matrix has been transposed for display purposes.) The interleaved data comes from the top four rows of the three-column arrays shown above. Notice that some of the symbols in the first half of the interleaved data are default values of 0 , some of the symbols in the second half of the interleaved data were left in the array from the first call to helintrlv, and some of the input symbols ( 20,23 , and 24 ) do not appear in the interleaved data at all.

```
Interleaved data:
    Columns 1 through 10
\begin{tabular}{rrrrrrrrrr}
1 & 0 & 0 & 2 & 5 & 0 & 3 & 6 & 9 & 4 \\
13 & 8 & 11 & 14 & 17 & 12 & 15 & 18 & 21 & 16
\end{tabular}
    Columns 11 through 12
    7 10
        19 22
Values left in array after first interleaving operation:
ans =
    []
ans =
    8
ans =
    11 12
```

The example on the reference page for heldeintrlv also uses this function.

## helscandeintrlv

Restore ordering of symbols in helical pattern

## Syntax

deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep)

## Description

deintrlvd = helscandeintrlv(data,Nrows,Ncols,hstep) rearranges the elements in data by filling a temporary matrix with the elements in a helical fashion and then sending the matrix contents to the output row by row. Nrows and Ncols are the dimensions of the temporary matrix. hstep is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. hstep must be a nonnegative integer less than Nrows.

Helical fashion means that the function places input elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly Ncols, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If data is a vector, it must have Nrows*Ncols elements. If data is a matrix with multiple rows and columns, data must have Nrows*Ncols rows and the function processes the columns independently.

To use this function as an inverse of the helscanintrlv function, use the same Nrows, Ncols, and hstep inputs in both functions. In that case, the two functions are inverses in the sense that applying helscanintrlv followed by helscandeintrlv leaves data unchanged.

## Examples

The command below rearranges a vector using a 3-by-4 temporary matrix and diagonals of slope 1 .

```
d = helscandeintrlv(1:12,3,4,1)
d =
    Columns 1 through 10
        1 10[llllllllll
    Columns 11 through 12
        3 12
```

Internally, the function creates the 3-by-4 temporary matrix
$\left.\begin{array}{rrrr}{\left[\begin{array}{rrr}1 & 10 & 7 \\ 5 & 2 & 11\end{array}\right.} \\ 9 & 8 & 8 \\ 9 & 6 & 12\end{array}\right]$
using length-four diagonals. The function then sends the elements, row by row, to the output d .

## helscanintrlv

Reorder symbols in helical pattern

## Syntax

intrlvd = helscanintrlv(data,Nrows,Ncols,hstep)

## Description

intrlvd = helscanintrlv(data,Nrows,Ncols,hstep) rearranges the elements in data by filling a temporary matrix with the elements row by row and then sending the matrix contents to the output in a helical fashion. Nrows and Ncols are the dimensions of the temporary matrix. hstep is the slope of the diagonal, that is, the amount by which the row index increases as the column index increases by one. hstep must be a nonnegative integer less than Nrows.

Helical fashion means that the function selects elements along diagonals of the temporary matrix. The number of elements in each diagonal is exactly Ncols, after the function wraps past the edges of the matrix when necessary. The function traverses diagonals so that the row index and column index both increase. Each diagonal after the first one begins one row below the first element of the previous diagonal.

If data is a vector, it must have Nrows*Ncols elements. If data is a matrix with multiple rows and columns, data must have Nrows*Ncols rows and the function processes the columns independently.

## Examples

The command below rearranges a vector using diagonals of two different slopes.

```
i1 = helscanintrlv(1:12,3,4,1) % Slope of diagonal is 1.
i2 = helscanintrlv(1:12,3,4,2) % Slope of diagonal is 2.
```

The output is below.

```
i1 =
    Columns 1 through 10
        1 [llllllllll
    Columns 11 through 12
        7 12
i2 =
    Columns 1 through 10
        1 10[10
    Columns 11 through 12
```

## 312

In each case, the function internally creates the temporary 3-by-4 matrix
$\left.\begin{array}{rrrr}{[1} & 2 & 3 & 4 ; \\ 5 & 6 & 7 & 8 ; \\ 9 & 10 & 11 & 12\end{array}\right]$

To form i1, the function forms each slope-one diagonal by moving one row down and one column to the right. The first diagonal contains 1, 6, 11, and 4, while the second diagonal starts with 5 because that is beneath 1 in the temporary matrix.

To form i2, the function forms each slope-two diagonal by moving two rows down and one column to the right. The first diagonal contains 1, 10, 7, and 4, while the second diagonal starts with 5 because that is beneath 1 in the temporary matrix.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® $\mathrm{Coder}^{\mathrm{TM}}$.

## hex2poly

Convert hexadecimal character vector to binary coefficients

## Syntax

b = hex2poly(hex)
b = hex2poly(hex,ord)

## Description

$\mathrm{b}=$ hex2poly (hex) converts a hexadecimal character vector, hex, to a vector of binary coefficients, b .
b = hex2poly(hex,ord) specifies the power order, ord, of the coefficients that comprise the output. If omitted, ord is 'descending'.

## Examples

## Convert Hexadecimal Polynomial to Binary Vector

Convert the hexadecimal polynomial ' 1 AF' to a vector of binary coefficients. The coefficients represent the polynomial $x^{8}+x^{7}+x^{5}+x^{3}+x^{2}+x+1$.
b = hex2poly('1AF')
b $=1 \times 9$

## Convert Hexadecimal into Ascending Order Binary Vector

Convert hexadecimal ' $0 \times 82608$ EDB' to a vector of binary coefficients. Specify that the binary coefficients are in ascending order.
b = hex2poly('0x82608EDB','ascending')
$\mathrm{b}=1 \times 32$
$\begin{array}{lllllllllllllll}1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0\end{array}$

The binary representation corresponds to a polynomial of $x^{31}+x^{25}+x^{22}+x^{21}+x^{15}+x^{11}+x^{10}+x^{9}+x^{7}+x^{6}+x^{4}+x^{3}+x+1$.

## Input Arguments

## hex - Hexadecimal number

character vector

Hexadecimal number, specified as a character vector.
Example: 'FF'
Example: '0x3FA'
Data Types: char
ord - Power order
'descending' (default) | 'ascending '
Power order of the vector of binary coefficients, specified as a character vector having a value of 'ascending' or 'descending'.

Data Types: char

## Output Arguments

## b - Binary coefficients

vector
Binary coefficients representing a polynomial, returned as a row vector having length equal to $p+1$, where $p$ is the order of hexadecimal input.

## hilbiir

Design Hilbert transform IIR filter

## Syntax

```
hilbiir
hilbiir(ts)
hilbiir(ts,dly)
hilbiir(ts,dly,bandwidth)
hilbiir(ts,dly,bandwidth,tol)
[num,den] = hilbiir(...)
[num,den,sv] = hilbiir(...)
[a,b,c,d] = hilbiir(...)
[a,b,c,d,sv] = hilbiir(...)
```

## Description

The function hilbiir designs a Hilbert transform filter. The output is either

- A plot of the filter's impulse response, or
- A quantitative characterization of the filter, using either a transfer function model or a state-space model

## Background Information

An ideal Hilbert transform filter has the transfer function $H(s)=-j \operatorname{sgn}(s)$, where $\operatorname{sgn}($.$) is the$ signum function (sign in MATLAB). The impulse response of the Hilbert transform filter is

$$
h(t)=\frac{1}{\Pi t}
$$

Because the Hilbert transform filter is a noncausal filter, the hilbiir function introduces a group delay, dly. A Hilbert transform filter with this delay has the impulse response

$$
h(t)=\frac{1}{\Pi(t-\mathrm{dly})}
$$

## Choosing a Group Delay Parameter

The filter design is an approximation. If you provide the filter's group delay as an input argument, these two suggestions can help improve the accuracy of the results:

- Choose the sample time ts and the filter's group delay dly so that dly is at least a few times larger than ts and $\mathrm{rem}(\mathrm{dly}, \mathrm{ts})=\mathrm{ts} / 2$. For example, you can set ts to $2 * \mathrm{dly} / \mathrm{N}$, where N is a positive integer.
- At the point $t=d l y$, the impulse response of the Hilbert transform filter can be interpreted as 0 , -Inf, or Inf. If hilbiir encounters this point, it sets the impulse response there to zero. To improve accuracy, avoid the point $t=d l y$.

## Syntaxes for Plots

Each of these syntaxes produces a plot of the impulse response of the filter that the hilbiir function designs, as well as the impulse response of a corresponding ideal Hilbert transform filter.
hilbiir plots the impulse response of a fourth-order digital Hilbert transform filter with a onesecond group delay. The sample time is $2 / 7$ seconds. In this particular design, the tolerance index is 0.05 . The plot also displays the impulse response of the ideal Hilbert transform filter with a onesecond group delay.
hilbiir(ts) plots the impulse response of a fourth-order Hilbert transform filter with a sample time of ts seconds and a group delay of $\mathrm{ts} * 7 / 2$ seconds. The tolerance index is 0.05 . The plot also displays the impulse response of the ideal Hilbert transform filter having a sample time of ts seconds and a group delay of $\mathrm{ts} * 7 / 2$ seconds.
hilbiir(ts, dly) is the same as the syntax above, except that the filter's group delay is dly for both the ideal filter and the filter that hilbiir designs. See "Choosing a Group Delay Parameter" on page 2-484 above for guidelines on choosing dly.
hilbiir(ts,dly,bandwidth) is the same as the syntax above, except that bandwidth specifies the assumed bandwidth of the input signal and that the filter design might use a compensator for the input signal. If bandwidth $=0$ or bandwidth $>1 /(2 * t s)$, hilbiir does not use a compensator.
hilbiir(ts,dly, bandwidth, tol) is the same as the syntax above, except that tol is the tolerance index. If tol $<1$, the order of the filter is determined by

$$
\frac{\text { truncated-singular-value }}{\text { maximum-singular-value }}<\text { tol }
$$

If tol > 1, the order of the filter is tol.

## Syntaxes for Transfer Function and State-Space Quantities

Each of these syntaxes produces quantitative information about the filter that hilbiir designs, but does not produce a plot. The input arguments for these syntaxes (if you provide any) are the same as those described in "Syntaxes for Plots" on page 2-485.
[num,den] = hilbiir(...) outputs the numerator and denominator of the IIR filter's transfer function.
[num,den,sv] = hilbiir(...) outputs the numerator and denominator of the IIR filter's transfer function, and the singular values of the Hankel matrix that hilbiir uses in the computation.
[a,b,c,d] = hilbiir(...) outputs the discrete-time state-space model of the designed Hilbert transform filter. a, b, c, and d are matrices.
[a,b,c,d,sv] = hilbiir(...) outputs the discrete-time state-space model of the designed Hilbert transform filter, and the singular values of the Hankel matrix that hilbiir uses in the computation.

## Examples

For an example using the function's default values, type one of the following commands at the MATLAB prompt.
hilbiir
[num,den] = hilbiir

## Algorithms

The hilbiir function calculates the impulse response of the ideal Hilbert transform filter response with a group delay. It fits the response curve using a singular-value decomposition method. See the book by Kailath [1].

## huffmandeco

Huffman decoder

## Syntax

dsig = huffmandeco(comp,dict)

## Description

dsig = huffmandeco(comp, dict) decodes the numeric Huffman code vector comp using the code dictionary dict. The argument dict is an N-by-2 cell array, where N is the number of distinct possible symbols in the original signal that was encoded as comp. The first column of dict represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in dict is allowed to be the prefix of any other codeword in dict. You can generate dict using the huffmandict function and comp using the huffmanenco function. If all signal values in dict are numeric, dsig is a vector; if any signal value in dict is alphabetical, dsig is a one-dimensional cell array.

## Examples

## Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.

```
symbols = 1:6;
p = [.5 . 125 . 125 . 125 .0625 .0625];
```

Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
sig = randsrc(100,1,[symbols;p]);
```

Encode the random symbols.
comp $=$ huffmanenco(sig,dict);
Decode the symbols. Verify that the decoded symbols match the original symbols.

```
dsig = huffmandeco(comp,dict);
isequal(sig,dsig)
ans = logical
    1
```

Convert the original symbols to a binary symbols, and determine the length of the binary symbols.

```
binarySig = de2bi(sig);
seqLen = numel(binarySig)
```

```
seqLen = 300
```

Convert the Huffman-encoded symbols, and determine its length.

```
binaryComp = de2bi(comp);
encodedLen = numel(binaryComp)
encodedLen = 224
```

## Huffman Encoding and Decoding with Alphanumeric Signal

Define the alphanumeric symbols in cell array form.

```
sig = {'a2',44,'a3',55,'a1'}
sig=1\times5 cell array
    {'a2'} {[44]} {'a3'} {[55]} {'a1'}
```

Define a Huffman dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
dict=5\times2 cell array
    {'a1'} {[ 0]}
    {'a2'} {1x2 double}
    {'a3'} {1x3 double}
    {[44]} {1\times4 double}
    {[55]} {1x4 double}
```

Encode the alphanumeric symbols.
comp = huffmanenco(sig,dict);
Decode the symbols. Verify that the decoded symbols match the original symbols.

```
dsig = huffmandeco(comp,dict)
dsig=1\times5 cell array
    {'a2'} {[44]} {'a3'} {[55]} {'a1'}
isequal(sig,dsig)
ans = logical
    1
```

## huffmandict

Generate Huffman code dictionary for source with known probability model

## Syntax

[dict,avglen] = huffmandict(symbols, prob)
[dict,avglen] = huffmandict(symbols, prob,N)
[dict,avglen] = huffmandict(symbols, prob, N, variance)

## Description

[dict,avglen] = huffmandict(symbols, prob) generates a binary Huffman code dictionary, dict, for the source symbols, symbols, by using the maximum variance algorithm. The input prob specifies the probability of occurrence for each of the input symbols. The length of prob must equal the length of symbols. The function also returns average codeword length avglen of the dictionary, weighted according to the probabilities in the input prob.
[dict,avglen] = huffmandict(symbols, prob, N ) generates an N -ary Huffman code dictionary using maximum variance algorithm. N must not exceed the number of source symbols.
[dict,avglen] = huffmandict(symbols, prob, $N$, variance) generates an $N$-ary Huffman code dictionary with the specified variance.

## Examples

## Generate Huffman Code and View Results

Generate a binary Huffman code dictionary, additionally returning the average code length.
Specify a symbol alphabet vector and a symbol probability vector.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate a binary Huffman code, displaying the average code length and the cell array containing the codeword dictionary.

```
[dict,avglen] = huffmandict(symbols,prob)
dict=5\times2 cell array
    {[1]} {1x2 double}
    {[2]} {1x2 double}
    {[3]} {1\times2 double}
    {[4]} {1\times3 double}
    {[5]} {1x3 double}
avglen = 2.2000
```

Display the fifth codeword from the dictionary.

```
samplecode = dict{5,2} % Codeword for fifth signal value
samplecode = 1×3
    1 1 0
```

## Generate Ternary Huffman Codes

Use the code dictionary generator for Huffman coder function to generate binary and ternary Huffman codes.

Specify a symbol alphabet vector and a symbol probability vector.

```
symbols = (1:5); % Alphabet vector
prob = [.3 .3 .2 .1 .1]; % Symbol probability vector
```

Generate a binary Huffman code, displaying the cell array containing the codeword dictionary.

```
[dict,avglen] = huffmandict(symbols,prob);
dict(:,2) = cellfun(@num2str,dict(:,2),'UniformOutput',false)
dict=5\times2 cell array
\begin{tabular}{lllr}
\(\{[1]\}\) & \{'0 & \(1^{\prime}\) & \(\}\) \\
\(\{[2]\}\) & \(\left\{{ }^{\prime} 0\right.\) & 0 & \(\}\) \\
\(\{[3]\}\) & \(\left\{{ }^{\prime} 1\right.\) & \(0 '\) & \(\}\) \\
\(\{[4]\}\) & \(\left\{{ }^{\prime} 1\right.\) & 1 & \(\left.1^{\prime}\right\}\) \\
\(\{[5]\}\) & \(\left\{{ }^{\prime} 1\right.\) & 1 & \(\left.0^{\prime}\right\}\)
\end{tabular}
```

Generate a ternary Huffman code with minimum variance.

```
[dict,avglen] = huffmandict(symbols,prob,3,'min');
dict(:,2) = cellfun(@num2str,dict(:,2),'UniformOutput',false)
dict=5\times2 cell array
    {[1]} {'2' }
    {[2]} {'1' }
    {[3]} {'0 0'}
    {[4]} {'0 2'}
    {[5]} {'0}1'
```

## Input Arguments

## symbols - Source symbols

numeric vector | numeric cell array | alphanumeric cell array
Source symbols, specified as a numeric vector, numeric cell array, or an alphanumeric cell array. symbols lists the distinct signal values that the source produces. If symbols is a cell array, it must be a 1-by- $S$ or $S$-by-1 cell array, where $S$ is the number of symbols.
Data Types: double | cell

## prob - Probability of occurrence

numeric vector in the range [0,1]
Probability of occurrence for each symbol, specified as a numeric vector in the range [0, 1]. The elements of this vector must sum to 1 . The length this vector must equal the length of input symbols.

Data Types: double

## N - $\mathbf{N}$-ary Huffman code dictionary

numeric scalar in the range $[2,10]$
N -ary Huffman code dictionary, specified as a numeric scalar in the range [2, 10]. This value must be less than or equal to the length of input symbols.

Data Types: double
variance - Variance for Huffman code
'min'|'max'
Variance for Huffman code, specified as one of these values.

- 'min' - This function generates N -ary Huffman code dictionary with the minimum variance. If you do not specify the variance input argument, the function uses this case.
- 'max' - This function generates N -ary Huffman code dictionary with the maximum variance.

Data Types: char

## Output Arguments

## dict - Huffman code dictionary

two-column cell array
Huffman code dictionary, returned as a two-column cell array. The first column lists the distinct signal values from input symbols. The second column corresponds to Huffman codewords, where each Huffman codeword is represented as a numeric row vector. If you specify the input argument $\mathbf{N}$, the function returns dict as an N -ary Huffman code dictionary.
Data Types: double | cell
avglen - Average codeword length
positive numeric scalar
Average codeword length, weighted according to the probabilities in the input prob, returned as a positive numeric scalar.
Data Types: double

## huffmanenco

Huffman encoder

## Syntax

```
enco = huffmanenco(sig,dict)
```

## Description

enco = huffmanenco(sig,dict) encodes input signal sig using the Huffman codes described by input code dictionary dict. sig can have the form of a numeric vector, numeric cell array, or alphanumeric cell array. If sig is a cell array, it must be either a row or a column. dict is an N -by- 2 cell array, where $N$ is the number of distinct possible symbols to be encoded. The first column of dict represents the distinct symbols and the second column represents the corresponding codewords.
Each codeword is represented as a numeric row vector, and no codeword in dict can be the prefix of any other codeword in dict. You can generate dict using the huffmandict function.

## Examples

## Huffman Encoding and Decoding

Create unique symbols, and assign probabilities of occurrence to them.
symbols = 1:6;
$p=[.5$. 125 . 125 . 125 . 0625 . 0625];
Create a Huffman dictionary based on the symbols and their probabilities.

```
dict = huffmandict(symbols,p);
```

Generate a vector of random symbols.

```
sig = randsrc(100,1,[symbols;p]);
```

Encode the random symbols.

```
comp = huffmanenco(sig,dict);
```

Decode the symbols. Verify that the decoded symbols match the original symbols.

```
dsig = huffmandeco(comp,dict);
isequal(sig,dsig)
ans = logical
    1
```

Convert the original symbols to a binary symbols, and determine the length of the binary symbols.

```
binarySig = de2bi(sig);
seqLen = numel(binarySig)
```

```
seqLen = 300
```

Convert the Huffman-encoded symbols, and determine its length.

```
binaryComp = de2bi(comp);
encodedLen = numel(binaryComp)
encodedLen = 224
```

## Huffman Encoding and Decoding with Alphanumeric Signal

Define the alphanumeric symbols in cell array form.

```
sig = {'a2',44,'a3',55,'a1'}
sig=1\times5 cell array
    {'a2'} {[44]} {'a3'} {[55]} {'a1'}
```

Define a Huffman dictionary. Codes for signal letters must be numeric.

```
dict = {'a1',0; 'a2',[1,0]; 'a3',[1,1,0]; 44,[1,1,1,0]; 55,[1,1,1,1]}
dict=5\times2 cell array
    {'a1'} {[ 0]}
    {'a2'} {1x2 double}
    {'a3'} {1x3 double}
    {[44]} {1x4 double}
    {[55]} {1\times4 double}
```

Encode the alphanumeric symbols.
comp = huffmanenco(sig,dict);
Decode the symbols. Verify that the decoded symbols match the original symbols.

```
dsig = huffmandeco(comp,dict)
dsig=1\times5 cell array
    {'a2'} {[44]} {'a3'} {[55]} {'a1'}
isequal(sig,dsig)
ans = logical
    1
```

## Input Arguments

## sig - Input signal

numeric vector | numeric cell array | alphanumeric cell array

Input signal for compression, specified as a numeric vector, numeric cell array, or an alphanumeric cell array. sig can have the form of a numeric vector, numeric cell array, or alphanumeric cell array. If sig is a cell array, it must be a 1 -by- $S$ or $S$-by- 1 cell array, where $S$ is the number of symbols.

## Data Types: double | cell

## dict - Huffman code dictionary

N -by-2 cell array
Huffman code dictionary, specified as an $N$-by-2 cell array. $N$ is the number of distinct possible symbols for the function to encode. The first column of dict represents the distinct symbols and the second column represents the corresponding codewords. Each codeword is represented as a numeric row vector, and no codeword in dict can be the prefix of any other codeword in dict. You can generate dict by using the huffmandict function.

Data Types: double | cell

## Output Arguments

## enco - Encoded signal

numeric row vector
Encoded signal for input Huffman code dictionary dict, returned as a numeric row vector.

## ifft

Inverse discrete Fourier transform

## Syntax

ifft(x)

## Description

ifft (x) is the inverse discrete Fourier transform (DFT) of the Galois vector $x$. If $x$ is in the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, the length of x must be $2^{\mathrm{m}}-1$.

## Examples

For an example using ifft, see the reference page for fft .

## Limitations

The Galois field over which this function works must have 256 or fewer elements. In other words, x must be in the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, where m is an integer between 1 and 8 .

## Algorithms

If $x$ is a column vector, ifft applies dftmtx to the multiplicative inverse of the primitive element of the Galois field and multiplies the resulting matrix by $x$.

dftmtx|fft|gf
Topics
"Signal Processing Operations in Galois Fields"
Introduced before R2006a

## intdump

Integrate and dump

## Syntax

$y=$ intdump ( $\mathrm{x}, \mathrm{nsamp}$ )

## Description

$y=$ intdump ( $x$, nsamp) integrates the signal $x$ for one symbol period, then outputs the averaged one value into Y . nsamp is the number of samples per symbol. For two-dimensional signals, the function treats each column as one channel.

## Examples

An example in "Combine Pulse Shaping and Filtering with Modulation" uses this function in conjunction with modulation.

Processes two independent channels, each of which contain three symbols of data made up of four samples.

```
s = rng;
rng(68521);
nsamp = 4; % Number of samples per symbol
ch1 = randi([0 1],3*nsamp,1); % Random binary channel
ch2 = rectpulse([1 2 3]',nsamp); % Rectangular pulses
x = [ch1 ch2]; % Two-channel signal
y = intdump(x,nsamp)
rng(s);
```

The output is below. Each column corresponds to one channel, and each row corresponds to one symbol.
$y=$

| 0.5000 | 1.0000 |
| :--- | :--- |
| 0.5000 | 2.0000 |
| 1.0000 | 3.0000 |

## See Also

rectpulse

## Introduced before R2006a

## intrlv

Reorder sequence of symbols

## Syntax

intrlvd = intrlv(data,elements)

## Description

intrlvd = intrlv(data,elements) rearranges the elements of data without repeating or omitting any elements. If data is a length- N vector or an N -row matrix, elements is a length- N vector that permutes the integers from 1 to N . The sequence in elements is the sequence in which elements from data or its columns appear in intrlvd. If data is a matrix with multiple rows and columns, the function processes the columns independently.

## Examples

The command below rearranges the elements of a vector. Your output might differ because the permutation vector is random in this example.

```
p = randperm(10); % Permutation vector
a = intrlv(10:10:100,p)
```

The output is below.
$a=$
$\begin{array}{llllllllll}10 & 90 & 60 & 30 & 50 & 80 & 100 & 20 & 70 & 40\end{array}$
The command below rearranges each of two columns of a matrix.
b = intrlv([.1 .2 .3 . 4 .5; . 2 . 4 . 6 . 8 1]',[2 4301$])$
b =
$0.2000 \quad 0.4000$
$0.4000 \quad 0.8000$
$0.3000 \quad 0.6000$
$0.5000 \quad 1.0000$
$0.1000 \quad 0.2000$

## iqcoef2imbal

Convert compensator coefficient to amplitude and phase imbalance

## Syntax

```
[A,P] = iqcoef2imbal(C)
```

## Description

[A,P] = iqcoef2imbal(C) converts compensator coefficient $C$ to its equivalent amplitude and phase imbalance.

## Examples

## Estimate I/Q Imbalance from Compensator Coefficient

Use iqcoef2imbal to estimate the amplitude and phase imbalance for a given complex coefficient. The coefficients are an output from the step function of the IQImbalanceCompensator.

Create a raised cosine transmit filter to generate a 64-QAM signal.
$M=64 ;$
txFilt = comm.RaisedCosineTransmitFilter;
Modulate and filter random 64-ary symbols.

```
data = randi([0 M-1],100000,1);
dataMod = qammod(data,M);
txSig = step(txFilt,dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(li*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal
rxSig = rxSig/std(rxSig);
Remove the I/Q imbalance using the comm. IQImbalanceCompensator System object. Set the compensator object such that the complex coefficients are made available as an output argument.

```
hIQComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
```

[compSig, coef] = step(hIQComp,rxSig);

Estimate the imbalance from the last value of the compensator coefficient.
[ampImbEst,phImbEst] = iqcoef2imbal(coef(end));
Compare the estimated imbalance values with the specified ones. Notice that there is good agreement.

```
[ampImb phImb; ampImbEst phImbEst]
ans = 2\times2
    2.0000 15.0000
    2.0178 14.5740
```

## Input Arguments

C - Compensator coefficient
complex-valued scalar or vector
Coefficient used to compensate for an I/Q imbalance, specified as a complex-valued vector.
Example: 0.4+0.6i
Example: [0.1+0.2i; 0.3+0.5i]
Data Types: single | double

## Output Arguments

## A - Amplitude imbalance

real-valued vector
Amplitude imbalance in dB , returned as a real-valued vector with the same dimensions as C .
P - Phase imbalance
real-valued vector
Phase imbalance in degrees, returned as a real-valued vector with the same dimensions as C.

## More About

## I/Q Imbalance Compensation

The function iqcoef2imbal is a supporting function for the comm.IQImbalanceCompensator System object.

Given a scaling and rotation factor, $G$, compensator coefficient, $C$, and received signal, $x$, the compensated signal, $y$, has the form

$$
y=G[x+C \operatorname{conj}(x)] .
$$

In matrix form, this can be rewritten as

$$
\mathbf{Y}=\mathbf{R} \mathbf{X},
$$

where $\mathbf{X}$ is a 2-by-1 vector representing the imbalanced signal $\left[X_{I}, X_{Q}\right]$ and $\mathbf{Y}$ is a 2-by-1 vector representing the compensator output $\left[Y_{I}, Y_{Q}\right]$.

The matrix $\mathbf{R}$ is expressed as

$$
\mathbf{R}=\left[\begin{array}{cc}
1+\operatorname{Re}\{C\} & \operatorname{Im}\{C\} \\
\operatorname{Im}\{C\} & 1-\operatorname{Re}\{C\}
\end{array}\right]
$$

For the compensator to perfectly remove the I/Q imbalance, $\mathbf{R}=\mathbf{K}^{-1}$ because $\mathbf{X}=\mathbf{K} \mathbf{S}$, where $\mathbf{K}$ is a 2-by-2 matrix whose values are determined by the amplitude and phase imbalance and $\mathbf{S}$ is the ideal signal. Define a matrix $\mathbf{M}$ with the form

$$
\mathbf{M}=\left[\begin{array}{cc}
1 & -\alpha \\
\alpha & 1
\end{array}\right]
$$

Both $\mathbf{M}$ and $\mathbf{M}^{-1}$ can be thought of as scaling and rotation matrices that correspond to the factor $G$. Because $\mathbf{K}=\mathbf{R}^{-1}$, the product $\mathbf{M}^{-1} \mathbf{R} \mathbf{K} \mathbf{M}$ is the identity matrix, where $\mathbf{M}^{-1} \mathbf{R}$ represents the compensator output and $\mathbf{K} \mathbf{M}$ represents the I/Q imbalance. The coefficient $\alpha$ is chosen such that

$$
\mathbf{K} \mathbf{M}=L\left[\begin{array}{ll}
I_{\text {gain }} \cos \left(\theta_{I}\right) & Q_{\text {gain }} \cos \left(\theta_{Q}\right) \\
I_{\text {gain }} \sin \left(\theta_{I}\right) & Q_{\text {gain }} \sin \left(\theta_{Q}\right)
\end{array}\right]
$$

where $L$ is a constant. From this form, we can obtain $I_{\text {gain }}, Q_{\text {gain }}, \theta_{I}$, and $\theta_{Q}$. For a given phase imbalance, $\Phi_{\text {Imb }}$, the in-phase and quadrature angles can be expressed as

$$
\begin{gathered}
\theta_{I}=-(\Pi / 2)\left(\Phi_{\text {Imb }} / 180\right) \\
\theta_{Q}=\Pi / 2+(\Pi / 2)\left(\Phi_{I m b} / 180\right)
\end{gathered}
$$

Hence, $\cos \left(\theta_{Q}\right)=\sin \left(\theta_{I}\right)$ and $\sin \left(\theta_{Q}\right)=\cos \left(\theta_{I}\right)$ so that

$$
L\left[\begin{array}{ll}
I_{\text {gain }} \cos \left(\theta_{I}\right) & Q_{\text {gain }} \cos \left(\theta_{Q}\right) \\
I_{\text {gain }} \sin \left(\theta_{I}\right) & Q_{\text {gain }} \sin \left(\theta_{Q}\right)
\end{array}\right]=L\left[\begin{array}{ll}
I_{\text {gain }} \cos \left(\theta_{I}\right) & Q_{\text {gain }} \sin \left(\theta_{I}\right) \\
I_{\text {gain }} \sin \left(\theta_{I}\right) & Q_{\text {gain }} \cos \left(\theta_{I}\right)
\end{array}\right]
$$

The I/Q imbalance can be expressed as

$$
\begin{gathered}
\mathbf{K} \mathbf{M}=\left[\begin{array}{ll}
K_{11}+\alpha K_{12} & -\alpha K_{11}+K_{12} \\
K_{21}+\alpha K_{22} & -\alpha K_{21}+K_{22}
\end{array}\right] \\
=L\left[\begin{array}{ll}
I_{\text {gain }} \cos \left(\theta_{I}\right) & Q_{\text {gain }} \sin \left(\theta_{I}\right) \\
I_{\text {gain }} \sin \left(\theta_{I}\right) & Q_{\text {gain }} \cos \left(\theta_{I}\right)
\end{array}\right]
\end{gathered}
$$

Therefore,

$$
\left(K_{21}+\alpha K_{22}\right) /\left(K_{11}+\alpha K_{12}\right)=\left(-\alpha K_{11}+K_{12}\right) /\left(-\alpha K_{21}+K_{22}\right)=\sin \left(\theta_{I}\right) / \cos \left(\theta_{I}\right)
$$

The equation can be written as a quadratic equation to solve for the variable $\alpha$, that is $D_{1} \alpha^{2}+D_{2} \alpha+$ $D_{3}=0$, where

$$
\begin{gathered}
D_{1}=-K_{11} K_{12}+K_{22} K_{21} \\
D_{2}=K_{12}^{2}+K_{21}^{2}-K_{11}^{2}-K_{22}^{2} \\
D_{3}=K_{11} K_{12}-K_{21} K_{22}
\end{gathered}
$$

When $|C| \leq 1$, the quadratic equation has the following solution:

$$
\alpha=\frac{-D_{2}-\sqrt{D^{2}-4 D_{1} D_{3}}}{2 D_{1}}
$$

Otherwise, when $|C|>1$, the solution has the following form:

$$
\alpha=\frac{-D_{2}+\sqrt{D^{2}-4 D_{1} D_{3}}}{2 D_{1}}
$$

Finally, the amplitude imbalance, $A_{\text {Imb }}$, and the phase imbalance, $\Phi_{\text {Imb }}$, are obtained.

$$
\begin{gathered}
\mathbf{K}^{\prime}=\mathbf{K}\left[\begin{array}{cc}
1 & -\alpha \\
\alpha & 1
\end{array}\right] \\
A_{\text {Imb }}=20 \log _{10}\left(K_{11}^{\prime} / K_{22}^{\prime}\right) \\
\Phi_{I m b}=-2 \tan ^{-1}\left(K_{21}^{\prime} / K_{11}^{\prime}\right)(180 / \Pi)
\end{gathered}
$$

## Note

- If $C$ is real and $|C| \leq 1$, the phase imbalance is 0 and the amplitude imbalance is $20 \log _{10}((1-C) /$ $(1+C)$ )
- If $C$ is real and $|C|>1$, the phase imbalance is $180^{\circ}$ and the amplitude imbalance is $20 \log _{10}((C$ $+1) /(C-1)$ ).
- If $C$ is imaginary, $A_{\text {Imb }}=0$.

## iqimbal2coef

Convert I/Q imbalance to compensator coefficient

## Syntax

$\mathrm{C}=$ iqimbal $2 \operatorname{coef}(\mathrm{~A}, \mathrm{P})$

## Description

C = iqimbal2coef(A, P) converts an I/Q amplitude and phase imbalance to its equivalent compensator coefficient.

## Examples

## Generate Coefficients for I/Q Imbalance Compensation

Generate coefficients for the I/Q imbalance compensator System object ${ }^{\mathrm{Tm}}$ using iqimbal2coef. The compensator corrects for an I/Q imbalance using the generated coefficients.

Create a raised cosine transmit filter System object.

```
txRCosFilt = comm.RaisedCosineTransmitFilter;
```

Modulate and filter random 64-ary symbols.

```
M= 64;
data = randi([0 M-1],100000,1);
dataMod = qammod(data,M);
txSig = txRCosFilt(dataMod);
```

Specify amplitude and phase imbalance.

```
ampImb = 2; % dB
phImb = 15; % degrees
```

Apply the specified I/Q imbalance.

```
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;
```

Normalize the power of the received signal.
rxSig = rxSig/std(rxSig);
Remove the I/Q imbalance by creating and applying a comm. IQImbalanceCompensator object. Set the compensator such that the complex coefficients are made available as an output argument.
iqComp = comm.IQImbalanceCompensator('CoefficientOutputPort',true);
[compSig,coef] = iqComp(rxSig);

Compare the final compensator coefficient to the coefficient generated by the iqimbal2coef function. Observe that there is good agreement.

```
idealcoef = iqimbal2coef(ampImb,phImb);
[coef(end); idealcoef]
ans = 2x1 complex
    -0.1137 + 0.1296i
    -0.1126 + 0.1334i
```

## Input Arguments

## A - Amplitude imbalance

real-valued scalar or vector
Amplitude imbalance in dB, specified as a real-valued row or column vector.
Example: 3
Example: [0; 5]
Data Types: double

## P - Phase imbalance

real-valued scalar or vector
Phase imbalance in degrees, specified as a real-valued row or column vector.
Example: 10
Example: [15; 45]
Data Types: double

## Output Arguments

C - Compensator coefficient
complex-valued vector
Coefficient that perfectly compensates for the I/Q imbalance, returned as a complex-valued vector having the same dimensions as A and P.

## More About

## I/Q Imbalance Compensation

The function iqimbal2coef is a supporting function for the comm. IQImbalanceCompensator System object.

Define $\mathbf{S}$ and $\mathbf{X}$ as 2-by-1 vectors representing the I and Q components of the ideal and I/Q imbalanced signals, respectively.

$$
\mathbf{X}=\mathbf{K} \cdot \mathbf{S}
$$

where $\mathbf{K}$ is a 2-by- 2 matrix whose values are determined by the amplitude imbalance, $A$, and phase imbalance, $P$. $A$ is expressed in dB and $P$ is expressed in degrees.

The imbalance can be expressed as:

$$
\begin{aligned}
& I_{\text {gain }}=10^{0.5 A / 20} \\
& Q_{\text {gain }}=10^{-0.5 A / 20} \\
& \theta_{i}=-\left(\frac{P}{2}\right)\left(\frac{\Pi}{180}\right) \\
& \theta_{q}=\frac{\Pi}{2}+\left(\frac{P}{2}\right)\left(\frac{\Pi}{180}\right)
\end{aligned}
$$

Then $\mathbf{K}$ has the form:

$$
\mathbf{K}=\left[\begin{array}{ll}
I_{\text {gain }} \cos \left(\theta_{i}\right) & Q_{\text {gain }} \cos \left(\theta_{q}\right) \\
I_{\text {gain }} \sin \left(\theta_{i}\right) & Q_{\text {gain }} \sin \left(\theta_{q}\right)
\end{array}\right]
$$

The vector $\mathbf{Y}$ is defined as the I/Q imbalance compensator output.

$$
\mathbf{Y}=\mathbf{R} \cdot \mathbf{X}
$$

For the compensator to perfectly remove the I/Q imbalance, $\mathbf{R}$ must be the matrix inversion of $\mathbf{K}$, namely:

$$
\mathbf{R}=\mathbf{K}^{-1}
$$

Using complex notation, the vector $\mathbf{Y}$ can be rewritten as:

$$
\begin{gathered}
y=w_{1} x+w_{2} \operatorname{conj}(x) \\
=w_{1}\left(x+\left(w_{2} / w_{1}\right) \operatorname{conj}(x)\right)
\end{gathered}
$$

where,

$$
\begin{aligned}
& \operatorname{Re}\left\{w_{1}\right\}=\left(R_{11}+R_{22}\right) / 2 \\
& \operatorname{Im}\left\{w_{1}\right\}=\left(R_{21}-R_{12}\right) / 2 \\
& \operatorname{Re}\left\{w_{2}\right\}=\left(R_{11}-R_{22}\right) / 2 \\
& \operatorname{Im}\left\{w_{2}\right\}=\left(R_{21}+R_{12}\right) / 2
\end{aligned}
$$

The output of the function is $w_{2} / w_{1}$. To exactly obtain the original signal, the compensator output needs to be scaled and rotated by the complex number $w_{1}$.

Note There are cases for which the output of iqimbal2coef is unreliable.

- If the phase imbalance is $\pm 90^{\circ}$, the in-phase and quadrature components will become co-linear; consequently, the I/Q imbalance cannot be compensated.
- If the amplitude imbalance is 0 dB and the phase imbalance is $180^{\circ}, w_{1}=0$ and $w_{2}=1 \mathrm{i}$; therefore, the compensator takes the form of $y=1 i^{*} \operatorname{conj}(x)$.

## iqimbal

Apply I/Q imbalance to input signal

## Syntax

$y=$ iqimbal $(x, A)$
$y=$ iqimbal ( $x, A, P$ )

## Description

$\mathrm{y}=$ iqimbal ( $\mathrm{x}, \mathrm{A}$ ) applies I/Q amplitude imbalance A to input signal x .
$y=$ iqimbal ( $x, A, P$ ) applies $I / Q$ amplitude imbalance $A$ and phase imbalance $P$ to input signal $x$.

## Examples

## Apply Amplitude Imbalance to 16-QAM

Generate a 16 -QAM signal. Display the scatter plot.
$x=q a m m o d(r a n d i([015], 1000,1), 16) ;$
$h=s c a t t e r p l o t(x)$;
hold on

Apply a 10 dB amplitude imbalance. A positive amplitude imbalance causes horizontal stretching of the constellation.
y = iqimbal (x,10);
scatterplot(y, 1,0, 'ro',h)

Apply a - 10 dB amplitude imbalance. A negative amplitude imbalance causes vertical stretching of the constellation.
z = iqimbal( $x,-10$ );
scatterplot(z,1,0,'k*',h) hold off

## Apply Phase and Amplitude Imbalance to 16-QAM Signal

Generate a 16-QAM signal having two channels.
$x=$ qammod(randi([0 15],1000,2),16);
Apply a 3 dB amplitude imbalance and a 10 degree phase imbalance to the first channel. Apply a -5 dB amplitude imbalance and a -15 degree phase imbalance to the second channel.
y = iqimbal(x,[3 -5],[10 -15]);
Plot the constellation diagram of both channels of the impaired signal.

```
h = scatterplot(y(:,1),1,0,'b*');
hold on
scatterplot(y(:,2),1,0,'ro',h)
hold off
```

Scatter plot

The first channel is stretched horizontally, and the second channel is stretched vertically.

## Apply I/Q Imbalance and DC Offset to QPSK

Apply a $1 \mathrm{~dB}, 5$ degree I/Q imbalance to a QPSK signal. Then apply a DC offset. Visualize the offset using a spectrum analyzer.

Generate a QPSK sequence.
$x=$ pskmod(randi([0 3],1e4,1),4,pi/4);
Apply a 1 dB amplitude imbalance and 5 degree phase imbalance to a QPSK signal. Apply a $0.5+0.3 \mathrm{i}$ DC offset.
$y=$ iqimbal( $x, 1,5)$;
z = y + complex(0.5,0.3);
Plot the spectrum of the impaired signal.
sa = dsp.SpectrumAnalyzer('SampleRate',1000,'YLimits',[-50 30]); sa(z)

Display the corresponding scatter plot.
scatterplot(z)
grid

The effect of the I/Q imbalance and the DC offset is observable.

## Correct I/Q Imbalance on Noisy 8-PSK Signal

Generate random data and apply 8 -PSK modulation.

```
data = randi([0 7],2000,1);
txSig = pskmod(data,8,pi/8);
```

Pass the transmitted signal through an AWGN channel. Apply an I/Q imbalance.

```
noisySig = awgn(txSig,20);
rxSig = iqimbal(noisySig,2,20);
```

Create a constellation diagram object that displays only the last 1000 symbols. Plot the constellation diagram of the impaired signal.

```
cd = comm.ConstellationDiagram('ReferenceConstellation',pskmod(0:7,8,pi/8), ...
    'SymbolsToDisplaySource','Property','SymbolsToDisplay',1000);
cd(rxSig)
```

Correct for the I/Q imbalance by using a comm. IQImbalanceCompensator object. Plot the constellation diagram of the signal after compensation.
iqComp = comm.IQImbalanceCompensator('StepSize',1e-3);
compSig = iqComp(rxSig);
cd(compSig)

The compensator removes the I/Q imbalance.

## Input Arguments

## x - Input signal

column vector $\mid$ matrix
Input signal, specified as a column vector or matrix. The function supports multichannel operations, where the number of columns corresponds to the number of channels.

Example: pskmod(randi([0 3],100,1),4,pi/4)
Data Types: single|double

## A - Amplitude imbalance

real scalar | row vector
Amplitude imbalance in dB , specified as a real scalar or row vector.

- If A is a scalar, the function applies the same amplitude imbalance to each channel.
- If $A$ is a vector, then each element specifies the amplitude imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in A must equal the number of columns in $x$.

## Example: 3

Example: [0 5]
Data Types: single | double

## P - Phase imbalance

0 (default) | real scalar | row vector
Phase imbalance in degrees, specified as a real scalar or row vector.

- If P is omitted, a phase imbalance of zero degrees is used.
- If P is a scalar, the function applies the same phase imbalance to each channel.
- If P is a vector, then each element specifies the phase imbalance that is applied to the corresponding column (channel) of the input signal. The number of elements in $P$ must equal the number of columns in $x$.

Example: 10
Example: [2.5 7]
Data Types: single | double

## Output Arguments

## y - Output signal

vector | matrix

Output signal, returned as a vector or matrix having the same dimensions as x . The number of columns in y corresponds to the number of channels.

Data Types: single | double

## Algorithms

The iqimbal function applies an I/Q amplitude and phase imbalance to an input signal.
Given amplitude imbalance $I_{a}$ in dB , the gain, $g$, resulting from the imbalance is defined as

$$
g \triangleq g_{r}+i g_{i}=\left[10^{0.5 \frac{I_{a}}{20}}\right]+i\left[10^{-0.5 \frac{I_{a}}{20}}\right]
$$

Applying the I/Q imbalance to input signal $x$ results in output signal $y$ such that

$$
y=\operatorname{Re}(x) \cdot g_{r} e^{-i 0.5 I_{p(\Pi / 180)}}+i \operatorname{Im}(x) \cdot g_{i} e^{i 0.5 I_{p(\Pi / 180)}}
$$

where $g$ is the imbalance gain and $I_{p}$ is the phase imbalance in degrees.

## iscatastrophic

True for trellis corresponding to catastrophic convolutional code

## Syntax

iscatastrophic(s)

## Description

iscatastrophic (s) returns true if the trellis s corresponds to a convolutional code that causes catastrophic error propagation. Otherwise, it returns false.

## Examples

## Determine if a Convolutional Code is Catastrophic

Determine if a convolutional code causes catastrophic error propagation.
Create the trellis for the standard, rate $1 / 2$, constraint length 7 convolutional code.
$\mathrm{t}=$ poly2trellis(7,[171 133]);
Verify that the code is not catastrophic.

```
iscatastrophic(t)
ans = logical
    0
```

Create a trellis for a different convolutional code using the poly2trellis function.

```
u = poly2trellis(7,[161 143]);
```

Verify that the code is catastrophic.

```
iscatastrophic(u)
ans = logical
    1
```

## isprimitive

True for primitive polynomial for Galois field

## Syntax

isprimitive(a)

## Description

isprimitive (a) returns 1 if the polynomial that a represents is primitive for the Galois field $\mathrm{GF}\left(2^{\mathrm{m}}\right)$, and 0 otherwise. The input a can represent the polynomial using one of these formats:

- A nonnegative integer less than $2^{17}$. The binary representation of this integer indicates the coefficients of the polynomial. In this case, $m$ is floor (log2(a)).
- A Galois row vector in $\mathrm{GF}(2)$, listing the coefficients of the polynomial in order of descending powers. In this case, $m$ is the order of the polynomial represented by a.

## Examples

The example below finds all primitive polynomials for $\mathrm{GF}(8)$ and then checks using isprimitive whether specific polynomials are primitive.

```
a = primpoly(3,'all','nodisplay'); % All primitive polys for GF(8)
isp1 = isprimitive(13) % 13 represents a primitive polynomial.
isp2 = isprimitive(14) % 14 represents a nonprimitive polynomial.
```

The output is below. If you examine the vector a, notice that isp1 is true because 13 is an element in a, while isp2 is false because 14 is not an element in a.
isp1 =

1
isp2 =
0

## istrellis

True for valid trellis structure

## Syntax

[isok,status] = istrellis(s)

## Description

[isok,status] = istrellis(s) checks if the input s is a valid trellis structure. If the input is a valid trellis structure, isok is 1 and status is an empty character vector. Otherwise, isok is 0 and status indicates why $s$ is not a valid trellis structure.

A valid trellis structure is a MATLAB structure whose fields are as in the table below.
Fields of a Valid Trellis Structure for a Rate k/n Code

| Field in Trellis Structure | Dimensions | Meaning |
| :--- | :--- | :--- |
| numInputSymbols | Scalar | Number of input symbols to the <br> encoder: $2^{\mathrm{k}}$ |
| numOutputSymbols | Scalar | Number of output symbols from <br> the encoder: $2^{\mathrm{n}}$ |
| numStates | Scalar | Number of states in the encoder |
| nextStates | numStates-by-2 ${ }^{\mathrm{k}}$ matrix | Next states for all combinations <br> of current state and current <br> input |
| outputs | numStates-by-2 ${ }^{\mathrm{k}}$ matrix | Outputs (in octal) for all <br> combinations of current state <br> and current input |

In the nextStates matrix, each entry is an integer between 0 and numStates- 1 . The element in the sth row and uth column denotes the next state when the starting state is s-1 and the input bits have decimal representation $u-1$. To convert the input bits to a decimal value, use the first input bit as the most significant bit (MSB). For example, the second column of the nextStates matrix stores the next states when the current set of input values is $\{0, \ldots, 0,1\}$.

To convert the state to a decimal value, use this rule: If k exceeds 1, the shift register that receives the first input stream in the encoder provides the least significant bits in the state number, and the shift register that receives the last input stream in the encoder provides the most significant bits in the state number.

In the outputs matrix, the element in the sth row and uth column denotes the encoder's output when the starting state is $s-1$ and the input bits have decimal representation $u-1$. To convert to decimal value, use the first output bit as the MSB.

## Examples

These commands assemble the fields into a very simple trellis structure, and then verify the validity of the trellis structure.

```
trellis.numInputSymbols = 2;
trellis.numOutputSymbols = 2;
trellis.numStates = 2;
trellis.nextStates = [0 1;0 1];
trellis.outputs = [0 0;1 1];
[isok,status] = istrellis(trellis)
```

The output is below.
isok =
1
status $=$

Another example of a trellis is in "Trellis Description of a Convolutional Code".

## legacychannelsim

(To be removed) Toggles random number generation mode for channel objects

Note legacychannelsim will be removed in a future release. Use comm. RayleighChannel or comm.RicianChannel instead.

## Syntax

b = legacychannelsim
legacychannelsim(true)
legacychannelsim(false)
oldmode = legacychannelsim(newmode)

## Description

b = legacychannelsim returns FALSE if the code you are running uses the R2009b (or later) version of the random number generator for rayleighchan or ricianchan. (By default, these use the 2009b random number generator.) It returns TRUE if pre-R2009b versions are used. See Version 4.4. (R2009b) Communications Toolbox Release Notes for more information.
legacychannelsim(true) reverts the random number generation mode for channel objects to pre-2009b version.

Note legacychannelsim(true) will support the reset(chan, randstate) functionality.
legacychannelsim(false) sets the random number generation mode for channel objects to 2009b and later versions.
oldmode = legacychannelsim(newmode) sets the random number generation mode for channel objects to newmode and returns the previous mode, oldmode.

## Introduced in R2009b

## lineareq

(To be removed) Construct linear equalizer object

Note will be removed in a future release. Use comm. LinearEqualizer instead.

## Syntax

```
eqobj = lineareq(nweights,alg)
eqobj = lineareq(nweights,alg,sigconst)
eqobj = lineareq(nweights,alg,sigconst,nsamp)
```

## Description

The lineareq function creates an equalizer object that you can use with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
eqobj $=$ lineareq(nweights,alg) constructs a symbol-spaced linear equalizer object. The equalizer has nweights complex weights, which are initially all zeros. alg describes the adaptive algorithm that the equalizer uses; you should create alg using any of these functions: lms, signlms, normlms, varlms, rls, or cma. The signal constellation of the desired output is [-11], which corresponds to binary phase shift keying (BPSK).
eqobj = lineareq(nweights,alg, sigconst) specifies the signal constellation vector of the desired output.
eqobj = lineareq(nweights,alg,sigconst,nsamp) constructs a fractionally spaced linear equalizer object. The equalizer has nweights complex weights spaced at T/nsamp, where T is the symbol period and nsamp is a positive integer. nsamp = 1 corresponds to a symbol-spaced equalizer.

## Properties

The table below describes the properties of the linear equalizer object. To learn how to view or change the values of a linear equalizer object, see "Equalization".

Tip To initialize or reset the equalizer object eqobj, enter reset (eqobj).

| Property | Description |
| :--- | :--- |
| EqType | Fixed value, 'Linear Equalizer' |
| AlgType | Name of the adaptive algorithm represented by <br> alg |
| nWeights | Number of weights |

| Property | Description |
| :--- | :--- |
| nSampPerSym | Number of input samples per symbol (equivalent <br> to nsamp input argument). This value relates to <br> both the equalizer structure (see the use of K in <br> "Equalization") and an assumption about the <br> signal to be equalized. |
| RefTap (except for CMA equalizers) | Reference tap index, between 1 and nWeights. <br> Setting this to a value greater than 1 effectively <br> delays the reference signal and the output signal <br> by RefTap-1 with respect to the equalizer's <br> input signal. |
| SigConst | Signal constellation, a vector whose length is <br> typically a power of 2 |
| Weights | Vector of complex coefficients. This is the set of <br> wi values in the schematic in "Equalization". |
| WeightInputs | Vector of tap weight inputs. This is the set of u <br> in <br> values in the schematic in "Equalization". |
| ResetBeforeFiltering | If 1, each call to equalize resets the state of <br> eqobj before equalizing. If 0, the equalization <br> process maintains continuity from one call to the <br> next. |
| Properties specific to the adaptive algorithm <br> represented by alg | Number of samples the equalizer processed since <br> the last reset. When you create or reset eqobj, <br> this property value is 0. |
| See reference page for the adaptive algorithm <br> function that created alg: lms, signlms, <br> normlms, varlms, rls, or cma. |  |

## Relationships Among Properties

If you change nWeights, MATLAB maintains consistency in the equalizer object by adjusting the values of the properties listed below.

| Property | Adjusted Value |
| :--- | :--- |
| Weights | zeros(1, nWeights) |
| WeightInputs | zeros(1,nWeights) |
| StepSize (Variable-step-size LMS <br> equalizers) | InitStep*ones(1,nWeights) |
| InvCorrMatrix (RLS equalizers) | InvCorrInit*eye(nWeights) |

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
        'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(y0ld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

## Use LMS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\text {TM }}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS'
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0]
    WeightInputs: [0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: I
```

Call the equalizers.

```
y0ld = equalize(eq0ld,r,x(1:100));
```

yNew $=\operatorname{eqNew}(r, x(1: 100))$;

## Use RLS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings.

```
eq0ld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

```
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'RLS'
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    InvCorrInit: 0.1000
    InvCorrMatrix: [5×5 double]
    Weights: [0 0 0 0 0]
    WeightInputs: [0 0 0 0 0)]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ...
            'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'RLS'
    NumTaps: 5
    ForgettingFactor: 0.9500
    InitialInverseCorrelationMatrix: 0.1000
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

Configure lineareq and comm.LinearEqualizer objects with comparable settings. For the comm. LinearEqualizer object, set the initial inverse correlation matrix to eye(5)*0.2.

```
eq0ld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'RLS'
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ForgetFactor: 0.9500
    InvCorrInit: 0.1000
    InvCorrMatrix: [5*5 double]
    Weights: [0 0 0 0 0]
    WeightInputs: [0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','RLS', ....
            'ForgettingFactor',0.95,'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1, ...
            'InitialInverseCorrelationMatrix',eye(5)*0.2)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'RLS'
    NumTaps: 5
    ForgettingFactor: 0.9500
    InitialInverseCorrelationMatrix: [5\times5 double]
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
```

TrainingFlagInputPort: false
AdaptAfterTraining: true
InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1
Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

## Use CMA Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from CMA algorithm. The comm. LinearEqualizer System object ${ }^{\text {TM }}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,cma(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'Constant Modulus
    nWeights: 5
    nSampPerSym: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [1 0 0 0 0]
    WeightInputs: [0 0 0 0 0)]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','CMA','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputSamplesPerSymbol: 1
    AdaptWeightsSource: 'Property'
    AdaptWeights: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.

```
y0ld = equalize(eqOld,r);
```

yNew = eqNew(r);

## Use Linear Equalizers Considering Signal Delays

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the lineareq to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eq0ld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eq0ld =
    EqType: 'Linear Equalizer'
```

```
    AlgType: 'LMS
    nWeights: 16
    nSampPerSym: 2
    RefTap: }1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: I
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 16
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: I
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the comm.LinearEqualizer object, InputDelay is used to synchronize with the delayed signal. NumTaps and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 11
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: }1
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

## Compatibility Considerations

## lineareq will be removed

Warns starting in R2020a
lineareq will be removed in a future release. Use comm. LinearEqualizer instead. For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-527.

## lloyds

Optimize quantization parameters using Lloyd algorithm

## Syntax

[partition,codebook] = lloyds(training_set,initcodebook)
[partition, codebook] = lloyds(training_set,len)
[partition, codebook] = lloyds(training_set,....,tol)
[partition, codebook,distor] = lloyds(...)
[partition,codebook,distor,reldistor] = lloyds(...)

## Description

[partition,codebook] = lloyds(training_set,initcodebook) optimizes the scalar quantization parameters partition and codebook for the training data in the vector training_set. initcodebook, a vector of length at least 2, is the initial guess of the codebook values. The output codebook is a vector of the same length as initcodebook. The output partition is a vector whose length is one less than the length of codebook.

See "Represent Partitions", "Represent Codebooks", or the reference page for quantiz in this chapter, for a description of the formats of partition and codebook.

Note lloyds optimizes for the data in training_set. For best results, training_set should be similar to the data that you plan to quantize.
[partition,codebook] = lloyds(training_set,len) is the same as the first syntax, except that the scalar argument len indicates the size of the vector codebook. This syntax does not include an initial codebook guess.
[partition, codebook] = lloyds(training_set, ...,tol) is the same as the two syntaxes above, except that tol replaces $10^{-7}$ in condition 1 of the algorithm description below.
[partition, codebook, distor] = lloyds(...) returns the final mean square distortion in the variable distor.
[partition, codebook, distor, reldistor] = lloyds(...) returns a value reldistor that is related to the algorithm's termination. In condition 1 of the algorithm below, reldistor is the relative change in distortion between the last two iterations. In condition 2, reldistor is the same as distor.

## Examples

The code below optimizes the quantization parameters for a sinusoidal transmission via a three-bit channel. Because the typical data is sinusoidal, training_set is a sampled sine wave. Because the channel can transmit three bits at a time, lloyds prepares a codebook of length $2^{3}$.

```
% Generate a complete period of a sinusoidal signal.
x = sin([0:1000]*pi/500);
[partition,codebook] = lloyds(x,2^3)
The output is below.
```

```
partition =
```

partition =
Columns 1 through 6
Columns 1 through 6
-0.8540 -0.5973 -0.3017 0.0031 0.3077 0.6023

Columns 1 through 6
-0.9504 -0.7330 -0.4519 -0.1481 0.1558 0.4575
-0.9504 -0.7330 -0.4519 -0.1481 0.1558 0.4575
Columns 7 through 8
Columns 7 through 8
0.7372 0.9515

```
        0.7372 0.9515
```

## Algorithms

lloyds uses an iterative process to try to minimize the mean square distortion. The optimization processing ends when either

- The relative change in distortion between iterations is less than $10^{-7}$.
- The distortion is less than eps*max (training_set), where eps is the MATLAB floating-point relative accuracy.

## Ims

(To be removed) Construct least mean square (LMS) adaptive algorithm object
$\overline{\text { Note }}$ will be removed in a future release. Use comm. LinearEqualizer or comm.DecisionFeedbackEqualizer instead.

## Syntax

alg $=$ lms(stepsize)
alg = lms(stepsize,leakagefactor)

## Description

The lms function creates an adaptive algorithm object that you can use with the lineareq function or dfe function to create an equalizer object. You can then use the equalizer object with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
alg = lms(stepsize) constructs an adaptive algorithm object based on the least mean square (LMS) algorithm with a step size of stepsize.
alg $=$ lms(stepsize,leakagefactor) sets the leakage factor of the LMS algorithm.
leakagefactor must be between 0 and 1 . A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

## Properties

The table below describes the properties of the LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see "Equalization".

| Property | Description |
| :--- | :--- |
| AlgType | Fixed value, ' LMS ' |
| StepSize | LMS step size parameter, a nonnegative real <br> number |
| LeakageFactor | LMS leakage factor, a real number between 0 and <br> 1 |

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{T M}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
        'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
        InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(y0ld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

## Use LMS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\text {TM }}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
eq0ld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0]
    WeightInputs: [0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
    'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.
y0ld = equalize(eq0ld,r);
yNew $=$ eqNew(r);

## Use Linear Equalizers Considering Signal Delays

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the lineareq to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eq0ld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps)
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 16
    nSampPerSym: 2
    RefTap: 13
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 16
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
```

$y 0 l d 2=$ equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset (eqNew)
yNew2 $=$ eqNew(r,x(1:100));

In the comm. LinearEqualizer object, InputDelay is used to synchronize with the delayed signal. NumTaps and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 11
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: }1
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

```
yNew1 = eqNew(r2,x(1:100));
reset(eqNew)
yNew2 = eqNew(r2,x(1:100));
```

## Algorithms

Referring to the schematics presented in "Equalization", define $w$ as the vector of all weights $w_{i}$ and define $u$ as the vector of all inputs $u_{i}$. Based on the current set of weights, $w$, this adaptive algorithm creates the new set of weights given by
(LeakageFactor) w $+\quad$ (StepSize) ${ }^{*}$ e
where the * operator denotes the complex conjugate.

## Compatibility Considerations

## lms will be removed

Warns starting in R2020a

- lms will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead with the adaptive algorithm set to LMS.
- The comm. LinearEqualizer or comm. DecisionFeedback System objects do not have a leakage factor property. This is equivalent to setting LeakageFactor to 1 in the lms function.
- For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-535.

## log

Logarithm in Galois field

## Syntax

$y=\log (x)$

## Description

$y=\log (x)$ computes the logarithm of each element in the Galois array $x . y$ is an integer array that solves the equation $A .{ }^{\wedge} y=x$, where $A$ is the primitive element used to represent elements in $x$. More explicitly, the base $A$ of the logarithm is $g f(2, x . m)$ or $g f\left(2, x . m, x . p r i m \_p o l y\right)$. All elements in $x$ must be nonzero because the logarithm of zero is undefined.

## Examples

The code below illustrates how the logarithm operation inverts exponentiation.

```
m = 4; x = gf([8 1 6; 3 5 7; 4 9 2],m);
y = log(x);
primel = gf(2,m); % Primitive element in the field
z = primel .^ y; % This is now the same as x.
ck = isequal(x,z)
```

The output is
ck =

1
The code below shows that the logarithm of 1 is 0 and that the logarithm of the base (primel) is 1 .

```
m = 4; primel = gf(2,m);
yy = log([1, primel])
```

The output is
yy $=$
$0 \quad 1$

## marcumq

Generalized Marcum Q function

## Syntax

$Q=\operatorname{marcumq}(a, b)$
$Q=\operatorname{marcumq}(a, b, m)$

## Description

$Q=\operatorname{marcumq}(a, b)$ computes the Marcum $Q$ function of $a$ and $b$, defined by

$$
Q(a, b)=\int_{b}^{\infty} x \exp \left(-\frac{x^{2}+a^{2}}{2}\right) I_{0}(a x) d x
$$

where a and b are nonnegative real numbers. In this expression, $I_{0}$ is the modified Bessel function of the first kind of zero order.
$\mathrm{Q}=\operatorname{marcumq}(\mathrm{a}, \mathrm{b}, \mathrm{m})$ computes the generalized Marcum Q , defined by

$$
Q(a, b)=\frac{1}{a^{m-1}} \int_{b}^{\infty} x^{m} \exp \left(-\frac{x^{2}+a^{2}}{2}\right) I_{m-1}(a x) d x
$$

where a and b are nonnegative real numbers, and m is a positive integer. In this expression, $I_{\mathrm{m}-1}$ is the modified Bessel function of the first kind of order $m-1$.

If any of the inputs is a scalar, it is expanded to the size of the other inputs.

## Examples

## Generate and Plot Marcum Q Function Data

This example shows how to use the marcumq function.
Create an input vector, $x$.
$\mathrm{x}=(0: 0.1: 10)$ ';
Generate two output vectors for $\mathrm{a}=0$ and $\mathrm{a}=2$.
Q1 $=\operatorname{marcumq}(0, x)$;
Q2 $=\operatorname{marcumq}(2, x)$;
Plot the resultant Marcum Q functions.
plot(x,[Q1 Q2])

## mask2shift

Convert mask vector to shift for shift register configuration

## Syntax

shift = mask2shift(prpoly,mask)

## Description

shift = mask2shift(prpoly,mask) returns the shift that is equivalent to a mask, for a linear feedback shift register whose connections are specified by the primitive polynomial prpoly. The prpoly input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The mask input is a binary vector whose length is the degree of the primitive polynomial.

Note To save time, mask2shift does not check that prpoly is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use primpoly or see [2].

For more information about how masks and shifts are related to pseudonoise sequence generators, see shift2mask.

## Definition of Equivalent Shift

If $A$ is a root of the primitive polynomial and $m(A)$ is the mask polynomial evaluated at $A$, the equivalent shift s solves the equation $A^{s}=m(A)$. To interpret the vector mask as a polynomial, treat mask as a list of coefficients in order of descending powers.

## Examples

## Convert Mask to Shift

Convert masks into shifts for a linear feedback shift register.
Convert a mask of $x^{3}+1$ into an equivalent shift for the linear feedback shift register whose connections are specified by the primitive polynomial $x^{4}+x^{3}+1$.

```
s1 = mask2shift([1 1 0 0 1],[1 0 0 1])
s1 = 4
```

Convert a mask of 1 to a shift. The mask is equivalent to a shift of 0 .

```
s2 = mask2shift([1 1 0 0 1],[0 0 0 1])
s2 = 0
```

Convert a mask of $x^{2}$ into an equivalent shift for the primitive polynomial $x^{3}+x+1$.
s3 = mask2shift('x3+x+1','x2')
s3 $=2$

## matdeintrlv

Restore ordering of symbols by filling matrix by columns and emptying it by rows

## Syntax

```
deintrlvd = matdeintrlv(data,Nrows,Ncols)
```

## Description

deintrlvd = matdeintrlv(data,Nrows,Ncols) rearranges the elements in data by filling a temporary matrix with the elements column by column and then sending the matrix contents, row by row, to the output. Nrows and Ncols are the dimensions of the temporary matrix. If data is a vector, it must have Nrows*Ncols elements. If data is a matrix with multiple rows and columns, data must have Nrows*Ncols rows and the function processes the columns independently.

To use this function as an inverse of the matintrlv function, use the same Nrows and Ncols inputs in both functions. In that case, the two functions are inverses in the sense that applying matintrlv followed by matdeintrlv leaves data unchanged.

## Examples

The code below illustrates the inverse relationship between matintrlv and matdeintrlv.

```
Nrows = 2; Ncols = 3;
data = [1 2 3 4 5 6; 2 4 6 8 10 12]';
a = matintrlv(data,Nrows,Ncols); % Interleave.
b = matdeintrlv(a,Nrows,Ncols) % Deinterleave.
```

The output below shows that b is the same as data.
$\mathrm{b}=$

| 1 | 2 |
| ---: | ---: |
| 2 | 4 |
| 3 | 6 |
| 4 | 8 |
| 5 | 10 |
| 6 | 12 |

## matintrlv

Reorder symbols by filling matrix by rows and emptying it by columns

## Syntax

intrlvd = matintrlv(data,Nrows,Ncols)

## Description

intrlvd = matintrlv(data,Nrows,Ncols) rearranges the elements in data by filling a temporary matrix with the elements row by row and then sending the matrix contents, column by column, to the output. Nrows and Ncols are the dimensions of the temporary matrix. If data is a vector, it must have Nrows*Ncols elements. If data is a matrix with multiple rows and columns, data must have Nrows*Ncols rows and the function processes the columns independently.

## Examples

The command below rearranges each of two columns of a matrix.
b = matintrlv([1 $23456 ; 246810$ 12]',2,3)
b $=$

| 1 | 2 |
| :--- | ---: |
| 4 | 8 |
| 2 | 4 |
| 5 | 10 |
| 3 | 6 |
| 6 | 12 |

To form the first column of the output, the function creates the temporary 2-by-3 matrix [1 2 3; 4

## mil188qamdemod

MIL-STD-188-110 B/C standard-specific quadrature amplitude demodulation

## Syntax

$z=\operatorname{mil} 188 q a \operatorname{mdemod}(y, M)$
$z=\operatorname{mil188q}$ amdemod $(y, M$, Name, Value)

## Description

$z=\operatorname{mil188qamdemod}(y, M)$ performs QAM demodulation on an input signal, $y$, that was modulated in accordance with MIL-STD-188-110 and the modulation order, M. For a description of MIL-
STD-188-110 QAM demodulation, see "MIL-STD-188-110 QAM Hard Demodulation" on page 2-553 and "MIL-STD-188-110 QAM Soft Demodulation" on page 2-554.
$z=$ mil188qamdemod $(y, M$,Name, Value) specifies options using one or more name-value pair arguments. For example, 'OutputDataType', 'double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

## Demodulate MIL-STD-188-110B Specific 16-QAM Signal

Demodulate a 16-QAM signal that was modulated as specified in MIL-STD-188-110B. Plot the received constellation and verify that the output matches the input.

Set the modulation order and generate random data.

```
M = 16;
numSym = 20000;
x = randi([0 M-1],numSym,1);
```

Modulate the data and pass through a noisy channel.

```
txSig = mil188qammod(x,M);
rxSig = awgn(txSig,25,'measured');
```

Plot the transmitted and received signal.

```
plot(rxSig,'b*')
hold on; grid
plot(txSig,'r*')
xlim([-1.5 1.5]);
ylim([-1.5 1.5])
xlabel('In-Phase')
ylabel('Quadrature')
legend('Received constellation','Reference constellation')
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(rxSig,M);
isequal(x,z)
ans = logical
    1
```

## Demodulate MIL-STD-188-110C Specific 64-QAM Signal

Demodulate a 64-QAM signal that was modulated as specified in MIL-STD-188-110C. Compute hard decision bit output and that verify the output matches the input.

Set the modulation order and generate random bit data.

```
M = 64;
numBitsPerSym = log2(M);
x = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','PlotConstellation',true);
```

Demodulate the received signal. Compare the demodulated data to the original data.

```
z = mil188qamdemod(txSig,M,'OutputType','bit');
isequal(z,x)
ans = logical
    1
```

## Soft Bit Demodulate MIL-STD-188-110 Specific 32-QAM Signal

Demodulate a 32-QAM signal and calculate soft bits.
Set the modulation order and generate a random bit sequence.

```
M = 32;
numSym = 20000;
numBitsPerSym = log2(M);
x = randi([0 1], numSym*numBitsPerSym,1);
```

Modulate the data. Use name-value pairs to specify bit input data and unit average power, and to plot the constellation.

```
txSig = mil188qammod(x,M,'InputType','bit','UnitAveragePower',true, ...
    'PlotConstellation',true);
```

Pass the transmitted data through white Gaussian noise.
rxSig = awgn(txSig,10,'measured');
View the constellation using a scatter plot.

```
scatterplot(rxSig)
```

Demodulate the signal, computing soft bits using the approximate LLR algorithm.

```
z = mil188qamdemod(rxSig,M,'OutputType','approxllr', ...
    'NoiseVariance',10^(-1));
```

## Input Arguments

## y - Modulated signal <br> scalar | vector | matrix

Modulated signal, specified as a complex scalar, vector, or matrix. When y is a matrix, each column is treated as an independent channel.
y must be modulated in accordance with MIL-STD-188-110 [1].
Data Types: single | double
Complex Number Support: Yes

## M - Modulation order

integer
Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.

Example: 16

## Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: y = mil188qamdemod(x,M,'OutputType','bit','OutputDataType','single');

## OutputType - Output type

'integer' (default)|'bit'|'llr'|'approxllr'
Output type, specified as the comma-separated pair consisting of OutputType and 'integer', 'bit','llr', or 'approxllr'.
Data Types: char \| string

## OutputDataType - Output data type

'double' (default) |...
Output data type, specified as the comma-separated pair consisting of OutputDataType and one of the indicated data types. Acceptable values for OutputDataType depend on the OutputType value.

| OutputType Value | Acceptable OutputDataType Values |
| :--- | :--- |
| 'integer' | 'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', <br> or 'uint32' |
| 'bit' | 'double', 'single', 'int8', 'int16', 'int32', 'uint8', 'uint16', <br>  $\mathbf{~ u i n t 3 2 ' , ~ o r ~ ' l o g i c a l ' ~}$ |

## Dependencies

This name-value pair argument applies only when OutputType is set to 'integer' or 'bit'.
Data Types: char \| string
UnitAveragePower - Unit average power flag
false (default) | true
Unit average power flag, specified as the comma-separated pair consisting of UnitAveragePower and a logical scalar. When this flag is true, the function scales the constellation to an average power of 1 watt referenced to 1 ohm . When this flag is false, the function scales the constellation based on specifications in the relevant standard, as described in [1].
Data Types: logical

## NoiseVariance - Noise variance

1 (default) | positive scalar | vector of positive values
Noise variance, specified as the comma-separated pair consisting of NoiseVariance and a positive scalar or vector of positive values.

- When specified as a scalar, the same noise variance value is used on all input elements.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see "MIL-STD-188-110 QAM Soft Demodulation" on page 2-554 for algorithm selection considerations.

## Dependencies

This name-value pair argument applies only when OutputType is set to ' $l l r$ ' or 'approxllr'.
Data Types: double
PlotConstellation - Option to plot constellation
false (default) |true
Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.

Data Types: logical

## Output Arguments

z - Demodulated signal
scalar | vector | matrix
Demodulated signal, returned as a scalar, vector, or matrix. The dimensions of $z$ depend on the specified OutputType value.

| OutputType <br> Value | Return Value of <br> mil188qamdemod | Dimensions of z |
| :--- | :--- | :--- |
| 'integer' | Demodulated integer values <br> from 0 to (M - 1) | z has the same dimensions as input y. |
| 'bit' | Demodulated bits | The number of rows in z is $\log _{2}$ (sum(M)) times the <br> number of rows in y. Each demodulated symbol is <br> mapped to a group of $\log _{2}$ (sum(M)) elements in a <br> column, where the first element represents the <br> MSB and the last element represents the LSB. |
| 'llr' | Log-likelihood ratio value for <br> each bit | Approximate log-likelihood ratio <br> value for each bit |
| 'approxllr' |  |  |

## More About

## MIL-STD-188-110 QAM Hard Demodulation

The hard demodulation algorithm uses optimum decision region-based demodulation. Since all the constellation points are equally probable, maximum a posteriori probability (MAP) detection reduces to a maximum likelihood (ML) detection. The ML detection rule is equivalent to choosing the closest constellation point to the received symbol. The decision region for each constellation point is designed by drawing perpendicular bisectors between adjacent points. A received symbol is mapped to the proper constellation point based on which decision region it lies in.

Since all MIL-STD constellations are quadrant-based symmetric, for each symbol the optimum decision region-based demodulation:

- Maps the received symbol into the first quadrant
- Chooses the decision region for the symbol
- Maps the constellation point back to its original quadrant using the sign of real and imaginary parts of the received symbol

## MIL-STD-188-110 QAM Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. This table compares these algorithms.

| Algorithm | Accuracy | Execution Speed |
| :--- | :--- | :--- |
| Exact LLR | more accurate | slower execution |
| Approximate LLR | less accurate | faster execution |

For further description of these algorithms, see "Exact LLR Algorithm" and "Approximate LLR Algorithm".

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. Computation of exponentials with very large positive or negative magnitudes might yield:

- Inf or - Inf if the noise variance is a very large value
- NaN if both the noise variance and signal power are very small values

When the output returns any of these values, try using the approximate LLR algorithm because it does not compute exponentials.

## mil188qammod

MIL-STD-188-110 B/C standard-specific quadrature amplitude modulation (QAM)

## Syntax

```
y = mil188qammod(x,M)
y = mil188qammod(x,M,Name,Value)
```

## Description

$y=\operatorname{mil} 188 q$ ammod $(x, M)$ performs QAM modulation on the input signal, $x$, in accordance with MIL-STD-188-110 and the modulation order, M. For more information, see "MIL-STD-188-110" on page 2-560.
$y=\operatorname{mil} 188 q a m m o d(x, M, N a m e, V a l u e)$ specifies options using one or more name-value pair arguments. For example, 'OutputDataType', 'double' specifies the desired output data type as double. Specify name-value pair arguments after all other input arguments.

## Examples

## Apply 32-QAM to Data Per MIL-STD-188-110C

Modulate data using 32-QAM as specified in the MIL-188-110C standard. Display the result using a scatter plot.

Set M to 32 and create a data vector containing all possible symbols.
M = 32;
$x=(0: M-1)$;
Modulate the data using QAM as specified in MIL-STD-188-110C.
$y=\operatorname{mil} 188 q \operatorname{ammod}(x, M)$;
Display the constellation as a scatter plot.
scatterplot(y)

## Normalize 16-QAM Modulated MIL-STD-188-110B Signal by Average Power

Modulate data using 16-QAM as specified in the MIL-STD-188-110B standard. Normalize the modulator output so that it has an average signal power of 1 W .

Set M and generate random data.
M = 16;
$x=\operatorname{randi}([0 \mathrm{M}-1], 1 e 5,1)$;
Modulate the data applying 16-QAM as specified in MIL-STD-188-110B. Using name-value pairs, set the unit average power to true and enable the constellation plot.

```
y = mil188qammod(x,M,'UnitAveragePower',true,'PlotConstellation',true);
```

Verify that the signal has approximately unit average power.
avgPow $=$ mean(abs(y).^2)
avgPow $=1.0012$

## Apply 64-QAM MIL-STD-188-110B Modulation to Bit Data

Modulate a sequence of bits using 64-QAM as specified by MIL-STD188-110B. Display the constellation.

Set the modulation order and generate a sequence of random bits.

```
M = 64;
numBitsPerSym = log2(M);
data = randi([0 1],1000*numBitsPerSym,1);
```

Modulate the data applying 64-QAM as specified by MIL-STD-188-110B, and output constellation symbols of single data type.
y = mil188qammod(data, M,'InputType','bit','OutputDataType','single');
Plot the result constellation using a scatter plot.

```
scatterplot(y)
```

## Input Arguments

## x - Input signal

scalar | vector | matrix
Input signal, specified as a scalar, vector, or matrix. The elements of x must be binary values or integers that range from 0 to $(M-1)$, where $M$ is the modulation order.

Note To process input signal as binary elements, set the 'InputType ' value to 'bit'. For binary inputs, the number of rows must be an integer multiple of $\log _{2}(\mathrm{M})$. Groups of $\log _{2}(\mathrm{M})$ bits in a column are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: double | single | int8|int16| int32 |uint8|uint16|uint32|logical

## M - Modulation order

integer
Modulation order, specified as a power of two. The modulation order specifies the total number of points in the signal constellation.
Example: 16
Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: y = mil188qammod(data,M,'InputType','bit','OutputDataType','single');

## InputType - Input type <br> 'integer' (default)|'bit'

Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. If you specify 'integer', the input signal must consist of integers from 0 to $M-1$. If you specify 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of $\log _{2}(\mathrm{M})$.

Data Types: char|string

## OutputDataType - Output data type

'double' (default)|'single'
Output data type, specified as the comma-separated pair consisting of OutputDataType and 'double' or 'single'.

## Data Types: char|string

## UnitAveragePower - Unit average power flag

false (default) | true
Unit average power flag, specified as the comma-separated pair consisting of 'UnitAveragePower' and a logical scalar. When this flag is true, the function scales the constellation to an average power of 1 watt referenced to 1 ohm . When this flag is false, the function scales the constellation based on specifications in the relevant standard, as described in [1].
Data Types: logical

## PlotConstellation - Option to plot constellation <br> false (default) | true

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a logical scalar. To plot the constellation, set PlotConstellation to true.
Data Types: logical

## Output Arguments

## y - Modulated signal

scalar | vector | matrix
Modulated signal, returned as a complex scalar, vector, or matrix. The dimension of the output depends on the specified InputType value.

| InputType | Dimensions of Output |
| :--- | :--- |
| 'integer' | y has the same dimensions as input $x$. |

| InputType | Dimensions of Output |
| :--- | :--- |
| 'bit' | The number of rows in $y$ equals the number of rows in $x$ divided by $\log _{2}(\mathrm{M})$. |

Data Types: double | single

## More About

## MIL-STD-188-110

MIL-STD-188-110 is a US Department of Defense standard for HF communications using serial PSK mode of both data and voice signals.

The standard specifies physical layer modulation schemes for tactical and long-haul communications. The modulation scheme specified by the standard is a mix of QAM and APSK. For a detailed description of the modulation scheme, see [1].

## minpol

Find minimal polynomial of Galois field element

## Syntax

$\mathrm{pl}=\operatorname{minpol}(\mathrm{x})$

## Description

$\mathrm{pl}=\operatorname{minpol}(\mathrm{x})$ finds the minimal polynomial of each element in the Galois column vector, x . The output pl is an array in $\mathrm{GF}(2)$. The kth row of pl lists the coefficients, in order of descending powers, of the minimal polynomial of the kth element of $x$.

Note The output is in GF(2) even if the input is in a different Galois field.

## Examples

The code below uses $m=4$ and finds that the minimal polynomial of $g(2, m)$ is just the primitive polynomial used for the field $\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)$. This is true for any value of m , not just the value used in the example.

```
m = 4;
A = gf(2,m)
pl = minpol(A)
```

The output is below. Notice that the row vector [ $\left.\begin{array}{lllll}1 & 0 & 0 & 1 & 1\end{array}\right]$ represents the polynomial D^4 + D + 1 .

```
A = GF(2^4) array. Primitive polynomial = D^4+D+1 (19 decimal)
```

Array elements =
2
$\mathrm{pl}=\mathrm{GF}(2)$ array.
Array elements =
$\begin{array}{lllll}1 & 0 & 0 & 1 & 1\end{array}$

Another example is in "Minimal Polynomials".

## Topics

"Polynomials over Galois Fields"

Introduced before R2006a

## mldivide

Matrix left division \of Galois arrays

## Syntax

$x=A \backslash B$

## Description

$x=A \backslash B$ divides the Galois array $A$ into $B$ to produce a particular solution of the linear equation $A * x$ $=B$. In the special case when $A$ is a nonsingular square matrix, $x$ is the unique solution, $\operatorname{inv}(A) * B$, to the equation.

## Examples

The code below shows that $\mathrm{A} \backslash$ eye(size(A)) is the inverse of the nonsingular square matrix A .

```
m = 4; A = gf([8 1 6; 3 5 7; 4 9 2],m);
Id = gf(eye(size(A)),m);
X = A \ Id;
ck1 = isequal(X*A, Id)
ck2 = isequal(A*X, Id)
```

The output is below.
ck1 =
1
ck2 =

1

Other examples are in "Solving Linear Equations".

## Limitations

The matrix A must be one of these types:

- A nonsingular square matrix
- A matrix, in which there are more rows than columns, such that $A^{\prime} * A$ is nonsingular
- A matrix, in which there are more columns than rows, such that $A^{*} A^{\prime}$ is nonsingular

## Algorithms

If $A$ is an $M-$ by- $N$ matrix where $M>N, A \backslash B$ is the same as $\left(A^{\prime} * A\right) \backslash\left(A^{\prime} * B\right)$.
If $A$ is an $M$-by-N matrix where $M<N, A \backslash B$ is the same as $A^{\prime} *\left(\left(A^{*} A^{\prime}\right) \backslash B\right)$. This solution is not unique.

## mlseeq

Equalize linearly modulated signal using MLSE

## Syntax

```
y = mlseeq(x,chcffs,const,tblen,opmode)
y = mlseeq(
```

$\qquad$

``` , nsamp)
y = mlseeq( ___, nsamp,preamble,postamble)
y = mlseeq( ___,nsamp,init_metric,init_states,init_inputs)
[y,final_metric,final_states,final_inputs] = mlseeq(___)
```

## Description

$y=m l s e e q(x, c h c f f s$, const,tblen,opmode) equalizes the baseband signal vector $x$ using the maximum likelihood sequence estimation (MLSE). chcffs provides estimated channel coefficients. const provides the ideal signal constellation points. tblen specifies the traceback depth. opmode specifies the operation mode of the equalizer. MLSE is implemented using the "Viterbi Algorithm" on page 2-572.
$y=m l$ seeq (__ , nsamp) specifies the number of samples per symbol in $x$, in addition to arguments in the previous syntax.
y = mlseeq( __ , nsamp, preamble, postamble) specifies the number of samples per symbol in x , preamble, and postamble, in addition to arguments in the first syntax. This syntax applies when opmode is 'rst' only. For more information, see "Preamble and Postamble in Reset Operation Mode" on page 2-572.
$y=m l s e e q(\ldots, \quad$ nsamp, init_metric,init_states,init_inputs) specifies the number of samples per symbol in $x$, initial likelihood state metrics, initial traceback states, and initial traceback inputs for the equalizer, in addition to arguments in the first syntax. These three inputs are typically the final_metric, final_states, and final_inputs outputs from a previous call to this function. This syntax applies when opmode is ' cont ' only. For more information, see "Initialization in Continuous Operation Mode" on page 2-572.
[y,final_metric,final_states,final_inputs] = mlseeq(__ ) returns the normalized final likelihood state metrics, final traceback states, and final traceback inputs at the end of the traceback decoding process, using any of the previous input argument syntaxes. This syntax applies when opmode is ' cont' only. For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## Examples

## Using MLSE Equalizer Reset Operating Mode

Use the reset operating mode of the ml seeq equalizer. Demodulate the signal and check the bit error rate.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, and message length.

```
M = 2;
tblen = 10;
nsamp = 2;
msgLen = 1000;
```

Generate the reference constellation.

```
const = pammod([0:M-1],M);
```

Generate a message with random data. Modulate and upsample the signal.

```
msgData = randi([0 M-1],msgLen,1);
msgSym = pammod(msgData,M);
msgSymUp = upsample(msgSym,nsamp);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chanest = [0.986; 0.845; 0.237; 0.12345+0.31i];
msgFilt = filter(chanest,1,msgSymUp);
msgRx = awgn(msgFilt,5,'measured');
```

Equalize and then demodulate the signal to recover the message. To initialize the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, number of samples per symbol, and set the operating mode to reset. Check the message bit error rate. Your results might vary because this example uses random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp);
eqMsg = pamdemod(eqSym,M);
[nerrs ber] = biterr(msgData, eqMsg)
nerrs = 1
ber = 1.0000e-03
```

## Recover Message Containing Preamble

Recover a message that includes a preamble, equalize the signal, and check the symbol error rate.
Specify the modulation order, equalizer traceback depth, number of samples per symbol, preamble, and message length.

```
M = 4;
tblen = 16;
nsamp = 1;
preamble = [3;1];
msgLen = 500;
```

Generate the reference constellation.
const $=$ pskmod (0:3,4);

Generate a message by using random data and prepend the preamble to the message. Modulate the random data.

```
msgData = randi([0 M-1],msgLen,1);
msgData = [preamble; msgData];
msgSym = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chcoeffs = [0.623; 0.489+0.234i; 0.398i; 0.21];
chanest = chcoeffs;
msgFilt = filter(chcoeffs,1,msgSym);
msgRx = awgn(msgFilt,9,'measured');
```

Equalize the received signal. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and preamble. The same preamble symbols appear at the beginning of the message vector and in the syntax for ml seeq. Because the system does not use a postamble, an empty vector is specified as the last input argument in this ml seeq syntax.

Check the symbol error rate of the equalized signal. Run-to-run results vary due to use of random numbers.

```
eqSym = mlseeq(msgRx,chanest,const,tblen,'rst',nsamp,preamble,[]);
```

[nsymerrs,ser] = symerr(msgSym,eqSym)
nsymerrs = 8
ser $=0.0159$

## Using MLSE Equalizer Continuous Operating Mode

Use the continuous operating mode of the ml seeq equalizer. Demodulate received signal packets and check the symbol error statistics.

Specify the modulation order, equalizer traceback depth, number of samples per symbol, message length, and number of packets to process.

```
M = 4;
tblen = 10;
nsamp = 1;
msgLen = 1000;
numPkts = 25;
```

Generate the reference constellation.

```
const = pskmod(0:M-1,M);
```

Set the initial input parameters for the metric, states, and inputs of the equalizer to empty vectors. These initial assignments represent the parameters for the first packet transmitted.

```
eq_metric = [];
eq_states = [];
eq_inputs = [];
```

Assign variables for symbol error statistics.

```
ttlSymbErrs = 0;
aggrPktSER = 0;
```

Send and receive multiple message packets in a simulation loop. Between the packet transmission and reception filter each packet through a distortion channel and add Gaussian noise.

```
for jj = 1:numPkts
```

Generate a message with random data. Modulate the signal.

```
msgData = randi([0 M-1],msgLen,1);
msgMod = pskmod(msgData,M);
```

Filter the data through a distortion channel and add Gaussian noise to the signal.

```
chanest = [.986; .845; .237; .12345+.31i];
msgFilt = filter(chanest,1,msgMod);
msgRx = awgn(msgFilt,10,'measured');
```

Equalize the received symbols. To configure the equalizer, provide the channel estimate, reference constellation, equalizer traceback depth, operating mode, number of samples per symbol, and the equalizer initialization information. Continuous operating mode is specified for the equalizer. In continuous operating mode, the equalizer initialization information (metric, states, and inputs) are returned and used as inputs in the next iteration of the for loop.

```
[eqSym,eq_metric,eq_states,eq_inputs] = ...
    mlseeq(msgRx,chanest,const,tblen,'cont',nsamp, ...
    eq_metric,eq_states,eq_inputs);
```

Save the symbol error statistics. Update the symbol error statistics with the aggregate results. Display the total number of errors. Your results might vary because this example uses random numbers.

```
    [nsymerrs,ser] = symerr(msgMod(1:end-tblen),eqSym(tblen+1:end));
    ttlSymbErrs = ttlSymbErrs + nsymerrs;
    aggrPktSER = aggrPktSER + ser;
end
printTtlErr = 'A total of %d symbol errors over the %d packets received.\n';
fprintf(printTtlErr,ttlSymbErrs,numPkts);
A total of }155\mathrm{ symbol errors over the 25 packets received.
```

Display the aggregate symbol error rate.
printAggrSER = 'The aggregate symbol error rate was \%6.5d.\n';
fprintf(printAggrSER,aggrPktSER/numPkts);
The aggregate symbol error rate was 6.26263e-03.

## Input Arguments

x - Input signal
vector
Input signal, specified as a vector of modulated symbols. The vector length of x must be an integer multiple of nsamp.

## Data Types: double

Complex Number Support: Yes

## chcffs - Channel coefficients

vector
Channel coefficients, specified as a vector. The channel coefficients provide an estimate of the channel response. When nsamp > 1, the chcffs input specifies the oversampled channel coefficients.
Data Types: double
Complex Number Support: Yes

## const - Reference constellation

vector
Reference constellation, specified as a vector with $M$ elements. $M$ is the modulation order. const lists the ideal signal constellation points in the sequence used by the modulator.

Data Types: double
Complex Number Support: Yes

## tblen - Traceback depth

positive integer
Traceback depth, specified as a positive integer. The equalizer traces back from the likelihood state with the maximum metric.
Data Types: double

## opmode - Operation mode <br> 'rst'| 'cont'

Operation mode, specified as 'rst' or 'cont'.

| Value | Usage |
| :--- | :--- |
| 'rst' | Run equalizer using reset operating mode. Enables you to specify a <br> preamble and postamble that accompany the input signal. The <br> function processes the input signal, $x$, independently of the input <br> signal from any other invocations of this function. This operating <br> mode does not incur an output delay. For more information, see <br> "Preamble and Postamble in Reset Operation Mode" on page 2- <br> 572. |
| ' cont ' | Run equalizer using continuous operating mode. Enables you to <br> save the internal state information of the equalizer for use in a <br> subsequent invocation of this function. Continuous operating mode <br> is useful if the input signal is partitioned into a stream of packets <br> processed within a loop. This operating mode incurs an output delay <br> of tblen symbols. For more information, see "Initialization in <br> Continuous Operation Mode" on page 2-572. |

## Data Types: char

## nsamp - Number of samples per symbol

1 (default) | positive integer

Number of samples per symbol, specified as a positive integer. nsamp is the oversampling factor.

## Dependencies

The input signal, $x$, must be an integer multiple of nsamp.
Data Types: double
preamble - Input signal preamble
vector of integers
Input signal preamble, specified as a vector of integers between 0 and $M-1$, where $M$ is the modulation order. To omit a preamble, specify [ ].

For more information, see "Preamble and Postamble in Reset Operation Mode" on page 2-572.

## Dependencies

This input argument applies only when opmode is set to 'rst'.
Data Types: double

## postamble - Input signal postamble

vector of integers
Input signal postamble, specified as a vector of integers between 0 and $M-1$, where $M$ is the modulation order. To omit a postamble, specify [ ].

For more information, see "Preamble and Postamble in Reset Operation Mode" on page 2-572.

## Dependencies

This input argument applies only when opmode is set to 'rst'.
Data Types: double
init_metric - Initial state metrics
[ ] (default) | column vector
Initial state metrics, specified as a column vector with $N_{\text {states }}$ elements. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## Dependencies

This input argument applies only when opmode is set to ' cont '. If specifying [] for init_metric, you must also specify [] for init_states and init_inputs.
Data Types: double

## init_states - Initial traceback states

[ ] (default) | matrix of integers
Initial traceback states, specified as an $N_{\text {states }}$-by-tblen matrix of integers with values between 0 and $N_{\text {states }}-1$. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## Dependencies

This input argument applies only when opmode is set to 'cont '. If specifying [] for init_states, you must also specify [] for init_metric and init_inputs.

## Data Types: double

## init_inputs - Initial traceback inputs

[ ] (default) | matrix of integers
Initial traceback inputs, specified as an $N_{\text {states }}$-by-tblen matrix of integers with values between 0 and $M-1$. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## Dependencies

This input argument applies only when opmode is set to ' cont '. If specifying [] for init_inputs, you must also specify [] for init_metric and init_states.
Data Types: double

## Output Arguments

## y - Output signal

vector
Output signal, returned as a vector of modulated symbols.

## final_metric - Final normalized state metrics <br> vector

Final normalized state metrics, returned as a vector with $N_{\text {states }}$ elements. final_metric corresponds to the final state metrics at the end of the traceback decoding process. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## final_states - Final traceback states <br> vector

Final traceback states, returned as a $N_{\text {states }}$-by-tblen matrix of integers with values between 0 and $N_{\text {states }}-1$. final_states corresponds to the final traceback states at the end of the traceback decoding process. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## final_inputs - Final traceback inputs

vector
Final traceback inputs, returned as an $N_{\text {states }}$-by-tblen matrix of integers with values between 0 and $M-1$. final_inputs corresponds to the final traceback inputs at the end of the traceback decoding process. $M$ is the order of the modulation. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

For more information, see "Initialization in Continuous Operation Mode" on page 2-572.

## More About

## Viterbi Algorithm

The Viterbi algorithm is a sequential trellis search algorithm used to perform maximum likelihood sequence detection.

The MLSE equalizer uses the Viterbi algorithm to recursively search for the sequences that maximize the likelihood function. Using the Viterbi algorithm reduces the number of sequences in the trellis search by eliminating sequences as new data is received. The metric used to determine the maximum likelihood sequence is the correlation between the received signal and an estimated signal for each received symbol over the "Number of Likelihood States" on page 2-573.

For more information, see [1] and [2].

## Preamble and Postamble in Reset Operation Mode

When operating the MLSE equalizer in reset mode, you can specify a preamble and postamble as input arguments. Specify preamble and postamble as vectors equal to the preamble and postamble that are prepended and appended, respectively, to the input signal. The preamble and postamble vectors consist of integers between 0 and $M-1$, where $M$ is the number of elements in const. To omit the preamble or postamble input argument, specify [].

When the function applies the Viterbi algorithm, it initializes state metrics in a way that depends on whether you specify a preamble, a postamble, or both:

- If preamble is nonempty, the function decodes the preamble and assigns a metric of 0 to the decoded state. If the preamble does not decode to a unique state (that is, if the length of the preamble is less than the channel memory), the decoder assigns a metric of 0 to all states that are represented by the preamble. The traceback path ends at one of the states represented by the preamble.
- If preamble is [], the decoder initializes the metrics of all states to 0 .
- If postamble is nonempty, the traceback path begins at the smallest of all possible decoded states that are represented by the postamble.
- If postamble is [ ], the traceback path starts at the state with the smallest metric.

## Initialization in Continuous Operation Mode

When operating the MLSE equalizer in continuous mode, you can initialize the equalization based on values returned in the previous call of the function.

At the end of the traceback decoding process, the function returns final_metric, final_states, and final_inputs. When opmode is 'cont', assign these outputs to init_metric, ini $\overline{\mathrm{t}}$ _states, and init_inputs, respectively for the next call of the function. These assignments initialize the equalizer to start with the final state metrics, final traceback states, and final traceback inputs from the previous call of the function.

Each real number in init_metric represents the starting state metric of the corresponding state. init_states and init_inputs jointly specify the initial traceback memory of the equalizer.

| Output <br> Argument | Input Argument | Meaning | Matrix Size | Range of Values |
| :--- | :--- | :--- | :--- | :--- |
| final_metric | init_metric | State metrics | 1 -by- $N_{\text {states }}$ | Real numbers |
| final_states | init_states | Traceback states | $N_{\text {states }}$-by-tblen | Integers between 0 <br> and $N_{\text {states }}-1$ |
| fianl_inputs | init_inputs | Traceback inputs | $N_{\text {states }}$-by-tblen | Integers between 0 <br> and $M-1$ |

To use default values for init_metric, init_states, and init_inputs, specify each as []. For the description of $N_{\text {states }}$, see "Number of Likelihood States" on page 2-573.

## Number of Likelihood States

The number of likelihood states, $N_{\text {states }}$, is the number of correlative phase states in the trellis. $N_{\text {states }}$ is equal to $M^{L-1}$, where $M$ is the number of elements in const and $L$ is the number of symbols in the nonoversampled impulse response of the channel.

## modnorm

Scaling factor for normalizing modulation output

## Syntax

normfactor $=$ modnorm(refconst,type, power)

## Description

normfactor $=$ modnorm(refconst, type, power) returns a scale factor for normalizing a PAM or QAM modulator output using the specified reference constellation, normalization type, and output power.

## Examples

## Normalize Power of QAM Signal

Generate a 16-QAM reference constellation.
refconst $=$ qammod(0:15,16);
Generate random symbols and apply 16-QAM modulation.
x = randi([0 15],1000,1);
$\mathrm{y}=\mathrm{qammod}(\mathrm{x}, 16)$;
Plot the constellation.
h = scatterplot(y);

Compute the normalization factor so that the output signal has a peak power of 1 W .

```
nf = modnorm(refconst,'peakpow',1);
```

z = nf*y;

Confirm that no element of the normalized signal has a power greater than 1 W .

```
max(z.*conj(z))
ans = 1.0000
```

Plot the scatter plot of the normalized constellation.

```
hold on
scatterplot(z,1,0,'r+',h)
hold off
```

## Input Arguments

refconst - Reference constellation
vector
Reference constellation, specified as a vector of complex elements that comprise the reference constellation points.
Example: qammod (0:15,16)
Data Types: double
Complex Number Support: Yes

## type - Normalization type

'avpow'| 'peakpow'
Normalization type, specified as either 'avpow' or 'peakpow '.

- If type is 'avpow' , the normalization factor is calculated based on average power.
- If type is 'peakpow', the normalization factor is calculated based on peak power.

Data Types: char
power - Target power
scalar

Target power, specified as a real scalar. The target power is the intended power of the modulated signal multiplied by normfactor.
Data Types: double

## Output Arguments

## normfactor - Normalization factor <br> scalar

Normalization factor, returned as a real scalar. When a modulated signal is multiplied by the normalization factor, its average or peak power matches the target power. The function assumes that the signal you want to normalize has a minimum distance of 2 .

## See Also

pamdemod | pammod | qamdemod | qammod
Introduced before R2006a

## mskdemod

Minimum shift keying demodulation

## Syntax

```
z = mskdemod(y,nsamp)
z = mskdemod(y,nsamp,dataenc)
z = mskdemod(y,nsamp,dataenc,ini_phase)
z = mskdemod(y,nsamp,dataenc,ini_phase,ini_state)
[z,phaseout] = mskdemod(...)
[z,phaseout,stateout] = mskdemod(...)
```

## Description

$z=m s k d e m o d(y, n s a m p)$ demodulates the complex envelope $y$ of a signal using the differentially encoded minimum shift keying (MSK) method. nsamp denotes the number of samples per symbol and must be a positive integer. The initial phase of the demodulator is 0 . If $y$ is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.
$z=$ mskdemod(y,nsamp,dataenc) specifies the method of encoding data for MSK. dataenc can be either 'diff' for differentially encoded MSK or 'nondiff' for nondifferentially encoded MSK.
z = mskdemod(y,nsamp,dataenc,ini_phase) specifies the initial phase of the demodulator. ini_phase is a row vector whose length is the number of channels in $y$ and whose values are integer multiples of pi/2. To avoid overriding the default value of dataenc, set dataenc to [].
z = mskdemod(y,nsamp,dataenc,ini_phase,ini_state) specifies the initial state of the demodulator. ini_state contains the last half symbol of the previously received signal. ini_state is an nsamp-by-C matrix, where C is the number of channels in y .
[ $z$, phaseout] = mskdemod (...) returns the final phase of $y$, which is important for demodulating a future signal. The output phaseout has the same dimensions as the ini_phase input, and assumes the values $0, \mathrm{pi} / 2$, pi, and $3 * \mathrm{pi} / 2$.
[ $z$, phaseout, stateout] $=$ mskdemod (...) returns the final nsamp values of $y$, which is useful for demodulating the first symbol of a future signal. stateout has the same dimensions as the ini_state input.

## Examples

## MSK Demodulation

Modulate and demodulate a noisy MSK signal. Display the number of received errors.
Define the number of samples per symbol for the MSK signal.
nsamp = 16;

Initialize the simulation parameters.

```
numerrs = 0;
modPhase = zeros(1,2);
demodPhase = zeros(1,2);
demodState = complex(zeros(nsamp,2));
```

The main processing loop includes these steps:

- Generate binary data.
- MSK modulate the data.
- Pass the signal through an AWGN channel.
- Demodulate the MSK signal.
- Determine the number of bit errors.

```
for iRuns = 1:20
    txData = randi([0 1],100,2);
    [modSig,modPhase] = mskmod(txData,nsamp,[],modPhase);
    rxSig = awgn(modSig,20,'measured');
    [rxData,demodPhase,demodState] = mskdemod(rxSig,nsamp,[],demodPhase,demodState);
    numerrs = numerrs + biterr(txData,rxData);
end
```

Display the number of bit errors.
numerrs
numerrs = 0

## mskmod

Minimum shift keying modulation

## Syntax

$y=\operatorname{mskmod}(x, n s a m p)$
$y=\operatorname{mskmod}(x, n s a m p, d a t a e n c)$
$y=\operatorname{mskmod}(x, n s a m p$, dataenc,ini_phase)
[y, phaseout] $=\operatorname{mskmod}(\ldots)$

## Description

$y=\operatorname{mskmod}(x, n s a m p)$ outputs the complex envelope $y$ of the modulation of the message signal $x$ using differentially encoded minimum shift keying (MSK) modulation. The elements of $x$ must be 0 or 1. nsamp denotes the number of samples per symbol in $y$ and must be a positive integer. The initial phase of the MSK modulator is 0 . If x is a matrix with multiple rows and columns, the function treats the columns as independent channels and processes them independently.
$\mathrm{y}=\mathrm{mskmod}(\mathrm{x}, \mathrm{nsamp}$, dataenc) specifies the method of encoding data for MSK. dataenc can be either 'diff' for differentially encoded MSK or 'nondiff' for nondifferentially encoded MSK.
y = mskmod(x,nsamp,dataenc,ini_phase) specifies the initial phase of the MSK modulator. ini_phase is a row vector whose length is the number of channels in $y$ and whose values are integer multiples of pi/2. To avoid overriding the default value of dataenc, set dataenc to [].
[ $y$, phaseout] $=\operatorname{mskmod}(\ldots)$ returns the final phase of $y$. This is useful for maintaining phase continuity when you are modulating a future bit stream with differentially encoded MSK. phaseout has the same dimensions as the ini_phase input, and assumes the values $0, \mathrm{pi} / 2, \mathrm{pi}$, and $3^{*} \mathrm{pi} / 2$.

## Examples

## Eye Diagram of MSK Signal

Generate a random binary signal.
x = randi([0 1],100,1);
MSK modulate the data.
$y=\operatorname{mskmod}(x, 8,[], p i / 2)$;
Pass the signal through an AWGN channel. Display the eye diagram.

```
z = awgn(y,30,'measured');
eyediagram(z,16);
```

## muxdeintrlv

Restore ordering of symbols using specified shift registers

## Syntax

```
deintrlved = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay)
[deintrlved,state] = muxdeintrlv(data,delay,init_state)
```

## Description

deintrlved = muxdeintrlv(data, delay) restores the ordering of elements in data by using a set of internal shift registers, each with its own delay value. delay is a vector whose entries indicate how many symbols each shift register can hold. The length of delay is the number of shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If data is a matrix with multiple rows and columns, the function processes the columns independently.
[deintrlved,state] = muxdeintrlv(data,delay) returns a structure that holds the final state of the shift registers. state. value stores any unshifted symbols. state.index is the index of the next register to be shifted.
[deintrlved,state] = muxdeintrlv(data,delay,init_state) initializes the shift registers with the symbols contained in init_state.value and directs the first input symbol to the shift register referenced by init_state.index. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding interleaver.

## Using an Interleaver-Deinterleaver Pair

To use this function as an inverse of the muxintrlv function, use the same delay input in both functions. In that case, the two functions are inverses in the sense that applying muxintrlv followed by muxdeintrlv leaves data unchanged, after you take their combined delay of length(delay)*max(delay) into account. To learn more about delays of convolutional interleavers, see "Delays of Convolutional Interleavers".

## Examples

The example below illustrates how to use the state input and output when invoking muxdeintrlv repeatedly. Notice that [deintrlved1; deintrlved2] is the same as deintrlved.

```
delay = [0 4 8 12]; % Delays in shift registers
symbols = 100; % Number of symbols to process
% Interleave random data.
intrlved = muxintrlv(randi([0 1],symbols,1),delay);
% Deinterleave some of the data, recording state for later use.
[deintrlvedl,state] = muxdeintrlv(intrlved(1:symbols/2),delay);
% Deinterleave the rest of the data, using state as an input argument.
deintrlved2 = muxdeintrlv(intrlved(symbols/2+1:symbols),delay,state);
% Deinterleave all data in one step.
deintrlved = muxdeintrlv(intrlved,delay);
isequal(deintrlved,[deintrlved1; deintrlved2])
```

The output is below.
ans =

1
Another example using this function is in "Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB".

Introduced before R2006a

## muxintrlv

Permute symbols using shift registers with specified delays

## Syntax

intrlved = muxintrlv(data,delay)
[intrlved,state] = muxintrlv(data,delay)
[intrlved,state] = muxintrlv(data,delay,init_state)

## Description

intrlved = muxintrlv(data, delay) permutes the elements in data by using internal shift registers, each with its own delay value. delay is a vector whose entries indicate how many symbols each shift register can hold. The length of delay is the number of shift registers. Before the function begins to process data, it initializes all shift registers with zeros. If data is a matrix with multiple rows and columns, the function processes the columns independently.
[intrlved,state] = muxintrlv(data, delay) returns a structure that holds the final state of the shift registers. state.value stores any unshifted symbols. state.index is the index of the next register to be shifted.
[intrlved,state] = muxintrlv(data,delay,init state) initializes the shift registers with the symbols contained in init state. value and directs the first input symbol to the shift register referenced by init_state.index. The structure init_state is typically the state output from a previous call to this same function, and is unrelated to the corresponding deinterleaver.

## Examples

The examples in "Convolutional Interleaving and Deinterleaving Using a Sequence of Consecutive Integers in MATLAB" and on the reference page for the convintrlv function use muxintrlv.

The example on the reference page for muxdeintrlv illustrates how to use the state output and init_state input with that function; the process is analogous for this function.

## noisebw

Equivalent noise bandwidth of filter

## Syntax

bw = noisebw(num, den, numsamp, Fs)

## Description

bw = noisebw(num, den, numsamp, Fs) returns the two-sided equivalent noise bandwidth, in Hz , of a digital lowpass filter given in descending powers of z by numerator vector num and denominator vector den. The bandwidth is calculated over numsamp samples of the impulse response. Fs is the sampling rate of the signal that the filter would process; this is used as a scaling factor to convert a normalized unitless quantity into a bandwidth in Hz .

## Examples

## Noise Equivalent Bandwidth of Butterworth Filter

Computes the equivalent noise bandwidth of a Butterworth filter over 100 samples of the impulse response.

Set the sampling rate, Nyquist frequency, and carrier frequency.

```
fs = 16;
```

$\mathrm{fNyq}=\mathrm{fs} / 2$;
$\mathrm{fc}=0.5$;

Generate the Butterworth filter.

```
[num,den] = butter(2,fc/fNyq);
```

Determine the noise bandwidth.

```
bw = noisebw(num,den,100,fs)
bw = 1.1049
```

## Algorithms

The two-sided equivalent noise bandwidth is
$\frac{\mathrm{Fs} \sum_{i=1}^{N}|h(i)|^{2}}{\left|\sum_{i=1}^{N} h(i)\right|^{2}}$
where $h$ is the impulse response of the filter described by num and den, and $N$ is numsamp.

## normlms

(To be removed) Construct normalized least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Consider using comm. LinearEqualizer or comm. DecisionFeedback instead.

## Syntax

alg = normlms(stepsize)
alg = normlms(stepsize,bias)

## Description

The normlms function creates an adaptive algorithm object that you can use with the lineareq function or dfe function to create an equalizer object. You can then use the equalizer object with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
alg = normlms(stepsize) constructs an adaptive algorithm object based on the normalized least mean square (LMS) algorithm with a step size of stepsize and a bias parameter of zero.
alg = normlms(stepsize,bias) sets the bias parameter of the normalized LMS algorithm. bias must be between 0 and 1. The algorithm uses the bias parameter to overcome difficulties when the algorithm's input signal is small.

## Properties

The table below describes the properties of the normalized LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see "Equalization".

| Property | Description |
| :--- | :--- |
| AlgType | Fixed value, ' Normalized LMS ' |
| StepSize | LMS step size parameter, a nonnegative real <br> number |
| LeakageFactor | LMS leakage factor, a real number between 0 and <br> 1. A value of 1 corresponds to a conventional <br> weight update algorithm, while a value of 0 <br> corresponds to a memoryless update algorithm. |
| Bias | Normalized LMS bias parameter, a nonnegative <br> real number |

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{\text {TM }}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 +
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(y0ld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

## Use LMS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0)]
    WeightInputs: [0 0 0 0 0)
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.
y0ld = equalize(eq0ld,r);
yNew = eqNew(r);

## Use Linear Equalizers Considering Signal Delays

Configure lineareq and comm. LinearEqualizer objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the lineareq to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eqOld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 16
    nSampPerSym: 2
    RefTap: 13
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
        'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.LinearEqualizer with properties
    Algorithm: 'LMS
    NumTaps: 16
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071-0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the comm. LinearEqualizer object, InputDelay is used to synchronize with the delayed signal. NumTaps and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 11
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: }1
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
```

InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1

```
yNew1 = eqNew(r2,x(1:100));
```

reset (eqNew)
$y$ New2 $=$ eqNew(r2,x(1:100));

## Algorithms

Referring to the schematics presented in "Equalization", define $w$ as the vector of all weights $w_{\mathrm{i}}$ and define $u$ as the vector of all inputs $u_{i}$. Based on the current set of weights, $w$, this adaptive algorithm creates the new set of weights given by

$$
\text { (LeakageFactor) } w+\frac{(\text { StepSize }) u^{*} e}{u^{H} u+\operatorname{Bias}}
$$

where the * operator denotes the complex conjugate and $H$ denotes the Hermitian transpose.

## Compatibility Considerations

## normlms will be removed

Warns starting in R2020a

- normlms will be removed in a future release. Consider using comm. LinearEqualizer or comm. DecisionFeedback instead with the adaptive algorithm set to LMS.
- The comm. LinearEqualizer or comm. DecisionFeedback System objects do not have a leakage factor property. This is equivalent to setting LeakageFactor to 1 in the normlms function.
- For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-587.

## oct2dec

Convert octal to decimal numbers

## Syntax

$d=\operatorname{oct} 2 \operatorname{dec}(c)$

## Description

$\mathrm{d}=\operatorname{oct} 2 \mathrm{dec}(\mathrm{c})$ converts an octal matrix c to a decimal matrix d , element by element. In both octal and decimal representations, the rightmost digit is the least significant.

## Examples

## Convert Octal Matrix to Decimal Equivalent

Convert a 2-by-2 octal matrix its decimal equivalent.

```
d = oct2dec([12 144;0 25])
d = 2\times2
    10 100
    0}2
```

The octal number 144 is equivalent to 100 because $144=1\left(8^{2}\right)+4\left(8^{1}\right)+4\left(8^{0}\right)=100$.

## oct2poly

Convert octal number to binary coefficients

## Syntax

b = oct2poly(oct)
b = oct2poly(oct,ord)

## Description

$\mathrm{b}=$ oct2poly(oct) converts an octal number, oct, to a vector of binary coefficients, b .
b = oct2poly(oct,ord) specifies the power order, ord, of the coefficients that comprise the output. If omitted, ord is 'descending'.

## Examples

## Convert Octal Number to Binary Vector

Convert the octal number 11 to a binary vector.
b = oct2poly(11)
b $=1 \times 4$
$\begin{array}{llll}1 & 0 & 0 & 1\end{array}$

The binary vector corresponds to the polynomial $x^{3}+1$.

## Convert Octal Number to Ascending Order Binary Vector

Convert the octal number 65 to an ascending order binary vector.
b = oct2poly(65,'ascending')
b $=1 \times 6$
$\begin{array}{llllll}1 & 0 & 1 & 0 & 1 & 1\end{array}$

Sixty-five octal is the generator polynomial of a $(15,10)$ Hamming code in the Bluetooth v4.0 standard. The binary representation of 65 octal is 110101 and the $\mathrm{GF}(2)$ polynomial is $1+x^{2}+x^{4}+x^{5}$ or [101011] in ascending powers.

## Input Arguments

## oct - Octal number

scalar
Octal number, specified as a positive integer scalar.
Example: 15
Example: 3177
Data Types: double
ord - Power order
'descending' (default)|'ascending'
Power order of the binary coefficients vector, specified as a character vector having a value of 'ascending' or 'descending'.

Data Types: char

## Output Arguments

## b - Binary coefficients

vector
Binary coefficients representing a polynomial, returned as a row vector having length equal to $p+1$, where $p$ is the order of octal input.

## ofdmdemod

Demodulate time-domain signal using orthogonal frequency division multiplexing (OFDM)

## Syntax

```
outSym = ofdmdemod(ofdmSig,nfft,cplen)
outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset)
outSym = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx)
[outSym,pilots] = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx)
```

## Description

outSym = ofdmdemod(ofdmSig,nfft,cplen) performs OFDM demodulation on the input time domain signal specified in ofdmSig, using an FFT size specified by nfft and cyclic prefix length specified by cplen. For information, see "OFDM Demodulation" on page 2-599.
outSym = ofdmdemod(ofdmSig,nfft,cplen, symOffset) applies the symbol sampling offset, sym0ffset, for each OFDM symbol before demodulation of the input.
outSym = ofdmdemod(ofdmSig,nfft,cplen,sym0ffset,nullidx) removes null subcarriers from the locations specified in nullidx. For this syntax, the symbol sampling offset is applied to each OFDM symbol and the number of rows in the output is nfft - length(nullidx), which accounts for the removal of null subcarriers. Use null subcarriers to account for guard bands and DC subcarriers. For information, see "Subcarrier Allocation and Guard Bands" on page 2-600.
[outSym,pilots] = ofdmdemod(ofdmSig,nfft,cplen,symOffset,nullidx,pilotidx) returns pilot subcarriers for the pilot indices specified in pilotidx. For this syntax, the symbol sampling offset is applied to each OFDM symbol and number of rows in the output is nfft length(nullidx) - length(pilotidx), which accounts for the removal of null and pilot subcarriers. The function assumes that pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

## Examples

## OFDM Demodulation with Different CP Lengths

OFDM-demodulate a signal with different CP lengths for different symbols.
Initialize input parameters defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft = 64;
cplen = [16 32];
nSym = 2;
dataIn = complex(randn(nfft,nSym),randn(nfft,nSym));
y1 = ofdmmod(dataIn,nfft,cplen);
```

Demodulate the OFDM symbols. Compare the results to the original input data. The difference between the signals is negligible.

```
x1 = ofdmdemod(y1,nfft,cplen);
max(x1-dataIn)
ans = 1\times2 complex
10-15}
    0.2220 - 0.7772i 0.2498-0.8882i
```

## OFDM Mod-Demod SISO link

Apply OFDM multiplexing to a 16-QAM signal SISO link with Rayleigh fading.

```
s1 = RandStream('mt19937ar','Seed',12345);
nFFT = 64;
cpLen = 16;
nullIdx = [1:6 33 64-4:64].';
numTones = nFFT-length(nullIdx);
k = 4; % bits per symbol
M = 2^k;
constSym = qammod((0:M-1),M,'UnitAveragePower',true);
maxDopp = 1;
pathDelays = [0 4e-3 8e-3];
pathGains = [0 -2 -3];
sRate = 1000;
sampIdx = round(pathDelays/(1/sRate)) + 1;
chan = comm.RayleighChannel('PathGainsOutputPort',true, ...
    'MaximumDopplerShift',maxDopp,'PathDelays',pathDelays, ...
    'AveragePathGains',pathGains,'SampleRate',sRate, ...
    'RandomStream','mt19937ar with seed');
data = randi(s1,[0 M-1],numTones,1);
modOut = qammod(data,M,'UnitAveragePower',true);
```

Apply OFDM modulation and pass the signal through the channel.

```
y = ofdmmod(modOut,nFFT,cpLen,nullIdx);
[fadSig,pg] = chan(y);
```

Determine symbol sampling offset.

```
symOffset = min(max(sampIdx),cpLen)
symOffset = 9
```

OFDM demodulate the received signal.

```
x = ofdmdemod(fadSig,nFFT,cpLen,symOffset,nullIdx); % with a time shift
```

Convert path gains, pg, to scalar taps gains. Use the tap gains for equalization during signal recovery.

```
hImp = complex(zeros(1,nFFT));
```

hImp(:,sampIdx) = mean $(\mathrm{pg}, 1)$;

```
hall = fftshift(fft(hImp.'),1);
dataIdx = double(setdiff((1:nFFT)',nullIdx));
h = hall(dataIdx);
```

Equalize the signal.

```
eqH = conj(h)./(conj(h).*h);
eqSig = eqH.*x;
cdScope = comm.ConstellationDiagram('ShowReferenceConstellation',true, ...
    'ReferenceConstellation',constSym);
cdScope(eqSig);
```

Demodulate the 16-QAM symbols to recover the signal. Compute the bit error rate.
rxSym = qamdemod(eqSig, M,'UnitAveragePower',true);
numErr = symerr(data, rxSym);
disp(['Number of symbol errors: ' num2str(numErr) ' out of ' num2str(length(data)) ' symbols.'])

```
Number of symbol errors: 2 out of 52 symbols.
```

## OFDM Demodulation with Null and Pilot Packing

OFDM-demodulate data input that includes null and pilot packing.
Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.

```
nfft = 64;
cplen = 16;
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataIn = complex(randn(numDataCarrs,nSym),randn(numDataCarrs,nSym));
pilots = repmat(pskmod((0:3).',4),1,nSym);
y2 = ofdmmod(dataIn,nfft,cplen,nullIdx,pilotIdx,pilots);
```

Demodulate the OFDM symbols. Compare the results to the original input data to show that there is negligible difference between the demodulated signal and the original data and pilot signals.

```
symOffset = cplen;
[x2,rxPilots] = ofdmdemod(y2,nfft,cplen,symOffset,nullIdx,pilotIdx);
max(x2-dataIn)
ans = 1\times10 complex
10-15 x
    0.5551 + 0.2220i 0.2220 + 0.4441i 0.4441 - 0.2220i 0.4718 - 0.3331i -0.1665 - 0.4441i
max(rxPilots-pilots)
ans = 1\times10 complex
10-15 x
    0.0000 + 0.3331i 0.1837 - 0.2220i -0.4441 - 0.2776i 0.2220 + 0.2220i 0.2220 - 0.1665i
```

## Input Arguments

## ofdmSig - Modulated OFDM symbols

2-D array of complex symbols
Modulated OFDM symbols, specified as a 2-D array of complex symbols.

- If cplen is a scalar, the array size is $\left((n f f t+c p l e n) \times N_{\text {Sym }}\right)$-by- $N_{R}$.
- If cplen is a row vector, the array size is $\left(\left(\mathrm{nfft} \times N_{\mathrm{Sym}}\right)+\operatorname{sum}(\mathrm{cplen})\right)$-by- $N_{\mathrm{R}}$.
$N_{\text {Sym }}$ is the number of symbols per antenna and $N_{\mathrm{R}}$ is the number of receive antennas.
Data Types: double | single

## Complex Number Support: Yes

## nfft - FFT length

integer greater than or equal to 8
FFT length, specified as an integer greater than or equal to 8 . nfft is equivalent to the number of subcarriers used in the demodulation process.
Data Types: double

## cplen - Cyclic prefix length

scalar | row vector of length $N_{\text {Sym }}$
Cyclic prefix length, specified as a scalar or as a row vector of length $N_{\text {Sym }}$.

- When you specify cplen as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify cplen as a row vector of length $N_{\text {Sym }}$, the cyclic prefix length can vary across symbols but remains the same length through all antennas.

Data Types: double

## symOffset - Symbol sampling offset

cplen (default) | scalar | row vector
Symbol sampling offset, specified as values from 0 to cplen.

- If you do not specify symOffset, the default value is an offset equal to cplen.
- If you specify symOffset as a scalar, the same offset is used for all symbols.
- If you specify symOffset as a row vector, the offset value can be different for each symbol.

For information, see "Windowing and Symbol Offset" on page 2-601.
Data Types: double

## nullidx - Indices of null subcarrier locations

column vector
Indices of null subcarrier locations, specified as a column vector with element values from 1 to nfft . If you specify nullidx, the number of rows in outSym is ( $n f f t-l e n g t h(n u l l i d x)$ ). For information, see "Subcarrier Allocation and Guard Bands" on page 2-600.
Data Types: double
pilotidx - Indices of pilot subcarrier locations
column vector
Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to nfft . If you specify pilotidx, the number of rows in outSym is (nfft-length(nullidx)length(pilotidx)).For information, see "Subcarrier Allocation and Guard Bands" on page 2-600.
Data Types: double

## Output Arguments

## outSym - Output demodulated symbols

numeric 3-D array

Output demodulated symbols, returned as an $N_{\mathrm{D}}$-by- $N_{\text {Sym }}$-by- $N_{\mathrm{R}}$ numeric array of symbols. $N_{\mathrm{D}}$ must equal $n f f t$ - length (nullidx) - length (pilotidx). $N_{\text {Sym }}$ is the number of OFDM symbols per antenna. $N_{\mathrm{R}}$ is the number of receive antennas. For information, see "OFDM Demodulation" on page 2-599.

## pilots - Pilot subcarriers

numeric 3-D array
Pilot subcarriers, returned as an $N_{\text {Pilot }}$-by- $N_{\text {Sym }}$-by- $N_{\mathrm{R}}$ numeric array of symbols. $N_{\text {Pilot }}$ must equal the length of pilotidx. $N_{\text {Sym }}$ is the number of OFDM symbols per antenna. $N_{\mathrm{R}}$ is the number of receive antennas. The function assumes that the pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the comm. OFDMDemodulator to vary pilot subcarrier locations across OFDM symbols or antennas.

## More About

## OFDM Demodulation

An OFDM demodulator demultiplexes a multi-subcarrier time-domain signal using orthogonal frequency division modulation.

The OFDM demodulation uses an FFT operation that results in $N$ parallel data streams. An OFDM demodulator consists of a bank of $N$ correlators, with one correlator assigned to each OFDM subcarrier, followed by a parallel-to-serial conversion.

$$
f_{k}=k \Delta f
$$

## Subcarrier Allocation and Guard Bands

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.
As shown here, subcarriers are designated as data, DC, pilot, of guard band subcarriers.

- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
- The null DC subcarrier is the center of the frequency band with an index value of ( $\mathrm{nfft} / 2+1$ ) if $n f f t$ is even, or $((n f f t+1) / 2)$ if $n f f t$ is odd.
- The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

## Windowing and Symbol Offset

To reduce intersymbol interference (ISI) introduced by signal windowing applied at the transmitter, the function applies a fractional symbol offset before demodulation of each OFDM symbol. Signal windowing is often applied to transmitted OFDM symbols to smooth the discontinuity between consecutive OFDM symbols. Windowing reduces intersymbol out-of-band emissions but increases ISI.

The windowed OFDM symbol consists of the cyclic prefix (CP), ODFM symbol data, plus windowing regions at the beginning and end of the symbol. The leading and trailing windowing shoulders have tails as shown in the figure.

Windowed OFDM Symbol

To reduce ISI, you can align signal sample timing by specifying a symbol sampling offset that gets applied before OFDM symbol demodulation.

Specify the symbol sampling offset as a value from 0 to $L_{\text {CP }}$.

- When the symbol sampling offset is a scalar from 0 to $L_{\mathrm{CP}}$, the FFT window begins at the $X+1$ sample of the CP length.
- When the symbol sampling offset is zero, no offset is applied and the FFT window starts at the first sample of the symbol.
- When the symbol sampling offset is the cyclic prefix length, $L_{\mathrm{CP}}$, the FFT window begins after the last CP sample. This offset is the default setting if symbol sampling offset is not specified.

## Introduced in R2018a

## ofdmmod

Modulate frequency-domain signal using orthogonal frequency division multiplexing (OFDM)

## Syntax

```
ofdmSig = ofdmmod(inSym,nfft,cplen)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx)
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx,pilotidx,pilots)
```

## Description

ofdmSig = ofdmmod(inSym,nfft,cplen) performs OFDM modulation on the frequency-domain input data subcarriers, inSym, using an FFT size specified by nfft and cyclic prefix length specified by cplen. For information, see "OFDM Modulation" on page 2-606.
ofdmSig = ofdmmod(inSym,nfft,cplen, nullidx) inserts null subcarriers into the frequency domain input data signal prior to performing OFDM modulation. The null subcarriers are inserted at index locations from 1 to nfft , as specified by nullidx. For this syntax, the number of rows in the input inSym must be nfft - length (nullidx). Use null carriers to account for guard bands and DC subcarriers. For information, see "Subcarrier Allocation and Guard Bands" on page 2-607.
ofdmSig = ofdmmod(inSym,nfft,cplen,nullidx, pilotidx,pilots) inserts null and pilot subcarriers into the frequency domain input data symbols prior to performing OFDM modulation. The null subcarriers are inserted at the index locations specified by nullidx. The pilot subcarriers, pilots, are inserted at the index locations specified by pilotidx. For this syntax, the number of rows in the input inSym must be nfft - length(nullidx) - length(pilotidx). The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna.

## Examples

## OFDM Modulation Over Two Antennas

OFDM-modulate a fully packed input over two transmit antennas.
Initialize input parameters, generate random data, and perform OFDM modulation.

```
nfft = 128;
cplen = 16;
nSym = 5;
nt = 2;
dataIn = complex(randn(nfft,nSym,nt),randn(nfft,nSym,nt));
y1 = ofdmmod(dataIn,nfft,cplen);
```

## Apply OFDM Assigning Null Subcarriers

Apply OFDM modulation assigning null subcarriers.

Initialize input parameters and generate random data.

```
M = 16; % Modulation order for 16QAM
nfft = 64;
cplen = 16;
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSig = randi([0 M-1],numDataCarrs,nSym);
QAM modulate data. Perform OFDM modulation.
```

```
qamSym = qammod(inSig,M,'UnitAveragePower',true);
```

qamSym = qammod(inSig,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSym,nfft,cplen,nullIdx);

```

\section*{Perform OFDM Modulation Varying Cyclic Prefix per Symbol}

Perform OFDM modulation to input frequency domain data signal varying cyclic prefix length applied to each symbol.

Initialize input parameters and generate random data.
```

M = 16; % Modulation order for 16QAM
nfft = 64;
cplen = [4 8 10 7 2 2 4 11 16 3];
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
numDataCarrs = nfft-length(nullIdx);
inSig = randi([0 M-1],numDataCarrs,nSym);

```

QAM modulate data. Perform OFDM modulation.
```

qamSym = qammod(inSig,M,'UnitAveragePower',true);
outSig = ofdmmod(qamSym,nfft,cplen,nullIdx);

```

\section*{Apply OFDM to QPSK Signal Spatially Multiplexed Over Two Antennas}

Apply OFDM modulation to a QPSK signal that is spatially multiplexed over two transmit antennas.
Initialize input parameters and generate random data for each antenna.
```

M = 4; % Modulation order for QPSK
nfft = 64;
cplen = 16;
nSym = 5;
nt = 2;
nullIdx = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
pilots = repmat(pskmod((0:M-1).',M),1,nSym,2);
ant1 = randi([0 M-1],numDataCarrs,nSym);
ant2 = randi([0 M-1],numDataCarrs,nSym);

```

QPSK modulate data individually for each antenna. Perform OFDM modulation.
```

qpskSym(:,:,1) = pskmod(ant1,M);
qpskSym(:,:,2) = pskmod(ant2,M);
y1 = ofdmmod(qpskSym,nfft,cplen,nullIdx,pilotIdx,pilots);

```

\section*{OFDM Modulation with Null and Pilot Packing}

OFDM-modulate data input, specifying null and pilot packing.
Initialize input parameters, defining locations for null and pilot subcarriers. Generate random data and perform OFDM modulation.
```

nfft = 64;
cplen = 16;
nSym = 10;
nullIdx = [1:6 33 64-4:64]';
pilotIdx = [12 26 40 54]';
numDataCarrs = nfft-length(nullIdx)-length(pilotIdx);
dataIn = complex(randn(numDataCarrs,nSym),randn(numDataCarrs,nSym));
pilots = repmat(pskmod((0:3).',4),1,nSym);
y2 = ofdmmod(dataIn,nfft,cplen,nullIdx,pilotIdx,pilots);

```

\section*{Input Arguments}

\section*{inSym - Input data subcarriers}
numeric 3-D array
Input data subcarriers, specified as an \(N_{D}\)-by- \(N_{\text {Sym }}\)-by- \(N_{T}\) numeric array of symbols. The number of data subcarriers, \(N_{\mathrm{D}}\), must equal nfft - length (nullidx) - length(pilotidx). \(N_{\text {Sym }}\) is the number of OFDM symbols per transmit antenna, \(N_{\mathrm{T}}\) is the number of transmit antennas.

Input data symbols to an OFDM modulator are typically created with a baseband digital modulator, such as qammod.
Data Types: double|single
Complex Number Support: Yes

\section*{nfft - FFT length}
integer greater than or equal to 8
FFT length, specified as an integer greater than or equal to 8 . nfft is equivalent to the number of subcarriers used in the modulation process.
Data Types: double
cplen - Cyclic prefix length
scalar | row vector of length \(N_{\text {Sym }}\)
Cyclic prefix length, specified as a scalar or as a row vector of length \(N_{\text {Sym }}\).
- When you specify cplen as a scalar, the cyclic prefix length is the same for all symbols through all antennas.
- When you specify cplen as a row vector of length \(N_{\text {Sym }}\), the cyclic prefix length can vary across symbols but remains the same length through all antennas.

For more information, see "Guard Intervals" on page 2-608.
Data Types: double
nullidx - Indices of null subcarrier locations
column vector
Indices of null subcarrier locations, specified as a column vector with element values from 1 to nfft .
Data Types: double
pilotidx - Indices of pilot subcarrier locations
column vector
Indices of pilot subcarrier locations, specified as a column vector with element values from 1 to nfft .
Data Types: double

\section*{pilots - Pilot subcarriers}
numeric 3-D array
Pilot subcarriers, specified as an \(N_{\text {Pilot }}\)-by- \(N_{\text {Sym }}\)-by- \(N_{T}\) numeric array of symbols. \(N_{\text {Pilot }}\) must equal the length of pilotidx. \(N_{\text {Sym }}\) is the number of OFDM symbols per transmit antenna. \(N_{\mathrm{T}}\) is the number of transmit antennas. The function assumes pilot subcarrier locations are the same across each OFDM symbol and transmit antenna. Use the comm. OFDMModulator to vary pilot subcarrier locations across OFDM symbols or antennas.
Data Types: double | single

\section*{Output Arguments}

\section*{ofdmSig - Modulated OFDM symbols}

2-D array of complex symbols
Modulated OFDM symbols, returned as a 2-D array of complex symbols.
- If cplen is a scalar, the array size is \(\left((n f f t+c p l e n) \times N_{\text {Sym }}\right)\)-by- \(N_{T}\).
- If cplen is a row vector, the array size is \(\left(\left(\mathrm{nfft} \times N_{\mathrm{Sym}}\right)+\operatorname{sum}(\mathrm{cplen})\right)\)-by- \(N_{\mathrm{T}}\).
\(N_{\mathrm{Sym}}\) is the number of symbols per transmit antenna and \(N_{\mathrm{T}}\) is the number of transmit antennas.

\section*{More About}

\section*{OFDM Modulation}

An OFDM modulator multiplexes a frequency-domain input signal over multiple subcarriers using orthogonal frequency division modulation.

The OFDM operation divides a high-rate transmit data stream into \(N\) lower data rate substreams. The individual substreams are sent over \(N\) parallel and orthogonal subchannels. Using an inverse fast

Fourier transform (IFFT) to process the transmission data, OFDM can be transmitted with a single radio. Intersymbol interference (ISI) is reduced because the lower data rate substreams have symbol durations larger than the channel delay spread.

The output is a baseband representation of the modulated signal:
\[
v(t)=\sum_{k=0}^{N-1} X_{k} e^{j 2 \pi k \Delta f t}, \quad 0 \leq t \leq T,
\]
where \(\left\{X_{\mathrm{k}}\right\}\) are data symbols, \(N\) is the number of subcarriers, and \(T\) is the OFDM symbol time. Using a subcarrier spacing of \(\Delta f=1 / T\), the subcarriers are orthogonal over each symbol period, as expressed in this equation:
\[
\frac{1}{T} \int_{0}^{T}\left(e^{j 2 \pi m \Delta f t}\right)^{*}\left(e^{j 2 \pi n \Delta f t}\right) d t=\frac{1}{T} \int_{0}^{T} e^{j 2 \pi(m-n) \Delta f t} d t=0 \quad \text { for } m \neq n .
\]

The data symbols, \(X_{\mathrm{k}}\), are typically complex and can be from any digital modulation alphabet (for example, QPSK, 16-QAM, 64-QAM).

An OFDM modulator consists of a serial-to-parallel conversion followed by a bank of \(N\) complex modulators, individually corresponding to each OFDM subcarrier.

\section*{Subcarrier Allocation and Guard Bands}

Individual OFDM subcarriers are allocated as data, pilot, or null subcarriers.
As shown here, subcarriers are designated as data, DC, pilot, of guard band subcarriers.

- Data subcarriers transmit user data.
- Pilot subcarriers are used for channel estimation.
- Null subcarriers transmit no data. Subcarriers with no data are used to provide a DC null and serve as buffers between OFDM resource blocks.
- The null DC subcarrier is the center of the frequency band with an index value of ( \(\mathrm{nfft} / 2+1\) ) if \(n f f t\) is even, or \(((n f f t+1) / 2)\) if \(n f f t\) is odd.
- The guard bands provide buffers between consecutive OFDM symbols to protect the integrity of transmitted signals by reducing intersymbol interference.

Null subcarriers enable you to model guard bands and DC subcarrier locations for specific standards, such as the various 802.11 formats, LTE, WiMAX, or for custom allocations. You can allocate the location of nulls by assigning a vector of null subcarrier indices.

\section*{Guard Intervals}

Similar to guard bands, guard intervals are used in OFDM to protect the integrity of transmitted signals by reducing intersymbol interference.

Assignment of guard intervals is analogous to the assignment of guard bands. You can model guard intervals to provide temporal separation between OFDM symbols. The guard intervals help preserve intersymbol orthogonality after the signal passes through time-dispersive channels. Guard intervals are created by using cyclic prefixes. Cyclic prefix insertion copies the last part of an OFDM symbol as the first part of the OFDM symbol.

As long as the span of the time dispersion does not exceed the duration of the cyclic prefix, the benefit of cyclic prefix insertion is maintained.

Inserting a cyclic prefix results in a fractional reduction of user data throughput because the cyclic prefix occupies bandwidth that could be used for data transmission.

\section*{pamdemod}

Pulse amplitude demodulation

\section*{Syntax}
z = pamdemod(y, M)
z = pamdemod(y, M,ini_phase)
\(z=\operatorname{pamdemod}\left(y, M, i n i \_p h a s e, s y m b o l \_o r d e r\right)\)

\section*{Description}
\(z=\operatorname{pamdemod}(y, M)\) demodulates the complex envelope \(y\) of a pulse amplitude modulated signal. M is the alphabet size. The ideal modulated signal should have a minimum Euclidean distance of 2.
\(z=\) pamdemod(y,M,ini_phase) specifies the initial phase of the modulated signal in radians.
z = pamdemod(y,M,ini_phase, symbol_order) specifies how the function assigns binary words to corresponding integers. If symbol_order is set to 'bin' (default), the function uses a natural binary-coded ordering. If symbol_order is set to 'gray ', it uses a Gray-coded ordering.

\section*{Examples}

\section*{Demodulate PAM Signal}

Modulate and demodulate random integers using pulse amplitude modulation. Verify that the output data matches the original data.

Set the modulation order and generate 100 M -ary data symbols.
```

M = 12;
dataIn = randi([0 M-1],100,1);

```

Perform modulation and demodulation operations.
```

modData = pammod(dataIn,M);
dataOut = pamdemod(modData,M);

```

Compare the first five symbols.
```

[dataIn(1:5) data0ut(1:5)]
ans = 5*2
9 9
10 10
1 1
10 10
7 7

```

Verify that there are no symbol errors in the entire sequence.
```

symErrors = symerr(dataIn,dataOut)
symErrors = 0

```

\section*{pammod}

Pulse amplitude modulation

\section*{Syntax}
\(y=\operatorname{pammod}(x, M)\)
\(y=\operatorname{pammod}(x, M\), ini_phase)
y \(=\) pammod(x, M,ini_phase,symbol_order)

\section*{Description}
\(y=\operatorname{pammod}(x, M)\) outputs the complex envelope \(y\) of the modulation of the message signal \(x\) using pulse amplitude modulation. \(M\) is the alphabet size. The message signal must consist of integers between 0 and \(\mathrm{M}-1\). The modulated signal has a minimum Euclidean distance of 2 . If x is a matrix with multiple rows, the function processes the columns independently.
\(\mathrm{y}=\operatorname{pammod}(\mathrm{x}, \mathrm{M}\), ini_phase) specifies the initial phase of the modulated signal in radians.
y = pammod(x,M,ini_phase,symbol_order) specifies how the function assigns binary words to corresponding integers. If symbol_order is set to 'bin' (default), the function uses a natural binary-coded ordering. If symbol_order is set to 'gray', it uses a Gray constellation ordering.

\section*{Examples}

\section*{Modulate Data Symbols with PAM}

Generate random data symbols and apply pulse amplitude modulation.
Set the modulation order.
\(\mathrm{M}=8\);
Generate random integers and apply PAM modulation having an initial phase of \(\pi / 4\).
```

data = randi([0 M-1],100,1);
modData = pammod(data,M,pi/4);

```

Display the PAM constellation diagram.
```

scatterplot(modData)

```

\section*{Scatter plot}

\section*{PAM Symbol Mapping}

Plot PAM symbol mapping for Gray and natural binary encoded data.
Set the modulation order, and then create a data sequence containing a complete set of constellation points.
```

M = 8;
data = [0:M-1];

```

Modulate and demodulate Gray and natural binary encoded data.
```

symgray = pammod(data,M,0,'gray');
mapgray = pamdemod(symgray,M,0,'gray');
symbin = pammod(data,M,0,'bin');
mapbin = pamdemod(symbin,M,0,'bin');

```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.
- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.
```

scatterplot(symgray,1,0,'b*');
for k = 1:M
text(real(symgray(k))-0.6,imag(symgray(k))+0.6,···
dec2base(mapgray(k),2,4));
text(real(symgray(k))-0.2,imag(symgray(k))+1.2,...
num2str(mapgray(k)));
text(real(symbin(k))-0.6,imag(symbin(k))-0.6,...
dec2base(mapbin(k),2,4),'Color',[1 0 0]);
text(real(symbin(k))-0.2,imag(symbin(k))-1.2,...
num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-M M -2 2])

```

\section*{channelDelay}

Channel timing delay

\section*{Syntax}
[delay,mag] = channelDelay(pathGains,pathFilters)

\section*{Description}
[delay,mag] = channelDelay(pathGains,pathFilters) computes the channel timing delay by finding the peak of the channel impulse response. The function reconstructs the impulse response from a channel path gains array and a path filter impulse response matrix. The function returns the channel timing delay, in samples, and the channel impulse response magnitude. For more information, see "Channel Delay and Magnitude Computation" on page 2-621.

\section*{Examples}

\section*{Compute Timing Delay for 2-by-2 MIMO Channel}

Configure a 2-by-2 MIMO channel. Use the info object function to retrieve the path filters.
```

chan = comm.MIMOChannel('SampleRate',1000,'PathDelays',[0 1.5e-3], ...
'AveragePathGains',[1 0.8],'RandomStream','mt19937ar with seed', ...
'Seed',10,'PathGains0utputPort',true);
chanInfo = info(chan);
pathFilters = chanInfo.ChannelFilterCoefficients;

```

Compute the path gains by passing an impulse through the channel.
```

[~,pathGains] = chan(ones(1,2));

```

Compute the channel timing delay, specifying the retrieved path filters and computed path gains.
```

delay = channelDelay(pathGains,pathFilters)
delay = 6

```

\section*{Input Arguments}

\section*{pathGains - Channel path gains}

4-D numeric array
Channel path gains, specified as an \(N_{c s}-\) by \(-N_{\mathrm{p}}\)-by- \(N_{\mathrm{t}}-\) by \(-N_{\mathrm{r}}\) numeric array, where:
- \(N_{\text {cs }}\) is the number of channel snapshots.
- \(N_{\mathrm{p}}\) is the number of paths.
- \(N_{\mathrm{t}}\) is the number of transmit antennas.
- \(N_{\mathrm{r}}\) is the number of receive antennas.

If any element in pathGains is NaN, the function assumes that no path exists between the transmitter and the receiver.

Data Types: double
Complex Number Support: Yes
pathFilters - Path filter impulse response
numeric matrix
Path filter impulse response, specified as an \(N_{\mathrm{p}}\)-by- \(N_{\mathrm{h}}\) numeric matrix. \(N_{\mathrm{p}}\) is the number of paths, and \(N_{\mathrm{h}}\) is the number of impulse response samples.

Data Types: double
Complex Number Support: Yes

\section*{Output Arguments}

\section*{delay - Channel timing delay}
integer
Channel timing delay in samples, returned as an integer. This value represents the number of samples of delay relative to the first sample of the channel impulse response reconstructed from the pathGains and pathFilters inputs. The function computes the channel timing delay by finding the peak of the composite channel impulse response. For more information, see "Channel Delay and Magnitude Computation" on page 2-621.

\section*{mag - Channel impulse response magnitude} numeric matrix

Channel impulse response magnitude for each receive antenna, returned as an \(N_{\mathrm{h}}\)-by- \(N_{\mathrm{r}}\) numeric matrix. \(N_{\mathrm{h}}\) is the number of impulse response samples, and \(N_{\mathrm{r}}\) is the number of receive antennas. For more information, see "Channel Delay and Magnitude Computation" on page 2-621.

\section*{More About}

\section*{Channel Delay and Magnitude Computation}

The computation of the channel delay and impulse response magnitudes uses the composite channel impulse response.

The composite channel impulse response results from averaging the impulse response across all channel snapshots as represented in the path gains array. The input path gains array must be of the format \(N_{\mathrm{cs}}\)-by- \(N_{\mathrm{p}}\)-by- \(N_{\mathrm{t}}\)-by- \(N_{\mathrm{r}}\), where:
- \(\quad N_{\mathrm{cs}}\) is the number of channel snapshots.
- \(N_{\mathrm{p}}\) is the number of paths.
- \(N_{\mathrm{t}}\) is the number of transmit antennas.
- \(N_{\mathrm{r}}\) is the number of receive antennas.

The channel timing delay, output as a single value, is relative to the first sample of the channel impulse response. The function computes this value by finding the peak of the composite channel
impulse response. The composite channel impulse response is the summation of the impulse responses across all transmit and receive antennas.

The receive impulse response magnitudes are output as an \(N_{\mathrm{h}}\)-by- \(N_{\mathrm{r}}\) matrix. \(N_{\mathrm{h}}\) is the number of impulse response samples, and \(N_{\mathrm{r}}\) is the number of receive antennas. To compute the receive impulse response magnitudes,

1 Path gains are summed across all channel snapshots.
2 The contribution from each path is added to the channel impulse response across all transmit and receive antennas.
3 The transmit antenna paths are combined in the channel impulse response array, leaving a matrix of impulse response samples versus receive antennas.

\section*{Extended Capabilities}

\section*{plot (channel)}
(To be removed) Plot channel characteristics with channel visualization tool

Note This function will be removed in a future release. Use function associated with comm.RicianChannel or comm.RayleighChannel instead.

\section*{Syntax}
plot(h)

\section*{Description}
\(\mathrm{plot}(\mathrm{h})\), where h is a channel object, launches the channel visualization tool. This GUI tool allows you to plot channel characteristics in various ways. See Channel Visualization for details.

\section*{ExamplesVisualize RF Impairments}

Apply various RF impairments to a QAM signal. Observe the effects by using constellation diagrams, time-varying error vector magnitude (EVM) plots, and spectrum plots. Estimate the equivalent signal-to-noise ratio (SNR).

\section*{Initialization}

Set the sample rate, modulation order, and SNR. Calculate the reference constellation points.
fs = 1000;
M = 16;
snrdB = 30;
refConst = qammod(0:M-1,M,'UnitAveragePower',true);
Create constellation diagram and time scope objects to visualize the impairment effects.
```

constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
timeScope = dsp.TimeScope('YLimits',[0 40],'SampleRate',fs,'TimeSpan',1, ...
'ShowGrid',true,'YLabel','EVM (%)');

```

\section*{White Noise}

Generate a 16-QAM signal, and pass it through an AWGN channel. Plot its constellation.
```

data = randi([0 M-1],1000,1);
modSig = qammod(data,M,'UnitAveragePower',true);
noisySig = awgn(modSig,snrdB);
constDiagram(noisySig)

```

Estimate the EVM of the noisy signal from the reference constellation points.
evm \(=\) comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ... 'ReferenceConstellation', refConst, ...
'Normalization','Average constellation power');
rmsEVM = evm(noisySig)
rmsEVM =
3.1768

The modulation error rate (MER) closely corresponds to the SNR. Create an MER object, and estimate the SNR.
```

mer = comm.MER('ReferenceSignalSource','Estimated from reference constellation', ...
'ReferenceConstellation',refConst);
snrEst = mer(noisySig)
snrEst =
30.1071

```

The estimate is quite close to the specified SNR of 30 dB .

\section*{Amplifier Distortion}

Create an amplifier using the memoryless nonlinearity object.
amp = comm.MemorylessNonlinearity('IIP3',38,'AMPMConversion',0);
Pass the modulated signal through the nonlinear amplifier, and plot its constellation diagram.
```

txSig = amp(modSig);
constDiagram(txSig)

```

The corner points of the constellation have moved toward the origin due to amplifier gain compression.

Introduce a small AM/PM conversion, and display the received signal constellation.
amp.AMPMConversion = 1 ;
txSig = amp(modSig);
constDiagram(txSig)

The constellation has rotated due to the AM/PM conversion. To compute the time-varying EVM, release the EVM object and set the AveragingDimensions property to 2 . To estimate the EVM against an input signal, omit the ReferenceSignalSource property definition. This method produces more accurate results.
evm = comm.EVM('AveragingDimensions',2);
evmTime \(=\) evm(modSig,txSig);
Plot the time-varying EVM of the distorted signal.
timeScope(evmTime)

Compute the RMS EVM.
evmRMS \(=\) sqrt(mean(evmTime.^2))
evmRMS = 35.5919

Compute the MER.
mer \(=\) comm.MER;
snrEst \(=\) mer(modSig,txSig)
snrEst =
8.1392

The SNR ( \(\approx 8 \mathrm{~dB}\) ) is reduced from its initial value ( \(\infty\) ) due to amplifier distortion.

Specify input power levels ranging from 0 to 40 dBm . Convert those levels to their linear equivalent in W. Initialize the output power vector.
```

powerIn = 0:40;
pin = 10.^((powerIn-30)/10);
powerOut = zeros(length(powerIn),1);

```

Measure the amplifier output power for the range of input power levels.
```

for k = 1:length(powerIn)
data = randi([0 15],1000,1);
txSig = qammod(data,16,'UnitAveragePower',true)*sqrt(pin(k));
ampSig = amp(txSig);
powerOut(k) = 10*log10(var(ampSig))+30;
end

```

Plot the power output versus power input curve.
figure
plot(powerIn, power0ut, powerIn, powerIn, ' - - ')
legend('Amplifier Output','Ideal Output','location','se')
xlabel('Power In (dBm)')
ylabel('Power Out (dBm)')
grid

The output power levels off at 30 dBm . The amplifier exhibits nonlinear behavior for input power levels greater than 25 dBm .

\section*{I/Q Imbalance}

Apply an amplitude and phase imbalance to the modulated signal.
```

ampImb = 3;
phImb = 10;
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(modSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(modSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;

```

Plot the received constellation.
constDiagram(rxSig)

The magnitude and phase of the constellation has changed as a result of the I/Q imbalance.
Calculate and plot the time-varying EVM.
evmTime \(=\) evm(modSig,rxSig);
timeScope(evmTime)

The EVM exhibits a behavior that is similar to that experienced with a nonlinear amplifier though the variance is smaller.

Create a 100 Hz sine wave having a 1000 Hz sample rate.
sinewave = dsp.SineWave('Frequency',100,'SampleRate',1000, ...
'SamplesPerFrame', 1e4, 'Complex0utput', true);
x = sinewave();
Apply the same 3 dB and 10 degree I/Q imbalance.
```

ampImb = 3;
phImb = 10;
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(x)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(x)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
y = imbI + imbQ;

```

Plot the spectrum of the imbalanced signal.
```

spectrum = dsp.SpectrumAnalyzer('SampleRate',1000,'PowerUnits','dBW');

```
spectrum(y)

The I/Q imbalance introduces a second tone at -100 Hz , which is the inverse of the input tone.
Phase Noise
Apply phase noise to the transmitted signal. Plot the resulting constellation diagram.
pnoise \(=\) comm.PhaseNoise('Level',-50,'Frequency0ffset',20,'SampleRate',fs); pnoiseSig = pnoise(modSig);
constDiagram(pnoiseSig)

The phase noise introduces a rotational jitter.
Compute and plot the EVM of the received signal.
evmTime \(=\) evm(modSig,pnoiseSig);
timeScope(evmTime)

Determine the RMS EVM.
evmRMS \(=\operatorname{sqrt}(\) mean (evmTime.^2) \()\)
evmRMS =
6.1989

\section*{Filter Effects}

Specify the samples per symbol parameter. Create a pair of raised cosine matched filters.
sps = 4;
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.2,'FilterSpanInSymbols',8, ... 'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
rxfilter = comm.RaisedCosineReceiveFilter('RolloffFactor',0.2,'FilterSpanInSymbols',8, ... 'InputSamplesPerSymbol',sps,'Gain',1/sqrt(sps), ... 'DecimationFactor',sps);

Determine the delay through the matched filters.
```

fltDelay = 0.5*(txfilter.FilterSpanInSymbols + rxfilter.FilterSpanInSymbols);

```

Pass the modulated signal through the matched filters.
```

filtSig = txfilter(modSig);
rxSig = rxfilter(filtSig);

```

To account for the delay through the filters, discard the first fltDelay samples.
```

rxSig = rxSig(fltDelay+1:end);

```

To accommodate the change in the number of received signal samples, create new constellation diagram and time scope objects.
```

constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);
timeScope = dsp.TimeScope('YLimits',[0 40],'SampleRate',fs,'TimeSpan',1, ...
'ShowGrid',true,'YLabel','EVM (%)');

```

Estimate EVM. Plot the received signal constellation diagram and the time-varying EVM.
```

evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
'ReferenceConstellation',refConst, ...
'Normalization','Average constellation power','AveragingDimensions',2);
evmTime = evm(rxSig);
constDiagram(rxSig)
timeScope(evmTime)

```

Determine the RMS EVM.
evmRMS \(=\) sqrt(mean(evmTime.^2))
evmRMS =
2.7199

Determine the equivalent SNR.
mer \(=\) comm.MER;
snrEst \(=\) mer(modSig(1:end-fltDelay),rxSig)
snrEst \(=\)
31.4603

\section*{Combined Effects}

Combine the effects of the filters, nonlinear amplifier, AWGN, and phase noise. Display the constellation and EVM diagrams.

Create EVM, time scope and constellation diagram objects.
```

evm = comm.EVM('ReferenceSignalSource','Estimated from reference constellation', ...
'ReferenceConstellation',refConst, ...
'Normalization','Average constellation power','AveragingDimensions',2);
timeScope = dsp.TimeScope('YLimits',[0 40],'SampleRate',fs,'TimeSpan',1, ...
'ShowGrid',true,'YLabel','EVM (%)');
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refConst);

```

Specify the nonlinear amplifier and phase noise objects.
```

amp = comm.MemorylessNonlinearity('IIP3',45,'AMPMConversion',0);
pnoise = comm.PhaseNoise('Level',-55,'Frequency0ffset',20,'SampleRate',fs);

```

Filter and then amplify the modulated signal.
```

txfiltOut = txfilter(modSig);
txSig = amp(txfiltOut);

```

Add phase noise. Pass the impaired signal through the AWGN channel. Plot the constellation diagram.
```

rxSig = awgn(txSig,snrdB);
pnoiseSig = pnoise(rxSig);
rxfiltOut = rxfilter(pnoiseSig);
constDiagram(rxfiltOut)

```

Calculate the time-varying EVM. Plot the result.
evmTime \(=\) evm(rxfiltOut);
timeScope (evmTime)

Determine the RMS EVM.
evmRMS = sqrt(mean(evmTime.^2))
evmRMS =
6.6444

Estimate the SNR.
mer = comm.MER('ReferenceSignalSource','Estimated from reference constellation', ...
'ReferenceConstellation', refConst);
snrEst \(=\) mer(rxfiltOut)
snrEst =
23.6978

This value is approximately 6 dB worse than the specified value of 30 dB , which means that the effects of the other impairments are significant and will degrade the bit error rate performance.

\section*{More About}

\section*{Use the Channel Visualization Tool}

You can use a graphical plotting function that helps you visualize the characteristics of a fading channel. For example, the following code opens the channel visualization tool showing a three-path Rayleigh channel through which a random signal is passed:
```

% Three-Path Rayleigh channel
h = rayleighchan(1/100000, 130, [0 1.5e-5 3.2e-5], [0, -3, -3]);
tx = randi([0 1],500,1); % Random bit stream
hmod = comm.DBPSKModulator; % Create DBPSKModulator
dpskSig = step(hmod,tx); % DPSK signal
h.StoreHistory = true; % Allow states to be stored
y = filter(h, dpskSig); % Run signal through channel
plot(h); % Call Channel Visualization Tool

```

See "Fading Channels" for a description of fading channels and objects.

\section*{plotPhaseNoiseFilter}

Plot response of phase noise filter block

\section*{Syntax}
plotPhaseNoiseFilter(blockname)

\section*{Description}
plotPhaseNoiseFilter(blockname) plots the response of the phase noise filter associated with the Phase Noise block specified by the variable blockname.

\section*{Examples}

\section*{View Filter Response of Phase Noise Block}

This example shows how to use the plotPhaseNoiseFilter function to view the filter response of a Phase Noise block in a Simulink model.

Load a Simulink model that contains a Phase Noise block. The load_system command loads a model into memory without making its model window visible. The function will also work with models whose window is visible. The example, slex_phasenoise, contains a Phase Noise block.
load_system('slex_phasenoise')
Run the plotPhaseNoiseFilter function to view the filter response of the block Phase Noise.
plotPhaseNoiseFilter('slex_phasenoise/Phase Noise')

\section*{Input Arguments}

\section*{blockname - Phase noise block name}
character vector
The name of a Phase Noise block in a Simulink model
Example: plotPhaseNoiseFilter('Model Name/Phase Noise')
Data Types: char

\section*{pmdemod}

Phase demodulation

\section*{Syntax}
```

z = pmdemod(y,Fc,Fs,phasedev)
z = pmdemod(y,Fc,Fs,phasedev,ini_phase)

```

\section*{Description}
\(\mathrm{z}=\mathrm{pmdemod}(\mathrm{y}, \mathrm{Fc}, \mathrm{Fs}\), phasedev \()\) demodulates the phase-modulated signal y at the carrier frequency Fc (hertz). z and the carrier signal have sampling rate Fs (hertz), where Fs must be at least \(2 *\) Fc. The phasedev argument is the phase deviation of the modulated signal, in radians.
\(z=\) pmdemod (y,Fc,Fs, phasedev,ini_phase) specifies the initial phase of the modulated signal, in radians.

\section*{Examples}

\section*{Recover Phase Modulated Signal from AWGN Channel}

Set the sample rate. To plot the signals, create a time vector.
fs \(=50\);
\(\mathrm{t}=\left(0: 2^{*} \mathrm{fs}+1\right)^{\prime} / \mathrm{fs}\);
Create a sinusoidal input signal.
\(x=\sin (2 * \mathrm{pi} * \mathrm{t})+\sin (4 * \mathrm{pi} * \mathrm{t})\);
Set the carrier frequency and phase deviation.
```

fc = 10;
phasedev = pi/2;

```

Modulate the input signal.
tx \(=\operatorname{pmmod}(\mathrm{x}, \mathrm{fc}, \mathrm{fs}, \mathrm{phasedev})\);
Pass the signal through an AWGN channel.
rx = awgn(tx, 10,'measured');
Demodulate the noisy signal.
```

y = pmdemod(rx,fc,fs,phasedev);

```

Plot the original and recovered signals.
```

figure; plot(t,[x y]);

```
legend('Original signal','Recovered signal');
xlabel('Time (s)')
ylabel('Amplitude (V)')

\section*{poly2trellis}

Convert convolutional code polynomials to trellis description

\section*{Syntax}
trellis = poly2trellis(ConstraintLength,CodeGenerator)
trellis = poly2trellis(ConstraintLength,CodeGenerator,FeedbackConnection)

\section*{Description}
trellis = poly2trellis(ConstraintLength,CodeGenerator) returns the trellis structure description corresponding to the conversion for a rate \(K / N\) feedforward encoder. \(K\) is the number of input bit streams to the encoder, and \(N\) is the number of output connections. ConstraintLength specifies the delay for the input bit streams to the encoder. CodeGenerator specifies the output connections for the input bit streams to the encoder.

The poly2trellis function accepts a polynomial description of a convolutional encoder and returns the corresponding trellis structure description. This output can be used as an input to the convenc and vitdec functions. It can also be used as a mask parameter value for the Convolutional Encoder, Viterbi Decoder, and APP Decoder blocks.

Note When used with a feedback polynomial, poly2trellis makes a feedback connection to the input of the trellis.
trellis = poly2trellis(ConstraintLength,CodeGenerator,FeedbackConnection) returns the trellis structure description corresponding to the conversion for a rate \(K / N\) feedback encoder. \(K\) is the number of input bit streams to the encoder, and \(N\) is the number of output connections. ConstraintLength specifies the delay for the input bit streams to the encoder. CodeGenerator specifies the output connections for the input bit streams to the encoder. FeedbackConnection specifies the feedback connection for each of the \(K\) input bit streams to the encoder.

\section*{Examples}

\section*{Use Trellis Structure for Rate \(\mathbf{1 / 2}\) Feedback Convolutional Encoder}

Create a trellis structure to represent the rate \(1 / 2\) systematic convolutional encoder with feedback shown in this diagram.

This encoder has 5 for its constraint length, [37 33] as its generator polynomial matrix, and 37 for its feedback connection polynomial.

The first generator polynomial is octal 37. The second generator polynomial is octal 33. The feedback polynomial is octal 37. The first generator polynomial matches the feedback connection polynomial because the first output corresponds to the systematic bits.

The binary vector [ \(\left.\begin{array}{lllll}1 & 1 & 1 & 1 & 1\end{array}\right]\) represents octal 37 and corresponds to the upper row of binary digits in the diagram. The binary vector \(\left[\begin{array}{llll}1 & 1 & 0 & 1\end{array} 1\right.\) ] represents octal 33 and corresponds to the lower row of binary digits in the diagram. These binary digits indicate connections from the outputs of the registers to the two adders in the diagram. The initial 1 corresponds to the input bit.

Convert the polynomial to a trellis structure by using the poly2trellis function. When used with a feedback polynomial, poly2trellis makes a feedback connection to the input of the trellis.
```

trellis = poly2trellis(5,[37 33],37)
trellis = struct with fields:
numInputSymbols: 2
numOutputSymbols: 4
numStates: 16
nextStates: [16x2 double]
outputs: [16x2 double]

```

Generate random binary data. Convolutionally encode the data by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.
```

data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34; % Traceback depth for Viterbi decoder
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');

```

Verify the decoded data has zero bit errors.
biterr(data,decodedData)
ans \(=0\)

\section*{Trellis Structure for 2/3 Feedforward Convolutional Encoder}

Create a trellis structure for a rate \(2 / 3\) feedforward convolutional code and display a portion of the next states of the trellis. See convenc for an example using this encoder.

The diagram shows a rate \(2 / 3\) encoder with two input streams, three output streams, and seven shift registers.

Create a trellis structure. Set the constraint length of the upper path to 5 and the constraint length of the lower path to 4 . The octal representation of the code generator matrix corresponds to the taps from the upper and lower shift registers.
```

trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
trellis = struct with fields:
numInputSymbols: 4
numOutputSymbols: 8
numStates: 128
nextStates: [128x4 double]
outputs: [128\times4 double]

```

The structure field numInputSymbols equals 4 because two bit streams can produce four different input symbols. The structure field numOutputSymbols equals 8 because three bit streams produce eight different output symbols. Because the encoder has seven total shift registers, the number of possible states is \(2^{7}=128\), as shown by the nextStates field.

Display the first five rows of the 128-by-4 trellis.nextStates matrix.
```

trellis.nextStates(1:5,:)

```
ans \(=5 \times 4\)
\begin{tabular}{rrrr}
0 & 64 & 8 & 72 \\
0 & 64 & 8 & 72 \\
1 & 65 & 9 & 73 \\
1 & 65 & 9 & 73 \\
2 & 66 & 10 & 74
\end{tabular}

\section*{Use Trellis Structure for Rate 1/2 Feedforward Convolutional Encoder}

Use a trellis structure to configure the rate \(1 / 2\) feedforward convolutional code in this diagram.

Create a trellis structure, setting the constraint length to 3 and specifying the code generator as a cell array of polynomial character vectors.
```

trellis = poly2trellis(3,{'1 + x^2','1 + x + x^2'})
trellis = struct with fields:
numInputSymbols: 2
numOutputSymbols: 4
numStates: 4
nextStates: [4\times2 double]
outputs: [4x2 double]

```

Generate random binary data. Convolutionally encode the data, by using the specified trellis structure. Decode the coded data by using the Viterbi algorithm with the specified trellis structure, 34 for its traceback depth, truncated operation mode, and hard decisions.
```

data = randi([0 1],70,1);
codedData = convenc(data,trellis);
tbdepth = 34;
decodedData = vitdec(codedData,trellis,tbdepth,'trunc','hard');

```

Verify the decoded data has zero bit errors.
```

biterr(data,decodedData)
ans = 0

```

\section*{Create User Defined Trellis Structure}

This example demonstrates creation of a nonstandard trellis structure for a convolutional encoder with uncoded bits and feedback. The encoder cannot be created using poly2trellis because the peculiar specifications for the encoder do not match the input requirements of poly2trellis.

You can manually create the trellis structure, and then use it as the input trellis structure for an encoder and decoder. The Convolutional Encoder and Viterbi Decoder blocks used in the
"Convolutional Encoder with Uncoded Bits and Feedback" model load the trellis structure created here using a PreLoadFcn callback.

\section*{Convolutional Encoder}

Create a rate \(3 / 4\) convolutional encoder with feedback connection whose MSB bit remains uncoded.

Declare variables according to the specifications.
\(K=3 ;\)
\(\mathrm{N}=4\);
constraintLength = 4;

\section*{Create trellis structure}

A trellis is represented by a structure with the following fields:
- numInputSymbols - Number of input symbols
- numOutputSymbols - Number of output symbols
- numStates - Number of states
- nextStates - Next state matrix
- outputs - Output matrix

For more information about these structure fields, see istrellis.
Reset any previous occurrence of myTrellis structure.
clear myTrellis;
Define the trellis structure fields.
myTrellis.numInputSymbols = 2^K;
myTrellis.numOutputSymbols = 2^N;
myTrellis.numStates \(=2^{\wedge}(\) constraintLength-1);

\section*{Create nextStates Matrix}

The nextStates matrix is a [numStates x numInputSymbols] matrix. The ( \(i, j\) ) element of the next state matrix is the resulting final state index that corresponds to a transition from the initial state \(i\) for an input equal to \(j\).
```

myTrellis.nextStates = [$$
\begin{array}{lllllllllll}{0}&{1}&{2}&{3}&{0}&{1}&{2}&{3;}&{\ldots}\end{array}
$$)
6
1
7
2
4
3

```
myTrellis = struct with fields:
    numInputSymbols: 8
    numOutputSymbols: 16
        numStates: 8
        nextStates: [8x8 double]

\section*{Plot nextStates Matrix}

Use the commcnv_plotnextstates helper function to plot the nextStates matrix to illustrate the branch transitions between different states for a given input.
commenv_plotnextstates(myTrellis.nextStates);

\section*{Create outputs Matrix}

The outputs matrix is a [numStates x numInputSymbols] matrix. The ( \(i, j\) ) element of the output matrix is the output symbol in octal format given a current state \(i\) for an input equal to \(j\).
```

outputs = [$$
\begin{array}{rrrlllllll}{0}&{2}&{4}&{6}&{10}&{12}&{14}&{16;}&{\ldots}\\{1}&{3}&{5}&{7}&{11}&{13}&{15}&{17;}&{...}\end{array}
$$]

| 0 | 2 | 4 | 6 | 10 | 12 | 14 | $16 ;$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |$..$

| 1 | 3 | 5 | 7 | 11 | 13 | 15 | $17 ;$ | $\ldots$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

| 0 | 2 | 4 | 6 | 10 | 12 | 14 | $16 ;$ | $\ldots$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

| 1 | 3 | 5 | 7 | 11 | 13 | 15 | $17 ;$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |$\ldots$

| 0 | 2 | 4 | 6 | 10 | 12 | 14 | $16 ;$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |$..$

    1
    ```
outputs \(=8 \times 8\)
\begin{tabular}{llllllll}
0 & 2 & 4 & 6 & 10 & 12 & 14 & 16 \\
1 & 3 & 5 & 7 & 11 & 13 & 15 & 17 \\
0 & 2 & 4 & 6 & 10 & 12 & 14 & 16 \\
1 & 3 & 5 & 7 & 11 & 13 & 15 & 17 \\
0 & 2 & 4 & 6 & 10 & 12 & 14 & 16 \\
1 & 3 & 5 & 7 & 11 & 13 & 15 & 17 \\
0 & 2 & 4 & 6 & 10 & 12 & 14 & 16 \\
1 & 3 & 5 & 7 & 11 & 13 & 15 & 17
\end{tabular}

Use oct2dec to display these values in decimal format.
```

outputs_dec = oct2dec(outputs)
outputs_dec = 8×8

| 0 | 2 | 4 | 6 | 8 | 10 | 12 | 14 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 3 | 5 | 7 | 9 | 11 | 13 | 15 |
| 0 | 2 | 4 | 6 | 8 | 10 | 12 | 14 |
| 1 | 3 | 5 | 7 | 9 | 11 | 13 | 15 |
| 0 | 2 | 4 | 6 | 8 | 10 | 12 | 14 |
| 1 | 3 | 5 | 7 | 9 | 11 | 13 | 15 |
| 0 | 2 | 4 | 6 | 8 | 10 | 12 | 14 |
| 1 | 3 | 5 | 7 | 9 | 11 | 13 | 15 |

```

Copy outputs matrix into the myTrellis structure.
```

myTrellis.outputs = outputs
myTrellis = struct with fields:
numInputSymbols: 8
numOutputSymbols: 16
numStates: 8
nextStates: [8x8 double]
outputs: [8x8 double]

```

Plot outputs Matrix
Use the commcnv_plotoutputs helper function to plot the outputs matrix to illustrate the possible output symbols for a given state depending on the input symbol.
```

commcnv_plotoutputs(myTrellis.outputs, myTrellis.numOutputSymbols);

```

\section*{Check Resulting Trellis Structure}
```

istrellis(myTrellis)
ans = logical
1

```

A return value of 1 confirms the trellis structure is valid.

\section*{Implement Soft-Decision Decoding}

Decode with 3-bit soft decisions partitioned so that values near 0 map to 0 , and values near 1 map to 7. If your application requires better decoding performance, refine the partition to obtain finer quantization.

The example decodes the code and computes the bit error rate. When comparing the decoded data with the original message, the example must take the decoding delay into account. The continuous operation mode of the Viterbi decoder causes a delay equal to the traceback length, so msg (1) corresponds to decoded(tblen+1) rather than to decoded(1).

\section*{System Setup}

Initialize runtime variables for the message data, trellis, bit error rate computations, and traceback length.
```

stream = RandStream.create('mt19937ar', 'seed',94384);
prevStream = RandStream.setGlobalStream(stream);
msg = randi([0 1],4000,1); % Random data
trellis = poly2trellis(7,[171 133]); % Define trellis
ber = zeros(3,1); % Store BER values
tblen = 48; % Traceback length

```

Create an AWGN channel System object, a Viterbi decoder System object, and an error rate calculator System object. Account for the receive delay caused by the traceback length of the Viterbi decoder.
```

awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',6);
vitDec = comm.ViterbiDecoder(trellis,'InputFormat','Soft', ...
'SoftInputWordLength',3,'TracebackDepth',tblen,'TerminationMethod','Continuous');
errorCalc = comm.ErrorRate('ReceiveDelay', tblen);

```

\section*{Run Coding and Decoding}

Convolutionally code the message, pass in through an AWGN filter, quantize the noisy message for soft-decision decoding. Perform Viterbi decoding using the trellis generated using poly2trellis.
```

code = convenc(msg,trellis);
awgnChan.SignalPower = (code'*code)/length(code);
ncode = awgnChan(code);

```

Use quantiz to map the noisy data values to appropriate decision-value integers between 0 and 7 . The second argument in quantiz is a partition vector that determines which data values map to 0,1 , 2 , etc.
```

qcode = quantiz(ncode,[0.001,0.1,0.3,0.5,0.7,0.9,0.999]);

```
decoded \(=\) vitDec(qcode);

Compute bit error rate.
```

ber = errorCalc(msg,decoded);
ratio = ber(1)
ratio = 0.0013
number = ber(2)
number = 5

```
RandStream.setGlobalStream(prevStream);

\section*{Input Arguments}

\section*{ConstraintLength - Constraint length}
row vector

Constraint length, specified as a 1-by-K row vector defining the delay for each of the \(K\) input bit streams to the encoder.

Data Types: double

\section*{CodeGenerator - Code generator}
matrix | cell array of character vector | string array
Code generator, specified as a \(K\)-by- \(N\) matrix of octal numbers, a \(K\)-by- \(N\) cell array of polynomial character vectors, or a \(K\)-by- \(N\) string array. CodeGenerator specifies the \(N\) output connections for each of the \(K\) input bit streams to the encoder.

For more information, see "Character Representation of Polynomials".
Data Types: double | char | string

\section*{FeedbackConnection - Feedback connection}
row vector
Feedback connection, specified as a 1-by-K row vector of octal numbers defining the feedback connection for each of the \(K\) input bit streams to the encoder.
Data Types: double

\section*{Output Arguments}

\section*{trellis - Trellis description}
structure
Trellis description, returned as a structure with these fields. For more about this structure, see the istrellis function.

\section*{Trellis Structure Fields for Rate K/N Code}
numInputSymbols - Number of input symbols
scalar
Number of input symbols, returned as a scalar with a value of \(2^{K}\). This value represents the number of input symbols to the encoder and \(K\) represents the number of input bit streams.

\section*{numOutputSymbols - Number of output symbols}
scalar
Number of output symbols, returned as a scalar with a value of \(2^{N}\). This value represents the number of output symbols from the encoder and \(N\) represents the number of output bit streams.

\section*{numStates - Number of states}
scalar
Number of states in the encoder, returned as a scalar.

\section*{nextStates - Next states}
matrix
Next states for all combinations of current states and current inputs, returned as a numStates-by- \(2^{K}\) matrix, where \(K\) represents the number of input bit streams.
```

outputs - Outputs

```

\section*{matrix}

Outputs for all combinations of current states and current inputs, returned as a numStates-by- \(2^{K}\) matrix, \(K\) represents the number of input bit streams. The elements of this matrix are octal numbers.

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder \(^{\text {TM }}\).
Inputs must be constants, of which there can be at most 3 (ConstraintLength, CodeGenerator, FeedbackConnection).

\section*{primpoly}

Find primitive polynomials for Galois field

\section*{Syntax}
```

pr = primpoly(m)
pr = primpoly(m,opt)
pr = primpoly(m...,'nodisplay')

```

\section*{Description}
\(\mathrm{pr}=\) primpoly \((\mathrm{m})\) returns the primitive polynomial for \(\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)\), where \(m\) is an integer between 2 and 16. The Command Window displays the polynomial using "D" as an indeterminate quantity. The output argument pr is an integer whose binary representation indicates the coefficients of the polynomial.
\(\operatorname{pr}=\) primpoly (m,opt) returns one or more primitive polynomials for \(\mathrm{GF}\left(2^{\wedge} m\right)\). The output pol depends on the argument opt as shown in the table below. Each element of the output argument pr is an integer whose binary representation indicates the coefficients of the corresponding polynomial. If no primitive polynomial satisfies the constraints, pr is empty.
\begin{tabular}{|l|l|}
\hline opt & Meaning of pr \\
\hline 'min' & \begin{tabular}{l} 
One primitive polynomial for GF(2^m) having the \\
smallest possible number of nonzero terms
\end{tabular} \\
\hline 'max' & \begin{tabular}{l} 
One primitive polynomial for GF(2^m) having the \\
greatest possible number of nonzero terms
\end{tabular} \\
\hline 'all' & All primitive polynomials for \(\mathrm{GF}\left(2^{\wedge} \mathrm{m}\right)\)
\end{tabular}
pr = primpoly(m...,' nodisplay') prevents the function from displaying the result as polynomials in "D" in the Command Window. The output argument pr is unaffected by the 'nodisplay' option.

\section*{Examples}

The first example below illustrates the formats that primpoly uses in the Command Window and in the output argument pr. The subsequent examples illustrate the display options and the use of the opt argument.
```

pr = primpoly(4)
pr1 = primpoly(5,'max','nodisplay')
pr2 = primpoly(5,'min')
pr3 = primpoly(5,2)
pr4 = primpoly(5,3);

```

The output is below.
```

Primitive polynomial(s) =
D^4+D^1+1
pr =
1 9
pr1 =
6 1
Primitive polynomial(s) =
D^5+D^2+1
pr2 =
3 7
No primitive polynomial satisfies the given constraints.
pr3 =
[]
Primitive polynomial(s) =
D^5+D^2+1
D^5+D^3+1

```

\section*{pskdemod}

Phase shift keying demodulation

\section*{Syntax}
\(z=\operatorname{pskdemod}(y, M)\)
\(z=\operatorname{pskdemod}\left(y, M, i n i \_p h a s e\right)\)
z = pskdemod(y,M,ini_phase,symorder)

\section*{Description}
\(z=\operatorname{pskdemod}(y, M)\) demodulates the complex envelope, \(y\), of a PSK-modulated signal having modulation order \(M\).
\(z=p s k d e m o d\left(y, M, i n i \_p h a s e\right)\) specifies the initial phase of the PSK-modulated signal.
\(z=p s k d e m o d\left(y, M, i n i \_p h a s e, s y m o r d e r\right)\) specifies the symbol order of the PSK-modulated signal.

\section*{Examples}

\section*{Compare Phase Noise Effects on PSK and PAM Signals}

Compare PSK and PAM modulation schemes to demonstrate that PSK is more sensitive to phase noise. This is the expected result because the PSK constellation is circular while the PAM constellation is linear.

Specify the number of symbols and the modulation order parameters. Generate random data symbols.
```

len = 10000;
M = 16;
msg = randi([0 M-1],len,1);

```

Modulate msg using both PSK and PAM to compare the two methods.
```

txpsk = pskmod(msg,M);
txpam = pammod(msg,M);

```

Perturb the phase of the modulated signals by applying a random phase rotation.
```

phasenoise = randn(len,1)*.015;
rxpsk = txpsk.*exp(2i*pi*phasenoise);
rxpam = txpam.*exp(2i*pi*phasenoise);

```

Create scatter plots of the received signals.
```

scatterplot(rxpsk);
title('Noisy PSK Scatter Plot')

```

Demodulate the received signals.
```

recovpsk = pskdemod(rxpsk,M);
recovpam = pamdemod(rxpam,M);

```

Compute the number of symbol errors for each modulation scheme. The PSK signal experiences a much greater number of symbol errors.
```

numerrs_psk = symerr(msg,recovpsk);
numerrs_pam = symerr(msg,recovpam);
[numerrs_psk numerrs_pam]
ans = 1\times2
343 1

```

\section*{Modulate and Demodulate QPSK Signal in AWGN}

Generate random symbols.
```

dataIn = randi([0 3],1000,1);

```

QPSK modulate the data.
txSig \(=\) pskmod (dataIn, 4, pi/4);

Pass the signal through an AWGN channel.
```

rxSig = awgn(txSig,10);

```

Demodulate the received signal and compute the number of symbol errors.
```

dataOut = pskdemod(rxSig,4,pi/4);
numErrs = symerr(dataIn,dataOut)
numErrs = 2

```

\section*{PSK Symbol Mapping}

Plot PSK symbol mapping for Gray and natural binary encoded data.
Set the modulation order, and then create a data sequence containing a complete set of constellation points.
```

M = 8;
data = (0:M-1);
phz = 0;

```

Modulate and demodulate the data using Gray and natural binary encoded data.
```

symgray = pskmod(data,M,phz,'gray');
mapgray = pskdemod(symgray,M,phz,'gray');
symbin = pskmod(data,M,phz,'bin');
mapbin = pskdemod(symbin,M,phz,'bin');

```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.
- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.
```

scatterplot(symgray,1,0,'b*');
for k = 1:M
text(real(symgray(k))-0.2,imag(symgray(k))+.15,...
dec2base(mapgray(k),2,4));
text(real(symgray(k))-0.2,imag(symgray(k))+.3,...
num2str(mapgray(k)));
text(real(symbin(k))-0.2,imag(symbin(k))-.15,...
dec2base(mapbin(k),2,4),'Color',[1 0 0]);
text(real(symbin(k))-0.2,imag(symbin(k))-.3,...
num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-2 2 -2 2])

```

\section*{Input Arguments}

\section*{y - PSK-modulated input signal}
vector | matrix
PSK-modulated input signal, specified as a real or complex vector or matrix. If \(y\) is a matrix, the function processes the columns independently.
Data Types: double
Complex Number Support: Yes

\section*{M - Modulation order}
integer power of two
Modulation order, specified as an integer power of two.
Example: 2 | 4 | 16
Data Types: double
ini_phase - Initial phase
0 (default) | scalar | []
Initial phase of the PSK modulation, specified in radians as a real scalar.
If ini_phase is empty, then pskdemod uses an initial phase of 0 .

Example: pi/4
Data Types: double
symorder - Symbol order
'bin' (default)|'gray'
Symbol order, specified as 'bin' or 'gray'. This argument specifies how the function assigns binary vectors to corresponding integers.
- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

\section*{Output Arguments}

\section*{z - PSK-demodulated output signal}
vector | matrix
PSK-demodulated output signal, returned as a vector or matrix having the same number of columns as input signal y.

\section*{See Also}
comm. PSKDemodulator | modnorm | pskmod

\section*{Topics}
"Phase Modulation"

Introduced before R2006a

\section*{pskmod}

Phase shift keying modulation

\section*{Syntax}
```

y $=\operatorname{pskmod}(x, M)$
y = pskmod(x,M,ini_phase)
$\mathrm{y}=\mathrm{pskmod}(\mathrm{x}, \mathrm{M}$, ini_phase,symorder)

```

\section*{Description}
\(\mathrm{y}=\mathrm{pskmod}(\mathrm{x}, \mathrm{M})\) modulates the input signal, x , using phase shift keying (PSK) with modulation order M.
\(y=p s k m o d\left(x, M, i n i \_p h a s e\right)\) specifies the initial phase of the PSK-modulated signal.
\(y=p s k m o d\left(x, M, i n i \_p h a s e, s y m o r d e r\right)\) specifies the symbol order of the PSK-modulated signal.

\section*{Examples}

\section*{Modulate PSK Signal}

Modulate and plot the constellations of QPSK and 16-PSK signals.
QPSK
Set the modulation order to 4 .
M = 4;
Generate random data symbols.
data \(=\) randi([0 M-1],1000,1);
Modulate the data symbols.
txSig = pskmod(data, M, pi/M);
Pass the signal through white noise and plot its constellation.
```

rxSig = awgn(txSig,20);

```
scatterplot(rxSig)

\section*{16-PSK}

Change the modulation order from 4 to 16 .
M = 16;
Generate random data symbols.
```

data = randi([0 M-1],1000,1);

```

Modulate the data symbols.
txSig = pskmod(data, M, pi/M);
Pass the signal through white noise and plot its constellation.
```

rxSig = awgn(txSig,20);

```
scatterplot(rxSig)

\section*{Modulate and Demodulate QPSK Signal in AWGN}

Generate random symbols.
```

dataIn = randi([0 3],1000,1);

```

QPSK modulate the data.
```

txSig = pskmod(dataIn,4,pi/4);

```

Pass the signal through an AWGN channel.
```

rxSig = awgn(txSig,10);

```

Demodulate the received signal and compute the number of symbol errors.
```

dataOut = pskdemod(rxSig,4,pi/4);
numErrs = symerr(dataIn,dataOut)
numErrs = 2

```

\section*{PSK Symbol Mapping}

Plot PSK symbol mapping for Gray and natural binary encoded data.

Set the modulation order, and then create a data sequence containing a complete set of constellation points.
```

M = 8;
data = (0:M-1);
phz = 0;

```

Modulate and demodulate the data using Gray and natural binary encoded data.
```

symgray = pskmod(data,M,phz,'gray');
mapgray = pskdemod(symgray,M,phz,'gray');
symbin = pskmod(data,M,phz,'bin');
mapbin = pskdemod(symbin,M,phz,'bin');

```

Plot the constellation points using one of the symbol sets. For each constellation point, assign a label indicating the Gray and natural binary values for each symbol.
- For Gray binary symbol mapping, adjacent constellation points differ by a single binary bit and are not numerically sequential.
- For natural binary symbol mapping, adjacent constellation points follow the natural binary encoding and are sequential.
```

scatterplot(symgray,1,0,'b*');
for k = 1:M
text(real(symgray(k))-0.2,imag(symgray(k))+.15,...
dec2base(mapgray(k),2,4));
text(real(symgray(k))-0.2,imag(symgray(k))+.3,...
num2str(mapgray(k)));
text(real(symbin(k))-0.2,imag(symbin(k))-.15,...
dec2base(mapbin(k),2,4),'Color',[1 0 0]);
text(real(symbin(k))-0.2,imag(symbin(k))-.3,...
num2str(mapbin(k)),'Color',[1 0 0]);
end
axis([-2 2 -2 2])

```

\section*{Input Arguments}
x - Input signal
vector | matrix
Input signal, specified as a vector or matrix of positive integers. The elements of \(x\) must have values in the range of \([0, \mathrm{M}-1]\).
Example: randi([0 3],100,1)
Data Types: double

\section*{M - Modulation order}
integer power of two
Modulation order, specified as an integer power of two.
Example: 2 | 4 | 16
Data Types: double

\section*{ini_phase - Initial phase}

0 (default) | scalar | []
Initial phase of the PSK modulation, specified in radians as a real scalar.
If you specify ini_phase as empty, then pskmod uses an initial phase of 0 .

Example: pi/4
Data Types: double
symorder - Symbol order
'bin' (default)|'gray'
Symbol order, specified as 'bin' or 'gray '. This argument specifies how the function assigns binary vectors to corresponding integers.
- If symorder is 'bin', the function uses a natural binary-coded ordering.
- If symorder is 'gray', the function uses a Gray-coded ordering.

Data Types: char

\section*{Output Arguments}

\section*{y - PSK-modulated output signal}
vector | matrix
Complex baseband representation of a PSK-modulated signal, returned as vector or matrix of complex values. The columns of \(y\) represent independent channels.

\section*{See Also}
comm. PSKModulator | modnorm | pskdemod

\section*{Topics}
"Phase Modulation"

Introduced before R2006a

\section*{qamdemod}

Quadrature amplitude demodulation

\section*{Syntax}
```

z = qamdemod(y,M)
z = qamdemod(y,M,symOrder)
z = qamdemod(

```
\(\qquad\)

\section*{Description}
\(z=\) qamdemod \((y, M)\) returns a demodulated signal, \(z\), given quadrature amplitude modulation (QAM) signal y of modulation order M.
\(z=\) qamdemod \((y, M\), sym0rder \()\) returns a demodulated signal, \(z\), and specifies the symbol order for the demodulation.
z = qamdemod( \(\qquad\) ,Name, Value) specifies options using one or more name-value pair arguments. For example, 'OutputType' , 'bit' sets the type of output signal to bits.

\section*{Examples}

\section*{Demodulate 8-QAM Signal}

Demodulate an 8-QAM signal and plot the points corresponding to symbols 0 and 3.
Generate random 8-ary data symbols.
```

data = randi([0 7],1000,1);

```

Modulate data by applying 8-QAM.
txSig = qammod(data, 8 );
Pass the modulated signal through an AWGN channel.
```

rxSig = awgn(txSig,18,'measured');

```

Demodulate the received signal using an initial phase of \(\Pi / 8\).
```

rxData = qamdemod(rxSig.*exp(-1i*pi/8),8);

```

Generate the reference constellation points.
```

refpts = qammod((0:7)',8) .* exp(1i*pi/8);

```

Plot the received signal points corresponding to symbols 0 and 3 and overlay the reference constellation. The received data corresponding to those symbols is displayed.
```

plot(rxSig(rxData==0),'g.');
hold on

```
```

plot(rxSig(rxData==3),'c.');
plot(refpts,'r*')
text(real(refpts)+0.1,imag(refpts),num2str((0:7)'))
xlabel('In-Phase')
ylabel('Quadrature')
legend('Points corresponding to 0','Points corresponding to 3', ...
'Reference constellation','location','nw');

```

\section*{QAM Demodulation with WLAN Symbol Mapping}

Modulate and demodulate random data by using 16-QAM with WLAN symbol mapping. Verify that the input data symbols match the demodulated symbols.

Generate a 3-D array of random symbols.
\(x=\operatorname{randi}([0,15], 20,4,2)\);
Create a custom symbol mapping for the 16-QAM constellation based on WLAN standards.
wlanSymMap \(=\left[\begin{array}{llllllllllll}2 & 3 & 0 & 6 & 5 & 14 & 15 & 12 & 11 & 9\end{array}\right] ;\)
Modulate the data, and set the constellation to have unit average signal power. Plot the constellation.
\(y=\) qammod(x,16,wlanSymMap,'UnitAveragePower', true,'PlotConstellation',true);

Demodulate the received signal.
```

z = qamdemod(y,16,wlanSymMap,'UnitAveragePower',true);

```

Verify that the demodulated signal is equal to the original data.
```

isequal(x,z)
ans = logical
1

```

\section*{Demodulate QAM Fixed-Point Signal}

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.
Set the modulation order as 64, and determine the number of bits per symbol.
```

M = 64;
bitsPerSym = log2(M);

```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.
```

x = randi([0 1],10*bitsPerSym,1);

```

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16 -bit word length and a 10 -bit fraction length.
```

y = qammod(x,M,'bin','InputType','bit','OutputDataType', ...
numerictype(1,16,10));

```
```

z = qamdemod(y,M,'bin','OutputType','bit');

```
z = qamdemod(y,M,'bin','OutputType','bit');
s = isequal(x,double(z))
s = isequal(x,double(z))
s = logical
s = logical
    1
```

    1
    ```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.

\section*{Estimate BER for Hard and Soft Decision Viterbi Decoding}

Estimate bit error rate (BER) performance for hard-decision and soft-decision Viterbi decoders in AWGN. Compare the performance to that of an uncoded 64-QAM link.

Set the simulation parameters.
```

clear; close all
rng default
M = 64; %Modulation order
k = log2(M); % Bits per symbol
EbNoVec = (4:10)'; % Eb/No values (dB)
numSymPerFrame = 1000; % Number of QAM symbols per frame
Initialize the BER results vectors.
berEstSoft = zeros(size(EbNoVec));
berEstHard = zeros(size(EbNoVec));

```

Set the trellis structure and traceback depth for a rate \(1 / 2\), constraint length 7 , convolutional code.
```

trellis = poly2trellis(7,[171 133]);
tbl = 32;
rate = 1/2;

```

The main processing loops performs these steps:
- Generate binary data
- Convolutionally encode the data
- Apply QAM modulation to the data symbols. Specify unit average power for the transmitted signal
- Pass the modulated signal through an AWGN channel
- Demodulate the received signal using hard decision and approximate LLR methods. Specify unit average power for the received signal
- Viterbi decode the signals using hard and unquantized methods
- Calculate the number of bit errors

The while loop continues to process data until either 100 errors are encountered or \(10^{7}\) bits are transmitted.
```

for n = 1:length(EbNoVec)
% Convert Eb/No to SNR
snrdB = EbNoVec(n) + 10*log10(k*rate);
% Noise variance calculation for unity average signal power.
noiseVar = 10.^(-snrdB/10);
% Reset the error and bit counters
[numErrsSoft,numErrsHard,numBits] = deal(0);
while numErrsSoft < 100 \&\& numBits < le7
% Generate binary data and convert to symbols
dataIn = randi([0 1],numSymPerFrame*k,1);
% Convolutionally encode the data
dataEnc = convenc(dataIn,trellis);
% QAM modulate
txSig = qammod(dataEnc,M,'InputType','bit','UnitAveragePower',true);
% Pass through AWGN channel
rxSig = awgn(txSig,snrdB,'measured');
% Demodulate the noisy signal using hard decision (bit) and
% soft decision (approximate LLR) approaches.
rxDataHard = qamdemod(rxSig,M,'OutputType','bit','UnitAveragePower',true);
rxDataSoft = qamdemod(rxSig,M,'OutputType','approxllr', ...
'UnitAveragePower',true,'NoiseVariance',noiseVar);
% Viterbi decode the demodulated data
dataHard = vitdec(rxDataHard,trellis,tbl,'cont','hard');
dataSoft = vitdec(rxDataSoft,trellis,tbl,'cont','unquant');
% Calculate the number of bit errors in the frame. Adjust for the
% decoding delay, which is equal to the traceback depth.
numErrsInFrameHard = biterr(dataIn(1:end-tbl),dataHard(tbl+1:end));
numErrsInFrameSoft = biterr(dataIn(1:end-tbl),dataSoft(tbl+1:end));
% Increment the error and bit counters
numErrsHard = numErrsHard + numErrsInFrameHard;
numErrsSoft = numErrsSoft + numErrsInFrameSoft;
numBits = numBits + numSymPerFrame*k;
end
% Estimate the BER for both methods
berEstSoft(n) = numErrsSoft/numBits;
berEstHard(n) = numErrsHard/numBits;
end

```

Plot the estimated hard and soft BER data. Plot the theoretical performance for an uncoded 64-QAM channel.
```

semilogy(EbNoVec,[berEstSoft berEstHard],'-*')
hold on
semilogy(EbNoVec, berawgn(EbNoVec, 'qam',M))
legend('Soft','Hard','Uncoded','location','best')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')

```

As expected, the soft decision decoding produces the best results.

\section*{Soft-Decision OQPSK Modulation-Demodulation}

Use the qamdemod function to simulate soft decision output for OQPSK-modulated signals.
Generate an OQPSK modulated signal.
```

sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);

```

Add noise to the generated signal.
impairedSig = awgn(oqpskSig,15);

\section*{Perform Soft-Decision Demodulation}

Create QPSK equivalent signal to align in-phase and quadrature.
impairedQPSK = complex(real(impairedSig(1+sps/2:end-sps/2)), imag(impairedSig(sps+1:end)));
Apply matched filtering to the received OQPSK signal.
```

halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps,halfSinePulse,'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);

```

To perform soft demodulation of the filtered OQPSK signal use the qamdemod function. Align symbol mapping of qamdemod with the symbol mapping used by the comm.0QPSKModulator, then demodulate the signal.
oqpskModSymbolMapping = [11302];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping,'OutputType','llr');

\section*{Input Arguments}
y - Input signal
scalar | vector | matrix | 3-D array
Input signal that resulted QAM, specified as a scalar, vector, matrix, or 3-D array of complex values. Each column in the matrix and 3-D array is considered as an independent channel.

Data Types: single|double|fi
Complex Number Support: Yes

\section*{M - Modulation order}
scalar integer
Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.

Data Types: single|double|int8|int16|int32|int64|uint8|uint16|uint32|uint64
sym0rder - Symbol order
'gray' (default)|'bin'|vector
Symbol order, specified as one of these options:
- 'gray ' - Use "Gray Code" on page 2-681 ordering.
- 'bin' - Use natural binary-coded ordering.
- Vector - Use custom symbol ordering. The vector must be of length M. Vectors must use unique elements whose values range from 0 to \(M-1\). The first element corresponds to the upper left point of the constellation, with subsequent elements running down column-wise from left to right.

Data Types: char | double

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: z = qamdemod(y,M,symOrder,'OutputType','bit')

\section*{UnitAveragePower - Unit average power flag}
false or 0 (default) | true or 1
Unit average power flag, specified as the comma-separated pair consisting of 'UnitAveragePower' and a numeric or logical 0 (false) or 1 (true). When this flag is 1 (true), the function scales the
constellation to the average power of one watt referenced to 1 ohm . When this flag is 0 (false), the function scales the constellation so that the QAM constellation points are separated by a minimum distance of two.

\section*{OutputType - Type of output}
'integer' (default)|'bit'|'llr'|'approxllr'
Type of output, specified as the comma-separated pair consisting of 'OutputType' and 'integer', 'bit', 'llr', or 'approxllr'.
Data Types: char

\section*{NoiseVariance - Noise variance}

1 (default) | positive scalar | vector of positive values
Noise variance, specified as the comma-separated pair consisting of 'NoiseVariance' and one of these options:
- Positive scalar - The same noise variance value is used on all input elements.
- Vector of positive values - The vector length must be equal to the number of elements in the last dimension of the input signal. Each element of the vector specifies the noise variance for all the elements of the input along the corresponding last dimension.

Tip When 'OutputType' is 'llr', if the demodulation computation outputs Inf or - Inf value, it is likely because the specified noise variance values are smaller than the signal-to-noise ratio (SNR). Because the Log-Likelihood algorithm computes exponentials using finite precision arithmetic, the computation of exponentials with large or small numbers can yield positive or negative infinity. For more details, see "Exact LLR Algorithm".

To avoid this issue, set 'OutputType ' to 'approxllr' instead. The approximate LLR algorithm does not compute exponentials.

\section*{Dependencies}

To enable this name-value pair argument, set 'OutputType' is 'llr' or 'approxllr'.

\section*{Data Types: double}

\section*{PlotConstellation - Option to plot constellation \\ false or 0 (default) | true or 1}

Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a numeric or logical 0 (false) or 1 (true) To plot the QAM constellation, set 'PlotConstellation' to true.

\section*{Output Arguments}

\section*{z - Demodulated output signal \\ scalar | vector | matrix | 3-D array}

Demodulated output signal, returned as a scalar, vector, matrix, or 3-D array. The data type is the same as that of the input signal, y . The value and dimension of this output vary depending on the specified 'OutputType' value, as shown in this table.
\begin{tabular}{|l|l|l|}
\hline 'OutputType' & Return Value of qamdemod & Dimensions of Output \\
\hline 'integer' & \begin{tabular}{l} 
Demodulated integer values \\

\section*{More About}

\section*{Gray Code}

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

\section*{Compatibility Considerations}

\section*{Initial Phase Input Removed}

Errors starting in R2018b
Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the qamdemod function.

Instead, use the genqamdemod function to offset the initial phase of the QAM signal being demodulated. Alternatively, you can multiply the modulated input of qamdemod by the desired initial phase, as shown in this code
```

z = qamdemod(y.*exp(-1i*initPhase,M))

```

\section*{Extended Capabilities}

\section*{C/C++ Code Generation}

Generate C and C++ code using MATLAB® Coder \(^{\text {TM }}\).

\section*{qammod}

Quadrature amplitude modulation (QAM)

\section*{Syntax}
\(y=\operatorname{qammod}(x, M)\)
\(y=\) qammod \((x, M\), sym0rder \()\)
\(y=\) qammod \((\) , Name, Value)

\section*{Description}
\(\mathrm{y}=\mathrm{qammod}(\mathrm{x}, \mathrm{M})\) modulates input signal x by using QAM with the specified modulation order M .
Output y is the modulated signal.
\(y=\operatorname{qammod}(x, M\), sym0rder \()\) specifies the symbol order.
y = qammod ( ,Name, Value) specifies options using name-value pair arguments in addition to any of the input argument combinations from previous syntaxes.

\section*{Examples}

\section*{Modulate Data Using QAM}

Modulate data using QAM and display the result in a scatter plot.
Set the modulation order to 16 and create a data vector containing each of the possible symbols.
\(M=16 ;\)
\(x=(0: M-1)^{\prime} ;\)
Modulate the data using the qammod function.
\(y=\operatorname{qammod}(x, M)\);
Display the modulated signal constellation using the scatterplot function.
scatterplot(y)

Set the modulation order to 256 , and display the scatter plot of the modulated signal.
```

M = 256;
x = (0:M-1)';
y = qammod(x,M);
scatterplot(y)

```

\section*{Normalize QAM Signal by Average Power}

Modulate random data symbols using QAM. Normalize the modulator output so that it has an average signal power of 1 W .

Set the modulation order and generate random data.
```

M = 64;
x = randi([0 M-1],1000,1);

```

Modulate the data. Use the 'UnitAveragePower' name-value pair to set the output signal to have an average power of 1 W .
```

y = qammod(x,M,'UnitAveragePower',true);

```

Confirm that the signal has unit average power.
```

avgPower = mean(abs(y).^2)
avgPower = 1.0070

```

Plot the resulting constellation.
```

scatterplot(y)

```
title('64-QAM, Average Power = 1 W ')

\section*{QAM Symbol Ordering}

Plot QAM constellations for Gray, binary, and custom symbol mappings.
Set the modulation order, and create a data sequence that includes a complete set of symbols for the modulation scheme.
```

M = 16;
d = [0:M-1];

```

Modulate the data, and plot its constellation. The default symbol mapping uses Gray ordering. The ordering of the points is not sequential.
```

y = qammod(d,M,'PlotConstellation',true);

```

Repeat the modulation process with binary symbol mapping. The symbol mapping follows a natural binary order and is sequential.
z = qammod(d,M,'bin','PlotConstellation',true);

Create a custom symbol mapping.
smap \(=\) randperm(M)-1;
Modulate and plot the constellation.
w = qammod(d, M, smap, 'PlotConstellation',true);

\section*{Quadrature Amplitude Modulation with Bit Inputs}

Modulate a sequence of bits using 64-QAM. Pass the signal through a noisy channel. Display the resultant constellation diagram.

Set the modulation order, and determine the number of bits per symbol.
\(\mathrm{M}=64\);
\(\mathrm{k}=\log 2(\mathrm{M})\);
Create a binary data sequence. When using binary inputs, the number of rows in the input must be an integer multiple of the number of bits per symbol.
data \(=\) randi([0 1],1000*k,1);
Modulate the signal using bit inputs, and set it to have unit average power.
txSig = qammod(data, M,'InputType','bit','UnitAveragePower',true);
Pass the signal through a noisy channel.
rxSig = awgn(txSig,25);
Plot the constellation diagram.
```

cd = comm.ConstellationDiagram('ShowReferenceConstellation',false);

```
step(cd,rxSig)

\section*{Demodulate QAM Fixed-Point Signal}

Demodulate a fixed-point QAM signal and verify that the data is recovered correctly.
Set the modulation order as 64 , and determine the number of bits per symbol.
```

M = 64;
bitsPerSym = log2(M);

```

Generate random bits. When operating in bit mode, the length of the input data must be an integer multiple of the number of bits per symbol.
\(x=\operatorname{randi}([01], 10 *\) bitsPerSym,1);

Modulate the input data using a binary symbol mapping. Set the modulator to output fixed-point data. The numeric data type is signed with a 16-bit word length and a 10-bit fraction length.
```

y = qammod(x,M,'bin','InputType','bit','OutputDataType', ...
numerictype(1,16,10));

```

Demodulate the 64-QAM signal. Verify that the demodulated data matches the input data.
```

z = qamdemod(y,M,'bin','OutputType','bit');
s = isequal(x,double(z))
s = logical
1

```

\section*{Input Arguments}

\section*{x - Input signal}
scalar \| vector | matrix | 3-D array
Input signal, specified as a scalar, vector, matrix, or 3-D array. The elements of \(x\) must be binary values or integers that range from 0 to \((M-1)\), where \(M\) is the modulation order.

Note To process input signal as binary elements, set the 'InputType' name-value pair to 'bit '. For binary inputs, the number of rows must be an integer multiple of \(\log _{2}(M)\). Groups of \(\log _{2}(M)\) bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: double | single|fi|int8|int16|uint8|uint16

\section*{M - Modulation order}
scalar integer
Modulation order, specified as a power-of-two scalar integer. The modulation order specifies the number of points in the signal constellation.
Example: 16
Data Types: double

\section*{sym0rder - Symbol order}
'gray' (default)|'bin'|vector
Symbol order, specified as 'gray', 'bin', or a vector.
- 'gray' - Use "Gray Code" on page 2-693 ordering
- 'bin' - Use natural binary-coded ordering
- Vector - Use custom symbol ordering

Vectors must use unique elements whose values range from 0 to \(M-1\). The first element corresponds to the upper-left point of the constellation, with subsequent elements running down column-wise from left to right.
Example: [0 312 2]

\section*{Data Types: char | double}

\section*{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.
Example: y = qammod(x,M,sym0rder,'InputType','bit')

\section*{InputType - Input type}
'integer' (default)|'bit'
Input type, specified as the comma-separated pair consisting of 'InputType' and either 'integer' or 'bit'. If you specify 'integer', the input signal must consist of integers from 0 to \(M-1\). If you specify 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of \(\log _{2}(M)\).

\section*{Data Types: char}

\section*{UnitAveragePower - Unit average power flag}
false or 0 (default) | true or 1
Unit average power flag, specified as the comma-separated pair consisting of 'UnitAveragePower' and a numeric or logical 0 (false) or 1 (true). When this flag is 1 (true), the function scales the constellation to the average power of one watt referenced to 1 ohm . When this flag is 0 (false), the function scales the constellation so that the QAM constellation points are separated by a minimum distance of two.

\section*{OutputDataType - Output data type}
numerictype object
Output data type, specified as the comma-separated pair consisting of 'OutputDataType' and a numerictype object.

For more information on constructing these objects, see numerictype. If you do not specify 'OutputDataType ', data type is double if the input is of data type double or built-in integer and single if the input is of data type single.

\section*{PlotConstellation - Option to plot constellation}
false or 0 (default) | true or 1
Option to plot constellation, specified as the comma-separated pair consisting of 'PlotConstellation' and a numeric or logical 0 (false) or 1 (true) To plot the QAM constellation, set 'PlotConstellation' to true.

\section*{Output Arguments}

\section*{y - Modulated signal}
scalar | vector | matrix | 3-D array
Modulated signal, returned as a complex scalar, vector, matrix, or 3-D array of numeric values. For integer inputs, output y has the same dimensions as input signal x. For bit inputs, the number of rows in \(y\) is the number of rows in \(x\) divided by \(\log _{2}(\mathrm{M})\).
Data Types: double | single

\section*{More About}

\section*{Gray Code}

A Gray code, also known as a reflected binary code, is a system where the bit patterns in adjacent constellation points differ by only one bit.

\section*{Compatibility Considerations}

Initial Phase Input Removed
Errors starting in R2018b
Starting in R2018b, you can no longer offset the initial phase for the QAM constellation using the qammod function.

Instead use genqammod to offset the initial phase of the data being modulated, or you can multiply the qammod output by the desired initial phase:
\(y=q a m m o d(x, M) . * \exp (1 i * i n i t P h a s e)\)
to adjust the initial phase of the QAM data.

\section*{Extended Capabilities}

\section*{qfunc}

Q function

\section*{Syntax}
\(y=q\) func \((x)\)

\section*{Description}
\(y=q\) func \((x)\) returns the output of the \(Q\) function for each element of the real-valued input. The Q function is ( \(1-f\) ), where \(f\) is the result of the cumulative distribution function of the standardized normal random variable. For more information, see

\section*{Examples}

\section*{Calculate Q Function Value and Plot Results}

Calculate the Q function values for a real-valued input vector.
```

x = -4:0.1:4;
y = qfunc(x);

```

Plot the results.
plot ( \(x, y\) )
grid

\section*{Calculate QPSK Error Probability Using Q Function}

Calculate the QPSK error probability at an \(E_{\mathrm{b}} / N_{0}\) setting of 7 dB by using the Q function.
Convert the \(E_{\mathrm{b}} / N_{0}\) in dB to its linear equivalent.
ebnodB = 7;
ebno \(=10^{\wedge}(\) ebnodB/10);
Using the Q function, calculate the QPSK error probability, \(P_{b}=Q\left(\sqrt{2 \frac{E_{b}}{N_{0}}}\right)\).
\(\mathrm{Pb}=\mathrm{qfunc}(\) sqrt(2*ebno))
\(\mathrm{Pb}=7.7267 \mathrm{e}-04\)

\section*{Input Arguments}
x - Input
scalar | vector | matrix | array
Input, specified as a real-valued scalar, matrix, or array.

Data Types: double

\section*{Output Arguments}
\(\mathbf{y}-\mathbf{Q}\) function output
scalar | vector | matrix | array
Q function output, returned as a scalar, matrix, or array. y has the same dimensions as input x . Output values are in the range \([0,1]\).

\section*{Algorithms}

For a scalar \(x\), the Q function is \((1-f)\), where \(f\) is the result of the cumulative distribution function of the standardized normal random variable. The Q function is defined as
\[
Q(x)=\frac{1}{\sqrt{2 \pi}} \int_{x}^{\infty} \exp \left(-t^{2} / 2\right) d t
\]

The Q function is related to the complementary error function, erfc, according to
\[
Q(x)=\frac{1}{2} \operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)
\]

\section*{qfuncinv}

Inverse Q function

\section*{Syntax}
\(z=q f u n c i n v(y)\)

\section*{Description}
\(z=q\) funcinv ( \(y\) ) returns the input argument of the Q function for which the output value of the Q function is \(y\). For more information, see "Algorithms" on page 2-698.

\section*{Examples}

\section*{Recover Argument of Q Function}

Recover the Q function input argument by using the inverse Q function. Show the inverse relationship between Q function and its inverse.

Calculate the Q function values for a real-valued input.
```

x1 = [0 1 2; 3 4 5];
y1 = qfunc(xl)
y1 = 2\times3
0.5000 0.1587 0.0228
0.0013 0.0000 0.0000

```

Recover the Q function input argument by calculating the inverse Q function values for y 1 .
```

x1_recovered = qfuncinv(y1)
x1_recovered = 2×3
0

```

Confirm the original and recovered Q functions arguments are the same.
```

isequal (x1,x1_recovered)
ans = logical
1

```

Calculate the inverse of values representing Q function output values.
y2 = 0:0.2:1;
x2 = qfuncinv(y2)
```

x2 = 1×6

```
Inf 0.8416 0.2533 -0.2533 -0.8416 - Inf

Recover the Q function output argument by calculating the Q function values for x 2 .
y2_recovered = qfunc (x2)
y2_recovered \(=1 \times 6\)
0
0.2000

0.8000
1.0000

Confirm the original values and recovered inverse Q functions arguments are the same.
```

isequal (y2,y2_recovered)
ans = logical
1

```

\section*{Input Arguments}

\section*{\(\mathbf{y}-\mathbf{Q}\) function output}
scalar | vector \(\mid\) matrix | array
Q function output, specified as a scalar, matrix, or array. Input values must be in the range [0, 1].
Data Types: double

\section*{Output Arguments}

\section*{z - Q function input argument}
scalar | vector | matrix | N-D array
Q function input argument, returned as a real-valued scalar, matrix, or array. \(z\) has the same dimensions as input y.

\section*{Algorithms}

For a scalar \(x\), the Q function is ( \(1-f\) ), where \(f\) is the result of the cumulative distribution function of the standardized normal random variable. The Q function is defined as
\[
Q(x)=\frac{1}{\sqrt{2 \pi}} \int_{\chi}^{\infty} \exp \left(-t^{2} / 2\right) d t
\]

The Q function is related to the complementary error function, erfc, according to
\[
Q(x)=\frac{1}{2} \operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)
\]

\section*{See Also}

\section*{Functions}
erf|erfc|erfcinv|erfcx|erfinv|qfunc Introduced before R2006a

\section*{quantiz}

Produce quantization index and quantized output value

\section*{Syntax}
index = quantiz(sig,partition)
[index,quants] = quantiz(sig,partition,codebook)
[index, quants,distor] = quantiz(sig,partition,codebook)

\section*{Description}
index = quantiz(sig, partition) returns the quantization levels in the real vector signal sig using the parameter partition. partition is a real vector whose entries are in strictly ascending order. If partition has length n , index is a vector whose kth entry is
- 0 if \(\operatorname{sig}(\mathrm{k}) \leq\) partition(1)
- mif partition(m) < sig(k) \(\leq\) partition \((m+1)\)
- n if partition(n) < sig(k)
[index, quants] = quantiz(sig,partition, codebook) is the same as the syntax above, except that codebook prescribes a value for each partition in the quantization and quants contains the quantization of sig based on the quantization levels and prescribed values. codebook is a vector whose length exceeds the length of partition by one. quants is a row vector whose length is the same as the length of sig. quants is related to codebook and index by
```

quants(ii) = codebook(index(ii)+1);

```
where \(i i\) is an integer between 1 and length(sig).
[index, quants, distor] = quantiz(sig, partition, codebook) is the same as the syntax above, except that distor estimates the mean square distortion of this quantization data set.

\section*{Examples}

The command below rounds several numbers between 1 and 100 up to the nearest multiple of 10 . quants contains the rounded numbers, and index tells which quantization level each number is in.
[index,quants] = quantiz([3 348440 23],10:10:90,10:10:100)
The output is below.
index =
\(\begin{array}{lllll}0 & 3 & 8 & 3\end{array}\)
quants =
\begin{tabular}{lllll}
10 & 40 & 90 & 40 & 30

\section*{randdeintrlv}

Restore ordering of symbols using random permutation

\section*{Syntax}
```

deintrlvd = randdeintrlv(data,state)

```

\section*{Description}
deintrlvd = randdeintrlv(data,state) restores the original ordering of the elements in data by inverting a random permutation. The state parameter initializes the random number generator that the function uses to determine the permutation. state is either a scalar or a \(35 \times 1\) vector, and is described in the rand function, which is used in randintrlv. The function is predictable for a given state, but different states produce different permutations. If data is a matrix with multiple rows and columns, the function processes the columns independently.

To use this function as an inverse of the randintrlv function, use the same state input in both functions. In that case, the two functions are inverses in the sense that applying randintrlv followed by randdeintrlv leaves data unchanged.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

Note Using the state parameter causes this function to switch random generators to use the 'state' algorithm of the rand function.

See rand for details on the generator algorithm.

\section*{Examples}

For an example using random interleaving and deinterleaving, see "Improve Error Rate Using Block Interleaving in MATLAB".

\section*{See Also}
rand | randintrlv

\section*{randerr}

Generate bit error patterns

\section*{Syntax}
```

out = randerr(m)
out = randerr(m,n)
out = randerr(m,n,errors)
out = randerr(m,n,errors,seed)
out = randerr(m,n,errors,randstream)

```

\section*{Description}

Use the randerr function to generate bit error patterns. For all syntaxes, randerr treats each row of the output independently.
out = randerr(m) generates an m-by-m binary matrix, where each row has exactly one nonzero entry in a random position. Each permutation has an equal probability.
out = randerr(m,n) generates an m-by-n binary matrix, where each row has exactly one nonzero entry in a random position. Each permutation has an equal probability.
out \(=\) randerr(m,n,errors) uses the errors input to determine the number of nonzero entries in each row of the output \(m\)-by-n binary matrix.
out \(=\) randerr ( \(m, n\), errors, seed) specifies a seed value for initializing the uniform random number generator of the rand function.
out \(=\) randerr(m,n,errors, randstream) specifies a random stream object to generate uniform random noise samples by using the rand function. Providing a random stream object or using the reset function on the default random stream object enables you to generate repeatable noise samples.

Note To generate repeatable noise samples, use the same seed input value for each call of randerr or reset the random stream input before calling randerr. For more information on resetting the random stream, see the RandStream object.

\section*{Examples}

\section*{Generate Random Error Matrix}

Generate an 8 -by- 7 binary matrix in which each row is equally likely to have either zero or two nonzero elements.
```

out = randerr(8,7,[0 2])
out = 8×7

```
\begin{tabular}{lllllll}
0 & 1 & 0 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 1 & 0 & 0
\end{tabular}

Generate a matrix in which each row is three times more likely to have two nonzero elements rather than zero nonzero elements.
```

out = randerr(8,7,[0 2; 0.25 0.75])
out = 8\times7

```
\begin{tabular}{lllllll}
0 & 0 & 0 & 0 & 1 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0
\end{tabular}

\section*{Generate Repeatable Random Error Matrix}

Demonstrate generation of a random error matrix without a seed input value for a nonrepeatable output and with the seed input value for a repeatable output.

Specify input parameters for the output matrix dimensions, the number of errors, and a seed value.
```

m = 2;
n = 8;
errors = 2;
seed = 1234;

```

Use the randerr function to generate a random error binary matrix twice with the same command. The output binary matrix values are the same for each execution of the randerr function.
```

out = randerr(m,n,errors,seed)
out = 2\times8
0
out = randerr(m,n,errors,seed)
out = 2×8
0

```
```

0

```

Change the seed value and call the randerr function twice. The binary matrix output values are the same for each execution of the randerr function, but they differ from the binary matrix values output using the previous seed value.
```

seed = 345;
out = randerr(m,n,errors,seed)
out = 2×8

| 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |

out = randerr(m,n,errors,seed)
out = 2×8
0
lllllllll

```

Use the randerr function to generate a random error binary matrix twice with the same command, not specifying a seed input value. The output matrix values change for each execution of the randerr function.
```

out = randerr(m,n,errors)
out = 2×8

```
\begin{tabular}{llllllll}
0 & 1 & 0 & 0 & 0 & 1 & 0 & 0
\end{tabular}
    \(\begin{array}{llllllll}0 & 1 & 0 & 0 & 0 & 0 & 0 & 1\end{array}\)
out \(=\) randerr(m,n,errors)
out \(=2 \times 8\)
\begin{tabular}{llllllll}

0 & 0 & 0 & 1 & 0 & 1 & 0 & 0
\end{tabular}

\section*{Input Arguments}

\section*{m - Size of random binary matrix}
positive integer
Size of the random binary matrix, specified as a positive integer.
- When you specify only the input \(m\), the random binary matrix output is of size \(m\)-by-m.
- When you specify the inputs \(m\) and \(n\), the random binary matrix output is of size \(m\)-by-n.

Data Types: double

\section*{\(\mathbf{n}\) - Column size of random binary matrix}

1 (default) | positive integer
Column size of the random binary matrix, specified as a positive integer.
Data Types: double

\section*{errors - Number of nonzero entries}

1 (default) | nonnegative integer | nonnegative integer row vector | nonnegative two-row matrix
Number of nonzero entries, specified as one of these forms.
- If specified as a integer, errors defines the number of 1 s in each row.
- If specified as a integer row vector, errors defines the number of 1 s possible in each row. Every number of 1 s included in this vector occurs with equal probability.
- If specified as a two-row matrix, the first row of errors defines the integer number of 1s possible in any given row of the output matrix. The second row specifies the probabilities of each corresponding number of ones. The elements in the second row of errors must sum to 1.

Data Types: double
seed - Seed value
nonnegative integer value less than \(2^{32}\)
Seed value for initializing the uniform random number generator used in the rand function, specified as nonnegative integer value less than \(2^{32}\).
Data Types: double
randstream - Random stream object
RandStream object
Random stream object to generate uniform random noise samples by using the rand function, specified as a RandSt ream object. Providing a random stream object or using the reset function on the default random stream object enables you to generate repeatable noise samples.

\section*{Output Arguments}

\section*{out - Random binary matrix output}
matrix
Random binary matrix output, returned as a matrix of binary values.
- When you specify only the input \(m\), this output is of size \(m\)-by-m.
- When you specify the inputs \(m\) and \(n\), this output is of size \(m\)-by-n.

Data Types: double

Reorder symbols using random permutation

\section*{Syntax}
intrlvd = randintrlv(data,state)

\section*{Description}
intrlvd = randintrlv(data,state) rearranges the elements in data using a random permutation. The state parameter initializes the random number generator that the function uses to determine the permutation. state is either a scalar or a 35 x 1 vector, and is described in the rand function, which is used in randintrlv. The function is predictable and invertible for a given state, but different states produce different permutations. If data is a matrix with multiple rows and columns, the function processes the columns independently.

This function uses, by default, the Mersenne Twister algorithm by Nishimura and Matsumoto.

Note Using the state parameter causes this function to switch random generators to use the 'state' algorithm of therand function.

See rand for details on the generator algorithm.

\section*{Examples}

For an example using random interleaving and deinterleaving, see "Improve Error Rate Using Block Interleaving in MATLAB".

\section*{See Also}

Introduced before R2006a

\section*{randseed}
(To be removed) Generate prime numbers for use as random number seeds

\section*{Compatibility}
randseed will be removed in a future release. Use rng( \(N\) ) or rng ('shuffle') instead. For more information, see "Compatibility Considerations" on page 2-710.

\section*{Syntax}
```

out = randseed
out = randseed(state)
out = randseed(state,m)
out = randseed(state,m,n)
out = randseed(state,m,n,rmin)
out = randseed(state,m,n,rmin,rmax)

```

\section*{Description}

The randseed function produces random prime numbers that work well as seeds for random source blocks or noisy channel blocks in Communications Toolbox software.

Note The randseed function uses a local stream of numbers that is independent from the global stream of numbers in the MATLAB software. Use of this function does not affect the state of the global random number stream.
out \(=\) randseed generates a random prime number between 31 and \(2^{17}-1\), using the MATLAB function rand.
out \(=\) randseed(state) generates a random prime number after setting the state of rand to the positive integer state. This syntax produces the same output for a particular value of state.
out \(=\) randseed (state, \(m\) ) generates a column vector of \(m\) random primes.
out = randseed(state, \(\mathrm{m}, \mathrm{n}\) ) generates an m-by-n matrix of random primes.
out \(=\) randseed (state, \(m, n, r m i n)\) generates an \(m\)-by- \(n\) matrix of random primes between rmin and \(2^{17}-1\).
out \(=\) randseed (state, \(m, n, r m i n, r m a x)\) generates an \(m\)-by-n matrix of random primes between rmin and rmax.

\section*{Examples}

To generate a two-element sample-based row vector of random bits using the Bernoulli Random Binary Generator block, you can set Probability of a zero to [0.1 0.5] and set Initial seed to randseed (391,1,2).

To generate three streams of random data from three different blocks in a single model, you can define out \(=\) randseed \((93,3)\) in the MATLAB workspace and then set the three blocks' Initial seed parameters to out (1), out (2), and out (3), respectively.

\section*{Compatibility Considerations}

\section*{randseed will be removed}

Warns starting in R2019a
The functionality provided by randseed is no longer necessary for controlling random number generation. Instead, use rng(seed), where seed specifies a nonnegative integer seed for the random number generator, or use rng('shuffle') to seed the random number generator based on the current time.

\section*{See Also}
primes | rand | rng
Introduced before R2006a

\section*{randsrc}

Generate random matrix using prescribed alphabet

\section*{Syntax}
```

out = randsrc
out = randsrc(m)
out = randsrc(m,n)
out = randsrc(m,n,alphabet)
out = randsrc(m,n,[alphabet; prob])
out = randsrc(m,n,

```
\(\qquad\)
``` , seed)
out = randsrc(m,n,
```

$\qquad$

``` , streamhandle)
```

## Description

out $=$ randsrc generates a random scalar that is either -1 or 1 , with equal probability.
out $=$ randsrc(m) generates an m-by-m random bipolar matrix. Each entry independently takes the value -1 or 1 with equal probability.
out $=$ randsrc( $m, n$ ) generates an m-by-n random bipolar matrix. Each entry independently takes the value - 1 or 1 with equal probability.
out $=$ randsrc(m,n,alphabet) generates an m-by-n matrix, with each entry independently chosen from the entries in the row vector alphabet. Each entry in alphabet occurs in out with equal probability. Duplicate values in alphabet are ignored.
out $=$ randsrc(m,n, [alphabet; prob]) generates an m-by-n matrix, with each entry independently chosen from the entries in the row vector alphabet. Duplicate values in alphabet are ignored. The row vector prob lists corresponding probabilities, so that the symbol alphabet (k) occurs with probability $\operatorname{prob}(k)$, where $k$ is any integer between one and the number of columns of alphabet. The elements of prob must add up to 1.
out $=$ randsrc(m,n, $\qquad$ , seed) accepts input combinations from prior syntaxes and a seed value, for initializing the uniform random number generator, rand.
out $=$ randsrc( $m, n$, $\qquad$ , streamhandle) accepts input combinations from prior syntaxes and a random stream handle to generate uniform random noise samples by using rand. Providing a random stream handle or using the reset function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling randsrc or use the same seed input. For more information, see RandStream.

## Examples

## Generate Random Matrix from Prescribed Alphabet

Generate a 10 -by-10 matrix from the set of $\{-3,-1,1,3\}$.

```
out = randsrc(10,10,[-3 -1 1 3])
out = 10\times10
\begin{tabular}{rrrrrrrrrr}
3 & -3 & 1 & 1 & -1 & -1 & 3 & 3 & -1 & -3 \\
3 & 3 & -3 & -3 & -1 & 1 & -1 & -1 & 3 & -3 \\
-3 & 3 & 3 & -1 & 3 & 1 & 1 & 3 & 1 & 1 \\
3 & -1 & 3 & -3 & 3 & -3 & 1 & -3 & 1 & 3 \\
1 & 3 & 1 & -3 & -3 & -3 & 3 & 3 & 3 & 3 \\
-3 & -3 & 3 & 3 & -1 & -1 & 3 & -1 & -1 & -3 \\
-1 & -1 & 1 & 1 & -1 & 3 & 1 & -3 & 3 & 1 \\
1 & 3 & -1 & -1 & 1 & -1 & -3 & -1 & 3 & -1 \\
3 & 3 & 1 & 3 & 1 & 1 & -3 & 1 & -1 & -3 \\
3 & 3 & -3 & -3 & 3 & -3 & -1 & -1 & 1 & -1
\end{tabular}
```

Plot the histogram. Each of the four possible element values occur with equal probability. Your values might differ.
histogram(out,[-4 -2 0 2 4])

Generate a matrix in which the likelihood of a -1 or 1 is four times higher than the likelihood of a -3 or 3.

```
out = randsrc(10,10,[-3 -1 1 3; 0.1 0.4 0.4 0.1])
out = 10×10
```

| -1 | -1 | -1 | -1 | 1 | -1 | 1 | -1 | 1 | 3 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | -3 | 3 | 3 | 1 | -3 | -1 | -1 | -1 | 1 |
| -1 | -1 | -3 | -1 | -1 | 3 | -1 | 1 | 1 | -1 |
| 1 | 3 | 1 | -1 | 1 | 3 | -1 | -3 | -1 | -1 |
| -1 | -1 | 1 | -1 | -1 | -1 | -3 | -3 | 1 | -1 |
| 1 | 1 | 1 | -1 | -3 | -1 | -1 | -1 | -1 | -1 |
| -1 | 1 | -3 | 1 | -1 | -1 | 3 | 1 | -1 | 1 |
| 1 | 3 | -1 | 1 | -1 | 3 | 3 | 1 | 1 | 1 |
| 1 | -3 | -1 | 1 | -1 | -1 | 1 | 1 | 1 | 1 |
| 1 | -1 | 1 | -1 | -1 | -1 | -3 | -1 | -3 | 1 |

Plot the histogram. Values of -1 and 1 are more likely.

```
histogram(out,[-4 -2 0 2 4])
```

## Input Arguments

## m - Bipolar matrix size

1 (default) | scalar
Size of random bipolar matrix, specified as a scalar. If $n$ is specified, then $m$ is the row size of the random bipolar matrix.
Data Types: double

## n - Bipolar matrix column size

1 (default) | scalar
Column size of random binary matrix, specified as a scalar.
Data Types: double
alphabet - Possible element values
[-1 1] (default)| vector | matrix
Possible elements of output vector or matrix. If alphabet is a row vector, the contents of alphabet define which possible elements randsrc output. If alphabet is a two-row matrix, then the first row is defines the possible elements, and the second row defines the probabilities for each corresponding element in the first row. The elements of the second row must sum to one. If all entries of alphabet are distinct, then the probability distribution is uniform.

Data Types: double
prob - Element probabilities
[0.5 0.5] (default) | vector
Row vector of probabilities that correspond to elements of the corresponding alphabet vector.

## Data Types: double

## seed - Seed value

scalar
Seed value for initializing the uniform random number generator, rand.
Data Types: double

## streamhandle - Random stream handle

RandStream Object
Random stream handle to generate uniform random noise samples by using rand. Providing a random stream handle or using the reset function on the default random stream object enables you to generate repeatable noise samples. If you want to generate repeatable noise samples, then either reset the random stream input before calling randsrc or use the same seed input. For more information, see RandStream.

Data Types: double

## Output Arguments

## out - Random matrix output

scalar | vector | matrix
Random output, returned as a scalar, vector, or matrix. The dimensions of the output are specified by arguments m and n , otherwise it is a 1 -by- 1 scalar. The possible elements of the output and their probabilities are specified by alphabet, prob respectively, otherwise the elements of the output are -1 and 1 , with equal distribution.
Data Types: double

## rayleighchan

(To be removed) Construct Rayleigh fading channel object

Note rayleighchan will be removed in a future release. Use comm. RayleighChannel instead.

## Syntax

```
chan = rayleighchan(ts,fd)
chan = rayleighchan(ts,fd,tau,pdb)
chan = rayleighchan
```

## Description

chan = rayleighchan(ts,fd) constructs a frequency-flat ("single path") Rayleigh fading channel object. ts is the sample time of the input signal, in seconds. fd is the maximum Doppler shift, in hertz. You can model the effect of the channel on a signal x by using the syntax $\mathrm{y}=$ filter(chan,x).
chan = rayleighchan(ts,fd,tau,pdb) constructs a frequency-selective ("multiple path") fading channel object that models each discrete path as an independent Rayleigh fading process. tau is a vector of path delays, each specified in seconds. pdb is a vector of average path gains, each specified in dB .

With the above two syntaxes, a smaller fd ( a few hertz to a fraction of a hertz) leads to slower variations, and a larger fd (a couple hundred hertz) to faster variations.
chan = rayleighchan constructs a frequency-flat Rayleigh channel object with no Doppler shift. This is a static channel. The sample time of the input signal is irrelevant for frequency-flat static channels.

## Properties

The tables below describe the properties of the channel object, chan, that you can set and that MATLAB technical computing software sets automatically. To learn how to view or change the values of a channel object, see "Displaying and Changing Object Properties".

## Writeable Properties

| Property | Description |
| :--- | :--- |
| InputSamplePeriod | Sample period of the signal on which the channel <br> acts, measured in seconds. |
| DopplerSpectrum | Doppler spectrum object(s). The default is a Jakes <br> Doppler object. |
| MaxDopplerShift | Maximum Doppler shift of the channel, in hertz <br> (applies to all paths of a channel). |
| PathDelays | Vector listing the delays of the discrete paths, in <br> seconds. |
| AvgPathGaindB | Vector listing the average gain of the discrete <br> paths, in decibels. |
| NormalizePathGains | If 1, the Rayleigh fading process is normalized <br> such that the expected value of the path gains' <br> total power is 1. |
| StoreHistory | If this value is 1, channel state information <br> needed by the channel visualization tool is stored <br> as the channel filter function processes the <br> signal. The default value is 0. |
| StorePathGains | If set to 1, the complex path gain vector is stored <br> as the channel filter function processes the <br> signal. The default value is 0. |
| ResetBeforeFiltering | If 1, each call to filter resets the state of chan <br> before filtering. If 0, the fading process maintains <br> continuity from one call to the next. |

Read-Only Properties

| Property | Description | When MATLAB Sets or <br> Updates Value |
| :--- | :--- | :--- |
| ChannelType | Fixed value, 'Rayleigh ' | When you create object |
| PathGains | Complex vector listing the current <br> gains of the discrete paths. When <br> you create or reset chan, <br> PathGains is a random vector <br> influenced by AvgPathGaindB and <br> NormalizePathGains. | When you create object, <br> reset object, or use it to filter <br> a signal |
| ChannelFilterDelay | Delay of the channel filter, measured <br> in samples. <br> The ChannelFilterDelay property <br> returns a delay value that is valid <br> only if the first value of the PathGain <br> is the biggest path gain. In other <br> words, main channel energy is in <br> the first path. | When you create object or <br> change ratio of <br> InputSamplePeriod to <br> PathDelays |
| NumSamplesProcessed | Number of samples the channel <br> processed since the last reset. When <br> you create or reset chan, this <br> property value is 0. | When you create object, <br> reset object, or use it to filter <br> a signal |

## Relationships Among Properties

The PathDelays and AvgPathGaindB properties of the channel object must always have the same vector length, because this length equals the number of discrete paths of the channel. The DopplerSpectrum property must either be a single Doppler object or a vector of Doppler objects with the same length as PathDelays.

If you change the length of PathDelays, MATLAB truncates or zero-pads the value of AvgPathGaindB if necessary to adjust its vector length (MATLAB may also change the values of read-only properties such as PathGains and ChannelFilterDelay). If DopplerSpectrum is a vector of Doppler objects, and you increase or decrease the length of PathDelays, MATLAB will add Jakes Doppler objects or remove elements from DopplerSpectrum, respectively, to make it the same length as PathDelays.

If StoreHistory is set to 1 (the default is 0 ), the object stores channel state information as the channel filter function processes the signal. You can then visualize this state information through a GUI using the plot (channel) method.

Note Setting StoreHistory to 1 will result in a slower simulation. If you do not want to visualize channel state information using plot (channel), but want to access the complex path gains, then set StorePathGains to 1 , while keeping StoreHistory as 0.

## Visualization of Channel

The characteristics of a channel can be plotted using the channel visualization tool, plot (channel). You can use the channel visualization tool in Normal mode and Accelerator mode.

## Examples

The example below illustrates that when you change the value of PathDelays, MATLAB automatically changes the values of other properties to make their vector lengths consistent with that of the new value of PathDelays.

```
c1 = rayleighchan(le-5,130) % Create object.
c1.PathDelays = [0 le-6] % Change the number of delays.
```

MATLAB automatically changes the size of c1.AvgPathGaindB, c1.PathGains, and c1.ChannelFilterDelay. The output below displays all the properties of the channel object before and after the change in the value of the PathDelays property. In the second listing of properties, the AvgPathGaindB, PathGains, and ChannelFilterDelay properties all have different values compared to the first listing of properties.

```
c1 =
    ChannelType: 'Rayleigh'
        InputSamplePeriod: 1.0000e-005
        DopplerSpectrum: [1x1 doppler.jakes]
        MaxDopplerShift: 130
            PathDelays: 0
                AvgPathGaindB: 0
        NormalizePathGains: 1
            StoreHistory: 0
                PathGains: 0.2035 + 0.1014i
        ChannelFilterDelay: 0
ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
c1 =
                    ChannelType: 'Rayleigh'
        InputSamplePeriod: 1.0000e-005
            DopplerSpectrum: [1x1 doppler.jakes]
            MaxDopplerShift: 130
                    PathDelays: [0 1.0000e-006]
            AvgPathGaindB: [0 0]
    NormalizePathGains: 1
                StoreHistory: 0
                    PathGains: [0.6108 - 0.4688i 0.1639 - 0.0027i]
    ChannelFilterDelay: 4
ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
```

## Algorithms

The methodology used to simulate fading channels is described in "Methodology for Simulating Multipath Fading Channels". The properties of the channel object are related to the quantities of the latter section as follows:

- The InputSamplePeriod property contains the value of $T_{s}$.
- The PathDelays vector property contains the values of $\left\{\tau_{k}\right\}$, where $1 \leq k \leq K$.
- The PathGains read-only property contains the values of $\left\{a_{k}\right\}$, where $1 \leq k \leq K$.
- The AvgPathGaindB vector property contains the values of $10 \log _{10}\left\{E\left[\left|a_{k}\right|^{2}\right]\right\}$, where $1 \leq k \leq K$, and $E[\cdot]$ denotes statistical expectation.
- The ChannelFilterDelay read-only property contains the value of $N_{1}$.

## rectpulse

Rectangular pulse shaping

## Syntax

$y=\operatorname{rectpulse}(x, n s a m p)$

## Description

$y=$ rectpulse(x,nsamp) applies rectangular pulse shaping to $x$ to produce an output signal having nsamp samples per symbol. Rectangular pulse shaping means that each symbol from $x$ is repeated nsamp times to form the output y . If x is a matrix with multiple rows, the function treats each column as a channel and processes the columns independently.

Note To insert zeros between successive samples of $x$ instead of repeating the samples of $x$, use the upsample function instead.

## Examples

An example in "Combine Pulse Shaping and Filtering with Modulation" uses this function in conjunction with modulation.

The code below processes two independent channels, each containing three symbols of data. In the pulse-shaped matrix $y$, each symbol contains four samples.

```
nsamp = 4; % Number of samples per symbol
nsymb = 3; % Number of symbols
s = RandStream('mt19937ar', 'Seed', 0);
ch1 = randi(s, [0 1], nsymb, 1); % Random binary channel
ch2 = [1:nsymb]';
x = [ch1 ch2] % Two-channel signal
y = rectpulse(x,nsamp)
```

The output is below. In $y$, each column corresponds to one channel and each row corresponds to one sample. Also, the first four rows of $y$ correspond to the first symbol, the next four rows of $y$ correspond to the second symbol, and the last four rows of $y$ correspond to the last symbol.

## reset (channel)

(To be removed) Reset channel object

Note This function will be removed in a future release. Use function associated with comm.RicianChannel or comm. RayleighChannel instead.

## Syntax

```
reset(chan)
reset(chan,randstate)
```

## Description

reset (chan) resets the channel object chan, initializing the PathGains and NumSamplesProcessed properties as well as internal filter states. This syntax is useful when you want the effect of creating a new channel.
reset (chan, randstate) resets the channel object chan and initializes the state of the random number generator that the channel uses. randstate is a two-element column vector. This syntax is useful when you want to repeat previous numerical results that started from a particular state.

Note reset(chan, randstate) will not support randstate in a future release. See the legacychannel sim function for more information.

## Examples

The example below shows how to obtain repeatable results. The example chooses a state for the random number generator immediately after defining the channel object and later resets the random number generator to that state.

```
%% Set up channel.
% Assume you want to maintain continuity
% from one filtering operation to the next, except
% when you explicitly reset the channel.
c = rayleighchan(1e-4,100);
c.ResetBeforeFiltering = 0;
% Filter all ones.
sig = ones(100,1);
y1 = [filter(c,sig(1:50)); filter(c,sig(51:end))];
% Reset the channel and filter all ones.
reset(c);
%Generate an independent channel
y2 = [filter(c,sig(1:50)); filter(c,sig(51:end))];
% Plot the magnitude of the channel output
```

```
plot(abs([y1; y2]),'*')
```

grid on

This example generates a plot similar to this figure.

## Topics

"Equalization"

## Introduced before R2006a

## ricianchan

(To be removed) Construct Rician fading channel object

Note ricianchan will be removed in a future release. Use comm. RicianChannel instead.

## Syntax

```
chan = ricianchan(ts,fd,k)
chan = ricianchan(ts,fd,k,tau,pdb)
chan = ricianchan(ts,fd,k,tau,pdb,fdlos)
chan = ricianchan
```

## Description

chan = ricianchan(ts,fd,k) constructs a frequency-flat (single path) Rician fading-channel object. ts is the sample time of the input signal, in seconds. fd is the maximum Doppler shift, in hertz. k is the Rician K-factor in linear scale. You can model the effect of the channel chan on a signal $x$ by using the syntax $y=$ filter (chan, $x$ ).
chan = ricianchan(ts,fd,k,tau,pdb) constructs a frequency-selective (multiple paths) fadingchannel object. If k is a scalar, then the first discrete path is a Rician fading process (it contains a line-of-sight component) with a K-factor of $k$, while the remaining discrete paths are independent Rayleigh fading processes (no line-of-sight component). If $k$ is a vector of the same size as tau, then each discrete path is a Rician fading process with a K-factor given by the corresponding element of the vector $k$. tau is a vector of path delays, each specified in seconds. pdb is a vector of average path gains, each specified in dB.
chan $=$ ricianchan(ts,fd,k,tau,pdb,fdlos) specifies fdlos as the Doppler shift(s) of the line-of-sight component(s) of the discrete path(s), in hertz. fdlos must be the same size as k. If $k$ and fdlos are scalars, the line-of-sight component of the first discrete path has a Doppler shift of fdlos, while the remaining discrete paths are independent Rayleigh fading processes. If fdlos is a vector of the same size as k , the line-of-sight component of each discrete path has a Doppler shift given by the corresponding element of the vector fdlos. By default, fdlos is 0 . The initial phase(s) of the line-ofsight component(s) can be set through the property DirectPathInitPhase.
chan $=$ ricianchan sets the maximum Doppler shift to 0, the Rician K-factor to 1, and the Doppler shift and initial phase of the line-of-sight component to 0 . This syntax models a static frequency-flat channel, and, in this trivial case, the sample time of the signal is unimportant.

## Properties

The following tables describe the properties of the channel object, chan, that you can set and that MATLAB technical computing software sets automatically. To learn how to view or change the values of a channel object, see "Displaying and Changing Object Properties".

## Writeable Properties

| Property | Description |
| :--- | :--- |
| InputSamplePeriod | Sample period of the signal on which the channel <br> acts, measured in seconds. |
| DopplerSpectrum | Doppler spectrum object(s). The default is a Jakes <br> doppler object. |
| MaxDopplerShift | Maximum Doppler shift of the channel, in hertz <br> (applies to all paths of a channel). |
| KFactor | Rician K-factor (scalar or vector). The default <br> value is 1 (line-of-sight component on the first <br> path only). |
| PathDelays | Vector listing the delays of the discrete paths, in <br> seconds. |
| AvgPathGaindB | Vector listing the average gain of the discrete <br> paths, in decibels. |
| DirectPathDopplerShift | Doppler shift(s) of the line-of-sight component(s) <br> in hertz. The default value is 0. |
| DirectPathInitPhase | Initial phase(s) of line-of-sight component(s) in <br> radians. The default value is 0. |
| NormalizePathGains | If this value is 1, the Rayleigh fading process is <br> normalized such that the expected value of the <br> path gains' total power is 1. |
| StoreHistory | If this value is 1, channel state information <br> needed by the channel visualization tool is stored <br> as the channel filter function processes the <br> signal. The default value is 0. |
| StorePathGains | If this value is 1, the complex path gain vector is <br> stored as the channel filter function processes the <br> signal. The default value is 0. |
| ResetBeforeFiltering | If this value is 1, each call to filter resets the <br> state of chan before filtering. If it is 0, the fading <br> process maintains continuity from one call to the <br> next. |

Read-Only Properties

| Property | Description | When MATLAB Sets or <br> Updates Value |
| :--- | :--- | :--- |
| ChannelType | Fixed value, 'Rician '. | When you create object. |
| PathGains | Complex vector listing the current <br> gains of the discrete paths. When <br> you create or reset chan, <br> PathGains is a random vector <br> influenced by AvgPathGaindB and <br> NormalizePathGains. | When you create object, <br> reset object, or use it to filter <br> a signal. |
| ChannelFilterDelay | Delay of the channel filter, measured <br> in samples. <br> The ChannelFilterDelay property <br> returns a delay value that is valid <br> only if the first value of the PathGain <br> is the biggest path gain. In other <br> words, main channel energy is in <br> the first path. | When you create object or <br> change ratio of <br> InputSamplePeriod to <br> PathDelays. |
| NumSamplesProcessed | Number of samples the channel <br> processed since the last reset. When <br> you create or reset chan, this <br> property value is 0. | When you create object, <br> reset object, or use it to filter <br> a signal. |

## Relationships Among Properties

Changing the length of PathDelays also changes the length of AvgPathGaindB, the length of KFactor if KFactor is a vector (no change if it is a scalar), and the length of DopplerSpectrum if DopplerSpectrum is a vector (no change if it is a single object).

## DirectPathDopplerShift and DirectPathInitPhase both follow changes in KFactor.

The PathDelays and AvgPathGaindB properties of the channel object must always have the same vector length, because this length equals the number of discrete paths of the channel. The DopplerSpectrum property must either be a single Doppler object or a vector of Doppler objects with the same length as PathDelays.

If you change the length of PathDelays, MATLAB truncates or zero-pads the value of AvgPathGaindB if necessary to adjust its vector length (MATLAB may also change the values of read-only properties such as PathGains and ChannelFilterDelay). If DopplerSpectrum is a vector of Doppler objects, and you increase or decrease the length of PathDelays, MATLAB will add Jakes Doppler objects or remove elements from DopplerSpectrum, respectively, to make it the same length as PathDelays.

If StoreHistory is set to 1 (the default is 0 ), the object stores channel state information as the channel filter function processes the signal. You can then visualize this state information through a GUI using the plot (channel) method.

Note Setting StoreHistory to 1 will result in a slower simulation. If you do not want to visualize channel state information using plot (channel), but want to access the complex path gains, then set StorePathGains to 1 , while keeping StoreHistory as 0.

## Reset Method

If MaxDopplerShift is set to 0 (the default), the channel object, chan, models a static channel.
Use the syntax reset (chan) to generate a new channel realization.

## Algorithm

The methodology used to simulate fading channels is described in "Methodology for Simulating Multipath Fading Channels", where the properties specific to the Rician channel object are related to the quantities of this section as follows:

- The Kfactor property contains the value of $K_{r}$ (if it's a scalar) or $\left\{K_{r, k}\right\}, 1 \leq k \leq K$ (if it's a vector).
- The DirectPathDopplerShift property contains the value of $f_{d, L O S}$ (if it's a scalar) or $\left\{f_{d, L O S,}\right\}, 1 \leq k \leq K$ (if it's a vector).
- The DirectPathInitPhase property contains the value of $\theta_{\text {LOS }}$ (if it's a scalar) or $\left\{\theta_{L O S, k}\right\}$, $1 \leq k \leq K$ (if it's a vector).

The rayleighchan reference page includes descriptions for properties common to both Rayleigh and Rician channel objects.

## Channel Visualization

The characteristics of a channel can be plotted using the channel visualization tool, plot (channel). You can use the channel visualization tool in Normal mode and Accelerator mode.

## Topics

"Fading Channels"

## Introduced before R2006a

## rls

(To be removed) Construct recursive least squares (RLS) adaptive algorithm object

Note will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead.

## Syntax

alg = rls(forgetfactor)
alg = rls(forgetfactor,invcorr0)

## Description

The rls function creates an adaptive algorithm object that you can use with the lineareq function or dfe function to create an equalizer object. You can then use the equalizer object with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
alg = rls(forgetfactor) constructs an adaptive algorithm object based on the recursive least squares (RLS) algorithm. The forgetting factor is forgetfactor, a real number between 0 and 1. The inverse correlation matrix is initialized to a scalar value.
alg $=r l s(f o r g e t f a c t o r, i n v c o r r 0)$ sets the initialization parameter for the inverse correlation matrix. This scalar value is used to initialize or reset the diagonal elements of the inverse correlation matrix.

## Properties

The table below describes the properties of the RLS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see "Equalization".

| Property | Description |
| :--- | :--- |
| AlgType | Fixed value, 'RLS' ' |
| ForgetFactor | Forgetting factor |
| InvCorrInit | Scalar value used to initialize or reset the <br> diagonal elements of the inverse correlation <br> matrix |

Also, when you use this adaptive algorithm object to create an equalizer object (via the lineareq function or dfe function), the equalizer object has an InvCorrMatrix property that represents the inverse correlation matrix for the RLS algorithm. The initial value of InvCorrMatrix is InvCorrInit*eye( N ), where N is the total number of equalizer weights.

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
        'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:
\% plot(yNew,'*')
\% hold on
\% plot(yOld,'o')
\% hold off; legend('New Eq','Old Eq'); grid on

## Use RLS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings.

```
eqOld = lineareq(5,rls(0.95),pskmod(0:3,4,pi/4))
```

eqold $=$
EqType: 'Linear Equalizer'
AlgType: 'RLS'
nWeights: 5
nSampPerSym: 1
RefTap: 1
SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071-0.7071i 0.7071-0.7071i]
InvCorrInit: 0.1000
InvCorrMatrix: [5×5 double]
Weights: [0 0 0 0 0]
WeightInputs: [0 0 0 0 0]
ResetBeforeFiltering: 1
NumSamplesProcessed: 0
eqNew $=$ comm.LinearEqualizer('NumTaps',5,'Algorithm', 'RLS', . .
'ForgettingFactor', 0.95, 'Constellation', pskmod(0:3,4, pi/4), 'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
Algorithm: 'RLS'

InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1

```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.
```

y0ld1 = equalize(eqOld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));

```

\section*{Algorithms}

Referring to the schematics presented in "Equalization", define \(w\) as the vector of all weights \(w_{i}\) and define \(u\) as the vector of all inputs \(u_{i}\). Based on the current set of inputs, \(u\), and the current inverse correlation matrix, \(P\), this adaptive algorithm first computes the Kalman gain vector, \(K\)
\[
K=\frac{P u}{(\text { ForgettingFactor })+u^{H} P u} .
\]
where \(H\) denotes the Hermitian transpose.
Then the new inverse correlation matrix is given by
and the new set of weights is given by
```

w
$+$
where the * operator denotes the complex conjugate.

## Compatibility Considerations

rls will be removed
Warns starting in R2020a
rls will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead with the adaptive algorithm set to RLS. For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-730.

## rsdec

Reed-Solomon decoder

## Syntax

```
decoded = rsdec(code,n,k)
decoded = rsdec(code,n,k,genpoly)
decoded = rsdec(...,paritypos)
[decoded,cnumerr] = rsdec(...)
[decoded,cnumerr,ccode] = rsdec(...)
```

## Description

decoded $=r \operatorname{sdec}($ code $, \mathrm{n}, \mathrm{k})$ attempts to decode the received signal in code using an $[\mathrm{n}, \mathrm{k}]$ ReedSolomon decoding process with the narrow-sense generator polynomial. code is a Galois array of symbols having $m$ bits each. Each $n$-element row of code represents a corrupted systematic codeword, where the parity symbols are at the end and the leftmost symbol is the most significant symbol. n is at most $2^{\mathrm{m}}-1$. If n is not exactly $2^{\mathrm{m}}-1$, rsdec assumes that code is a corrupted version of a shortened code.

In the Galois array decoded, each row represents the attempt at decoding the corresponding row in code. A decoding failure occurs if rsdec detects more than ( $n-k$ )/2 errors in a row of code. In this case, rsdec forms the corresponding row of decoded by merely removing $n-k$ symbols from the end of the row of code.
decoded $=r \operatorname{sdec}($ code $, \mathrm{n}, \mathrm{k}$, genpoly) is the same as the syntax above, except that a nonempty value of genpoly specifies the generator polynomial for the code. In this case, genpoly is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree $n-k$. To use the default narrow-sense generator polynomial, set genpoly to [].
decoded $=$ rsdec (..., paritypos) specifies whether the parity symbols in code were appended or prepended to the message in the coding operation. paritypos can be either 'end ' or
'beginning'. The default is 'end'. If paritypos is 'beginning', a decoding failure causes rsdec to remove $n-k$ symbols from the beginning rather than the end of the row.
[decoded, cnumerr] = rsdec (...) returns a column vector cnumerr, each element of which is the number of corrected errors in the corresponding row of code. A value of - 1 in cnumerr indicates a decoding failure in that row in code.
[decoded,cnumerr,ccode] = rsdec (...) returns ccode, the corrected version of code. The Galois array ccode has the same format as code. If a decoding failure occurs in a certain row of code, the corresponding row in ccode contains that row unchanged.

## Examples

## Reed-Solomon Decoding

Set the RS code parameters.

```
m}=3;\quad%\mathrm{ Number of bits per symbol
n = 2^m-1; % Codeword length
k = 3; % Message length
```

Generate three codewords composed of 3-bit symbols. Encode the message with a $(7,3)$ RS code.

```
msg = gf([2 7 3; 4 0 6; 5 1 1],m);
code = rsenc(msg,n,k);
```

Introduce one error on the first codeword, two errors on the second codeword, and three errors on the third codeword.

```
errors = gf([2 0 0 0 0 0 0; 3 4 0 0 0 0 0; 5 6 7 0 0 0 0],m);
noisycode = code + errors;
```

Decode the corrupted codeword.
[rxcode, cnumerr] = rsdec(noisycode, $n, k$ );
Observe that the number of corrected errors matches the introduced errors for the first two rows. In row three, the number of corrected errors is -1 because a $(7,3)$ RS code cannot correct more than two errors.
cnumerr
cnumerr $=3 \times 1$
1
2

- 1

## Limitations

n and k must differ by an even integer. n must be between 3 and 65535.

## Algorithms

rsdec uses the Berlekamp-Massey decoding algorithm. For information about this algorithm, see the works listed in "References" on page 2-735 below.

gf | rsenc | rsgenpoly

## Topics

"Block Codes"

Introduced before R2006a

## rsenc

Reed-Solomon encoder

## Syntax

```
code = rsenc(msg,n,k)
code = rsenc(msg,n,k,genpoly)
code = rsenc(...,paritypos)
```

## Description

code $=r \operatorname{senc}(m s g, n, k)$ encodes the message in msg using an $[n, k]$ Reed-Solomon code with the narrow-sense generator polynomial. msg is a Galois array of symbols having $m$ bits each. Each $k$ element row of msg represents a message word, where the leftmost symbol is the most significant symbol. n is at most $2^{\mathrm{m}}-1$. If n is not exactly $2^{\mathrm{m}}-1$, r senc uses a shortened Reed-Solomon code. Parity symbols are at the end of each word in the output Galois array code.
code $=$ rsenc (msg, $n, k$, genpoly) is the same as the syntax above, except that a nonempty value of genpoly specifies the generator polynomial for the code. In this case, genpoly is a Galois row vector that lists the coefficients, in order of descending powers, of the generator polynomial. The generator polynomial must have degree $\mathrm{n}-\mathrm{k}$. To use the default narrow-sense generator polynomial, set genpoly to [].
code $=$ rsenc(..., paritypos) specifies whether rsenc appends or prepends the parity symbols to the input message to form code. paritypos can be either 'end ' or 'beginning'. The default is 'end'.

## Examples

## Reed-Solomon Code Generation

Set the code parameters.

```
m = 3; % Number of bits per symbol
n = 2^m - 1; % Codeword length
k = 3; % Message length
```

Create two messages based on GF(8).

```
msg = gf([2 7 3; 4 0 6],m)
msg = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
    2 7 3
    4 0 6
```

Generate RS $(7,3)$ codewords.

```
code = rsenc(msg,n,k)
code = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
Array elements =
    2
    4}0
```

The codes are systematic so the first three symbols of each row match the rows of msg.

## Limitations

n and k must differ by an integer. n between 7 and 65535 .

## rsgenpoly

Generator polynomial of Reed-Solomon code

## Syntax

```
genpoly = rsgenpoly(N,K)
genpoly = rsgenpoly(N,K,prim_poly)
genpoly = rsgenpoly(N,K,prim_poly,B)
genpoly = rsgenpoly(N,K,prim_poly,B,outputFormat)
[genpoly,T] = rsgenpoly(
```

$\qquad$

## Description

genpoly $=$ rsgenpoly ( $\mathrm{N}, \mathrm{K}$ ) returns the narrow-sense generator polynomial of an $[\mathrm{N}, \mathrm{K}]$ ReedSolomon code. The output genpoly is a Galois field array that represents the coefficients of the generator polynomial in order of descending powers. A narrow-sense BCH code is a BCH code with B $=1$. Here, the narrow-sense generator polynomial is $\left(X-\alpha^{1}\right)\left(X-\alpha^{2}\right) \ldots\left(X-\alpha^{N-K}\right)$, where $\alpha$ is a root of the default primitive polynomial for the field $\mathrm{GF}(\mathrm{N}+1)$. For additional information, see Narrow-Sense BCH Codes and "Reed-Solomon Codes".
genpoly $=$ rsgenpoly (N,K, prim_poly) also specifies the primitive polynomial, prim_poly, for $\mathrm{GF}(\mathrm{N}+1)$ that has $\alpha$ as a root.
genpoly $=$ rsgenpoly( $\mathrm{N}, \mathrm{K}$, prim_poly, B$)$ returns the generator polynomial, $\left(X-\alpha^{\mathrm{B}}\right)\left(X-\alpha^{B+1}\right)$... ( $X-\alpha^{B+N-K-1}$ ), where $B$ is an integer.
genpoly $=$ rsgenpoly( $N, K$, prim_poly, $B$, outputFormat) specifies the output format of genpoly as a Galois field array or double-precision array.
[genpoly, T] = rsgenpoly (__ ) also returns the error-correction capability of the [ $\mathrm{N}, \mathrm{K}$ ] ReedSolomon code, T , using any of the preceding input argument syntaxes.

## Examples

## Create Narrow-Sense Generator Polynomial

Specify the codeword length, $n$, and message length, $k$.
n = 7;
k = 3;
Create the narrow-sense generator polynomial for the [ $\mathrm{n}, \mathrm{k}$ ] Reed-Solomon code. genpoly is a Galois field array, by default, that represents the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k)
genpoly = GF(2^3) array. Primitive polynomial = D^3+D+1 (11 decimal)
```

```
Array elements =
```

    13123
    
## Create Narrow-Sense Generator Polynomial Specifying Primitive Polynomial

Create the narrow-sense generator polynomial of a Reed-Solomon code with respect to the primitive polynomial $D^{3}+D^{2}+1$.

Specify the codeword length, n , message length, k , and primitive polynomial $D^{3}+D^{2}+1$ represented in decimal form.

```
n = 7;
k = 3;
prim_poly = 13;
```

Create the narrow-sense generator polynomial for the [ $\mathrm{n}, \mathrm{k}$ ] Reed-Solomon code with respect to primitive polynomial $D^{3}+D^{2}+1$ for $\mathrm{GF}(8)$. genpoly is a Galois field array, by default, that represent the coefficients of this generator polynomial in order of descending powers.

```
genpoly = rsgenpoly(n,k,prim_poly)
genpoly = GF(2^3) array. Primitive polynomial = D^3+D^2+1 (13 decimal)
Array elements =
    1 4 5 1 5
```

## Create Generator Polynomial for Specified B

Create the generator polynomial of a Reed-Solomon code with respect to the default primitive polynomial.

Specify the codeword length, n , message length, k , and exponent of $\alpha, \mathrm{b}$.
n = 7;
k = 3;
b = 4;
Create the generator polynomial $\left(X-\alpha^{4}\right)\left(X-\alpha^{5}\right)\left(X-\alpha^{6}\right)\left(X-\alpha^{7}\right)$, with respect to the default primitive polynomial. genpoly is a Galois field array that represents the coefficients of this generator polynomial in order of descending powers. Display the error-correcting capability of the code.
[genpoly,t] = rsgenpoly(n, $k,[], b)$
genpoly $=$ GF(2^3) array. Primitive polynomial $=$ D^3+D+1 $^{(11}$ decimal)
Array elements =

```
    1 5 5 3 2
```

$\mathrm{t}=2$

## Create Generator Polynomial for DVB-S and WiMAX

Create the generator polynomial of a Reed-Solomon code with respect to the primitive polynomial $D^{8}+D^{4}+D^{3}+D^{2}+1$.

Specify the codeword length, $n$, message length, $k$, the primitive polynomial represented in decimal form, and the exponent of $\alpha, \mathrm{b}$.

```
n = 255;
k = 239;
prim_poly = 285;
b = 0;
```

Create the generator polynomial for the [ $n, k$ ] Reed-Solomon code. genpoly is a Galois field array that represents a generator polynomial and is compliant with DVB-S and WiMAX.

```
genpoly = rsgenpoly(n,k,prim_poly,b)
genpoly = GF(2^8) array. Primitive polynomial = D^8+D^4+D^3+D^2+1 (285 decimal)
Array elements =
    Columns 1 through 13
        1 [lllllllllllllllll
    Columns 14 through 17
        98 50 36 59
```

## Create Narrow-Sense Generator Polynomial with Output Format Double

Create the narrow-sense generator polynomial of a Reed-Solomon code. Specify the output data type as a double-precision array.

Specify the codeword length, $n$, and message length, $k$.
n = 7;
k $=3$;
Create the narrow-sense generator polynomial for the [ $n, k$ ] Reed-Solomon code. genpoly is a double-precision array, that represents the coefficients of this generator polynomial in order of descending powers. Specify defaults values for the primitive polynomial and exponent of $\alpha$ inputs by assigning [ ] for them.
genpoly $=$ rsgenpoly(n,k,[],[],'double')

```
genpoly = 1×5
    1 3
```

## Input Arguments

N - Codeword length
positive odd integer
Codeword length, specified as an integer of the form $N=2^{M}-1$, where $M$ is in the range [3,16]. For more information, see "Limitations" on page 2-743.

Example: Set $N$ to 15 for $M=4$.

## K - Message length

positive integer
Message length, specified as a positive integer. For more information, see "Limitations" on page 2743.
prim_poly - Primitive polynomial
GF(N+1) (default) | positive integer
Primitive polynomial, specified as a positive integer. prim_poly is an integer whose binary representation indicates the coefficients of the primitive polynomial. To use the default primitive polynomial GF(N+1), set prim_poly to [ ]. For more information, see "Default Primitive Polynomials" on page 2-743.
Example: 19 specifies the primitive polynomial $D^{4}+D+1$ because its binary representation is 10011 .

## B - Exponent of $\boldsymbol{\alpha}$

1 (default) | positive integer
Exponent of $\alpha$, specified as a positive integer. $\alpha$ is a root of prim_poly.

## outputFormat - Output format

'gf' (default)|'double'
Output format of genpoly, specified as:

- 'gf' - to output a Galois field array.
- 'double' - to output a double-precision array of the Galois field values.

For more information, see "Working with Galois Fields".

## Output Arguments

## genpoly - Generator polynomial coefficients

Galois field array | double-precision array
Generator polynomial coefficients in descending order, returned as a Galois field array or doubleprecision array. genpoly is a row vector that represents the coefficients of the narrow-sense generator polynomial of an $[\mathrm{N}, \mathrm{K}]$ Reed-Solomon code in order of descending powers.

## T - Error-correction capability

positive integer
Error-correction capability of the code, returned as a positive integer equal to $\lfloor(N-K) / 2\rfloor$.

## Limitations

- Valid values for $N=2^{M}-1$, where $M$ is an integer in the range [3,16]. The maximum allowable value of $N=2^{16}-1=65,535$.
- Valid values for $\mathrm{K}=[1, \mathrm{~N}-1]$.

## More About

## Default Primitive Polynomials

This table lists the default primitive polynomial used for each Galois field array GF $\left(2^{\mathrm{m}}\right)$. To use a different primitive polynomial, specify prim_poly as an input argument. prim_poly must be in the range $\left[\left(2^{m}+1\right),\left(2^{m+1}-1\right)\right]$ and must indicate an irreducible polynomial. For more information, see "Primitive Polynomials and Element Representations".

| Value of $\mathbf{m}$ | Default Primitive Polynomial | Integer Representation |
| :--- | :--- | :--- |
| 1 | $D+1$ | 3 |
| 2 | $D^{2}+D+1$ | 7 |
| 3 | $D^{3}+D+1$ | 11 |
| 4 | $D^{4}+D+1$ | 19 |
| 5 | $D^{5}+D^{2}+1$ | 37 |
| 6 | $D^{6}+D+1$ | 67 |
| 7 | $D^{7}+D^{3}+1$ | 137 |
| 8 | $D^{8}+D^{4}+D^{3}+D^{2}+1$ | 285 |
| 9 | $D^{9}+D^{4}+1$ | 529 |
| 10 | $D^{10}+D^{3}+1$ | 1033 |
| 11 | $D^{11}+D^{2}+1$ | 2053 |
| 12 | $D^{12}+D^{6}+D^{4}+D+1$ | 4179 |
| 13 | $D^{13}+D^{4}+D^{3}+D+1$ | 8219 |
| 14 | $D^{14}+D^{10}+D^{6}+D+1$ | 17475 |
| 15 | $D^{15}+D+1$ | 32771 |
| 16 | $D^{16}+D^{12}+D^{3}+D+1$ | 69643 |

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:
All inputs must be constants. Expressions or variables are allowed if their values do not change.

## rsgenpolycoeffs

Generator polynomial coefficients of Reed-Solomon code

## Syntax

$x=$ rsgenpolycoeffs(...)
[x,t] = rsgenpolycoeffs(...)

## Description

$x=$ rsgenpolycoeffs(.. ) returns the coefficients for the generator polynomial of the Reed-
Solomon code. The output is identical to genpoly $=$ rsgenpoly(...); $x=$ genpoly.x.
$[x, t]=r s g e n p o l y c o e f f s(\ldots)$ returns $t$, the error-correction capability of the code.

## Examples

## Generate Polynomial Coefficients for a Reed-Solomon Code

This example shows how to generate polynomial coefficients for a $(15,11)$ Reed-Solomon code.
Generate the coefficients using rsgenpolycoeffs.

```
genpoly = rsgenpolycoeffs(15,11)
genpoly = 1x5 uint32 row vector
    1
```

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
For C/C++ code generation, these usage notes and limitations apply:
All inputs must be constants. Expressions or variables are allowed if their values do not change.

Introduced in R2010b

## scatterplot

Generate scatter plot

## Syntax

```
scatterplot(x)
scatterplot(x,n)
scatterplot(x,n,offset)
scatterplot(x,n,offset,plotstring)
scatterplot(x,n,offset,plotstring,h)
h = scatterplot(
```

$\qquad$

``` )
```

## Description

scatterplot ( x ) creates a scatter plot for signal x .
scatterplot $(x, n)$ specifies decimation factor $n$. The function plot every nth value of $x$, starting from its first value.
scatterplot ( $\mathrm{x}, \mathrm{n}$, offset) specifies the offset value. The function plots every nth value of x , starting from its (offset +1 )th value.
scatterplot( $\mathrm{x}, \mathrm{n}$,offset, plotstring) specifies plot attributes for the scatter plot.
scatterplot ( $\mathrm{x}, \mathrm{n}$, offset, plotstring, h ) generates the scatter plot in an existing figure whose handle is h . To plot multiple signals in the same figure, use hold on.
h = scatterplot (__ ) returns the handle to the figure that contains the scatter plot. You can specify any of the input argument combinations from the previous syntaxes.

## Examples

## Generate Scatter Plot of 64-QAM Signal

Create a 64-QAM signal in which each constellation point is used.

```
d = (0:63)';
s = qammod(d,64);
```

Display the scatter plot of the constellation.

```
scatterplot(s)
```

## Input Arguments

## x - Input signal

numeric vector | numeric matrix
Input signal, specified as a numeric vector or numeric matrix.
The interpretation of $x$ depends on its shape and complexity.

- If x is a real-valued two-column matrix, the function interprets the first column as in-phase components and the second column as quadrature components.
- If x is a complex-valued vector, the function interprets the real part as in-phase components and the imaginary part as quadrature components.
- If x is a real-valued vector, the function interprets it as a real signal.

## Data Types: double

Complex Number Support: Yes

## n - Decimation factor

1 (default) | positive integer
Decimation factor, specified as a positive integer. The function plots every nth value of input signal x , starting from its first value.

Data Types: double

## offset - Offset value

0 (default) | nonnegative integer
Offset value, specified as a nonnegative integer. This offset value specifies the number of samples at the beginning of input $x$ that the function skips before generating the scatter plot.

Data Types: double
plotstring - Plot attributes
'b. ' (default) | character vector | string scalar
Plot attributes, specified as a character vector or string scalar containing symbols.
This argument sets the plotting symbol, line type, and color for the scatter plot. The format and meaning of the symbols are the same as in the plot function. For example, the default value 'b.' produces blue dots.
Data Types: char | string
h - Figure handle
Figure object
Figure handle to an existing figure that contains an scatter plot, specified as a Figure object. h must be a handle to a figure that scatterplot function previously generated.

## Output Arguments

h - Figure handle
Figure object
Figure handle, returned as a Figure object. To modify properties of this object, see Figure Properties

## semianalytic

Calculate bit error rate (BER) using semianalytic technique

## Syntax

```
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,EbNo)
ber = semianalytic(txsig,rxsig,modtype,M,Nsamp,num,den,EbNo)
[ber,avgampl,avgpower] = semianalytic(...)
```

## Description

ber $=$ semianalytic(txsig, rxsig, modtype, $M$, Nsamp) returns the bit error rate (BER) of a system that transmits the complex baseband vector signal txsig and receives the noiseless complex baseband vector signal rxsig. Each of these signals has Nsamp samples per symbol. Nsamp is also the sampling rate of txsig and rxsig, in Hz. The function assumes that rxsig is the input to the receiver filter, and the function filters rxsig with an ideal integrator. modtype is the modulation type of the signal and $M$ is the alphabet size. The table below lists the valid values for modtype and $M$.

| Modulation Scheme | Value of modtype | Valid Values of $\boldsymbol{M}$ |
| :--- | :--- | :--- |
| Differential phase shift keying <br> (DPSK) | 'dpsk' | 2,4 |
| Minimum shift keying (MSK) <br> with differential encoding | 'msk/diff' | 2 |
| Minimum shift keying (MSK) <br> with nondifferential encoding | 'msk/nondiff' | 2 |
| Phase shift keying (PSK) with <br> differential encoding, where the <br> phase offset of the constellation <br> is 0 | 'psk/diff' | 2,4 |
| Phase shift keying (PSK) with <br> nondifferential encoding, where <br> the phase offset of the <br> constellation is 0 | 'psk/nondiff' | $2,4,8,16,32$, or 64 |
| Offset quadrature phase shift <br> keying (OQPSK) | 'oqpsk' | 4 |
| Quadrature amplitude <br> modulation (QAM) | 'qam' | $4,8,16,32,64,128,256,512$, <br> 1024 |

'msk/diff' is equivalent to conventional MSK (setting the 'Precoding ' property of the MSK object to 'off'), while 'msk/nondiff' is equivalent to precoded MSK (setting the 'Precoding' property of the MSK object to ' on ').

Note The output ber is an upper bound on the BER in these cases:

- DQPSK (modtype = 'dpsk', M = 4)
- Cross QAM (modtype $=$ 'qam',$~ M$ not a perfect square). In this case, note that the upper bound used here is slightly tighter than the upper bound used for cross QAM in the berawgn function.

When the function computes the BER, it assumes that symbols are Gray-coded. The function calculates the BER for values of $E_{b} / N_{0}$ in the range of [0:20] dB and returns a vector of length 21 whose elements correspond to the different $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ levels.

Note You must use a sufficiently long vector txsig, or else the calculated BER will be inaccurate. If the system's impulse response is L symbols long, the length of txsig should be at least $\mathrm{M}^{\mathrm{L}}$. A common approach is to start with an augmented binary pseudonoise (PN) sequence of total length ( $\log _{2} \mathrm{M}$ ) $\mathrm{M}^{\mathrm{L}}$. An augmented PN sequence is a PN sequence with an extra zero appended, which makes the distribution of ones and zeros equal.
ber = semianalytic(txsig,rxsig, modtype, $M$, Nsamp, num,den) is the same as the previous syntax, except that the function filters rxsig with a receiver filter instead of an ideal integrator. The transfer function of the receiver filter is given in descending powers of $z$ by the vectors num and den.
ber = semianalytic(txsig, rxsig,modtype, $M$, Nsamp, EbNo) is the same as the first syntax, except that EbNo represents $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$, the ratio of bit energy to noise power spectral density, in dB. If EbNo is a vector, then the output ber is a vector of the same size, whose elements correspond to the different $\mathrm{E}_{\mathrm{b}} / \mathrm{N}_{0}$ levels.
ber $=$ semianalytic(txsig, rxsig, modtype, $M$, Nsamp, num, den, EbNo) combines the functionality of the previous two syntaxes.
[ber, avgampl,avgpower] = semianalytic(...) returns the mean complex signal amplitude and the mean power of rxsig after filtering it by the receiver filter and sampling it at the symbol rate.

## Examples

A typical procedure for implementing the semianalytic technique is in "Procedure for the Semianalytic Technique". Sample code is in "Using Semianalytic Technique".

## Limitations

The function makes several important assumptions about the communication system. See "When to Use the Semianalytic Technique" to find out whether your communication system is suitable for the semianalytic technique and the semianalytic function.

## Alternatives

As an alternative to the semianalytic function, invoke the BERTool GUI (bertool) and use the Semianalytic tab.

## shift2mask

Convert shift to mask vector for shift register configuration

## Syntax

mask = shift2mask(prpoly,shift)

## Description

mask = shift2mask(prpoly, shift) returns the mask that is equivalent to the shift (or offset) specified by shift, for a linear feedback shift register whose connections are specified by the primitive polynomial prpoly. The prpoly input can have one of these formats:

- A polynomial character vector
- A binary vector that lists the coefficients of the primitive polynomial in order of descending powers
- An integer scalar whose binary representation gives the coefficients of the primitive polynomial, where the least significant bit is the constant term

The shift input is an integer scalar.

Note To save time, shift2mask does not check that prpoly is primitive. If it is not primitive, the output is not meaningful. To find primitive polynomials, use primpoly or see [2].

## Definition of Equivalent Mask

The equivalent mask for the shift $s$ is the remainder after dividing the polynomial $x^{s}$ by the primitive polynomial. The vector mask represents the remainder polynomial by listing the coefficients in order of descending powers.

## Shifts, Masks, and Pseudonoise Sequence Generators

Linear feedback shift registers are part of an implementation of a pseudonoise sequence generator. Below is a schematic diagram of a pseudonoise sequence generator. All adders perform addition modulo 2.

The primitive polynomial determines the state of each switch labeled $g_{k}$, and the mask determines the state of each switch labeled $\mathrm{m}_{\mathrm{k}}$. The lower half of the diagram shows the implementation of the shift, which delays the starting point of the output sequence. If the shift is zero, the $\mathrm{m}_{0}$ switch is closed while all other $\mathrm{m}_{\mathrm{k}}$ switches are open. The table below indicates how the shift affects the shift register's output.

|  | $\mathbf{T}=\mathbf{0}$ | $\mathbf{T}=\mathbf{1}$ | $\mathbf{T}=\mathbf{2}$ | $\ldots$ | $\mathbf{T}=\mathbf{s}$ | $\mathbf{T}=\mathbf{s}+\mathbf{1}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Shift $=\mathbf{0}$ | $\mathrm{x}_{0}$ | $\mathrm{x}_{1}$ | $\mathrm{x}_{2}$ | $\ldots$ | $\mathrm{x}_{\mathrm{s}}$ | $\mathrm{x}_{\mathrm{s}+1}$ |
| Shift $=\mathbf{s}>\mathbf{0}$ | $\mathrm{x}_{\mathrm{s}}$ | $\mathrm{x}_{\mathrm{s}+1}$ | $\mathrm{x}_{\mathrm{s}+2}$ | $\ldots$ | $\mathrm{x}_{2 \mathrm{~s}}$ | $\mathrm{x}_{2 \mathrm{~s}+1}$ |

If you have Communications Toolbox software and want to generate a pseudonoise sequence in a Simulink model, see the PN Sequence Generator block reference page.

## Examples

## Convert Shift to Mask

Convert a shift in a linear feedback shift register into an equivalent mask.
Convert a shift of 5 into the equivalent mask $x^{3}+x+1$ for the linear feedback shift register whose connections are specified by the primitive polynomial $x^{4}+x^{3}+1$. The length of the mask is equal to the degree of the primitive polynomial, 4.

```
mk = shift2mask([1 1 0 0 1],5)
mk = 1\times4
```

| 1 | 0 | 1 | 1 |
| :--- | :--- | :--- | :--- |

Convert a shift of 7 to a mask of $x^{4}+x^{2}$ for the primitive polynomial $x^{5}+x^{2}+1$.

```
mk2 = shift2mask('x5+x2+1',7)
mk2 = 1\times5
```

| 1 | 0 | 1 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- |

## showcommblockdatatypetable

Communications Toolbox block characteristics

## Syntax

showcommblockdatatypetable

## Description

showcommblockdatatypetable shows a table of characteristics for the Communications Toolbox blocks. The table lists capabilities and limitations about code generation, variable size, and supported data types for each block. If a cell includes an "X", the corresponding block supports the capability indicated by the column heading. Descriptions for numbered footnotes, "(\#)", follow the table.

## Examples

## Show Communications Toolbox Block Characteristics

Show a table of Communications Toolbox block characteristics. The table opens in a separate window.

## signlms

(To be removed) Construct signed least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Consider using comm. LinearEqualizer or comm. DecisionFeedback instead.

## Syntax

alg = signlms(stepsize)
alg = signlms(stepsize,algtype)

## Description

The signlms function creates an adaptive algorithm object that you can use with the lineareq function or dfe function to create an equalizer object. You can then use the equalizer object with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
alg = signlms(stepsize) constructs an adaptive algorithm object based on the signed least mean square (LMS) algorithm with a step size of stepsize.
alg = signlms(stepsize,algtype) constructs an adaptive algorithm object of type algtype from the family of signed LMS algorithms. The table below lists the possible values of algtype.

| Value of algtype | Type of Signed LMS Algorithm |
| :--- | :--- |
| 'Sign LMS' | Sign LMS (default) |
| 'Signed Regressor LMS' | Signed regressor LMS |
| 'Sign Sign LMS' | Sign-sign LMS |

## Properties

The table below describes the properties of the signed LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see "Equalization".

| Property | Description |
| :--- | :--- |
| AlgType | Type of signed LMS algorithm, corresponding to <br> the algtype input argument. You cannot change <br> the value of this property after creating the <br> object. |
| StepSize | LMS step size parameter, a nonnegative real <br> number |
| LeakageFactor | LMS leakage factor, a real number between 0 and <br> 1. A value of 1 corresponds to a conventional <br> weight update algorithm, while a value of 0 <br> corresponds to a memoryless update algorithm. |

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
        InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 + ...
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:
\% plot(yNew,'*')
\% hold on
\% plot(yold,'o')
\% hold off; legend('New Eq','Old Eq'); grid on

## Use LMS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS'
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0]
    WeightInputs: [0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.

```
y0ld = equalize(eq0ld,r);
yNew = eqNew(r);
```

## Use Linear Equalizers Considering Signal Delays

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the lineareq to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eq0ld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS'
    nWeights: }1
    nSampPerSym: 2
    RefTap: 13
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
            'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
            'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 16
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the comm.LinearEqualizer object, InputDelay is used to synchronize with the delayed signal. NumTaps and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    ReferenceTap',',''InputDelay',filterDelay*sps)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS
    NumTaps: 11
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: }1
```

InputSamplesPerSymbol: 2
TrainingFlagInputPort: false
AdaptAfterTraining: true
InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1

```
yNew1 = eqNew(r2,x(1:100));
```

reset (eqNew)
$y N e w 2=$ eqNew(r2,x(1:100));

## Algorithms

Referring to the schematics presented in "Equalization", define $w$ as the vector of all weights $w_{i}$ and define $u$ as the vector of all inputs $u_{i}$. Based on the current set of weights, $w$, this adaptive algorithm creates the new set of weights given by

- (LeakageFactor) w + (StepSize) u*sgn(Re(e)), for sign LMS
- (LeakageFactor) $w+$ (StepSize) $\operatorname{sgn}(\operatorname{Re}(u)) \operatorname{Re}(e)$, for signed regressor LMS
- (LeakageFactor) w + (StepSize) sgn(Re(u)) sgn(Re(e)), for sign-sign LMS
where the * operator denotes the complex conjugate and sgn denotes the signum function (sign in MATLAB technical computing software).

## Compatibility Considerations

## signlms will be removed

Warns starting in R2020a

- signlms will be removed in a future release. Consider using comm. LinearEqualizer or comm. DecisionFeedback instead with the adaptive algorithm set to LMS.
- The comm. LinearEqualizer or comm. DecisionFeedback System objects do not have a leakage factor property. This is equivalent to setting LeakageFactor to 1 in the signlms function.
- For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-757.

## ssbdemod

Single sideband amplitude demodulation

## Syntax

z = ssbdemod (y, Fc,Fs)
z = ssbdemod(y,Fc,Fs,ini_phase)
z = ssbdemod(y,Fc,Fs,ini_phase,num,den)

## Description

## For All Syntaxes

z = ssbdemod(y,Fc,Fs) demodulates the single sideband amplitude modulated signal y from the carrier signal having frequency Fc (Hz). The carrier signal and y have sampling rate Fs (Hz). The modulated signal has zero initial phase, and can be an upper- or lower-sideband signal. The demodulation process uses the lowpass filter specified by [num, den] = butter(5,Fc*2/Fs).

Note The Fc and Fs arguments must satisfy Fs > 2 (Fc + BW), where BW is the bandwidth of the original signal that was modulated.
$z=s s b d e m o d\left(y, F c, F s, i n i \_p h a s e\right)$ specifies the initial phase of the modulated signal in radians.
$z=\operatorname{ssbdemod}(y, F c, F s$, ini_phase, num, den $)$ specifies the numerator and denominator of the lowpass filter used in the demodulation.

## Examples

## Demodulate Sideband Signal

Define the sampling frequency and original signal.

```
fs = 270000;
t = (0:1/fs:0.01)';
signal = sin(2*pi*300.*t)+2*sin(2*pi*600.*t);
```

Convert the original signal to upper-sideband and lower-sideband modulated signals using ssbmod. Use a cutoff frequency of 12000 and an initial phase of 0 .

```
fc = 12000;
initialPhase = 0;
lowerSidebandSignal = ssbmod(signal,fc,fs,initialPhase);
upperSidebandSignal = ssbmod(signal,fc,fs,initialPhase,'upper');
```

Demodulate the lower and upper sideband signals.

```
s1 = ssbdemod(lowerSidebandSignal,fc,fs);
s2 = ssbdemod(upperSidebandSignal,fc,fs);
```

Compare processed signals with original and verify reconstruction.
plot(t,signal,'k',t,s1,'r:',t,s2,'g-.');
legend('Original Signal','Demodulation of Lower Sideband','Demodulation of Upper Sideband');

## See Also

amdemod | ssbmod

## Topics

"Digital Modulation"

## Introduced before R2006a

## ssbmod

Single sideband amplitude modulation

## Syntax

$y=\operatorname{ssbmod}(x, F c, F s)$
$y=\operatorname{ssbmod}\left(x, F c, F s, i n i \_\right.$phase $)$
$y=s s b m o d\left(x, f c, f s, i n i \_p h a s e, ' u p p e r '\right)$

## Description

$y=\operatorname{ssbmod}(x, F c, F s)$ uses the message signal $x$ to modulate a carrier signal with frequency Fc (Hz) using single sideband amplitude modulation in which the lower sideband is the desired sideband. The generated output $y$ is a single side band signal with a suppressed carrier. The carrier signal and x have sample frequency Fs (Hz). The modulated signal has zero initial phase.
$y=\operatorname{ssbmod}\left(x, F c, F s, i n i \_p h a s e\right)$ specifies the initial phase of the modulated signal in radians.
y = ssbmod(x,fc,fs,ini_phase,'upper') uses the upper sideband as the desired sideband.

## Examples

## Compare Double-Sideband and Single-Sideband Amplitude Modulation

Set the sample rate to 100 Hz . Create a time vector 100 seconds long.

```
fs = 100;
t = (0:1/fs:100)';
```

Set the carrier frequency to 10 Hz . Generate a sinusoidal signal.

```
fc = 10;
x = sin(2*pi*t);
```

Modulate x using single- and double-sideband AM.

```
ydouble = ammod(x,fc,fs);
ysingle = ssbmod(x,fc,fs);
```

Create a spectrum analyzer object to plot the spectra of the two signals. Plot the spectrum of the double-sideband signal.

```
sa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PlotAsTwoSidedSpectrum',false, ...
    'YLimits',[-60 40]);
step(sa,ydouble)
```

Plot the single-sideband spectrum.
step(sa,ysingle)

## stdchan

Construct channel System object from set of standardized channel models

## Syntax

```
chan = stdchan(chantype,rs,fd)
```

## Description

chan $=$ stdchan(chantype,rs,fd) constructs a fading channel object chan according to the specified chantype. chantype is chosen from the channel models listed in "Supported Standards" on page 2-774. rs is the sampling rate of the input signal and fd is the maximum Doppler shift.

## Examples

## Filter Signal Through CDMA Channel

Set the sample rate and the maximum Doppler shift.

```
rs = 20e6;
fd = 3;
```

Create a CDMA Typical Urban channel model (TUx) channel object and turn on frequency response visualization.

```
chan = stdchan('cdmaTUx',rs,fd);
chan.Visualization = 'Frequency response';
```

Generate random data and apply QPSK modulation.

```
data = randi([0 3],10000,1);
txSig = pskmod(data,4,pi/4);
```

Filter the QPSK signal through the CDMA channel.
$y=$ chan(txSig) ;

## GSM and EDGE Channel Model

Create a channel model useful for GSM and EDGE simulations. Experiment with low speed and high speed conditions.

## Configure parameters and System objects

Frame configuration.

```
M = 8; % Modulation order, 8-PSK
Rbit = 9600; % Input bit rate
Rs = Rbit / log2(M); % Symbol rate
Nsamples = 5e2; % Number of samples per frame
Nframes = 10; % Number of frames
```

Speed and channel configuration.

```
v = 10 * 1e3/3600; % Mobile speed (m/s)
fc = 1800e6; % Carrier frequency
c = physconst('LightSpeed'); % Speed of light in free space
fd = v*fc/c; % Maximum Doppler shift of diffuse component
```

Create System objects for modulator and channel.

```
modulator = comm.PSKModulator(M,'PhaseOffset',0);
channel = stdchan('gsmeqx6',Rs,fd);
channel.RandomStream = 'mt19937ar with seed'; % set for reproducibility
channel.Visualization = 'Impulse and frequency responses';
channel.SamplesToDisplay = '100%';
refC = constellation(modulator);
constDiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',refC, ...
    'XLimits',[-3 3],'YLimits',[-3 3]);
```

## Simulate at low speed

```
for iFrames = 1:Nframes
    msg = randi([0 M-1], Nsamples, 1);
    modSignal = modulator(msg);
    chanOut = channel(modSignal);
    constDiagram(chanOut);
end
```

Processing

## Simulate at high speed

Release and reconfigure objects.
release(constDiagram);
release(channel);
$v=120 * 1 e 3 / 3600 ; \%$ Mobile speed (m/s)
fd $=v^{*} f c / c ; \%$ Maximum Doppler shift of diffuse component
channel.MaximumDopplerShift $=$ fd; \% Adjust maximum doppler shift
for iFrames = 1:Nframes
msg = randi([0 M-1], Nsamples, 1);
modSignal = modulator(msg);
chanOut = channel(modSignal);
constDiagram(chanOut);
end

Processing

## Input Arguments

## chantype - Channel type

string | character vector
Channel type, specified as a string or character vector. Valid options are listed in "Supported Standards" on page 2-774.
Example: stdchan('gsmRAx6c1', rs,fd), configures a channel model for the GSM typical case for rural area (RAx), 6 taps, case 1, with a sample rate rs, and maximum Doppler shift fd

Data Types: char | string

## rs - Sample rate

scalar
Sample rate in Hertz, specified as a scalar.

## Data Types: double

fd - Maximum Doppler shift
scalar
Maximum Doppler shift in Hertz, specified as a scalar.
Data Types: double

## Output Arguments

## chan - Channel object

System object
Channel object, returned as a comm. RayleighChannel or comm.RicianChannel System object.

## More About

## Supported Standards

For GSM, CDMA, and ITU-R HF standards, call stdchan to return a comm. RayleighChannel or comm.RicianChannel System object modeling one of these profiles.

GSM/EDGE channel models (3GPP TS 45.005 V7.9.0 (2007-2), 3GPP TS 05.05 V8.20.0 (2005-11)):

| Channel model | Profile |
| :--- | :--- |
| gsmRAx6c1 | Typical case for rural area (RAx), 6 taps, case 1 |
| gsmRAx4c2 | Typical case for rural area (RAx), 4 taps, case 2 |
| gsmHTx12c1 | Typical case for hilly terrain (HTx), 12 taps, case <br> 1 |
| gsmHTx12c2 | Typical case for hilly terrain (HTx), 12 taps, case <br> 2 |
| gsmHTx6c1 | Typical case for hilly terrain (HTx), 6 taps, case 1 |
| gsmHTx6c2 | Typical case for hilly terrain (HTx), 6 taps, case 2 |
| gsmTUx12c1 | Typical case for urban area (TUx), 12 taps, case 1 |
| gsmTUx12c1 | Typical case for urban area (TUx), 12 taps, case 2 |
| gsmTUx6c1 | Typical case for urban area (TUx), 6 taps, case 1 |
| gsmTUx6c2 | Typical case for urban area (TUx), 6 taps, case 2 |
| gsmEQx6 | Profile for equalization test (EQx), 6 taps |
| gsmTIx2 | Typical case for very small cells (TIx), 2 taps |

CDMA channel models for deployment evaluation (3GPP TR 25.943 V6.0.0 (2004-12)):

| Channel model | Profile |
| :--- | :--- |
| cdmaTUx | Typical Urban channel model (TUx) |
| cdmaRAx | Rural Area channel model (RAx) |

| Channel model | Profile |
| :--- | :--- |
| cdmaHTx | Hilly Terrain channel model (HTx) |

ITU-R HF channel models (ITU-R F. 1487 (2000)) (FD must be 1 to obtain the correct frequency spreads for these models.):

| Channel model | Profile |
| :--- | :--- |
| iturHFLQ | Low latitudes, Quiet conditions |
| iturHFLM | Low latitudes, Moderate conditions |
| iturHFLD | Low latitudes, Disturbed conditions |
| iturHFMQ | Medium latitudes, Quiet conditions |
| iturHFMM | Medium latitudes, Moderate conditions |
| iturHFMD | Medium latitudes, Disturbed conditions |
| iturHFMDV | Medium latitudes, Disturbed conditions near <br> vertical incidence |
| iturHFHQ | High latitudes, Quiet conditions |
| iturHFHM | High latitudes, Moderate conditions |
| iturHFHD | High latitudes, Disturbed conditions |

## symerr

Compute number of symbol errors and symbol error rate

## Syntax

[number, ratio] $=\operatorname{symer}(x, y)$
[number, ratio] $=\operatorname{symerr}(x, y, f l g)$
[number, ratio,loc] $=$ symerr(...)

## Description

[number, ratio] $=\operatorname{symerr}(x, y)$ compares the elements in $x$ and $y$. The sizes of $x$ and $y$ determine which elements are compared. The output number is a scalar or vector that indicates the number of elements that differ. The output ratio equals number divided by the total number of elements in the smaller input.
[number, ratio] $=\operatorname{symerr}(x, y, f l g)$ compares the elements in $x$ and $y$. Optional input $f l g$ and the size of $x$, and $y$, determine the size of number.
[number, ratio,loc] $=$ symerr(...) returns a binary matrix loc that indicates which elements of $x$ and $y$ differ. An element of loc is zero if the corresponding comparison yields no discrepancy, and one otherwise.

## Examples

## Compare Elements of Matrix

Compare Elements of Matrix with Another Matrix

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
x = 3x4
\begin{tabular}{llll}
1 & 1 & 3 & 1 \\
3 & 2 & 2 & 2 \\
3 & 3 & 8 & 3
\end{tabular}
aMatrix = [1,1,1,1;2,2,2,2;3,3,3,3]
aMatrix = 3×4
\begin{tabular}{llll}
1 & 1 & 1 & 1 \\
2 & 2 & 2 & 2 \\
3 & 3 & 3 & 3
\end{tabular}
```

```
[number1,ratiol] = symerr(x,aMatrix)
```

[number1,ratiol] = symerr(x,aMatrix)
numberl = 3

```
numberl = 3
```

```
ratiol = 0.2500
```

## Compare Elements of Matrix with Row Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
x = 3×4
    1
    3
aRowVector = [1, 2,3,1]
aRowVector = 1×4
    1 2 3 1
[number2,ratio2] = symerr(x,aRowVector)
number2 = 3×1
    1
        3
    4
ratio2 = 3×1
    0.2500
    0.7500
    1.0000
```

## Compare Elements of Matrix with Column Vector

```
x = [1,1,3,1;3,2,2,2;3,3,8,3]
```

$x=3 \times 4$
$\begin{array}{llll}1 & 1 & 3 & 1 \\ 3 & 2 & 2 & 2\end{array}$
$\begin{array}{llll}3 & 2 & 2 & 2 \\ 3 & 3 & 8 & 3\end{array}$
aColumnVector $=[1 ; 2 ; 3]$
aColumnVector $=3 \times 1$
1
2
3
[number3, ratio3] $=\operatorname{symerr}(x$, aColumnVector $)$

```
number3 = 1×4
    1 0 2 0
ratio3 = 1\times4
    0.3333 0 0.6667 0
```

## Use Alternative Type of Comparison

You can specify alternative comparison methods used by symerr. In this example, you use a flag to override the default row-by-row comparison. Notice that number and ratio are scalars.

```
format rat;
[number,ratio,loc] = symerr([1 2; 3 4],[1 3],'overall')
number =
    3
ratio =
    3/4
loc =
    0 1
    1 1
```

## Input Arguments

## x - First input to compare

scalar | vector | matrix
First input to compare, specified as a vector, or a matrix.
Data Types: double
y - Second input to compare
scalar | vector | matrix
Second input to compare, specified as a vector, or a matrix.
Data Types: double

## flg - Element comparison type

'overall'|'column-wise'|'row-wise'
Optional argument to override the defaults that govern which elements symerr compares and how symerr computes the outputs.

- 'overall ' -- x and y are compared element by element.
- 'column-wise' -- $m^{\text {th }}$ row of $x$ vs. $m^{\text {th }}$ row of $y$.
- 'row-wise' $--m^{\text {th }}$ column of $x$ vs. $m^{\text {th }}$ column of $y$.

See "Specifying Element Comparison" on page 2-780 for more information

## Output Arguments

## number - Number of differing elements

scalar | vector
Number of elements that differ between $x$ and $y$, returned as a scalar or vector. The size of number is determined by the optional input $f l g$ and by the dimensions of $x$ and $y$. See "Default Element Comparison" on page 2-779 and "Specifying Element Comparison" on page 2-780 for more information.

## ratio - Ratio of differing elements

scalar
The ratio of the number of differing elements, number, and the total number of elements of the smaller input, returned as a scalar.

## loc - Location of errors

scalar | vector | matrix
Logical array of same size and dimensions as $x$, and $y$, with corresponding locations of errors between inputs $x$ and $y$. An element of loc is zero if the corresponding comparison yields no discrepancy, and one otherwise.

## More About

## Default Element Comparison

The symerr function compares binary representations of elements in $x$ with those in $y$. When optional argument $f l g$ is not specified, symer uses the shape of the inputs $x$ and $y$ to determine the element comparison method. The schematics below illustrate how the shapes of $x$ and $y$ determine which elements symerr compares:

(a) Compares xl with yl , x 2 with y 2 , and so on.

(b) Compares column vector $y$ with each column of matrix $x$

(c) Compares row vector $y$ with each row of matrix $x$

- If $x$ and $y$ are matrices of the same dimensions, then symerr compares $x$ and $y$ element by element. number is a scalar. See schematic (a) in the figure.
- If one is a row (respectively, column) vector and the other is a two-dimensional matrix, then symer r compares the vector element by element with each row (resp., column) of the matrix. The length of the vector must equal the number of columns (resp., rows) in the matrix. number is a
column (resp., row) vector whose mth entry indicates the number of elements that differ when comparing the vector with the mth row (resp., column) of the matrix. See schematics (b) and (c) in the figure.

## Specifying Element Comparison

Use $f l g$ to override the defaults that govern which elements symerr compares and how symerr computes the outputs. The values of $f l g$ are 'overall', 'column-wise', and 'row-wise'. The table below describes the differences that result from various combinations of inputs. In all cases, ratio is number divided by the total number of elements in $y$.

Comparing a Two-Dimensional Matrix x with Another Input y

| Shape of y | flg | Type of Comparison | number |
| :---: | :---: | :---: | :---: |
| Two-dim. matrix | 'overall' (default) | Element by element | Total number of symbol errors |
|  | 'column-wise' | $m^{\text {th }}$ column of x vs. $m^{\text {th }}$ column of $y$ | Row vector whose entries count symbol errors in each column |
|  | 'row-wise' | $m^{\text {th }}$ row of $x$ vs. $m^{\text {th }}$ row of $y$ | Column vector whose entries count symbol errors in each row |
| Column vector | 'overall' | $y$ vs. each column of $x$ | Total number of symbol errors |
|  | ' column-wise' (default) | $y$ vs. each column of $x$ | Row vector whose entries count symbol errors in each column of X |
| Row vector | 'overall' | $y$ vs. each row of $x$ | Total number of symbol errors |
|  | ' row-wise' (default) | $y$ vs. each row of $x$ | Column vector whose entries count symbol errors in each row of $x$ |

## syndtable

Produce syndrome decoding table

## Syntax

$\mathrm{t}=$ syndtable( h )

## Description

$\mathrm{t}=$ syndtable( h ) returns a decoding table for an error-correcting binary code having codeword length n and message length k . h is an ( $\mathrm{n}-\mathrm{k}$ )-by-n parity-check matrix for the code. t is a $2^{\mathrm{n}-\mathrm{k}}$-by-n binary matrix. The rth row of $t$ is an error pattern for a received binary codeword whose syndrome has decimal integer value $\mathrm{r}-1$. (The syndrome of a received codeword is its product with the transpose of the parity-check matrix.) In other words, the rows of $t$ represent the coset leaders from the code's standard array.

When converting between binary and decimal values, the leftmost column is interpreted as the most significant digit. This differs from the default convention in the bi2de and de2bi commands.

## Examples

An example is in "Decoding Table".

## testconsole.Results

(To be removed) Gets results from test console simulations

## Compatibility

testconsole.Results will be removed in a future release. Use comm. ErrorRate or bertool instead. For more information, see "Compatibility Considerations" on page 2-796.

## Description

The getResults method of the Error Rate Test Console returns an instance of a testconsole.Results object containing simulation results data. You use methods of the results object to retrieve and plot simulations results data.

## Properties

A testconsole.Results object has the properties shown in the following table. All properties are writable except for the ones explicitly noted otherwise.

| Property | Description |
| :--- | :--- |
| TestConsoleName | Error Rate Test Console. This property is not <br> writable. |
| System Under Test Name | Name of the system under test for which the <br> Error Rate Test Console obtained results. This <br> property is not writable. |
| IterationMode | Iteration mode the Error Rate Test Console used <br> for obtaining results. This property is not <br> writable. |
| Metric | Specify the name of the registered test point for <br> which the results object parses results. The <br> getData, plot, and semilogy methods of the <br> Results object return data or create a plot for the <br> test point that the TestPoint property specifies. |
| TestParameter1 | Specify the name of the test metric for which the <br> results object parses results. The getData, plot, <br> and semilogy methods of the Results object <br> returns data or creates a plot for the metric that <br> the Metric property specifies. |
| TestParameter2 | Specifies the name of the first independent <br> variable for which the results object parses <br> results. | | Specifies the name of the second independent |
| :--- |
| variable for which the results object parses |
| results. |

## Methods

A testconsole.Results object has the following methods.

## getData

$d=$ getData ( $r$ ) returns results data matrix, $d$, available in the results object $r$. The returned results correspond to the test point currently specified in the TestPoint property of $r$, and to the test metric currently specified in the Metric property of $r$.

If IterationMode is 'Combinatorial' then $d$ is a matrix containing results for all the sweep values available in the test parameters specified in the TestParameter1 and TestParameter2 properties. The rows of the matrix correspond to results for all the sweep values available in TestParameter1. The columns of the matrix correspond to results for all sweep values available in TestParameter2. If more than two test parameters are registered to the Error Rate Test Console, $d$ contains results corresponding to the first value in the sweep vector of all parameters that are not TestParameterl or TestParameter2.

If IterationMode is 'Indexed', then $d$ is a vector of results corresponding to each indexed combination of all the test parameter values registered to the Error Rate Test Console.

## plot

$p l o t(r)$ creates a plot for the results available in the results object r. The plot corresponds to the test point and test metric, specified by the TestPoint and Metric properties of $r$

If IterationMode is 'Combinatorial' then the plot contains a set of curves. The sweep values in TestParameter1 control the x-axis and the number of sweep values for TestParameter2 specifies how many curves the plot contains. If more than two test parameters are registered to the Error Rate Test Console, the curves correspond to results obtained with the first value in the sweep vector of all parameters that are not TestParameter1, or TestParameter2.

No plots are available when 'IterationMode' is 'Indexed'.

## semilogy

semilogy (...) is the same as plot (. . .) , except that the Y-Axis uses a logarithmic (base 10) scale.

## surf

surf(r) creates a 3-D, color, surface plot for the results available in the results object, r. The surface plot corresponds to following items:

- The test point you specify using the TestPoint property of the results object
- The test metric currently you specify in the Metric property of the results object

You can specify parameter/value pairs for the results object, which establishes additional properties of the surface plot.

When you select 'Combinatorial' for the IterationMode, the sweep values available in the test parameter you specify for the TestParameter1 property control the x-axis of the surface plot. The sweep values available in the test parameter you specify for the TestParameter2 property control the $y$-axis.

If more than two test parameters are registered to the test console, the surface plot corresponds to the results obtained with the parameter sweep values previously specified with the setParsingValues method of the results object.

You display the current parsing values by calling the getParsingValues method of the results object. The parsing values default to the first value in the sweep vector of each test parameter. By default, the surf method ignores the parsing values for any parameters currently set as TestParameter1 or TestParameter2.

No surface plots are available if the IterationMode is 'Indexed', when less than two registered test parameters exist, or TestParameter2 is set to 'None'.

## setParsingValues

setParsingValues(R,'ParameterName1', 'Value1', ... 'ParameterName2',
'Value2', ...) sets the parsing values to the values you specify using the parameter-value pairs. Parameter name inputs must correspond to names of registered test parameters, and value inputs must correspond to a valid test parameter sweep value.

You use this method for specifying single sweep values for test parameters that differ from the values for TestParameter1 and TestParameter2. When you define this method, the results object returns the data values or plots corresponding to the sweep values you set for the setParsingValues method. The parsing values default to the first value in the sweep vector of each test parameter.

You display the current parsing values by calling the getParsingValues method of the results object. You may set parsing values for parameters in TestParameter1 and TestParameter2, but the results object ignores the values when getting data or returning plots.

Parsing values are irrelevant when IterationMode is 'Indexed'.

## getParsingValues

getParsingValues displays the current parsing values for the Error Rate Test Console.
$s=$ getParsingValues $(r)$ returns a structure, $s$, with field names equal to the registered test parameter names and with values corresponding to the current parsing values.

Parsing values are irrelevant when IterationMode is 'Indexed'.

## Examples

## Error Rate Simulation Sweeps

The commtest.ErrorRate and testconsole.Results object packages will be removed in a future release. They can be used to perform parameter sweeps to analyze communication system performance. This example demonstrates a workflow that uses them and along with recommended alternate workflows.

## Multiple Parameter Sweep and Parallel Run using commtest.ErrorRate

Obtain bit error rate and symbol error rate of an M-PSK system for different modulation orders and EbNo values. System under test is commtest. MPSKSystem.

```
% Create an M-ary PSK system
systemUnderTest = commtest.MPSKSystem;
% Instantiate an Error Rate Test Console and attach the system
errorRateTester = commtest.ErrorRate(systemUnderTest);
```

Warning: commtest.ErrorRate will be removed in the future. Use comm.ErrorRate or bertool instead
errorRateTester.SimulationLimitOption = 'Number of errors or transmissions';
errorRateTester.MaxNumTransmissions = 1e5;
\% Set sweep values for simulation test parameters
setTestParameterSweepValues(errorRateTester,'M',2.^[11 23 4],'EbNo',(-5:10))
\% Register a test point
registerTestPoint(errorRateTester,'MPSK BER','TxInputBits','Rx0utputBits')
\% Get information about the simulation settings
info(errorRateTester)
Test console name: commtest.ErrorRate
System under test name: commtest.MPSKSystem
Available test inputs: NumTransmissions, RandomIntegerSource
Registered test inputs: NumTransmissions
Registered test parameters: EbNo, M
Registered test probes: RxOutputBits, RxOutputSymbols, TxInputBits, TxInputSymbols
Registered test points: MPSK_BER
Metric calculator functions: @commtest.ErrorRate.defaultErrorCalculator
Test metrics: ErrorCount, TransmissionCount, ErrorRate
\% Run the M-PSK simulations
run(errorRateTester)
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
12 workers available for parallel computing. Simulations will be distributed among these workers
Running simulations...
\% Get the results
mpskResults = getResults(errorRateTester);
Warning: testconsole.Results will be removed in the future. See <a href="matlab:helpview(fullfil
\% Get a semi-log scale plot of EbNo versus bit error rate for
\% different values of modulation order M
mpskResults. TestParameter2 = 'M';
semilogy(mpskResults,'*-')

## Multiple Parameter Sweep and Parallel Run using nested for loops and comm.ErrorRate

Run an error rate simulation over $\mathrm{M}=2 . \wedge(1: 4)$ and $\mathrm{EbNo}=-5: 10$. Use comm. ErrorRate to collect both bit error rate (BER) and symbol error rate (SER) data. Run the simulations to collect a minimum of 100 symbol errors or for a maximum of 1 e 5 symbols.

```
% Set the M sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester,'M')
ans = 1\times4
    2 4 8 16
MSweep = 2.^[ll 2 3 4];
% Set EbNo sweep values same as the commtest.ErrorRate object
getTestParameterSweepValues(errorRateTester,'EbNo')
ans = 1\times16
    llllllllllllllllll
```

EbNoSweep $=-5: 10$;
\% Set minumum number of errors same as the commtest.ErrorRate object
errorRateTester.MinNumErrors

```
ans = 100
minNumErrors = 100;
% Set maximum number of transmissions same as the commtest.ErrorRate
% object. In this example a transmission is a symbol.
errorRateTester.MaxNumTransmissions
ans = 100000
MaxNumTransmissions = 1e5;
% Set frame length same as the commtest.ErrorRate object
errorRateTester.FrameLength
ans = 500
frameLength = 500;
% Find out if there is a parallel pool and how many workers are available
[licensePCT,~] = license('checkout','distrib_computing_toolbox');
if (licensePCT && ~isempty(ver('parallel')))
    p = gcp;
    if isempty(p)
            numWorkers = 1;
    else
            numWorkers = p.NumWorkers
    end
else
    numWorkers = 1;
end
numWorkers = 12
minNumErrorsPerWorker = minNumErrors/numWorkers;

## Multiple Variable Sweeps using BERTool

BERTool computes the BER as a function of signal-to-noise ratio. It analyzes performance either with Monte-Carlo simulations of MATLAB® functions and Simulink ${ }^{\circledR}$ models or with theoretical closedform expressions for selected types of communication systems. The bertool function opens the BERTool. Here BERTool is configured to call the simulation defined in the function mpsksim included below.

```
function [ber,numBits] = mpsksim(EbNo,minNumErrs,maxNumBits)
% Import the Java class for BERTool, so that you will be able to stop the simulation using the ".
import com.mathworks.toolbox.comm.BERTool;
frameLength = 500;
M = 16; % Can be 2, 4, 8, 16
bitsPerSymbol = log2(M);
maxNumSymbols = maxNumBits/bitsPerSymbol;
SNR = EbNo + 10*log10(bitsPerSymbol);
% Initialize variables related to exit criteria.
numBitErrors = 0;
numSymbols = 0;
while (numBitErrors < minNumErrs) || (numSymbols < maxNumSymbols)
```

```
    % Check if the user clicked the Stop button of BERTool.
    if (BERTool.getSimulationStop)
        break;
    end
    % Generate frameLength source outputs
    txMsg = randi([0 M-1],frameLength,1);
    numSymbols = numSymbols+frameLength;
    % Modulate the data
    txOutput = pskmod(txMsg,M,0,'gray');
    % Pass data through an AWGN channel with current SNR value
    chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
    % Demodulate the data
    rxOutput = pskdemod(chnlOutput,M,0,'gray');
    % Convert symbol streams to bit streams
    bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
    bTx = bTx(:);
    bRx = de2bi(rx0utput,bitsPerSymbol,'left-msb')';
    bRx = bRx(:);
    % Calculate number of bit errors
    numBitErrors = numBitErrors+sum(bTx~=bRx);
end
% Assign values to the output variables.
numBits = numSymbols*bitsPerSymbol;
ber = numBitErrors/numBits;
```

Configure BERTool as follows.

Set $\mathrm{M}=2$ in the mpsksim function and click Run. Set the BER Data Set name to ' $\mathrm{M}=\mathbf{2}^{\prime}$.

| -) Bit Error Rate Analysis Tool |  |  |  |  |  | - |  | $\times$ |

|  |  |  |  |  |  |  | Run | Stop |

Display the BER curve for $\mathrm{M}=2$.

Update the value for $M$ in the mpsksim function, repeating this process for $M=4,8,16$. You will see results similar to those below in the Bit Error Rate Analysis Tool window and the BER figure.

## Parallel SNR Sweep using BERTool

Using parfor, run each simulation point in parallel by configuring your simulation function similar to the mpsksim_parfor function included below. Since parfor cannot work with the Java class for BERTool, you will not be able to stop the simulation using the Stop button.

```
function [ber,numBits] = mpsksim_parfor(EbNo,minNumErrs,maxNumBits)
% Find out if there is a parallel pool and how many workers are available
if license('test','Distrib Computing_Toolbox')
    p = gcp;
    if isempty(p)
        numWorkers = 1;
```

```
    else
        numWorkers = p.NumWorkers;
    end
else
    numWorkers = 1;
end
M = 2;
bitsPerSymbol = log2(M);
maxNumSymbols = maxNumBits/bitsPerSymbol;
minNumErrorsPerWorker = minNumErrs/numWorkers;
maxNumSymbolsPerWorker = maxNumSymbols/numWorkers;
frameLength = 500;
SNR = EbNo + 10*log10(bitsPerSymbol);
% Initialize variables related to exit criteria.
numBitErrors = zeros(numWorkers,1);
numSymbols = zeros(numWorkers,1);
parfor worker = 1:numWorkers
    while (numBitErrors(worker) < minNumErrorsPerWorker) ...
            || (numSymbols(worker) < maxNumSymbolsPerWorker)
        % Generate frameLength source outputs
        txMsg = randi([0 M-1],frameLength,1);
        numSymbols(worker) = numSymbols(worker)+frameLength;
        % Modulate the data
        txOutput = pskmod(txMsg, M, 0, 'gray');
        % Pass data through an AWGN channel with current SNR value
        chnlOutput = awgn(txOutput,SNR,'measured',[],'dB');
        % Demodulate the data
        rxOutput = pskdemod(chnlOutput,M,0,'gray');
        % Convert symbol streams to bit streams
        bTx = de2bi(txMsg,bitsPerSymbol,'left-msb')';
        bTx = bTx(:);
        bRx = de2bi(rx0utput,bitsPerSymbol,'left-msb')';
        bRx = bRx(:);
        % Calculate number of bit errors
        numBitErrors(worker) = numBitErrors(worker)+sum(bTx~=bRx);
    end
end
% Assign values to the output variables.
ber = sum(numBitErrors)/sum(numSymbols);
numBits = sum(numSymbols)*bitsPerSymbol;
```

## Compatibility Considerations

## testconsole. Results will be removed

Warns starting in R2019b
testconsole.Results will be removed in a future release. Use comm. ErrorRate or bertool instead. The "Error Rate Simulation Sweeps" on page 2-784 example demonstrates alternate workflows using comm. ErrorRate and bertool.

## tpcdec

Turbo product code (TPC) decoder

## Syntax

```
decoded = tpcdec(llr,N,K)
decoded = tpcdec(llr,N,K,S)
decoded = tpcdec(llr,N,K,S,maxnumiter)
decoded = tpcdec(llr,N,K,S,maxnumiter,earlyterm)
[decoded,actualnumiter] = tpcdec(
```

$\qquad$

``` )
```

## Description

decoded $=\operatorname{tpcdec}(l l r, N, K)$ performs 2-D TPC decoding on input log likelihood ratios, $\mathrm{ll} r$, using two linear block codes specified by codeword length $N$ and message length K. For a description of 2-D TPC decoding, see "Algorithms" on page 2-803.
decoded $=\operatorname{tpcdec}(l l r, N, K, S)$ performs 2-D TPC decoding on the shortened llr using a 2-D TPC decoder specified by codeword length $(\mathrm{N}-\mathrm{K}+\mathrm{S})$ and message length S .
decoded = tpcdec(llr,N,K,S,maxnumiter) performs 2-D TPC decoding for maxnumiter iterations. To use maxnumiter with full-length messages, specify S as empty, [ ].
decoded $=$ tpcdec (llr, N, K, S, maxnumiter, earlyterm) performs 2-D TPC decoding and terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before maxnumiter decoding iterations. To use maxnumiter and earlyterm with full-length messages, specify S as empty, [ ].
[decoded,actualnumiter] = tpcdec ( __ ) also returns the actual number of decoding iterations after performing 2-D TPC decoding using any of the prior syntaxes.

## Examples

## Decode Using Full-Length TPC Codes

Decode an approximate log-likelihood ratio output signal from 16-QAM demodulation.
Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify the ( $\mathrm{N}, \mathrm{K}$ ) code pairs to use for TPC encoding.

```
N = [32;16];
K = [21;11];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the message bits as a vector with length equal to the product of the elements in K .

```
msg = randi([0 1],prod(K),1);
code = tpcenc(msg,N,K);
```

Apply 16-QAM modulation. Add AWGN to the signal. Demodulate the signal, outputting approximate LLRs.

```
M = 16;
snr = 10;
txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);
rxsig = awgn(txsig,snr,'measured');
llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10));
```

Perform TPC decoding using three iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the number of bit errors in the decoded signal.

```
iterations = 3;
decoded = tpcdec(-llr,N,K,[],iterations);
numerr = biterr(msg,decoded)
numerr = 0
```

## Decode Using Shortened TPC Codes

Decode a shortened TPC code. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify ( $\mathrm{N}, \mathrm{K}$ ) code pairs and S for TPC encoding.

```
N = [32;32];
K = [21;26];
S = [19;24];
```

Generate a column vector of random message bits and TPC-encode the message. Specify the shortened message bits as a vector with length equal to the product of the elements in S .

```
msg = randi([0 1],prod(S),1);
code = tpcenc(msg,N,K,S); LLRs.
```

```
M = 4;
```

M = 4;
snr = 3;
snr = 3;
txsig = qammod(code,M,'InputType','bit', ...
txsig = qammod(code,M,'InputType','bit', ...
'UnitAveragePower',true);
'UnitAveragePower',true);
rxsig = awgn(txsig,snr,'measured');

```
rxsig = awgn(txsig,snr,'measured');
```

Apply QPSK modulation. Add AWGN to the signal. Demodulate the signal and output approximate

```
llr = qamdemod(rxsig,M,'OutputType','approxllr', ...
    'UnitAveragePower',true,'NoiseVariance',10.^(-snr/10)) ;
```

Perform TPC decoding using two iterations. Because the demodulator output is negative bipolar mapped and TPC decoder expects positive bipolar mapped input, the demodulated signal output must be negated at the decoder input. Check the bit error rate of the decoded signal.

```
iterations = 2;
decoded = tpcdec(-llr,N,K,S,iterations);
[~,ber] = biterr(msg,decoded)
ber = 0.0066
```

## TPC Decoding with Shortening and Early Termination

Decode a shortened TPC code and specify early termination of decoding. Apply QPSK modulation and output the approximate log-likelihood ratio signal obtained from QPSK demodulation.

Begin by encoding a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes. Specify ( $\mathrm{N}, \mathrm{K}$ ) code pairs and S for TPC encoding, and a maximum of 10 decoding iterations. Perform QPSK modulation on the signal.

```
n = [64; 32];
k = [51; 26];
s = [49; 24];
maxnumiter = 10;
M = 4;
msg = randi([0 1],prod(s),1); % Random bits
code = tpcenc(msg,n,k,s);
txsig = qammod(code,M,'InputType','bit', ...
    'UnitAveragePower',true);
```

Add noise to the transmitted signal.

```
snr = 5;
rxsig = awgn(txsig,snr,'measured');
```

Demodulate the received signal using approximate LLR demapping.

```
llr = qamdemod(rxsig,M,'OutputType', ...
    'approxllr','UnitAveragePower',true, ...
    'NoiseVariance',10.^(-snr/10));
```

Specify the maximum number of TPC decoding iterations and return the actual number of iterations performed. Early termination of the TPC decoding is on by default. Display the number of errors and the number of iterations performed.

```
[decoded,actualNumIter] = tpcdec(-llr,n,k,s,maxnumiter);
numErr = biterr(msg,decoded);
disp(['Terminated after ' num2str(actualNumIter) ' iterations.' ...
    Number of errors = ' num2str(numErr) '.']);
```

Terminated after 4 iterations. Number of errors $=0$.

## Input Arguments

## llr - Log likelihood ratios

column vector
Log likelihood ratios, specified as a column vector.

- For full-length codes, the length of the input column vector is the product of the elements in N .
- For shortened codes, the length of the input column vector is the product of the elements in ( $\mathrm{N}-\mathrm{K}$ +S ).

Data Types: double | single
N - Codeword length
two-element integer vector
Codeword length, specified as a two-element integer vector, $\left[N_{\mathrm{R}} ; N_{\mathrm{C}}\right]$. $N_{\mathrm{R}}$ represents the number of rows in the product code matrix. $N_{\mathrm{C}}$ represents the number of columns in the product code matrix. For more information about $N_{\mathrm{R}}$ and $N_{\mathrm{C}}$, see "Algorithms" on page 2-803. For a list of valid ( $N(i), K(i)$ ) code pairs, see "More About" on page 2-802.
Data Types: double

## K - Message length

two-element integer vector
Message length, specified as a two-element integer vector, [ $K_{R} ; K_{C}$ ]. For a full-length message, the input column vector containing the input LLRs is arranged into a $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix. $K_{\mathrm{R}}$ represents the number of rows in the message matrix. $K_{\mathrm{C}}$ represents the number of columns in the message matrix. For more information about $K_{\mathrm{R}}$ and $K_{\mathrm{C}}$, see "Algorithms" on page 2-803. For a list of valid ( $N(i), K(i)$ ) code pairs, see "More About" on page 2-802.
Data Types: double

## S - Shortened message length

two-element integer vector
Shortened message length, specified as a two-element integer vector, [ $S_{\mathrm{R}} ; S_{\mathrm{C}}$ ]. For a shortened message, the input column vector containing the input LLRs is arranged into an $S_{\mathrm{R}}$-by- $S_{\mathrm{C}}$ matrix. $S_{\mathrm{R}}$ represents the number of rows in the matrix. $S_{\mathrm{C}}$ represents the number of columns in the matrix. For more information about $S_{\mathrm{R}}$ and $S_{\mathrm{C}}$, see "Algorithms" on page 2-803.

When you specify this parameter, specify $N$ and $K$ vectors for the full-length TPC codes that are shortened to ( $N(i)-K(i)+S(i), S(i)$ ) codes.
Data Types: double

## maxnumiter - Maximum number of decoding iterations

4 (default) | positive integer
Maximum number of decoding iterations, specified as a positive integer.
Data Types: double

## earlyterm - Enable early termination

true (default) | false
Enable early termination of decoding, specified as a logical. When earlyterm is true the decoding terminates early if the calculated syndrome or parity-check of the component code evaluates to zero before maxnumiter decoding iterations.

Data Types: double

## Output Arguments

## decoded - TPC decoded message

column vector
TPC decoded message, returned as a column vector.

- For full-length codes, the length of the returned column vector is the product of the elements in K.
- For shortened codes, the length of the returned column vector is the product of the elements in S.

Data Types: logical

## actualnumiter - Actual number of decoding iterations

positive integer
Actual number of decoding iterations performed, returned as a positive integer.
Data Types: double

## More About

## Component Codes

This table lists the supported component code pairs for the row ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) and column ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) parameters.

- $N_{\mathrm{R}}$ and $K_{\mathrm{R}}$ represent the number of rows in the product code matrix and message matrix, respectively.
- $N_{\mathrm{C}}$ and $K_{\mathrm{C}}$ represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

| Code type | Component Code Pairs $\left(N_{\mathrm{R}}, K_{\mathrm{R}}\right)$ <br> and $\left(N_{\mathrm{C}}, K_{\mathrm{C}}\right)$ | Error-Correction Capability <br> (T) |
| :--- | :--- | :--- |
| Hamming code | $(255,247)$ | 1 |
| $(127,120)$ | 1 |  |
| $(63,57)$ | 1 |  |
|  | 1 |  |
|  | 1 |  |
|  | $(7,4)$ | 1 |

| Extended Hamming code | $(256,247)$ | 1 |
| :--- | :--- | :--- |
| $(128,120)$ | 1 |  |

## Algorithms

Turbo product codes (TPC) are a form of concatenated codes used as forward error correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. For a detailed description, see [1] and [2]. This decoder implements an iterative soft input, soft output 2-D product code decoding, as described in [2], using two "Linear Block Codes". The decoder expects the soft bit log likelihood ratios (LLRs) obtained from digital demodulation as the input signal.

Note The TPC decoder expects a positive bipolar mapped input, specifically -1 mapped to 0 and +1 mapped to 1 . The output from demodulators in the Communications Toolbox is negative bipolar mapping, specifically +1 mapped to 0 and -1 mapped to +1 . Therefore, the LLR output from demodulators must be negated to provide the positive bipolar mapped input expected by the TPC decoder.

## TPC Decoding Full-Length Messages

TPC encoded full-length input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair and column-wise decoding uses the ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. The input vector length must be $N_{\mathrm{R}} \times N_{\mathrm{C}}$. To perform the 2-D TPC decoding, the column vector of the input LLRs, composed of the message and parity bits, is arranged into an $N_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix.

The TPC decoder achieves near-optimum decoding of product codes using Chase decoding and the Pyndiah algorithm to perform iterative soft input, soft output decoding. Chase decoding forms a set of possible codewords for each row or column. The Pyndiah algorithm calculates soft information required for the next decoding step.

## Iterative Soft Input, Soft Output Decoder

The iterative soft input, soft output decoding, as shown in the block diagram, carries out two decoding steps for each iteration.

The soft inputs for decoding are $\boldsymbol{R}(m)=\boldsymbol{R}+\alpha(m) \boldsymbol{W}(m)$.

- Iteration loop counter $i$ increments from $i=1$ to the specified number of iterations.
- $m=2 i-1$ is the decoding step index.
- $\boldsymbol{R}$ is the received LLR matrix.
- $\boldsymbol{R}(m)$ is the soft input for the $m$ th decoding step.
- $\boldsymbol{W}(m)$ is the input extrinsic information for the $m$ th decoding step.
- $\alpha(m)=[0,0.2,0.3,0.5,0.7,0.9,1,1, \ldots]$, where $\alpha$ is a weighting factor applied based on the decoding step index. For higher decoding steps, $\alpha=1$.
- $\beta(m)=[0.2,0.4,0.6,0.8,1,1, \ldots]$, where $\beta$ is a reliability factor applied based on the decoding step index. For higher decoding steps, $\beta=1$.
- D contains the decoded message bits. The output message bits are formed from $\boldsymbol{D}$ by mapping -1 to 0 and +1 to 1 , then reshaping the message block into a column vector.

The output message bits are formed after iterating through the specified number of iterations, or, if early termination is enabled, after code convergence.

## Early Termination of TPC Decoding

If early termination is enabled, a code convergence check is performed on the hard decision of the soft input in each row-wise and column-wise decoding step. Early termination can be triggered after either the row-wise decoding or column-wise decoding converges.

The code is converged if, for all rows or all columns,

- The syndrome evaluates to zero in the codes (Hamming codes, Extended Hamming codes, BCH codes, or Extended BCH codes).
- The parity check is evaluated to zero in parity check codes.

The reported number of iterations evaluates to the iteration value that is currently in progress. For example, if the code convergence check is satisfied after row-wise decoding in the third iteration (after 2.5 decoding steps), then the number of iteration returned is 3.

## TPC Decoding Shortened Messages

TPC encoded shortened input messages are decoded using specified 2-D TPC code pairs. Row-wise decoding uses the ( $N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}, S_{\mathrm{C}}$ ) code pair and column-wise decoding uses the ( $N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}, S_{\mathrm{R}}$ ) code pair. The input vector length must be $\left(N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}\right) \times\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$. To perform the 2-D TPC decoding of shortened messages, the column vector of the input LLRs, composed of the shortened message and parity bits, is arranged into an $\left(N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}\right)$-by- $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$ matrix.

The TPC decoder processes the received shortened message LLRs similar to full length codes, with these exceptions:

- The shortened bit positions in the received codeword are set to -1 .
- The Chase algorithm does not consider the shortened bit positions while choosing the least reliable bits.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{Tm}}$.
Usage notes and limitations:

- TPC parameters $N, K$, and $S$ must be constant values. If the value used for each of these parameters does not change, then you can assign them by expression or variable.

## Blocks

TPC Decoder

Introduced in R2018a

## tpcenc

Turbo product code (TPC) encoder

## Syntax

```
code = tpcenc(msg,N,K)
code = tpcenc(msg,N,K,S)
```

## Description

code $=$ tpcenc(msg, $\mathrm{N}, \mathrm{K}$ ) performs 2-D TPC encoding of the input message, msg, using two linear block codes specified by codeword length $N$ and message length K. For a description of 2-D TPC encoding, see "Algorithms" on page 2-811.
code $=$ tpcenc (msg, $\mathrm{N}, \mathrm{K}, \mathrm{S}$ ) performs 2-D TPC encoding on the shortened input message of length S , using a 2-D TPC encoder specified by codeword length ( $\mathrm{N}-\mathrm{K}+\mathrm{S}$ ) and message length S .

## Examples

## Encode Using Full-Length TPC Codes

Encode a random bit vector using 2-D turbo product coding (TPC) with extended Hamming codes and extended BCH codes.

Specify ( $\mathrm{N}, \mathrm{K}$ ) code pairs for TPC encoding.
$\mathrm{N}=[32 ; 64]$;
K = $[21 ; 57]$;
Generate a column vector of random message bits. The desired length for the message bits is the product of elements in K .

```
msg = randi([0 1],prod(K),1);
```

TPC-encode the message.

```
code = tpcenc(msg,N,K);
```

Verify that the length of the encoded codeword is the product of elements in N .

```
size(code)
ans = 1\times2
    2048
prod(N)
ans = 2048
```

## Encode Shortened Message Using Turbo Product Coding

Encode a random bit vector using 2-D turbo product coding (TPC), applying message shortening.
Specify ( $\mathrm{N}, \mathrm{K}$ ) code pairs and S for TPC encoding.
$N=[32 ; 64]$;
K = [21;57];
S = [19;24];
Generate a column vector of random message bits. The desired length for the shortened message bits is the product of the elements in S .

```
msg = randi([0 1],prod(S),1);
```

TPC-encode the shortened message.

```
code = tpcenc(msg,N,K,S);
```

Verify that the length of the encoded codeword is the product of elements in $(\mathrm{N}-\mathrm{K}+\mathrm{S})$.

```
size(code)
```

ans $=1 \times 2$
$930 \quad 1$
$\operatorname{prod}(N-K+S)$
ans $=930$

## Input Arguments

msg - Input message bits to encode
column vector
Input message bits to encode, specified as a column vector.

- For a full-length input messages, the length of the column vector must be the product of the elements in K.
- For a shortened input messages, the length of the column vector must be the product of the elements in S .

Data Types: single | double | int8|int16|int32|uint8|uint16|uint32|logical
N - Codeword length
two-element integer vector
Codeword length, specified as a two-element integer vector, $\left[N_{\mathrm{R}} ; N_{\mathrm{C}}\right] . N_{\mathrm{R}}$ represents the number of rows in the product code matrix. $N_{\mathrm{C}}$ represents the number of columns in the product code matrix. For more information about $N_{\mathrm{R}}$ and $N_{\mathrm{C}}$, see "Algorithms" on page 2-811. For a list of valid ( $N(i), K(i)$ ) code pairs, see "Component Codes" on page 2-810.

Data Types: double

## K - Message length

two-element integer vector
Message length, specified as a two-element integer vector, [ $K_{R} ; K_{C}$ ]. For a full-length message, the input column vector containing the message bits to encode is arranged into a $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix. $K_{\mathrm{R}}$ represents the number of rows in the message matrix. $K_{\mathrm{C}}$ represents the number of columns in the message matrix. For more information about $K_{\mathrm{R}}$ and $K_{\mathrm{C}}$, see "Algorithms" on page 2-811. For a list of valid ( $N(i), K(i)$ ) code pairs, see "Component Codes" on page 2-810.
Data Types: double

## S - Shortened message length

two-element integer vector
Shortened message length, specified as a two-element integer vector, [ $S_{\mathrm{R}} ; S_{\mathrm{C}}$ ]. For a shortened message, the input column vector containing the message bits to encode is arranged into an $S_{\mathrm{R}}$-by- $S_{\mathrm{C}}$ matrix. $S_{\mathrm{R}}$ represents the number of rows in the matrix. $S_{\mathrm{C}}$ represents the number of columns in the matrix. For more information about $S_{\mathrm{R}}$ and $S_{\mathrm{C}}$, see "Algorithms" on page 2-811.

When you specify this parameter, specify $N$ and $K$ vectors for the full-length TPC codes that are shortened to ( $N(i)-K(i)+S(i), S(i))$ codes.

Data Types: double

## Output Arguments

code - TPC-encoded message
column vector
TPC-encoded message, returned as a column vector with the same data type as the input message bits.

- For full-length input messages, the length of the returned column vector is the product of the elements in N .
- For shortened input messages, the length of the returned column vector is the product of the elements in $(\mathrm{N}-\mathrm{K}+\mathrm{S})$.

## More About

## Component Codes

This table lists the supported component code pairs for the row ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) and column ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) parameters.

- $N_{\mathrm{R}}$ and $K_{\mathrm{R}}$ represent the number of rows in the product code matrix and message matrix, respectively.
- $N_{\mathrm{C}}$ and $K_{\mathrm{C}}$ represent the number of columns in the product code matrix and message matrix, respectively.

Within each code type, any two component code pairs can form a 2-D TPC code. The table also includes the error-correction capability for each code pair.

| Code type | Component Code Pairs $\left(N_{\mathrm{R}}, K_{\mathrm{R}}\right)$ and ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) | Error-Correction Capability (T) |
| :---: | :---: | :---: |
| Hamming code | $(255,247)$ | 1 |
|  | $(127,120)$ | 1 |
|  | $(63,57)$ | 1 |
|  | $(31,26)$ | 1 |
|  | $(15,11)$ | 1 |
|  | $(7,4)$ | 1 |
| Extended Hamming code | $(256,247)$ | 1 |
|  | $(128,120)$ | 1 |
|  | $(64,57)$ | 1 |
|  | $(32,26)$ | 1 |
|  | $(16,11)$ | 1 |
|  | $(8,4)$ | 1 |
| BCH code | $(255,239)$ | 2 |
|  | $(127,113)$ | 2 |
|  | $(63,51)$ | 2 |

|  | $(16,15)$ | - |
|  | $(8,7)$ | - |
|  | (4,3) | - |

## Algorithms

Turbo product codes (TPC) are a form of concatenated codes used as forward error-correcting (FEC) codes. Two or more component block codes, such as systematic linear block codes, are used to construct TPCs. This encoder implements 2-D product code encoding, as described in [1], using two "Linear Block Codes".

## Construction of Full-Length Message Product Codes

Full-length input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair and column-wise encoding uses the ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. The input vector length must be $K_{\mathrm{R}} \cdot K_{\mathrm{C}}$. The input message bits vector is arranged into a $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix.

Row-wise encoding uses an ( $N_{C}, K_{C}$ ) systematic linear block encoder with $K_{C}$ bits per row. The rowwise encoding results in a $K_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix that includes parity bits added to each row.

Next, column-wise encoding uses an ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) systematic linear block encoder on each of the $N_{\mathrm{C}}$ columns. Applying this 2-D TPC encoding to the initial $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix results in an $N_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix that includes parity bits added to each row and column.

The 2-D TPC full-code matrix is reshaped into a column vector of length $N_{\mathrm{R}} \cdot N_{\mathrm{C}}$ and returned as the TPC-encoded output.

## Construction of Shortened Message Product Codes

Shortened input messages are encoded using specified 2-D TPC code pairs. Row-wise encoding uses the ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) code pair and column-wise encoding uses an ( $N_{\mathrm{R}}, K_{\mathrm{R}}$ ) code pair. The input vector length must be $S_{\mathrm{R}} \cdot S_{\mathrm{C}}$. The input shortened message bits vector is arranged into an $S_{\mathrm{R}}$-by- $S_{\mathrm{C}}$ matrix. The shortened message matrix prepends two dimensions by padding the beginning of the message matrix with zeros. The resulting matrix is a $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix.

Row-wise encoding uses an ( $N_{\mathrm{C}}, K_{\mathrm{C}}$ ) systematic linear block encoder with $K_{\mathrm{C}}$ bits per row. The rowwise encoding results in a $K_{\mathrm{R}}$-by- $N_{\mathrm{C}}$ matrix that includes parity bits added to each row.

Next, the column-wise encoding uses an $\left(N_{\mathrm{R}}, K_{\mathrm{R}}\right)$ systematic linear block encoder on each of the $N_{\mathrm{C}}$ columns.

Applying this 2-D TPC encoding to the initial $K_{\mathrm{R}}$-by- $K_{\mathrm{C}}$ matrix and excluding the zero-padded bits from the output results in an ( $N_{\mathrm{R}}-K_{\mathrm{R}}+S_{\mathrm{R}}$ )-by- $\left(N_{\mathrm{C}}-K_{\mathrm{C}}+S_{\mathrm{C}}\right)$ matrix. This matrix includes parity bits added to each row and column.

The 2-D TPC shortened-code matrix is reshaped into a column vector of length ( $\left.N_{R}-K_{R}+S_{R}\right) \cdot\left(N_{\mathrm{C}}-K_{\mathrm{C}}\right.$ $+S_{\mathrm{C}}$ ) and returned as the TPC-encoded output.

## References

[1] Pyndiah, R. M. "Near-Optimum Decoding of Product Codes: Block Turbo Codes." IEEE
Transactions on Communications. Volume 46, Number 8, August 1998, pp. 1003-1010.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.
Usage notes and limitations:

- TPC parameters $N, K$, and $S$ must be constant values. If the value used for each of these parameters does not change, then you can assign them by expression or variable.

## varlms

(To be removed) Construct variable-step-size least mean square (LMS) adaptive algorithm object

Note will be removed in a future release. Use comm. LinearEqualizer or comm. DecisionFeedback instead.

## Syntax

alg = varlms(initstep,incstep,minstep,maxstep)

## Description

The varlms function creates an adaptive algorithm object that you can use with the lineareq function or dfe function to create an equalizer object. You can then use the equalizer object with the equalize function to equalize a signal. To learn more about the process for equalizing a signal, see "Equalization".
alg = varlms(initstep,incstep, minstep, maxstep) constructs an adaptive algorithm object based on the variable-step-size least mean square (LMS) algorithm. initstep is the initial value of the step size parameter. incstep is the increment by which the step size changes from iteration to iteration. minstep and maxstep are the limits between which the step size can vary.

## Properties

The table below describes the properties of the variable-step-size LMS adaptive algorithm object. To learn how to view or change the values of an adaptive algorithm object, see "Equalization".

| Property | Description |
| :--- | :--- |
| AlgType | Fixed value, 'Variable Step Size LMS' |
| LeakageFactor | LMS leakage factor, a real number between 0 and <br> 1. A value of 1 corresponds to a conventional <br> weight update algorithm, while a value of 0 <br> corresponds to a memoryless update algorithm. |
| InitStep | Initial value of step size when the algorithm <br> starts |
| IncStep | Increment by which the step size changes from <br> iteration to iteration |
| MinStep | Minimum value of step size |
| MaxStep | Maximum value of step size |

Also, when you use this adaptive algorithm object to create an equalizer object (via the lineareq or dfe function), the equalizer object has a StepSize property. The property value is a vector that lists the current step size for each weight in the equalizer.

## Examples

## Configuring Linear Equalizers

This example configures the recommended comm. LinearEqualizer System object ${ }^{\text {TM }}$ and the legacy lineareq feature with comparable settings.

## Initialize Variables and Supporting Objects

```
d = randi([0 3],1000,1);
x = pskmod(d,4,pi/4);
r = awgn(x,25);
sps = 2; %samples per symbol for oversampled cases
nTaps = 6;
txFilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',nTaps, ...
    'OutputSamplesPerSymbol',4);
rxFilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',nTaps, ...
    'InputSamplesPerSymbol',4,'DecimationFactor',2);
x2 = txFilter(x);
r2 = rxFilter(awgn(x2,25,0.5));
filterDelay = txFilter.FilterSpanInSymbols/2 +
    rxFilter.FilterSpanInSymbols/2; % Total filter delay in symbols
```

To compare the equalized output, plot the constellations using code such as:

```
% plot(yNew,'*')
% hold on
% plot(y0ld,'o')
% hold off; legend('New Eq','Old Eq'); grid on
```

## Use LMS Algorithm with Linear Equalizer

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The LeakageFactor property has been removed from LMS algorithm. The comm. LinearEqualizer System object ${ }^{\mathrm{TM}}$ assumes that leakage factor is always 1.

```
eq0ld = lineareq(5,lms(0.05),pskmod(0:3,4,pi/4))
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 5
    nSampPerSym: 1
    RefTap: 1
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0500
    LeakageFactor: 1
    Weights: [0 0 0 0 0)]
    WeightInputs: [0 0 0 0 0)
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',5,'Algorithm','LMS','StepSize',0.05, ...
            'Constellation',pskmod(0:3,4,pi/4),'ReferenceTap',1)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 5
    StepSize: 0.0500
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 1
    InputDelay: 0
    InputSamplesPerSymbol: 1
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers.
y0ld = equalize(eq0ld,r);
yNew = eqNew(r);

## Use Linear Equalizers Considering Signal Delays

Configure lineareq and comm.LinearEqualizer objects with comparable settings. The transmit and receive filters result in a signal delay between the transit and receive signals. Account for this delay by setting the RefTap property of the lineareq to a value close to the delay value in samples. Additionally, nWeights must be set to a value greater than RefTap.

```
eq0ld = lineareq(filterDelay*sps+4,lms(0.01),pskmod(0:3,4,pi/4),sps);
eqOld.RefTap = filterDelay*sps+1 % Adjust to synchronize with delayed signal
eqOld =
    EqType: 'Linear Equalizer'
    AlgType: 'LMS
    nWeights: 16
    nSampPerSym: 2
    RefTap: 13
    SigConst: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    StepSize: 0.0100
    LeakageFactor: 1
    Weights: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    WeightInputs: [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
    ResetBeforeFiltering: 1
    NumSamplesProcessed: 0
eqNew = comm.LinearEqualizer('NumTaps',16,'Algorithm','LMS','StepSize',0.01, ...
    Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
        'ReferenceTap',filterDelay*sps+1,'InputDelay',0)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 16
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071-0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 13
    InputDelay: 0
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Call the equalizers. When ResetBeforeFiltering is set to true, each call of the equalize object resets the equalizer. To get the equivalent behavior call reset after each call of the comm. LinearEqualizer object.

```
y0ld1 = equalize(eq0ld,r,x(1:100));
y0ld2 = equalize(eq0ld,r,x(1:100));
yNew1 = eqNew(r,x(1:100));
reset(eqNew)
yNew2 = eqNew(r,x(1:100));
```

In the comm. LinearEqualizer object, InputDelay is used to synchronize with the delayed signal. NumTaps and ReferenceTap are independent of delay value. We can reduce the number of taps by utilizing the InputDelay to synchronize instead of reference tap. Reducing the number of taps also reduces equalizer self noise.

```
eqNew = comm.LinearEqualizer('NumTaps',11,'Algorithm','LMS','StepSize',0.01, ...
    'Constellation',pskmod(0:3,4,pi/4),'InputSamplesPerSymbol',sps, ...
    'ReferenceTap',6,'InputDelay',filterDelay*sps)
eqNew = comm.LinearEqualizer with properties:
    Algorithm: 'LMS'
    NumTaps: 11
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    ReferenceTap: 6
    InputDelay: }1
    InputSamplesPerSymbol: 2
    TrainingFlagInputPort: false
    AdaptAfterTraining: true
```

InitialWeightsSource: 'Auto'
WeightUpdatePeriod: 1
yNew1 = eqNew(r2,x(1:100));
reset (eqNew)
$y N e w 2=\operatorname{eqNew}(r 2, x(1: 100))$;

## Algorithms

Referring to the schematics presented in "Equalization", define $w$ as the vector of all current weights $w_{\mathrm{i}}$ and define $u$ as the vector of all inputs $u_{i}$. Based on the current step size, $\mu$, this adaptive algorithm first computes the quantity
$\mu_{0} \quad=\quad \mu \quad+\quad$ Re(gg prev $)$
where $g=u e^{*}, g_{\text {prev }}$ is the analogous expression from the previous iteration, and the * operator denotes the complex conjugate.

Then the new step size is given by

- $\mu_{0}$, if it is between MinStep and MaxStep
- MinStep, if $\mu_{0}<$ MinStep
- MaxStep, if $\mu_{0}>$ MaxStep

The new set of weights is given by

(LeakageFactor) w $+\quad$| $\mu$ | $g^{*}$ |
| :--- | :--- | :--- | :--- |

## Compatibility Considerations

varlms will be removed
Warns starting in R2020a

- varlms will be removed in a future release. Consider using comm. LinearEqualizer or comm. DecisionFeedback instead with the adaptive algorithm set to LMS.
- The comm. LinearEqualizer or comm. DecisionFeedback System objects do not have a leakage factor property. This is equivalent to setting LeakageFactor to 1 in the varlms function.
- For examples comparing setup of comm. LinearEqualizer to lineareq, see "Configuring Linear Equalizers" on page 2-816.

## Topics

"Equalization"

Introduced before R2006a

## vec2mat

(Not recommended) Change dimension

Note is not recommended. Use reshape instead. For more information, see "Compatibility Considerations".

## Syntax

```
mat = vec2mat(vec,matcol)
mat = vec2mat(vec,matcol,padding)
[mat,padded] = vec2mat(
```

$\qquad$

``` )
```

## Description

mat $=$ vec2mat(vec, matcol) converts vector vec to matrix mat with matcol columns. The function creates the matrix one row at a time, filling the rows with elements from vec in order. If the length of vec is not a multiple of matcol, then the function pads the last row of mat with zeros until the row contains matcol elements.
mat $=$ vec $2 \mathrm{mat}(\mathrm{vec}$, matcol, padding $)$ specifies values for the function to use to pad the last row of mat. The function uses the value from padding in order.
[mat, padded] = vec2mat (__) also returns padded, the number of padded elements in the last row of mat. You can specify any of the input argument combinations from previous syntaxes.

## Examples

## Reshape Vector and Add Padding

This example uses shows you how to add padding, as needed, when converting a vector to matrix.
Create a vector that will be converted to a matrix and a vector to provide padding values.

```
vec = [10;20;30;40;50];
padding = [1,2;3,4;5,6];
n = 4;
```

When using vec2mat to convert the vector to a matrix, the function determines needed padding.

```
[mat4,numPadded4] = vec2mat(vec,n,padding)
mat4 =
    10}20\quad30 4
    50 1 3 5
numPadded4 =
    3
```

When using reshape to convert the vector to a matrix, the needed padding must be computed and appended to the vector before converting the vector to a matrix.

```
numPadded = mod(numel(vec),n);
if numPadded > 0
    numPadded = n - numPadded
    mat = reshape([vec.' padding(1:numPadded)], n, []).'
else
    numPadded % No padding required
    mat = reshape(vec.', n, []).'
end
numPadded =
    3
mat =
    10
```

## Input Arguments

## vec - Input array

vector
Input array, specified as a vector.

```
Data Types: single| double| int8| int16| int32|int64|uint8|uint16|uint32|uint64|
logical
Complex Number Support: Yes
```

## matcol - Number of columns

```
positive integer
```

Number of columns for the output matrix mat, specified as a positive integer. If the length of vec is not a multiple of matcol, then the function pads the last row of mat with zeros until the row contains matcol elements.
Data Types: double

## padding - Padding values

vector | matrix
Padding values for the last row of mat, specified as a vector or matrix. The padding input inherits the data type of the vec input. The function uses the values from padding in order. If padding has fewer elements than what the function needs to complete the last row of mat, then the function repeats the last element of padding until mat is full.

## Output Arguments

## mat - Output array

## matrix

Output array, returned as a matrix with elements from vec and having matcol columns. The output inherits the data type of the input. The number of rows is equal to ceil(length(vec)/matcol).

## padded - Number of padded elements

positive integer
Number of padded elements in the last row of mat, returned as a positive integer.

## Compatibility Considerations

## vec2mat is not recommended

Not recommended starting in R2020a

- vec2mat is not recommended. Use reshape instead.
- Given a vector input, reshape creates its corresponding matrix one column at a time (instead of one row at a time).
- reshape requires its input and output arrays to have the same number of elements, whereas vec2mat pads its output matrix if necessary.
- For an example comparing use of reshape to vec2mat, see "Reshape Vector and Add Padding" on page 2-821.

## vitdec

Convolutionally decode binary data by using Viterbi algorithm

## Syntax

```
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,'soft',nsdec)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat)
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat,eraspat)
decodedout = vitdec(codedin,trellis,tbdepth,'cont',dectype,
```

$\qquad$

``` ,imetric,
istate,iinput)
[decodedout,fmetric,fstate,finput] = vitdec(codedin,trellis,tbdepth,'cont',
__)
```

## Description

decodedout = vitdec(codedin,trellis,tbdepth,opmode, dectype) decodes each symbol of the codedin input by using the Viterbi algorithm. All other inputs specify the convolutional coding trellis, traceback depth, operating mode, and decision type, respectively and collectively configure the Viterbi algorithm at runtime.
decodedout = vitdec(codedin,trellis,tbdepth,opmode,'soft',nsdec) configures the Viterbi algorithm for soft-decision decoding for dectype and with nsdec bits of quantization.
decodedout = vitdec(codedin,trellis,tbdepth,opmode, dectype,puncpat) decodes each symbol of the punctured codedin input, where puncpat is the puncture pattern.
decodedout = vitdec(codedin,trellis,tbdepth,opmode, dectype, puncpat,eraspat) specifies an erasure pattern, eraspat. To not use puncturing, specify puncpat as [].
decodedout = vitdec (codedin,trellis, tbdepth, 'cont', dectype, __, imetric, istate, iinput) specifies a continuous operation mode for opmode for any of the preceding syntaxes. The decoder starts with its initial state metrics, traceback states, and traceback inputs specified by imetric, istate, and iinput, respectively.

Continuous operation mode enables you to save the internal state information of the decoder for use in subsequent calls to this function. Repeated calls to this function can be useful if your data is partitioned into a series of vectors that you process within a loop. For workflows that require repeated calls to the Viterbi decoding algorithm, see "Tips" on page 2-833.
[decodedout,fmetric,fstate,finput] = vitdec(codedin,trellis,tbdepth,'cont', ) also returns the final state metrics, traceback states, and traceback inputs at the end of the decoding process when using a continuous operation mode for any of the preceding syntaxes. Use fmetric, fstate, and finput as the initial settings of imetric, istate, and iinput, respectively, in subsequent calls to this function. For workflows that require repeated calls to the Viterbi decoding algorithm, see "Tips" on page 2-833.

## Examples

## Decode Convolutional Code by Using Viterbi Decoder

Convolutionally encode a vector of 1 s by using the convenc function, and decode it by using the vitdec function.

Define a trellis structure, by using the poly2trellis function. Use the trellis structure to configure the convenc function when encoding a vector of ones.

```
trellis = poly2trellis([4 3],[4 5 17;7 4 2]);
x = ones(100,1);
code = convenc(x,trellis);
```

When decoding the encoded message, configure the Viterbi decoder to use the trellis structure defined previously, a traceback depth of 2 , the truncated operating mode, and hard decisions.

```
tb = 2;
decoded = vitdec(code,trellis,tb,'trunc','hard');
```

Verify that the decoded message is a vector of 100 1s.

```
isequal(decoded,ones(100,1))
ans = logical
    1
```

## Decode Punctured Signal Using Viterbi Algorithm

Apply Viterbi decoding to a punctured signal. The puncturing changes the code rate from $1 / 2$ to $3 / 4$.
Initialize parameters for the encoding and decoding operations.

```
trellis = poly2trellis(7,[171 133])
trellis = struct with fields:
    numInputSymbols: 2
    numOutputSymbols: 4
        numStates: 64
        nextStates: [64x2 double]
            outputs: [64x2 double]
puncpat = [1;1;0;1;1;0];
tbdepth = 96;
opmode = 'trunc';
dectype = 'hard';
```

Calculate the unpunctured and punctured code rates.

```
K = log2(trellis.numInputSymbols); % Number of input streams
N = log2(trellis.numOutputSymbols); % Number of output streams
unpunc_coderate = K/N % Unpunctured code rate
unpunc_coderate = 0.5000
punc_coderate = (K/N)*(length(puncpat)/sum(puncpat)) % Punctured code rate
```

punc_coderate $=0.7500$
Convolutionally encode an all 1 s bit message with puncturing applied to the coded output.

```
msg = ones(100*length(puncpat),1);
puncturedcode = convenc(msg,trellis,puncpat);
```

Show the lengths of the message, the punctured code, and the puncture pattern.

```
length(msg)
ans = 600
length(puncturedcode)
ans = 800
length(puncpat)
ans = 6
```

Apply Viterbi decoding to the punctured coded message. Compare the decoded output to the original message. Even with puncturing applied to the coded message, the Viterbi decoding recovered the message with zero error.

```
codedin = puncturedcode;
decodedout = vitdec(codedin,trellis,tbdepth,opmode,dectype,puncpat);
isequal(msg,decodedout)
ans = logical
    1
```

## Estimate BER for Rate 2/3 Convolutional Code

Estimate the bit error rate (BER) simulation for a link that uses a rate $2 / 3$ convolutional code, applies 16-QAM modulation, and transmits data through an AWGN channel. This diagram shows a rate $2 / 3$ encoder with two input streams, three output streams, and seven shift registers.

Define the convolutional coding trellis represented by the diagram.

```
trellis = poly2trellis([5 4],[23 35 0; 0 5 13])
trellis = struct with fields:
    numInputSymbols: 4
    numOutputSymbols: 8
        numStates: 128
        nextStates: [128x4 double]
            outputs: [128x4 double]
K = log2(trellis.numInputSymbols); % Number of input bit streams
N = log2(trellis.numOutputSymbols); % Number of output bit streams
coderate = K/N;
fprintf('K is %d and N is %d. The code rate is %3.2f.\n', ...
    K,N,coderate)
K is 2 and N is 3. The code rate is 0.67.
```

Set the modulation order, and compute the number of bits per modulation symbol. Generate random binary data. The input bit stream must be a multiple of number of the input bit streams (K) for the coding operation and must be a multiple of the number of bits per modulation symbol (bps) for the modulation operation.

```
M = 16; % Modulation order
bps = log2(M); % Bits per modulation symbol
numSymPerFrame = 5000;
dataIn = randi([0 1],K*bps*numSymPerFrame,1);
```

Convolutionally encode the input data.

```
codedout = convenc(dataIn,trellis);
```

Apply 16-QAM modulation to the encoded symbols.
txSig = qammod(codedout, $M$, 'InputType','bit');
Using the number of bits per symbol (bps) and the code rate (coderate), convert the ratio of energy per bit to noise power spectral density (EbNo) to an signal-to-noise ( snr ) value for use by the awgn function. Convert a $10 \mathrm{~dB} \mathrm{~Eb} / \mathrm{No}$ to an equivalent SNR ratio. Pass the signal through an AWGN channel.

```
EbNo = 9;
snr = EbNo + 10*log10(bps*coderate);
rxSig = awgn(txSig,snr,'measured');
```

Demodulate the received signal.

```
demodSig = qamdemod(rxSig,M,'OutputType','bit');
```

Specify the traceback depth of the Viterbi decoder.

```
tbdepth = 16;
```

Decode the binary demodulated signal by using a Viterbi decoder operating in a continuous termination mode.

```
dataOut = vitdec(demodSig,trellis,tbdepth,'cont','hard');
```

Calculate the delay through the decoder, and account for the decoding delay when computing the BER. Compare the coded BER with the theoretical uncoded BER to see the improved BER for the coded data.

```
decDelay = K*tbdepth;
berCoded = biterr(dataIn(1:end-decDelay),data0ut(decDelay+1:end))/length(data0ut(decDelay+1:end)
berUncoded = berawgn(EbNo,'qam',M);
fprintf(' The coded BER is %6.5f.\nThe uncoded BER is %6.5f.\n', ...
    berCoded,berUncoded)
    The coded BER is 0.00060.
The uncoded BER is 0.00439.
```

## Input Arguments

codedin - Convolutionally encoded message
vector of binary values | vector of numeric values
Convolutionally encoded message, specified as a vector of binary or numeric values. Each symbol in codedin consists of log2(trellis.numOutputSymbols) bits.
Data Types: double | logical

## trellis - Trellis description

structure
Trellis description, specified as a structure with these fields for a rate $K / N$ code. $K$ represents the number of input bit streams, and $N$ represents the number of output bit streams. You can either use the poly2trellis function to create the trellis structure or create it manually. For more about this structure, see "Trellis Description of a Convolutional Code" and the istrellis function.

Trellis Structure Fields for Rate K/N Code
numInputSymbols - Number of input symbols
integer
Number of input symbols, specified as an integer with a value of $2^{K}$. This value represents the number of symbols input to the encoder.

Data Types: double

## numOutputSymbols - Number of output symbols

integer
Number of output symbols, specified as an integer with a value of $2^{N}$. This value represents the number of symbols output from the encoder.
Data Types: double
numStates - Number of states
integer
Number of states in the encoder, specified as an integer. numStates must be a power of 2 .
Data Types: double

## nextStates - Next states

matrix of integer values
Next states for all combinations of current states and current inputs, specified as a numStates-by-2 ${ }^{N}$ matrix of integer values.

Data Types: double

## outputs - Outputs

matrix of integer values
Outputs for all combinations of current states and current inputs, specified as a numStates-by-2 ${ }^{N}$ matrix of integer values. The elements of this matrix must be octal numbers.

Data Types: double

## tbdepth - Traceback depth

## positive integer

Traceback depth, specified as a positive integer. For more information, see "Traceback Depth Estimates" on page 2-833.
Data Types: double

## opmode - Operating mode

'cont'|'term'|'trunc'
Operating mode, specified as 'cont ', 'term', or 'trunc'. This input indicates the operating mode of the decoder and these assumptions made about the operation of the corresponding encoder.

- ' cont ' - Specifies continuous operating mode. In continuous operating mode, the encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. A delay equal to input tbdepth symbols elapses before the first decoded symbol appears in the output. This mode is appropriate when you call this function repeatedly and want to preserve continuity between successive calls. For workflows that require repeated calls to the Viterbi decoding algorithm, see "Tips" on page 2-833.
- 'term' - Specifies terminated operating mode. In terminated operating mode, the encoder is assumed to have started and ended at the all-zeros state, which is true for the default syntax of the convenc function. The decoder traces back from the all-zeros state. This mode incurs zero delay.

This mode is appropriate when the message input to the convenc function has enough zeros at its end to fill all memory registers of the encoder. The zero-valued tail bits flush all message data bits out of the encoder. Using the polynomial description of the encoder, for an encoder with $K$ input bits and the constraint length vector ConstraintLength, the number of zeros required to flush the encoder is $K \times \max ($ ConstraintLength -1 ). The constraint length vector is the first input argument to the poly2trellis function.

- 'trunc' - Specifies truncated operating mode. In truncated operating mode, the encoder is assumed to have started at the all-zeros state. The decoder traces back from the state with the best metric. This mode incurs zero delay. This mode is appropriate when you cannot assume the encoder ended at the all-zeros state and when you do not want to preserve continuity between successive calls to this function.

For the 'term' and 'trunc' modes, the traceback depth, tbdepth, must be a positive integer, less than or equal to the number of input symbols in input codedin.

For more information, see "Traceback and Decoding Delay" on page 2-832 and "Traceback Depth Estimates" on page 2-833.
Data Types: char | string

## dectype - Decoding type

'unquant' | 'hard'|'soft'
Decoding type, specified as 'unquant ', 'hard', or 'soft'. This parameter indicates the type of decoding decision that the decoder makes and influences the type of data the decoder expects as input in codedin.

- ' unquant ' - The decoder expects signed numeric input values, where positive values map to a logical 0 and negative values map to a logical 1.
- 'hard ' - The decoder expects binary input values of 0 or 1.
- 'soft ' - The decoder expects integer input values in the range [0, (2 $\left.2^{\text {nsdec }}-1\right)$ ]. The Viterbi algorithm decision criteria regards 0 as the most confident 0 and $2^{\text {nsdec }}-1$ as the most confident 1.

## Data Types: char | string

## nsdec - Number of soft decision quantization bits

integer in the range $[1,13]$
Number of soft decision quantization bits, specified as a integer in the range [1, 13]. For reference, soft decision decoding with 3 bits of quantization improves error decoding recovery by approximately 2 dB as compared to hard decision decoding.

## Dependencies

To enable this input argument set the dectype input argument to 'soft'.
Data Types: double
puncpat - Puncture pattern
vector of binary values
Puncture pattern, specified as a vector of binary values. Indicate punctured bits with 0 s and unpunctured bits with 1 s . The input code length divided by the number of 1 s in the puncture pattern times the length of the puncture pattern must be an integer multiple of the number of bits in an input symbol.

## Data Types: double

## eraspat - Erasure pattern

vector of binary values
Erasure pattern, specified as a vector of binary values. Indicate erased bits with 1 s and nonerased bits with 0 s . The length of the erasures pattern must be the same as the input code length.

## Data Types: double

## imetric - Decoder state metrics

integer | vector of integer values
Decoder state metrics, specified as an integer or a vector of integer values. Each value in imetric represents the starting state metric of the corresponding decoder state. When you set imetric to a
vector, the length must be trellis.numStates. To use the default decoder state metrics, specify imetric as [].

## Dependencies

To enable this input argument set the opmode input argument to ' cont '.
Data Types: double

## istate - Decoder initial traceback states

matrix of integer values
Decoder initial traceback states, specified as a trellis.numStates-by-tbdepth matrix of integer values in the range [0, (trellis.numStates-1)]. To use the default decoder initial traceback states, specify istate as [].

Inputs istate and iinput jointly specify the initial traceback memory of the decoder. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in istate, and the shift register that receives the last input stream provides the most significant bits in istate.

## Dependencies

To enable this input argument set the opmode input argument to ' cont '.

## Data Types: double

## iinput - Decoder initial traceback inputs

matrix of integer values
Decoder initial traceback inputs, specified as a trellis.numStates-by-tbdepth matrix of integer values in the range [ 0 , (trellis.numStates - 1)]. To use the default decoder initial traceback inputs, specify iinput as [].

Inputs istate and iinput jointly specify the initial traceback memory of the decoder.

## Dependencies

To enable this input argument set the opmode input argument to ' cont '.
Data Types: double

## Output Arguments

## decodedout - Decoded message

vector of binary values
Decoded message, returned as a vector of binary values. Each symbol in the vector decodedout consists of log2(trellis.numInputSymbols) bits.

## fmetric - Decoder final state metrics

vector of integer values
Decoder final state metrics, returned as an vector of integer values with trellis.numStates elements. Each value in fmetric represents the final state metric of the corresponding decoder state.

When calling vitdec in continuous mode, fmetric is typically used to set imetric for subsequent calls to the vitdec function.

## Dependencies

This output applies when the opmode parameter is set to 'cont '.
Data Types: double

## fstate - Decoder final traceback states

matrix of integer values
Decoder final traceback states, returned as a trellis.numStates-by-tbdepth matrix of integer values in the range [0, (trellis.numStates - 1 )].

Outputs fstate and finput jointly describe the final traceback memory of the decoder. If the encoder schematic has more than one input stream, the shift register that receives the first input stream provides the least significant bits in fstate, and the shift register that receives the last input stream provides the most significant bits in fstate.

When calling vitdec in continuous mode, fstate is typically used to set istate for subsequent calls to the vitdec function.

## Dependencies

This output applies when the opmode parameter is set to 'cont '.

## Data Types: double

## finput - Decoder final traceback inputs

matrix of integer values
Decoder final traceback inputs, returned as a trellis.numStates-by-tbdepth matrix of integer values in the range [0, (trellis.numStates - 1)].

Outputs fstate and finput jointly specify the final traceback memory of the decoder.
When calling vitdec in continuous mode, finput is typically used to set iinput for subsequent calls to the vitdec function.

## Dependencies

This output applies when the opmode parameter is set to 'cont '.

## Data Types: double

## More About

## Traceback and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

## Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times (ConstraintLength - 1) / ( 1 - coderate). The constraint length of the code, ConstraintLength, is equal to $(\log 2($ trellis.numStates $)+1)$. The coderate is equal to $(K / N) \times(l e n g t h(P u n c t u r e P a t t e r n) /$ sum(PuncturePattern).
$K$ is the number of input symbols, $N$ is the number of output symbols, and PuncturePattern is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate $1 / 2$ code has a traceback depth of 5(ConstraintLength - 1 ).
- A rate $2 / 3$ code has a traceback depth of 7.5(ConstraintLength - 1).
- A rate $3 / 4$ code has a traceback depth of 10(ConstraintLength - 1).
- A rate $5 / 6$ code has a traceback depth of 15 (ConstraintLength - 1 ).

For more information, see [7].

## Tips

- Consider using the comm. ViterbiDecoder System object when successive calls to the Viterbi algorithm are needed. The System object simplifies the required state retention operation by inherently retaining state metrics, traceback states, and inputs between calls.

## wgn

Generate white Gaussian noise samples

## Syntax

```
noise = wgn(m,n,power)
noise = wgn(m,n,power,imp)
noise = wgn(m,n,power,imp,randobject)
noise = wgn(m,n,power,imp,seed)
noise = wgn(
```

$\qquad$

``` , powertype)
noise = wgn(
```

$\qquad$

``` ,outputtype)
```

## Description

noise $=\mathrm{wgn}(\mathrm{m}, \mathrm{n}$, power) generates an m-by-n matrix of white Gaussian noise samples in volts. power specifies the power of noise in dBW.
noise $=\mathrm{wgn}(\mathrm{m}, \mathrm{n}$, power, imp) specifies the load impedance in ohms.
noise $=w g n(m, n$, power, imp, randobject) specifies a random number stream object to use when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see "Tips" on page 2-837.
noise $=\mathrm{wgn}(\mathrm{m}, \mathrm{n}$, power, imp, seed) specifies a seed value for initializing the normal random number generator that is used when generating the matrix of white Gaussian noise samples. For information about producing repeatable noise samples, see "Tips" on page 2-837.
noise $=$ wgn( $\qquad$ , powertype) specifies the units of power as 'dBW', 'dBm', or 'linear' in addition to the input arguments in any of the previous syntaxes.
noise $=$ wgn (__ , , outputtype) specifies the output type as 'real' or 'complex' in addition to the input arguments in any of the previous syntaxes.

## Examples

## Generate White Gaussian Noise

Generate real and complex white Gaussian noise (WGN) samples. Check the power of output WGN matrices.

Generate a 1000 -element column vector of real WGN samples and confirm that the power is approximately 1 watt, which is 0 dBW .

```
y1 = wgn(1000,1,0);
var(y1)
ans = 0.9979
```

Generate a 1000 -element column vector of complex WGN samples and confirm that the power is approximately 0.25 watts, which is -6 dBW .
y2 = wgn(1000,1,-6,'complex');
$\operatorname{var}(\mathrm{y} 2)$
ans $=0.2522$

## Input Arguments

m - Number of white Gaussian noise samples
positive integer
Number of white Gaussian noise samples desired per channel, specified as a positive integer.
Data Types: double
n - Number of channels
positive integer
Number of channels of white Gaussian noise samples desired, specified as a positive integer.
Data Types: double
power - Power of noise samples
scalar
Power of noise samples, specified as a scalar. The default units for power is dBW. Use powertype to change the units of power.

## Data Types: double

## imp - Load impedance

1 (default) | scalar
Load impedance in ohms, specified as a scalar.
Data Types: double
randobject - Random number stream object
RandStream object
Random number stream object, specified as a RandSt ream object. The state of the random stream object determines the sequence of numbers produced by the randn function. Configure the random stream object using the reset function and its properties.
wgn generates normal random noise samples using randn. The randn function uses one or more uniform values from the RandStream object to generate each normal value.

For information about producing repeatable noise samples, see "Tips" on page 2-837.

## seed - Random number generator seed

nonnegative integer
Random number generator seed, specified as a nonnegative integer. For more information on the random number generator, see randn.

## powertype - Signal power unit

## 'dBW' (default) | 'dBm' |'linear'

Signal power unit, specified as 'dBW', 'dBm', or 'linear'. Linear power is in watts.

## outputtype - Output type

'real' (default)|'complex'
Output type, specified as 'real' or 'complex'. If outputtype is 'complex', then the real and imaginary parts of noise each have a noise power of (power / 2).

## Output Arguments

## noise - Output white Gaussian noise samples

scalar | vector | array
Output white Gaussian noise samples in volts, returned as an m-by-n matrix.

Note Unless the default impedance for imp is changed, a load of 1 ohm is used for power calculations.

## Tips

- To generate repeatable white Gaussian noise samples, use one of these tips:
- Provide a static seed value as an input to wgn.
- Use the reset function on the randobject before passing it as an input to wgn.
- Provide randobject in a known state as an input to wgn. For more information, see RandStream.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.
Usage notes and limitations:
Code generation supported, except for syntaxes that include a RandStream object.

"Sources and Sinks"

Introduced before R2006a

## winner2.AntennaArray

Create antenna array

## Syntax

```
antArray = winner2.AntennaArray
antArray = winner2.AntennaArray(Name,Value)
```

## Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see "Get and Manage Add-Ons" (MATLAB).
antArray $=$ winner2.AntennaArray returns a structure representing an antenna array with one isotropic antenna element. Both the antenna array and the single element have no rotation and are located at the origin, $[0 ; 0 ; 0]$.
antArray = winner2. AntennaArray (Name, Value) returns a structure representing an antenna array defined using one or more Name, Value pair arguments.

For more information, see "Antenna Array Model" on page 2-842.

## Examples

## Create WINNER2 Eight Element Uniform Circular Array

Use the winner2.AntennaArray function to create an eight element uniform circular array (UCA-8) with a 1 cm radius.

```
UCA8 = winner2.AntennaArray('UCA',8,0.01);
```

Plot element positions

```
pos = {UCA8.Element(:).Pos};
plot(cellfun(@(x) x(1),pos),cellfun(@(x) x(2),pos),'+');
xlim([-0.02 0.02]);
ylim([-0.02 0.02]);
title('UCA-8 Element Positions');
```

## Create WINNER2 Two Element Uniform Linear Array

Use the winner2. AntennaArray function to create a two element uniform linear array (ULA-2) with 50 cm spacing and the dipole elements slanted at +45 and -45 degrees.

```
az = -180:179; % 1-degree spacing
pattern = cat(1,shiftdim(winner2.dipole(az,45),-1), ...
    shiftdim(winner2.dipole(az,-45),-1));
ULA2 = winner2.AntennaArray('ULA',2,0.5, ...
    'FP-ECS',pattern,'Azimuth',az);
```

## Input Arguments

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: 'Pos',[1 0 0; 0 1 0],'Rot',[0 0 0; 0 pi() 0] indicates the coordinates and rotation angles for two antenna elements.

## Pos - Position of each antenna element

0 (default) | column vector | matrix
Position of each antenna element, specified as the comma-separated pair consisting of 'Pos ' and a column vector or an $N_{\mathrm{E}}$-by- 3 matrix. The three columns represent the x-, y-, and z-coordinates in meters from the origin. $N_{\mathrm{E}}$ indicates the number of elements in the antenna array. The elements have no rotation. When there is more than one element, the 'Element' field of antArray is a row vector of structures representing all the elements.
Example: 'Pos',[63.1 10.2 11.5; 6211 12] indicates the coordinates for two antenna elements.

Data Types: double

## Rot - Rotation angle of each antenna element

0 (default) | column vector | matrix | optional
Rotation angle of each antenna element, specified as the comma-separated pair consisting of 'Rot ' and a column vector or an $N_{\mathrm{E}}$-by- 3 matrix. The three columns represent the $\operatorname{Rot}_{\mathrm{X}}, \operatorname{Rot}_{\mathrm{Y}}$, and $\operatorname{Rot}_{\mathrm{Z}}$ rotation angles of each antenna element in radians. $N_{\mathrm{E}}$ indicates the number of elements in the antenna array. Rot only applies when Pos is specified. If not specified with Pos, the rotation angle is 0.

Example: 'Rot', [2 1.5 0; 0 pi() 0] indicates the rotation angles for two antenna elements. Data Types: double

## UCA - Uniform circular antenna array

N, 1 (default) | N,Rad
Uniform circular antenna array, specified as the comma-separated pair consisting of ' UCA ' and N, Rad. In this argument, N indicates the number of elements $\left(N_{\mathrm{E}}\right)$ and Rad indicates the radius in meters. If Rad is not specified, the default radius is 1 meter.
Example: 'UCA' , 8, 0. 5 indicates an eight element uniform circular array with 0.5 meter radius.
Data Types: double

## ULA - Uniform linear antenna array <br> N, 1/N (default) | N, Spacing

Uniform linear antenna array, specified as the comma-separated pair consisting of 'ULA' and $N$, Spacing. In this argument, $N$ indicates the number of elements $\left(N_{\mathrm{E}}\right)$ and Spacing indicates the separation between adjacent elements in meters. If Spacing is not specified, the default separation is $1 / \mathrm{N}$ meters.

ULA elements are placed along $x$-axis with the center of the array at [ $0 ; 0 ; 0$ ]. For an even number of elements, there is no antenna element at $[0 ; 0 ; 0]$.
Example: 'ULA' , $3,0.25$ indicates a three element uniform linear array with 0.25 meter spacing between adjacent elements.
Data Types: double
FP-ECS - Field pattern of element coordinate system
4-D array

Field pattern of element coordinate system, specified as the comma-separated pair consisting of ' FPECS ' and a $P$-by-2-by1-by- $N_{\mathrm{AZ}}$ array.

- The first dimension, $P$, can be either 1 or any number greater than or equal to the number of elements in the antenna array $\left(N_{\mathrm{E}}\right)$. When $P=1$, the same pattern applies to all elements. When $P>N_{\mathrm{E}}$, the first $N_{\mathrm{E}}$ rows apply.
- The second dimension, 2 , indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization.
- The third dimension, 1 , indicates that one elevation angle characterizes the field pattern.
- The fourth dimension, $N_{\mathrm{AZ}}$, is the number of field pattern samples taken between -180 and 180 degrees. $N_{\mathrm{AZ}}$ equals the number of elements specified in Azimuth or when Azimuth is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

Data Types: double

## FP-ACS - Field pattern array coordinate system

## 4-D array

Field pattern array coordinate system, specified as the comma-separated pair consisting of 'FP-ACS' and a $P$-by-2-by1-by- $N_{\mathrm{Az}}$ array. Array format is the same as the FP-ECS syntax, except that the field pattern is specified in the array-coordinate-system (ACS).

- The first dimension, $P$, can be either 1 or any number greater than or equal to the number of elements in the antenna array $\left(N_{\mathrm{E}}\right)$. When $P=1$, the same pattern applies to all elements. When $P>N_{\mathrm{E}}$, the first $N_{\mathrm{E}}$ rows apply.
- The second dimension, 2 , indicates that two polarizations characterize the field pattern. The first dimension in the field pattern stores vertical polarization, and the second one stores horizontal polarization. Missing polarization dimensions of the field pattern are substituted with zeros.
- The third dimension, 1 , indicates that one elevation angle characterizes the field pattern.
- The fourth dimension, $N_{\mathrm{AZ}}$, is the number of field pattern samples taken between -180 and 180 degrees. $N_{\mathrm{AZ}}$ equals the number of elements specified in Azimuth or when Azimuth is not present it equals the number of equidistant field pattern samples taken over azimuth angle.

## Data Types: double

## Azimuth - Azimuth angles for 'FP-ACS' or 'FP-ECS' field patterns row vector

Azimuth angles for FP-ACS or FP-ECS field patterns in degrees, specified as the comma-separated pair consisting of 'Azimuth' and an 1-by- $N_{\mathrm{AZ}}$ row vector. The values in the row vector indicate azimuth angles for elements in the field patterns.

Note Azimuth applies only when FP-ACS or FP-ECS are defined. If Azimuth is not specified, uniform spacing is used for elements in the field pattern.

Example: 'Azimuth',[0 102090180270340 350]
Data Types: double

## Output Arguments

## antArray - Antenna array definition

structure
Antenna array definition, returned as a structure containing these fields.

## Name - Antenna array name

character vector
Antenna array name, returned as a character vector.

## Pos - Antenna array position

vector
Antenna array position, returned as a 3-by-1 vector, representing the x -, y -, and z -coordinates in meters from the origin.

## Rot - Antenna array rotation

vector
Antenna array rotation, returned as a 3 -by- 1 vector, representing the $R o t_{\mathrm{X}}, \operatorname{Rot}_{\mathrm{Y}}$, and $\operatorname{Rot}_{\mathrm{Z}}$ rotation angles of each antenna element in radians.

## Element - Element definition

row vector of structures
Element definition, returned as a row vector of structures, with each structure representing one element and containing these fields.

## Pos - Antenna array position

vector
Antenna array position, returned as a 3 -by-1 vector, representing the $\mathrm{x}-\mathrm{y}$-, and z -coordinates in meters from the origin.

## Rot - Antenna array rotation

vector
Antenna array rotation, returned as a 3 -by- 1 vector, representing the $\operatorname{Rot}_{\mathrm{X}}, \operatorname{Rot}_{\mathrm{Y}}$, and $\operatorname{Rot}_{\mathrm{Z}}$ rotation angles of each antenna element in radians.

## Aperture - Aperture definition <br> structure

Aperture definition, returned as a structure representing the antenna aperture.

## More About

## Antenna Array Model

To create an antenna array model, you must define the geometry of array elements (positions and rotation) and the element field patterns. The arguments provided to winner2. AntennaArray are always processed such that the array geometry is created first, and then the field patterns are assigned.

For a detailed description of the antenna array specification for the WINNER channel model, see WINNER II Channel Models [1], Section 4.1.

## winner2.dipole

Calculate field pattern of half-wavelength dipole

## Syntax

```
pat = winner2.dipole(az)
pat = winner2.dipole(az,slant)
```

## Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see "Get and Manage Add-Ons" (MATLAB).
pat $=$ winner2.dipole(az) returns the azimuth field pattern of a 0 -degree slanted dipole at the azimuth angles specified in az.
pat $=$ winner2.dipole(az,slant) returns the azimuth field pattern of a slanted dipole at the azimuth angles specified in az.

## Examples

## Create 45 and 90 Degree Slanted Dipoles

```
az = -180:179; % 1 degree spacing
pattern45 = squeeze(winner2.dipole(az, 45));
pattern90 = squeeze(winner2.dipole(az, 90));
fh = figure;
set(fh, 'Position', [100 100 1000 500]);
fh.Name = 'Dipole Pattern Plots';
subplot(1,2,1);
polarplot(az/180*pi, pattern45(1,:), 'r');
hold on;
polarplot(az/180*pi, pattern90(1,:), 'b');
rlim([0 1.5]);
legend('45 degree', '90 degree');
title('Vertical');
subplot(1,2,2);
polarplot(az/180*pi, pattern45(2,:), 'r');
hold on;
polarplot(az/180*pi, pattern90(2,:), 'b');
rlim([0 1.5]);
legend('45 degree','90 degree');
title('Horizontal');
```

## Input Arguments

## az - Azimuth angles

vector
Azimuth angles, specified as a vector indicating the azimuth angles to compute the field pattern gain. Units are in degrees.
Data Types: double
slant - Slant angle
scalar
Slant angle, specified as a scalar representing the counterclockwise angle seen from the front of the dipole. Units are in degrees.

Data Types: double

## Output Arguments

## pat - Field pattern

3-D array
Field pattern, returned as a 2-by-1-by- $N_{\mathrm{AZ}}$ array representing the vertical and horizontal field pattern, where $N_{\mathrm{AZ}}$ is the number of elements in the az input vector.

## References

See Also<br>winner2.AntennaArray|winner2.layoutparset<br>Introduced in R2017a

## winner2.layoutparset

WINNER II layout parameter configuration

## Syntax

cfgLayout = winner2.layoutparset(msIdx,bsIdx, K, arrays)
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax)
cfgLayout $=$ winner2.layoutparset(msIdx, bsIdx, K, arrays, rmax, seed)

## Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see "Get and Manage Add-Ons" (MATLAB).
cfgLayout = winner2.layoutparset(msIdx,bsIdx, K, arrays) returns a structure of randomly generated WINNER II network layout parameters given mobile station (MS) indices, base station (BS) indices, BS to MS links, and antenna array configurations.
cfgLayout = winner2.layoutparset(msIdx,bsIdx,K,arrays,rmax) additionally specifies the maximum layout range used when generating MS and BS positions.
cfgLayout = winner2.layoutparset(msIdx,bsIdx, K, arrays,rmax, seed) additionally specifies a seed value for repeatability. To assign seed when not assigning rmax, specify rmax as [ ].

## Examples

## Create Two MS to One BS WINNER 2 System Layout

Create a WINNER 2 system layout with two mobile stations (MS) connecting to the same base station (BS).

Define antenna arrays for one BS and two MS.

```
BSAA = winner2.AntennaArray('UCA', 8, 0.02); % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA', 2, 0.01); % ULA-2 array for MS
MSAA2 = winner2.AntennaArray('ULA', 4, 0.005); % ULA-4 array for MS
```

Create system layout.

```
MSIdx = [2 3];
BSIdx = {1};
K = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx, ...
    K,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Visualize BS and MS positions.

```
BSPos = cfgLayout.Stations(cfgLayout.Pairing(1,1)).Pos;
MS1Pos = cfgLayout.Stations(cfgLayout.Pairing(2,1)).Pos;
```

```
MS2Pos = cfgLayout.Stations(cfgLayout.Pairing(2,2)).Pos;
plot3(BSPos(1),BSPos(2),BSPos(3),'bo', ...
    MS1Pos(1),MS1Pos(2),MS1Pos(3),'rs', ...
    MS2Pos(1),MS2Pos(2),MS2Pos(3),'rd');
grid on;
xlim([0 500]);
ylim([0 500]);
zlim([0 35]);
xlabel('X-position (m)');
ylabel('Y-position (m)');
zlabel('Elevation (m)');
legend('BS','MS1','MS2','Location','northeast');
```

## Input Arguments

msIdx - Mobile station index
row vector

Mobile station index, specified as a row vector indicating the indices in arrays to serve as mobile stations.

Data Types: double
bsIdx - Base station index
column cell array
Base station index, specified as a column cell array, with each element representing one base station. Each cell element is an integer-valued row vector to indicate the indices in arrays to serve as different sectors of that base station.

Data Types: double

## K - Number of links

scalar
Number of links, specified as a scalar representing the number of BS-MS links to be formulated.
Data Types: double

## arrays - Antenna array configurations

vector of structures
Antenna array configurations, specified as a vector of structures defining all available arrays. All MS and BS sectors are chosen from this vector. The array of elements is typically created using the winner2. AntennaArray function.
Data Types: double

## rmax - Maximum layout range

500 (default) | scalar
Maximum layout range, specified as a scalar representing the maximum layout range in meters used to randomly generate the MS and BS positions.
Data Types: double

## seed - Seed value

integer
Seed value used to provide repeatability, specified as an integer. When seed is not specified, the global random number generator is used. To assign seed when not assigning rmax, specify rmax as [].
Data Types: double

## Output Arguments

## cfgLayout - Configuration layout

structure
Configuration layout, returned as a structure containing these fields, which represent the location and orientation parameters for all simulated stations.

## Stations - Active stations

row vector of structures

Active stations, returned as a row vector of structures describing the antenna arrays for active stations. Stations is created from the arrays input and adds an additional Velocity field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about $1.42 \mathrm{~m} / \mathrm{s}$ with a randomly assigned direction.

## NofSect - Number of sectors

vector
Number of sectors, returned as a vector indicating the number of sectors in each BS.

## Pairing - BS to MS pairing

matrix
BS to MS pairing, returned as a 2-by- $N_{\mathrm{L}}$ matrix, where $N_{\mathrm{L}}$ specifies the number of links to be modeled. See Stations for BS and MS row ordering.

## ScenarioVector - Spatial scenario

1 (default) | vector
Spatial scenario, returned as a 1 -by- $N_{\mathrm{L}}$ vector of scenario numbers. The default is 1 , which specifies scenario A1.

The scenarios numbers map as $\{1=\mathrm{A} 1,2=\mathrm{A} 2,3=\mathrm{B} 1,4=\mathrm{B} 2,5=\mathrm{B} 3,6=\mathrm{B} 4,10=\mathrm{C} 1,11=\mathrm{C} 2,12=\mathrm{C} 3$, $13=C 4,14=D 1,15=D 2 a\}$.

For more information, see WINNER II Channel Models [1], Section 2.3.

## PropagConditionVector - Propagation condition

1 (default) | vector
Propagation condition, returned as a 1-by- $N_{\mathrm{L}}$ vector of propagation conditions (LOS = 1 and NLOS $=$ 0 ) for each link. The default is 1 .

## StreetWidth - Street width

20 (default) | vector
Street width, returned as a 1-by- $N_{\mathrm{L}}$ vector of identical values that specify the average width (in meters) of the streets. StreetWidth is used for the path loss model of the B1 and B2 scenarios. See ScenarioVector for the scenario number mapping. All elements must have the same value. StreetWidth applies only when the PathLossModelUsed field from winner2. wimparset is set to 'yes'.

## Dist1 - Distances from BS to the last LOS point

NaN (default) | vector
Distances from BS to the last LOS point, returned as a 1-by- $N_{\mathrm{L}}$ vector. Dist1 is used for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in path loss function. See ScenarioVector for the scenario number mapping. Dist1 applies only when the PathLossModelUsed field from winner2.wimparset is set to 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

## NumFloors - Floor numbers

1 (default) | vector

Floor numbers, returned as a 1 -by- $N_{\mathrm{L}}$ vector indicating the floor number where the indoor BS or MS is located. The NumFloors property is used for the path loss model of the A2 and B4 scenarios only. See ScenarioVector for the scenario number mapping. NumFloors applies only when the PathLossModelUsed field from winner2.wimparset is set to 'yes'.

NumPenetratedFloors - Number of floors penetrated
0 (default) | vector
Number of floors penetrated, returned as a 1-by- $N_{\mathrm{L}}$ vector indicating the number of penetrated floors between BS and MS. The NumPenetratedFloors property is used for the NLOS path loss model of the A1 scenario. See ScenarioVector for the scenario number mapping. NumPenetratedFloors applies only when the PathLossModelUsed field from winner2. wimparset is set to 'yes'.

For more information, see WINNER II Channel Models [1], Table 4-4.

Introduced in R2017a

## winner2.wim

Generate channel coefficients using WINNER II channel model

## Syntax

```
chanCoef = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays] = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout)
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout,initCond)
```

## Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see "Get and Manage Add-Ons" (MATLAB).
chanCoef = winner2.wim(cfgWim,cfgLayout) returns channel coefficients based on the WINNER II model parameters for all links defined in the WINNER II network layout.
[chanCoef, pathDelays] = winner2.wim(cfgWim,cfgLayout) also returns the path delays for all links.
[chanCoef, pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout) also returns the final condition of the system after generating the channel coefficients.
[chanCoef,pathDelays,finalCond] = winner2.wim(cfgWim,cfgLayout,initCond) generates the channel coefficients by using the initial system conditions rather than of performing random initialization. initCond is of the same form as finalCond and is typically the finalCond output from the prior call of this function. Use this syntax to repeatedly generate channel coefficients for continuous time samples.

## Examples

## Continuously Generate WINNER 2 Channel Coefficients

Continuously generate channel coefficients for each link in a two-link system layout.
Configure model parameters.

```
cfgWim = winner2.wimparset;
cfgWim.SampleDensity = 20;
cfgWim.RandomSeed = 10; % For repeatability
```

Configure layout parameters.

```
BSAA = winner2.AntennaArray('UCA',8,0.02); % UCA-8 array for BS
MSAA1 = winner2.AntennaArray('ULA',2,0.01); % ULA-2 array for MS1
MSAA2 = winner2.AntennaArray('ULA',4,0.005); % ULA-4 array for MS2
MSIdx = [2,3];
```

```
BSIdx = {1};
NL = 2;
rndSeed = 5;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL,[BSAA,MSAA1,MSAA2],[],rndSeed);
```

Generate channel coefficients for the first time.
[H1,~,finalCond] = winner2.wim(cfgWim,cfgLayout);
Generate a second set of channel coefficients.
[H2,~,finalCond] = winner2.wim(cfgWim,cfgLayout,finalCond);
Concatenate H 1 and H 2 in time domain.
H = cellfun(@(x,y) cat(4, x,y), H1, H2, 'UniformOutput', false);
Plot H for the first link, 1st Tx, 1st Rx, and 1st path.

```
figure;
```

Ts = finalCond.delta_t(1); \% Sample time for the 1st link
plot(Ts*(0:2*cfgWim. N̄umTimeSamples-1)', ...
abs(squeeze(H\{1\}(1,1,1,:))));
xlabel('Time (s)');
ylabel('Amplitude');
title('First Path Coefficient of 1st Link, 1st Tx, and 1st Rx');

The image shows the channel continuity over the two outputs from the winner2.wim function.

## Input Arguments

cfgWim - Configuration layout
structure
Configuration model, specified as a structure containing these fields. cfgWim is typically created using the winner2.wimparset function.

## NumTimeSamples - Number of time samples

100 (default) | scalar
Number of time samples, specified as a scalar.

## FixedPdpUsed - Use predefined path delays and powers for specific scenarios

 'no' (default)| 'yes'Use predefined path delays and powers for specific scenarios, specified as 'no' or 'yes'.
FixedAnglesUsed - Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios
'no' (default)|'yes'
Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as 'yes' or 'no'.

## IntraClusterDsUsed - Divide each of the two strongest clusters into three subclusters per link

'yes' (default)|'no'
Divide each of the two strongest clusters into three subclusters per link, specified as 'yes ' or 'no '.

## PolarisedArrays - Use dual-polarized arrays

'yes' (default)|'no'
Use dual-polarized arrays, specified as 'yes' or 'no'.
UseManualPropCondition - Use manually defined propagation conditions
'yes' (default)|'no'
Use manually defined propagation conditions, specified as 'yes ' or 'no'. Set to 'yes' to enforce the use of manually defined propagation conditions (LOS/NLOS) in the PropagConditionVector structure field returned by winner2. layoutparset. Set to 'no' to draw propagation conditions from pre-defined LOS probabilities.

## CenterFrequency - Carrier frequency

5.25e9 (default) | scalar

Carrier frequency in Hz , specified as a scalar.
UniformTimeSampling - Enforce uniform time sampling
'no' (default) |'yes'
Enforce all links to be sampled at the same time instants, specified as 'no ' or 'yes '.

## SampleDensity - Number of time samples per half wavelength <br> 2e6 (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

## DelaySamplingInterval - Sampling interval

5e-9 (default) | scalar
Sampling interval, specified as an scalar indicating the input signal sample time in seconds. DelaySamplingInterval defines the sampling grid to which the path delays are rounded. A value of 0 seconds indicates no rounding on path delays.

## ShadowingModelUsed - Use shadow fading <br> 'no' (default)|'yes'

Use shadow fading, specified as 'no' or 'yes'.

## PathLossModelUsed - Use path loss model

'no' (default)|'yes'
Use path loss model, specified as 'no' or 'yes'.

## PathLossModel - Path loss model

'pathloss' (default) | character vector
Path loss model, specified as a character vector representing a valid function name. PathLossModel applies only when PathLossModelUsed is set to 'yes'.

## PathLossOption - Wall material

'CR_light' (default) | 'CR_heavy ' | 'RR_light'|'RR_heavy'
Wall material, specified as 'CR_light', 'CR_heavy', 'RR_light', or 'RR_heavy', indicating the wall material for the A1 scenario NLOS path loss calculation. PathLossOption applies only when PathLossModelUsed is set to 'yes'.

## RandomSeed - Seed for random number generators

[] (default) | scalar
Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [ ], indicate that the global random stream is used.

## cfgLayout - Configuration layout

structure
Configuration layout, specified as a structure containing these fields, which represent the location and orientation parameters for all simulated stations. cfgLayout is typically created using the winner2.layoutparset function.

## Stations - Active stations

row vector of structures
Active stations, specified as a row vector of structures describing the antenna arrays for active stations. Stations is created from the arrays input of winner2. layoutparset and adds an additional Velocity field. The row ordering specifies base station (BS) sectors first, followed by the mobile stations (MS). The BS sector and MS positions are randomly assigned. The BS sectors have no velocity. Each MS has a velocity of about $1.42 \mathrm{~m} / \mathrm{s}$ with a randomly assigned direction.

## NofSect - Number of sectors

vector
Number of sectors, specified as a vector indicating the number of sectors in each BS.

## Pairing - BS to MS pairing

matrix
BS to MS pairing, specified as a 2-by- $N_{\mathrm{L}}$ matrix, where $N_{\mathrm{L}}$ specifies the number of links to be modeled. See Stations for BS and MS row ordering.

## ScenarioVector - Spatial scenario

1 (default) | vector
Spatial scenario, specified as a 1 -by- $N_{\mathrm{L}}$ vector of scenario numbers. The default is 1 , which specifies scenario A1.

The scenarios numbers map as $\{1=\mathrm{A} 1,2=\mathrm{A} 2,3=\mathrm{B} 1,4=\mathrm{B} 2,5=\mathrm{B} 3,6=\mathrm{B} 4,10=\mathrm{C} 1,11=\mathrm{C} 2,12=\mathrm{C} 3$, $13=C 4,14=D 1,15=D 2 \mathrm{a}\}$.

For more information, see WINNER II Channel Models [1], Section 2.3.

## PropagConditionVector - Propagation condition

1 (default) | vector
Propagation condition, specified as a 1-by- $N_{\mathrm{L}}$ vector of propagation conditions (LOS = 1 and NLOS $=$ 0 ) for each link.

## StreetWidth - Street width

20 (default) | vector
Street width, specified as a 1-by- $N_{\mathrm{L}}$ vector of identical values that specify the average width (in meters) of the streets. StreetWidth is used for the path loss model of the B1 and B2 scenarios. See ScenarioVector for the scenario number mapping. All elements must have the same value. StreetWidth applies only when cfgWim.PathLossModelUsed is set to 'yes'.

## Dist1 - Distances from BS to the last LOS point <br> NaN (default) | vector

Distances from BS to the last LOS point, specified as a 1-by- $N_{\mathrm{L}}$ vector. Dist1 is used for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in path loss function. See ScenarioVector for the scenario number mapping. Dist1 applies only when cfgWim.PathLossModelUsed is set to 'yes'.

For more information, see WINNER II Channel Models [1], Figure 4-3.

## NumFloors - Floor numbers

1 (default) | vector
Floor numbers, specified as a 1-by- $N_{\mathrm{L}}$ vector indicating the floor number where the indoor BS or MS is located. The default value is 1 . The NumFloors field is used for the path loss model of the A2 and B4 scenarios only. See ScenarioVector for the scenario number mapping. NumFloors applies only when cfgWim.PathLossModelUsed is set to 'yes'.

## NumPenetratedFloors - Number of floors penetrated <br> 0 (default) | vector

Number of floors penetrated, specified as a 1-by- $N_{\mathrm{L}}$ vector indicating the number of penetrated floors between BS and MS. The default value is 0 . The NumPenetratedFloors is used for the NLOS path loss model of the A1 scenario. See ScenarioVector for the scenario number mapping. NumPenetratedFloors field applies only when cfgWim.PathLossModelUsed is set to 'yes '.

For more information, see WINNER II Channel Models [1], Table 4-4.

## initCond - Initial system condition

structure | optional
Initial system condition, specified as a structure. initCond is of the same form as finalCond and is typically the finalCond output from the prior call of winner2. wim.

## Data Types: struct

## Output Arguments

## chanCoef - Channel coefficients

cell array containing 4-D arrays of complex values
Channel coefficients, returned as an $N_{\mathrm{L}}$-by- 1 cell array. $N_{\mathrm{L}}$ is the number of links in the system. The $i$ th element of chanCoef is an $N_{\mathrm{R}}(i)$-by- $N_{\mathrm{T}}(i)$-by- $N_{\mathrm{P}}(i)$-by- $N_{\mathrm{S}}$ array. $N_{\mathrm{R}}, N_{\mathrm{T}}$, and $N_{\mathrm{P}}$ are link specific. $N_{\mathrm{S}}$ is the same for all the links.

- $\quad N_{\mathrm{R}}(i)$ is the number of receive antenna elements at MS for the $i$ th link.
- $\quad N_{\mathrm{T}}(i)$ is the number of transmit antenna elements at BS for the $i$ th link.
- $\quad N_{\mathrm{P}}(i)$ is the number of paths for the $i$ th link.
- $N_{\mathrm{S}}$ is the number of time samples given by cfgWim.NumTimeSamples.

For more information, see "Channel Power" on page 2-858.
Data Types: cell

## pathDelays - Path delays

matrix

Path delays, returned as an $N_{\mathrm{L}}$-by-max $N_{\mathrm{P}}$ matrix. $N_{\mathrm{L}}$ is the number of links in the system and max $N_{\mathrm{P}}$ is the maximum number of paths among all links. Each row of the matrix applies to each link. When a link has fewer than $\max N_{P}$ paths, the corresponding row in pathDelays is NaN padded.
Data Types: double

## finalCond - Final system condition

structure
Final system condition, returned as a structure. When generating channel coefficients for continuous time samples, use finalCond as the initCond input for the next call to winner2. wim.

For more information, see WINNER II Channel Models [1], Section 5.2.
Data Types: struct

## More About

## Channel Power

When path loss and shadowing are off, path gains of the computed WINNER channel are normalized. Specifically, path gains are normalized when the ShadowingModelUsed and PathLossModelUsed parameters are set to 'no'.

## winner2.wimparset

WINNER II model parameter configuration

## Syntax

cfgWim $=$ winner2.wimparset

## Description

Download Required: To use this function, first download the WINNER II Channel Model for Communications Toolbox from the Add-On Explorer. For more information on downloading add-ons, see "Get and Manage Add-Ons" (MATLAB).
cfgWim = winner2.wimparset returns a structure of WINNER II model parameters with their default values.

## Examples

## Create a WINNER II model parameter set

cfgWim = winner2.wimparset;
Adjust default settings.
cfgWim.RandomSeed $=31$; set the rng seed for repeatability
cfgWim.NumTimeSamples = 250;
cfgWim. CenterFrequency $=4 e 9$;

## Output Arguments

cfgWim - Configuration layout
structure
Configuration model, returned as a structure containing these fields.

## NumTimeSamples - Number of time samples

100 (default) | scalar
Number of time samples, specified as a scalar.

## FixedPdpUsed - Use predefined path delays and powers for specific scenarios 'no' (default) | 'yes'

Use predefined path delays and powers for specific scenarios, specified as ' no ' or 'yes'.
FixedAnglesUsed - Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios

```
'no' (default)| 'yes
```

Use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as 'yes' or 'no'.

## IntraClusterDsUsed - Divide each of the two strongest clusters into three subclusters per link <br> 'yes' (default)| 'no'

Divide each of the two strongest clusters into three subclusters per link, specified as 'yes ' or 'no '.

## PolarisedArrays - Use dual-polarized arrays

'yes' (default)|'no'
Use dual-polarized arrays, specified as 'yes' or 'no'.
UseManualPropCondition - Use manually defined propagation conditions 'yes' (default)|'no'

Use manually defined propagation conditions, specified as 'yes ' or 'no'. Set to 'yes' to enforce the use of manually defined propagation conditions (LOS/NLOS) in the PropagConditionVector structure field returned by winner2. layoutparset. Set to 'no' to draw propagation conditions from pre-defined LOS probabilities.

## CenterFrequency - Carrier frequency

5.25 e 9 (default) | scalar

Carrier frequency in Hz , specified as a scalar.
UniformTimeSampling - Enforce uniform time sampling
'no' (default)|'yes'
Enforce all links to be sampled at the same time instants, specified as 'no' or 'yes '.

## SampleDensity - Number of time samples per half wavelength

2e6 (default) | scalar
Number of time samples per half wavelength, specified as a scalar.

## DelaySamplingInterval - Sampling interval

5e-9 (default) | scalar
Sampling interval, specified as an scalar indicating the input signal sample time in seconds. DelaySamplingInterval defines the sampling grid to which the path delays are rounded. A value of 0 seconds indicates no rounding on path delays.

## ShadowingModelUsed - Use shadow fading <br> 'no' (default)|'yes'

Use shadow fading, specified as 'no' or 'yes'.

## PathLossModelUsed - Use path loss model <br> 'no' (default)|'yes'

Use path loss model, specified as 'no' or 'yes'.

## PathLossModel - Path loss model

'pathloss' (default) | character vector
Path loss model, specified as a character vector representing a valid function name. PathLossModel applies only when PathLossModelUsed is set to 'yes'.

## PathLossOption - Wall material

'CR_light' (default)|'CR_heavy'|'RR_light'| 'RR_heavy'
Wall material, specified as 'CR_light', 'CR_heavy', 'RR_light', or 'RR_heavy', indicating the wall material for the A1 scenario NLOS path loss calculation. PathLoss0ption applies only when PathLossModelUsed is set to 'yes'.

## RandomSeed - Seed for random number generators

[ ] (default) | scalar
Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [ ], indicate that the global random stream is used.

Introduced in R2017a

## zadoffChuSeq

Generate root Zadoff-Chu sequence

## Syntax

seq $=$ zadoffChuSeq( $\mathrm{R}, \mathrm{N}$ )

## Description

seq $=$ zadoffChuSeq $(R, N)$ generates the Rth root Zadoff-Chu sequence with length $N$, as defined in 3GPP TS 36.211.

The function generates the sequence using the algorithm given by
$\operatorname{seq}(m+1)=\exp (-j \cdot \pi \cdot R \cdot m \cdot(m+1) / N)$, for $m=0, \ldots, N-1$.
The function uses a negative polarity on the argument of the exponent, that is, a clockwise sequence of phases.

## Examples

## Examine Correlation Properties of Root Zadoff-Chu Sequence

Generate the 25th root Zadoff-Chu sequence with a length of 139 .
Plot the absolute values of the output sequence.

```
seq = zadoffChuSeq(25,139);
plot(abs(xcorr(seq)./length(seq)))
```

## Input Arguments

## R - Root of Zadoff-Chu sequence <br> positive integer

Root of the Zadoff-Chu sequence, specified as a positive integer.
Example: 25
Data Types: double

## N - Length of Zadoff-Chu sequence

odd positive integer
Length of the Zadoff-Chu sequence, specified as an odd positive integer.
Example: 139
Data Types: double

## Output Arguments

## seq - Rth root Zadoff-Chu sequence

column vector of complex values
Rth root Zadoff-Chu sequence, returned as an N -by-1 vector of complex values.

## Compatibility Considerations

lteZadoffChuSeq was renamed to zadoffChuSeq
Behavior changed in R2019a
In release R2019a, the lteZadoffChuSeq function was renamed to zadoffChuSeq

## bleATTPDU

Generate BLE ATT PDU

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

attPDU = bleATTPDU(cfgATT)

## Description

attPDU $=$ bleATTPDU(cfgATT) generates a Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU) corresponding to the BLE ATT PDU configuration object cfgATT.

## Examples

## Generate BLE ATT PDUs

Generate two unique BLE ATT PDUs of type 'Read by type request' and 'Error response'.
Create a BLE ATT PDU configuration object with default settings.
cfgATT = bleATTPDUConfig;
Change the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.

```
cfgATT.Opcode = 'Read by type request'
cfgATT =
    bleATTPDUConfig with properties:
            Opcode: 'Read by type request'
        StartHandle: '0001'
            EndHandle: 'FFFF'
        AttributeType: '2800'
```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

attPDU $=7 \times 2$ char array
'08'
'01'
'00'
'FF'
'FF'

```
'00'
'28'
```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode to 'Error response'. View the applicable properties of the opcode 'Error response'.

```
cfgATT = bleATTPDUConfig('Opcode','Error response')
cfgATT =
    bleATTPDUConfig with properties:
            Opcode: 'Error response'
        RequestedOpcode: 'Read request'
        AttributeHandle: '0001'
            ErrorMessage: 'Invalid handle'
```

Generate a BLE ATT PDU corresponding to this configuration object.

```
attPDU = bleATTPDU(cfgATT)
```

attPDU $=5 \times 2$ char array
'01'
'0A'
'01'
'00'
'01'

## Input Arguments

cfgATT - BLE ATT PDU configuration object
bleATTPDUConfig object
BLE ATT PDU configuration object, specified as a bleATTPDUConfig object. This value defines the type of BLE ATT PDU and its applicable properties.

## Output Arguments

## attPDU - Generated BLE ATT PDU

character array
Generated BLE ATT PDU, returned as a character array. Each row in this array is the hexadecimal representation of an octet.

## bleATTPDUDecode

Decode BLE ATT PDU

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[status,cfgATT] = bleATTPDUDecode(attPDU)

## Description

[status,cfgATT] = bleATTPDUDecode(attPDU) decodes the specified Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU), returning the corresponding BLE ATT PDU configuration object, cfgATT, and the decoding status, status.

## Examples

## Decode BLE ATT PDUs

Decode two unique BLE ATT PDUs of type 'Read by type request' and 'Error response'.
Create a BLE ATT PDU configuration object with default settings.

```
cfgATT = bleATTPDUConfig;
```

Change the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.

```
cfgATT.Opcode = 'Read by type request'
```

```
cfgATT =
```

    bleATTPDUConfig with properties:
            Opcode: 'Read by type request'
            StartHandle: '0001'
            EndHandle: 'FFFF'
        AttributeType: '2800'
    Generate a BLE ATT PDU using the corresponding configuration object.
attPDU $=$ bleATTPDU(cfgATT)
attPDU $=7 \times 2$ char array
'08'
'01'
'00'
'FF'

```
'FF'
'00'
'28'
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode 'Read by type request'.

```
[status, cfg] = bleATTPDUDecode(attPDU)
status =
Success
cfg=
    bleATTPDUConfig with properties:
                Opcode: 'Read by type request'
        StartHandle: '0001'
            EndHandle: 'FFFF'
        AttributeType: '2800'
```

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode as 'Error response'. View the applicable properties of the opcode 'Error response'.

```
cfgATT = bleATTPDUConfig('Opcode','Error response')
cfgATT =
    bleATTPDUConfig with properties:
            Opcode: 'Error response'
        RequestedOpcode: 'Read request'
        AttributeHandle: '0001'
            ErrorMessage: 'Invalid handle'
```

Generate a BLE ATT PDU using the corresponding configuration object.

```
attPDU = bleATTPDU(cfgATT)
attPDU = 5x2 char array
    '01'
    '0A'
    '01'
    '00'
    '01'
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode 'Error response'.

```
[status, cfg] = bleATTPDUDecode(attPDU)
status =
Success
cfg =
    bleATTPDUConfig with properties:
```

Opcode: 'Error response'
RequestedOpcode: 'Read request'
AttributeHandle: '0001'
ErrorMessage: 'Invalid handle'

## Decode Corrupted BLE ATT PDU

Specify a BLE ATT PDU containing corrupted data values.

```
attPDU = ['09'; '03'; '01'; '00'; '18'; '0D']; % Sample corrupted BLE ATT PDU
```

Decode the specified BLE ATT PDU. The returned status indicates that the decoding failed due to mismatched attribute data lengths. In case of failed decoding, BLE ATT PDU configuration object, ' cfgATT' ' displays no properties.

```
[status, cfgATT] = bleATTPDUDecode(attPDU)
```

status =
MismatchAttributeDataLength
cfgATT $=$
bleATTPDUConfig with properties:

## Input Arguments

attPDU - BLE ATT PDU
character vector | string scalar | numeric vector | character array
BLE ATT PDU, specified as one of these values:

- Character vector - This vector represent octets in hexadecimal format.
- String scalar - This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range $[0,255]$ - This vector represent octets in decimal format.
- $n$-by- 2 character array - Each row represent an octet in hexadecimal format.

Data Types: char | uint8|uint16|uint32 | double | string

## Output Arguments

## cfgATT - BLE ATT PDU configuration object

bleATTPDUConfig object
BLE ATT PDU configuration object, returned as a bleATTPDUConfig object. This value denotes the decoded BLE ATT PDU configuration.

## status - Packet decoding status

nonpositive integer

Packet decoding status, returned as a nonpositive number of type blePacketDecodeStatus. This value represents the result of an ATT PDU decoding. Each value of status corresponds to a member of the blePacketDecodeStatus enumeration class, which indicates the packet decoding status according to this table.

| Enumeration Value | Member of Enumeration <br> Class | Decoding Status |
| :--- | :--- | :--- |
| 0 | Success | Packet decoding succeeded |
| -401 | UnsupportedATTOpcode | Invalid ATT opcode |
| -402 | IncompleteATTPDU | Incomplete ATT PDU |
| -403 | InvalidATTReqOpcodeInErr <br> orResp | Invalid requested opcode in <br> "Error Response" PDUs |
| -404 | InvalidATTErrorCode | Invalid error code |
| -405 | InvalidATTRxMTU | Invalid received MTU |
| -406 | InvalidAttributeHandleRa <br> nge | Invalid attribute handle range |
| -407 | InvalidAttributeType | Invalid attribute type flag |
| -408 | InvalidATTExecuteWriteFl <br> ag | Invalid execute write flag |
| -409 | MismatchAttributeDataLen <br> gth | Length mismatches with actual <br> length |
| -410 | InvalidATTDataFormat | Invalid Data Format |

An enumeration value other than 0 means that the BLE ATT PDU decoding failed. If the decoding fails, object cfgATT displays no output.

## bleGAPDataBlock

Generate BLE GAP data block

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

dataBlock = bleGAPDataBlock(cfgGAP)

## Description

dataBlock = bleGAPDataBlock(cfgGAP) generates a Bluetooth low energy (BLE) generic access profile (GAP) data block of type advertising data (AD) or scan response data (SRD) corresponding to the BLE GAP data block configuration object cfgGAP.

## Examples

## Generate BLE GAP AD Blocks

Generate three unique BLE GAP AD blocks: first one with AD types 'Flags ' and 'Tx power level', the second one with AD types 'Advertising interval' and 'Local name' and the third one with AD type 'Flags ' and having simultaneous support for low energy (LE) and basic rate/ enhanced data rate (BR/EDR) at the host.

Create a configuration object for a BLE GAP AD block and specify the AD types as 'Flags' and 'Tx power level'. Assign the values of LED discoverability as 'Limited ' and Tx power level as 45.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.AdvertisingDataTypes = {'Flags';'Tx power level'};
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.TxPowerLevel = 45;
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
dataBlock = 6x2 char array
    '02'
    '01'
    '05'
    '02'
    '0A'
    '2D'
```

Create a configuration object for a BLE GAP AD block, this time with advertising data types as 'Advertising interval' and 'Local name'. Specify the values of the advertising interval as 48, the local name as 'MathWorks ' and the local name shortening as true.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval', ...
    'Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true;
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
dataBlock = 15x2 char array
    '03'
    '1A'
    '30'
    '00'
    '0A'
    '08'
    '4D'
    '61'
    '74'
    '68'
    '57'
    '6F'
    '72'
    '6B'
    '73'
```

Create a configuration object for a BLE GAP AD block with type ' Flags'. Specify the values of LE discoverability as 'Limited ', BR/EDR support as true, and simultaneous support for LE and BR/EDR as 'Host'.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.BREDR = true;
cfgGAP.LE = 'Host';
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP)
dataBlock = 3x2 char array
    '02'
    '01'
    '11'
```

## Input Arguments

## cfgGAP - BLE GAP data block configuration object

bleGAPDataBlockConfig (default) | object

BLE GAP data block configuration object, specified as a bleGAPDataBlockConfig object. This value defines the type of BLE GAP data block and its applicable properties.

## Output Arguments

## dataBlock - Generated BLE GAP data block

character array
Generated BLE GAP data block, returned as a character array. Each row in this array is the hexadecimal representation of an octet.

## bleGAPDataBlockDecode

Decode BLE GAP data block

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[status,cfgGAP] = bleGAPDataBlockDecode(dataBlock)

## Description

[status,cfgGAP] = bleGAPDataBlockDecode(dataBlock) decodes a Bluetooth low energy (BLE) generic access profile (GAP) data block, dataBlock, of the type advertising data (AD) or scan response data (SRD), returning the decoding status, status, and the BLE GAP data block configuration object, cfgGAP.

## Examples

## Decode BLE GAP AD Blocks

Decode two unique BLE GAP AD blocks: one with AD types 'Flags' and 'Tx power level' and the other with AD types 'Advertising interval' and 'Local name'.

Create a configuration object for a BLE GAP AD block. Specify the AD types as 'Flags' and 'Tx power level'. Set the values of LE discoverability as 'Limited' and Tx power level to 45. View the properties of the configuration object 'cfgGAP'.

```
cfgGAP = bleGAPDataBlockConfig;
cfgGAP.AdvertisingDataTypes = {'Flags'; 'Tx power level'};
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.TxPowerLevel = 45
cfgGAP =
    bleGAPDataBlockConfig with properties:
        AdvertisingDataTypes: {2x1 cell}
            LEDiscoverability: 'Limited'
                    BREDR: 0
                    TxPowerLevel: 45
```

Generate a BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of 'status' and 'cfgGAP'.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
status =
Success
cfgGAP =
    bleGAPDataBlockConfig with properties:
        AdvertisingDataTypes: {2x1 cell}
        LEDiscoverability: 'Limited'
                    BREDR: 0
            TxPowerLevel: 45
```

Create another BLE GAP AD block configuration object, this time specifying AD types 'Advertising interval' and 'Local name'. Set the values of advertising interval as 48, local name as
'MathWorks', and local name shortening as true. View the properties of the configuration object 'cfgGAP'.

```
cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
    {'Advertising interval','Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true
cfgGAP =
    bleGAPDataBlockConfig with properties:
        AdvertisingDataTypes: {2x1 cell}
            LocalName: 'MathWorks'
        LocalNameShortening: 1
        AdvertisingInterval: 48
```

Generate the BLE GAP AD block from the corresponding configuration object.

```
dataBlock = bleGAPDataBlock(cfgGAP);
```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful. View the output of 'status' and 'cfgGAP'.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
status =
Success
cfgGAP =
    bleGAPDataBlockConfig with properties:
        AdvertisingDataTypes: {2x1 cell}
            LocalName: 'MathWorks'
        LocalNameShortening: 1
        AdvertisingInterval: 48
```

## Decode Corrupted BLE GAP AD Block

Specify a BLE GAP AD block containing corrupted data values.

```
dataBlock = ['010106010202']; % Sample BLE GAP AD block with corrupted data values
```

Decode the specified BLE GAP AD block. The returned status indicates that the decoding failed due to the corrupted input BLE GAP AD block. In this case, when decoding fails, the BLE GAP AD block configuration object, ' cfgGAP' , displays no properties.

```
[status, cfgGAP] = bleGAPDataBlockDecode(dataBlock)
status =
MismatchGAPADLength
cfgGAP =
    bleGAPDataBlockConfig with properties:
```

## Input Arguments

## dataBlock - BLE GAP data block

character vector $\mid$ string scalar | numeric vector | character array
BLE GAP data block, specified as one of these values:

- Character vector - This vector represents octets in hexadecimal format.
- String scalar - This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] - This vector represents octets in decimal format.
- $n$-by- 2 character array - Each row represents an octet in hexadecimal format.

Data Types: char | string | double

## Output Arguments

## status - BLE GAP data block decoding status

nonpositive integer
BLE GAP data block decoding status, returned as a nonpositive integer of type
blePacketDecodeStatus. This value represents the result of an BLE GAP data block decoding. Each value of status corresponds to a member of the blePacketDecodeStatus enumeration class, which indicates the packet decoding status according to this table.

| Enumeration Value | Member of Enumeration <br> Class | Decoding Status |
| :--- | :--- | :--- |
| 0 | Success | Packet decoding succeeded |
| -201 | InvalidGAPADLength | GAP AD length is not valid |
| -202 | MismatchGAPADLength | Received AD length does not <br> match with actual length |

| -203 | UnsupportedGAPADType | Advertising data type is not <br> valid or not supported |
| :--- | :--- | :--- |
| -204 | InvalidGAPAdvertisingInt <br> erval | Advertising interval is not valid |
| -205 | InvalidGAPConnectionInte <br> rvalRange | Invalid connection interval |
| -206 | InvalidGAPConnectionInte <br> rvalMinimum | Invalid interval minimum |
| -207 | InvalidGAPConnectionInte <br> rvalMaximum | Invalid interval maximum |

An enumeration value other than 0 means that the BLE GAP data block decoding failed. If the decoding fails, object cfgGAP displays no output.

## cfgGAP - BLE GAP data block configuration object

bleGAPDataBlockConfig|object
BLE GAP data block configuration object, returned as a bleGAPDataBlockConfig object. This value defines the type of BLE GAP data block and its applicable properties.

## bleIdealReceiver

Ideal receiver for BLE PHY waveform

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{mm}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[bits,accessAddr] = bleIdealReceiver(waveform)
[bits,accessAddr] = bleIdealReceiver(waveform,Name,Value)

## Description

[bits,accessAddr] = bleIdealReceiver(waveform) decodes the Bluetooth low energy (BLE) waveform, generated by bleWaveformGenerator, and returns the received bits, bits, and the access address information, accesAddr.
[bits,accessAddr] = bleIdealReceiver(waveform,Name,Value) also specifies options using one or more name-value pair arguments. For example, 'Mode ' , 'LE2M' specifies the physical (PHY) layer transmission mode of the desired BLE waveform.

## Examples

## Decode BLE Waveform Using Default Settings

Create an input message column vector of length 1000 containing random binary values. Generate a BLE transmit waveform from the transmission bits by using the bleWaveformGenerator function.

```
txBits = randi([0 1],1000,1);
txWaveform = bleWaveformGenerator(txBits);
```

Pass the transmit waveform through a noisy channel and obtain the received waveform.

```
snr = 30; % specified in dB
rxWaveform = awgn(txWaveform,snr);
```

Recover data bits from the received BLE waveform using bleIdealReceiver. Check for the number of bit errors in the recovered bits. The returned value indicates that the BLE waveform was successfully decoded.

```
[rxBits,accessAddr] = bleIdealReceiver(rxWaveform);
numErr = biterr(txBits,rxBits)
numErr = 0
```

## Decode BLE Waveform Using Specified Name-Value Pairs

Specify the values of PHY generating mode, channel index and samples per symbol (sps).

```
phyMode = 'LE125K';
chanIndex = 2;
sps = 4
```

Generate transmission bits containing random binary values. Obtain the BLE transmit waveform from the transmission bits and the specified name-value pairs using the bleWaveformGenerator function.

```
txBits = randi([0 1],100,1);
txWaveform = bleWaveformGenerator(txBits,'Mode',phyMode,...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIndex);
```

Recover the data bits, and then compare them with the transmission bits. The recovered data bits match the transmission bits, indicating there are no errors in the decoded BLE waveform.

```
rxBits = bleIdealReceiver(txWaveform,'Mode',phyMode,...
    'SamplesPerSymbol',sps,'ChannelIndex',chanIndex);
isequal(txBits,rxBits)
ans = logical
    1
```

## Input Arguments

waveform - Received time-domain signal
complex-valued vector
Received time-domain signal, specified as a complex-valued signal with size $N_{\mathrm{s}}$-by-1, where $N_{\mathrm{s}}$ represents the number of received samples. The values of $N_{\mathrm{s}}$ depend on the 'Mode' and 'SamplesPerSymbol ' (sps) name-value pairs, according to the constraints specified in this table. For example, if the value of 'Mode' is 'LE1M' and the value of 'SamplesPerSymbol' is 4 then the value of $N_{\mathrm{s}}$ must be greater than or equal to 160 and a multiple of 'SamplesPerSymbol' .

| Value of 'Mode' | Value of $\boldsymbol{N}_{\mathbf{s}}$ | Multiple of |
| :--- | :--- | :--- |
| 'LE1M' | $\geq 40 \times s p s$ | $s p s$ |
| 'LE2M' | $\geq 48 \times s p s$ | $s p s$ |
| 'LE500K' | $\geq 376 \times s p s$ | $2 \times s p s$ |
| 'LE125K' | $\geq 376 \times s p s$ | $8 \times s p s$ |

## Data Types: double | single

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: bleIdealReceiver(waveform, 'Mode', 'LE2M' ', 'ChannelIndex' , 36)

## Mode - PHY transmission mode

'LE1M' (default) |'LE2M' | 'LE500K' | 'LE125K'
PHY transmission mode, specified as the comma-separated pair consisting of 'Mode' and 'LE1M', 'LE2M', 'LE500K', or 'LE125K'. This value indicates the type of PHY used to decode the received BLE waveform.

Data Types: string|char

## ChannelIndex - Channel Index

37 (default) | integer in the range [0, 39]
Channel index, specified as the comma-separated pair consisting of 'Channel Index' and an integer in the range [0, 39]. For data channels, this value must be in the range [0, 36]. For advertising channels, this value must be in the range [37, 39]. This value is used by the data-dewhitening block.
Data Types: single | double

## SamplesPerSymbol - Samples per symbol <br> 8 (default) | positive integer

Samples per symbol, specified as the comma-separated pair consisting of 'SamplesPerSymbol' and a positive integer. This value is used for the Gaussian frequency shift keying (GFSK) modulation.
Data Types: single | double

## Output Arguments

## bits - Payload bits

column vector
Payload bits, returned as a column vector of maximum length 260 bytes. This output represents the recovered information bits.

## accessAddr - Access address information

32-bit column vector
Access address information, returned as a 32-bit column vector. This output is used by the higher layers for validating a packet.

## bleL2CAPFrame

Generate BLE L2CAP frame

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

L2CAPFrame = bleL2CAPFrame(cfgL2CAP)
L2CAPFrame = bleL2CAPFrame(cfgL2CAP,SDU)

## Description

L2CAPFrame = bleL2CAPFrame(cfgL2CAP) generates a Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) frame, L2CAPF rame, for a given BLE L2CAP configuration object, cfgL2CAP. Use this syntax to generate the signaling frames.

L2CAPFrame = bleL2CAPFrame(cfgL2CAP,SDU) generates a BLE L2CAP frame, L2CAPFrame, for a given BLE L2CAP configuration object cfgL2CAP and the upper-layer payload service data unit (SDU), SDU. Use this syntax to generate the data frames.

## Examples

## Generate BLE L2CAP Signaling Command Frame

Create a BLE L2CAP configuration object, ' cfgL2CAP' , and view the corresponding default properties.

```
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
            ChannelIdentifier: '0005'
                            CommandType: 'Credit based connection request'
            SignalIdentifier: '01'
        SourceChannelIdentifier: '0040'
                            LEPSM: '001F'
            MaxTransmissionUnit: 23
                MaxPDUPayloadSize: 23
                            Credits: 1
```

Change the value of credits to 10 .

```
cfgL2CAP.Credits = 10;
```

Generate a BLE L2CAP signaling command frame from the corresponding configuration object.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP)
l2capFrame = 18x2 char array
    '0E'
    '00'
    '05'
    '00'
    '14
    '01'
    '0A'
    '00'
    '1F'
    '00'
    '40'
    '00'
    '17'
    '00'
    '17'
    '00'
    '0A'
    '00'
```

## Generate BLE L2CAP Data Frames

Generate two unique BLE L2CAP data frames: one with SDU from the attribute protocol (ATT) layer as '0A0100' and the other with an upper-layer payload SDU, '0A01E2D3'.

Create a BLE L2CAP configuration object, ' cfgL2CAP' , and view the default properties.
cfgL2CAP $=$ bleL2CAPFrameConfig
cfgL2CAP =
bleL2CAPFrameConfig with properties:
ChannelIdentifier: '0005'
CommandType: 'Credit based connection request' SignalIdentifier: '01' SourceChannelIdentifier: '0040'

LEPSM: '001F'
MaxTransmissionUnit: 23
MaxPDUPayloadSize: 23
Credits: 1

Change the value of channel identifier to '0004 '.
cfgL2CAP.ChannelIdentifier = '0004'; \% Channel identifier for ATT
Generate a BLE L2CAP data frame from ' cfgL2CAP', specifying the upper-layer payload SDU from the ATT layer as '0A0100'.

```
l2capFrame = bleL2CAPFrame(cfgL2CAP,"0A0100")
l2capFrame = 7x2 char array
        '03'
```

```
'00'
'04'
'00'
'0A'
'01'
'00'
```

Create another BLE L2CAP configuration object, ' cfgL2CAP', with default properties. Set the value of channel identifier to '007A'.

```
cfgL2CAP = bleL2CAPFrameConfig;
cfgL2CAP.ChannelIdentifier = '007A'; % Dynamic channel identifier
```

Generate a BLE L2CAP data frame from 'cfgL2CAP' , specifying the upper-layer payload SDU as '0A01E2D3'.
l2capFrame = bleL2CAPFrame(cfgL2CAP,['0A'; '01'; 'E2'; 'D3'])
l2capFrame = 10x2 char array
'06'
'00'
'7A'
'00'
'04'
'00'
'0A'
'01'
'E2'
'D3'

## Input Arguments

## cfgL2CAP - BLE L2CAP configuration object

bleL2CAPFrameConfig object
BLE L2CAP configuration object, specified as a bleL2CAPF rameConfig object. The function uses this object to configure the BLE L2CAP frame and its applicable properties.

## SDU - Upper-layer payload

character vector | string scalar | numeric vector | character array
Upper-layer payload, specified as one of these types:

- Character vector - This vector represents octets in hexadecimal format.
- String scalar - This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] - This vector represents octets in decimal format.
- $n$-by- 2 character array - Each row represents an octet in hexadecimal format.

Data Types: char|double | string

## Output Arguments

## L2CAPFrame - Generated BLE L2CAP frame

character array

Generated BLE L2CAP frame, returned as a character array. Each row of the array represents an octet in hexadecimal format. This value represents the output BLE L2CAP frame.

## bleL2CAPFrameDecode

Decode BLE L2CAP frame

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[status,cfgL2CAP,SDU] = bleL2CAPFrameDecode(L2CAPFrame)

## Description

[status,cfgL2CAP,SDU] = bleL2CAPFrameDecode(L2CAPFrame) decodes the specified Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) frame, L2CAPF rame. The function returns the decoding status, status, the corresponding BLE L2CAP configuration object, cfgL2CAP, and the upper-layer payload service data unit (SDU), SDU.

## Examples

## Decode BLE L2CAP Data Frame with SDU

Create a BLE L2CAP configuration object, ' cfgL2CAP' , with default properties and view the applicable properties. Change the value of channel identifier to '0004'.

```
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
        ChannelIdentifier: '0005'
                            CommandType: 'Credit based connection request'
            SignalIdentifier: '01'
        SourceChannelIdentifier: '0040'
                            LEPSM: '001F'
            MaxTransmissionUnit: 23
                MaxPDUPayloadSize: 23
                            Credits: 1
cfgL2CAP.ChannelIdentifier = '0004'; % Channel identifier for ATT
```

Generate a BLE L2CAP data frame from ' cfgL2CAP' , specifying the upper-layer payload SDU from attribute protocol (ATT) layer as '0A0100'.

L2CAPFrame = bleL2CAPFrame(cfgL2CAP, "0A0100");
Decode the generated BLE L2CAP data frame. The returned status indicates decoding was successful. View the output of 'status', 'cfgL2CAP' and the 'SDU'.

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(L2CAPFrame)
status =
Success
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
    ChannelIdentifier: '0004'
SDU = 3x2 char array
    '0A'
    '01'
    '00'
```

## Decode Corrupted BLE L2CAP Frame

Specify a BLE L2CAP frame containing corrupted data values.
l2capFrame $=$ ['090005000107040060005000']; \% Sample frame
Decode the specified BLE L2CAP frame. The returned status indicates that the decoding failed due to the corrupted input L2CAP frame. In this case, when decoding fails, the output displays the reason of failure and the BLE L2CAP frame configuration object, ' cfgL2CAP' , displays no properties.

```
[status, cfgL2CAP, SDU] = bleL2CAPFrameDecode(l2capFrame)
status =
MismatchL2CAPHeaderLength
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
SDU =
    1x0 empty char array
```

## Input Arguments

## L2CAPFrame - BLE L2CAP frame

character vector $\mid$ string scalar $\mid$ numeric vector $\mid$ character array
BLE L2CAP frame, specified as one of these values:

- Character vector - This vector represents octets in hexadecimal format.
- String scalar - This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] - This vector represents octets in decimal format.
- $n$-by-2 character array - Each row represents an octet in hexadecimal format.

## Data Types: char|double|string

## Output Arguments

## status - Packet decoding status

nonpositive integer
Packet decoding status, returned as a nonpositive integer of type blePacketDecodeStatus. This value represents the result of decoding a BLE L2CAP frame. Each value of status corresponds to a member of the blePacketDecodeStatus enumeration class, which indicates the packet decoding status according to this table.

| Enumeration Value | Member of Enumeration <br> Class | Decoding Status |
| :--- | :--- | :--- |
| 0 | Success | Packet decoding succeeded |
| -301 | InvalidL2CAPConnectionIn <br> tervalRange | Invalid connection intervals |
| -302 | InvalidL2CAPSLaveLatency | Invalid slave latency |
| -303 | InvalidLECredits | Invalid low energy (LE) credits |
| -304 | L2CAPSegmentationUnsuppo <br> rted | Segmentation is not supported |
| -305 | MismatchL2CAPHeaderLengt <br> h | Length mismatches with actual <br> length |
| -306 | InvalidL2CAPChannelIdent <br> ifier | Invalid L2CAP channel identifier <br> sufficient to decode |
| -307 | InvalidL2CAPCommand | Invalid L2CAP command code |
| -308 | InvalidL2CAPCommandRejec <br> tReason | Invalid command reject reason <br> code |
| -309 | InvalidL2CAPParameterUpd <br> ateResult | Invalid parameters update <br> result |
| -310 | InvalidL2CAPConnectionRe <br> sult | Invalid connection result code |
| -311 | IllegalL2CAPSignalIdenti <br> fier | Illegal signal identifier in L2CAP |
| -312 | InvalidL2CAPConnectionIn <br> tervalMinimum | Invalid interval minimum |
| -313 | InvalidL2CAPConnectionIn <br> tervalMaximum | Invalid interval maximum |
| -314 | InvalidL2CAPConnectionTi <br> meout | Invalid connection timeout |
| -315 | InvalidLEPSM | Invalid LE protocol/service <br> multiplexer |
| -316 |  |  |

| -317 | InvalidL2CAPChannelMTU | Invalid maximum transmission <br> unit |
| :--- | :--- | :--- |
| -318 | InvalidL2CAPChannelMPS | Invalid maximum PDU payload <br> size |
| -319 | InvalidL2CAPSDULength | Invalid SDU length |
| -320 | MismatchL2CAPSignalFrame <br> Length | Length mismatches with actual <br> length |
| -321 | IncompleteL2CAPSignalFra <br> me | L2CAP signal frame is not valid <br> or not sufficient |

An enumeration value other than 0 means that the BLE ATT PDU decoding failed. If the decoding fails, object cfgATT displays no output.

## cfgL2CAP - BLE L2CAP frame configuration object

bleL2CAPFrameConfig object
BLE L2CAP frame configuration object, returned as a bleL2CAPFrameConfig object. This value denotes the decoded BLE L2CAP frame configuration.

## SDU - Upper-layer payload

character array
Upper-layer payload, returned as a character array. Each row represents an octet in hexadecimal format.

Data Types: char|string

## bleLLAdvertisingChanneIPDU

Generate BLE LL advertising channel PDU

Note Download Required: To use, first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

pdu = bleLLAdvertisingChannelPDU(cfgLLAdv)

## Description

pdu = bleLLAdvertisingChannelPDU(cfgLLAdv) generates a Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU) corresponding to the BLE LL advertising channel PDU configuration object cfgLLAdv.

## Examples

## Generate BLE LL Advertising Channel PDUs

Generate two unique BLE LL advertising channel PDUs: first one of the type 'Advertising indication' using advertising data '020106' and the other of type 'Connection indication' using a set of data channels to be used.

Create a BLE LL advertising channel PDU configuration object, 'cfgLLAdv' , with the opcode as 'Advertising indication' by using advertising data '020106'. View the configured properties corresponding to the opcode.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig;
cfgLLAdv.AdvertisingData = '020106'
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
            PDUType: 'Advertising indication'
            ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
            AdvertisingData: [3x2 char]
```

Generate the BLE LL advertising channel PDU by using the corresponding configuration object. Display the PDU length in octets.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
numel(pdu)/8
ans = 14
```

Display the first octet of the generated BLE LL advertising channel PDU.

```
pdu(1:8)
ans = 8\times1
```

    0
    0
    0
    0
    0
    0
    1
    0
    Create another BLE LL advertising channel PDU configuration object, this time using the name-value pairs. Change the BLE LL advertising channel PDU opcode to 'Connection indication'. View the active configured properties of the specified opcode.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig('PDUType', ...
    'Connection indication')
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
            PDUType: 'Connection indication'
            ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
        InitiatorAddressType: 'Random'
            InitiatorAddress: '0123456789CD'
                AccessAddress: '01234567'
            CRCInitialization: '012345'
                WindowSize: 1
                    WindowOffset: 0
            ConnectionInterval: 6
                    SlaveLatency: 0
            ConnectionTimeout: 10
                    UsedChannels: [1\times37 double]
                    HopIncrement: 5
            SleepClockAccuracy: '251 to 500 ppm'
```

Specify the value of connection interval as 8 and the set of data channels as [0 $\begin{array}{lllllllll}0 & 12 & 16 & 18 & 24\end{array}$ 25]. View the configured properties.

```
cfgLLAdv.ConnectionInterval = 8; % in milliseconds
cfgLLAdv.UsedChannels = [l0 4 12 16 18 24 25]
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
                            PDUType: 'Connection indication'
                ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
        InitiatorAddressType: 'Random'
```

```
    InitiatorAddress: '0123456789CD'
    AccessAddress: '01234567'
CRCInitialization: '012345'
            WindowSize: 1
        WindowOffset: 0
ConnectionInterval: 8
            SlaveLatency: 0
ConnectionTimeout: 10
        UsedChannels: [0 4 12 16 18 24 25]
        HopIncrement: 5
SleepClockAccuracy: '251 to 500 ppm'
```

Generate the BLE LL advertising channel PDU from the corresponding configuration object. Display the PDU length in octets.

```
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
numel(pdu)/8
ans = 39
```

Display the first octet of the generated BLE LL advertising channel PDU.

```
pdu(1:8)
ans = 8\times1
    1
    0
    1
    0
    0
    0
    1
    1
```

## Input Arguments

cfgLLAdv - BLE LL advertising channel PDU configuration object
bleLLAdvertisingChannelPDUConfig object
BLE LL advertising channel PDU configuration object, specified as a bleLLAdvertisingChannelPDUConfig object. This value defines the type of generated BLE LL advertising channel PDU and its applicable properties.

## Output Arguments

## pdu - Generated BLE LL advertising channel PDU

binary column vector
Generated BLE LL advertising channel PDU, returned as a binary column vector. This value represents the output BLE LL advertising channel PDU.

Decode BLE LL advertising channel PDU

Note Download Required: To use, first download Communications Toolbox ${ }^{\text {TM }}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)
[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu,Name,Value)

## Description

[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)decodes the specified Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU), returning the decoding status, status, and the corresponding BLE LL advertising channel PDU configuration object, cfgLLAdv.
[status,cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu,Name,Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, 'InputFormat' , ' octets ' specifies the input BLE LL advertising channel PDU in the form of octets.

## Examples

## Decode BLE LL Advertising Channel PDU Given in Bits

Create a BLE LL advertising channel PDU configuration object, ' cfgLLAdv ' , with default settings and view the corresponding applicable properties.

```
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
                            PDUType: 'Advertising indication'
            ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
                AdvertisingData: [3x2 char]
```

Generate the BLE LL advertising channel PDU from the corresponding configuration object.
pdu = bleLLAdvertisingChannelPDU(cfgLLAdv);
Decode the generated BLE LL advertising channel PDU. The returned status indicates decoding is successful. View the output of 'status'and 'cfgLLAdv'.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu)
status =
Success
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
                            PDUType: 'Advertising indication'
            ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
                AdvertisingData: [3x2 char]
```

## Decode BLE LL Advertising Channel PDU Given in Octets

Specify a sample BLE LL advertising channel PDU in octets.

```
pdu = 'C409AB8967452301020106A8F1DF'; % Sample PDU in octets
```

Decode the specified BLE LL advertising channel PDU by specifying 'InputFormat' to 'octets'. The returned status indicates decoding is successful. View the output of 'status ' and 'cfgLLData'.

```
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, ...
    'InputFormat','octets')
status =
Success
cfgLLAdv =
    bleLLAdvertisingChannelPDUConfig with properties:
                            PDUType: 'Scan response'
                ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
                ScanResponseData: [3\times2 char]
```

## Decode Corrupted BLE LL Advertising Channel PDU

Specify a BLE LL advertising channel PDU containing corrupted data values.

```
pdu = 'D409AB89674523010201'; % Sample corrupted PDU
```

Decode the specified BLE LL advertising channel PDU. The returned status indicates that the decoding failed due to corrupted input BLE LL advertising channel PDU. In case of failed decoding, the reason of failure is indicated and the BLE LL advertising channel PDU configuration object, 'cfgLLAdv', displays no properties.
[status, cfgLLAdv] = bleLLAdvertisingChannelPDUDecode(pdu, ...
'InputFormat', 'octets')
status =
CRCFailed
cfgLLAdv =
bleLLAdvertisingChannelPDUConfig with properties:

## Input Arguments

## pdu - BLE LL advertising channel PDU

character vector $\mid$ string scalar $\mid$ numeric vector $\mid$ character array | binary vector
BLE LL advertising channel PDU, specified as one of these types:

- Character vector - This vector represents octets in hexadecimal format.
- String scalar - This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] - This vector represents octets in decimal format.
- n -by- 2 character array - Each row represents an octet in hexadecimal format.
- Binary vector - This vector represents the BLE LL advertising channel PDU bits.

Data Types: char | double | string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: [status,cfgLLAdv] =
bleLLAdvertisingChannelPDUDecode('pdu','InputFormat','octets')

## InputFormat - BLE LL advertising channel PDU format 'bits' (default)|'octets'

BLE LL advertising channel PDU format, specified as 'bits' or'octets'. When specified as 'bits', the InputFormat is a binary vector. When specified as 'octets', InputFormat is a numeric vector representing octets in decimal format or a character array or a string scalar representing octets in hexadecimal format.

Data Types: char|string

## Output Arguments

## status - BLE LL advertising channel PDU decoding status <br> nonpositive integer

BLE LL advertising channel PDU decoding status, returned as a nonpositive number of type blePacketDecodeStatus. This value represents the result of BLE LL advertising channel PDU decoding. Each value of status corresponds to a member of the blePacketDecodeStatus enumeration class, which indicates the packet decoding status listed in this table.

| Enumeration Value | Member of Enumeration <br> Class | Decoding Status |
| :--- | :--- | :--- |
| 0 | Success | Packet decoding succeeded |
| -1 | CRCFailed | Link Layer PDU is corrupted |
| -2 | InvalidLLSlaveLatency | Length field does not match <br> with actual PDU length |
| -3 | Invalid slave latency <br> ut |  |
| -4 | InvalidLLWindowSize | Invalid window size |
| -5 | InvalidLLWindow0ffset | Invalid window offset |
| -6 | InvalidLLConnectionInter <br> val | Invalid connection interval |
| -7 | InvalidLLChannelMap | Invalid channel map |
| -8 | IncompleteLLAdvertisingC <br> hannelPDU | Insufficient octets in advertising <br> channel PDU |
| -51 | InvalidLLHopIncrement | Invalid hop increment value |
| -52 | InvalidLLAdvertisingData <br> Length | Invalid advertising data |
| -53 | InvalidLLScanResponseDat <br> aLength | Invalid scan response data |
| -54 | UnsupportedLLAdvertising <br> PDUType | Unsupported advertising <br> channel PDU |
| -55 |  |  |

An enumeration value other than 0 means that the BLE LL advertising channel PDU decoding failed. If the decoding fails, object cfgLLAdv displays no output.
cfgLLAdv - BLE LL advertising channel PDU configuration object
bleLLAdvertisingChannelPDUConfig object
BLE LL advertising channel configuration object, returned as a
bleLLAdvertisingChannelPDUConfig object. This value represents the decoded BLE LL advertising channel PDU configuration.

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

pdu = bleLLDataChannelPDU(cfgLLData)
pdu = bleLLDataChannelPDU(cfgLLData,LLPayload)

## Description

pdu = bleLLDataChannelPDU(cfgLLData) generates a Bluetooth low energy (BLE) link layer
(LL) data channel protocol data unit (PDU), pdu, for a given BLE LL data channel configuration object cfgLLData. This syntax is used for generating BLE LL control PDUs.
pdu = bleLLDataChannelPDU(cfgLLData,LLPayload) generates a BLE LL data channel PDU, pdu, containing the upper-layer payload LLPayload for a given BLE LL data channel configuration object cfgLLData. This syntax is used for generating BLE LL data PDUs.

## Examples

## Generate BLE LL Control PDU of Type Connection Update Indication

Create a BLE LL control PDU configuration object for a control PDU using the default configuration. View the corresponding default properties.

```
cfgControl = bleLLControlPDUConfig
cfgControl =
    bleLLControlPDUConfig with properties:
                Opcode: 'Connection update indication'
                WindowSize: 1
            WindowOffset: 0
        ConnectionInterval: 6
            SlaveLatency: 0
        ConnectionTimeout: 10
            Instant: 0
```

Create a BLE LL data channel PDU configuration object for a control PDU of type 'Connection update indication' by configuring the values of link layer identifier (LLID) as 'Control ' and ControlConfig as 'cfgControl'. View the corresponding properties.
cfgLLData = bleLLDataChannelPDUConfig('LLID', 'Control', ...
'ControlConfig', cfgControl)

```
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
            LLID: 'Control'
            NESN: 0
        SequenceNumber: 0
            MoreData: 0
        ControlConfig: [1x1 bleLLControlPDUConfig]
```

Generate a BLE LL data channel PDU of type 'Connection update indication ' by using the configuration object 'cfgLLData'. Display the PDU length in octets.

```
pdu = bleLLDataChannelPDU(cfgLLData);
numel(pdu)/8
ans = 17
```

Display the first octet of the generated BLE LL data channel PDU.

```
pdu(1:8)
ans = 8\times1

## Generate BLE LL Data PDU Using Upper-Layer Payload

Create a BLE LL data channel PDU configuration object, ' cfgLLData' , for a data PDU by using the default configuration. View the corresponding default properties.

```
cfgLLData = bleLLDataChannelPDUConfig
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
        LLID: 'Data (continuation fragment/empty)'
            NESN: 0
        SequenceNumber: 0
            MoreData: 0
```

Generate a BLE LL data PDU by using the corresponding configuration object, ' cgLLData ' and the upper-layer payload '030004000A0100'. Display the PDU length in octets.

```
pdu = bleLLDataChannelPDU(cfgLLData,'030004000A0100');
```

numel(pdu)/8

```
ans = 12
```

Display the first octet of the generated BLE LL data PDU.

```
pdu(1:8)
```

ans $=8 \times 1$

## Input Arguments

## cfgLLData - BLE LL data channel configuration object

bleLLDataChannelPDUConfig object
BLE LL data channel configuration object, specified as a bleLLDataChannelPDUConfig object. This object is used to configure the BLE LL data channel PDU and its applicable properties.

## LLPayload - Upper-layer payload

character vector | string scalar | numeric vector | character array
Upper-layer payload, specified as one of these types:

- Character vector - This vector represents octets in hexadecimal format.
- String scalar - This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range $[0,255]$ - This vector represents octets in decimal format.
- n -by- 2 character array - Each row represents an octet in hexadecimal format.

Data Types: char|double|string

## Output Arguments

## pdu - Generated BLE LL data channel PDU

binary vector
Generated BLE LL data channel PDU, returned as a binary column vector. This value represents the output BLE LL data channel PDU.

# bleLLDataChanneIPDUDecode 

Decode BLE LL data channel PDU

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[status,cfgLLData, LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit) [status,cfgLLData,LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit Name, Value)

## Description

[status,cfgLLData, LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit) decodes a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU), returning the decoding status, status, the BLE LL data channel PDU configuration object, cfgLLData, and the upper-layer payload, LLPayload. The CRCinit denotes the initialization value of cyclic redundancy check (CRC).
[status,cfgLLData,LLPayload] = bleLLDataChannelPDUDecode(pdu,CRCinit
Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, 'InputFormat ' , 'bits' specifies the format of input BLE LL data channel PDU in bits.

## Examples

## Decode BLE LL Data Channel PDU Given in Bits

Create a BLE LL data channel PDU configuration object by using default settings and view the corresponding applicable properties.

```
cfgLLData = bleLLDataChannelPDUConfig
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
                            LLID: 'Data (continuation fragment/empty)'
            NESN: 0
        SequenceNumber: 0
            MoreData: 0
```

Initialize and set the LLID value to 'start fragment/complete' indicating the BLE LL data channel PDU with the upper-layer payload. Initialize the cyclic redundancy check (CRC) value to 'ED321C'.

```
cfgLLData.LLID = 'Data (start fragment/complete)';
cfgLLData.CRCInitialization = 'ED321C';
crcInit = 'ED321C'; % CRC initialization value
```

Generate the BLE LL data channel PDU with upper-layer payload given in hexadecimal octets.
pdu = bleLLDataChannelPDU(cfgLLData,'030004000A0100');
Decode the generated BLE LL data channel PDU. The returned status indicates decoding is successful. View the output of 'status', 'cfgLLData' and 'llPayload'.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(pdu,crcInit)
status =
Success
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
            LLID: 'Data (start fragment/complete)'
            NESN: 0
        SequenceNumber: 0
                MoreData: 0
llPayload = 7x2 char array
    '03'
    '00'
    '04'
    '00'
    '0A'
    '01'
    '00'
```

## Decode BLE LL Data Channel PDU Given in Octets

Specify a sample BLE LL data channel PDU in octets.

```
pdu = '030C00010000060000000A000000FCD2A6'; % Sample PDU in octets
```

Initialize the CRC value.
crcInit $=$ 'ED323C'; \% CRC initialization value
Decode the specified BLE LL data channel PDU by specifying 'InputFormat' to 'octets '. The specified PDU is a control PDU. The returned status indicates decoding is successful. View the output of 'status', 'cfgLLData' and 'llPayload'. You can see the decoded configuration of the specified PDU in the 'ControlConfig' property of 'cfgLLData'.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(...
    pdu, crcInit, ...
    'InputFormat', ...
    'octets')
status =
Success
```

```
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
            LLID: 'Control'
            NESN: 0
        SequenceNumber: 0
            MoreData: 0
        ControlConfig: [1x1 bleLLControlPDUConfig]
llPayload =
    1x0 empty char array
```

## Decode Corrupted BLE LL Data Channel PDU

Specify a BLE LL data channel PDU containing corrupted data values. Initialize the CRC value.

```
pdu = '040C00010000060000000A00'; % Sample corrupted PDU
crcInit = 'CD3234'; % CRC initialization value
```

Decode the specified BLE LL data channel PDU. The returned status indicates that the decoding failed due to the corrupted BLE LL data channel PDU. If the decoding fails, the reason is indicated and the BLE LL data channel PDU configuration object, 'cfgLLData', displays no properties.

```
[status, cfgLLData, llPayload] = bleLLDataChannelPDUDecode(...
    pdu, crcInit, ...
    'InputFormat', ...
    'octets')
status =
CRCFailed
cfgLLData =
    bleLLDataChannelPDUConfig with properties:
llPayload =
    1x0 empty char array
```

## Input Arguments

## pdu - BLE LL data channel PDU

character vector $\mid$ string scalar | numeric vector | character array | binary vector
BLE LL data channel PDU, specified as one of these values:

- Character vector - This vector represents octets in hexadecimal format.
- String scalar - This scalar represents octets in hexadecimal format.
- Numeric vector of elements in the range $[0,255]$ - This vector represents octets in decimal format.
- n -by-2 character array - Each row represents an octet in hexadecimal format.
- Binary vector - This vector represents BLE LL data channel PDU bits.

Data Types: char | string | double

## CRCinit - CRC initialization value

character vector | string scalar
CRC initialization value, specified as a 6 -element character vector or a string scalar representing 3octet hexadecimal value.

Data Types: char \| string

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.
Example: [status,cfgLLData,LLPayload] =
bleLLDecodeDataChannelPDU('pdu','CRCInit','InputFormat','octets')

## InputFormat - BLE LL data channel PDU format <br> 'bits' (default)|'octets'

BLE LL data channel PDU format, specified as 'bits' or' octets'. When specified as 'bits', InputFormat is a binary vector. When specified as 'octets', InputFormat is a numeric vector representing octets in decimal format or a character array or a string scalar representing octets in hexadecimal format.
Data Types: char | string | double

## Output Arguments

## status - BLE LL data channel PDU decoding status

nonpositive integer
BLE LL data channel PDU decoding status, returned as a nonpositive number of type blePacketDecodeStatus. This value represents the result of a BLE LL data channel PDU decoding. Each value of status corresponds to a member of the blePacketDecodeStatus enumeration class, which indicates the packet decoding status as listed in this table.

| Enumeration Value | Member of Enumeration <br> Class | Decoding Status |
| :--- | :--- | :--- |
| 0 | Success | Packet decoding succeeded |
| -1 | CRCFailed | Link Layer PDU is corrupted |
| -2 | LLPDULengthMismatch | Length field does not match <br> with actual PDU length |
| -3 | InvalidLLSlaveLatency | Invalid slave latency |
| -4 | InvalidLLConnectionTimeo <br> ut | Invalid connection timeout |

| -5 | InvalidLLWindowSize | Invalid window size |
| :--- | :--- | :--- |
| -6 | InvalidLLWindowOffset | Invalid window offset |
| -7 | InvalidLLConnectionInter <br> val | Invalid connection interval |
| -8 | InvalidLLChannelMap | Invalid channel map |
| -101 | IncompleteLLDataChannelP <br> DU | Insufficient octets in data <br> channel PDU |
| -102 | InvalidLLID | Invalid LLID |
| -103 | UnsupportedLLOpCode | Unsupported opcode |
| -104 | InvalidLLErrorCode | Invalid error code |
| -105 | InvalidBluetoothVersion | Invalid version |
| -106 | ExpectedNonZeroPayload | Nonzero payload expected |
| -107 | MICNotSupported | Payload contains MIC |

An enumeration value other than 0 means that the BLE LL data channel PDU decoding failed. If decoding fails, object cfgLLData displays no output.
cfgLLData - BLE LL data channel configuration object
bleLLDataChannelPDUConfig object
BLE LL data channel configuration object, returned as a bleLLDataChannelPDUConfig object. This value represents the decoded BLE LL data channel PDU configuration.

## LLPayload - Upper-layer payload

array
Upper-layer payload, returned as a character array where each row is the hexadecimal representation of an octet.

## bluetoothIdealReceiver

Ideal receiver for Bluetooth BR/EDR PHY waveform

Note Download Required: To use, first download Communications Toolbox ${ }^{\text {TM }}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

[bits,decodedInfo] = bluetoothIdealReceiver(waveform,rxConfig)
$\qquad$ ,pktValidStatus,decodedCRC] = bluetoothIdealReceiver( $\qquad$ )

## Description

[bits,decodedInfo] = bluetoothIdealReceiver(waveform,rxConfig) demodulates and decodes a synchronized time-domain Bluetooth waveform, waveform, generated by the bluetoothWaveformGenerator function for a given system configuration object, rxConfig. The function returns the decoded payload bits, bits, and decoded information, decodedInfo.
[__, pktValidStatus,decodedCRC] = bluetoothIdealReceiver (__ ) returns a flag, pktValidStatus, to indicate the validity of the received Bluetooth BR/EDR packet. The function also returns the decoded cyclic redundancy check (CRC), decodedCRC, of the received Bluetooth packet.

## Examples

## Demodulate and Decode Time-Domain Bluetooth BR/EDR Waveform

Demodulate and decode time-domain Bluetooth BR/EDR waveform using two different ways to get physical layer (PHY) information. First, use the bluetoothIdealReceiver function with the bluetoothPhyConfig object. Then, use with the bluetoothWaveformConfig object.

## Use the bluetoothPhyConfig object to get PHY information

Create a Bluetooth BR/EDR waveform configuration object with default settings.
txconfig = bluetoothWaveformConfig;
Create a random input bit vector to generate the payload. Generate the time-domain Bluetooth $\mathrm{BR} / E D R$ waveform using the payload.

```
dataBits = randi([0 1],getPayloadLength(txconfig)*8,1);
waveform = bluetoothWaveformGenerator(dataBits,txconfig);
```

Create a configuration object for Bluetooth BR/EDR PHY with default settings. This object sends the PHY information to the ideal receiver.

```
rxConfig = bluetoothPhyConfig;
```

Demodulate and decode the Bluetooth BR/EDR waveform. The generated output displays the decoded bits and a structure containing the decoded information.

```
[bits,decodedInfo] = bluetoothIdealReceiver(waveform,rxConfig)
bits = 144×1
    1
    1
    0
    1
    1
    0
    0
    1
    1
    1
decodedInfo = struct with fields:
                            LAP: [1 0 1 0 0 1 1 0 1 1 0 0 0 1 0 0 1 0 0 0 0 1 1 1]
        PacketType: 'FHS'
    LogicalTransportAddress: [ 3\times1 double]
        HeaderControlBits: [ 3\times1 double]
        PayloadLength: 18
            LLID: [2×1 double]
            FlowIndicator: 0
```

## Use the bluetoothWaveformConfig object to get PHY information

Create a Bluetooth BR/EDR waveform configuration object with default settings. Set the packet type to ' DM1 ' and payload length to 10.

```
cfg = bluetoothWaveformConfig;
cfg.PacketType = 'DM1';
cfg.PayloadLength = 10;
```

Create a random input bit vector to generate the payload.

```
numBits = getPayloadLength(cfg)*8;
dataBits = randi([0 1],numBits,1);
```

Generate the time-domain Bluetooth BR/EDR waveform using the payload.

```
waveform = bluetoothWaveformGenerator(dataBits,cfg);
```

Get PHY information from the bluetoothWaveformConfig object function, getPhyConfigProperties.

```
rxConfig = getPhyConfigProperties(cfg);
```

Demodulate and decode the Bluetooth BR/EDR waveform. The generated output displays the decoded bits, a structure containing the decoded information, the packet status, and the decoded CRC.

```
[bits,decodedInfo,pktStatus,crc] = bluetoothIdealReceiver(waveform,rxConfig)
bits = 80×1
```

## Input Arguments

## waveform - Synchronized time-domain Bluetooth waveform

complex-valued column vector
Synchronized time-domain Bluetooth waveform, specified as a complex-valued column vector.
Data Types: double
Complex Number Support: Yes
rxConfig - System configuration object
bluetoothPHYConfig object
System configuration object, specified as a bluetoothPhyConfig object. The function uses this value to set its configuration parameters.

## Output Arguments

## bits - Decoded payload bits

binary-valued column vector
Decoded payload bits, returned as a binary-valued column vector.
Data Types: double
decodedInfo - Decoded information
structure
Decoded information, returned as a structure containing these fields:

| Field | Value | Description |
| :---: | :---: | :---: |
| PacketType | 'ID','NULL','POLL',' FHS', 'HV1',''HV2','HV3','DV', 'EV3', 'EV4','EV5',' $A U X 1 ', ~$ 'DM3',' DM1','DH1','DM5', 'DH3','DH5','2-DH1','2- DH3','2-DH5','2-DH1','2- DH3','2-DH5','2-EV3','2- EV5', '3-EV3', or '3-EV5' | Type of received Bluetooth BR/EDR packet |
| LAP | 24-bit column vector of type double. | Decoded lower address part (LAP) of the Bluetooth device address |
| PayloadLength | Scalar of type double | Number of payload bytes in the received Bluetooth BR/EDR packet |
| LogicalTransportAddress | 3-bit vector of type double | Active destination slave for a Bluetooth BR/EDR packet in a master-to-slave transmission slot |
| HeaderControlBits | 3-bit vector of type double | Link control information containing flow control information (FLOW), acknowledgement for successfully receiving a Bluetooth BR/EDR packet payload (ARQN), and sequencing scheme for received packets (SEQN) bits |
| LLID | 2-bit binary vector of type double | Logical link identifier. This field is applicable only if the value of PacketType field is one of these: 'DM1', 'DH1', 'DM3' <br> 'DH3', 'DM5', 'DH5', 'AUX1', <br> 'DV', '2-DH1', '2-DH3', '2- <br> DH5', '3-DH1', '3-DH3', or '3-DH5'. |

| Field | Value | Description |
| :---: | :---: | :---: |
| FlowIndicator | Scalar of type double | Control data flow indicator over logical channels. This field is applicable only if the value of PacketType field is one of these: 'DM1', 'DH1','DM3' 'DH3', 'DM5', 'DH5', 'AUX1', 'DV','2-DH1', '2-DH3', '2- DH5','3-DH1', '3-DH3', or '3-DH5' |

## Data Types: struct

## pktValidStatus - Flag indicating validity of received Bluetooth BR/EDR packet 1|0

Flag indicating validity of received Bluetooth BR/EDR packet, returned as 1 or 0 of data type logical. Validity is based on the Bluetooth BR/EDR packet header error check (HEC) and cyclic redundancy check (CRC).

## Dependencies

To enable this output argument, set the PacketType field value of the "decodedInfo" on page 2-0 output argument to any one of these: 'NULL','POLL', 'FHS', 'HV1', 'HV2', 'HV3', 'DV', 'EV3', 'EV4', 'EV5', 'AUX1','DM3','DM1','DH1','DM5','DH3','DH5', '2-DH1','2-DH3','2DH5', '2-DH1','2-DH3', '2-DH5', '2-EV3', '2-EV5', '3-EV3', or '3-EV5'.
Data Types: logical

## decodedCRC - Decoded CRC

16-bit binary-valued column vector
Decoded CRC, specified as the CRC of the received Bluetooth BR/EDR packet.

## Dependencies

To enable this output argument, set the packet type field value of the decoded information output argument to any one of these: 'FHS', 'DV', 'EV3', 'EV4', 'EV5', 'DM3', 'DM1', 'DH1', 'DM5', 'DH3','DH5','2-DH1','2-DH3','2-DH5','2-DH1','2-DH3','2-DH5','2-EV3','2-EV5', '3-EV3', or '3-EV5'.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{Tm}}$.

Usage notes and limitations:

- Properties must be given as: coder. Constant().

## See Also

## Functions <br> bleIdealReceiver|bleWaveformGenerator | bluetoothWaveformGenerator <br> Objects <br> bluetoothPhyConfig| bluetoothWaveformConfig <br> Topics <br> "Bluetooth Protocol Stack" <br> "Bluetooth Packet Structure" <br> Introduced in R2020a

## bluetoothWaveformGenerator

Waveform generator for Bluetooth BR/EDR PHY

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

waveform = bluetoothWaveformGenerator(data,cfgFormat)

## Description

waveform = bluetoothWaveformGenerator(data,cfgFormat) generates waveform, a multipacket time-domain Bluetooth BR/EDR waveform, for input information bits data and a given format configuration cfgFormat.

## Examples

## Generate Multipacket Bluetooth BR/EDR Waveform with HV1 Packets

Specify the number of HV1 packets.
numPackets = 10;
Create a Bluetooth BR/EDR waveform configuration object. Specify the packet type as HV1.
cfg = bluetoothWaveformConfig;
cfg.PacketType = 'HV1';
Create a random input bit vector containing concatenated payloads.

```
numBits = getPayloadLength(cfg)*8*numPackets; % Byte to bit conversion
dataBits = randi([0 1],numBits,1);
```

Set the symbol rate.

```
symbolRate = 1e6; % In MHz
```

Generate the Bluetooth waveform.

```
waveform = bluetoothWaveformGenerator(dataBits,cfg);
```

Create a dsp.SpectrumAnalyzer System object to display the frequency spectrum of the generated Bluetooth BR/EDR waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;
scope.SampleRate = cfg.SamplesPerSymbol*symbolRate;
```

Plot the Bluetooth $B R / E D R$ waveform.

```
scope(waveform);
```

## Generate Bluetooth BR/EDR Waveform for Single Enhanced Data Rate Packet

Create a Bluetooth BR/EDR waveform configuration object.
cfg = bluetoothWaveformConfig;
To generate enhanced data rate packet 2-EV3, specify the packet type as EV3 and the transmission mode as EDRM2.
cfg.PacketType = 'EV3';
cfg.Mode = 'EDR2M';
Create a random input bit vector to generate the payload for a single packet.
numBits $=$ getPayloadLength $(c f g) * 8$; \% Byte to bit conversion
dataBits $=$ randi([0 1],numBits,1);
Generate the Bluetooth BR/EDR waveform.
txWaveform = bluetoothWaveformGenerator(dataBits,cfg);

## Input Arguments

## data - Input information bits

binary-valued column vector
Input information bits, specified as a binary-valued column vector with data type double. This value represents multiple concatenated payloads. The length of data must be an exact multiple of the payload length derived from the getPayloadLength object function for the bluetoothWaveformConfig object.

Data Types: double
cfgFormat - Format configuration object
bluetoothWaveformConfig object
Format configuration object, specified as a bluetoothWaveformConfig object. The function uses this value to set its configuration parameters.

## Output Arguments

## waveform - Generated time-domain Bluetooth BR/EDR waveform

complex-valued column vector
Generated time-domain Bluetooth BR/EDR waveform, returned as a complex-valued column vector containing the generated Bluetooth BR/EDR waveform. The function appends this value with zero samples to accommodate a packet-specific slot duration.
Data Types: double

## bleWaveformGenerator

Waveform generator for BLE PHY

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

waveform = bleWaveformGenerator(message)
waveform = bleWaveformGenerator(message,Name,Value)

## Description

waveform = bleWaveformGenerator(message) generates waveform, a time-domain Bluetooth low energy (BLE) physical layer (PHY) waveform by using the input information bits message.
waveform = bleWaveformGenerator(message,Name,Value) also specifies options using one or more name-value pair arguments. For example, 'Mode' , 'LE2M' specifies the generating mode value of the desired BLE waveform.

## Examples

## Generate BLE Waveform Using Default Settings

Create an input message column vector of length 2056 containing random binary values. Set the symbol rate to default value.

```
message = randi([0 1],2056,1);
symbolRate = le6;
```

Generate the BLE waveform.
waveform = bleWaveformGenerator(message);
Create a dsp.SpectrumAnalyzer System object to display the frequency spectrum of the generated BLE waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;
scope.SampleRate = 8*symbolRate;
```

Plot the BLE waveform.
scope(waveform);

## Generate BLE Waveform Using Specified Name-Value Pairs

Create an input message column vector of length 640 containing random binary values.

```
message = randi([0 1],640,1);
```

Specify the values of generating mode, channel index, samples per symbol and access address. Set symbol rate to default value.

```
phyMode = 'LE125K';
chanIdx = 2;
sps = 4;
accAdd = [1 1 1 1 0 1 0 0 1 1 0 1 0 0 1 0 0 1 1 0 1 1 1 0 1 ...
    0 1 0 1 1 0 0].';
symbolRate = 1e6;
```

Create a dsp. SpectrumAnalyzer System object to display the frequency spectrum of the generated BLE waveform. Set the sample rate of the frequency spectrum.

```
scope = dsp.SpectrumAnalyzer;
scope.SampleRate = sps*symbolRate;
```

Generate the BLE waveform using specified name-value pair arguments. Plot the BLE waveform.
waveform = bleWaveformGenerator(message,'Mode',phyMode, ...
'SamplesPerSymbol', sps, 'ChannelIndex', chanIdx, 'AccessAddress' , accAdd) ; scope(waveform);

## Input Arguments

## message - Input message bits

binary-valued column vector
Input message bits, specified as a binary-valued column vector of numerical or logical values. This message contains the protocol data unit (PDU) and cyclic redundancy check (CRC) data. The maximum length of this value is 2080 bits.

Data Types: double | logical | single |int

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.
Example: bleWaveformGenerator(message, 'Mode', 'LE2M', 'ChannelIndex' , 36)

## Mode - Generating mode

'LE1M' (default) | 'LE2M' | 'LE500K' | 'LE125K'
Generating mode, specified as the comma-separated pair consisting of 'Mode' and 'LE1M', 'LE2M', 'LE500K' , or 'LE125K'. This value indicates the type of BLE waveform.

Data Types: string | char

## ChannelIndex - Channel Index

37 (default) | integer in the range [0, 39]
Channel index, specified as the comma-separated pair consisting of 'Channel Index'and an integer in the range [0, 39]. For data channels, this value must be in the range [0, 36]. For advertising channels, this value must be in the range [37, 39]. This value is used by the data-whitening block to randomize the bits.

Data Types: single | double

## SamplesPerSymbol - Samples per symbol

8 (default) | positive integer
Samples per symbol, specified as the comma-separated pair consisting of 'SamplesPerSymbol ' and a positive integer. This value is used for the Gaussian frequency-shift keying (GFSK) modulation.
Data Types: single | double
AccessAddress - Access address
$\left[\begin{array}{cccccccccccccccccccccccccccccccc}0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 1]\end{array}\right.$ (default)|32bit column vector

Access address, specified as the comma-separated pair consisting of 'AccessAddress ' and a 32-bit column vector of numerical or logical values.
Data Types: logical| single | double | int

## Output Arguments

## waveform - Output time-domain waveform

## complex-valued column vector

Output time-domain waveform, returned as a complex-valued column vector of size Ns -by-1, where Ns represents the number of time-domain samples. The waveform is generated in the form of complex in-phase quadrature (IQ) samples.

Introduced in R2019b

## getPayloadLength

Payload length in bytes for Bluetooth BR/EDR format configuration

Note Download Required: To use , first download Communications Toolbox ${ }^{T M}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

payloadLength $=$ getPayloadLength(cfg)

## Description

payloadLength $=$ getPayloadLength(cfg) returns the payload length, in bytes, for the Bluetooth BR/EDR format configuration, cfg.

## Examples

Get Payload Length for Bluetooth BR/EDR Format Configuration
Create a Bluetooth BR/EDR waveform configuration object with default properties.

```
cfg = bluetoothWaveformConfig
```

cfg =
bluetoothWaveformConfig with properties:
Mode: 'BR'
PacketType: 'FHS'
DeviceAddress: '0123456789AB'
LogicalTransportAddress: [ $3 \times 1$ double]
HeaderControlBits: [ $3 \times 1$ double]
ModulationIndex: 0.3200
SamplesPerSymbol: 8
WhitenStatus: 'On'
WhitenInitialization: [7×1 double]

Get the payload length of the default ' FHS' packet.
payloadLength $=$ getPayloadLength(cfg)
payloadLength = 18
Create another Bluetooth BR/EDR waveform configuration object. Set the packet type as 'HV1'.
cfgHV1 = bluetoothWaveformConfig('PacketType','HV1');
Get the payload length of the specified 'HV1' packet.

```
payloadLength = getPayloadLength(cfgHV1)
payloadLength = 10
```

## Input Arguments

cfg - Bluetooth BR/EDR format configuration
bluetoothWaveformConfig object
Bluetooth BR/EDR format configuration, specified as bluetoothWaveformConfig object.

## Output Arguments

payloadLength - Payload length of packet
18 (default) | nonnegative integer
Payload length of packet, returned as a nonnegative integer. This value indicates the number of bytes to be processed in a packet.

Data Types: double

## getPhyConfigProperties

Updated configuration properties of Bluetooth BR/EDR PHY configuration object

Note Download Required: To use , first download Communications Toolbox ${ }^{\mathrm{TM}}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Syntax

cfgPHY = getPhyConfigProperties(cfg)

## Description

cfgPHY = getPhyConfigProperties (cfg) returns updated Bluetooth BR/EDR PHY configuration properties, cfgPHY for the Bluetooth BR/EDR waveform format configuration object, cfg.

## Examples

## Get PHY Configuration Properties of Bluetooth BR/EDR PHY Configuration Object

Create a Bluetooth BR/EDR waveform configuration object with default properties.

```
cfg = bluetoothWaveformConfig
cfg =
    bluetoothWaveformConfig with properties:
            Mode: 'BR'
            PacketType: 'FHS'
            DeviceAddress: '0123456789AB'
        LogicalTransportAddress: [ }3\times1\mathrm{ double]
        HeaderControlBits: [3\times1 double]
            ModulationIndex: 0.3200
        SamplesPerSymbol: 8
            WhitenStatus: 'On'
        WhitenInitialization: [7×1 double]
```

Get the PHY configuration properties for the created Bluetooth BR/EDR waveform configuration object.

```
cfgPHY = getPhyConfigProperties (cfg)
cfgPHY =
    bluetoothPhyConfig with properties:
                            Mode: 'BR'
        DeviceAddress: '0123456789AB'
            ModulationIndex: 0.3200
        SamplesPerSymbol: 8
```

WhitenStatus: 'On'
WhitenInitialization: [7×1 double]

Create another Bluetooth BR/EDR waveform configuration object and specify the PHY transmission mode as 'EDR2M'.
cfgEDR = bluetoothWaveformConfig('Mode','EDR2M');
Get the PHY configuration properties for this Bluetooth BR/EDR waveform configuration object.

```
cfgPHY = getPhyConfigProperties (cfgEDR)
cfgPHY =
    bluetoothPhyConfig with properties:
                            Mode: 'EDR2M'
                DeviceAddress: '0123456789AB'
                ModulationIndex: 0.3200
        SamplesPerSymbol: 8
            WhitenStatus: 'On'
        WhitenInitialization: [7×1 double]
```

## Input Arguments

cfg - Bluetooth BR/EDR format configuration
bluetoothWaveformConfig object
Bluetooth BR/EDR Format configuration, specified as bluetoothWaveformConfig object.

## Output Arguments

cfgPHY - Configuration object for Bluetooth BR/EDR PHY
bluetoothPHYConfig object
Configuration object for Bluetooth BR/EDR PHY, returned as a bluetoothPhyConfig object.

## addCustomBasemap

Add custom basemap

## Syntax

addCustomBasemap(basemapName,URL) addCustomBasemap (__ ,Name, Value)

## Description

addCustomBasemap (basemapName, URL) adds the custom basemap specified by URL to the list of basemaps available for use with mapping functions. basemapName is the name you choose to call the custom basemap. Added basemaps remain available for use in future MATLAB sessions.
addCustomBasemap( $\qquad$ ,Name, Value) specifies name-value pairs that set additional parameters of the basemap.

## Examples

## Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from siteviewer.

Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: $\mathrm{a}, \mathrm{b}$, or c .
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

Use addCustomBasemap to load the custom basemap, and then create a siteviewer object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```

After a custom basemap is added to siteviewer, the custom map is available for future calls to siteviewer. Note the 'Open Topo Map' icon in the Imagery tab.
siteviewer;

Use removeCustomBasemap to remove the custom basemap from future calls to siteviewer. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.
removeCustomBasemap (name)
siteviewer;

## Input Arguments

## basemapName - Name used to identify basemap programmatically

string scalar | character vector
Name used to identify basemap programmatically, specified as a string scalar or character vector.
Example: 'openstreetmap'
Data Types: string |char

## URL - Parameterized map URL

string scalar | character vector
Parameterized map URL, specified as a string scalar or character vector. A parameterized URL is an index of the map tiles, formatted as $\$\{z\} / \$\{x\} / \$\{y\}$. png or $\{z\} /\{x\} /\{y\}$. png, where:

- $\$\{z\}$ or $\{z\}$ is the tile zoom level.
- $\$\{x\}$ or $\{x\}$ is the tile column index.
- $\$\{y\}$ or $\{y\}$ is the tile row index.

Example: 'https://hostname/\$\{z\}/\$\{x\}/\$\{y\}.png'
Data Types: string | char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## Example: addCustomBasemap(basemapName,URL, 'Attribution' ,attribution)

## Attribution - Attribution of custom basemap

'Tiles courtesy of DOMAIN_NAME_OF_URL' (default) | string scalar \| string array | character vector | cell array of character vectors

Attribution of custom basemap, specified as the comma-separated pair consisting of 'Attribution' and a string scalar, string array, character vector, or cell array of character vectors. If the host is ' localhost', or if URL contains only IP numbers, specify an empty value (' ' ). To create a multiline attribution, specify a string array or nonscalar cell array of character vectors.

If you do not specify an attribution, the default attribution is 'Tiles courtesy of
DOMAIN_NAME_OF_URL', where the addCustomBasemap function obtains the domain name from the URL input argument.
Example: 'Credit: U.S. Geological Survey'
Data Types: string|char|cell

## DisplayName - Display name of custom basemap

string scalar | character vector
Display name of the custom basemap, specified as the comma-separated pair consisting of 'DisplayName' and a string scalar or character vector.
Example: 'OpenStreetMap'
Data Types: string | char

## MaxZoomLevel - Maximum zoom level of basemap

18 (default) | integer in the range [0, 25]
Maximum zoom level of the basemap, specified as the comma-separated pair consisting of 'MaxZoomLevel ' and an integer in the range [ 0,25 ].
Data Types: single | double | int8 | int16 | int32 | int64 | uint8|uint16|uint32|uint64

## Tips

- You can find tiled web maps from various vendors, such as OpenStreetMap ${ }^{\circledR}$, the USGS National Map, Mapbox, DigitalGlobe, Esri ${ }^{\oplus}$ ArcGIS Online, the Geospatial Information Authority of Japan (GSI), and HERE Technologies. Abide by the map vendors terms-of-service agreement and include accurate attribution with the maps you use.
- To access a list of available basemaps, press Tab before specifying the basemap in your plotting function.

## See Also

geoaxes | geobasemap | geobubble | removeCustomBasemap

# removeCustomBasemap 

Remove custom basemap

## Syntax

removeCustomBasemap(basemapName)

## Description

removeCustomBasemap (basemapName) removes the custom basemap specified by basemapName from the list of available basemaps.

## Examples

## Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from siteviewer.

Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: $\mathrm{a}, \mathrm{b}$, or c .
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';
url = 'a.tile.opentopomap.org';
copyright = char(uint8(169));
attribution = copyright + "OpenStreetMap contributors";
displayName = 'Open Topo Map';
```

Use addCustomBasemap to load the custom basemap, and then create a siteviewer object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution','DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```

After a custom basemap is added to siteviewer, the custom map is available for future calls to siteviewer. Note the 'Open Topo Map' icon in the Imagery tab.
siteviewer;

Use removeCustomBasemap to remove the custom basemap from future calls to siteviewer. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.
removeCustomBasemap (name)
siteviewer;

## Input Arguments

## basemapName - Name of custom basemap

string scalar | character vector
Name of the custom basemap to remove, specified as a string scalar or character vector. You define the basemap name when you add the basemap using the addCustomBasemap function.

Data Types: string | char

## buildingMaterialPermittivity

Permittivity and conductivity of building materials

## Syntax

[epsilon,sigma,complexepsilon] = buildingMaterialPermittivity(material,fc)

## Description

[epsilon,sigma,complexepsilon] = buildingMaterialPermittivity(material,fc) calculates the relative permittivity, conductivity, and complex relative permittivity for the specified material at the specified frequency. The methods and equations modeled in the buildingMaterialPermittivity function are presented in Recommendation ITU-R P. 2040 [1].

## Examples

## Calculate Permittivity of Various Building Materials

Calculate relative permittivity and conductivity at 9 GHz for various building materials as defined by textual classifications in ITU-R P.2040, Table 3.

```
material = ["vacuum";"concrete";"brick";"plasterboard";"wood"; ...
    "glass";"ceiling-board";"chipboard";"floorboard";"metal"];
fc = repmat(9e9,size(material)); % Frequency in Hz
[permittivity,conductivity] = ...
    arrayfun(@(x,y)buildingMaterialPermittivity(x,y),material,fc);
```

Display the results in a table.

```
varNames = ["Material";"Permittivity";"Conductivity"];
table(material,permittivity,conductivity,'VariableNames',varNames)
ans=10\times3 table
    Material Permittivity Conductivity
    "vacuum" 1 0
    "concrete" 5.31 0.19305
    "brick" 3.75 0.038
    "plasterboard" 2.94 0.054914
    "wood" 1.99 0.049528
    "glass" 6.27 0.059075
    "ceiling-board" 1.5 0.0064437
    "chipboard" 2.58 0.12044
    "floorboard" 3.66 0.085726
    "metal" 1 1e+07
```

## Plot Permittivity and Conductivity of Concrete at Various Frequencies

Calculate the relative permittivity and conductivity for concrete at frequencies specified.

```
fc = ((1:1:10)*10e9); % Frequency in Hz
[permittivity,conductivity] = ...
    arrayfun(@(y)buildingMaterialPermittivity("concrete",y),fc);
```

Plot the relative permittivity and conductivity of concrete across the range of frequencies.

```
figure
yyaxis left
plot(fc,permittivity)
ylabel('Relative Permittivity')
yyaxis right
plot(fc,conductivity)
ylabel('Conductivity (S/m)')
xlabel('Frequency (Hz)')
title('Permittivity and Conductivity of Concrete')
```

## Input Arguments

## material - Building material

"vacuum" | "concrete"|"brick"| "plasterboard"|...
Building material, specified as vector of strings including one or more of these options:

| "vacuum" | "glass" | "very-dry-ground" |
| :--- | :--- | :--- |
| "concrete" | "ceiling-board" | "medium-dry-ground" |
| "brick" | "floorboard" | "wet-ground" |
| "plasterboard" | "chipboard" |  |
| "wood" | "metal" |  |
| Example: ["vacuum" "brick"] <br> Data Types: char \| string <br> fc - Carrier frequency <br> positive scalar |  |  |

Carrier frequency in Hz , specified as a positive scalar.

Note fc must be in the range [1e6, 10e6] when the material is "very-dry-ground", "medium-dry-ground" or "wet-ground".

## Data Types: double

## Output Arguments

## epsilon - Relative permittivity

nonnegative scalar | nonnegative row vector
Relative permittivity of the building material, returned as a nonnegative scalar or row vector. The output dimension of epsilon matches that of the input argument material.

## sigma - Conductivity

nonnegative scalar | nonnegative row vector
Conductivity, in Siemens $/ \mathrm{m}$, of the building material, returned as a nonnegative scalar or row vector. The output dimension of sigma matches that of the input argument material.

## complexepsilon - Complex relative permittivity

complex scalar
Complex relative permittivity of the building material, returned as a complex scalar calculated by complexepsilon $=$ epsilon-1i sigma / $\left(2 п f \subset \varepsilon_{0}\right)$,
where $\varepsilon_{0}=8.854187817 \mathrm{e}-12$ Farads $/ \mathrm{m}$. $\varepsilon_{0}$ is the electric constant for the permittivity of free space.
The output dimension of complexepsilon matches that of the input argument material.

Introduced in R2020a

## earthSurfacePermittivity

Permittivity and conductivity of earth surface materials

## Syntax

[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('pure-water',fc, temp)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('dry-ice',fc,temp)
[epsilon,sigma, complexepsilon] = earthSurfacePermittivity('sea-water',fc, temp, salinity)
[epsilon,sigma, complexepsilon] = earthSurfacePermittivity('wet-ice',fc, liqfrac)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',fc,temp, sandpercent,claypercent,specificgravity, vwc)
[epsilon,sigma, complexepsilon] = earthSurfacePermittivity('soil', $\qquad$ ,
bulkdensity)
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('vegetation',fc, temp,gwc)

## Description

The earthSurfacePermittivity function computes electrical characteristics (relative permittivity, conductivity, and complex relative permittivity) of earth surface materials based on the methods and equations presented in ITU-R P. 527 [1]. The earthSurfacePermittivity function provides various syntaxes to account for characteristics germane to the specified surface material.
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('pure-water',fc, temp) calculates the electrical characteristics for pure water at the specified frequency and temperature. For pure-water, the temperature setting must be greater than $0^{\circ} \mathrm{C}$.
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('dry-ice',fc,temp) calculates the electrical characteristics for dry-ice at the specified frequency and temperature. For dry-ice, the temperature must be less than or equal to $0^{\circ} \mathrm{C}$.
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('sea-water',fc, temp, salinity) calculates the electrical characteristics for sea water at the specified frequency, temperature, and salinity. For sea-water, the temperature must be greater than $-2{ }^{\circ} \mathrm{C}$.
[epsilon,sigma, complexepsilon] = earthSurfacePermittivity('wet-ice',fc, liqfrac) calculates the electrical characteristics for wet ice at the specified frequency, and liquid water volume fraction. For wet-ice, the temperature is $0^{\circ} \mathrm{C}$.
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil',fc,temp, sandpercent, claypercent, specificgravity, vwc) calculates the electrical characteristics for soil at the specified frequency, temperature, sand percentage, clay percentage, specific gravity, and volumetric water content.
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('soil', $\qquad$ , bulkdensity) sets the soil bulk density in addition to input arguments from the previous syntax.
[epsilon,sigma,complexepsilon] = earthSurfacePermittivity('vegetation',fc, temp, gwc) calculates the electrical characteristics for vegetation at the specified frequency, temperature, and gravimetric water content. For vegetation, the temperature must be greater than or equal to $-20^{\circ} \mathrm{C}$.

## Examples

## Compare Permittivity and Conductivity of Salt-free Sea Water to Pure Water

Compare the relative permittivity and conductivity for salt-free (zero-salinity) sea water to pure water.

Specify a carrier frequency of 9 GHz , temperature of $30^{\circ} \mathrm{C}$, and salinity of zero.

```
fc = 9e9; % Carrier frequency in Hz.
temp = 30;
salinity = 0;
```

Compute the relative permittivity and conductivity.

```
[epsilon_pure_water,sigma_pure_water] = earthSurfacePermittivity('pure-water',fc,temp);
[epsilon_sea_water,sigma_sea_wäter] = earthSurfacePermittivity('sea-water',fc,temp,salinity);
```

Confirm that salt-free sea water and pure water have equal relative permittivity and conductivity.

```
isequal(epsilon_pure_water,epsilon_sea_water)
ans = logical
    1
```

isequal(sigma_pure_water,sigma_sea_water)
ans $=$ logical
1

## Compare Permittivity and Conductivity of Wet Ice to Dry Ice

Compare the relative permittivity and conductivity for wet ice with no liquid water to dry ice at $0^{\circ} \mathrm{C}$. Confirm the results differ by a negligible amount.

Specify a carrier frequency of 12 GHz .

```
fc = 12e9; % Carrier frequency in Hz.
```

Calculate the relative permittivity and conductivity for wet ice with zero liquid water by volume.

```
liqfrac = 0;
[epsilon_wet_ice_0,sigma_wet_ice_0] = earthSurfacePermittivity('wet-ice',fc,liqfrac); % Set liqu
```

Calculate the relative permittivity and conductivity for dry ice at $0^{\circ} \mathrm{C}$.

```
temp = 0; conductivity.
```

```
epsilon_wet_ice_0-epsilon_dry_ice_0
```

epsilon_wet_ice_0-epsilon_dry_ice_0
ans = 8.8818e-16
ans = 8.8818e-16
sigma_wet_ice_0-sigma_dry_ice_0
sigma_wet_ice_0-sigma_dry_ice_0
ans = -9.2179e-16

```
ans = -9.2179e-16
```

[epsilon_dry_ice_0,sigma_dry_ice_0] = earthSurfacePermittivity('dry-ice',fc,temp); \% Set tempera

Compare the relative permittivity and conductivity for wet ice with no liquid to dry ice at $0^{\circ} \mathrm{C}$.
Confirm that wet ice with no liquid and dry ice at $0^{\circ} \mathrm{C}$ have essentially equal relative permittivity and

Plot permittivity and conductivity versus frequency for dry ice and for wet ice. For dry ice, vary the temperature. For wet ice, vary the liquid water volume fraction. Calculate the permittivity and conductivity values by using arrayfun to apply the earthSurfacePermittivity function to the elements of the arrayed inputs.

```
freq = repmat([0.1,10,20,40,60]*1e9,6,1);
temp = repmat((-100:20:0)',1,5);
liqfrac = repmat((0:0.2:1)',1,5);
[epsilon_dry_ice, sigma_dry_ice] = arrayfun(@(x,y)earthSurfacePermittivity('dry-ice',x,y),freq,t
[epsilon_wet_ice, sigma_wet_ice] = arrayfun(@(x,y)earthSurfacePermittivity('wet-ice',x,y),freq,l
```

Display tiled surface plots across specified ranges.

```
figure
tiledlayout(2,2)
nexttile
surf(temp,freq,epsilon_dry_ice,'FaceColor','interp')
title('Permittivity of Dry Ice')
xlabel('Temperature ('}\mp@subsup{}{}{\circ}\textrm{C})'

```

## Calculate Permittivity and Conductivity of Various Soil Mixtures

Calculate relative permittivity and conductivity for various soil mixtures as defined by textual classifications in ITU-R P.527, Table 1.

Initialize computation variables for constant values and arrayed values.

```
fc = 28e9; % Frequency in Hz
temp = 23; % Temperature in }\mp@subsup{}{}{\circ}\textrm{C
vwc = 0.5; % Volumetric water content
pSand = [51.52; 41.96; 30.63; 5.02]; % Sand percentage
pClay = [13.42; 8.53; 13.48; 47.38]; % Clay percentage
sg = [2.66; 2.70; 2.59; 2.56]; % Specific gravity
bd = [1.6006; 1.5781; 1.5750; 1.4758]; % Bulk density (g/cm^3)
```

Calculate the relative permittivity and conductivity for these textual classifications: sandy loam, loam, silty loam, and silty clay. Use arrayfun to apply the earthSurfacePermittivity function to the elements of the arrayed inputs. Tabulate the results.

```
[Permittivity,Conductivity] = arrayfun(@(w,x,y,z)earthSurfacePermittivity( ...
    'soil',fc,temp,w,x,y,vwc,z),pSand,pClay,sg,bd);
pSilt = 100 - (pSand + pClay); % Silt percentage
soilType = ["Sandy Loam";"Loam";"Silty Loam";"Silty Clay"];
```

```
varNames1 = ["Soil Textual Classification";"Sand";"Clay";"Silt";"Specific Gravity";"Bulk Density
varNames2 = ["Soil Textual Classification";"Permittivity";"Conductivity"];
```

ITU-R P.527, Table 1 specifies the sand percentage, clay percentage, specific gravity, and bulk density for soil mixtures with these soil textual classifications.

```
table(soilType,pSand,pClay,pSilt,sg,bd,'VariableNames',varNames1)
ans=4\times6 table
\begin{tabular}{crllllll}

"Silty Loam" & 13.965 & 16.011 \\
"Silty Clay" & 12.861 & 14.647
\end{tabular}
```

## Calculate Permittivity and Conductivity of Vegetation

Calculate relative permittivity and conductivity versus frequency for vegetation, varying gravimetric water content and temperature.

Calculate relative permittivity and conductivity for vegetation at specified settings.

```
fc = 10e9; % Frequency in Hz
temp = 23; % Temperature in }\mp@subsup{}{}{\circ}\textrm{C
gwc = 0.68; % Gravimetric water content
[epsilon_veg,sigma_veg] = ...
    earth\SurfacePermittivity('vegetation',fc,temp,gwc)
epsilon_veg = 20.5757
sigma_veg = 4.9320
```

Calculate values necessary to plot permittivity and conductivity by using arrayfun to apply the earthSurfacePermittivity function to the elements of the arrayed inputs.

For a range of temperatures, calculate values to plot permittivity and conductivity versus frequency for vegetation at a 0.68 gravimetric water content.

```
fc = repmat([0.1,10,20,40,60]*1e9,6,1);
gwcl = 0.68;
temp1 = repmat((-20:20:80)',1,5);
[epsilon_veg_gwc,sigma_veg_gwc] = ...
    arrayfun(@(x,y)earthSurfacePermittivity('vegetation',x,y,gwc1),fc,temp1);
```

For a range of gravimetric water contents, calculate values to plot permittivity and conductivity versus frequency for vegetation at $10^{\circ} \mathrm{C}$.

```
temp2 = 10;
gwc2 = repmat((0.2:0.1:0.7)',1,5);
[epsilon_veg_tmp, sigma_veg_tmp] = ...
    arrayfun(@(x,z)earthSurfacePermittivity('vegetation',x,temp2,z),fc,gwc2);
```

Display tiled surface plots across specified ranges.

```
figure
tiledlayout(2,2)
nexttile
surf(temp1,fc,epsilon_veg_gwc,'FaceColor','interp')
title('Permittivity o\overline{f Vegetation at 0.68 gwc')}
xlabel('Temperature ('`C)')
ylabel('Frequency (Hz)')
nexttile
surf(templ,fc,sigma_veg_gwc,'FaceColor','interp')
title('Conductivity of Vegetation at 0.68 gwc')
nexttile
surf(gwc2,fc,epsilon_veg_tmp,'FaceColor','interp')
title('Permittivity of Vegetation at 10 ' C')
xlabel('Gravimetric Water Content')
ylabel('Frequency (Hz)')
nexttile
surf(gwc2,fc,sigma_veg_tmp,'FaceColor','interp')
title('Conductivity of Vegetation at 10}\mp@subsup{}{}{\circ}\textrm{C}'
```

## Input Arguments

## fc - Carrier frequency

scalar in the range ( $0,1 \mathrm{e} 12$ ]
Carrier frequency in Hz , specified as a scalar in the range ( $0,1 \mathrm{e} 12$ ].

## Data Types: double

## temp - Temperature

## numeric scalar

Temperature in ${ }^{\circ} \mathrm{C}$, specified as a numeric scalar. Valid surfaces and associated temperature limits are indicated in this table.

| Surface | Valid Temperature $\left({ }^{\circ} \mathbf{C}\right)$ |
| :--- | :--- |
| pure-water | greater than 0 |
| dry-ice | less than or equal to 0 |
| sea-water | greater than or equal to -2 |
| soil | any numeric |
| vegetation | $\geq-20$ |

Note When the surface is wet-ice, the temperature is $0^{\circ} \mathrm{C}$.

Data Types: double
salinity - Salinity of sea water
nonnegative scalar
Salinity of the sea water in $\mathrm{g} / \mathrm{Kg}$, specified as a nonnegative scalar.
Data Types: double

## liqfrac - Liquid water volume fraction of wet ice

numeric scalar in the range [0, 1]
Liquid water volume fraction of the wet ice, specified as a numeric scalar in the range [0, 1].
Data Types: double
sandpercent - Sand percentage of soil
numeric scalar in the range [0, 100]
Sand percentage of the soil, specified as a numeric scalar in the range [ 0,100 ]. The sum of sandpercent and claypercent must be less than or equal to 100 .

Data Types: double

## claypercent - Clay percentage of soil

numeric scalar in the range [0,100]
Clay percentage of the soil, specified as a numeric scalar in the range [ 0,100 ]. The sum of sandpercent and claypercent must be less than or equal to 100 .
Data Types: double
specificgravity - Specific gravity of soil
nonnegative scalar
Specific gravity of the soil, specified as a nonnegative scalar. The specific gravity is the mass density of the soil sample divided by the mass density of the amount of water in the soil sample.
Data Types: double
vwc - Volumetric water content of soil
numeric scalar in the range [ 0,1 ]
Volumetric water content of the soil, specified as a numeric scalar in the range [0, 1]. For more information, see "Soil Water Content" on page 2-955.
Data Types: double

## bulkdensity - Bulk density of soil

nonnegative scalar
Bulk density, in $\mathrm{g} / \mathrm{cm}^{3}$, of the soil, specified as a nonnegative scalar. For more information, see "Soil Water Content" on page 2-955.
Data Types: double

## gwc - Gravimetric water content of vegetation

numeric scalar in the range [0, 0.7]
Gravimetric water content of the vegetation, specified as a numeric scalar in the range [0, 0.7]. For more information, see "Soil Water Content" on page 2-955.
Data Types: double

## Output Arguments

## epsilon - Relative permittivity

nonnegative scalar
Relative permittivity of the earth surface, returned as a nonnegative scalar.

## sigma - Conductivity

nonnegative scalar
Conductivity of the earth surface in Siemens per meter ( $\mathrm{S} / \mathrm{m}$ ), returned as a nonnegative scalar.

## complexepsilon - Complex relative permittivity

complex scalar
Complex relative permittivity of the earth surface, returned as a complex scalar calculated by complexepsilon $=$ epsilon-1i sigma / $\left(2 \Pi f c \varepsilon_{0}\right)$,
where $\varepsilon_{0}=8.854187817 \mathrm{e}-12$ Farads per meter ( $\mathrm{F} / \mathrm{m}$ ). $\varepsilon_{0}$ is the electric constant for the permittivity of free space.

## More About

## ITU Terrain Materials

ITU-R P. 527 [1] presents methods and equations to calculate complex relative permittivity at carrier frequencies up to $1,000 \mathrm{GHz}$ for these common earth surface materials.

- Water
- Sea Water
- Dry or Wet Ice
- Dry or Wet Soil (combination of sand, clay, and silt)
- Vegetation (above and below freezing)

As described in ITU-R P.527, specific textural classification applies to these mixtures of sand, clay, and silt in soil with associated specific gravities and bulk densities.

| Soil Designation <br> Textural Class | Sandy Loam | Loam | Silty Loam | Silty Clay |
| :--- | :--- | :--- | :--- | :--- |
| \% Sand | 51.52 | 41.96 | 30.63 | 5.02 |
| \% Clay | 13.42 | 8.53 | 13.48 | 47.38 |
| \% Silt | 35.06 | 49.51 | 55.89 | 47.60 |

| Soil Designation <br> Textural Class | Sandy Loam | Loam | Silty Loam | Silty Clay |
| :--- | :--- | :--- | :--- | :--- |
| Specific gravity <br> $\left(\rho_{\mathrm{s}}\right)$ | 2.66 | 2.70 | 2.59 | 2.56 |
| Bulk Density $\left(\rho_{\mathrm{b}}\right)$ in <br> $\mathrm{g} / \mathrm{cm}^{3}$ | 1.6006 | 1.5781 | 1.5750 | 1.4758 |

## Soil Water Content

Soil water content is expressed on a gravimetric or volumetric basis. Gravimetric water content, gwc, is the mass of water per mass of dry soil. Volumetric water content, vwc, is the volume of liquid water per volume of soil. The bulk density, bulkdensity, is the ratio of the dry soil weight to the volume of the soil sample. The relationship between gwc and vwc is vwc = gwc $\square$ bulkdensity. When bulk density is not specified, the value of bulkdensity is computed by using ITU-R P.527, Equation 36:
bulkdensity $=1.07256+0.078886 \ln (p S a n d)+0.038753 \ln (p$ Clay $)+0.032732 \ln (p S i l t)$, where

- pSand = sandpercent
- pClay = claypercent
- pSilt = 100 - (sandpercent + claypercent)

## Functions

buildingMaterialPermittivity| raypl|raytrace

## Objects

comm. Ray

## Introduced in R2020a

## raypl

Calculate path loss and phase shift for ray

## Syntax

```
[pl,phase] = raypl (ray)
[pl,phase] = raypl (ray,Name,Value)
```

## Description

[ pl , phase] = raypl (ray) returns the path loss in dB and phase shift in radians based on the properties specified by ray. The path loss and path shift computations consider the free space loss and reflection loss derived from the propagation path, reflection materials, and polarizations. The function accounts for geometric coupling between horizontal and vertical polarizations only when both transmit and receive antennas are polarized. For more information, see "Path Loss Computation" on page 2-960.
[pl, phase] = raypl (ray,Name, Value) calculates the path loss and phase shift with additional options specified by one or more name-value pair arguments.

## Examples

## Reevaluate Path Loss Changing Reflection Materials and Frequency

Change the reflection materials and frequency for a ray and reevaluate the path loss and phase shift.
Launch Site Viewer with buildings in Hong Kong. Specify transmitter and receiver sites.

```
viewer = siteviewer("Buildings","hongkong.osm");
tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
    "AntennaHeight",10,"TransmitterPower",5, ...
    "TransmitterFrequency",28e9);
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...
    "AntennaHeight",1);
```

Perform ray tracing between the sites.

```
rays = raytrace(tx,rx,"NumReflections",0:2);
```

Find the first ray with 2 -order reflections from the result. Display the ray characteristics. Plot the ray to see the ray reflect off two buildings.

```
ray = rays{1}(find([rays{1}.NumReflections] == 2,1))
ray =
    Ray with properties:
        PathSpecification: 'Locations'
        CoordinateSystem: 'Geographic'
        TransmitterLocation: [3\times1 double]
```

```
        ReceiverLocation: [3×1 double]
        LineOfSight: 0
ReflectionLocations: [ 3\times2 double]
            Frequency: 2.8000e+10
        PathLossSource: 'Custom'
            PathLoss: 125.5038
            PhaseShift: 1.4198
Read-only properties:
    PropagationDelay: 8.3062e-07
PropagationDistance: 249.0122
    AngleOfDeparture: [2×1 double]
        AngleOfArrival: [2×1 double]
        NumReflections: 2
```

```
plot(ray);
```

By default, all buildings have concrete building material electrical characteristics. Change the material to metal for the second reflection and re-evaluate path loss. Use the raypl function to reevaluate the pathloss for the ray. Display the ray path to compare the change in path loss. Replot to show the slight change in color due to the path loss change of the ray.

```
[ray.PathLoss,ray.PhaseShift] = raypl(ray, ...
    "ReflectionMaterials",["concrete","metal"])
ray =
    Ray with properties:
            PathSpecification: 'Locations'
                CoordinateSystem: 'Geographic'
        TransmitterLocation: [3\times1 double]
            ReceiverLocation: [ }3\times1\mathrm{ double]
                    LineOfSight: 0
        ReflectionLocations: [3\times2 double]
                Frequency: 2.8000e+10
                PathLossSource: 'Custom'
                            PathLoss: 127.6379
                        PhaseShift: 4.6001
        Read-only properties:
                PropagationDelay: 8.3062e-07
            PropagationDistance: 249.0122
                AngleOfDeparture: [2\times1 double]
                AngleOfArrival: [2×1 double]
                NumReflections: 2
ray =
    Ray with properties:
            PathSpecification: 'Locations'
                CoordinateSystem: 'Geographic'
            TransmitterLocation: [ }3\times1\mathrm{ double]
                ReceiverLocation: [ }3\times1\mathrm{ double]
                    LineOfSight: 0
        ReflectionLocations: [3\times2 double]
                    Frequency: 2.8000e+10
```

```
        PathLossSource: 'Custom'
            PathLoss: 127.6379
            PhaseShift: 4.6001
Read-only properties:
    PropagationDelay: 8.3062e-07
    PropagationDistance: 249.0122
    AngleOfDeparture: [2×1 double]
        AngleOfArrival: [2×1 double]
        NumReflections: 2
plot(ray);
```

Change the frequency and reevaluate the path loss and phase shift. Plot the ray again and observe the obvious color change.

```
ray.Frequency = 2e9;
[ray.PathLoss,ray.PhaseShift] = raypl(ray, ...
    "ReflectionMaterials",["concrete","metal"]);
plot(ray);
```

## Input Arguments

## ray - Ray configuration

comm. Ray object
Ray configuration, specified as one comm. Ray object. The object must have the PathSpecification property set to "Locations".
Data Types: comm. Ray

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: raypl(ray,'TransmitterPolarization','H','ReceiverPolarization','H'), specifies the horizontal polarizations for the transmit and receive antennas for ray.

## ReflectionMaterials - Reflection materials

"concrete" (default) | string scalar | 1-by-NR string vector | 2-by-1 numeric vector | 2-by-NR numeric matrix

Reflection materials for a non-line-of-sight (NLOS) ray, specified as a string scalar, 1-by-NR string vector, 2-by-1 numeric vector, or 2-by- $N R$ numeric matrix. $N R$ represents the number of reflections as specified by the comm. Ray.NumReflections property.

- When ReflectionMaterials is specified as a string scalar or string vector, the reflection material must be one of "concrete", "brick", "wood", "glass", "metal", "water", "vegetation", "loam", or "perfect-reflector". When specified as a string scalar, the setting applies to all the reflections.
- When ReflectionMaterials is specified as a 2-by-1 numeric vector, the [relative permittivity; conductivity] value pair applies to all the reflections.
- When ReflectionMaterials is specified as a 2-by-NR numeric matrix, the [relative permittivity; conductivity] value pair in each column applies for each of the $N R$ reflection points, respectively.

Example: "ReflectionMaterials", ["concrete", "water"], specifies that a ray with two reflections will use electrical characteristics of concrete at the first reflection point and water at the second reflection point.

Data Types: string | char | double
TransmitterPolarization - Transmit antenna polarization type
"none" (default) | "H" | "V" | "RHCP" | "LHCP" | normalized 2-by-1 Jones vector
Transmit antenna polarization type, specified as "none", "H", "V", "RHCP", "LHCP", or a normalized [H; V] Jones vector. For more information, see "Jones Vector Notation" on page 2-962.

Example: 'TransmitterPolarization', 'RHCP', specifies right-hand circular polarization for the transmit antenna.
Data Types: double | char | string

## ReceiverPolarization - Receive antenna polarization type

"none" (default) | "H" | "V" | "RHCP" | "LHCP" | normalized 2-by-1 Jones vector
Receive antenna polarization type, specified as "none", "H", "V", "RHCP", "LHCP", or a normalized [H; V] Jones vector. For more information, see "Jones Vector Notation" on page 2-962.
Example: 'ReceiverPolarization', [1;0], specifies horizontal polarization for the receive antenna by using Jones vector notation.
Data Types: double | char | string

## TransmitterAxes - Orientation of transmit antenna axes

3-by-3 identity matrix (default) | 3-by-3 unitary matrix
Orientation of the transmit antenna axes, specified as a 3-by-3 unitary matrix indicating the rotation from the transmitter local coordinate system (LCS) into the global coordinate system (GCS). When the CoordinateSystem property of the comm. Ray is set to "Geographic", the GCS orientation is the local East-North-Up (ENU) coordinate system at transmitter. For more information, see "Coordinate System Orientation" on page 2-960.

Example: 'TransmitterAxes', eye(3), specifies that the local coordinate system for the transmitter axes is aligned with the global coordinate system. This is the default orientation.
Data Types: double

## ReceiverAxes - Orientation of receive antenna axes

3-by-3 identity matrix (default) | 3-by-3 unitary matrix
Orientation of the receive antenna axes, specified as a 3-by-3 unitary matrix indicating the rotation from the receiver local coordinate system (LCS) into the global coordinate system (GCS). The GCS orientation is the local East-North-Up (ENU) coordinate system at receiver when the .CoordinateSystem property of the comm. Ray is set to "Geographic". For more information, see "Coordinate System Orientation" on page 2-960.
Example: 'ReceiverAxes',[0-1 0; 1 0 0; 001$]$, specifies a $90^{\circ}$ rotation around the z -axis of the local receiver coordinate system with respect to the global coordinate system.
Data Types: double

## Output Arguments

## pl - Path loss

scalar
Path loss in dB, returns the path loss calculated for the input ray object, accounting for any modifications specified by Name, Value pairs.

## phase - Phase shift

scalar
Phase shift in radians, returns the phase shift calculated for the input ray object, accounting for any modifications specified by Name, Value pairs.

## More About

## Coordinate System Orientation

This image shows the orientation of the electromagnetic fields in the global coordinate system (GCS) and the local coordinate systems of the transmitter and receiver.

When the CoordinateSystem property of the comm. Ray is set to "Geographic", the GCS orientation is the local East-North-Up (ENU) coordinate system at observer. The path loss computation accounts for the round-earth differences between ENU coordinates at the transmitter and receiver.

## Path Loss Computation

The path loss computations in raypl follow the path loss and reflection matrix computations as described in IEEE Document 802.11-09/0334r8 [1]. The function accounts for geometric coupling
between horizontal and vertical polarizations only when both transmit and receive antennas are polarized.

For a first order signal reflection, the reflection matrix, $H_{\text {ref1 }}$, is computed as

$$
H_{r e f 1}=\left[\begin{array}{cc}
\cos \left(\psi_{r \chi}\right) & \sin \left(\psi_{r \chi}\right) \\
-\sin \left(\psi_{r \chi}\right) & \cos \left(\psi_{r \chi}\right)
\end{array}\right] \times\left[\begin{array}{cc}
R_{\perp}\left(\alpha_{i n c}\right) & 0 \\
0 & R_{\|}\left(\alpha_{i n c}\right)
\end{array}\right] \times\left[\begin{array}{cc}
\cos \left(\psi_{t \chi}\right) & \sin \left(\psi_{t \chi}\right) \\
-\sin \left(\psi_{t \chi}\right) & \cos \left(\psi_{t x}\right)
\end{array}\right]
$$

The terms in the channel propagation matrix computation represent

- RX geometric coupling matrix - Recalculation of the polarization vector from the plane of incidence basis to RX coordinates.
- Polarization matrix - Matrix includes the reflection coefficients $R \square$ and $R \|$ for the perpendicular and parallel components of the electric field $E \square$ and $E \|$ respectively.
- TX geometric coupling matrix - Recalculation of the polarization vector from the TX coordinates basis to the plane of incidence.

This figure illustrates a first order reflected signal path.

Where

- The reflection plane is offset from the global coordinate system origin.
- $k$ represents the waveform propagation vector.
- $n$ represents the vector normal to the incident plane.
- $E_{\theta}$ and $E_{\varphi}$ represent the vertical and horizontal electromagnetic field vectors.
- $\alpha_{\text {inc }}$ represents the incident angle of $k$.
- $\psi_{\mathrm{tx}}$ represents the angle between $E_{\theta}$ and a normal to the incident plane.
- TX represents the transmit antenna.
- RX represents the receive antenna.

The reflection matrix computations for second order signal reflections extend from the first order signal reflection computations. For more information, see IEEE Document 802.11-09/0334r8 [1].

## Jones Vector Notation

For Jones vector notation, the raypl function describes signal polarization using Jones calculus.
The orthogonal components of Jones vectors are defined for $E_{\theta}$ and $E_{\varphi}$. This table shows the Jones vector corresponding to various antenna polarizations.

| Antenna Polarization Type | Corresponding Jones Vector |
| :--- | :---: |
| Linear polarized in the $\theta$ direction | $\binom{H}{V}=\binom{0}{1}$ |
| Linear polarized in the $\varphi$ direction | $\binom{H}{V}=\binom{1}{0}$ |
| Left-hand circular polarized (LHCP) | $\binom{H}{V}=\frac{1}{\sqrt{2}}\binom{j}{1}$ |
| Right-hand circular polarized (RHCP) | $\binom{H}{V}=\frac{1}{\sqrt{2}}\binom{-j}{1}$ |

## blkdiagbfweights

MIMO channel block diagonalized weights

## Syntax

[wp,wc] = blkdiagbfweights(chanmat,ns)
[wp,wc] = blkdiagbfweights(chanmat,ns,pt)

## Description

[wp,wc] = blkdiagbfweights(chanmat,ns) returns precoding weights, wp, and combining weights, wc, derived from the channel response matrices contained in a MATLAB cell array chanmat.

- You can specify multiple user channels by putting each channel in a chanmat cell. chanmat \{k\} represents the $k^{\text {th }}$ channel from the transmitter to the user.
- For a single frequency, specify the channel cell as a matrix.
- For multiply frequencies, specify the channel cell as a three-dimensional array where the rows represent different subcarriers.
- Specify multiple subchannels per channel using the ns argument. Subchannels represent different data streams. ns specifies the number of subchannels for each user channel. Multiply the data streams by the precoding weights, wp.

The precoding and combining weights diagonalize the channel into independent subchannels so that for the $k^{\text {th }}$ user, the matrix wp*chanmat $\{\mathrm{k}\}^{*} \mathrm{wc}\{\mathrm{k}\}$ is diagonal for each subcarrier.
[wp,wc] = blkdiagbfweights(chanmat,ns,pt) also specifies the total transmitted power, pt, per subcarrier.

## Examples

## Spatial Multiplexing with Block Diagonal Weights

Start with a base station consisting of a uniform linear array (ULA) with 16 antennas, and two users having receiver ULA arrays with 8 and 4 antennas, respectively. Show that using block diagonalization-based precoding and combining weights achieves spatial multiplexing, where the received signal at each user can be decoded without interference from the other user. Specify two data streams for each user.

Specify the transmitter location in txpos and two user receiver locations in rxpos1 and rxpos2. Array elements are spaced one-half wavelength apart.

```
txpos = (0:15)*0.5;
rxpos1 = (0:7)*0.5;
rxpos2 = (0:3)*0.5;
```

Create the channel matrix cell array using scatteringchanmtx and then compute the beamforming weights wp and wc. Each channel corresponds to a user. Assume that the channels have 10 scatterers. Each channel has two subchannels specified by the vector ns.

```
chanmat = {scatteringchanmtx(txpos,rxpos1,10), ...
    scatteringchanmtx(txpos,rxpos2,10)};
ns = [2 2];
[wp,wc] = blkdiagbfweights(chanmat,ns);
```

The weights diagonalize the channel matrices for each user.
For channel 1:

```
disp(wp*chanmat{1}*wc{1})
8.2269 - 0.0000i 0.0000 - 0.0000i
0.0000 + 0.0000i 6.1371 - 0.0000i
0.0000 - 0.0000i -0.0000 + 0.0000i
0.0000 - 0.0000i 0.0000 + 0.0000i
```

For channel 2:

```
disp(wp*chanmat{2}*wc{2})
\begin{tabular}{rr}
\(-0.0000+0.0000 i\) & \(-0.0000+0.0000 i\) \\
\(-0.0000+0.0000 i\) & \(-0.0000+0.0000 i\) \\
\(8.7543-0.0000 i\) & \(0.0000-0.0000 i\) \\
\(0.0000+0.0000 i\) & \(4.4372+0.0000 i\)
\end{tabular}
```

First create four subchannels to carry the data streams: two subchannels per channel. Each data stream contains 20 samples of $\pm 1$. Precode the input streams and combine the streams to produce the recovered signals.

```
x = 2*round(rand([20,4])) - 1;
xp = x*wp;
y1 = xp*chanmat{1} + 0.1*randn(20,8);
y2 = xp*chanmat{2} + 0.1*randn(20,4);
y = [y1*wc{1},y2*wc{2}];
```

Overlay stem plots of the input and recovered signals to show that the received user signals are the same as the transmitted signals.

```
for m = 1:4
    subplot(4,1,m)
    s = stem([x(:,m) 2*((real(y(:,m)) > 0) - 0.5)]);
    s(1).LineWidth = 2;
    s(2).MarkerEdgeColor = 'none';
    s(2).MarkerFaceColor = 'r';
    ylabel('Signal')
    title(sprintf('User %d Stream %d',ceil(m/2),rem(m-1,2) + 1))
    if m==1
        legend('Input','Recovered','Location','best')
    end
end
xlabel('Samples')
```

## Spatial Multiplexing with Specified Power

Start with a base station consisting of a uniform linear array (ULA) with 16 antennas, and two users having receiver ULA arrays with 8 and 5 antennas, respectively. Show how to use three-dimensional arrays of channel matrices to handle two subcarriers. Then, the channel matrix for the first user takes the form 2 -by- $16-$ by- 8 and the channel matrix for the second users takes the form 2 -by- 16 -by- 5 . Also assume that there are two data streams for each user.

Specify the transmitter location in txpos and two user receiver locations in rxpos1 and rxpos2. Array elements are spaced one-half wavelength apart.

```
nr1 = 8;
nr2 = 5;
txpos = (0:15)*0.5;
rxpos1 = (0:(nr1-1))*0.5;
rxpos2 = (0:(nr2-1))*0.5;
```

Create the channel matrices using scatteringchanmtx and put them in a cell array. To create a second subchannel for each receiver, duplicate each channel matrix. Assume 10 point scatterers in computing the channel matrix.

```
smtmp1 = scatteringchanmtx(txpos,rxpos1,10);
smtmp2 = scatteringchanmtx(txpos,rxpos2,10);
sm1 = zeros(2,16,8);
```

```
sm2 = zeros(2,16,5);
sm1(1,:,:) = smtmp1;
sm1(2,:,:) = smtmpl;
sm2(1,:,:) = smtmp2;
sm2(2,:,:) = smtmp2;
chanmat = {sm1,sm2};
```

Specify that there are two data streams for each user.
ns = [2 2];
Specify the transmitted powers for each subcarrier.

```
pt = [1.0 1.5];
```

Compute the beamforming weights.

```
[wp,wc] = blkdiagbfweights(chanmat,ns,pt);
```

Show that the channels are diagonalized for the first subcarrier.

```
ksubcr = 1;
wpx = squeeze(wp(ksubcr,:,:));
chanmat1 = squeeze(chanmat{1}(ksubcr,:,:));
chanmat2 = squeeze(chanmat{2}(ksubcr,:,:));
wc1 = squeeze(wc{1}(ksubcr,:,:));
wc2 = squeeze(wc{2}(ksubcr,:,:));
wpx*chanmat1*wcl
ans = 4×2 complex
    8.2104 + 0.0000i -0.0000 - 0.0000i
    0.0000 - 0.0000i 5.9732 - 0.0000i
    0.0000 - 0.0000i -0.0000 - 0.0000i
    0.0000 - 0.0000i 0.0000 - 0.0000i
```

wpx*chanmat2*wc2
ans $=4 \times 2$ complex
$-0.0000+0.0000 i \quad 0.0000+0.0000 i$
$-0.0000+0.0000 i \quad 0.0000+0.0000 i$
$8.8122+0.0000 i-0.0000+0.0000 i$
$0.0000+0.0000 i \quad 4.8186-0.0000 i$

Propagate the signals to each user and then decode. Generate four streams of random data containing -1 's and +1 's and having two columns for each user. Each stream is a subchannel.

```
x = 2*(round(rand([20 4]))) - 1;
```

Precode the data streams.

```
xp = x*wpx;
```

$\mathrm{y} 1=x p *$ chanmat $1+0.1 * \operatorname{randn}(20,8)$;
y2 $=$ xp*chanmat2 $+0.1 *$ randn $(20,5)$;

Decode the data streams.
$y=\left[y 1 * w c 1, y 2{ }^{*} w c 2\right] ;$
Overlay stem plots of the input and recovered signals to show that the received user signals are the same as the transmitted signals.

```
for m = 1:4
    subplot(4,1,m)
    s = stem([x(:,m) 2*((real(y(:,m)) > 0) - 0.5)]);
    s(1).LineWidth = 2;
    s(2).MarkerEdgeColor = 'none';
    s(2).MarkerFaceColor = 'r';
    ylabel('Signal')
    title(sprintf('User %d Stream %d',ceil(m/2),rem(m-1,2) + 1))
    if m==1
        legend('Input','Recovered','Location','best')
    end
end
xlabel('Samples')
```

## Input Arguments

## chanmat - Channel response matrices

$N_{\mathrm{u}}$-element cell array
Channel response matrices, specified as an $N_{\mathrm{u}}$-element cell array. $N_{\mathrm{u}}$ is the number of receive arrays. Each cell corresponds to a different channel and contains a channel response matrix or a three
dimensional MATLAB array. The cell array must contain either all matrices or all arrays. For matrices, the number of rows for all matrices must be the same. For three-dimensional arrays, the number of rows and columns must be the same.

- If the $k^{\text {th }}$ cell is a matrix, the matrix has the size $N_{\mathrm{t}}$-by- $N_{\mathrm{r}}(k)$. $N_{\mathrm{t}}$ is the number of elements in the transmitting array and $N_{\mathrm{r}}(k)$ is the number of elements in the $k^{\text {th }}$ receiving array.
- If the $k^{\text {th }}$ cell is an array, the array has the size $L$-by- $N_{\mathrm{t}}$-by- $N_{\mathrm{r}}(k) . L$ is the number of subcarriers. $N_{\mathrm{t}}$ is the number of elements in the transmit array and $N_{\mathrm{r}}(k)$ is the number of elements in the $k^{\text {th }}$ receive array.

## Data Types: double

Complex Number Support: Yes

## ns - Number of data streams per receive array

$N_{\mathrm{u}}$-element row vector of positive integers
Number of data streams per receive array, specified as an $N_{\mathrm{u}}$-element row vector of positive integers. $N_{\mathrm{u}}$ is the number of receive arrays.
Data Types: double

## pt - Total transmitted power per subcarrier

1 (default) | positive scalar | $L$-element vector of positive values
Total transmitted power per subcarrier, specified as a positive scalar or an $L$-element vector of positive values. $L$ is the number of subcarriers. If pt is a scalar, all subcarriers have the same transmitted power. If pt is a vector, each vector element specifies the transmitted power for the corresponding subcarrier. Power is in linear units.

## Data Types: double

## Output Arguments

## wp - Precoding weights

complex-valued $N_{\text {st }}$-by- $N_{\mathrm{t}}$ matrix | complex-valued $L$-by- $N_{\mathrm{st}}$-by- $N_{\mathrm{t}}$ MATLAB array
Precoding weights, returned as a complex-valued $N_{\mathrm{st}}$-by- $N_{\mathrm{t}}$ matrix or a complex-valued $L$-by- $N_{\mathrm{st}}$-by- $N_{\mathrm{t}}$ MATLAB array.

- If chanmat contains matrices, wp is a complex-valued $N_{\mathrm{st}}$-by- $N_{\mathrm{t}}$ matrix where $N_{\mathrm{st}}$ is the total number of data channels (sum(ns)).
- If chanmat contains three-dimensional MATLAB arrays, wp is a complex-valued $L$-by- $N_{s t}$-by- $N_{\mathrm{t}}$ MATLAB array where $N_{\text {st }}$ is the total number of data channels (sum(ns)).

Units are dimensionless.
Data Types: double
wc - Combining weights
$N_{\mathrm{u}}$-element cell array
Combining weights, returned as an $N_{\mathrm{u}}$-element cell array. Units are dimensionless.

- If chanmat contains matrices, the $k^{\text {th }}$ cell in wc contains a complex valued $N_{\mathrm{r}}(k)$-by- $N_{\mathrm{s}}(k)$ matrix. $N_{\mathrm{s}}(k)$ is the value of the argument ns for the $k^{\text {th }}$ receive array.
- If chanmat contains three-dimensional MATLAB arrays, the $k^{\text {th }}$ cell of wc contains a complexvalued $L$-by- $N_{\mathrm{r}}(k)$-by- $N_{\mathrm{s}}(k)$ MATLAB array. $N_{\mathrm{s}}(k)$ is the value of the $k^{\text {th }}$ entry of the ns vector.

Data Types: double

## cart2sphvec

Convert vector from Cartesian components to spherical representation

## Syntax

vs = cart2sphvec(vr,az,el)

## Description

vs = cart2sphvec(vr,az,el) converts the components of a vector or set of vectors, vr, from their representation in a local Cartesian coordinate system to a spherical basis representation contained in vs. A spherical basis representation is the set of components of a vector projected into a basis given by ( $\widehat{\mathbf{e}}_{a z}, \widehat{\mathbf{e}}_{e l}, \widehat{\mathbf{e}}_{R}$ ). The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, az, and elevation, el.

## Examples

## Spherical Representation of Unit Z-Vector

Start with a vector in Cartesian coordinates pointing along the $z$-direction and located at $45^{\circ}$ azimuth, $45^{\circ}$ elevation. Compute its components with respect to the spherical basis at that point.

```
vr = [0;0;1];
vs = cart2sphvec(vr,45,45)
vs = 3\times1
```

## Input Arguments

## vr - Vector in Cartesian basis representation

3-by-1 column vector | 3-by-N matrix
Vector in Cartesian basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of $v r$ contains the three components of a vector in the right-handed Cartesian basis $x, y, x$.

## Example: [4.0; -3.5; 6.3]

Data Types: double
Complex Number Support: Yes

## az - Azimuth angle <br> scalar in range [-180,180]

Azimuth angle specified as a scalar in the closed range [-180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The
azimuth angle is the angle in the $x y$-plane from the positive $x$-axis to the vector's orthogonal projection into the $x y$-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the $x$-axis while an azimuth angle of $90^{\circ}$ and an elevation angle of zero specify a point on the $y$ axis.
Example: 45
Data Types: double

## el - Elevation angle

scalar in range [-90,90]
Elevation angle specified as a scalar in the closed range [-90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the $x y$-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and $\pm 90^{\circ}$ elevation define the north and south poles, respectively.

Example: 30
Data Types: double

## Output Arguments

## vs - Vector in spherical basis

3-by-1 column vector | 3-by-N matrix
Spherical representation of a vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as vs. Each column of vs contains the three components of the vector in the righthanded ( $\widehat{\mathbf{e}}_{a z}, \widehat{\mathbf{e}}_{e l}, \widehat{\mathbf{e}}_{R}$ ) basis.

## More About

## Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ( $\widehat{\mathbf{e}}_{a z}, \widehat{\mathbf{e}}_{e l}, \widehat{\mathbf{e}}_{R}$ ) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of $R$ so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:

For any point on the sphere specified by $a z$ and $e l$, the basis vectors are given by:

$$
\begin{aligned}
& \widehat{\mathbf{e}}_{\mathbf{a z}}=-\sin (a z) \widehat{\mathbf{i}}+\cos (a z) \widehat{\mathbf{j}} \\
& \widehat{\mathbf{e}}_{\mathbf{e l}}=-\sin (e l) \cos (a z) \widehat{\mathbf{i}}-\sin (e l) \sin (a z) \widehat{\mathbf{j}}+\cos (e l) \widehat{\mathbf{k}} \\
& \widehat{\mathbf{e}}_{\mathbf{R}}=\cos (e l) \cos (a z) \widehat{\mathbf{i}}+\cos (e l) \sin (a z) \widehat{\mathbf{j}}+\sin (e l) \widehat{\mathbf{k}} .
\end{aligned}
$$

Any vector can be written in terms of components in this basis as $\mathbf{v}=v_{a z} \widehat{\mathbf{e}}_{\mathbf{a z}}+v_{e l} \widehat{\mathbf{e}}_{\mathbf{e l}}+v_{R} \widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$
\left[\begin{array}{l}
v_{x} \\
v_{y} \\
v_{z}
\end{array}\right]=\left[\begin{array}{ccc}
-\sin (a z) & -\sin (e l) \cos (a z) & \cos (e l) \cos (a z) \\
\cos (a z) & -\sin (e l) \sin (a z) & \cos (e l) \sin (a z) \\
0 & \cos (e l) & \sin (e l)
\end{array}\right]\left[\begin{array}{c}
v_{a z} \\
v_{e l} \\
v_{R}
\end{array}\right]
$$

and

$$
\left[\begin{array}{l}
v_{a z} \\
v_{e l} \\
v_{R}
\end{array}\right]=\left[\begin{array}{ccc}
-\sin (a z) & \cos (a z) & 0 \\
-\sin (e l) \cos (a z) & -\sin (e l) \sin (a z) & \cos (e l) \\
\cos (e l) \cos (a z) & \cos (e l) \sin (a z) & \sin (e l)
\end{array}\right]\left[\begin{array}{c}
v_{x} \\
v_{y} \\
v_{z}
\end{array}\right] .
$$

## cranerainpl

RF signal attenuation due to rainfall using Crane model

## Syntax

L = cranerainpl(range,freq, rainrate)
L = cranerainpl(range,freq, rainrate,elev)
L = cranerainpl(range,freq, rainrate, elev,tau)

## Description

$L=$ cranerainpl(range,freq, rainrate) returns the signal attenuation, $L$, due to rain based on the Crane rain model [1]. Signal attenuation is a function of the signal path length, range, the signal frequency, freq, and the rain rate, rainrate. The rain rate is defined as the long-term statistical rain rate. The attenuation model applies only for frequencies from 1 GHz to 1000 GHz and is valid for ranges up to 22.5 km . The Crane model accounts for the cellular nature of rainstorms.
$\mathrm{L}=\mathrm{cranerainpl}($ range, freq, rainrate,elev) also specifies the elevation angle, elev, of the signal path.
$\mathrm{L}=$ cranerainpl(range,freq, rainrate, elev,tau) also specifies the polarization tilt angle, tau, of the signal.

## Examples

## Compare Attenuation for Two Rain Rates Using Crane Model

Use the Crane rain model to compute the signal attenuation caused by rain for a 20 GHz signal sent over a distance of 10 km . Use rain rates of 10.0 and $100.0 \mathrm{~mm} / \mathrm{hr}$.

First, set the rain rate to $10 \mathrm{~mm} / \mathrm{hr}$.

```
rr = 10.0;
L = cranerainpl(10e3,20.0e9,rr)
L = 12.5988
```

Repeat the computation using a rain rate of $100.0 \mathrm{~mm} / \mathrm{hr}$.

```
rr = 100.0;
L = cranerainpl(10e3,20.0e9,rr)
L = 73.1912
```

## Rain Attenuation as a Function of Frequency Using Crane Model

Plot the signal attenuation due to rain for signals in the frequency range from 1 to 1000 GHz . Use the Crane model to compute the attenuation for a rain rate of $30.0 \mathrm{~mm} / \mathrm{hr}$ and a signal path distance of 10 km .
$r r=30.0 ;$
freq = [1:1000]*1e9;
L = cranerainpl(10e3,freq,rr);
semilogx(freq/1e9, L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')

## Rain Attenuation as a Function of Elevation Using Crane Model

Plot the signal attenuation due to rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 10 km and a signal frequency of 10 GHz . The rain rate is $100 \mathrm{~mm} / \mathrm{hr}$.
rr = 100.0;
Set the elevation angles, frequency, and path length.

```
elev = [0:1:90];
freq = 10.0e9;
rng = 10e3*ones(size(elev));
```

Compute and plot the loss.

```
L = cranerainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```

## Rain Attenuation as a Function of Polarization Using Crane Model

Plot the signal attenuation due to rainfall as a function of the polarization tilt angle. Assume a path distance of 10 km , a signal frequency of 10 GHz , and a path elevation angle of 0 degrees. Set the rainfall rate to $70 \mathrm{~mm} /$ hour. Plot the signal attenuation against polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.

```
tau = -90:90;
```

Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 10.0e9;
```

```
rng = 10e3*ones(size(tau));
rr = 70.0;
```

Compute and plot the attenuation.

```
L = cranerainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```

## Input Arguments

## range - Signal path length

positive scalar | real-valued 1-by- $M$ vector of positive values | real-valued $M$-by-1 vector of positive values

Signal path length, specified as a positive scalar, a real-valued 1-by- $M$ vector of positive values, or real-valued $M$-by-1 vector of positive values. Units are in meters.

Example: [13000.0,14000.0]

## freq - Signal frequency

positive scalar | real-valued 1-by- $N$ vector of positive values | real-valued $N$-by-1 vector of positive values

Signal frequency, specified as a positive scalar, a real-valued 1-by- $N$ vector of positive values, or a real-valued $N$-by-1 vector of positive values. Units are in Hz . Frequencies must lie in the range 11000 GHz .
Example: [2.0:2:10.0]*1e9]
rainrate - Rain rate
nonnegative scalar
Rain rate, specified as a nonnegative scalar. Rain rate represents the long-term statistical rainfall rate provided by Crane (see [1]). Units are in $\mathrm{mm} / \mathrm{hr}$.
Example: 100.5

## elev - Signal path elevation angle

0.0 (default) | scalar | real-valued 1 -by- $M$ vector | real-valued $M$-by-1 vector

Signal path elevation angle, specified as a real-valued scalar, or real-valued $M$-by-1 or real-valued 1-by-M vector. Units are in degrees between $-90^{\circ}$ and $90^{\circ}$.

- If elev is a scalar, all propagation paths have the same elevation angle.
- If elev is a vector, its length must match the length of range and each element in elev corresponds to a propagation range.

Example: [0,45]

## tau - Tilt angle of signal polarization ellipse

0.0 (default) | scalar | real-valued 1 -by- $M$ vector | real-valued $M$-by-1 vector

Tilt angle of the signal polarization ellipse, specified as a scalar, a real-valued 1-by- $M$ vector, or a realvalued $M$-by- 1 vector. Tilt angle values are in the range $-90^{\circ}$ and $90^{\circ}$, inclusive. Units are in degrees.

- If tau is a scalar, all signals have the same tilt angle.
- If tau is a vector, its length must match the length of range. In that case, each element in tau corresponds to a propagation path in range.

The tilt angle is defined as the angle between the semimajor axis of the polarization ellipse and the $x$ axis. Because the ellipse is symmetrical, a tilt angle of $10^{\circ}$ corresponds to the same polarization state as a tilt angle of $-80^{\circ}$. Thus, the tilt angle need only be specified between $\pm 90^{\circ}$.
Example: [45, 30]

## Output Arguments

## L - Signal attenuation

real-valued $M$-by- $N$ matrix
Signal attenuation, returned as a real-valued $M$-by- $N$ matrix. Each matrix row represents a different path where $M$ is the number of paths. Each column represents a different frequency where $N$ is the number of frequencies. Units are in dB .

## More About

## Crane Rainfall Attenuation Model

The Crane model calculates the attenuation of signals that propagate through regions of rainfall. The model was developed for use on Earth-space or terrestrial propagation paths and is a commonly-used method for the calculation of rain attenuation. The model is based on observations of rain rate, rain structure, and the vertical variation of temperature in the atmosphere. The Crane model (see Electromagnetic Wave Propagation through Rain) is primarily applicable to North America. The Crane model generally predicts losses greater than those of the ITU rain attenuation model used in the rainpl function. However, the uncertainty of both models and the short-term variation of fade can be large.

The ITU and Crane models are very similar but have some differences. The ITU and Crane rain attenuation models both require statistical annual rainfall rates and utilize an effective path length reduction factor to account for the cellular nature of storms. The $0.01 \%$ rainfall rate tables provided by Crane and the ITU are different. The Crane rainfall zones are similar to the ITU zones but more zones are defined in the US than in the ITU model. The ITU rainfall zones are discussed in ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods. The Crane model is more complex consisting of a piecewise combination of path profiles composed of exponential functions.

The Crane model utilizes two exponential functions to span the distance from 0 to 22.5 km .

- For $\delta<D<22.5$,

$$
L=\gamma\left(\frac{e^{y \delta}-1}{y}-\frac{b^{\alpha} e^{z \delta}}{z}+\frac{b^{\alpha} e^{z D}}{z}\right)
$$

- For $0<D<\delta$,

$$
L=\gamma\left(\frac{e^{y D}-1}{y}\right)
$$

where

- $L=$ path attenuation (dB)
- $\quad$ ㅁ= propagation distance (km)
- $R=$ statistical $0.01 \%$ rain rate ( $\mathrm{mm} / \mathrm{hr}$ )
- $\gamma=$ specific attenuation identical to that calculated in rainpl.

$$
\gamma_{R}=k R^{\alpha},
$$

The parameters $k$ and $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. These coefficients, given by both Crane Electromagnetic Wave Propagation through Rain and the ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods, are identical and are valid from 1 GHz to 1000 GHz . The specific attenuation model is valid for frequencies from $1-1000 \mathrm{GHz}$. Rainfall specific attenuation is computed according to the ITU rainfall model in ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods.

The remaining parameters are empirical constants defined as:

- $b=2.3 R^{-0.17}$
- $\quad c=0.026-0.03 \ln R$
- $\delta=3.8-0.6 \ln R$
- $u=\ln \left(b e^{c \delta}\right) / \delta$
- $y=\alpha u$
- $z=\alpha c$

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the propagation distance.

You can also apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## fogpl

RF signal attenuation due to fog and clouds

## Syntax

$L=f o g p l(R, f r e q, T, d e n)$

## Description

$L=f o g p l(R, f r e q, T, d e n)$ returns attenuation, $L$, when signals propagate in fog or clouds. $R$ represents the signal path length. freq represents the signal carrier frequency, $T$ is the ambient temperature, and den specifies the liquid water density in the fog or cloud.

The fogpl function applies the International Telecommunication Union (ITU) cloud and fog attenuation model to calculate path loss of signals propagating through clouds and fog. See [1] (Phased Array System Toolbox). Fog and clouds are the same atmospheric phenomenon, differing only by height above ground. Both environments are parametrized by their liquid water density. Other model parameters include signal frequency and temperature. This function applies to cases when the signal path is contained entirely in a uniform fog or cloud environment. The liquid water density does not vary along the signal path. The attenuation model applies only for frequencies at $10-1000 \mathrm{GHz}$.

## Examples

## Attenuation in Cumulus Clouds

Compute the attenuation of signals propagating through a cloud that is 1 km long at 1000 meters altitude. Compute the attenuation for frequencies from 15 to 1000 GHz . A typical value for the cloud liquid water density is $0.5 \mathrm{~g} / \mathrm{m}^{3}$. Assume the atmospheric temperature at 1000 meters is $20^{\circ} \mathrm{C}$.

```
R = 1000.0;
freq = [15:5:1000]*1e9;
T = 20.0;
lwd = 0.5;
L = fogpl(R,freq,T,lwd);
```

Plot the specific attenuation as a function of frequency. Specific attenuation is the attenuation or loss per kilometer.

```
loglog(freq/le9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```

## Input Arguments

## R - Signal path length

positive real-valued scalar | $M$-by-1 nonnegative real-valued vector | 1-by- $M$ nonnegative real-valued vector

Signal path length, specified as a scalar or as an $M$-by-1 or 1-by- $M$ vector of nonnegative real-values. Total attenuation is the specific attenuation multiplied by the path length. Units are meters.

Example: [1300.0,1400.0]

## freq - Signal frequency

positive real-valued scalar | $N$-by-1 nonnegative real-valued column vector | 1 -by- $N$ nonnegative realvalued row vector

Signal frequency, specified as a positive real-valued scalar or as an $N$-by-1 nonnegative real-valued vector or 1-by- N nonnegative real-valued vector. Frequencies must lie in the range $10-1000 \mathrm{GHz}$.
Example: [14.0e9,15.0e9]

## T - Ambient temperature

real-valued scalar
Ambient temperature in fog or cloud, specified as a real-valued scalar. Units are in degrees Celsius.
Example: -10.0

## den - Liquid water density

nonnegative real-valued scalar
Liquid water density, specified as a nonnegative real-valued scalar. Units are $\mathrm{g} / \mathrm{m}^{3}$. Typical values for liquid water density in fog range from approximately $0.05 \mathrm{~g} / \mathrm{m}^{3}$ for medium fog to approximately 0.5 $\mathrm{g} / \mathrm{m}^{3}$ for thick fog. For medium fog, visibility is about 300 meters. For heavy fog, visibility is about 50 meters. Cumulus cloud liquid water density is typically $0.5 \mathrm{~g} / \mathrm{m}^{3}$.
Example: 0.01

## Output Arguments

## L - Signal attenuation

real-valued $M$-by- $N$ matrix
Signal attenuation, returned as a real-valued $M$-by- $N$ matrix. Each matrix row represents a different path where $M$ is the number of paths. Each column represents a different frequency where $N$ is the number of frequencies. Units are in dB .

## More About

## Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.
Fog and cloud attenuation are the same atmospheric phenomenon. The ITU model, Recommendation ITU-R P.840-6: Attenuation due to clouds and fog is used. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$
\gamma_{C}=K_{l}(f) M,
$$

where $M$ is the liquid water density in $\mathrm{gm} / \mathrm{m}^{3}$. The quantity $K_{l}(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies $10-1000 \mathrm{GHz}$. Units for the specific attenuation coefficient are $(\mathrm{dB} / \mathrm{km}) /\left(\mathrm{g} / \mathrm{m}^{3}\right)$.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length $R$. Total attenuation is $L_{c}=R \gamma_{c}$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## fspl

Free space path loss

## Syntax

$L=f s p l(R, l a m b d a)$

## Description

$L=f s p l(R, l a m b d a)$ returns the free space path loss in decibels for a waveform with wavelength lambda propagated over a distance of $R$ meters. The minimum value of $L$ is zero, indicating no path loss.

## Input Arguments

## R

real-valued 1-by-M or M-by-1 vector
Propagation distance of signal. Units are in meters.

## lambda

real-valued 1-by- N or N -by-1 vector
The wavelength is the speed of propagation divided by the signal frequency. Wavelength units are meters.

## Output Arguments

## L

Path loss in decibels. $M$-by- $N$ nonnegative matrix. A value of zero signifies no path loss. When lambda is a scalar, L has the same dimensions as R .

## Examples

## Calculate Free-Space Path Loss

Calculate the free-space path loss (in dB ) of a 10 GHz radar signal over a distance of 10 km .
$\mathrm{fc}=10.0 \mathrm{e} 9$;
lambda = physconst('LightSpeed')/fc;
R = 10e3;
L = fspl(R,lambda)
$\mathrm{L}=132.4478$

## More About

## Free Space Path Loss

The free-space path loss, $L$, in decibels is:

$$
L=20 \log _{10}\left(\frac{4 \pi R}{\lambda}\right)
$$

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in a loss smaller than 0 dB , equivalent to a signal gain. For this reason, the loss is set to 0 dB for range values $R \leq \lambda / 4 \Pi$.

## gaspl

RF signal attenuation due to atmospheric gases

## Syntax

L = gaspl(range,freq,T,P,den)

## Description

$\mathrm{L}=$ gaspl (range, freq, $\mathrm{T}, \mathrm{P}$, den ) returns the attenuation, L , when signals propagate through the atmosphere. range represents the signal path length, and freq represents the signal carrier frequency. T represents the ambient temperature, P represents the atmospheric pressure, and den represents the atmospheric water vapor density.

The gaspl function applies the International Telecommunication Union (ITU) atmospheric gas attenuation model [1] to calculate path loss for signals primarily due to oxygen and water vapor. The model computes attenuation as a function of ambient temperature, pressure, water vapor density, and signal frequency. The function requires that the signal path is contained entirely in a uniform environment. Atmospheric parameters do not vary along the signal path. The attenuation model applies only for frequencies at $1-1000 \mathrm{GHz}$.

## Examples

## Atmospheric Gas Attenuation Spectrum

Compute the attenuation spectrum from 1 to 1000 GHz for an atmospheric pressure of 101.300 kPa and a temperature of $15^{\circ} \mathrm{C}$. Plot the spectrum for a water vapor density of $7.5 \mathrm{~g} / \mathrm{m}^{3}$ and then plot the spectrum for dry air (zero water vapor density).

Set the attenuation frequencies.
freq $=[1: 1000] * 1 e 9 ;$
Assume a 1 km path distance.
R = 1000.0;
Compute the attenuation for air containing water vapor.
$\mathrm{T}=15$;
$P=101300.0$;
W = 7.5;
L = gaspl(R,freq, $\mathrm{T}, \mathrm{P}, \mathrm{W}$ );
Compute the attenuation for dry air.
L0 = gaspl(R,freq,T,P,0.0);
Plot the attenuations.

```
semilogy(freq/1e9,L)
hold on
semilogy(freq/le9,L0)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB)')
hold off
```

## Plot Attenuation Due to Atmospheric Gases and Free Space

First, plot the specific attenuation of atmospheric gases for frequencies from 1 GHz to 1000 GHz .
Assume a sea-level dry air pressure of 101.325 e 5 kPa and a water vapor density of $7.5 \mathrm{~g} / \mathrm{m}^{3}$. The air temperature is $20^{\circ} \mathrm{C}$. Specific attenuation is defined as dB loss per kilometer. Then, plot the actual attenuation at 10 GHz for a span of ranges.

## Plot Specific Atmospheric Gas Attenuation

Set the atmosphere temperature, pressure, water vapor density.

```
T = 20.0;
Patm = 101.325e3;
rho_wv = 7.5;
```

Set the propagation distance, speed of light, and frequencies.

```
km = 1000.0;
c = physconst('LightSpeed');
freqs = [1:1000]*le9;
```

Compute and plot the atmospheric gas loss.

```
loss = gaspl(km,freqs,T,Patm,rho_wv);
semilogy(freqs/1e9,loss)
grid on
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```

## Plot Actual Atmospheric and Free Space Attenuation

Compute both free space loss and atmospheric gas loss at 10 GHz for ranges from 1 to 100 km . The frequency corresponds to an $X$-band radar. Then, plot the free space loss and the total (atmospheric + free space) loss.

```
ranges = [1:100]*1000;
freq xband = 10e9;
loss_gas = gaspl(ranges,freq_xband,T,Patm,rho_wv);
lambda = c/freq_xband;
loss_fsp = fspl(ranges,lambda);
semi\
legend('Atmospheric + Free Space Loss','Free Space Loss','Location','SouthEast')
xlabel('Range (km)')
ylabel('Loss (dB)')
```

## Input Arguments

## range - Signal path length

nonnegative real-valued scalar | M-by-1 nonnegative real-valued column vector | 1-by-M nonnegative real-valued row vector

Signal path length used to compute attenuation, specified as a nonnegative real-valued scalar or vector. You can specify multiple path lengths simultaneously. Units are in meters.
Example: [13000.0,14000.0]

## freq - Signal frequency

positive real-valued scalar | $N$-by-1 nonnegative real-valued column vector | 1 -by- $N$ nonnegative realvalued row vector

Signal frequency, specified as a positive real-valued scalar, or as an N -by-1 nonnegative real-valued vector or 1 -by- $N$ nonnegative real-valued vector. You can specify multiple frequencies simultaneously. Frequencies must lie in the range $1-1000 \mathrm{GHz}$. Units are in hertz.
Example: [1.4e9,2.0e9]

## T - Ambient temperature

real-valued scalar
Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.
Example: -10.0

## P - Dry air pressure

positive real-valued scalar
Dry air pressure, specified as a positive real-valued scalar. Units are in Pa. One standard atmosphere at sea level is 101325 Pa .

Example: 101300.0
den - Water vapor density
nonnegative real-valued scalar
Water vapor density or absolute humidity, specified as a nonnegative real-valued scalar. Units are $\mathrm{g} / \mathrm{m}^{3}$. The maximum water vapor density of air at $30^{\circ} \mathrm{C}$ is approximately $30.0 \mathrm{~g} / \mathrm{m}^{3}$. The maximum water vapor density of air at $0^{\circ} \mathrm{C}$ is approximately $5.0 \mathrm{~g} / \mathrm{m}^{3}$.
Example: 4.0

## Output Arguments

## L - Signal attenuation

real-valued $M$-by- $N$ matrix
Signal attenuation, returned as a real-valued $M$-by- $N$ matrix. Each matrix row represents a different path where $M$ is the number of paths. Each column represents a different frequency where $N$ is the number of frequencies. Units are in dB.

## More About

## Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.
Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz . The ITU model Recommendation ITU-R P.676-10: Attenuation by atmospheric gases is used. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1-1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$
\gamma=\gamma_{o}(f)+\gamma_{w}(f)=0.1820 f N^{\prime \prime}(f) .
$$

The quantity $N^{\prime \prime}()$ is the imaginary part of the complex atmospheric refractivity and consists of a spectral line component and a continuous component:

$$
N^{\prime \prime}(f)=\sum_{i} S_{i} F_{i}+N^{\prime \prime}{ }_{D}(f)
$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_{i}$, multiplied by a spectral line strength, $S_{i}$. For atmospheric oxygen, each spectral line strength is

$$
S_{i}=a_{1} \times 10^{-7}\left(\frac{300}{T}\right)^{3} \exp \left[a_{2}\left(1-\left(\frac{300}{T}\right)\right] P .\right.
$$

For atmospheric water vapor, each spectral line strength is

$$
S_{i}=b_{1} \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp \left[b_{2}\left(1-\left(\frac{300}{T}\right)\right] W .\right.
$$

$P$ is the dry air pressure, $W$ is the water vapor partial pressure, and $T$ is the ambient temperature. Pressure units are in hectoPascals (hPa) and temperature is in degrees Kelvin. The water vapor partial pressure, $W$, is related to the water vapor density, $\rho$, by

$$
W=\frac{\rho T}{216.7} .
$$

The total atmospheric pressure is $P+W$.
For each oxygen line, $S_{i}$ depends on two parameters, $a_{1}$ and $a_{2}$. Similarly, each water vapor line depends on two parameters, $b_{1}$ and $b_{2}$. The ITU documentation cited at the end of this section contains tabulations of these parameters as functions of frequency.

The localized frequency bandwidth functions $F_{i}(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, $R$. Then, the total attenuation is $L_{g}=R\left(\gamma_{o}+\gamma_{w}\right)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

## global2localcoord

Convert global to local coordinates

## Syntax

lclCoord = global2localcoord(gCoord, OPTION)
gCoord = global2localcoord( $\qquad$ ,localOrigin)
gCoord = global2localcoord( $\qquad$ ,localAxes)

## Description

lclCoord $=$ global2localcoord(gCoord, OPTION) converts global coordinates gCoord to local coordinates lclCoord. OPTION determines the type of global-to-local coordinate transformation. In this syntax, the global coordinate origin is located at $(0,0,0)$ and the coordinate axes are the unit vectors in the $x, y$, and $z$ directions.
gCoord = global2localcoord( $\qquad$ , localOrigin) specifies the origin of the local coordinate system, localOrigin.
gCoord = global2localcoord( $\qquad$ , localAxes) specifies the axes of the local coordinate system, localAxes.

## Input Arguments

gCoord
Global coordinates in rectangular or spherical coordinate, specified as a 3-by-N matrix. Each column represents one set of global coordinates.

If the coordinates are in rectangular form, each column contains the $(x, y, z)$ components. Units are in meters.

If the coordinates are in spherical form, each column contains ( $a z, e l, r$ ) components. $a z$ is the azimuth angle on page 2-995 in degrees, $e l$ is the elevation angle on page 2-995 in degrees, and $r$ is the radius in meters.

The origin of the global coordinate system is assumed to be located at ( $0,0,0$ ). The global system axes are the standard unit basis vectors in three-dimensional space, ( $1,0,0$ ), ( $0,1,0$ ), and ( $0,0,1$ ).

## OPTION

Type of coordinate transformation, specified as a character vector. Valid types are

| OPTION | Transformation |
| :--- | :--- |
| 'rr' | Global rectangular to local rectangular |
| 'rs' | Global rectangular to local spherical |
| 'sr' | Global spherical to local rectangular |

\section*{| OPTION |
| :--- |
| 'ss' |
| localOrigin |}

Origin of local coordinate system, specified as a 3-by-N matrix containing the rectangular coordinates of the local coordinate system origin with respect to the global coordinate system. $N$ must match the number of columns of gCoord. Each column represents a separate origin. However, you can specify localOrigin as a 3 -by- 1 vector. In this case, localOrigin is expanded into a 3 -by- N matrix with identical columns.

Default: [0;0;0]

## localAxes

Axes of local coordinate system, specified as a 3-by-3-by-N array. Each page contains a 3-by-3 matrix representing a different local coordinate system axes. The columns of the 3 -by- 3 matrices specify the local $x, y$, and $z$ axes in rectangular form with respect to the global coordinate system. However, you can specify localAxes as a single 3 -by- 3 matrix. In this case, localAxes is expanded into a 3 -by-3-by- $N$ array with identical 3 -by- 3 matrices. The default is the identity matrix.

Default: [1 0 0;0 1 0;0 0 1]

## Output Arguments

## lclCoord

Local coordinates in rectangular or spherical coordinate form, returned as a 3-by- $N$ matrix. The dimensions of lclCoord match the dimensions of gCoord.

## Examples

## Convert Global Coordinates to Local Coordinates

Convert global rectangular coordinates, $(0,1,0)$, to local rectangular coordinates. The local coordinate origin is $(1,1,1)$.

```
lclCoord = global2localcoord([0;1;0],'rr',[1;1;1])
lclCoord = 3\times1
    -1
    0
    -1
```

Convert global spherical coordinates to local rectangular coordinates.

```
lclCoord = global2localcoord([45;45;50],'sr',[50;50;50])
lclCoord = 3\times1
```

## More About

## Azimuth and Elevation Angles

The azimuth angle of a vector is the angle between the $x$-axis and the orthogonal projection of the vector onto the $x y$ plane. The angle is positive in going from the $x$ axis toward the $y$ axis. Azimuth angles lie between -180 and 180 degrees. The elevation angle is the angle between the vector and its orthogonal projection onto the $x y$-plane. The angle is positive when going toward the positive $z$-axis from the xy plane. By default, the boresight direction of an element or array is aligned with the positive $x$-axis. The boresight direction is the direction of the main lobe of an element or array.

Note The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive $z$-axis. The MATLAB and Communications Toolbox products do not use this definition.

This figure illustrates the azimuth and elevation angles of a direction vector.

## rainpl

RF signal attenuation due to rainfall

## Syntax

L = rainpl(range,freq,rainrate)
L = rainpl(range,freq, rainrate,elev)
$\mathrm{L}=$ rainpl(range,freq, rainrate,elev,tau)
$\mathrm{L}=$ rainpl(range,freq, rainrate,elev,tau, pct)

## Description

$L=$ rainpl(range,freq, rainrate) returns the signal attenuation, $L$, due to rainfall. In this syntax, attenuation is a function of signal path length, range, signal frequency, freq, and rain rate, rainrate. The path elevation angle and polarization tilt angles are assumed to zero.

The rainpl function applies the International Telecommunication Union (ITU) rainfall attenuation model to calculate path loss of signals propagating in a region of rainfall [1]. The function applies when the signal path is contained entirely in a uniform rainfall environment. Rain rate does not vary along the signal path. The attenuation model applies only for frequencies at $1-1000 \mathrm{GHz}$.
$L=$ rainpl(range,freq, rainrate,elev) also specifies the elevation angle, elev, of the propagation path.
$L=r a i n p l(r a n g e, f r e q, r a i n r a t e, e l e v, t a u)$ also specifies the polarization tilt angle, tau, of the signal.
$L=r a i n p l(r a n g e, f r e q, r a i n r a t e, e l e v, t a u, p c t)$ also specifies the specified percentage of time, pct. pct is a scalar in the range of 0.001-1, inclusive. The attenuation, L , is computed from a power law using the long-term statistical $0.01 \%$ rain rate (in $\mathrm{mm} / \mathrm{h}$ ).

## Examples

## Signal Attenuation Due to Rainfall

Compute the signal attenuation due to rainfall for a 20 GHz signal over a distance of 10 km in light and heavy rain.

Propagate the signal in a light rainfall of $1 \mathrm{~mm} / \mathrm{hr}$.

```
rr = 1.0;
L = rainpl(10000,20.0e9,rr)
L = 1.3009
L = 0.7104
L = 0.7104
```

Propagate the signal in a heavy rainfall of $10 \mathrm{~mm} / \mathrm{hr}$.

```
rr = 10.0;
L = rainpl(10000,20.0e9,rr)
L = 8.1584
L = 7.8413
L = 7.8413
```

## Signal Attenuation Due to Rainfall as Function of Frequency

Plot the signal attenuation due to moderate rainfall for signals in the frequency range from 1 to 1000 GHz . The path distance is 10 km .

Set the rain rate value for moderate rainfall to $20 \mathrm{~mm} / \mathrm{hr}$.
rr = 20.0;
freq $=[1: 1000] * 1 e 9$;
L = rainpl(10000,freq,rr);
semilogx(freq/le9, L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')

## Signal Attenuation Due to Rainfall as Function of Elevation Angle

Compute the signal attenuation due to heavy rain as a function of elevation angle. Elevation angles vary from 0 to 90 degrees. Assume a path distance of 100 km and a signal frequency of 100 GHz .

Set the rain rate to $10 \mathrm{~mm} / \mathrm{hr}$.
rr = 10.0;
Set the elevation angles, frequency, range.

```
elev = [0:1:90];
freq = 100.0e9;
rng = 100000.0*ones(size(elev));
```

Compute and plot the loss.

```
L = rainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```

## Signal Attenuation Due to Rainfall as Function of Polarization

Compute the signal attenuation due to heavy rainfall as a function of the polarization tilt angle. Assume a path distance of 100 km , a signal frequency of 100 GHz signal, and a path elevation angle of 0 degrees. Set the rainfall rate to $10 \mathrm{~mm} /$ hour. Plot the signal attenuation versus polarization tilt angle.

Set the polarization tilt angle to vary from -90 to 90 degrees.
tau $=-90: 90 ;$
Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 100.0e9;
rng = 100e3*ones(size(tau));
rr = 10.0;
```

Compute and plot the attenuation.
$\mathrm{L}=$ rainpl(rng,freq,rr,elev,tau);
plot(tau, L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')

## Input Arguments

## range - Signal path length

nonnegative real-valued scalar | nonnegative real-valued $M$-by-1 column vector | nonnegative realvalued 1-by-M row vector

Signal path length, specified as a nonnegative real-valued scalar, or as a $M$-by-1 or 1-by- $M$ vector. Units are in meters.
Example: [13000.0,14000.0]

## freq - Signal frequency

positive real-valued scalar | nonnegative real-valued $N$-by-1 column vector | nonnegative real-valued 1-by- $N$ row vector

Signal frequency, specified as a positive real-valued scalar, or as a nonnegative $N$-by-1 or 1-by- $N$ vector. Frequencies must lie in the range $1-1000 \mathrm{GHz}$.

## Example: [1400.0e6,2.0e9]

## rainrate - Long-term statistical rain rate

nonnegative real-valued scalar
Long-term statistical rain rate, specified as a nonnegative real-valued scalar. The long-term statistical rain rate is the rain rate that is exceeded $0.01 \%$ of the time. You can adjust the percent of time using the pct argument. Units are in $\mathrm{mm} / \mathrm{hr}$.

## Example: 1.5

## elev - Signal path elevation angle

0.0 (default) | real-valued scalar | real-valued $M$-by-1 column vector | real-valued 1-by-M row vector

Signal path elevation angle, specified as a real-valued scalar, or as an $M$-by-1 or 1-by- $M$ vector. Units are in degrees between $-90^{\circ}$ and $90^{\circ}$. If elev is a scalar, all propagation paths have the same elevation angle. If elev is a vector, its length must match the dimension of range and each element in elev corresponds to a propagation range in range.
Example: [0,45]

## tau - Tilt angle of polarization ellipse

0.0 (default) | real-valued scalar | real-valued $M$-by-1 column vector | real-valued 1-by- $M$ row vector

Tilt angle of the signal polarization ellipse, specified as a real-valued scalar, or as an $M$-by-1 or 1-by$M$ vector. Units are in degrees between $-90^{\circ}$ and $90^{\circ}$. If tau is a scalar, all signals have the same tilt angle. If tau is a vector, its length must match the dimension of range. In that case, each element in tau corresponds to a propagation path in range.

The tilt angle is defined as the angle between the semi-major axis of the polarization ellipse and the $x$ axis. Because the ellipse is symmetrical, a tilt angle of $100^{\circ}$ corresponds to the same polarization state as a tilt angle of $-80^{\circ}$. Thus, the tilt angle need only be specified between $\pm 90^{\circ}$.
Example: $[45,30]$
pct - Exceedance percentage of rainfall
0.01 (default) | positive scalar between 0.001 and 1

Exceedance percentage of rainfall, specified as a positive scalar between 0.001 and 1. The long-term statistical rain rate is the rain rate that is exceeded pct of the time. Units are dimensionless.
Data Types: double

## Output Arguments

## L - Signal attenuation

real-valued $M$-by- $N$ matrix
Signal attenuation, returned as a real-valued $M$-by- $N$ matrix. Each matrix row represents a different path where $M$ is the number of paths. Each column represents a different frequency where $N$ is the number of frequencies. Units are in dB .

## More About

## Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall. Rain attenuation is a dominant fading mechanism and can vary from location-to-location and from year-toyear.

Electromagnetic signals are attenuated when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. The specific attenuation, $\gamma_{R}$, is modeled as a power law with respect to rain rate

$$
\gamma_{R}=k R^{\alpha},
$$

where $R$ is rain rate. Units are in $\mathrm{mm} / \mathrm{hr}$. The parameter $k$ and exponent $\alpha$ depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from $1-1000 \mathrm{GHz}$.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the an effective propagation distance, $d_{\text {eff. }}$. Then, the total attenuation is $L=$ $d_{\text {eff }} \gamma_{R}$.

The effective distance is the geometric distance, $d$, multiplied by a scale factor

$$
r=\frac{1}{0.477 d^{0.633} R_{0.01}^{0.073 \alpha} f^{0.123}-10.579(1-\exp (-0.024 d))}
$$

where $f$ is the frequency. The article Recommendation ITU-R P.530-17 (12/2017): Propagation data and prediction methods required for the design of terrestrial line-of-sight systems presents a complete discussion for computing attenuation.

The rain rate, $R$, used in these computations is the long-term statistical rain rate, $R_{0.01}$. This is the rain rate that is exceeded $0.01 \%$ of the time. The calculation of the statistical rain rate is discussed in Recommendation ITU-R P.837-7 (06/2017): Characteristics of precipitation for propagation modelling. This article also explains how to compute the attenuation for other percentages from the $0.01 \%$ value.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

``` ,model)
```

## Description

The function rangeangle determines the propagation path length and path direction of a signal from a source point or set of source points to a reference point. The function supports two propagation models - the free space model and the two-ray model. The free space model is a single line-of-sight path from a source point to a reference point. The two-ray multipath model generates two paths. The first path follows the free-space path. The second path is a reflected path off a boundary plane at $z=$ 0 . Path directions are defined with respect to either the global coordinate system at the reference point or a local coordinate system at the reference point. Distances and angles at the reference point do not depend upon which direction the signal is travelling along the path.
[rng,ang] = rangeangle(pos) returns the propagation path length, rng, and direction angles, ang, of a signal path from a source point or set of source points, pos, to the origin of the global coordinate system. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the origin. Signals follow a line-of-sight path from the source point to the origin. The line-of-sight path corresponds to the geometric straight line between the points.
[rng,ang] = rangeangle(pos,refpos) also specifies a reference point or set of reference points, refpos. rng now contains the propagation path length from the source points to the reference points. The direction angles are the azimuth and elevation with respect to the global coordinate axes at the reference points. You can specify multiple points and multiple reference points.
[rng,ang] = rangeangle(pos,refpos,refaxes) also specifies local coordinate system axes, refaxes, at the reference points. Direction angles are the azimuth and elevation with respect to the local coordinate axes centered at refpos.
[rng, ang] = rangeangle(___, model), also specifies a propagation model. When model is set to 'freespace', the signal propagates along a line-of-sight path from source point to reception point. When model is set to 'two-ray', the signal propagates along two paths from source point to reception point. The first path is the line-of-sight path. The second path is the reflecting path. In this case, the function returns the distances and angles for two paths for each source point and corresponding reference point.

## Input Arguments

pos
Source point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by- $N$ matrix. A matrix represents multiple source points. The columns contain the Cartesian coordinates of $N$ points in the form $[x ; y ; z]$.

When pos is a 3 -by- $N$ matrix, you must specify refpos as a 3 -by- $N$ matrix for $N$ reference positions. If all the reference points are identical, you can specify refpos by a single 3-by-1 vector.

Position units are meters.

## refpos

Reference point position, specified as a real-valued 3-by-1 vector or a real-valued 3-by- N matrix. A matrix represents multiple reference points. The columns contain the Cartesian coordinates of $N$ points ins the form $[x ; y ; z]$.

When refpos is a 3 -by- $N$ matrix, you must specify pos as a 3 -by- $N$ matrix for $N$ source positions. If all the source points are identical, you can specify pos by a single 3-by-1 vector.

Position units are meters.
Default: [0;0;0]
refaxes
Local coordinate system axes, specified as a real-valued 3-by-3 matrix or a 3-by-3-by-N array. For an array, each page corresponds to a local coordinate axes at each reference point. The columns in refaxes specify the direction of the coordinate axes for the local coordinate system in Cartesian coordinates. $N$ must match the number of columns in pos or refpos when these dimensions are greater than one.

Default: [1 0 0;0 1 0;0 0 1]
model
Propagation model, specified as 'freespace' or 'two-ray'. Choosing 'freespace' invokes the free space propagation model. Choosing 'two-ray' invokes the two-ray propagation model.

Default: ' freespace'

## Output Arguments

## rng

Propagation range, returned as a real-valued 1-by- $N$ vector or real-valued 1 -by- 2 N vector.
When model is set to 'freespace', the size of rng is 1-by-N. The propagation range is the length of the direct path from the position defined in pos to the corresponding reference position defined in refpos.

When model is set to 'two-ray', rng contains the ranges for the direct path and the reflected path. Alternate columns of rng refer to the line-of-sight path and reflected path, respectively for the same source-reference point pair. Position units are meters.

## ang

Azimuth and elevation angles, returned as a 2 -by- $N$ matrix or 2-by- $2 N$ matrix. Each column represents a direction angle in the form [azimuth; elevation].

When model is set to ' freespace', ang is a 2-by- $N$ matrix and represents the angle of the path from a source point to a reference point.

When model is set to 'two-ray', ang is a 2 -by- $2 N$ matrix. Alternate columns of ang refer to the line-of-sight path and reflected path, respectively.

Angle units are in degrees.

## Examples

## Range and Angle Computation

Compute the range and angle of a target located at $(1000,2000,50)$ meters from the origin.

```
TargetLoc = [1000;2000;50];
[tgtrng,tgtang] = rangeangle(TargetLoc)
tgtrng = 2.2366e+03
tgtang = 2×1
    63.4349
        1.2810
```

## Range and Angle With Respect to Local Origin

Compute the range and angle of a target located at $(1000,2000,50)$ meters with respect to a local origin at $(100,100,10)$ meters.

```
TargetLoc = [1000;2000;50];
Origin = [100;100;10];
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin)
tgtrng = 2.1028e+03
tgtang = 2×1
    64.6538
        1.0900
```

## Range and Angle With Respect to Local Coordinates

Compute the range and angle of a target located at $(1000,2000,50)$ meters but with respect to a local coordinate system origin at $(100,100,10)$ meters. Choose a local coordinate reference frame that is rotated about the z -axis by $45^{\circ}$ from the global coordinate axes.

```
targetpos = [1000;2000;50];
origin = [100;100;10];
```

```
refaxes = [1/sqrt(2) -1/sqrt(2) 0; 1/sqrt(2) 1/sqrt(2) 0; 0 0 1];
[tgtrng,tgtang] = rangeangle(targetpos,origin,refaxes)
tgtrng = 2.1028e+03
tgtang = 2×1
    19.6538
    1.0900
```

## More About

## Angles in Local and Global Coordinate Systems

The rangeangle function returns the path distance and path angles in either the global or local coordinate systems. By default, the rangeangle function determines the angle a signal path makes with respect to global coordinates. If you add the refaxes argument, you can compute the angles with respect to local coordinates. As an illustration, this figure shows a 5-by-5 uniform rectangular array (URA) rotated from the global coordinates ( $x y z$ ) using refaxes. The $x^{\prime}$ axis of the local coordinate system ( $x^{\prime} y^{\prime} z^{\prime}$ ) is aligned with the main axis of the array and moves as the array moves. The path length is independent of orientation. The global coordinate system defines the azimuth and elevations angles ( $\Phi, \theta$ ) and the local coordinate system defines the azimuth and elevations angles ( $\Phi^{\prime}, \theta^{\prime}$ ).

Local and Global Coordinate Axes

## Free Space Propagation Model

The free-space signal propagation model states that a signal propagating from one point to another in a homogeneous, isotropic medium travels in a straight line, called the line-of-sight or direct path. The straight line is defined by the geometric vector from the radiation source to the destination.

## Two-Ray Propagation Model

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line line-of-sight path from point 1 to point 2 . In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at $z=$ 0 . There are at most two rays propagating from point 1 to point 2 . The first ray path propagates along the same line-of-sight path as in the free-space channel. The line-of-sight path is often called the direct path. The second ray reflects off the boundary before propagating to point 2 . According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The figure illustrates two propagation paths. From the source position, $s_{s}$, and the receiver position, $s_{r}$, you can compute the arrival angles of both paths, $\theta_{l o s}^{\prime}$ and $\theta_{r p}^{\prime}$. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, $\theta_{\text {los }}$ and $\theta_{r r .}$. In the global coordinates, the angle of reflection at the boundary is the same as the angles $\theta_{r p}$ and $\theta_{r p}^{\prime}$. The reflection angle is important to know when you use angledependent reflection-loss data. You can determine the reflection angle by using the rangeangle function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by $R_{\text {los }}$ which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{r p}=R_{1}+R_{2}$. The quantity $L$ is the ground range between source and receiver.

You can easily derive exact formulas for path lengths and angles in terms of the ground range and object heights in the global coordinate system.

$$
\begin{aligned}
& \vec{R}=\vec{x}_{s}-\vec{x}_{r} \\
& R_{l o s}=|\vec{R}|=\sqrt{\left(z_{r}-z_{s}\right)^{2}+L^{2}} \\
& R_{1}=\frac{z_{r}}{z_{r}+z_{z}} \sqrt{\left(z_{r}+z_{s}\right)^{2}+L^{2}} \\
& R_{2}=\frac{z_{s}}{z_{S}+z_{r}} \sqrt{\left(z_{r}+z_{s}\right)^{2}+L^{2}} \\
& R_{r p}=R_{1}+R_{2}=\sqrt{\left(z_{r}+z_{s}\right)^{2}+L^{2}} \\
& \tan \theta_{l o s}=\frac{\left(z_{s}-z_{r}\right)}{L} \\
& \tan \theta_{r p}=-\frac{\left(z_{S}+z_{r}\right)}{L} \\
& \theta_{l o s}^{\prime}=-\theta_{l o s} \\
& \theta_{r p}^{\prime}=\theta_{r p}
\end{aligned}
$$

## sph2cartvec

Convert vector from spherical basis components to Cartesian components

## Syntax

vr = sph2cartvec(vs,az,el)

## Description

$\mathrm{vr}=\mathrm{sph} 2 \mathrm{cartvec}(\mathrm{vs}, \mathrm{az}, \mathrm{el})$ converts the components of a vector or set of vectors, vs , from their spherical basis representation to their representation in a local Cartesian coordinate system. A spherical basis representation is the set of components of a vector projected into the right-handed spherical basis given by ( $\widehat{\mathbf{e}}_{a z}, \widehat{\mathbf{e}}_{e l}, \widehat{\mathbf{e}}_{R}$ ). The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, az, and elevation, el.

## Examples

## Cartesian Representation of Azimuthal Vector

Start with a vector in a spherical basis located at $45^{\circ}$ azimuth, $45^{\circ}$ elevation. The vector points along the azimuth direction. Compute the vector components with respect to Cartesian coordinates.

```
vs = [1;0;0];
vr = sph2cartvec(vs,45,45)
vr = 3x1
    -0.7071
    0.7071
            0
```

## Input Arguments

## vs - Vector in spherical basis representation

3-by-1 column vector | 3 -by-N matrix
Vector in spherical basis representation specified as a 3-by-1 column vector or 3 -by- $N$ matrix. Each column of vs contains the three components of a vector in the right-handed spherical basis $\left(\widehat{\mathbf{e}}_{a z}, \widehat{\mathbf{e}}_{e l}, \widehat{\mathbf{e}}_{R}\right)$.

Example: [4.0; -3.5; 6.3]
Data Types: double
Complex Number Support: Yes

## az - Azimuth angle

scalar in range [-180,180]

Azimuth angle specified as a scalar in the closed range [-180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the $x y$-plane from the positive $x$-axis to the vector's orthogonal projection into the $x y$-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the $x$-axis while an azimuth angle of $90^{\circ}$ and an elevation angle of zero specify a point on the $y$ axis.

Example: 45
Data Types: double

## el - Elevation angle

scalar in range [-90,90]
Elevation angle specified as a scalar in the closed range [-90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the $x y$-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and $\pm 90^{\circ}$ elevation define the north and south poles, respectively.

Example: 30
Data Types: double

## Output Arguments

## vr - Vector in Cartesian representation

3 -by-1 column vector | 3 -by-N matrix
Cartesian vector returned as a 3 -by- 1 column vector or 3 -by- $N$ matrix having the same dimensions as vs. Each column of vr contains the three components of the vector in the right-handed $x, y, z$ basis.

## More About

## Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors ( $\widehat{\mathbf{e}}_{a z}, \widehat{\mathbf{e}}_{e l}, \widehat{\mathbf{e}}_{R}$ ) defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of $R$ so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:

For any point on the sphere specified by $a z$ and $e l$, the basis vectors are given by:

$$
\begin{aligned}
& \widehat{\mathbf{e}}_{\mathbf{a z}}=-\sin (a z) \widehat{\mathbf{i}}+\cos (a z) \widehat{\mathbf{j}} \\
& \widehat{\mathbf{e}}_{\mathbf{e l}}=-\sin (e l) \cos (a z) \widehat{\mathbf{i}}-\sin (e l) \sin (a z) \widehat{\mathbf{j}}+\cos (e l) \widehat{\mathbf{k}} \\
& \widehat{\mathbf{e}}_{\mathbf{R}}=\cos (e l) \cos (a z) \widehat{\mathbf{i}}+\cos (e l) \sin (a z) \widehat{\mathbf{j}}+\sin (e l) \widehat{\mathbf{k}} .
\end{aligned}
$$

Any vector can be written in terms of components in this basis as $\mathbf{v}=v_{a z} \widehat{\mathbf{e}}_{\mathbf{a z}}+v_{e l} \widehat{\mathbf{e}}_{\mathbf{e l}}+v_{R} \widehat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$
\left[\begin{array}{l}
v_{x} \\
v_{y} \\
v_{z}
\end{array}\right]=\left[\begin{array}{ccc}
-\sin (a z) & -\sin (e l) \cos (a z) & \cos (e l) \cos (a z) \\
\cos (a z) & -\sin (e l) \sin (a z) & \cos (e l) \sin (a z) \\
0 & \cos (e l) & \sin (e l)
\end{array}\right]\left[\begin{array}{c}
v_{a z} \\
v_{e l} \\
v_{R}
\end{array}\right]
$$

and

$$
\left[\begin{array}{l}
v_{a z} \\
v_{e l} \\
v_{R}
\end{array}\right]=\left[\begin{array}{ccc}
-\sin (a z) & \cos (a z) & 0 \\
-\sin (e l) \cos (a z) & -\sin (e l) \sin (a z) & \cos (e l) \\
\cos (e l) \cos (a z) & \cos (e l) \sin (a z) & \sin (e l)
\end{array}\right]\left[\begin{array}{c}
v_{x} \\
v_{y} \\
v_{z}
\end{array}\right] .
$$

## comm.ACPR

Package: comm
Adjacent Channel Power Ratio measurements

## Description

The ACPR System object measures adjacent channel power ratio (ACPR) of an input signal.
To measure adjacent channel power:
1 Define and set up your adjacent channel power object. See "Construction" on page 3-2.
2 Call step to measure the adjacent channel power ratio according to the properties of comm.ACPR. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

$\mathrm{H}=$ comm. ACPR creates a System object, H , that measures adjacent channel power ratio (ACPR) of an input signal.

H = comm.ACPR(Name, Value) creates object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as
(Name1,Value1,...,NameN,ValueN).

## Properties

## NormalizedFrequency

Assume normalized frequency values
Specify whether the frequency values are normalized. If you set this property to true, the object assumes that frequency values are normalized (in the [-1 1] range). The default is false. If you set this property to false, the object assumes that frequency values are measured in Hertz.

## SampleRate

Sample rate of input signal
Specify the sample rate of the input signal, in samples per second, as a double-precision, positive scalar. The default is le6 samples per second. This property applies when you set the NormalizedFrequency property to false.

## MainChannelFrequency

Main channel center frequency

Specify the main channel center frequency as a double-precision scalar. The default is 0 Hz .
When you set the NormalizedFrequency property to true, you must specify the center frequency as a normalized value between -1 and 1 .

When you set the NormalizedFrequency property to false, you must specify the center frequency in Hertz. The object measures the main channel power in the bandwidth that you specify in the MainMeasurementBandwidth property. This measurement is taken at the center of the frequency that you specify in the MainMeasurementBandwidth property.

## MainMeasurementBandwidth

Main channel measurement bandwidth
Specify the main channel measurement bandwidth as a double-precision, positive scalar. The default is 50 e 3 Hz .

When you set the NormalizedFrequency property to true, you must specify the measurement bandwidth as a normalized value between 0 and 1 .

When you set the NormalizedFrequency property to false, you must specify the measurement bandwidth in Hertz. The object measures the main channel power in the bandwidth that you specify in the MainMeasurementBandwidth property. This measurement is taken at the center of the frequency that you specify in the MainChannelFrequency property.

## AdjacentChannelOffset

Adjacent channel frequency offsets
Specify the adjacent channel offsets as a double-precision scalar or as a row vector comprising frequencies that define the location of adjacent channels of interest. The default is [-100e3 100e3] Hz .

When you set the NormalizedFrequency property to true, you must specify normalized frequency offset values between - 1 and 1 . When you set the NormalizedFrequency property to false, you must specify frequency offset values in Hertz. The offset values indicate the distance between the main channel center frequency and adjacent channel center frequencies. Positive offsets indicate adjacent channels to the right of the main channel center frequency. Negative offsets indicate adjacent channels to the left of the main channel center frequency.

## AdjacentMeasurementBandwidth

Adjacent channel measurement bandwidths
Specify the measurement bandwidth for each adjacent channel. The default is the scalar, 50 e 3 . The object assumes that each adjacent bandwidth is centered at the frequency defined by the corresponding frequency offset. You define this offset in the AdjacentChannelOffset property. Set this property to a double-precision scalar or row vector of length equal to the number of specified offsets in the AdjacentChannelOffset property.

When you set this property to a scalar, the object obtains all adjacent channel power measurements within equal measurement bandwidths. When you set the NormalizedFrequency property to true, you must specify normalized bandwidth values between 0 and 1 . When you set the NormalizedFrequency property to false, you must specify the adjacent channel bandwidth values in Hertz.

## MeasurementFilterSource

Source of the measurement filter
Specify the measurement filter source as one of None | Property. The default is None. When you set this property to None the object does not apply filtering to obtain ACPR measurements. When you set this property to Property, the object applies a measurement filter to the main channel before measuring the average power. Each of the adjacent channel bands also receives a measurement filter. In this case, you specify the measurement filter coefficients in the MeasurementFilter property.

## MeasurementFilter

## Measurement filter coefficients

Specify the measurement filter coefficients as a double-precision row vector containing the coefficients of an FIR filter in descending order of powers of z. Center the response of the filter at DC. The ACPR object automatically shifts and applies the filter response at each of the main and adjacent channel center frequencies before obtaining the average power measurements. The internal filter states persist and clear only when you call the reset method. This property applies when you set the MeasurementFilterSource property to Property. The default is 1 , which is an all-pass filter that has no effect on the measurements.

## SpectralEstimation

Spectral estimation control
Specify the spectral estimation control as one of Auto|Specify frequency resolution | Specify window parameters. The default is Auto.

When you set this property to Auto, the object obtains power measurements with a Welch spectral estimator with zero-percent overlap, a Hamming window, and a segment length equal to the length of the input data vector. In this setting, the spectral estimator set should achieve the maximum frequency resolution attainable with the input data length.

When you set this property to Specify frequency resolution, you specify the desired spectral frequency resolution, in normalized units or in Hertz, using the FrequencyResolution property. In this setting, the object uses the value in the FrequencyResolution property to automatically compute the size of the spectral estimator data window.

When you set this property to Specify window parameters, several spectral estimator properties become available so that you can control the Welch spectral estimation settings. These properties are: SegmentLength, OverlapPercentage, Window, and SidelobeAttenuation. Sidelobe attenuation applies only when you set the Window property to Chebyshev.

When you set this property to Specify window parameters, the FrequencyResolution property does not apply, and you control the resolution using the above properties.

## SegmentLength

Segment length
Specify the segment length, in samples, for the spectral estimator as a numeric, positive, integer scalar. The default is 64 . The length of the segment allows you to make tradeoffs between frequency resolution and variance in the spectral estimates. A long segment length results in better resolution.

A short segment length results in more averaging and a decrease in variance. This property applies when you set the SpectralEstimation property to Specify window parameters.

## OverlapPercentage

Overlap percentage
Specify the percentage of overlap between each segment in the spectral estimator as a doubleprecision scalar in the [0 100] interval. This property applies when you set the SpectralEstimation property to Specify window parameters. The default is 0 percent.

## Window

Window function
Specify a window function for the spectral estimator as one of Bartlett | Bartlett-Hanning | Blackman | Blackman-Harris | Bohman | Chebyshev | Flat Top | Hamming | Hann | Nuttall| Parzen | Rectangular |Triangular. The default is Hamming. A Hamming window has 42.5 dB of sidelobe attenuation. This attenuation may mask spectral content below this value, relative to the peak spectral content. Choosing different windows allows you to make tradeoffs between resolution and sidelobe attenuation. This property applies when you set the SpectralEstimation property to Specify window parameters.

## SidelobeAttenuation

Sidelobe attenuation for Chebyshev window
Specify the sidelobe attenuation, in decibels, for the Chebyshev window function as a doubleprecision, nonnegative scalar. The default is 100 dB . This property applies when you set the SpectralEstimation property to Specify window parameters and the Window property to Chebyshev.

## FrequencyResolution

## Frequency resolution

Specify the frequency resolution of the spectral estimator as a double-precision scalar. The default is 10625 Hz .

When you set the NormalizedFrequency property to true, you must specify the frequency resolution as a normalized value between 0 and 1 . When you set the NormalizedFrequency property to false, you must specify the frequency resolution in Hertz. The object uses the value in the
FrequencyResolution property to calculate the size of the data window used by the spectral estimator. This property applies when you set the SpectralEstimation property to Specify frequency resolution.

## FFTLength

FFT length
Specify the FFT length that the Welch spectral estimator uses as one of Next power of 2 |Same as segment length|Custom. The default is Next power of 2.

When you set this property to Custom, the CustomFFTLength property becomes available to specify the desired FFT length.

When you set this property to Next power of 2, the object sets the length of the FFT to the next power of 2 . This length is greater than the spectral estimator segment length or 256 , whichever is greater.

When you set this property to Same as segment length, the object sets the length of the FFT. This length equals the spectral estimator segment length or 256 , whichever is greater.

## CustomFFTLength

Custom FFT length
Specify the number of FFT points that the spectral estimator uses as a numeric, positive, integer scalar. This property applies when you set the FFTLength property to Custom. The default is 256 .

## MaxHold

Max-hold setting control
Specify the maximum hold setting. The default is false.
When you set this property to true, the object compares two vectors. One vector compared is the current estimated power spectral density vector (obtained with the current input data frame). The object checks this vector against the previous maximum-hold accumulated power spectral density vector, (obtained at the previous call to the step method). The object stores the maximum values at each frequency bin and uses them to compute average power measurements. You clear the maximumhold spectrum by calling the reset method on the object. When you set this property to false, the object obtains power measurements using instantaneous power spectral density estimates. This property is tunable.

## PowerUnits

Power units
Specify power measurement units as one of $\mathrm{dBm}|\mathrm{dBW}|$ Watts. The default is dBm .
When you set this property to dBm , or dBW , the step method outputs ACPR measurements in a dBc scale (adjacent channel power referenced to main channels power). If you set this property to Watts, the step method outputs ACPR measurements in a linear scale.

## MainChannelPowerOutputPort

Enable main channel power measurement output
When you set this property to true, the step method outputs the main channel power measurement. The default is false. The main channel power is the power of the input signal measured in the band that you define with the MainChannelFrequency and MainMeasurementBandwidth properties. The step method returns power measurements in the units that you specify in the PowerUnits property.

## AdjacentChannelPowerOutputPort

Enable adjacent channel power measurements output
When you set this property to true, the step method outputs a vector of adjacent channel power measurements. The default is false. The adjacent channel powers correspond to the input signal's power measured in the bands that you define with the AdjacentChannelOffset and

AdjacentMeasurementBandwidth properties. The step method returns power measurements in the units that you specify in the PowerUnits property.

## Methods

| reset | Reset states of ACPR measurement object |
| :--- | :--- |
| step | Adjacent Channel Power Ratio measurements |

## Common to All System Objects

release Allow System object property value changes

## Examples

## Measure ACPR of a 16-QAM signal with symbol rate of 3.84 Msps

Generate data with an alphabet size of 16 and modulate the data

```
x = randi([0 15],5000,1);
y = qammod(x,16);
```

Upsample the data by $\mathrm{L}=8$ using a rectangular pulse shape
$\mathrm{L}=8$;
yPulse $=$ rectpulse(y,L);
Create an ACPR measurement object and measure the modulated signal

```
acpr = comm.ACPR(...
    'SampleRate', 3.84e6*8,...
    'MainChannelFrequency', 0,...
    'MainMeasurementBandwidth', 3.84e6,...
    'AdjacentChannelOffset', [-5e6 5e6],...
    'AdjacentMeasurementBandwidth', 3.84e6,...
    'MainChannelPowerOutputPort', true,...
    'AdjacentChannelPowerOutputPort', true);
[ACPR,mainChnlPwr,adjChnlPwr] = acpr(yPulse)
ACPR = 1\times2
    -14.3659 -14.3681
mainChnlPwr = 38.8668
adjChnlPwr = 1×2
    24.5010 24.4988
```

## Algorithms

Note The following conditions must be true, otherwise power measurements fall out of the Nyquist interval.

$$
\begin{aligned}
& \mid \text { MainChannelFreq } \left. \pm \frac{\text { MainChannelMeasBW }}{2} \right\rvert\,<\text { Fmax } \\
& \mid \text { (MainChannelFreq }+ \text { AdjChannelOffset }) \left. \pm \frac{\text { AdjChannelMeasBW }}{2} \right\rvert\,<\text { Fmax }
\end{aligned}
$$

$\mathrm{F}_{\max }=\mathrm{Fs} / 2$ if NormalizedFrequency $=$ false
$\mathrm{F}_{\max }=1$ if NormalizedFrequency $=$ true

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\text {TM }}$.
Usage notes and limitations:

- Supports MEX code generation. Does not support code generation for standalone applications.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

See Also<br>comm. CCDF | comm.EVM | comm.MER<br>Introduced in R2012a

## reset

System object: comm. ACPR
Package: comm
Reset states of ACPR measurement object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the ACPR object, H .

## step

System object: comm.ACPR
Package: comm
Adjacent Channel Power Ratio measurements

## Syntax

A = step ( $\mathrm{H}, \mathrm{X}$ )
[A,MAINPOW] = step(H,X)
[A,ADJPOW] = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.
$A=\operatorname{step}(H, X)$ returns a vector of the adjacent channel power ratio, $A$, measured in the input data, $X$. The measurements are at the frequency bands that you specify with the MainChannelFrequency, MainMeasurementBandwidth, AdjacentChannelOffset, and AdjacentMeasurementBandwidth properties. Input $X$ must be a double precision column vector. The length of the output vector, $A$, equals the number of adjacent channels that you specify in the AdjacentChannelOffset property.
[A,MAINPOW] = step $(H, X)$ returns the measured main channel power, MAINPOW, when you set the MainChannelPowerOutputPort property to true. The step method outputs the main channel power measured within the main channel frequency band of interest that you specify with the MainChannelFrequency and MainMeasurementBandwidth properties.
[A, ADJPOW] = step $(H, X)$ returns a vector of the measured adjacent channel powers, ADJPOW, when you set the AdjacentChannelPowerOutputPort property to true. The adjacent channel powers are measured at the adjacent frequency bands of interest that you specify with the AdjacentChannelOffset and AdjacentMeasurementBandwidth properties. The length of the output vector, ADJPOW, equals the length of the vector that you specify in the AdjacentChannelOffset property. You can combine optional output arguments when you set their enabling properties. Optional outputs must be listed in the same order as the order of the enabling properties. For example,

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.AGC

Package: comm
Adaptively adjust gain for constant signal-level output

## Description

The comm. AGC System object creates an automatic gain controller (AGC) that adaptively adjusts its gain to achieve a constant signal level at the output.

To adaptively adjust gain for constant signal-level output:
1 Define and set up your automatic gain controller object. See "Construction" on page 3-11.
2 Call step to adaptively adjust gain and achieve a constant signal level at the output according to the properties of comm. AGC. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

$H=$ comm. AGC creates an AGC System object, $H$, that adaptively adjusts its gain to achieve a constant signal level at the output.

H = comm. AGC(Name, Value) creates an AGC object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## AdaptationStepSize

Step size for gain updates
Specify the step size as a real positive scalar. The default is 0.01 . Increasing the step size permits the AGC to respond more quickly to changes in the input signal level but increases variation in the output signal level during steady-state operation.

## DesiredOutputPower

Target output power level
Specify the desired output power level as a real positive scalar. The power is measured in Watts referenced to 1 ohm . The default is 1 .

## AveragingLength

Length of the averaging window

Specify the length of the averaging window in samples as a positive integer scalar. The default is 100.

Note If you use the AGC with higher-order QAM signals, inspect the scatter plot at the output of the AGC during steady-state operation and increase the averaging length if you see frequent gain adjustments. An increase in AveragingLength reduces execution speed.

## MaxPowerGain

Maximum power gain in decibels
Specify the maximum gain of the AGC in decibels as a positive scalar. The default is 60.
Large gain adjustments can cause clipping when a small input signal power suddenly increases. Use MaxPowerGain to avoid large gain adjustments by limiting the gain that the AGC applies to the input signal.

## Methods

reset Reset internal states of automatic gain controller
step Apply adaptive gain to input signal

```
Common to All System Objects
release Allow System object property value changes
```

## Examples

## Vary AGC Averaging Length

Apply different AGC averaging lengths to QAM modulated signals. Compare the variance and plot of the signals after AGC is applied.

Initialize three AGC System objects with average window length set to 10, 100, and 1000 samples.

```
agc1 = comm.AGC('AveragingLength',10);
agc2 = comm.AGC('AveragingLength',100);
agc3 = comm.AGC('AveragingLength',1000);
```

Generate M-QAM modulated and raised cosine pulse shaped packetized data.

```
M = 16;
```

$\mathrm{d}=$ randi([0 M-1],1000,1);
$\mathrm{s}=\operatorname{qammod}(\mathrm{d}, \mathrm{M})$;
$\mathrm{x}=0.1^{*} \mathrm{~s}$;
pulseShaper $=$ comm.RaisedCosineTransmitFilter;
$y=\operatorname{awgn}(p u l s e S h a p e r(x), i n f)$;

Apply AGC.

```
r1 = agcl(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot and compare the signals.

```
figure(1)
subplot(4,1,1)
plot(abs(y))
title('AGC input')
subplot(4,1,2)
plot(abs(rl))
axis([0 8000 0 10])
title('AGC output (AveragingLength = 10 samples)')
text(4000, 5, sprintf('Variance = %f',var(rl(3000:end))))
subplot(4,1,3)
plot(abs(r2))
axis([0 8000 0 10])
title('AGC output (AveragingLength = 100 sample)')
text(4000, 5, sprintf('Variance = %f',var(r2(3000:end))))
subplot(4,1,4)
plot(abs(r3))
axis([0 8000 0 10])
title('AGC output (AveragingLength = 1000 samples)')
text(4000, 5, sprintf('Variance = %f', var(r3(3000:end))))
```

As the averaging length increases the variance at the output of the AGC decreases.

## Vary AGC Maximum Gain

Apply different AGC maximum gain level to QPSK modulated signals. With the maximum gain too small the signal after AGC will not reach desired amplitude. With the maximum gain too large the signal after AGC will overshoot and can saturate resulting in signal loss at the start of received packets. With the maximum gain at the optimal level, the signal after AGC reaches the desired amplitude without signal loss due to saturation. Compare the plot of the signals after AGC is applied.

Initialize three AGC System objects with maximum gain values set to $10 \mathrm{~dB}, 20 \mathrm{~dB}$, and 30 dB .

```
agc1 = comm.AGC('MaxPowerGain', 10);
agc2 = comm.AGC('MaxPowerGain', 20);
agc3 = comm.AGC('MaxPowerGain', 30);
```

Generate QPSK modulated and raised cosine pulse shaped packetized data.

```
M = 4;
pktLen = 10000;
d = randi([0 M-1],pktLen,1);
s = pskmod(d,M,pi/4);
x = repmat([zeros(pktLen,1); 0.3*s],3,1);
pulseShaper = comm.RaisedCosineTransmitFilter;
y = awgn(pulseShaper(x),50);
```

Apply AGC and plot.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot and compare the signals.

```
figure(1)
subplot(4,1,1)
plot(abs(y))
title('AGC input')
subplot(4,1,2)
plot(abs(r1))
title('AGC output (MaxPowerGain = 10 dB)')
subplot(4,1,3)
plot(abs(r2))
title('AGC output (MaxPowerGain = 20 dB)')
subplot(4,1,4)
plot(abs(r3))
title('AGC output (MaxPowerGain = 30 dB)')
```

This plot compares the signal input to AGC and output from AGC with various maximum gain levels. With the maximum gain set to 10 dB , the AGC output cannot reach the desired output power level. With the maximum gain set to 20 dB , the AGC output reaches the desired level without saturating. With the maximum gain set to 30 dB , the AGC output overshoots risking signal saturation and data loss. Between packets there is only noise in the input signal.

As shown in the plots, with packet transmissions there may be extended periods when no data is received. This results in AGC increasing to the maximum gain setting. If a packet arrives when the AGC gain is too high, the output power overshoots until the AGC can respond to the change in the input power level and reduce its gain.

## Vary AGC Step Size

Apply different AGC step sizes to QPSK modulated signals. Compare the signals after AGC is applied.
Initialize three AGC System objects with step sizes set to $1 \mathrm{e}-1,1 \mathrm{e}-3$, and $1 \mathrm{e}-4$.

```
agc1 = comm.AGC('AdaptationStepSize',1e-1);
agc2 = comm.AGC('AdaptationStepSize',1e-3);
agc3 = comm.AGC('AdaptationStepSize',1e-4);
```

Generate QPSK modulated data with raised cosine pulse shaping.

```
d = randi([0 3],500,1);
s = pskmod(d,4,pi/4);
x = 0.1*s;
```

```
pulseShaper = comm.RaisedCosineTransmitFilter;
```

y = pulseShaper(x);

Apply AGC.

```
r1 = agc1(y);
r2 = agc2(y);
r3 = agc3(y);
```

Plot the signal input to AGC and output after various AGC step sizes.
figure
subplot (4,1,1)
plot(abs(y))
title('AGC input')
subplot(4,1,2)
plot(abs(r1))
title('AGC output (AdaptionStepSize = 1e-1)')
subplot(4,1,3)
plot(abs(r2))
title('AGC output (AdaptionStepSize = 1e-3)')
subplot (4,1,4)
plot(abs(r3))
title('AGC output (AdaptionStepSize = 1e-4)')

With the step size set to $1 \mathrm{e}-1$, the AGC output overshoot but converges very quickly. With the step size set to $1 \mathrm{e}-3$, the AGC output overshoot disappears and the AGC converges smoothly but more slowly. With the maximum gain set to $1 \mathrm{e}-4$, the AGC takes a very long time to converge.

## Adaptively Adjust Received Signal Amplitude Using AGC

Modulate and amplify a QPSK signal. Set the received signal amplitude to approximately 1 volt using an AGC. Then plot the output.

Create a QPSK modulated signal using the QPSK System object.

```
data = randi([0 3],1000,1);
qpsk = comm.QPSKModulator;
modData = qpsk(data);
```

Attenuate the modulated signal.
$\mathrm{txSig}=0.1^{*}$ modData;
Create an AGC System object ${ }^{T M}$ and pass the transmitted signal through it using the step function. The AGC adjusts the received signal power to approximately 1 W .

```
agc = comm.AGC;
rxSig = agc(txSig);
```

Plot the signal constellations of the transmit and received signals after the AGC reaches steady-state.

```
h = scatterplot(txSig(200:end),1,0,'*');
hold on
scatterplot(rxSig(200:end),1,0,'or',h);
legend('Input of AGC', 'Output of AGC')
```

Measure and compare the power of the transmitted and received signals after the AGC reaches a steady state. The power of the transmitted signal is 100 times smaller than the power of the received signal.

```
txPower = var(txSig(200:end));
rxPower = var(rxSig(200:end));
[txPower rxPower]
ans = 1\times2
    0.0100 0.9970
```

## Plot Effect of Step Size on AGC Performance

Create two AGC System objects ${ }^{\text {TM }}$ to adjust the level of the received signal using two different step sizes with identical update periods.

Generate an 8-PSK signal having power equal to 10 W .

```
data = randi([0 7],200,1);
modData = sqrt(10)*pskmod(data,8,pi/8,'gray');
```

Create a pair of raised cosine matched filters with their Gain property set so that they have unity output power.

```
txfilter = comm.RaisedCosineTransmitFilter('Gain',sqrt(8));
rxfilter = comm.RaisedCosineReceiveFilter('Gain',sqrt(1/8));
```

Filter the modulated signal through the raised cosine transmit filter object.

```
txSig = txfilter(modData);
```

Create two AGC objects to adjust the received signal level. Select a step size of 0.01 and 0.1 , respectively. Set the update period to 10 .

```
agc1 = comm.AGC('AdaptationStepSize',0.01);
agc2 = comm.AGC('AdaptationStepSize',0.1);
```

Pass the modulated signal through the two AGC objects.

```
agcOut1 = agc1(txSig);
agcOut2 = agc2(txSig);
```

Filter the AGC output signals by using the raised cosine receive filter object.

```
rxSig1 = rxfilter(agcOut1);
rxSig2 = rxfilter(agcOut2);
```

Plot the power of the filtered AGC responses while accounting for the 10 symbol delay through the transmit-receive filter pair.

```
plot([abs(rxSig1(11:110)).^2 abs(rxSig2(11:110)).^2])
grid on
xlabel('Symbols')
ylabel('Power (W)')
legend('Step Size 0.01','Step Size 0.1')
```

The signal with the larger step size converges faster to the AGC target power level of 1 W .
Plot the power of the steady-state filtered AGC signals by including only the last 100 symbols.

```
plot((101:200),[abs(rxSig1(101:200)).^2 abs(rxSig2(101:200)).^2])
grid on
xlabel('Symbols')
ylabel('Power (W)')
legend('Step Size 0.01','Step Size 0.1')
```

The larger AGC step size results in less accurate gain correction.
The reduced accuracy suggests a trade off with the AdaptationStepSize property. Larger values result in faster convergence at the expense of less accurate gain control.

## Demonstrate Effect of Maximum AGC Gain on Packet Data

Pass attenuated QPSK packet data to two AGCs having different maximum gains. Then display the results.

Create two, 200-symbol QSPK data packets. Transmit the packets over a 1200 -symbol frame.

```
modDatal = pskmod(randi([0 3],200,1),4,pi/4);
modData2 = pskmod(randi([0 3],200,1),4,pi/4);
txSig = [modDatal; zeros(400,1); modData2; zeros(400,1)];
```

Attenuate the transmitted burst signal by 20 dB and plot its power.

```
rxSig = 0.1*txSig;
rxSigPwr = abs(rxSig).^2;
plot(rxSigPwr)
grid
xlabel('Symbols')
ylabel('Power (W)')
```

Create two AGCs, where agc1 has a maximum power gain of 30 dB and agc2 has a maximum power gain of 24 dB .

```
agc1 = comm.AGC('MaxPowerGain',30, ...
    'AdaptationStepSize',0.02);
agc2 = comm.AGC('MaxPowerGain',24, ...
    'AdaptationStepSize',0.02);
```

Pass the attenuated signal through the AGCs and calculate the output power.

```
rxAGC1 = agcl(rxSig);
rxAGC2 = agc2(rxSig);
pwrAGC1 = abs(rxAGC1).^2;
pwrAGC2 = abs(rxAGC2).^2;
```

Plot the output power.

```
plot([pwrAGC1 pwrAGC2])
legend('AGC1','AGC2')
grid
xlabel('Symbols')
ylabel('Power (W)')
```

Initially, for the second packet, the agc1 output signal power is too high because the AGC applied its maximum gain during the period when no data was transmitted. The corresponding agc2 output signal power does not overshoot the target power level of 1 W by the same amount. It converges to the correct power more quickly due to its smaller maximum gain.

## Algorithms

## Logarithmic Loop AGC

For the logarithmic loop AGC, the output signal is the product of the input signal and the exponential of the loop gain. The error signal is the difference between the reference level and the product of the logarithm of the detector output and the exponential of the loop gain. After multiplying by the step size, the AGC passes the error signal to an integrator.

The logarithmic loop AGC provides good performance for a variety of signal types, including amplitude modulation. Unlike the previous AGC (R2015a and earlier), the detector is applied to the input signal, which results in faster convergence times and increased signal power variation at the detector input. The larger variation is not a problem for floating point systems. A block diagram of the algorithm is shown.

Mathematically, the algorithm is summarized as

$$
\begin{aligned}
& y(n)=x(n) \cdot \exp (g(n-1)) \\
& z(n)=D(x(n)) \cdot \exp (2 g(n-1)) \\
& e(n)=A-\ln (z(n)) \\
& g(n)=g(n-1)+K \cdot e(n),
\end{aligned}
$$

where

- $x$ represents the input signal.
- $y$ represents the output signal.
- $g$ represents the loop gain.
- $D(\bullet)$ represents the detector function.
- $z$ represents the detector output.
- A represents the reference value.
- $e$ represents the error signal.
- $K$ represents the step size.

## AGC Detector

The AGC detector output, $z$, computes a square law detector:

$$
z(m)=\frac{1}{N} \sum_{n=m N}^{(m+1) N-1}|y(n)|^{2},
$$

where $N$ represents the update period.

## AGC Performance Criteria

- Attack time - The duration it takes the AGC to respond to an increase in the input amplitude.
- Decay time - The duration it takes the AGC to respond to a decrease in the input amplitude.
- Gain pumping - The variation in the gain value during steady-state operation.

Increasing the step size decreases the attack time and decay times, but it also increases gain pumping.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

AGC

Introduced in R2013a

## reset

System object: comm. AGC
Package: comm
Reset internal states of automatic gain controller

## Syntax

reset(H)

## Description

reset $(H)$ resets the filter states of the automatic gain controller filter object, $H$, to their initial values.

## step

System object: comm. AGC
Package: comm
Apply adaptive gain to input signal

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ applies an adaptive gain to the input signal X , to achieve a reference signal level at the output, Y. You must specify X as a double-precision or single-precision column vector. The AGC object uses a square law detector to determine the output signal level.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.AlgebraicDeinterleaver

Package: comm
(To be removed) Deinterleave input symbols using algebraically derived permutation vector

## Compatibility

comm.AlgebraicDeinterleaver will be removed in a future release. Use algdeintrlv instead. For more information, see "Compatibility Considerations" on page 3-31.

## Description

The AlgebraicDeinterleaver object restores the original ordering of a sequence that was interleaved using the AlgebraicInterleaver object. In typical usage, the properties of the two objects have the same values.

To deinterleave input symbols using an algebraically derived permutation vector:
1 Define and set up your algebraic deinterleaver object. See "Construction" on page 3-28.
2 Call step to deinterleave the input symbols according to the properties of
comm.AlgebraicDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.AlgebraicDeinterleaver creates a deinterleaver System object, H. This object restores the original ordering of a sequence from the corresponding algebraic interleaver object.

H = comm.AlgebraicDeinterleaver(Name,Value) creates an Algebraic deinterleaver System object, $H$, with each specified property set to the specified value. You can specify additional namevalue pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## Method

Algebraic method to generate permutation vector
Specify the algebraic method as one of Takeshita-Costello| Welch-Costas. The default is Takeshita-Costello. The algebraic interleaver performs all computations in modulo $N$, where $N$ equals the length you set in the Length property.

For the Welch-Costas method, the value of $(N+1)$ must be a prime number, where $N$ equals the value you specify in the Length property. You must set the PrimitiveElement property to an integer, $A$, between 1 and $N$. This integer represents a primitive element of the finite field $G F(N+1)$.

For the Takeshita-Costello method, you must set the Length property to a value equal to $2^{m}$, for any integer $m$. You must also set the MultiplicativeFactor property to an odd integer that is less than the value of the Length property. The CyclicShift property requires a nonnegative integer which is less than the value of the Length property. The Takeshita-Costello interleaver method uses a cycle vector of length $N$, which you specify in the Length property. The cycle vector calculation uses the equation, $\bmod \left(k \times(n-1) \times \frac{n}{2}, N\right)+1$, for any integer $n$, between 1 and $N$. The object creates an intermediate permutation function using the relationship, $P(c(n))=c(n+1)$. You can shift the elements of the intermediate permutation vector to the left by the amount specified by the CyclicShift property. Doing so produces the interleaver's actual permutation vector.

## Length

## Number of elements in input vector

Specify the number of elements in the input as a positive, integer, scalar. When you set the Method property to Welch-Costas, then the value of Length +1 must equal a prime number. When you set the Method property to Takeshita-Costello, then the value of the Length property requires a power of two. The default is 256 .

## MultiplicativeFactor

Cycle vector computation factor
Specify the factor the object uses to compute the interleaver's cycle vector as a positive, integer, scalar. This property applies when you set the Method property to Takeshita-Costello. The default is 13 .

## CyclicShift

Amount of cyclic shift
Specify the amount by which the object shifts indices, when the object creates the final permutation vector, as a nonnegative, integer, scalar. The default is 0 . This property applies when you set the Method property to Takeshita-Costello.

## PrimitiveElement

## Primitive element

Specify the primitive element as an element of order $N$ in the finite field $G F(N+1) . N$ is the value you specify in the Length on page 3-0 property. You can express every nonzero element of $G F(N+1)$ as the value of the PrimitiveElement property raised to some integer power. In a Welch-Costas interleaver, the permutation maps the integer $k$ to $\bmod \left(\mathrm{A}^{\mathrm{k}}, \mathrm{N}+1\right)-1$, where $A$ represents the value of the PrimitiveElement property. This property applies when you set the Method property to Welch-Costas. The default is 6 .

(To be removed) Deinterleave input symbols using algebraically derived permutation vector

## Compatibility

step will be removed in a future release. Use algdeintrlv instead.

## Syntax

```
Y = step(H,X)
```

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ restores the original ordering of the sequence, $X$, that was interleaved using an algebraic interleaver. An algebraically derived permutation vector based on the algebraic method you specify in the Method property forms the base of the output, Y. X must be a column vector of length specified by the Length property. $X$ can be numeric, logical, or fixed-point (fi objects). $Y$ has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.AlgebraicInterleaver

Package: comm
(To be removed) Permute input symbols using algebraically derived permutation vector

## Compatibility

comm.AlgebraicInterleaver will be removed in a future release. Use algintrlv instead. For more information, see "Compatibility Considerations" on page 3-36.

## Description

The AlgebraicInterleaver object rearranges the elements of its input vector using an algebraically derived permutation.

To interleave input symbols using an algebraically derived permutation vector:
1 Define and set up your algebraic interleaver object. See "Construction" on page 3-33.
2 Call step to interleave the input symbols according to the properties of comm.AlgebraicInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.AlgebraicInterleaver creates an interleaver System object, H, that permutes the symbols in the input signal. This permutation is based on an algebraically derived permutation vector.

H = comm.AlgebraicInterleaver(Name, Value) creates an algebraic interleaver object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## Method

Algebraic method to generate permutation vector
Algebraic method to generate permutation vector
Specify the algebraic method as one of Takeshita-Costello| Welch-Costas. The default is
Takeshita-Costello. The algebraic interleaver performs all computations in modulo $N$, where $N$ is the length you set in the Length property.

For the Welch-Costas method, the value of ( $N+1$ ) must be a prime number, where $N$ is the value you specify in the Length property. You must set the PrimitiveElement property to an integer, $A$, between 1 and $N$. This integer represents a primitive element of the finite field $G F(N+1)$.

For the Takeshita-Costello method, you must set the Length property to a value equal to $2^{m}$, for any integer $m$. You must also set the MultiplicativeFactor property to an odd integer which is less than the value of the Length property. In addition, you must set the CyclicShift property to a nonnegative integer which is less than the value of the Length property. The Takeshita-Costello interleaver method uses a cycle vector of length $N$, which you specify in the Length property. The cycle vector calculation uses the equation, $\bmod \left(k \times(n-1) \times \frac{n}{2}, N\right)+1$, for any integer $n$, between 1 and $N$. The object creates an intermediate permutation function using the relationship, $P(c(n))=c(n+1)$. You can shift the elements of the intermediate permutation vector to the left by the amount specified by the CyclicShift property. Doing so produces the actual permutation vector of the interleaver.

## Length

Number of elements in input vector
Specify the number of elements in the input as a positive, integer, scalar. When you set the Method property to Welch-Costas, then the value of Length +1 must equal a prime number. When you set the Method property to Takeshita-Costello, then the value of the Length property requires a power of two. The default is 256 .

## MultiplicativeFactor

Cycle vector computation method
Specify the factor the object uses to compute the cycle vector for the interleaver as a positive, integer, scalar. This property applies when you set the Method on page 3-0 property to Takeshita-Costello. The default is 13 .

## CyclicShift

Amount of cyclic shift
Specify the amount by which the object shifts indices, when it creates the final permutation vector, as a nonnegative, integer, scalar. This property applies when you set the Method on page 3-0 property to Takeshita-Costello. The default is 0 .

## PrimitiveElement

## Primitive element

Specify the primitive element as an element of order $N$ in the finite field $G F(N+1) . N$ is the value you specify in the Length property. You can express every nonzero element of $G F(N+1)$ as the value of the PrimitiveElement property raised to an integer power. In a Welch-Costas interleaver, the permutation maps the integer $k$ to $\bmod \left(\mathrm{A}^{\mathrm{k}}, \mathrm{N}+1\right)-1$, where $A$ represents the value of the PrimitiveElement property. This property applies when you set the Method property to WelchCostas. The default is 6 .

## Syntax

$Y=\operatorname{step}(H, X)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ permutes input sequence, $X$, and returns interleaved sequence, $Y$. The object uses an algebraically derived permutation vector, based on the algebraic method you specify in the Method property, to form the output. The input $X$ must be a column vector of length specified by the Length property. X can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.APPDecoder

Decode convolutional code by using APP method

## Description

The APPDecoder system object performs a posteriori probability (APP) decoding of a convolutional code.

To decode convolutional code by using APP method:
1 Create the comm. APPDecoder object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
appDec = comm.APPDecoder
appDec = comm.APPDecoder(Name,Value)
appDec = comm.APPDecoder(TRELLIS,Name,Value)
Description
```

appDec $=$ comm. APPDecoder creates an APP decoder System object, appDec, that decodes a convolutional code using the APP method.
appDec $=$ comm.APPDecoder(Name, Value) sets properties using one or more name-value pairs. For example, comm. APPDecoder('Algorithm', 'True APP') configures the System object, appDec, to implement true a posteriori probability decoding. Enclose each property name in quotes.
appDec $=$ comm. APPDecoder(TRELLIS, Name, Value) creates an APP decoder object, appDec, with the "TrellisStructure" on page 3-0 property set to TRELLIS.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

TrellisStructure - Trellis structure of convolutional code poly2trellis(7,[171 133],171) (default)|structure

Trellis structure of convolutional code, specified as a structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure.

Data Types: struct

## TerminationMethod - Termination method of encoded frame

'Truncated' (default)| 'Terminated '
Termination method of encoded frame, specified as 'Truncated ' or 'Terminated '. When you set this property to 'Truncated ', this System object assumes that the encoder stops after encoding the last symbol in the input frame. When you set this property to 'Terminated ', this System object assumes that the encoder forces the trellis to end each frame in the all-zeros state by encoding additional symbols. If you use the comm. ConvolutionalEncoder System object to generate the encoded frame, this property value must match the property value of the convolutional encoder and this System object.
Data Types: char | string

## Algorithm - Decoding algorithm

'Max*' (default) | 'True APP'| 'Max'
Decoding algorithm, specified as 'Max*', 'True APP', or 'Max'. When you set this property to 'True APP', this System object implements true APP decoding. When you set this property to any other value, this System object uses approximations to increase the speed of the computations. For more information, see "Algorithms" on page 3-42.
Data Types: char | string

## NumScalingBits - Number of scaling bits

3 (default) | integer in the range [0, 8]
Number of scaling bits, specified as an integer in the range [0, 8]. This property specifies the number of bits the decoder uses to scale the input data to avoid losing precision during the computations.

## Dependencies

To enable this property, set the "Algorithm" on page 3-0 property to 'Max*'.

## Data Types: double

## CodedBitLLROutputPort - Option to enable coded-bit log-likelihood ratio output true or 1 (default)|false or 0

Option to enable coded-bit log-likelihood ratio (LLR) output, specified as a numeric or logical 1 (true) or 0 (false). To disable the second output when you call this System object, set this property to 0 (false).
Data Types: logical

## Usage

## Syntax

```
[LUD,LCD] = appDec(LU,LC)
LUD = appDec(LU,LC)
```

## Description

[LUD,LCD] = appDec(LU, LC) performs APP decoding on the sequence of LLRs of encoder input bits, LU, and the sequence of LLRs of encoded bits, LC. The System object returns LUD and LCD. These output values are the updated versions of LU and LC, respectively, and are obtained based on the encoder information.

LUD = appDec (LU, LC) performs APP decoding with the LCD output disabled. To disable the LCD output, set the "CodedBitLLROutputPort" on page 3-0 property to 0 (false).

## Input Arguments

## LU - Sequence of LLRs of encoder input data

real-valued column vector
Sequence of LLRs of encoder input data, specified as a real-valued column vector. A positive soft input is interpreted as a logical 1, and a negative soft input is interpreted as a logical 0.
Data Types: single | double

## LC - Sequence of LLRs of encoded data

real-valued column vector
Sequence of LLRs of encoded data, specified as a real-valued column vector of. A positive soft input is interpreted as a logical 1 , and a negative soft input is interpreted as a logical 0 .

Data Types: single | double

## Output Arguments

## LUD - Updated value of LU

real-valued column vector
Updated value of LU, returned as a real-valued column vector.
Data Types: single | double
LCD - Updated value of LC
real-valued column vector
Updated value of LC, returned as a real-valued column vector.
Data Types: single | double

Note If the convolutional code uses an alphabet of $2^{n}$ possible symbols, where $n$ is the number of bits per input symbol, then the LC and LCD vector lengths are $L \times n$ for some positive integer $L$. Similarly, if the decoded data uses an alphabet of $2^{k}$ output symbols, where $k$ is the number of bits per output symbol, then the LU and LUD vector lengths are $L \times k$.

This System object accepts a column vector input signal with any positive integer value for $L$. For variable-sized inputs, $L$ can vary during multiple calls.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Decode Convolutional Code Using the APP Decoder

Specify noise variance and the frame length in bits. Create convolutional encoder, PSK modulator, and AWGN channel System objects.

```
noiseVar = 2e-1;
frameLength = 300;
convEncoder = comm.ConvolutionalEncoder('TerminationMethod','Truncated');
pskMod = comm.PSKModulator('BitInput',true,'PhaseOffset',0);
awgnChan = comm.AWGNChannel('NoiseMethod','Variance', ...
    'Variance',noiseVar);
```

Create convolutional decoder, PSK demodulator, and error rate System objects.

```
appDecoder = comm.APPDecoder(...
    'TrellisStructure',poly2trellis(7,[171 133]), ...
    'Algorithm','True APP','CodedBitLLROutputPort',false);
pskDemod = comm.PSKDemodulator('Bit0utput',true,'PhaseOffset',0, ...
    'DecisionMethod','Approximate log-likelihood ratio', ...
    'Variance',noiseVar);
errRate = comm.ErrorRate;
```

Transmit a convolutionally encoded 8-PSK-modulated bit stream through an AWGN channel. Demodulate the received signal using soft-decision. Decode the demodulated signal using the APP decoder.

```
for counter = 1:5
    data = randi([0 1],frameLength,1);
    encodedData = convEncoder(data);
    modSignal = pskMod(encodedData);
    receivedSignal = awgnChan(modSignal);
    demodSignal = pskDemod(receivedSignal);
    % The APP decoder assumes a polarization of the soft inputs that is
    % inverse to that of the demodulator soft outputs. Change the sign of
    % demodulated signal.
    receivedSoftBits = appDecoder(zeros(frameLength,1),-demodSignal);
    % Convert from soft-decision to hard-decision.
    receivedBits = double(receivedSoftBits > 0);
    % Count errors
```

```
    errorStats = errRate(data,receivedBits);
end
```

Display the error rate information.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
Error rate = 0.000000
Number of errors = 0
```

## Algorithms

This System object implements the soft-input-soft-output APP decoding algorithm according to [1]. The 'True APP' option of the Algorithm property implements APP decoding as per the equations $20-23$ in section $V$ of [1]. To gain speed, the 'Max*' and 'Max' values of the "Algorithm" on page 30 property approximate expressions like $\log \sum_{i} \exp \left(a_{i}\right)$ by other quantities. The 'Max' option uses $\max \left(a_{i}\right)$ as the approximation. The 'Max*' option uses max $\left(a_{i}\right)$ plus a correction term given by the expression $\ln \left(1+\exp \left(-\left|a_{i-1}-a_{i}\right|\right)\right)$.

Setting the Algorithm property to 'Max*' enables the "NumScalingBits" on page 3-0 property of this System object. This property denotes the number of bits by which this System object scales the data it processes internally (multiplies the input by $2^{\text {NumScalingBits }}$ and divides the preoutput by the same factor). Use this property to avoid losing precision during computations.

## reset

Reset states of APP decoder object

## Syntax

reset(H)

## Description

reset $(H)$ resets the states of the APPDecoder object, $H$.

## step

Decode convolutional code using the a posteriori probability method

## Syntax

[LUD,LCD] $=\operatorname{step}(H, L U, L C)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
[LUD, LCD] = step( $\mathrm{H}, \mathrm{LU}, \mathrm{LC})$ performs APP decoding. The input LU is the sequence of loglikelihoods of encoder input data bits. The input LC is the sequence of log-likelihoods of encoded bits. Negative soft inputs are considered to be zeros and positive soft inputs are considered to be ones. The outputs, LUD and LCD, are updated versions of the input LU and LC sequences and are obtained based on information about the encoder. The inputs must be of the same data type, which can be double or single precision. The output data type is the same as the input data type. If the convolutional code uses an alphabet of $2^{\wedge} \mathrm{N}$ symbols, the LC and LCD vector lengths are multiples of N . If the decoded data uses an alphabet of $2^{\wedge} \mathrm{K}$ output symbols, the LU and LUD vector lengths are multiples of $K$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.AWGNChannel

Package: comm
Add white Gaussian noise to input signal

## Description

comm.AWGNChannel adds white Gaussian noise to the input signal.
When applicable, if inputs to the object have a variable number of channels, the EbNo, EsNo, SNR, BitsPerSymbol, SignalPower, SamplesPerSymbol, and Variance properties must be scalars.

To add white Gaussian noise to an input signal:
1 Create the comm. AWGNChannel object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

awgnchan = comm.AWGNChannel
awgnchan = comm.AWGNChannel(Name,Value)

## Description

awgnchan = comm.AWGNChannel creates an additive white Gaussian noise (AWGN) channel System object, awgnchan. This object then adds white Gaussian noise to a real or complex input signal.
awgnchan = comm.AWGNChannel (Name, Value) creates a AWGN channel object, awgnchan, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## NoiseMethod - Noise level method

'Signal to noise ratio (Eb/No)' (default)|'Signal to noise ratio (Es/No)'|
'Signal to noise ratio (SNR)'|'Variance'

Noise level method, specified as 'Signal to noise ratio (Eb/No)','Signal to noise ratio (Es/No)','Signal to noise ratio (SNR)', or 'Variance'. For more information, see Specifying the Variance Directly or Indirectly on page 3-65.

## Data Types: char

## EbNo - Ratio of energy per bit to noise power spectral density

10 (default) | scalar | row vector
Ratio of energy per bit to noise power spectral density (Eb/No) in decibels, specified as a scalar or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels.

Tunable: Yes

## Dependencies

This property applies when NoiseMethod is set to 'Signal to noise ratio (Eb/No)'.
Data Types: double
EsNo - Ratio of energy per symbol to noise power spectral density
10 (default) | scalar | row vector
Ratio of energy per symbol to noise power spectral density (Es/No) in decibels, specified as a scalar or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels.

Tunable: Yes
Dependencies
This property applies when NoiseMethod is set to 'Signal to noise ratio (Es/No)'.
Data Types: double
SNR - Ratio of signal power to noise power
10 (default) | scalar | row vector
Ratio of signal power to noise power in decibels, specified as a scalar or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels.

Tunable: Yes
Dependencies
This property applies when NoiseMethod is set to 'Signal to noise ratio (SNR)'.
Data Types: double

## BitsPerSymbol - Number of bits per symbol

1 (default) | positive integer
Number of bits per symbol, specified as a positive integer.

## Dependencies

This property applies when NoiseMethod is set to 'Signal to noise ratio (Eb/No)'.
Data Types: double

## SignalPower - Input signal power

1 (default) | positive scalar | row vector
Input signal power in watts, specified as a positive scalar or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels. The object assumes a nominal impedance of $1 \Omega$.

Tunable: Yes
Dependencies
This property applies when NoiseMethod is set to 'Signal to noise ratio (Eb/No)', 'Signal to noise ratio (Es/No)', or 'Signal to noise ratio (SNR)'.

Data Types: double

## SamplesPerSymbol - Number of samples per symbol

1 (default) | positive integer | row vector
Number of samples per symbol, specified as a positive integer or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels.

## Dependencies

This property applies when NoiseMethod is set to 'Signal to noise ratio (Eb/No)' or 'Signal to noise ratio (Es/No)'.

Data Types: double

## VarianceSource - Source of noise variance

'Property' (default)|'Input port'
Source of noise variance, specified as 'Property' or 'Input port'.

- Set VarianceSource to 'Property ' to specify the noise variance value using the Variance property.
- Set VarianceSource to 'Input port' to specify the noise variance value using an input to the object, when you call it as a function.

For more information, see Specifying the Variance Directly or Indirectly on page 3-65.

## Dependencies

This property applies when NoiseMethod is 'Variance'.
Data Types: char

## Variance - White Gaussian noise variance

1 (default) | positive scalar | row vector
White Gaussian noise variance, specified as a positive scalar or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels.

## Tunable: Yes

## Dependencies

This property applies when NoiseMethod is set to 'Variance' and VarianceSource is set to 'Property'.

## Data Types: double

## RandomStream - Source of random number stream

'Global stream' (default)|'mt19937ar with seed'
Source of random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- When you set RandomStream to 'Global stream', the object uses the MATLAB default random stream to generate random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream. For example reset (RandStream.getGlobalStream). For more information, see RandStream.
- When you set RandomStream to 'mt19937ar with seed', the object uses the mt19937ar algorithm for normally distributed random number generation. In this scenario, when you call the reset function, the object reinitializes the random number stream to the value of the Seed property. You can generate reproducible numbers by resetting the object.

For a complex input signal, the object creates the random data as follows:

```
noise = randn( (N, N
```

$N_{\mathrm{S}}$ is the number of samples and $N_{\mathrm{C}}$ is the number of channels.

## Dependencies

This property applies when NoiseMethod is set to 'Variance '.

## Data Types: char

## Seed - Initial seed

67 (default) | nonnegative integer
Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. For each call to the reset function, the object reinitializes the mt19937ar random number stream to the Seed value.

## Dependencies

This property applies when RandomStream is set to 'mt19937ar with seed'.

```
Data Types: double
```

## Usage

## Syntax

```
outsignal = awgnchan(insignal)
outsignal = awgnchan(insignal,var)
```

## Description

outsignal = awgnchan(insignal) adds white Gaussian noise, as specified by awgnchan, to the input signal. The result is returned in outsignal.
outsignal = awgnchan(insignal,var) specifies the variance of the white Gaussian noise. This syntax applies when you set the NoiseMethod to 'Variance' and VarianceSource to 'Input port'.

For example:

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','VarianceSource','Input port');
var = 12;
outsignal = awgnchan(insignal,var);
```

## Input Arguments

## insignal - Input signal

```
scalar | vector | matrix
```

Input signal, specified as a scalar, an $N_{\mathrm{S}}$-element vector, or an $N_{\mathrm{S}}$-by- $N_{\mathrm{C}}$ matrix. $N_{\mathrm{S}}$ is the number of samples and $N_{\mathrm{C}}$ is the number of channels.

```
Data Types: double
Complex Number Support: Yes
```

## var - Variance of additive white Gaussian noise

positive scalar | row vector
Variance of additive white Gaussian noise, specified as a positive scalar or 1-by- $N_{\mathrm{C}}$ vector. $N_{\mathrm{C}}$ is the number of channels, as determined by the number of columns in the input signal matrix.

## Output Arguments <br> outsignal - Output signal

matrix
Output signal, returned with the same dimensions as insignal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Create Default AWGN Channel System Object

Create an AWGN channel System object with the default configuration. Pass signal data through this channel.

Create an AWGN channel object and signal data.

```
awgnchan = comm.AWGNChannel;
insignal = randi([0 1],100,1);
Send the input signal through the channel.
outsignal = awgnchan(insignal);
```

## Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to observe the effects of noise.

Create a PSK modulator System object ${ }^{\text {TM }}$. The default modulation order for the PSK modulator object is 8 .
pskModulator $=$ comm. PSKModulator;
Modulate the signal.
modData $=$ pskModulator(randi([0 7],2000,1));
Add white Gaussian noise to the modulated signal by passing the signal through an AWGN channel.
channel $=$ comm.AWGNChannel('EbNo',20,'BitsPerSymbol', 3);
Transmit the signal through the AWGN channel.
channelOutput $=$ channel(modData);
Plot the noiseless and noisy data using scatter plots to observe the effects of noise.

```
scatterplot(modData)
```

scatterplot(channeloutput)

Change the EbNo property to 10 dB to increase the noise. channel.EbNo = 10;

Pass the modulated data through the AWGN channel.
channelOutput = channel(modData);
Plot the channel output. You can see the effects of increased noise.
scatterplot(channelOutput)

## Process Signals When Number of Channels Changes

Pass a single-channel and multichannel signal through an AWGN channel System object ${ }^{\text {TM }}$.
Create an AWGN channel System object with the Eb/No ratio set for a single channel input. In this case, the EbNo property is a scalar.
channel = comm.AWGNChannel('EbNo',15);
Generate random data and apply QPSK modulation.

```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.

```
rxSig = channel(modData);
```

Plot the noisy constellation.

```
scatterplot(rxSig)
```

Generate two-channel input data and apply QPSK modulation.

```
data = randi([0 3],2000,2);
modData = pskmod(data,4,pi/4);
```

Pass the modulated data through the AWGN channel.
rxSig = channel(modData);
Plot the noisy constellations. Each channel is represented as a single column in rxSig. The plots are nearly identical, because the same $\mathrm{Eb} / \mathrm{No}$ value is applied to both channels.

```
scatterplot(rxSig(:,1))
title('First Channel')
```

scatterplot(rxSig(:,2))
title('Second Channel')

Modify the AWGN channel object to apply a different Eb/No value to each channel. To apply different values, set the EbNo property to a 1-by-2 vector. When changing the dimension of the EbNo property, you must release the AWGN channel object.

```
release(channel)
channel.EbNo = [10 20];
```

Pass the data through the AWGN channel.
rxSig = channel(modData);
Plot the noisy constellations. The first channel has significantly more noise due to its lower Eb/No value.

```
scatterplot(rxSig(:,1))
title('First Channel')
```

scatterplot(rxSig(:,2))
title('Second Channel')

## Add AWGN Using Noise Variance Input Port

Apply the noise variance input as a scalar or a row vector, with a length equal to the number of channels of the current signal input.

Create an AWGN channel System object ${ }^{\text {TM }}$ with the NoiseMethod property set to 'Variance ' and the VarianceSource property set to 'Input port'.

```
channel = comm.AWGNChannel('NoiseMethod','Variance', ...
'VarianceSource','Input port');
```

Generate random data for two channels and apply 16-QAM modulation.

```
data = randi([0 15],10000,2);
txSig = qammod(data,16);
```

Pass the modulated data through the AWGN channel. The AWGN channel object processes data from two channels. The variance input is a 1 -by- 2 vector.
rxSig = channel(txSig,[0.01 0.1]);
Plot the constellation diagrams for the two channels. The second signal is noisier because its variance is ten times larger.

```
scatterplot(rxSig(:,1))
```

```
scatterplot(rxSig(:,2))
```

Repeat the process where the noise variance input is a scalar. The same variance is applied to both channels. The constellation diagrams are nearly identical.

```
rxSig = channel(txSig,0.2);
scatterplot(rxSig(:,1))
```

```
scatterplot(rxSig(:,2))
```

## Set Random Number Seed for Repeatability

Specify a seed to produce the same outputs when using a random stream in which you specify the seed.

Create an AWGN channel System object ${ }^{\text {TM }}$. Set the NoiseMethod property to 'Variance ', the RandomStream property to 'mt19937ar with seed', and the Seed property to 99.

```
channel = comm.AWGNChannel( ...
    'NoiseMethod','Variance', ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',99);
```

Pass data through the AWGN channel.
y1 = channel(zeros(8,1));
Pass another all-zeros vector through the channel.
y2 = channel(zeros(8,1));
Because the seed changes between function calls, the output is different.
isequal(y1,y2)

```
ans = logical
0
```

Reset the AWGN channel object by calling the reset function. The random data stream is reset to the initial seed of 99.
reset(channel);
Pass the all-zeros vector through the AWGN channel.
y3 $=$ channel(zeros $(8,1))$;
Confirm that the two signals are identical.

```
isequal(y1,y3)
```

ans = logical
1

## Algorithms

## Relationship Among Eb/No, Es/No, and SNR Modes

For uncoded complex input signals, comm.AWGNChannel relates $E_{\mathrm{b}} / N_{0}, E_{\mathrm{s}} / N_{0}$, and SNR according to these equations:

$$
\begin{aligned}
& E_{\mathrm{s}} / N_{0}=N_{\mathrm{sps}} \times S N R \\
& E_{\mathrm{s}} / N_{0}=E_{\mathrm{b}} / N_{0}+10 \log _{10}(k) \text { in } \mathrm{dB}
\end{aligned}
$$

where

- $E_{\mathrm{s}}$ represents the signal energy in joules.
- $E_{\mathrm{b}}$ represents the bit energy in joules.
- $N_{0}$ represents the noise power spectral density in watts/Hz.
- $N_{\text {sps }}$ represents the number of samples per symbol, SamplesPerSymbol.
- $k$ represents the number of information bits per input symbol, BitsPerSymbol.

For real signal inputs, the comm.AWGNChannel relates $E_{s} / N_{0}$ and $\operatorname{SNR}$ according to this equation:

$$
E_{\mathrm{s}} / N_{0}=0.5\left(N_{\mathrm{sps}}\right) \times S N R
$$

## Note

- All values of power assume a nominal impedance of 1 ohm.
- The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of $N_{0} / 2$ watts $/ \mathrm{Hz}$ for real input signals, versus $N_{0}$ watts/Hz for complex signals.

For more information, see AWGN Channel Noise Level.

## Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by comm.AWGNChannel, specify VarianceSource as:

- 'Property ', then set NoiseMethod to 'Variance' and specify the variance with the Variance property.
- 'Input port ' then specify the variance level for the object as an input with an input argument, var.

To specify variance indirectly, that is, to have it calculated by comm.AWGNChannel, specify VarianceSource as 'Property' and the NoiseMethod as:

- 'Signal to noise ratio (Eb/No)', where the object uses these properties to calculate the variance:
- EbNo, the ratio of bit energy to noise power spectral density
- BitsPerSymbol
- SignalPower, the actual power of the input signal samples
- SamplesPerSymbol
- 'Signal to noise ratio (Es/No)', where the object uses these properties to calculate the variance:
- EsNo, the ratio of signal energy to noise power spectral density
- SignalPower, the actual power of the input signal samples
- SamplesPerSymbol
- 'Signal to noise ratio (SNR)', where the object uses these properties to calculate the variance:
- SNR, the ratio of signal power to noise power
- SignalPower, the actual power of the input signal samples

Changing the number of samples per symbol ( SamplesPerSymbol) affects the variance of the noise added per sample, which also causes a change in the final error rate.

NoiseVariance $=$ SignalPower $\times$ SamplesPerSymbol $/ 10^{(\text {EsNo } / 10}$

Tip Select the number of samples per symbol based on what constitutes a symbol and the oversampling applied to it. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see AWGN Channel Noise Level.

## comm.BarkerCode

Package: comm
Generate bipolar Barker code

## Description

The comm. BarkerCode System object generates a bipolar Barker code. Barker codes have low autocorrelation properties. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see "Barker Codes" on page 3-70.

To generate a Barker code:
1 Create the comm. BarkerCode object and set its properties.
2 Call the object, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

barkerCode = comm. BarkerCode
barkerCode = comm. BarkerCode(Name,Value)

## Description

barkerCode $=$ comm. BarkerCode creates a bipolar Barker code generator System object to generate a Barker code.
barkerCode $=$ comm. BarkerCode(Name, Value) sets properties using one or more name-value pairs. For example, comm. BarkerCode('Length', 11, 'SamplesPerFrame', '11') configures a bipolar Barker code generator System object to output a length 11 Barker code in an 11-sample frame. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Length - Length of generated code

7 (default) | 123451113

Length of the generated code, specified as $1,2,3,4,5,7,11$, or 13 . For more information, see "Barker Codes" on page 3-70.
Example: 'Length' , 2 outputs the Barker code [-1;1].
Data Types: double

## SamplesPerFrame - Samples per output frame

1 (default) | positive integer
Samples per output frame, specified as a positive integer. If SamplesPerFrame is $M$, the object outputs a frame containing $M$ samples comprised of length $N$ Barker code sequences. If necessary, the object repeats the code sequence to reach $M$ samples. $N$ is the length of the generated code, which is set by the Length property.
Data Types: double

## OutputDataType - Output data type

double (default) | int8
Output data type, specified as double or int8.
Data Types: char|string

## Usage

Note For versions earlier than R2016b, use the step function to run the System object ${ }^{\text {TM }}$ algorithm. The arguments to step are the object you created, followed by the arguments shown in this section.

For example, $\mathrm{y}=\operatorname{step}(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\operatorname{obj}(\mathrm{x})$ perform equivalent operations.

## Syntax

y = barkerCode

## Description

$y=$ barkerCode outputs a Barker code frame, as a column vector. If the frame length exceeds the Barker code length, the object fills the frame by repeating the Barker code.

Set the data type of the output with the OutputDataType property.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Specific to comm. BarkerCode

clone Create duplicate System object
isLocked Determine if System object is in use

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Generate Barker Code Sequence

Create a Barker code System object with 10 samples per frame.

```
    barker = comm.BarkerCode('SamplesPerFrame',10)
```

barker =
comm.BarkerCode with properties:
Length: 7
SamplesPerFrame: 10
OutputDataType: 'double'

Generate multiple frames by using the default Barker code sequence of length 7. The code wraps within the frame and continues in the next frame.

```
    for ii = 1:2
        seq = barker()
    end
seq = 10\times1
            -1
            -1
            -1
            1
            1
            -1
            1
            -1
            -1
            -1
seq = 10\times1
            1
            1
            -1
            1
            -1
            -1
            -1
            1
            1
            -1
```

## Compute Barker Code Sidelobe Level

Compute the peak sidelobe level for each Barker code.

```
CodeLength = [1 2 3 4 5 7 11 13]';
psl = zeros(length(CodeLength),1);
ac = dsp.Autocorrelator;
barker = comm.BarkerCode;
for ii=1:length(CodeLength)
    spf = CodeLength(ii);
    barker.Length = CodeLength(ii);
    barker.SamplesPerFrame = spf;
    seq = barker();
    sll_dB = 20*log10(abs(ac(seq)));
    psl(ii) = -(max(sll_dB));
    release(barker);
    release(ac);
end
Sidelobe_dB = psl;
T = tabl\overline{e}(CodeLength,Sidelobe_dB)
T=8\times2 table
    CodeLength Sidelobe_dB
    *
                                    \
\begin{tabular}{rr}
1 & 0 \\
2 & -6.0206 \\
3 & -9.5424 \\
4 & -12.041 \\
5 & -13.979 \\
7 & -16.902 \\
11 & -20.828 \\
13 & -22.279
\end{tabular}
```

## More About

## Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe, $C_{k}$, for a $k$-symbol shift of an $N$-bit code sequence, $\left\{X_{j}\right\}$, is

$$
C_{k}=\sum_{j=1}^{N-k} X_{j} X_{j+k}
$$

For $j=1,2,3, \ldots, N, X_{j}$ is an individual code symbol that is equal to +1 or -1 . The adjacent symbols are assumed to be 0 .

The output code is in a bipolar format with 0 and 1 mapped to 1 and -1 . The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame
synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

| Barker <br> Code <br> Length | Barker Code | Sidelobe Level |
| :--- | :--- | :--- |
| 1 | $[-1]$ | 0 dB |
| 2 | $[-1 ; 1]$ | -6 dB |
| 3 | $[-1 ;-1 ; 1]$ | -9.5 dB |
| 4 | $[-1 ;-1 ; 1 ;-1]$ | -12 dB |
| 5 | $[-1 ;-1 ;-1 ; 1 ;-1]$ | -14 dB |
| 7 | $[-1 ;-1 ;-1 ; 1 ; 1 ;-1 ; 1]$ | -16.9 dB |
| 11 | $[-1 ;-1 ;-1 ; 1 ; 1 ; 1 ;-1 ; 1 ; 1 ;-1 ; 1]$ | -20.8 dB |
| 13 | $[-1 ;-1 ;-1 ;-1 ;-1 ; 1 ; 1 ;-1 ;-1 ; 1 ;-1 ; 1 ;-1]$ | -22.3 dB |

## comm.BasebandFileReader

Package: comm
Read baseband signals from file

## Description

The comm. BasebandFileReader object reads a baseband signal from a specific type of binary file written by comm. BasebandFileWriter. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz . The SampleRate and CenterFrequency properties are saved when the file is created. The comm. BasebandFileReader object automatically reads the sample rate, center frequency, number of channels, and any descriptive data and saves them to its read-only properties.

To create an input signal from a saved baseband file:
1 Create a comm. BasebandFileReader object and set the properties of the object.
2 Call step to generate a baseband signal from saved data.
3 Call release to close the file.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y=\operatorname{step}(\mathrm{obj})$ and $y=o b j()$ perform equivalent operations.

## Construction

$\mathrm{bbr}=$ comm. BasebandFileReader returns a baseband reader object, bbr, using the default properties.
$\mathrm{bbr}=$ comm.BasebandFileReader(fname) returns a baseband reader object and sets fname as the Filename property.
bbr = comm.BasebandFileReader(fname,spf) also sets spf as the SamplesPerFrame property.
bbr = comm.BasebandFileReader(__ ,Name, Value) specifies additional properties using Name, Value pairs. Unspecified properties have default values.

## Example:

bbr = comm.BasebandFileReader('recorded_data',100);

## Properties

## Filename - Name of the baseband file to read

'example.bb' (default) | character vector
Name of the baseband file to read, specified as a character vector. Specify the absolute path only if the file is not on the MATLAB path. Only the absolute path is saved and displayed.

## SampleRate - Sample rate of the saved baseband signal

## 1 (default) | positive scalar

This property is read-only.
Sample rate of the saved baseband signal in Hz .

## CenterFrequency - Center frequency of the saved baseband signal <br> 100000000 (default) | positive scalar | row vector

This property is read-only.
Center frequency of the saved baseband signal in Hz. When this property is a row vector, each element represents the center frequency of a channel in a multichannel signal.

## NumChannels - Number of channels of the saved baseband signal

1 (default) | positive integer
This property is read-only.
Number of channels of the saved baseband signal.

## Metadata - Data describing the baseband signal

struct() (default)| structure
This property is read-only.
Data describing the baseband signal. If the file has no descriptive data, this property is an empty structure.

## SamplesPerFrame - Number of samples per output frame

100 (default) | positive integer
Number of samples per output frame, specified as a positive integer.
Data Types: double

## CyclicRepetition - Flag to repeatedly read baseband file false (default) | true

Flag to repeatedly read baseband file, specified as a logical scalar. To repeatedly read the baseband file specified by Filename, set this property to true.

## Methods

info Characteristic information about baseband file reader

| Common to All System Objects |  |
| :--- | :--- |
| release | Allow System object property value changes |
| step | Generate baseband signal from file |
| reset | Reset states of baseband file reader object |
| isDone | Read status of baseband file samples |

## Examples

## Read Baseband Data from File

Read a baseband signal from file using the comm. BasebandFileReader System object.
Create a baseband file reader object.

```
bbr = comm.BasebandFileReader('example.bb')
bbr =
    comm.BasebandFileReader with properties:
                    Filename: 'C:\TEMP\Bdoc20a_1326390_10420\ibC22023\16\tp613ff4d7\comm-ex87872352\exam!
            SampleRate: 1
        CenterFrequency: 100000000
            NumChannels: 1
                Metadata: [1x1 struct]
        SamplesPerFrame: 100
        CyclicRepetition: false
```

Use the info method to gain additional information about bbr. The file contains 10000 samples of type 'double'. No samples have been read.

```
info(bbr)
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
        NumSamplesRead: 0
```

## Reading Data with Multiple Calls to Baseband File Reader Object

Since the NumSamplesPerFrame is 100, and NumSamplesInData is 10000, reading the entire contents of the example.bb file will require multiple calls to the bbr object. This can be achieved by using the isDone method to terminate a while loop.

```
y = [];
while ~isDone(bbr)
    x = bbr();
    y = cat(1,y,x);
end
```

Plot the absolute magnitude of the baseband data.

```
plot(abs(y))
```

Confirm that all the samples have been read.

```
info(bbr)
ans = struct with fields:
    NumSamplesInData: 10000
                DataType: 'double'
        NumSamplesRead: 10000
```

The total number of samples and the number of samples read are the same.
Release the baseband file reader resources.
release(bbr)

## Reading Data with Single Call to Baseband File Reader Object

Alternatively, to read all samples from the file in one call to the object, you can set the samples per frame equal to the number of samples in the data file.

```
bbrinfo = bbr.info
bbrinfo = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
    NumSamplesRead: 10000
```

```
bbr.SamplesPerFrame = bbrinfo.NumSamplesInData
bbr =
    comm.BasebandFileReader with properties:
```

Filename: 'C:\TEMP\Bdoc20a_1326390_10420\ibC22023\16\tp613ff4d7\comm-ex87872352\exam! SampleRate: 1 CenterFrequency: 100000000

NumChannels: 1
Metadata: [1x1 struct]
SamplesPerFrame: 10000
CyclicRepetition: false

Now read the entire contents of the example.bb file with a single call to the bbr object. Confirm that all the samples have been read.

```
xx = bbr();
isequal(y,xx)
ans = logical
    1
info(bbr)
ans = struct with fields:
    NumSamplesInData: 10000
            DataType: 'double'
        NumSamplesRead: 10000
```

## See Also

comm.BasebandFileWriter
Introduced in R2016b

## info

System object: comm. BasebandFileReader
Package: comm
Characteristic information about baseband file reader

## Syntax

s = info(bbr)

## Description

$\mathrm{s}=$ info(bbr) returns a structure, s , containing characteristic information for the BasebandFileReader System object, bbr. s has these fields:

- NumSamplesInData is the total number of baseband data samples in the file, returned as a positive integer.
- DataType is the data type of the baseband signal in the file.
- NumSamplesRead is the number of samples that have been read from the file, returned as a positive integer. It cannot exceed the NumSamplesInData property when CyclicRepetition is false.

## Introduced in R2016b

## comm.BasebandFileWriter

Package: comm
Write baseband signals to file

## Description

A baseband file is a specific type of binary file written by the comm. BasebandFileWriter System object. Baseband signals are typically down-converted from a nonzero center frequency to 0 Hz . The SampleRate and CenterFrequency properties are saved when the file is created.

To save a baseband signal to a file:
1 Create a comm. BasebandFileWriter object and set the properties of the object.
2 Call step to save a baseband signal to a file.
3 Call release to save the baseband signal to a file and to close the file.

Note Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y=$ step $(\mathrm{obj}, \mathrm{x})$ and $\mathrm{y}=\mathrm{obj}(\mathrm{x})$ perform equivalent operations.

## Construction

bbw = comm. BasebandFileWriter returns a baseband writer object, bbw, using the default properties.
bbw = comm.BasebandFileWriter(fname) returns bbw and sets fname as the Filename property.
bbw = comm.BasebandFileWriter(fname,fs) also sets fs as the SampleRate property.
bbw = comm.BasebandFileWriter(fname,fs,fc) also sets fc as the CenterFrequency property.
bbw = comm.BasebandFileWriter(fname,fs,fc,md) also sets structure md as the MetaData property.
bbw = comm.BasebandFileWriter(__ ,Name,Value) specifies additional properties using Name, Value pairs. Unspecified properties have default values.

## Example:

bbw = comm.BasebandFileWriter('qpsk_data.bb',10e6,2e9);

## Properties

## Filename - Name of saved file

' untitled.bb' (default) | character vector

Name of saved file, specified as a character vector. The filename can include a relative or an absolute path.

## SampleRate - Sample rate of output signal

1 (default) | positive scalar
Sample rate of the output signal, specified in Hz as a positive scalar.

## CenterFrequency - Center frequency of the baseband signal <br> 100000000 (default) | positive integer scalar | row vector

Center frequency of the baseband signal, specified in Hz as a positive integer scalar or row vector. If CenterFrequency is a row vector, each element corresponds to a channel.

## Metadata - Data describing the baseband signal

empty structure (default) | structure
Data describing the baseband signal, specified as a structure. The structure can have any number of fields and any field name. The field values can be of any numeric, logical, or character data type and have any number of dimensions.

## NumSamplesToWrite - Number of samples to save

Inf (default) | positive integer
Number of samples to save, specified as a positive integer.

- To write all the baseband signal samples to a file, set NumSamplesToWrite to Inf.
- To write only the last NumSamplesToWrite samples to a file, set NumSamplesToWrite to a finite number.

## Data Types: double

## Methods

$$
\begin{array}{ll}
\text { info } & \text { Characteristic information about baseband file writer } \\
\text { reset } & \text { Reset states of baseband file writer object } \\
\text { step } & \text { Write baseband signal to file }
\end{array}
$$

## Common to All System Objects

release
Allow System object property value changes

## Examples

## Write Baseband Signal to File

Create a baseband file writer object having a sample rate of 1 kHz and a 0 Hz center frequency.
bbw = comm.BasebandFileWriter('baseband_data.bb',1000,0);
Save today's date in the Metadata structure.

```
bbw.Metadata = struct('Date',date);
```

Generate two channels of QPSK-modulated data.

```
d = randi([0 3],1000,2);
x = pskmod(d,4,pi/4,'gray');
```

Write the baseband data to file 'baseband_data.bb'.
bbw ( x )
Display information about bbw. Release the object.

```
info(bbw)
ans = struct with fields:
            Filename: 'C:\TEMP\Bdoc20a_1326390_10420\ibC22023\1\tp9f63b6cc\comm-ex66490302\base
    SamplesPerFrame: 1000
        NumChannels: 2
            DataType: 'double'
    NumSamplesWritten: 1000
release(bbw)
```

Create a baseband file reader object to read the saved data. Read the metadata from the file.

```
bbr = comm.BasebandFileReader('baseband_data.bb','SamplesPerFrame',100);
bbr.Metadata
ans = struct with fields:
    Date: '29-Feb-2020'
```

Read the data from the file.
z = [];
while ~isDone(bbr)
$y=b b r() ;$
$z=\operatorname{cat}(1, z, y) ;$
end

Display information about bbr. Release bbr.

```
info(bbr)
ans = struct with fields:
    NumSamplesInData: 1000
            DataType: 'double'
        NumSamplesRead: 1000
```

release(bbr)

Confirm the original modulated data, $x$, matches the data read from file 'baseband_data.bb', $z$.

```
isequal(x,z)
ans = logical
    1
```

## Tips

- comm. BasebandFileWriter writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the zip function. For more information, see "Create and Extract from Zip Archives" (MATLAB).

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## See Also

comm. BasebandFileReader

Introduced in R2016b

## info

Characteristic information about baseband file writer

## Syntax

$\mathrm{s}=$ info(bbw)

## Description

$\mathrm{s}=$ info(bbw) returns a structure, s , containing characteristic information for the BasebandFileWriter System object, bbw. s has these fields:

- Filename is the name of the baseband data file, returned as a character vector. The filename shows the absolute path.
- SamplesPerFrame is the number of samples in each frame, returned as a positive integer.
- NumChannels is the number of channels, returned as a positive integer greater than or equal to 1.
- DataType is the input data type.
- NumSamplesWritten is the number of samples written to the file, returned as a positive integer. This field returns the smaller of the total number of samples processed by the object and the NumSamplesWritten property.

Note All fields are available when the object is locked. When the object is unlocked, only the Filename and NumSamplesWritten fields are available.

## reset

System object: comm.BasebandFileWriter
Package: comm
Reset states of baseband file writer object

## Syntax

reset (bbw)

## Description

reset (bbw) resets the states of the BasebandFileWriter object, bbw.
Introduced in R2016b

## step

System object: comm. BasebandFileWriter
Package: comm
Write baseband signal to file

## Syntax

step(bbw, x)
bbw(x)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
step (bbw, x) writes a baseband signal, $x$, to the file specified by the Filename property of the BasebandFileWriter object, bbw. The number of samples written to the file is determined by the NumSamplesToWrite property of bbw.
$\operatorname{bbw}(x)$ is equivalent to the first syntax.

Note bbw specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## Introduced in R2016b

## comm.BCHDecoder

Package: comm
Decode data using BCH decoder

## Description

The BCHDecoder object recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the codeword and message length values in this object must match the properties in the corresponding comm. BCHEncoder System object.

To decode a binary message from a BCH codeword:
1 Define and set up your BCH decoder object. See "Construction" on page 3-85.
2 Call step to recover a binary message vector from a binary BCH codeword vector according to the properties of comm. BCHDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

dec $=$ comm.BCHDecoder creates a BCH decoder System object, dec, that performs BCH decoding.
dec $=$ comm. $\mathrm{BCHDecoder}(\mathrm{N}, \mathrm{K})$ creates a BCH decoder object, dec, with the CodewordLength property set to N and the MessageLength property set to K .
dec $=$ comm. $\mathrm{BCHDecoder}(\mathrm{N}, \mathrm{K}, \mathrm{GP})$ creates a BCH decoder object, dec, with the CodewordLength property set to $N$, the MessageLength property set to $K$, and the GeneratorPolynomial property set to GP.
dec $=$ comm. BCHDecoder ( $\mathrm{N}, \mathrm{K}, \mathrm{GP}, \mathrm{S}$ ) creates a BCH decoder object, dec, with the CodewordLength property set to N , the MessageLength property set to K , the GeneratorPolynomial property set to GP, and the ShortMessageLength property set to S.
dec = comm.BCHDecoder(N,K,GP,S,Name,Value) creates a BCH decoder object, dec, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.
dec $=$ comm. BCHDecoder(Name, Value) creates a BCH decoder object, dec, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## CodewordLength

Codeword length
Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is 15 . The values of the CodewordLength and MessageLength on page 3-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of this property must take the form $2^{M}-1$, where $M$ is an integer such that $3 \leq M \leq 16$. The default is 15 .

## MessageLength

Message length
Specify the message length as a double-precision positive integer scalar. The values of the CodewordLength on page 3-0 and MessageLength properties must produce a valid narrow-sense BCH code. The default is 5 .

## ShortMessageLengthSource

Short message length source
Specify the source of the shortened message as either Auto or Property. When this property is set to Auto, the BCH code is defined by the CodewordLength on page 3-0 , MessageLength on page 3-0 , GeneratorPolynomial on page 3-0 , and PrimitivePolynomial on page 3-0 properties. When ShortMessageLengthSource is set to Property, you must specify the ShortMessageLength on page 3-0 property, which is used with the other properties to define the BCH code. The default is Auto.

## ShortMessageLength

Shortened message length
Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to MessageLength on page 3-0 . When
ShortMessageLength < MessageLength, the BCH code is shortened. The default is 5 .

## GeneratorPolynomialSource

Source of generator polynomial
Specify the source of the generator polynomial as either Auto or Property. Set this property to Auto to create the generator polynomial automatically. Set GeneratorPolynomialSource to Property to specify a generator polynomial using the GeneratorPolynomial on page 3-0 property. The default is Auto.

## GeneratorPolynomial

Generator polynomial
Specify the generator polynomial as a binary double-precision row vector, a binary Galois field row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of CodewordLength on page 3-0 -MessageLength on page 3-0 +1 . This property applies when you
set GeneratorPolynomialSource on page 3-0 to Property. The default is ' $\mathrm{X}^{\wedge} 10+\mathrm{X}^{\wedge} 8+$ $X^{\wedge} 5+X^{\wedge} 4+X^{\wedge} 2+X+1^{\prime}$, which is the result of bchgenpoly(15,5,[],'double') and corresponds to a 15,5 code.

## CheckGeneratorPolynomial

Enable generator polynomial checking
Set this property to true to perform a generator polynomial check the first time you call the step method. The default is true. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set GeneratorPolynomialSource on page 3-0 to Property. The default is true.

## PrimitivePolynomialSource

Source of primitive polynomial
Specify the source of the primitive polynomial as Auto or Property. Set this property to Auto to create a primitive polynomial of degree $M=$ ceil (log2 (CodewordLength on page 3-0 +1 )). Set PrimitivePolynomialSource to Property to specify a polynomial using the PrimitivePolynomial on page 3-0 property. The default is Auto.

## PrimitivePolynomial

Primitive polynomial
Specify the primitive polynomial of order M, that defines the finite Galois field GF(2). Use a doubleprecision, binary row vector with the coefficients of the polynomial in order of descending powers or a polynomial character vector. This property applies when you set the
PrimitivePolynomialSource on page 3-0 property to Property. The default is ' $\mathrm{X}^{\wedge} 4+\mathrm{X}+$ $1^{\prime}$, which is the result of fliplr(de2bi(primpoly(4))).

## PuncturePatternSource

Source of puncture pattern
Specify the source of the puncture pattern as None or Property. Set this property to None to disable puncturing. Set it to Property to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the PuncturePattern on page 3-0 property. The default is None.

## PuncturePattern

Puncture pattern vector
Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length CodewordLength on page 3-0 -MessageLength on page 3-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set PuncturePatternSource on page 3-0 to Property. The default is [ones $(8,1) ; \operatorname{zeros}(2,1)]$.

## ErasuresInputPort

Enable erasures input

Set this property to true to specify a vector of erasures as a step method input. The erasures vector is a double-precision or logical binary column vector that indicates which bits of the input codewords to erase or ignore. Values of 1 in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords. Set this property to false to disable erasures. The default is false.

## NumCorrectedErrorsOutputPort

Output number of corrected errors
Set this property to true so that the step method outputs the number of corrected errors. The default is true.

## Input and Output Signal Lengths in BCH and RS System Objects

The notation $\mathrm{y}=\mathrm{c} * \mathrm{x}$ denotes that y is an integer multiple of x .
The number of punctures equals the number of zeros in the puncture vector.
$M$ is the degree of the primitive polynomial. Each group of $M$ bits represents an integer between 0 and $2^{M}-1$ that belongs to the finite Galois field $\mathrm{GF}\left(2^{M}\right)$.

step
Decode data using a BCH decoder

## Common to All System Objects

release Allow System object property value changes

## Examples

## Transmit and decode an 8-DPSK-modulated signal, then count errors

\% The following code transmits a BCH-encoded, 8-DPSK-modulated bit stream
\% through an AWGN channel. Then, the example demodulates, decodes, and counts errors.

```
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);
for counter = 1:20
    data = randi([0 1], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedBits = step(dec, demodSignal);
    errorStats = step(errorRate, data, receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

Error rate $=0.015075$
Number of errors $=9$

## Transmit and receive a BPSK-modulated signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;
K = 239;
S = 63;
```

Create a BCH $(255,239)$ generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.

```
gp = bchgenpoly(255,239);
bchEncoder = comm.BCHEncoder(N,K,gp,S);
bchDecoder = comm. BCHDecoder(N,K,gp,S);
```

Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Main processing loop.

```
for counter = 1:20
    data = randi([0 1],630,1); % Generate binary data
    encodedData = bchEncoder(data); % BCH encode data
    modSignal = pskmod(encodedData,2); % BPSK modulate
    receivedSignal = awgn(modSignal,5); % Pass through AWGN channel
    demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate
    receivedBits = bchDecoder(demodSignal); % BCH decode data
```

```
    errorStats = errorRate(data,receivedBits); % Compute error statistics
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
Error rate = 0.000318
Number of errors = 4
```

## Shorten a BCH Code

Shorten a $(31,26)$ BCH code to an $(11,6)$ BCH code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a $(31,26)$ code. Specify the generator polynomial,
$x^{5}+x^{2}+1$, and a shortened message length of 6 .

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
ans = logical
    1
```

## See Also

bchdec|bchgenpoly | comm. BCHEncoder \| comm.RSDecoder \| primpoly

## step

System object: comm.BCHDecoder
Package: comm
Decode data using a BCH decoder

## Syntax

Y $=$ step $(H, X)$
[ $\mathrm{Y}, \mathrm{ERR}$ ] $=\operatorname{step}(\mathrm{H}, \mathrm{X})$
$Y=\operatorname{step}(H, X, E R A S U R E S)$

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ decodes input binary codewords in X using a (CodewordLength,MessageLength) BCH decoder with the corresponding narrow-sense generator polynomial. The step method returns the estimated message in Y. This syntax applies when you set the NumCorrectedErrorsOutputPort property to false. The input and output length of the step function equal the values listed in the table in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88.
[ $\mathrm{Y}, \mathrm{ERR}$ ] = step $(\mathrm{H}, \mathrm{X})$ returns the number of corrected errors in output ERR when you set the NumCorrectedErrorsOutputPort property to true. A non- negative value in the $i$-th element of the ERR output vector denotes the number of corrected errors in the $i$-th input codeword. A value of -1 in the $i$-th element of the ERR output indicates that a decoding error occurred for the $i$-th input codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the BCH code.

Y = step( $\mathrm{H}, \mathrm{X}$, ERASURES) uses ERASURES as the erasures pattern input when you set the ErasuresInputPort property to true. The object decodes the binary encoded data input, X , and treats as erasures the bits of the input codewords specified by the binary column vector, ERASURES. The length of ERASURES must equal the length of $X$, and its elements must be of data type double or logical. Values of 1 in the erasures vector correspond to erased bits in the same position of the (possibly punctured) input codewords.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.BCHEncoder

Package: comm
Encode data using BCH encoder

## Description

The BCHEncoder object creates a BCH code with specified message and codeword lengths.
To encode data using a BCH coding scheme:
1 Define and set up your BCH encoder object. See "Construction" on page 3-94.
2 Call step to create a BCH code with message and codeword lengths specified according to the properties of comm. BCHEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

enc $=$ comm.BCHEncoder creates a BCH encoder System object, enc, that performs BCH encoding.
enc $=$ comm.BCHEncoder $(N, K)$ creates a BCH encoder object, enc, with the CodewordLength property set to N and the MessageLength property set to K .
enc = comm.BCHEncoder( $\mathrm{N}, \mathrm{K}, \mathrm{GP}$ ) creates a BCH encoder object, enc, with the CodewordLength property set to N , the MessageLength property set to K and the GeneratorPolynomial property set to GP.
enc = comm.BCHEncoder( $\mathrm{N}, \mathrm{K}, \mathrm{GP}, \mathrm{S}$ ) creates a BCH encoder object, enc, with the CodewordLength property set to N , the MessageLength property set to K , the GeneratorPolynomial property set to GP and the ShortMessageLength property set to S.
enc = comm.BCHEncoder(N,K,GP,S,Name,Value) creates a BCH encoder object, enc, with the CodewordLength property set to N, the MessageLength property set to K, the GeneratorPolynomial property set to GP, the ShortMessageLength property set to S, and each specified property Name set to the specified Value.
enc = comm. BCHEncoder(Name,Value) creates a BCH encoder object, enc, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

Note The input and output signal lengths are listed in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88 on the comm. BCHDecoder reference page.

## CodewordLength

Codeword length
Specify the codeword length of the BCH code as a double-precision positive integer scalar. The default is 15 . The values of the CodewordLength and MessageLength on page 3-0 properties must produce a valid narrow-sense BCH code. For a full-length BCH code, the value of the property must use the form $2^{M}-1$, where $M$ is an integer such that $3 \leq M \leq 16$. The default is 15 .

## MessageLength

Message length
Specify the message length as a double-precision positive integer scalar. The values of the CodewordLength on page 3-0 and MessageLength properties must produce a valid narrow-sense BCH code. The default is 5 .

## ShortMessageLengthSource

Short message length source
Specify the source of the shortened message as either Auto or Property. When this property is set to Auto, the BCH code is defined by the CodewordLength on page 3-0 , MessageLength on page 3-0 , GeneratorPolynomial on page 3-0 , and PrimitivePolynomial on page 3-0 properties. When ShortMessageLengthSource is set to Property, you must specify the ShortMessageLength on page 3-0 property that is used with the other properties to define the RS code. The default is Auto.

## ShortMessageLength

Shortened message length
Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to MessageLength on page 3-0 . When
ShortMessageLength < MessageLength, the BCH code is shortened. The default is 5 .

## GeneratorPolynomialSource

Source of generator polynomial
Specify the source of the generator polynomial as either Auto or Property. Set this property to Auto to create the generator polynomial automatically. Set it to Property to specify a generator polynomial using the GeneratorPolynomial on page 3-0 property. The default is Auto.

## GeneratorPolynomial

Generator polynomial
Specify the generator polynomial as a binary double-precision row vector, a binary Galois row vector that represents the coefficients of the generator polynomial in order of descending powers, or as a polynomial character vector. The length of the generator polynomial requires a value of CodewordLength on page 3-0 -MessageLength on page 3-0 +1 . This property applies when you set GeneratorPolynomialSource on page 3-0 to Property. The default is ' $\mathrm{X}^{\wedge} 10+\mathrm{X}^{\wedge} 8+$ $X^{\wedge} 5+X^{\wedge} 4+X^{\wedge} 2+X+1^{\prime}$, which is the result of bchgenpoly (15,5,[],'double') and corresponds to a $(15,5)$ code.

## CheckGeneratorPolynomial

## Enable generator polynomial checking

Set this property to true to perform a generator polynomial check the first time you call the step method. This check verifies that the specified generator polynomial is valid. For larger codes, disabling the check reduces processing time. As a best practice, perform the check at least once before setting this property to false. This property applies when you set
GeneratorPolynomialSource on page 3-0 to Property. The default is true.

## PrimitivePolynomialSource

Source of primitive polynomial
Specify the source of the primitive polynomial as one of Auto or Property. Set this property to Auto to create a primitive polynomial of degree $M=$ ceil (log2 (CodewordLength on page 3-0 +1 )). Set it to Property to specify a polynomial using the PrimitivePolynomial on page 3-0 property. The default is Auto

## PrimitivePolynomial

## Primitive polynomial

Specify the primitive polynomial of order M, that defines the finite Galois field GF(2). Use a doubleprecision, binary row vector with the coefficients of the polynomial in order of descending powers or as a polynomial character vector. This property applies when you set the PrimitivePolynomialSource on page 3-0 property to Property. The default is ' $\mathrm{X} \wedge 4+X+$ $1^{\prime}$, which is the result of fliplr(de2bi(primpoly(4))).

## PuncturePatternSource

Source of puncture pattern
Specify the source of the puncture pattern as one of None or Property. Set this property to None to disable puncturing. Set it to Property to decode punctured codewords. This decoding is based on a puncture pattern vector you specify in the PuncturePattern on page 3-0 property. The default is None.

## PuncturePattern

Puncture pattern vector
Specify the pattern that the object uses to puncture the encoded data. Use a double-precision binary column vector of length CodewordLength on page 3-0 -MessageLength on page 3-0 . Zeros in the puncture pattern vector indicate the position of the parity bits that the object punctures or excludes from each codeword. This property applies when you set PuncturePatternSource on page 3-0 to Property. The default is [ones ( 8,1 ); zeros $(2,1)]$.

## Methods

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Transmit and decode an 8-DPSK-modulated signal, then count errors

```
% The following code transmits a BCH-encoded, 8-DPSK-modulated bit stream
% through an AWGN channel. Then, the example demodulates, decodes, and counts errors.
enc = comm.BCHEncoder;
mod = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('Bit0utput',true);
dec = comm.BCHDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);
for counter = 1:20
    data = randi([0 1], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedBits = step(dec, demodSignal);
    errorStats = step(errorRate, data, receivedBits);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
Error rate = 0.015075
Number of errors = 9
```

## Transmit and receive a BPSK-modulated signal

Transmit and receive a BPSK-modulated signal encoded with a shortened BCH code, then count errors.

Specify the codeword, message, and shortened message lengths.

```
N = 255;
K = 239;
S = 63;
```

Create a BCH $(255,239)$ generator polynomial. Use the generator polynomial to create a BCH encoder and decoder pair. The BCH code is based on the AMR standard.
gp = bchgenpoly(255,239);
bchEncoder $=$ comm. $\mathrm{BCHEncoder}(\mathrm{N}, \mathrm{K}, \mathrm{gp}, \mathrm{S})$;
bchDecoder $=$ comm. BCHDecoder(N,K,gp,S);
Create an error rate counter.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
Main processing loop.
```

```
for counter = 1:20
```

for counter = 1:20
data = randi([0 1],630,1); % Generate binary data
data = randi([0 1],630,1); % Generate binary data
encodedData = bchEncoder(data); % BCH encode data
encodedData = bchEncoder(data); % BCH encode data
modSignal = pskmod(encodedData,2); % BPSK modulate
modSignal = pskmod(encodedData,2); % BPSK modulate
receivedSignal = awgn(modSignal,5); % Pass through AWGN channel
receivedSignal = awgn(modSignal,5); % Pass through AWGN channel
demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate
demodSignal = pskdemod(receivedSignal,2); % BSPK demodulate
receivedBits = bchDecoder(demodSignal); % BCH decode data
receivedBits = bchDecoder(demodSignal); % BCH decode data
errorStats = errorRate(data,receivedBits); % Compute error statistics
errorStats = errorRate(data,receivedBits); % Compute error statistics
end

```
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
Error rate = 0.000318
Number of errors = 4
```

## Shorten a BCH Code

Shorten a $(31,26)$ BCH code to an $(11,6) \mathrm{BCH}$ code and use it to encode and decode random binary data.

Create a BCH encoder and decoder pair for a $(31,26)$ code. Specify the generator polynomial, $x^{5}+x^{2}+1$, and a shortened message length of 6 .

```
enc = comm.BCHEncoder(31,26,'x5+x2+1',6);
dec = comm.BCHDecoder(31,26,'x5+x2+1',6);
```

Encode and decode random binary data and verify that the decoded bit stream matches the original data.

```
x = randi([0 1],60,1);
y = step(enc,x);
z = step(dec,y);
isequal(x,z)
ans = logical
    1
```

## step

System object: comm.BCHEncoder
Package: comm
Encode data using a BCH encoder

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and $y=o b j(x)$ perform equivalent operations.

Y = step ( $\mathrm{H}, \mathrm{X}$ ) encodes input binary data, X , using a (CodewordLength,MessageLength) BCH encoder with the corresponding narrow-sense generator polynomial and returns the result in vector Y. The input and output length of the step function equal the values listed in the table in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-88.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.BitTolnteger

Package: comm
(To be removed) Convert vector of bits to vector of integers

Note will be removed in a future release. Use bi2de instead. For more information, see "Compatibility Considerations".

## Description

The BitToInteger object maps groups of bits in the input vector to integers in the output vector.
To map bits to integers:
1 Define and set up your bit to integer object. See "Construction" on page 3-101.
2 Call step to map groups of bits in the input vector to integers in the output vector according to the properties of comm. BitToInteger. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. BitToInteger creates a bit-to-integer converter System object, H, that maps a vector of bits to a corresponding vector of integer values.
$H=$ comm.BitToInteger(Name, Value) creates a bit-to-integer converter object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. BitToInteger(NUMBITS, Name, Value) creates a bit-to-integer converter System object, H This object has the BitsPerInteger on page 3-0 property set to NUMBITS and the other specified properties set to the specified values.

## Properties

## BitsPerInteger

Number of bits per integer
Specify the number of input bits that the object maps to each output integer. You can set this property to a scalar integer between 1 and 32 . The default is 3 .

## MSBFirst

Assume first bit of input bit words is most significant bit

Set this property to true to indicate that the first bit of the input bit words is the most significant bit (MSB). The default is true. You can set this property to false to indicate that the first bit of the input bit words is the least significant bit (LSB).

## SignedIntegerOutput

Output signed integers
Set this property to true to generate signed integer outputs. The default is false. You can set this property to false to generate unsigned integer outputs.

When you set this property to false, the output values are integers between 0 and $\left(2^{N}\right)-1$. In this case, $N$ is the value you specified in the BitsPerInteger on page 3-0 property.

When you set this property to true, the output values are integers between $-\left(2^{(N-1)}\right)$ and $\left(2^{(N-1)}\right)-1$.

## OutputDataType

Data type of output
Specify the output data type. The default is Full precision.
When you set the SignedIntegerOutput on page 3-0 property to false, set this property as one of Full precision|Smallest integer|Same as input|double|single|int8|uint8| int16|uint16| int32|uint32.

When you set this property to Same as input, and the input data type is numeric or fixed-point (fi object), the output data has the same type as the input data.

When the input signal is an integer data type, you must have a Fixed-Point Designer ${ }^{\mathrm{TM}}$ user license to use this property in Smallest unsigned integer or Full precision mode.

When you set the SignedIntegerOutput property to true, specify the output data type as one of Full precision|Smallest integer|double|single|int8|int16|int32.

When you set this property to Full precision, the object determines the output data type based on the input data type. If the input data type is double or single precision, the output data has the same type as the input data. Otherwise, the property determines the output data type in the same way as when you set this property to Smallest unsigned integer.

## Methods

step (To be removed) Convert vector of bits to vector of integers

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Convert random 4-bit words to integers

```
    hBitToInt = comm.BitToInteger(4);
\% Generate three 4-bit words
```

```
    bitData = randi([0 1],3*hBitToInt.BitsPerInteger,1);
    intData = step(hBitToInt,bitData)
intData = 3×1
```

    13
    9
    13
    
## Algorithms

This object implements the algorithm, inputs, and outputs described on the Bit To Integer Converter block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

## comm. BitToInteger will be removed in a future release. Use bi2de instead.

Not recommended starting in R2019b
Data types as supported by comm.BitToInteger are not inherently supported by functions. This code shows binary to decimal conversion for various data types using this function.

## Examples Using bi2de for Various Data Types

```
function compbi2de
% Number of integers
n = randi([1 100]);
% Default
h1 = comm.BitToInteger;
bpi = h1.BitsPerInteger;
x = randi([0,1],n*bpi,1);
y1 = h1(x);
y2 = bi2de(reshape(x,bpi,[])','left-msb');
isequal(y1,y2)
% Right MSB, logical input
h2 = comm.BitToInteger(
    'BitsPerInteger',5, ...
    'MSBFirst',false);
bpi = h2.BitsPerInteger;
x = logical(randi([0,1],n*bpi,1));
y1 = h2(x);
y2 = bi2de(reshape(x,bpi,[])','right-msb');
isequal(y1,y2)
% Right MSB, signed output, single input
h3 = comm.BitToInteger( ..
    BitsPerInteger',8,
    MSBFirst',false,
    SignedIntegerOutput',true)
bpi = h3.BitsPerInteger;
x = randi([0,1],n*bpi,1,'single');
y1 = h3(x);
y2 = bi2de(reshape(x,bpi,[])','right-msb');
N = 2^bpi;
y2 = y2 - (y2>=N/2)*N
isequal(y1,y2)
end
```

## step

## System object: comm.BitToInteger

Package: comm
(To be removed) Convert vector of bits to vector of integers

Note comm.BitToInteger will be removed in a future release. Use bi2de instead.

## Syntax

Y = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ converts binary input, $X$, to corresponding integers, $Y$. The input must be a scalar or a column vector and the data type can be numeric, numerictype $(0,1)$, or logical. The length of input $X$ must be an integer multiple of the value you specify in the BitsPerInteger property. The object outputs a column vector with a length equal to length $(\mathrm{X}) /$ BitsPerInteger. When you set the SignedIntegerOutput property to false, the object maps each group of bits to an integer between 0 and ( $2^{\text {BitsPerinteger })}-1$. A group of bits contains $N$ bits, where $N$ is the value of the BitsPerInteger property. If you set the SignedIntegerOutput property to true, the object maps each group of BitsPerInteger bits to an integer between $-\left(2^{(\text {BitsPerInteger-1) })}\right.$ ) and $\left(2^{\text {(BitsPerInteger-1) }}\right)-1$.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.BinarySymmetricChannel

Package: comm
(To be removed) Introduce binary errors

Note comm.BinarySymmetricChannel will be removed in a future release. Use bsc instead.

## Description

The BinarySymmetricChannel object introduces binary errors to the signal transmitted through this channel.

To introduce binary errors into the transmitted signal:
1 Define and set up your binary symmetric channel object. See "Construction" on page 3-106.
2 Call step to introduces binary errors into the signal transmitted through this channel according to the properties of comm. ACPR. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. BinarySymmetricChannel creates a binary symmetric channel System object, H, that introduces binary errors to the input signal with a prescribed probability.

H = comm.BinarySymmetricChannel (Name, Value) creates a binary symmetric channel object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## ErrorProbability

Probability of binary error
Specify the probability of a binary error as a scalar with a value between 0 and 1 . The default is 0.05 .

## ErrorVectorOutputPort

Enable error vector output
When you set this property to true, the step method outputs an error signal, ERR. This error signal, in vector form, indicates where errors were introduced in the input signal, X. A value of 1 at the $i$-th element of ERR indicates that an error was introduced at the $i$-th element of $X$. Set the property to false if you do not want the ERR vector at the output of the step method. The default is true.

## OutputDataType

Data type of output
Specify output data type as one of double | logical. The default is double.

## Methods

step (To be removed) Introduce binary errors

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Add Errors to Binary Input Signal

```
% Add binary errors with a probability of 0.2 to a binary input signal.
p = 0.2;
binSymChan = comm.BinarySymmetricChannel('ErrorProbability',p);
data = randi([0 1],1000,1);
[~,errl] = binSymChan(data);
% Confirm that the number errors is approximately
% equal to the probability value multiplied by the number of symbols.
[sum(errl) p*length(data)];
% Perform using the bsc function
[~,err2] = bsc(data,p);
[sum(err2) p*length(data)];
ans =
    192 200
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Binary Symmetric Channel block reference page. The object properties correspond to the block parameters, except:This object uses the MATLAB default random stream to generate random numbers. The block uses a random number generator based on the V5 RANDN (Ziggurat) algorithm. An initial seed, set with the Initial seed parameter initializes the random number generator. For every system run that contains the block, the block generates the same sequence of random numbers. To generate reproducible numbers using this object, you can reset the MATLAB default random stream using the following code.

```
reset(RandStream.getGlobalStream)
```

For more information, see help for RandStream.

## Compatibility Considerations

comm. BinarySymmetricChannel will be removed
Warns starting in R2019b
comm. BinarySymmetricChannel will be removed in a future release. Use bsc instead.

```
% This code provides examples using various syntaxes
% for the comm.BinarySymmetricChannel object versus the |bsc| function.
%% Simulate BSC with default comm.BinarySymmetricChannel object

Introduced in R2012a

## step

System object: comm.BinarySymmetricChannel
Package: comm
(To be removed) Introduce binary errors

Note comm. BinarySymmetricChannel will be removed in a future release. Use bsc instead.

## Syntax

$Y=\operatorname{step}(H, X)$
[Y,ERR] = step (H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ adds binary errors to the input signal X and returns the modified signal, Y . The input signal can be a vector or matrix with numeric, logical, or fixed-point (fi objects) data type elements. The step method output, $Y$, has the same dimensions as the input, $X$. If $X$ input contains a non-binary value, $V$, the object considers it to be 1 when $\mathbf{a b s}(V)>0$. This syntax applies when you set the ErrorVectorOutputPort property to false.
$[\mathrm{Y}, \mathrm{ERR}]=\operatorname{step}(\mathrm{H}, \mathrm{X})$ returns the error signal vector, ERR. A value of 1 at the $i$-th element of ERR indicates that an error was introduced at the $i$-th element of $X$. The outputs, $Y$ and ERR, have the same dimensions as the input, X . This syntax applies when you set the ErrorVectorOutputPort property to true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## bleATTPDUConfig

## Configuration object for BLE ATT PDU

Note Download Required: To use , first download Communications Toolbox ${ }^{T M}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Description

The bleATTPDUConfig creates a configuration object for a Bluetooth low energy (BLE) attribute protocol data unit (ATT PDU). You can configure a BLE ATT PDU using the applicable properties of bleATTPDUConfig.

## Creation

## Syntax

cfgATT = bleATTPDUConfig
cfgATT = bleATTPDUConfig(Name,Value)

## Description

cfgATT = bleATTPDUConfig creates a bleATTPDUConfig configuration object, cfgATT, for a BLE ATT PDU with default values.
cfgATT = bleATTPDUConfig(Name,Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, bleATTPDUConfig('Opcode', 'Error response') sets the Opcode property of cfgATT to 'Error response'.

## Properties

Note For more information about BLE ATT PDU properties and their respective values, see volume 3, part F, sections 3.3 and 3.4 of the Bluetooth Core Specification [2].

## Opcode - BLE ATT PDU operation code

'Read request' (default)|'MTU request'|'Information request'|...
BLE ATT PDU operation code, specified as one of the values in this list. Each valid value describes a BLE ATT PDU operation code.

- 'MTU request'
- 'Error response'
- 'Information request'
- 'Find by type value request'
- 'Read by type request'

- 'Handle value notification'
- 'Handle value indication'
- 'Handle value confirmation'
- 'Information response'
- 'Find by type value response'
- 'Read by type response'
- 'Read by group type response'

Data Types: char | string

## RequestedOpcode - Opcode of request BLE ATT PDU

'Read request' (default)| character vector \| string scalar
Opcode of request BLE ATT PDU, specified as one of the values in this list. Each valid value describes a request BLE ATT PDU (from a peer device) that caused an error.

- 'MTU request'
- 'Information request'
- 'Find by type value request'
- 'Read by type request'
- 'Read request'
- 'Read blob request'
- 'Read by group type request'
- 'Write request'
- 'Prepare to write request'
- 'Execute write request'

Data Types: char|string

## Format - Format of information data field

## '16 bit' (default)|'128 bit'

Format of information data field, specified as ' 16 bit' or ' 128 bit'. This value specifies the format of information data element in the PDU with opcode 'Information Response'.

Data Types: char|string

## AttributeHandle - Handle value of attribute

'0001' (default) | character vector of two-octet hexadecimal
Handle value of attribute, specified as the character vector of a two-octet hexadecimal value in the range [0x0001, 0xFFFF]. This value is a unique identifier. The server dynamically assigns this value.
Data Types: char|string
ErrorMessage - Error message corresponding to request BLE ATT PDU
'Invalid handle' (default)|'Invalid handle'|'Read not permitted'|...
Error message corresponding to request BLE ATT PDU, specified as one of the values in this list. Each value indicates the cause of an error corresponding to the request PDU from a peer device.

- 'Invalid handle'
- 'Read not permitted'
- 'Write not permitted'
- 'Invalid PDU'
- 'Insufficient authentication'
- 'Request not supported'
- 'Invalid offset'
- 'Insufficient authorization'
- 'Prepare queue full'
- 'Attribute not found'
- 'Attribute not long'
- 'Insufficient encryption key size'
- 'Invalid attribute value length'
- 'Unlikely error'
- 'Insufficient encryption'
- 'Unsupported group type'
- 'Insufficient resources'

Data Types: char|string
MaxTransmissionUnit - Maximum size of BLE ATT PDU
23 (default) | positive integer
Maximum size of BLE ATT PDU, specified as a positive integer in the range [ 23,65535 ]. This value sets the maximum size of the BLE ATT PDU in bytes that a client or server can receive.
Data Types: uint8

## StartHandle - Starting handle of handle range

'0001' (default) | character vector of two-octet hexadecimal value
Starting handle of handle range, specified as a two-octet hexadecimal value in the range [ $0 \mathrm{x} 0001,0 \mathrm{xFFFF}]$. This value indicates the handle value of a service or characteristic declaration or the starting handle of a handle range. This value must be less than the EndHandle.
Data Types: char | string

## EndHandle - Ending handle of handle range

'FFFF ' (default) | character vector of two-octet hexadecimal value
Ending handle of handle range, specified as a two-octet hexadecimal value in the range [0x0001,0xFFFF]. This value sets the end handle value of a service declaration or a characteristic declaration or the ending handle of a handle range. This value must be greater than the StartHandle.
Data Types: char | string

## AttributeType - Type of attribute

'2800' (Primary service) (default) | four-element or 32-element character vector | 2-octet or 16 -octet string scalar

Type of attribute, specified as a four-element or 32-element character vector or a string scalar denoting a two-octet or16-octet hexadecimal value.
Data Types: char | string

## AttributeValue - Value of attribute

' ' (default) | character vector | string scalar | numeric vector of elements in the range [0,255] | n-by-2 character array of maximum length 131068

Value of attribute, specified as one of these values:

- Character vector - This vector represent octets in hexadecimal format.
- String scalar - This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,255] - This vector represent octets in decimal format. The maximum length of the numeric vector is 65534 .
- n -by-2 character array - Each row represent an octet in hexadecimal format. The maximum length of the character array is 131068.

AttributeValue indicates the value of an attribute to be stored in or read from the attribute database. Specify this value in LSB first format.

```
Data Types: char|string | double
```

## Offset - Offset of next octet to be read

0 (default) | integer in the range [0, 65565]
Offset of next octet to be read, specified as an integer in the range [0, 65535]. You can use this value in the BLE ATT PDUs with opcodes 'Read blob request', 'Prepare write request', and 'Prepare write response' to identify an attribute value offset in the attribute database.
Data Types: double

## ExecuteWrite - Execute write flag

'Cancel all prepared writes' (default)|'Write all pending requests'
Execute write flag, specified as 'Cancel all prepared writes' or 'Write all pending requests '. You can determine the action (discard or write) to be performed when this property is used.

Data Types: char | string

## Object Functions

## Specific to This Object

bleATTPDU Generate BLE ATT PDU
bleATTPDUDecode Decode BLE ATT PDU

## Examples

## Create BLE ATT PDU Configuration Objects

Create two unique BLE ATT PDU configuration objects: one of type 'Read by type request' and the other of type 'Error response' using default settings and name-value pairs respectively.

Create a BLE ATT PDU configuration object with default settings.
cfgATT = bleATTPDUConfig;
Set the BLE ATT PDU opcode as 'Read by type request'. View the applicable properties of the opcode 'Read by type request'.
cfgATT.Opcode = 'Read by type request'
cfgATT =
bleATTPDUConfig with properties:
Opcode: 'Read by type request'
StartHandle: '0001'
EndHandle: 'FFFF'
AttributeType: '2800'

Create another BLE ATT PDU configuration object, this time using the name-value pairs. Change the BLE ATT PDU opcode to 'Error response'. View the applicable properties of the opcode 'Error response'.
cfgATT = bleATTPDUConfig('Opcode','Error response')
cfgATT $=$
bleATTPDUConfig with properties:
Opcode: 'Error response'
RequestedOpcode: 'Read request' AttributeHandle: '0001'

ErrorMessage: 'Invalid handle'

## End-to-End Workflow of BLE ATT PDU

Create a BLE ATT PDU configuration object. Change the value of opcode to 'Read by type request '. View the applicable properties of the specified value of opcode.

```
cfgTx = bleATTPDUConfig;
```

cfgTx.Opcode $=$ 'Read by type request'
$\operatorname{cfgTx}=$
bleATTPDUConfig with properties:
Opcode: 'Read by type request'
StartHandle: '0001'
EndHandle: 'FFFF'
AttributeType: '2800'

Generate a BLE ATT PDU from the corresponding configuration object.

```
attPDU = bleATTPDU(cfgTx);
```

Decode the generated BLE ATT PDU. The returned status indicates decoding is successful. View the applicable properties of the opcode 'Error response'.

```
[status, cfgRx] = bleATTPDUDecode(attPDU)
status =
Success
cfgRx =
    bleATTPDUConfig with properties:
            Opcode: 'Read by type request'
        StartHandle: '0001'
            EndHandle: 'FFFF'
        AttributeType: '2800'
```

Introduced in R2019b

## bleChanneISelection

BLE channel index for connection events

Note Download Required: To use, first download Communications Toolbox ${ }^{\text {TM }}$ Library for the Bluetooth ${ }^{\circledR}$ Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

## Description

The bleChannelSelection System object selects a Bluetooth low energy (BLE) channel index based on the selected algorithm. For more information, see Algorithm in property.

To select a BLE channel index:
1 Create the bleChannelSelection object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

csa = bleChannelSelection
csa = bleChannelSelection(Name,Value)

## Description

csa = bleChannelSelection creates a blechannelselection System object, csa, to select a BLE channel index for connection events or periodic advertising events.
csa = bleChannelSelection(Name,Value)sets properties using one or more name-value pairs. For example, bleChannelSelection('Algorithm', '2') configures the System object, csa, to select a BLE channel index based on 'Algorithm \#2'. Enclose each property name in quotes.

## Properties

Note For more information about BLE channel selection properties and their respective values, see volume 6, part B, section 4.5 .8 of the Bluetooth Core Specification [2].

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Algorithm - Type of BLE channel selection algorithm

1 (default) | 2
Type of BLE channel selection algorithm, specified as 1 or 2 representing 'Algorithm \#1' or 'Algorithm \#2' respectively. The property uses this algorithm to select the channel index.
Data Types: double

## HopIncrement - Hop increment count

5 (default) | integer in the range [5, 16]
Hop increment count, specified as an integer in the range [5,16]. This property indicates the hop increment count to be used for hopping between data channels. 'Algorithm \#1' uses this value as an input.

## Data Types: double

## AccessAddress - Unique connection address

'8E89BED6' (default) | eigh-element character vector \| string scalar denoting a four-octet
hexadecimal value
Unique connection address, specified as an eight-element character vector or a string scalar denoting a four-octet hexadecimal value. This value indicates a unique 32-bit address for the link layer connection between two devices. 'Algorithm \#2' uses this value as an input.

Data Types: char|string
UsedChannels - List of used (good) data channels
row vector containing all the channel indices [0,36] (default) | vector of integers in the range [0, 36]
List of used (good) data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This value indicates the set of good channels classified by the master.

Data Types: double

## Usage

## Syntax

channelIndex = csa()

## Description

channelIndex $=$ csa() selects a channel index based on the algorithm specified by the Algorithm property, the list of used data channels specified by the UsedChannels property, and other applicable properties dependent on the selected algorithm. The returned channel index, channelIndex, is of data type double.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

## Specific to bleChannelSelection

clone Create duplicate System object
isLocked Determine if System object is in use

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Select BLE Channel Indices Based on Type of Channel Selection Algorithm

Create a blechannelselection System object, 'csa', to select a BLE channel index based on the channel selection algorithm, 'Algorithm \#1'. View the corresponding applicable properties.

```
csa = bleChannelSelection
csa =
    bleChannelSelection with properties:
        Algorithm: 1
        HopIncrement: 5
        UsedChannels: [1x37 double]
        ChannelIndex: 0
        EventCounter: 0
Set the values of 'HopIncrement' to 7 and 'UsedChannels' to [ \(0,2,24,6,10,14,26,30,34,36]\). View the corresponding properties.
```

```
csa.HopIncrement = 7;
```

csa.HopIncrement = 7;
csa.UsedChannels = [0, 2, 24, 6, 10, 14, 26, 30, 34, 36]
csa.UsedChannels = [0, 2, 24, 6, 10, 14, 26, 30, 34, 36]
csa =
csa =
bleChannelSelection with properties:
bleChannelSelection with properties:
Algorithm: 1
HopIncrement: 7
UsedChannels: [0 2 6 10 14 24 26 30 34 36]
ChannelIndex: 0
EventCounter: 0

```

Select a BLE channel index from the corresponding system object using 'Algorithm \#1'.
```

channelIndex = csa()
channelIndex = 30

```

Create another blechannelselection System object, 'csa', this time to select a BLE channel index by specifying the type of channel selection algorithm as 'Algorithm \#2'. View the corresponding applicable properties.
```

csa2 = bleChannelSelection("Algorithm",2);

```

Change the values of 'AccessAddress' to '8E89BED6' and 'UsedChannels' to [ \(9,10,21,22,23,33,34,35,36]\). View the corresponding properties.
```

csa2.AccessAddress = '8E89BED6';
csa2.UsedChannels = [9, 10, 21, 22, 23, 33, 34, 35, 36]

```
csa2 =
    bleChannelSelection with properties:
            Algorithm: 2
        AccessAddress: '8E89BED6'
            UsedChannels: [9 10 212223333435 36]
            ChannelIndex: 0
            EventCounter: 0

Select a BLE channel index from the corresponding system object using 'Algorithm \#2'.
```

channelIndex2 = csa2()

```
channelIndex2 = 9

Configuration object for BLE LL control PDU payload configuration

Note Download Required: To use , first download Communications Toolbox \({ }^{\mathrm{TM}}\) Library for the Bluetooth \({ }^{\circledR}\) Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

\section*{Description}

The bleLLControlPDUConfig creates a configuration object for Bluetooth low energy (BLE) link layer (LL) control protocol data unit (PDU) payload configuration by using the default and specified values. You can configure a BLE LL control PDU payload configuration using the applicable properties of bleLLControlPDUConfig.

\section*{Creation}

\section*{Syntax}
cfgControl = bleLLControlPDUConfig
cfgControl = bleLLControlPDUConfig(Name,Value)

\section*{Description}
cfgControl = bleLLControlPDUConfig creates a configuration object, cfgControl, for a BLE LL control PDU payload configuration using default values.
cfgControl = bleLLControlPDUConfig(Name, Value)sets the properties using one or more name-value pairs. Enclose each property name in quotes. For example, bleLLControlPDUConfig('Opcode','Version indication') configures cfgControl with the operation code as 'Version indication'

\section*{Properties}

Note For more information about BLE LL control PDU properties and their respective values, see volume 6, part B, section 2.4 of the Bluetooth Core Specification [2].

\section*{Opcode - BLE LL control PDU payload configuration operation code}
'Connection update indication' (default)|'Channel map indication'|'Terminate indication'|'Unknown response'|'Version indication'|'Reject indication'

BLE LL control PDU payload configuration operation code, specified as one of the values in this list. Each valid value describes a BLE LL control PDU operation code.
- 'Connection update indication'
- 'Channel map indication'
- 'Terminate indication'
- 'Unknown response'
- 'Version indication'
- 'Reject indication'

Data Types: char \| string

\section*{WindowSize - Transmit window size}

1 (default) | nonnegative integer
Transmit window size, specified as a nonnegative integer in the range [1, Mws], where Mws is the lesser of 8 and (ConnectionInterval-1). This property indicates the window size within which the master transmits a data packet and the slave listens for a data packet after the connection is established. Each unit is taken as 1.25 ms so that the window size (WindowSize \(\times 1.25\) ) is in the range of 1.25 ms to the minimum of ( 10 ms , ((ConnectionInterval \(\times 1.25\) ) -1.25\() \mathrm{ms}\) ).
Data Types: double
ConnectionInterval - Connection interval
6 ( 7.5 ms ) (default) | integer in the range [6, 3200]
Connection interval, specified as an integer in the range [6, 3200]. This property indicates the interval between the start of two consecutive connection events. Each unit is taken as 1.25 ms so that the connection interval (ConnectionInterval \(\times 1.25\) ) is in the range of 7.5 ms to 4.0 s .

Data Types: double

\section*{SlaveLatency - Slave latency}

0 (default) | nonnegative integer
Slave latency, specified as a nonnegative integer in the range [0, Msl], where Msl is the lesser of 499 and ((ConnectionTimeout \(\times 10) /((\) ConnectionInterval \(\times 1.25) \times 2))-1\). This property indicates the number of connection events that a slave can ignore.
Data Types: double

\section*{ConnectionTimeout - Connection supervision timeout \\ 10 (default) | nonnegative integer}

Connection supervision timeout, specified as a nonnegative integer in the range [Mct, 3200], where Mct is the larger of 10 and ( \((1+\) SlaveLatency \() *(\) ConnectionInterval \(\times 1.25) \times 2) / 10\). If the slave does not receive a valid packet within this time, this property indicates the connection timeout. Each unit is taken as 10 ms so that the connection timeout (ConnectionInterval \(\times 10\) ) is in the range of 100 ms to 32.0 s .
Data Types: double

\section*{Instant - Connection event instant}

0 (default) | integer in the range [0, 65535]
Connection event instant, specified as an integer in the range [ 0,65535 ]. This property indicates the event count at which specific action must occur, for instance, using updated connection parameters.
Data Types: double

\section*{UsedChannels - List of used data channels}
row vector containing the channel indices between [0:36] (default)| integer vector with element values in the range [0, 36]

List of used data channels, specified as an integer vector with element values in the range [0, 36].
The vector length must be greater than 1 . At least two channels must be set as used (good) channels. This property indicates the set of good channels classified by the master.

Data Types: double

\section*{ErrorCode - Connection termination error code}
'Success' (default)|'Unknown connection identifier'|'Hardware failure'|...
Connection termination error code, specified as one of the values in this list. Each valid value describes the error description informing the remote device why the connection is about to be terminated.
- 'Success'
- 'Unknown connection identifier'
- 'Hardware failure'
- 'Memory capacity exceeded'
- 'Connection timeout'
- 'Connection limit exceeded'
- 'Connection already exists'
- 'Command disallowed'
- 'Connection accept timeout exceeded'
- 'Connection rejected due to limited resources'
- 'Invalid LL parameters'
- 'Connection rejected due to unacceptable BD_ADDR'
- 'Unspecified error'
- 'Unsupported LL parameter value'
- 'Role change not allowed'
- 'LL response timeout'
- 'LL procedure collision'
- 'Instant passed'
- 'Channel classification not supported'
- 'Extended inquiry response too large'
- 'Connection rejected due to no suitable channel found'
- 'Advertising timeout'
- 'Controller busy'
- 'Unacceptable connection parameters'
- 'Connection failed to be established'
- 'Unknown advertising identifier'
- 'Limit reached'
- 'Operation cancelled by host'

Data Types: char | string

\section*{UnknownOpcode - Unrecognized or unsupported operation code}
' 00 ' (default) | two-element character vector | string scalar denoting one-octet hexadecimal value
Unrecognized or unsupported operation code, specified as the comma-separated pair consisting of 'UnknownOpcode' and a two-element character vector or string scalar denoting a one-octet hexadecimal value. This property indicates the type of BLE LL control PDU that is not recognized or supported.

\section*{Data Types: char | string}

\section*{VersionNumber - Version number of Bluetooth specification}
'5.0' (default) | string scalar denoting a one-octet hexadecimal value
Version number of Bluetooth specification, specified as a string scalar denoting a one-octet hexadecimal value. You can specify the 'VersionNumber' as '4.0', '4.1', '4.2' or '4.3'. This property indicates the version number of the Bluetooth core specification.

Data Types: string
CompanyIdentifier - Manufacturer ID of Bluetooth controller
' FFFF' (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Manufacturer ID of Bluetooth controller, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. This property indicates the unique identifier assigned to your organization by Bluetooth Special Interest Group (SIG) [2].

\section*{Data Types: char | string}

\section*{SubVersionNumber - Subversion number of the Bluetooth controller}
' 0000 ' (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Subversion number of the Bluetooth controller, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property indicates the unique value for each implementation or revision of a Bluetooth controller implementation.
Data Types: char|string

\section*{Object Functions}

\section*{Specific to This Object}
bleLLDataChannelPDU
bleLLDataChannelPDUDecode
Generate BLE LL data channel PDU
bleLLDataChannelPDUConfig Configuration object for BLE LL data channel PDU

\section*{Examples}

\section*{Create BLE LL Control PDU Configuration Object Using Default Settings}

Create a BLE LL control PDU configuration object, ' cfgControl ' , using default settings. View the corresponding applicable properties.
```

cfgControl = bleLLControlPDUConfig
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Connection update indication'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 6
SlaveLatency: 0
ConnectionTimeout: 10
Instant: 0

```

Change the value of the connection interval to 64 . View the configured properties.
```

cfgControl.ConnectionInterval = 64
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Connection update indication'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 64
SlaveLatency: 0
ConnectionTimeout: 10
Instant: 0

```

\section*{Create BLE LL Control PDU Configuration Object Using Name-Value Pairs}

Create two unique BLE LL control PDU configuration objects using name-value pairs: first one of the type 'Terminate indication' and error code 'Connection timeout' and second one of the type 'Channel map indication' with used set of data channels.

Create a BLE LL control PDU configuration object, ' cfgControl' ', by specifying opcode as 'Terminate indication' and the error code as 'Connection timeout'. View the applicable properties corresponding to the specified opcode.
```

cfgControl = bleLLControlPDUConfig('Opcode','Terminate indication', ...
'ErrorCode','Connection Timeout')
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Terminate indication'
ErrorCode: 'Connection timeout'

```

Create another BLE LL control PDU payload configuration object, ' cfgControl' ' this time by setting the value of opcode as 'Channel map indication'. Specify the list of used data channels. View the configured properties corresponding to the specified opcode.
```

cfgControl = bleLLControlPDUConfig('Opcode','Channel map indication');
cfgControl.UsedChannels = [l0 3 12 12 16 18 24]
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Channel map indication'
Instant: 0
UsedChannels: [0 3 12 16 18 24]

```

Create a BLE LL data channel configuration object, 'cfgLLData', by specifying the values of 'LLID' as 'Control' and 'ControlConfig' as 'cfgControl'. View the properties of the configuration object 'cfgLLData'.
```

cfgLLData = bleLLDataChannelPDUConfig('LLID','Control');
cfgLLData.ControlConfig = cfgControl
cfgLLData =
bleLLDataChannelPDUConfig with properties:
LLID: 'Control'
NESN: 0
SequenceNumber: 0
MoreData: 0
ControlConfig: [1x1 bleLLControlPDUConfig]

```

\section*{End-to-End Workflow of BLE LL Control PDU}

Create a BLE LL data channel PDU configuration object for a control PDU by using default configuration. View the corresponding default properties.
```

cfgControl = bleLLControlPDUConfig
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Connection update indication'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 6
SlaveLatency: 0
ConnectionTimeout: 10
Instant: 0

```

Generate a BLE LL data channel PDU using 'cfgTx' by specifying the value of link layer identifier, 'LLID', as 'Control' and 'ControlConfig' as 'cfgControl'. Specify the cyclic redundancy check (CRC) value for the configuration object 'cfgTx'. View the properties of ' cfgTx '.
```

cfgTx = bleLLDataChannelPDUConfig('LLID', 'Control', ...
'ControlConfig',cfgControl);
cfgTx.CRCInitialization = 'E23456'
cfgTx =
bleLLDataChannelPDUConfig with properties:
LLID: 'Control'
NESN: 0
SequenceNumber: 0
MoreData: 0
ControlConfig: [1x1 bleLLControlPDUConfig]

```

Generate a BLE LL control PDU from ' cfgTx '.
pdu = bleLLDataChannelPDU(cfgTx);

Decode the generated BLE LL control PDU by initializing the CRC value. The returned status indicates decoding is successful. View the values of 'status', 'cfgRx' and 'llPayload'.
```

crcInit = 'E23456'; % Received during associaton
[status, cfgRx, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)
status =
Success
cfgRx =
bleLLDataChannelPDUConfig with properties:
LLID: 'Control'
NESN: 0
SequenceNumber: 0
MoreData: 0
ControlConfig: [1xl bleLLControlPDUConfig]
llPayload =
1x0 empty char array

```

\section*{bleL2CAPFrameConfig}

\author{
Configuration object for BLE L2CAP frame
}

Note Download Required: To use , first download Communications Toolbox \({ }^{\mathrm{TM}}\) Library for the Bluetooth \({ }^{\circledR}\) Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

\section*{Description}

The bleL2CAPFrameConfig creates a configuration object for Bluetooth low energy (BLE) logical link control and adaptation protocol (L2CAP) signaling frame or data frame using the default and specified values. You can configure a BLE L2CAP signaling frame or data frame using the applicable properties of bleL2CAPFrameConfig.

\section*{Creation}

\section*{Syntax}
cfgL2CAP = bleL2CAPFrameConfig
cfgL2CAP = bleL2CAPFrameConfig(Name, Value)

\section*{Description}
cfgL2CAP = bleL2CAPFrameConfig creates a configuration object, cfgL2CAP, for a BLE L2CAP signaling command frame or data frame with default values.
cfgL2CAP \(=\) bleL2CAPFrameConfig(Name, Value) specifies properties using one or more namevalue pairs. Enclose each property name in quotes. For example, bleL2CAPFrameConfig('CommandType','Command reject') configures cfgL2CAP with the type of signaling command frame as 'Command reject'.

\section*{Properties}

Note For more information about BLE L2CAP frame properties and their respective values, see volume 3, part A, section 3 of the Bluetooth Core Specification [2].

\section*{ChannelIdentifier - Identifier for logical channel endpoint}
'0005' (default) | four-element character vector | string scalar denoting a two-octet hexadecimal value

Identifier for a logical channel endpoint, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. The 'ChannelIdentifier' denotes the local name representing a logical channel endpoint. This property is used to identify the command and data frames. Command frames use ' \(0005^{\prime}\) as the 'ChannelIdentifier'. L2CAP B-frames use fixed
'ChannelIdentifier', '0004' for attribute protocol (ATT) and '0006' for security manager protocol (SMP).
Data Types: char|string

\section*{CommandType - Signaling command type}
'Credit Based Connection request' (default)|'Command reject'|'Disconnection request'|...

Signaling command type, specified as a character vector or a string scalar. You can specify CommandType as one of these values:
- 'Command reject'
- 'Disconnection request'
- 'Disconnection response'
- 'Connection Parameter Update request'
- 'Connection Parameter Update response'
- 'Credit Based Connection request'
- 'Credit Based Connection response'
- 'Flow Control Credit'

This property is applicable only when the value of ChannelIdentifier is set to '0005' (signaling channel identifier).
Data Types: char | string

\section*{SignalIdentifier - Identifier for request-response frame exchange}
'01' (default) | two-element character vector | string scalar denoting one-octet hexadecimal value
Identifier for a request-response frame exchange, specified as a two-element character vector or string scalar denoting a one-octet hexadecimal value. The requesting device sets the value of this property and the responding device uses the same value in its response. The value of this property cannot be set to ' 00 '.

Data Types: char|string
CommandRejectReason - Reason for rejecting received signaling command frame 'Command not understood' (default)|'Signaling MTU exceeded'|'Invalid CID in request'

Reason for rejecting the received signaling command frame, specified as a character vector or a string scalar. You can specify CommandRejectReason as one of these values:
- 'Command not understood'
- 'Signaling MTU exceeded'
- 'Invalid CID in request'

This property specifies the reason for rejecting a signaling command frame.

\section*{Data Types: char | string}

\section*{SourceChannelIdentifier - Source logical channel endpoint}
'0040' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value

Source logical channel endpoint, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property specifies the source channel endpoint from which the request is sent or a response is received. When the channel is created using credit-based connection procedure, data packets flowing to the sender of the request are sent to the SourceChannelIdentifier.
Data Types: char|string

\section*{DestinationChannelIdentifier - Destination logical channel endpoint}
'0040' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value
Destination logical channel endpoint, specified as a four-element character vector or string scalar denoting a two-octet hexadecimal value. This property specifies the destination channel endpoint from which the request is sent or a response is received. When the channel is created using creditbased connection procedure, data packets flowing to the destination of the request are sent to the DestinationChannelIdentifier.

Data Types: char | string

\section*{ConnectionIntervalRange - Connection interval range}
[6, 3200] (default) | two-element numeric vector specified as [MIN, MAX]
Connection interval range, specified as a two-element numeric vector in the form of [MIN, MAX]. MIN and MAX specify the minimum and the maximum value of the ConnectionIntervalRange respectively. You can specify the value of MIN and MAX in the range [6, 3200]. MIN must be less than or equal to MAX. Each unit for MIN or MAX is taken as 1.25 ms so the resultant value is in the range [7.5 ms, 4.0 s\(]\).

Data Types: double

\section*{ConnectionTimeout - Connection supervision timeout}

10 ( 100 ms ) (default) | integer in the range [Mct, 3200]
Connection supervision timeout, specified as an integer in the range [Mct, 3200], where Mct is the larger of 10 and \(((1+\) SlaveLatency \() \times(\) ConnectionInterval \(\times 1.25) \times 2) / 10\). This property indicates the timeout for a connection if no valid packet is received within this time. Each unit is taken as 10 ms so that the resultant connection timeout, (ConnectionInterval \(\times 10\) ), is in the range [ 100 ms , 32.0s].

Data Types: double

\section*{SlaveLatency - Number of link layer connection events a slave can ignore \\ 0 (default) | integer in the range [0, Msl]}

Number of link layer connection events a slave can ignore, specified as an integer in the range [0, Msl], where Msl is the lesser of 499 and ((ConnectionTimeout \(\times 10\) )/((ConnectionInterval×1.25) \(\times 2)\) )-1. This property indicates the number of connection events that a slave can ignore.
Data Types: double

\section*{ParameterUpdateResult - Result of connection parameters update 'Accepted' (default)|'Rejected'}

Result of the connection parameters update, specified as 'Accepted' or 'Rejected '. This property indicates the response to the 'Connection Parameter Update Request' value of the property CommandType and specifies the result after updating the connection parameters.

Data Types: char | string
LEPSM - LE protocol or service multiplexer
'001F' (default) | four-element character vector | string scalar denoting two-octet hexadecimal value
LE protocol or service multiplexer, specified as a four-element character vector or a string scalar denoting a two-octet hexadecimal value. The value of this property is a unique number specified by the Special Interest Group (SIG) for each protocol. The SIG assigns the value of this property within the range [0x0001, 0x007F] for a set of existing protocols. The SIG dynamically assigns the value of this property in the range [0x0080, 0x00FF] to the implemented protocols.
Data Types: char | string
MaxTransmissionUnit - Maximum service data unit (SDU) size
23 (default) | integer in the range of [23, 65,535]
Maximum service data unit (SDU) size, specified as an integer in the range of [23, 65,535] octets. This property specifies the maximum acceptable SDU size for the upper-layer entity.
Data Types: double
MaxPDUPayloadSize - Maximum protocol data unit (PDU) payload size
23 (default) | integer in the range of [23, 65,535]
Maximum protocol data unit (PDU) payload size, specified as an integer in the range of [23, 65,535] octets. This property specifies the maximum acceptable payload data for the L2CAP layer entity.
Data Types: double

\section*{Credits - Number of LE-frames peer device can send or receive \\ 1 (default) | integer in the range of [0,65,535]}

Number of LE-frames peer device can send or receive, specified as an integer in the range of [0, \(65,535]\) octets. This property indicates the number of LE-frames that the peer device can send or receive. If the value of CommandType property is set to 'Flow control credit', then this property cannot be set to 0 .
Data Types: double

\section*{ConnectionResult - Result of credit-based connection procedure}
'Successful' (default)|'LEPSM not supported'|'No resources available'|...
Result of the credit-based connection procedure, specified as a character vector or a string scalar. You can specify ConnectionResult as one of these values:
- 'Successful'
- 'LEPSM not supported'
- 'No resources available'
- 'Insufficient authentication'
- 'Insufficient authorization'
- 'Insufficient encryption key size'
- 'Insufficient encryption'
- 'Invalid Source CID'
- 'Source CID already allocated'
- 'Unacceptable parameters'

This property indicates the outcome of the connection request.
Data Types: char|string

\section*{Object Functions}

\section*{Specific to This Object}
bleL2CAPFrame
bleL2CAPFrameDecode

Generate BLE L2CAP frame
Decode BLE L2CAP frame

\section*{Examples}

\section*{Create BLE L2CAP Frame Configuration Object Using Default Settings}

Create a BLE L2CAP frame configuration object, ' cfgL2CAP' , using default properties. View the corresponding applicable properties. This configuration object generates a BLE L2CAP signaling frame of type 'Credit based connection request'.
```

cfgL2CAP = bleL2CAPFrameConfig

```
cfgL2CAP =
    bleL2CAPFrameConfig with properties:
        ChannelIdentifier: '0005'
            CommandType: 'Credit based connection request'
            SignalIdentifier: '01'
        SourceChannelIdentifier: '0040'
                            LEPSM: '001F'
            MaxTransmissionUnit: 23
            MaxPDUPayloadSize: 23
                            Credits: 1

Set the value of credits to 10 . View the corresponding properties of ' \(\mathrm{cfgL2CAP}\) '.
```

cfgL2CAP.Credits = 10
cfgL2CAP =
bleL2CAPFrameConfig with properties:
ChannelIdentifier: '0005'
CommandType: 'Credit based connection request'
SignalIdentifier: '01'
SourceChannelIdentifier: '0040'
LEPSM: '001F'
MaxTransmissionUnit: 23
MaxPDUPayloadSize: 23
Credits: 10

```

\section*{Create BLE L2CAP Configuration Object Using Name-Value pairs}

Create a BLE L2CAP frame configuration object, ' cfgL2CAP' , by setting the value of channel identifier as ' 0004 ' using name-value pairs. View the corresponding applicable properties. This configuration object generates a BLE L2CAP data frame (B-frame).
```

cfgL2CAP = bleL2CAPFrameConfig('ChannelIdentifier','0004')
cfgL2CAP =
bleL2CAPFrameConfig with properties:
ChannelIdentifier: '0004'

```

\section*{End-to-End Workflow of BLE L2CAP Frames}

Create a BLE L2CAP configuration object, 'bleL2CAPFrameConfig', to generate a BLE L2CAP data frame (B-frame). Set the value of channel identifier as '0004' and view the corresponding applicable properties.
```

cfgTx = bleL2CAPFrameConfig('ChannelIdentifier','0004')
cfgTx =
bleL2CAPFrameConfig with properties:
ChannelIdentifier: '0004'

```

Generate a BLE L2CAP data frame (B-frame) with service data unit (SDU) from ATT specified as '0A0100'.
l2capFrame = bleL2CAPFrame(cfgTx,"0A0100")
l2capFrame \(=7 \times 2\) char array
'03'
'00'
'04'
'00'
'0A'
'01'
'00'

Decode the generated BLE L2CAP data frame (B-frame). The returned status indicates decoding was successful. View the output of 'status', 'cfgRx' and 'SDU'.
```

[status, cfgRx, SDU] = bleL2CAPFrameDecode(l2capFrame)

```
status =

Success
cfgRx =
bleL2CAPFrameConfig with properties:
ChannelIdentifier: '0004'
```

SDU = 3x2 char array
'0A'
'01'
'00'

```

\section*{bleLLDataChannelPDUConfig}

\section*{Configuration object for BLE LL data channel PDU}

Note Download Required: To use , first download Communications Toolbox \({ }^{\mathrm{TM}}\) Library for the Bluetooth \({ }^{\circledR}\) Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

\section*{Description}

The bleLLDataChannelPDUConfig creates a configuration object for a Bluetooth low energy (BLE) link layer (LL) data channel protocol data unit (PDU) using the default and specified values. You can configure a BLE LL data PDU and a BLE LL control PDU using the applicable properties of bleLLDataChannelPDUConfig.

\section*{Creation}

\section*{Syntax}
cfgLLData = bleLLDataChannelPDUConfig
cfgLLData = bleLLDataChannelPDUConfig(Name,Value)

\section*{Description}
cfgLLData \(=\) bleLLDataChannelPDUConfig creates a configuration object, cfgLLData, for a BLE LL data channel PDU with default values.
cfgLLData = bleLLDataChannelPDUConfig(Name,Value) sets properties by using one or more name-value pairs. Enclose each property name in quotes. For example, bleLLDataChannelPDUConfig('LLID','Data (start fragment/complete)') configures cfgLLData with the type of BLE LL data channel PDU as a data PDU.

\section*{Properties}

Note For more information about BLE LL data channel PDU properties and their respective values, see volume 6, part B, section 2.4 of the Bluetooth Core Specification [2].

\section*{LLID - Link layer identifier}
'Data (continuation fragment/empty)' (default)|'Data (continuation fragment/ empty)'|'Control'

Link layer identifier, specified as a character vector or a string scalar to describe the type of a BLE LL data channel PDU. You can specify 'LLID' as one of these values:
- 'Data (continuation fragment/empty)'
- 'Data (start fragment/complete)'
- 'Control'

Data Types: char | string
NESN - Next expected sequence number
0 (default) | 1
Next expected sequence number, specified as 0 or 1 . This value indicates either an acknowledgment for the last received packet or a request for resending the last transmitted packet from the peer.
Data Types: scalar|logical|double

\section*{SequenceNumber - Transmitting packet sequence number 0 (default) | scalar | 1}

Transmitting packet sequence number, specified as 0 or 1 . This property indicates the sequence number of the packet being transmitted.

Data Types: scalar|logical | double
MoreData - Indication for more data
false or 0 (default) | true or 1
Indication for more data, specified as a numeric or a logical value of 1 (true) or 0 (false). A true or 1 value indicates that the sender has more data to send.
Data Types: logical

\section*{CRCInitialization - Cyclic redundancy check initialization value}
'012345' (default) | six-element character vector | string scalar denoting three-octet hexadecimal value

Cyclic redundancy check initialization value, specified as a six-element character vector or a string scalar denoting a three-octet hexadecimal value.
Data Types: char | string

\section*{ControlConfig - BLE LL control PDU payload configuration object}
bleLLControlPDUConfig object
BLE LL control PDU payload configuration object, specified as a bleLLControlPDUConfig object. The different fields of this value are configured using the settings of bleLLControlPDUConfig. The default value of this property is an object of type bleLLControlPDUConfig with all properties set to their default values. This property is applicable for generating and decoding a BLE LL control PDU.

\section*{Object Functions}

\section*{Specific to This Object}
bleLLDataChannelPDU
Generate BLE LL data channel PDU
bleLLDataChannelPDUDecode
bleLLControlPDUConfig

Decode BLE LL data channel PDU
Configuration object for BLE LL control PDU payload configuration

\section*{Examples}

\section*{Create BLE LL Data Channel PDU Configuration Object for Data PDU}

Create a BLE LL data channel PDU configuration object for a data PDU and view the corresponding default properties.
```

cfgLLData = bleLLDataChannelPDUConfig
cfgLLData =
bleLLDataChannelPDUConfig with properties:
LLID: 'Data (continuation fragment/empty)'
NESN: 0
SequenceNumber: 0
MoreData: 0

```

Specify the value of LLID as 'Data (start fragment/complete)' and view the corresponding properties.
```

cfgLLData.LLID = 'Data (start fragment/complete)'
cfgLLData =
bleLLDataChannelPDUConfig with properties:
LLID: 'Data (start fragment/complete)'
NESN: 0
SequenceNumber: 0
MoreData: 0

```

\section*{Create BLE LL Data Channel PDU Configuration Object for Control PDU}

Create two unique BLE LL data channel PDU configuration objects for a control PDU of type 'Channel map indication' and 'Version indication' using name-value pairs.

Create a BLE LL control PDU payload configuration object, 'cfgControl' ', for a control PDU with opcode 'Channel map indication'. View the applicable properties corresponding to the specified opcode.
```

cfgControl = bleLLControlPDUConfig('Opcode','Channel map indication')
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Channel map indication'
Instant: 0
UsedChannels: [1\times37 double]

```

Create a BLE LL data channel configuration object by specifying the values of 'LLID' as 'Control' and 'ControlConfig' as 'cfgControl'. View the properties of 'cfgLLData'.
```

cfgLLData = bleLLDataChannelPDUConfig('LLID','Control', ...
'ControlConfig',cfgControl)
cfgLLData =
bleLLDataChannelPDUConfig with properties:
LLID: 'Control'
NESN: 0
SequenceNumber: 0
MoreData: 0
ControlConfig: [1x1 bleLLControlPDUConfig]

```

Create another BLE LL data channel configuration object, 'cfgControl' for a control PDU, this time specifying the opcode as 'Version indication'. View the applicable properties of 'cfgControl' corresponding to the specified opcode.
```

cfgControl.Opcode = 'Version indication';
cfgControl.SubVersionNumber = '008E'
cfgControl =
bleLLControlPDUConfig with properties:
Opcode: 'Version indication'
VersionNumber: '5.0'
CompanyIdentifier: 'FFFF'
SubVersionNumber: '008E'

```

Create a BLE LL data channel configuration object, 'cfgLLData' , by specifying the values of 'ControlConfig' as 'cfgControl' and view the applicable properties.
cfgLLData.ControlConfig \(=\) cfgControl
cfgLLData =
bleLLDataChannelPDUConfig with properties:
LLID: 'Control'
NESN: 0
SequenceNumber: 0
MoreData: 0
ControlConfig: [1x1 bleLLControlPDUConfig]

\section*{End-to-End Workflow of BLE LL Data Channel PDU}

Create a BLE LL data channel PDU configuration object, 'cfgTx' , for a data PDU using default configuration. View the corresponding default properties.
```

cfgTx = bleLLDataChannelPDUConfig
cfgTx =
bleLLDataChannelPDUConfig with properties:
LLID: 'Data (continuation fragment/empty)'
NESN: 0

```

\section*{SequenceNumber: 0 \\ MoreData: 0}

Initialize the CRC value corresponding to the configuration object 'cfgTx'.
```

cfgTx.CRCInitialization = '123456';

```

Generate a BLE LL data channel PDU by using the data PDU configuration object, ' cfgTx' and the upper-layer payload '030004000A0100'.
pdu = bleLLDataChannelPDU(cfgTx,'030004000A0100');
Decode the generated BLE LL data channel PDU by initializing the CRC value. The returned status indicates decoding is successful. View the values of 'status', 'cfgRx' and 'llPayload'.
```

crcInit = '123456';
[status, cfgRx, llPayload] = bleLLDataChannelPDUDecode(pdu, crcInit)
status =
Success
cfgRx =
bleLLDataChannelPDUConfig with properties:
LLID: 'Data (continuation fragment/empty)'
NESN: 0
SequenceNumber: 0
MoreData: 0
llPayload = 7x2 char array
'03'
'00'
'04'
'00'
'0A'
'01'
'00'

```

\section*{bleLLAdvertisingChanneIPDUConfig}

Configuration object for BLE LL advertising channel PDU

Note Download Required: To use , first download Communications Toolbox \({ }^{\text {TM }}\) Library for the Bluetooth \({ }^{\circledR}\) Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

\section*{Description}

The bleLLAdvertisingChannelPDUConfig creates a configuration object for Bluetooth low energy (BLE) link layer (LL) advertising channel protocol data unit (PDU) using the default and specified values. You can configure a BLE LL advertising channel PDU using the applicable properties of bleLLAdvertisingChannelPDUConfig.

\section*{Creation}

\section*{Syntax}
cfgLLAdv = bleLLAdvertisingChannelPDUConfig
cfgLLAdv = bleLLAdvertisingChannelPDUConfig(Name,Value)

\section*{Description}
cfgLLAdv = bleLLAdvertisingChannelPDUConfig creates a configuration object, cfgLLAdv, for a BLE LL advertising channel PDU with default values.
cfgLLAdv = bleLLAdvertisingChannelPDUConfig (Name, Value) creates a BLE LL advertising channel PDU configuration object by specifying properties using one or more name-value pairs. Enclose each property name in quotation marks. For example, bleLLAdvertisingChannelPDUConfig('PDUType','Scan response') configures cfgLLAdv with the type of BLE LL advertising channel PDU as 'Scan response'.

\section*{Properties}

Note For more information about BLE LL advertising channel PDU properties and their respective values, see volume 6, part B, section 2.3 of the Bluetooth Core Specification [2].

\section*{PDUType - BLE LL advertising channel PDU type}
'Advertising indication' (default)|'Advertising direct indication'|'Advertising non connectable indication'|...

BLE LL advertising channel PDU type, specified as a character vector or a string scalar to describe the type of a BLE LL advertising channel PDU. You can specify 'PDUType ' as one of these values:
- 'Advertising indication'
- 'Advertising direct indication'
- 'Advertising non connectable indication'
- 'Scan request'
- 'Scan response'
- 'Connection indication'
- 'Advertising scannable indication'

Data Types: char|string

\section*{ChannelSelection - Channel selection algorithm}
'Algorithm1' (default)|'Algorithm2'
Channel selection algorithm, specified as 'Algorithm1' or 'Algorithm2' to indicate the type of algorithm used for hopping between channels.

Data Types: char|string
AdvertiserAddressType - Advertiser device address type
'Random' (default) | 'Public'
Advertiser device address type, specified as 'Random ' or 'Public' to indicate the type of advertiser address in the packet.

Data Types: char|string

\section*{AdvertiserAddress - Advertiser device address}
'0123456789AB' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Advertiser device address, specified as a 12-element character vector or a string scalar denoting a six-octet hexadecimal value to indicate the advertiser device address.
Data Types: char | string
TargetAddressType - Target device address type
'Random' (default)|'Public'
Target device address type, specified as 'Random ' or 'Public' to indicate the type of target device address when a directed advertisement packet is transmitted.
Data Types: char \| string
TargetAddress - Target device address
' \(0123456789 C D\) ' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Target device address, specified as a 12-element character vector or a string scalar denoting a sixoctet hexadecimal value to indicate the target device address when a directed advertisement packet is transmitted.

Data Types: char|string

\section*{ScannerAddressType - Scanner device address type \\ 'Random' (default)|'Public'}

Scanner device address type, specified as 'Random ' or 'Public' to indicate the type of scanner device address when a scan request packet is transmitted.

Data Types: char|string

\section*{ScannerAddress - Scanner device address}
'0123456789CD ' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Scanner device address, specified as a 12 -element character vector or a string scalar denoting a sixoctet hexadecimal value to indicate the scanner device address when a scan request packet is transmitted.

Data Types: char | string

\section*{InitiatorAddressType - Initiator device address type \\ 'Random' (default)|'Public'}

Initiator device address type, specified as 'Random ' or 'Public' to indicate the type of initiator device address when a connection indication packet is transmitted.

Data Types: char | string

\section*{InitiatorAddress - Initiator device address}
' 0123456789 CD ' (default) | 12-element character vector | string scalar denoting a six-octet hexadecimal value

Initiator device address, specified as a 12 -element character vector or a string scalar denoting a sixoctet hexadecimal value to indicate the initiator device address when a connection indication packet is transmitted.

\section*{Data Types: char | string}

\section*{AdvertisingData - Advertising data}
'020106 ' (default) | character vector | string scalar | numeric vector of elements in the range \([0,31]\)
| n -by-2 character array
Advertising data, specified as one of these values:
- Character vector - This vector represent octets in hexadecimal format.
- String scalar - This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range \([0,31]\) - This vector represent octets in decimal format.
- \(n\)-by- 2 character array - Each row represent an octet in hexadecimal format.

This property indicates the advertising data that the device sends out in an advertisement packet.

\section*{Data Types: char | string | double}

\section*{ScanResponseData - Scan response data}
'020106' (default) | character vector | string scalar | numeric vector of elements in the range \([0,31]\)
| n -by-2 character array
Scan response data, specified as one of these values:
- Character vector - This vector represent octets in hexadecimal format.
- String scalar - This scalar represent octets in hexadecimal format.
- Numeric vector of elements in the range [0,31] - This vector represent octets in decimal format.
- n -by-2 character array - Each row represent an octet in hexadecimal format.

This property indicates the scan response data that the device sends out in a scan response packet (when scan request is received).
Data Types: char | string | double

\section*{AccessAddress - Unique connection address}
'01234567' (default) | eight-element character vector or a string scalar
Unique connection address, specified as an eight-element character vector or a string scalar. This property indicates a unique 32 -bit address generated by the LL for the new connection or for a periodic advertisement between two devices.

Data Types: char|string

\section*{CRCInitialization - CRC initialization value}
'012345 ' (default) | six-element character vector | three-octet hexadecimal value
CRC initialization value, specified as a six-element character vector or a string scalar denoting a three-octet hexadecimal value. This property is used as initialization value for the CRC calculation.

Data Types: char \| string

\section*{WindowSize - Transmit window size}

1 (default) | nonnegative integer
Transmit window size, specified as a nonnegative integer in the range [1, Mws], where Mws is the lesser of 8 and ConnectionInterval-1. This property indicates the window size within which the master transmits the data packet and slave listens for the data packet after connection establishment. Each unit is taken as 1.25 ms so that the window size (WindowSize \(\times 1.25\) ) is in the range of 1.25 ms to the minimum of ( 10 ms , ((ConnectionInterval×1.25)-1.25) ms).

Data Types: double

\section*{WindowOffset - Transmit window offset}

0 (default) | nonnegative integer
Transmit window offset, specified as a nonnegative integer in the range [ \(0, \mathrm{Mwo}\) ], where Mwo is the lesser of 3200 and ConnectionInterval. This property indicates the window offset after which the transmit window starts. Each unit is taken as 1.25 ms so that the resultant window offset (WindowOffset \(\times 1.25\) ) is in the range of 0 ms to (ConnectionInterval \(\times 1.25\) ) ms.
Data Types: double

\section*{ConnectionInterval - Connection interval}

6 ( 7.5 ms ) (default) | positive integer
Connection interval, specified as a positive integer in the range [6, 3200]. This property indicates the interval between the start of two consecutive connection events. Each unit is taken as 1.25 ms so that the resultant connection interval (ConnectionInterval \(\times 1.25\) ) is in the range of 7.5 ms to 4.0 s .
Data Types: double

\section*{SlaveLatency - Slave latency}

0 (default) | nonnegative integer
Slave latency, specified as a nonnegative integer in the range [ \(0, \mathrm{Msl}\) ], where Msl is the lesser of 499 and ((ConnectionInterval×10)/((ConnectionInterval×1.25) \(\times 2))-1\). This property indicates the number of connection events that a slave can skip listening for packets from the master.

Data Types: double

\section*{ConnectionTimeout - Connection supervision timeout}

10 (default) | positive integer
Connection supervision timeout, specified as a positive integer in the range [Mct, 3200], where Mct is the larger of 10 and \(((1+\) SlaveLatency \() \times(\) ConnectionInterval \(\times 1.25) \times 2) / 10\). This property indicates the timeout for a connection if no valid packet is received within this time. Each unit is taken as 10 ms so that the resultant connection timeout (ConnectionInterval \(\times 10\) ) is in the range of 100 ms to 32.0 s .
Data Types: double

\section*{UsedChannels - List of used data channels}
row vector containing the channel indices between [0:36] (default)| integer vector with element values in the range [0, 36]

List of used data channels, specified as an integer vector with element values in the range [0, 36]. The vector length must be greater than 1. At least two channels must be set as used (good) channels. This property indicates the set of good channels classified by the master.

\section*{Data Types: double}

\section*{HopIncrement - Hop increment count}

5 (default) | positive integer
Hop increment count, specified as an integer in the range [5, 16]. This property indicates the hop increment count to be used for hopping between data channels.
Data Types: double

\section*{SleepClockAccuracy - Master sleep clock accuracy \\ '251 to 500 ppm' (default)|'151 to 250 ppm'|'101 to 150 ppm'|...}

Master sleep clock accuracy, specified as a character vector or a string scalar indicating the worst case master sleep clock accuracy. You can specify SleepClockAccuracy as one of these values:
- '251 to 500 ppm'
- '151 to 250 ppm'
- '101 to 150 ppm'
- '76 to 100 ppm'
- '51 to 75 ppm'
- '31 to 50 ppm'
- '21 to 30 ppm '
- '0 to 20 ppm'

Data Types: char | string

\section*{Object Functions}

\section*{Specific to This Object}
bleLLAdvertisingChannelPDU
bleLLAdvertisingChannelPDUDecode

Generate BLE LL advertising channel PDU
Decode BLE LL advertising channel PDU

\section*{Examples}

\section*{Create BLE LL Advertising Channel PDU Configuration Object Using Default Settings}

Create a BLE LL advertising channel configuration object and view the corresponding default properties.
```

cfgLLAdv = bleLLAdvertisingChannelPDUConfig
cfgLLAdv =
bleLLAdvertisingChannelPDUConfig with properties:
PDUType: 'Advertising indication'
ChannelSelection: 'Algorithm1'
AdvertiserAddressType: 'Random'
AdvertiserAddress: '0123456789AB'
AdvertisingData: [3x2 char]

```

\section*{Create BLE LL Advertising Channel PDU Configuration Object Using Name-Value Pairs}

Create two unique BLE LL advertising channel configuration objects of type 'Scan response' and 'Connection indication' using name-value pairs.

Create a BLE LL advertising channel PDU configuration object, ' cfgLLAdv' , by setting the values of PDU type as 'Scan response', advertiser address as '1234567890AB', and scan response data as '020106020AD3' using name-value pairs. View the corresponding properties.
```

cfgLLAdv = bleLLAdvertisingChannelPDUConfig(...
'PDUType','Scan response', ...
'AdvertiserAddress','1234567890AB', ...
'ScanResponseData','020106020AD3')
cfgLLAdv =
bleLLAdvertisingChannelPDUConfig with properties:
PDUType: 'Scan response'
ChannelSelection: 'Algorithm1'
AdvertiserAddressType: 'Random'
AdvertiserAddress: '1234567890AB'
ScanResponseData: [6x2 char]

```

Create another BLE LL advertising channel PDU configuration object, ' cfgLLAdv ', and change the type of PDU to 'Connection indication'. Set the values of the connection interval as 64 and the set of data channels as \(\left[\begin{array}{lllllll}0 & 4 & 12 & 16 & 18 & 24 & 25\end{array}\right]\). View the corresponding properties.
```

cfgLLAdv = bleLLAdvertisingChannelPDUConfig('PDUType', ...
'Connection indication');
cfgLLAdv.ConnectionInterval = 64;
cfgLLAdv.UsedChannels = [0 4 4 12 16 18 24 25]
cfgLLAdv =
bleLLAdvertisingChannelPDUConfig with properties:
PDUType: 'Connection indication'
ChannelSelection: 'Algorithm1'
AdvertiserAddressType: 'Random'
AdvertiserAddress: '0123456789AB'
InitiatorAddressType: 'Random'
InitiatorAddress: '0123456789CD'
AccessAddress: '01234567'
CRCInitialization: '012345'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 64
SlaveLatency: 0
ConnectionTimeout: 10
UsedChannels: [0 4 12 16 18 24 25]
HopIncrement: 5
SleepClockAccuracy: '251 to 500 ppm'

```

\section*{End-to-End Workflow of BLE LL Advertising Channel PDU}

Create a BLE LL advertising channel PDU configuration object, ' cfgTx '. Set the values of PDU type as 'Connection indication', the connection interval as 8 , and the set of data channels as [04 \(1216182425]\).
```

cfgTx = bleLLAdvertisingChannelPDUConfig('PDUType', ...

```
    'Connection indication');
cfgTx.ConnectionInterval = 8;

cfgTx \(=\)
    bleLLAdvertisingChannelPDUConfig with properties:
                    PDUType: 'Connection indication'
            ChannelSelection: 'Algorithm1'
        AdvertiserAddressType: 'Random'
            AdvertiserAddress: '0123456789AB'
        InitiatorAddressType: 'Random'
            InitiatorAddress: '0123456789CD'
                AccessAddress: '01234567'
            CRCInitialization: '012345'
                    WindowSize: 1
                    WindowOffset: 0
            ConnectionInterval: 8
                    SlaveLatency: 0
                ConnectionTimeout: 10
                    UsedChannels: [0 412161824 25]
                    HopIncrement: 5
```

SleepClockAccuracy: '251 to 500 ppm'

```

Generate a BLE LL advertising channel PDU by using the corresponding configuration object.
pdu = bleLLAdvertisingChannelPDU(cfgTx);
Decode the generated BLE LL advertising channel PDU. The returned status indicates decoding is successful. View the output of 'status' and 'cfgRx'.
```

[status, cfgRx] = bleLLAdvertisingChannelPDUDecode(pdu)
status =
Success
cfgRx =
bleLLAdvertisingChannelPDUConfig with properties:
PDUType: 'Connection indication'
ChannelSelection: 'Algorithm1'
AdvertiserAddressType: 'Random'
AdvertiserAddress: '0123456789AB'
InitiatorAddressType: 'Random'
InitiatorAddress: '0123456789CD'
AccessAddress: '01234567'
CRCInitialization: '012345'
WindowSize: 1
WindowOffset: 0
ConnectionInterval: 8
SlaveLatency: 0
ConnectionTimeout: 10
UsedChannels: [0 4 12 16 18 24 25]
HopIncrement: 5
SleepClockAccuracy: '251 to 500 ppm'

```

\section*{bleGAPDataBlockConfig}

Configuration object for BLE GAP data block

Note Download Required: To use , first download Communications Toolbox \({ }^{\mathrm{TM}}\) Library for the Bluetooth \({ }^{\circledR}\) Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

\section*{Description}

The bleGAPDataBlockConfig creates a configuration object for a Bluetooth low energy (BLE) generic access profile (GAP) data block of the type advertising data (AD) or scan response data (SRD). You can configure a BLE GAP data block using the applicable properties of bleGAPDataBlockConfig.

\section*{Creation}

\section*{Syntax}
cfgGAP = bleGAPDataBlockConfig
cfgGAP = bleGAPDataBlockConfig(Name, Value)

\section*{Description}
cfgGAP = bleGAPDataBlockConfig creates a configuration object, cfgGAP, for a BLE GAP data block of the type AD or SRD with default values.
cfgGAP = bleGAPDataBlockConfig(Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes. For example,
bleGAPDataBlockConfig('AdvertisingDataTypes','Tx power level') configures cfgGAP with block data advertising data type as 'Tx power level'.

\section*{Properties}

Note For more information about BLE GAP data block properties and their respective values, see vol 3, part C, section 4 of the Bluetooth Core Specification [2].

\section*{AdvertisingDataTypes - Block data advertising data types}
'Flags' (default)|'UUIDs'|'Local name'|'Tx power level'|'Connection interval range'|'Advertising interval'

Block data advertising data types, specified as a character vector or a string scalar or a cell array, containing the list of advertising data types for BLE GAP data block. You can specify AdvertisingDataTypes as one of these values:
- 'Flags'
- 'UUIDs'
- 'Local name'
- 'Tx power level'
- 'Connection interval range'
- 'Advertising interval'

Data Types: char \| string | cell

\section*{LEDiscoverability - LE discoverable mode}
'General' (default)|'None'|'Limited'|'Limited and general'
LE discoverable mode, specified as a character vector or a string scalar, describing the LE discoverable mode of the device. You can specify LEDiscoverability as one of these values:
- 'None'
- 'General'
- 'Limited'
- 'Limited and general'

Data Types: char | string

\section*{BREDR - Basic rate (BR) or enhanced data rate (EDR ) support}
false (default) | true
Basic rate (BR) or enhanced data rate (EDR ) support, specified as true or false. A true value indicates that BR or EDR is supported. This is used when AdvertisingDataTypes is set to 'Flags'.
Data Types: logical

\section*{LE - Simultaneous LE and BR or EDR support}
'None' (default)|'Host'|'Controller'|'Host and controller'
Simultaneous LE and BR/EDR support, specified as a character vector or a string scalar. You can specify 'LE' as one of these values:
- 'None'
- 'Host'
- 'Controller'
- 'Host and controller'

This property is applicable only when BREDR is set to true. Set this property to 'Host ' or 'Controller' to specify simultaneous LE and BR or EDR support at the host or the controller respectively. Set this property to 'Host and Controller' for simultaneous LE and BR or EDR support at the host and the controller.

\section*{Data Types: char|string}

\section*{LocalNameShortening - Enable shortening of local name \\ false (default)| true}

Local name shortened used, specified as a scalar logical value of false or true. Set this value to true value indicates that the name of the device is shortened.

\section*{Data Types: logical}

\section*{LocalName - UTF-8 encoded user-friendly descriptive name}
'Bluetooth ' (default) | character vector or a string scalar consisting of UTF-8 characters
UTF-8 encoded user-friendly descriptive name, specified as a character vector or a string scalar consisting of UTF-8 characters. This property specifies the local name assigned to the device.
Data Types: char|string
IdentifierType - Type of 16-bit service or service class identifiers
'Incomplete' (default)|'Complete'
Type of 16 -bit service or service class identifiers, specified as 'Incomplete' or 'Complete'. If this value is 'Incomplete', then the list of 16-bit service or service class identifiers list is incomplete.
Data Types: char \| string

\section*{Identifiers \(\mathbf{-}\) List of \(\mathbf{1 6}\)-bit service or service class identifiers}
' ' (empty) (default) | \(n\)-by-4 character array
List of 16 -bit service or service class identifiers, specified as an \(n\)-by- 4 character array. The value of \(n\) must be in the range \([0,127]\). Each row in the \(n\)-by- 4 character array is represented as a fourelement character vector or string scalar denoting a two-octet (16-bit) hexadecimal value of a service or service class universally unique identifier (UUID). These UUIDs are assigned by the Bluetooth Special Interest Group (SIG).

Data Types: char

\section*{AdvertisingInterval - Advertising interval}

32 (default) | integer in the range [32, 65,535]
Advertising interval, specified as an integer in the range [32, 65,535]. This property denotes the interval between the start of two consecutive advertising events. Incremental units are 0.625 ms steps, so the resultant range for [32, 65,535] is [20, 40.959375].

Data Types: double
TxPowerLevel - Packet transmit power level
0 (dBm) (default) | integer in the range [-127, 127]
Packet transmit power level, in dBm, specified as an integer in the range [-127, 127]. This property calculates the pathloss as pathloss \(=\) Tx Power Level - RSSI, where RSSI is the received signal strength indicator.
Data Types: double

\section*{ConnectionIntervalRange - Connection interval range}
[6,3200] (default) | two-element numeric vector [MIN, MAX]
Connection interval range, specified as a two-element numeric vector [ \(M I N, M A X\) ], where \(M I N\) and \(M A X\) must be in the range \([6,3200]\). MIN and \(M A X\) specify the minimum and maximum value for the connection interval respectively. MIN must be less than or equal to MAX. Incremental units are 1.25 ms steps, so that the resultant range for \([6,3200\) ] is [7.5, 4.0].

Data Types: double

\section*{Object Functions}

\section*{Specific to This Object}

\author{
bleGAPDataBlock \\ Generate BLE GAP data block \\ bleGAPDataBlockDecode Decode BLE GAP data block
}

\section*{Examples}

\section*{Create BLE GAP AD Block Configuration Object Using Default Settings}

Create two unique BLE GAP AD configuration objects: one with AD types ' \(F\) lags ' and 'Tx power level' and the other with AD type 'Flags' and simultaneous LE and BR or EDR support at the host.

Create a BLE GAP AD block configuration object using default settings. Set the values of AD types as 'Flags' and 'Tx power level', LE discoverability as 'Limited' and Tx power level as 45. View the properties of the corresponding configuration object.
```

cfgGAP = bleGAPDataBlockConfig;
cfgGAP.AdvertisingDataTypes = {'Flags';'Tx power level'};
cfgGAP.LEDiscoverability = 'Limited';
cfgGAP.TxPowerLevel = 45
cfgGAP =
bleGAPDataBlockConfig with properties:
AdvertisingDataTypes: {2x1 cell}
LEDiscoverability: 'Limited'
BREDR: 0
TxPowerLevel: 45

```

Create another BLE GAP AD block configuration object using default settings, this time with AD type 'Flags' and having simultaneous support for LE and BR/EDR. Set the values of LE discoverability as 'Limited ', enable BR or EDR support as true and enable simultaneous support for LE and BR or EDR as 'Host '. View the properties of the corresponding configuration object.
```

cfgGAP = bleGAPDataBlockConfig;
cfgGAP.LEDiscoverability = 'Limited and general';
cfgGAP.BREDR = true;
cfgGAP.LE = 'Host'
cfgGAP =
bleGAPDataBlockConfig with properties:
AdvertisingDataTypes: {'Flags'}
LEDiscoverability: 'Limited and general'
BREDR: 1
LE: 'Host'

```

\section*{Create BLE GAP AD Block Configuration Object Using Name-Value Pairs}

Create a configuration object for a BLE GAP AD block using name-value pairs. Set the values of AD types as 'Advertising interval' and 'Local name', advertising interval as 48, local name as 'MathWorks ' and local name shortening as true. View the properties of the corresponding configuration object.
```

cfgGAP = bleGAPDataBlockConfig('AdvertisingDataTypes', ...
{'Advertising interval', ...
'Local name'});
cfgGAP.AdvertisingInterval = 48;
cfgGAP.LocalName = 'MathWorks';
cfgGAP.LocalNameShortening = true
cfgGAP =
bleGAPDataBlockConfig with properties:
AdvertisingDataTypes: {2\times1 cell}
LocalName: 'MathWorks'
LocalNameShortening: 1
AdvertisingInterval: 48

```

\section*{End-to-End Workflow of BLE GAP AD Blocks}

Create a configuration object for a BLE GAP AD block using name-value pairs. Set the values of AD types as 'Advertising interval' and 'Local name', advertising interval as 48, local name as 'MathWorks', and local name shortening as true. View the properties of the corresponding configuration object.
```

cfgTx = bleGAPDataBlockConfig('AdvertisingDataTypes',{'Advertising interval','Local name'});
cfgTx.AdvertisingInterval = 48;
cfgTx.LocalName = 'MathWorks';
cfgTx.LocalNameShortening = true
cfgTx =
bleGAPDataBlockConfig with properties:
AdvertisingDataTypes: {2x1 cell}
LocalName: 'MathWorks'
LocalNameShortening: 1
AdvertisingInterval: 48

```

Create a BLE GAP AD block using the configuration object ' cfgTx'.
```

dataBlock = bleGAPDataBlock(cfgTx);

```

Decode the generated BLE GAP AD block. The returned status indicates decoding was successful.
View the output of 'status' and 'cfgRx'.
```

[status, cfgRx] = bleGAPDataBlockDecode(dataBlock)

```
```

status =
Success
cfgRx =
bleGAPDataBlockConfig with properties:
AdvertisingDataTypes: {2x1 cell}
LocalName: 'MathWorks'
LocalNameShortening: 1
AdvertisingInterval: 48

```

\section*{comm.BlockDeinterleaver}

Package: comm
(To be removed) Deinterleave input symbols using permutation vector

\section*{Compatibility}
comm.BlockDeinterleaver will be removed in a future release. Use deintrlv instead. For more information, see "Compatibility Considerations" on page 3-161.

\section*{Description}

The BlockDeinterleaver object, which can process variable-sized signals, rearranges the elements of its input vector without repeating or omitting any elements. The input can be real or complex.

To deinterleave the input vector:
1 Define and set up your block deinterleaver object. See "Construction" on page 3-159.
2 Call step to rearrange the elements of the input vector according to the properties of comm. BlockDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, x) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
\(\mathrm{H}=\) comm. BlockDeinterleaver creates a block deinterleaver System object, H. This object restores the original ordering of a sequence that was interleaved using the block interleaver System object.
\(H\) = comm. BlockDeinterleaver(Name, Value) creates object, H , with the specified property set to the specified value.

\section*{Properties}

\section*{PermutationVectorSource}

Permutation vector source
Specify the source of the permutation vector as either Property or Input port. The default value is Property.

\section*{PermutationVector}

Permutation vector
Specify the mapping used to permute the input symbol as a column vector of integers. The default is \([5 ; 4 ; 3 ; 2 ; 1]\). The mapping is a column vector of integers where the number of elements is equal to
the length, \(N\), of the input to the step method. Each element must be an integer, between 1 and \(N\), with no repeated values. The PermutationVector property is available only when the PermutationVectorSource property is set to Property.

\section*{Methods}
step (To be removed) Deinterleave input symbols using permutation vector

\section*{Common to All System Objects}
release Allow System object property value changes

\section*{Examples}

\section*{Block Interleaving and Deinterleaving}

Create interleaver and deinterleaver objects.
```

interleaver = comm.BlockInterleaver([3 4 1 2]');

```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the General Block Deinterleaver block reference page. The object properties correspond to the block parameters.

\section*{Compatibility Considerations}
comm. BlockDeinterleaver will be removed
Not recommended starting in R2019b
comm.BlockDeinterleaver will be removed in a future release. Use deintrlv instead.

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder \({ }^{\text {TM }}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{See Also}

\section*{Functions}
deintrlv|intrlv
Introduced in R2012a

\section*{step}

System object: comm.BlockDeinterleaver
Package: comm
(To be removed) Deinterleave input symbols using permutation vector

\section*{Compatibility}
step will be removed in a future release. Use deintrlv instead.

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(Y=\operatorname{step}(H, X)\) restores the original ordering of the sequence, \(X\), that was interleaved using a block interleaver. The step method forms the output, \(Y\), based on the mapping specified by the PermutationVector property as \(\operatorname{Output}(\operatorname{PermutationVector}(k))=\operatorname{Input}(k)\), for \(k=1: N\), where \(N\) is the length of the permutation vector. The input \(X\) must be a column vector of the same length, \(N\). The data type of X can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.BlockInterleaver}

Package: comm
(To be removed) Permute input symbols using permutation vector

\section*{Compatibility}
comm.BlockInterleaver will be removed in a future release. Use intrlv instead. For more information, see "Compatibility Considerations" on page 3-165.

\section*{Description}

The BlockInterleaver object permutes the symbols in the input signal. Internally, it uses a set of shift registers, each with its own delay value. This object processes variable-size signals.

To interleave the input signal:
1 Define and set up your block interleaver object. See "Construction" on page 3-163.
2 Call step to reorder the input symbols according to the properties of comm. BlockInterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm.BlockInterleaver creates a block interleaver System object, H This object permutes the symbols in the input signal based on a permutation vector.
\(H\) = comm.BlockInterleaver(Name,Value) creates object, \(H\), with specified property set to the specified value.

\section*{Properties}

\section*{PermutationVectorSource}

Permutation vector source
Specify the source of the permutation vector as either Property or Input port. The default value is Property.

\section*{PermutationVector}

Permutation vector
Specify the mapping used to permute the input symbols as an integer column vector. The default is [ \(5 ; 4 ; 3 ; 2 ; 1\) ]. The number of elements of the permutation vector property must equal the length of
the input vector. The PermutationVector property indicates the indices, in order, of the input elements that form the output vector. The relationship Output \((k)=\) Input(PermutationVector \((k)\) ) describes this order. Each integer, \(k\), must be between 1 and \(N\), where \(N\) is the number of elements in the permutation vector. The elements in the PermutationVector property must be integers between 1 and \(N\) with no repetitions. The PermutationVector property is available only when the PermutationVectorSource property is set to Property.

System object: comm.BlockInterleaver
Package: comm
(To be removed) Permute input symbols using a permutation vector

\section*{Compatibility}
step will be removed in a future release. Use intrlv instead.

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((\mathrm{obj}, \mathrm{x})\) and \(\mathrm{y}=\mathrm{obj}(\mathrm{x})\) perform equivalent operations.
\(Y=\operatorname{step}(H, X)\) permutes input sequence, \(X\), and returns interleaved sequence, \(Y\). The step method forms the output \(Y\), based on the mapping defined by the PermutationVector property as Output \((k)=\operatorname{Input}(\) PermutationVector \((k))\), for \(k=1: N\), where \(N\) is the length of the PermutationVector property. The input \(X\) must be a column vector of length \(N\). The data type of \(X\) can be numeric, logical, or fixed-point (fi objects). Y has the same data type as X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.BPSKDemodulator}

Package: comm
Demodulate using BPSK method

\section*{Description}

The BPSKDemodulator object demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a binary phase shift signal:
1 Define and set up your BPSK demodulator object. See "Construction" on page 3-167.
2 Call step to demodulate a signal according to the properties of comm. BPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. BPSKDemodulator creates a demodulator System object, H, that demodulates the input signal using the binary phase shift keying (BPSK) method.

H = comm.BPSKDemodulator(Name,Value) creates a BPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.BPSKDemodulator(PHASE,Name,Value) creates a BPSK demodulator object, H, with the PhaseOffset property set to PHASE, and the other specified properties set to the specified values.

\section*{Properties}

\section*{PhaseOffset}

Phase of zeroth point of constellation
Specify the phase offset of the zeroth point of the constellation, in radians, as a finite, real scalar. The default is 0 .

\section*{DecisionMethod}

Demodulation decision method
Specify the decision method the object uses as one of Hard decision | Log-likelihood ratio| Approximate log-likelihood ratio. The default is Hard decision.

\section*{VarianceSource}

Source of noise variance
Specify the source of the noise variance as one of Property | Input port. The default is Property. This property applies when you set the DecisionMethod on page 3-0 property to Loglikelihood ratio or Approximate log-likelihood ratio.

\section*{Variance}

Noise variance
Specify the variance of the noise as a nonzero, real scalar. The default is 1 . If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations can yield Inf or - Inf. This variance occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite precision arithmetic. As a best practice in such cases, use approximate LLR because this option's algorithm does not compute exponentials. This property applies when you set the VarianceSource on page 3-0 property to Property. This property is tunable.

\section*{OutputDataType}

Data type of output
Specify the output data type as one of Full precision | Smallest unsigned integer|double | single | int8 | uint8 | int16|uint16| int32 | uint32 | logical. The default is Full precision. This property applies only when you set the DecisionMethod on page 3-0 property to Hard decision. Thus, when you set the OutputDataType on page 3-0 property to Full precision, and the input data type is single or double precision, the output data has the same data type as the input. If the input data is of a fixed-point type, then the output data type behaves as if you had set the OutputDataType property to Smallest unsigned integer. If you set the DecisionMethod property to Log-likelihood ratio or Approximate log-likelihood ratio, the output data type is the same as that of the input. In this case, that data type can only be single or double precision.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in Smallest unsigned integer or Full precision mode.

\section*{Fixed-Point Properties}

\section*{DerotateFactorDataType}

\section*{Data type of derotate factor}

Specify the derotate factor data type as one of Same word length as input | Custom. The default is Same word length as input. This property applies when you set the DecisionMethod on page 3-0 property to Hard decision. The object uses the derotate factor in the computations only when certain conditions exist. The step method input must be of a fixed-point type, and the PhaseOffset on page 3-0 property must have a value that is not a multiple of \(\pi / 2\).

\section*{CustomDerotateFactorDataType}

Fixed-point data type of derotate factor
Specify the derotate factor fixed-point type as an unscaled, numerictype object with a Signedness of Auto. The default is numerictype ([],16). This property applies when you set the

DecisionMethod on page 3-0 property to Hard decision and the DerotateFactorDataType on page 3-0 property to Custom.

\section*{Methods}
\begin{tabular}{ll} 
constellation & Calculate or plot ideal signal constellation \\
step & Demodulate using BPSK method

\section*{Examples}

\section*{Demodulate BPSK Signal and Calculate Errors}

Generate a BPSK signal, pass it through an AWGN channel, demodulate the signal, and compute the error statistics.

Create BPSK modulator and demodulator System objects.
```

bpskModulator = comm.BPSKModulator;
bpskDemodulator = comm.BPSKDemodulator;

```

Create an error rate calculator System object.
errorRate = comm.ErrorRate;
Generate 50-bit random data frames, apply BPSK modulation, pass the signal through an AWGN channel, demodulate the received data, and compile the error statistics.
```

for counter = 1:100
% Transmit a 50-symbol frame
txData = randi([0 1],50,1); % Generate data
modSig = bpskModulator(txData); % Modulate
rxSig = awgn(modSig,5); % Pass through AWGN
rxData = bpskDemodulator(rxSig); % Demodulate
errorStats = errorRate(txData,rxData); % Collect error stats
end

```

Display the cumulative error statistics.
```

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
errorStats(1), errorStats(2))
Error rate = 0.005600
Number of errors = 28

```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the BPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder \(^{\text {TM }}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{constellation}

System object: comm. BPSKDemodulator
Package: comm
Calculate or plot ideal signal constellation

\section*{Syntax}
\(\mathrm{y}=\) constellation(h)
constellation(h)

\section*{Description}
\(y=\) constellation(h) returns the numerical values of the constellation.
constellation(h) generates a constellation plot for the object.

\section*{Examples}

\section*{Calculate Reference Signal Constellation for BPSK Demodulator}

Create BPSK Demodulator System object \({ }^{\mathrm{TM}}\) and calculate its reference constellation.
Create a comm. BPSKDemodulator System object.
h = comm.BPSKDemodulator;
Calculate and display the reference signal constellation by calling the constellation function.
```

refC = constellation(h)
refC = 2x1 complex
1.0000 + 0.0000i
-1.0000 + 0.0000i

```

\section*{Plot BPSK Demodulator Reference Signal Constellation}

Create a BPSK Demodulator System object \({ }^{T M}\) and then plot the reference signal constellation.
Create a comm. BPSKDemodulator System object.
h = comm.BPSKDemodulator;
Plot the reference constellation by calling the constellation function.
constellation(h)

\section*{step}

System object: comm. BPSKDemodulator
Package: comm
Demodulate using BPSK method

\section*{Syntax}
\(Y=\operatorname{step}(H, X)\)
Y = step(H,X,VAR)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})\) demodulates input data, X , with the BPSK demodulator System object, H , and returns Y . Input X must be a scalar or a column vector with double or single precision data type. When you set the DecisionMethod property to Hard decision, the data type of the input can also be signed integer, or signed fixed point (fi objects).
\(Y=\operatorname{step}(H, X, V A R)\) uses soft decision demodulation and noise variance VAR. This syntax applies when you set the DecisionMethod property to Log-likelihood ratio or Approximate loglikelihood ratio and the VarianceSource property to Input port. The data type of input VAR must be double or single precision.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{bluetoothPhyConfig}

\author{
Configuration object for Bluetooth BR/EDR PHY
}

Note Download Required: To use , first download Communications Toolbox \({ }^{\mathrm{TM}}\) Library for the Bluetooth \({ }^{\circledR}\) Protocol. For more information, see "Get and Manage Add-Ons" (MATLAB). Alternatively, see Communications Toolbox Library for the Bluetooth Protocol File Exchange.

\section*{Description}

The bluetoothPhyConfig object creates a configuration object for the Bluetooth physical layer (PHY) using default and specified values. You can configure the Bluetooth PHY by using the applicable properties of the bluetoothPhyConfig object.

\section*{Creation}

\section*{Syntax}
cfg = bluetoothPhyConfig
cfg = bluetoothPhyConfig(Name,Value)

\section*{Description}
cfg = bluetoothPhyConfig creates a configuration object, cfg, for Bluetooth PHY with default property values.
\(\mathrm{cfg}=\mathrm{bluetoothPhyConfig}(\) Name, Value) sets "Properties" on page 3-174 by using one or more name-value pairs. Enclose each property name in quotes. For example, bluetoothPhyConfig('Mode', 'EDR3M') sets the physical layer transmission mode to 3 Mbps.

\section*{Properties}

Note For more information about Bluetooth BR/EDR waveform generator properties and their respective values, see volume 2, part B, sections 6 and 7 of the Bluetooth Core Specification [2].

\section*{Mode - PHY transmission mode}
'BR' (default)|'EDR2M' | 'EDR3M'
PHY transmission mode, specified as 'BR', 'EDR2M' or 'EDR3M'. This value indicates the type of Bluetooth BR/EDR waveform.
Data Types: char|string

\section*{DeviceAddress - Bluetooth device address}
'0123456789AB' (default) | 12-element character vector | string scalar denoting 6-octet
hexadecimal value

Bluetooth device address, specified as a 12 -element character vector or a string scalar denoting a 6 octet hexadecimal value.
Data Types: char | string

\section*{ModulationIndex - Modulation Index}
0.32 (default) | scalar in the range [ \(0.28,0.35\) ]

Modulation index, specified as a scalar in the range [ \(0.28,0.35\) ]. This property is the modulation index that the object uses when performing Gaussian frequency shift keying (GFSK) modulation or demodulation.
Data Types: double

\section*{SamplesPerSymbol - Samples per symbol}

8 (default) | positive integer
Samples per symbol, specified as a positive integer. This value is used for GFSK modulation and demodulation.

Data Types: double
WhitenStatus - Data whiten status
'On' (default)| \({ }^{\prime}\) Off'
Data whiten status, specified as ' \(0 n\) ' or ' \(O f f\) '. Set this value to ' \(O n\) ' for the object to perform whitening on header and payload bits.

Data Types: char | string
WhitenInitialization - Whiten initialization
[1; 1; 1; 1; 1; 1; 1] (default) | 7-bit binary column vector
Whiten initialization, specified as a 7-bit binary column vector.

\section*{Dependencies}

To enable this property, set the "WhitenStatus" on page 3-0 property to ' \(0 n\) '.
Data Types: double

- '2-DH5'
- '3-DH5'

Data Types: char \| string

\section*{PayloadLength - Payload length of packet}

18 (default) | integer in the range [0, X]
Payload length of packet, specified as an integer in the range [ \(0, X\) ], where \(X\) depends on the "PacketType" on page 3-0 property. This value sets the number of bytes to be processed in a packet.

\section*{Dependencies}

To enable this property, set the value of packet type to 'DM1', 'DH1', 'DM3', 'DH3', 'DM5', 'DH5', 'AUX1', or 'DV'.

\section*{Data Types: double}

\section*{DeviceAddress - Bluetooth device address}
'0123456789AB' (default) | 12-element character vector | string scalar denoting 6-octet
hexadecimal value
Bluetooth device address, specified as a 12 -element character vector or string scalar denoting a 6 octet hexadecimal value.

Data Types: char \| string

\section*{LogicalTransportAddress - Logical transport address for packet}
[0; 0; 1] (default) | 3-bit binary column vector
Logical transport address for the packet, specified as a 3-bit binary column vector. This property indicates the active destination slave for a packet in the master-to-slave transmission slot.

Data Types: double

\section*{HeaderControlBits - Header control information}
[1; 1; 1] (default) | 3-bit binary column vector
Header control information, specified as a 3-bit binary column vector. This property indicates the header control information consisting of these three fields:
\begin{tabular}{|l|l|l|}
\hline Field & Size of Field & Field Information Indicates \\
\hline FLOW & 1 bit & Flow control information \\
\hline ARQN & 1 bit & \begin{tabular}{l} 
Acknowledgment for successful \\
reception of a CRC packet
\end{tabular} \\
\hline SEQN & 1 bit & \begin{tabular}{l} 
Sequencing scheme to order the \\
packet stream
\end{tabular} \\
\hline
\end{tabular}

\section*{Data Types: double}

\section*{ModulationIndex - Modulation Index}
0.32 (default) | scalar in the range [ \(0.28,0.35\) ]

Modulation index, specified as a scalar in the range [ \(0.28,0.35\) ]. This property is the modulation index that the object uses when performing Gaussian frequency shift keying (GFSK) modulation or demodulation.

Data Types: double

\section*{SamplesPerSymbol - Samples per symbol}

8 (default) | positive integer
Samples per symbol, specified as a positive integer. This value is used for GFSK modulation and demodulation.

Data Types: double

\section*{WhitenStatus - Data whiten status}
'On' (default)|'Off'
Data whiten status, specified as ' On ' or ' \(O f \mathrm{f}\) '. Set this value to ' \(O n\) ' for the object to perform whitening on the header and payload bits.

\section*{Data Types: char | string}

\section*{WhitenInitialization - Whiten initialization}

\section*{[1; 1; 1; 1; 1; 1; 1] (default) | 7-bit binary column vector}

Whiten initialization, specified as a 7-bit binary column vector.

\section*{Dependencies}

To enable this property, set the "WhitenStatus" on page 3-0 property to ' On'.
Data Types: double

\section*{LLID - Logical link identifier}

\section*{[1; 1] (default) | 2-bit binary column vector}

Logical link identifier, specified as a 2-bit binary column vector.

\section*{Dependencies}

To enable this property, set the value of "PacketType" on page 3-0 to 'DM1', 'DH1', 'DM3', 'DH3', 'DM5', 'DH5', 'AUX1', and 'DV'.

Data Types: double

\section*{FlowIndicator - Logical channel flow control indicator \\ true (default) | false}

Logical channel flow control indicator, specified as true or false.

\section*{Dependencies}

To enable this property, set the value of packet type to 'DM1', 'DH1', 'DM3', 'DH3', 'DM5', 'DH5', 'AUX1', and 'DV'.

Data Types: logical

\section*{Create Bluetooth BR/EDR Waveform Configuration Objects}

Create three unique Bluetooth BR/EDR waveform configuration objects for synchronous connection oriented (SCO), connectionless slave broadcast (CSB), and asynchronous connectionless (ACL) logical transports.

Create a Bluetooth BR/EDR waveform configuration object for an SCO logical transport by specifying packet type as HV1. For SCO logical transport, the PHY transmission mode must be basic rate (BR).
```

cfg = bluetoothWaveformConfig;
cfg.PacketType = 'HV1'
cfg=
bluetoothWaveformConfig with properties:
Mode: 'BR'
PacketType: 'HV1'
DeviceAddress: '0123456789AB'
LogicalTransportAddress: [ 3\times1 double]
HeaderControlBits: [ 3×1 double]
ModulationIndex: 0.3200
SamplesPerSymbol: 8
WhitenStatus: 'On'
WhitenInitialization: [7×1 double]

```

Create a second Bluetooth BR/EDR waveform configuration object for a CSB logical transport by specifying the packet type as DH1 and disabling the whiten status.
```

cfg = bluetoothWaveformConfig('PacketType','DH1','WhitenStatus','Off')
cfg =
bluetoothWaveformConfig with properties:
Mode: 'BR'
PacketType: 'DH1'
PayloadLength: 18
DeviceAddress: '0123456789AB'
LogicalTransportAddress: [3\times1 double]
HeaderControlBits: [3\times1 double]
ModulationIndex: 0.3200
SamplesPerSymbol: 8
WhitenStatus: 'Off'
LLID: [2×1 double]
FlowIndicator: 1

```

Create a third Bluetooth BR/EDR waveform configuration object for an ACL logical transport with enhanced data rate mode. Set the value of packet type to DH3, and payload length to 184 bytes.
```

cfg = bluetoothWaveformConfig;
cfg.Mode = 'EDR2M';
cfg.PacketType = 'DH3';
cfg.PayloadLength = 184 % in bytes
cfg=
bluetoothWaveformConfig with properties:
Mode: 'EDR2M'
PacketType: 'DH3'
PayloadLength: 184
DeviceAddress: '0123456789AB'
LogicalTransportAddress: [3\times1 double]
HeaderControlBits: [ 3\times1 double]
ModulationIndex: 0.3200
SamplesPerSymbol: 8
WhitenStatus: 'On'
WhitenInitialization: [7×1 double]

```

LLID: [2×1 double]
FlowIndicator: 1

\title{
comm.IQImbalanceCompensator
}

Package: comm
Compensate for I/Q imbalance

\section*{Description}

The IQImbalanceCompensator System object compensates for the imbalance between the in-phase and quadrature components of a modulated signal.

To compensate for I/Q imbalance:
1 Define and set up the IQImbalanceCompensator object. See "Construction" on page 3-184.
2 Call step to compensate for the I/Q imbalance according to the properties of comm. IQImbalanceCompensator. The behavior of step is specific to each object in the toolbox.

The adaptive algorithm inherent to the I/Q imbalance compensator is compatible with M-PSK, MQAM, and OFDM modulation schemes, where \(M>2\).

Note The output of the compensator might be scaled and rotated, that is, multiplied by a complex number, relative to the reference constellation. In practice, this is not an issue as receivers correct for this prior to demodulation through the use of channel estimation.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
\(\mathrm{H}=\) comm. IQImbalanceCompensator creates a compensator System object, H , that compensates for the imbalance between the in-phase and quadrature components of the input signal.

H = comm.IQImbalanceCompensator(Name, Value) creates an I/Q imbalance compensator object, H, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

\section*{CoefficientSource}

Source of compensator coefficients
Specify either Estimated from input signal or Input port. If the CoefficientSource property is set to Estimated from input signal, the compensator uses an adaptive algorithm to estimate the compensator coefficient from the input signal. If the CoefficientSource property is set to Input port, all other properties are disabled and the compensator coefficients must be
provided to the step function as an input argument. The default value is Estimated from input signal. This property is nontunable.

\section*{InitialCoefficent}

Initial coefficient used to compensate for I/Q imbalance
The initial coefficient is a complex scalar that can be either single or double precision. The default value is \(0+0 \mathrm{i}\). This property is nontunable.

\section*{StepSizeSource}

Source of step size for coefficient adaptation
Specify either Property or Input port. If StepSizeSource is set to Property, you specify the step size through the StepSize property. Otherwise, the step size is provided to the step function as an input argument. The default value is Property. This property is nontunable.

\section*{StepSize}

\section*{Adaptation step size}

Specifies the step size used by the algorithm in estimating the I/Q imbalance. This property is accessible only when StepSizeSource is set to Property. The default value is le-5. This property is tunable.

\section*{AdaptInputPort}

Creates input port to control compensator coefficient adaptation
When this logical property is true, an input port is created to enable or disable coefficient adaptation. If AdaptInputPort is false, the coefficients update after each output sample. The default value is false. This property is nontunable.

\section*{CoefficientOutputPort}

Create port to output compensator coefficients
When this logical property is true, the I/Q imbalance compensator coefficients are made available through an output argument of the step function. The default value is false. This property is nontunable.

\section*{Methods}
step Compensate I/Q Imbalance
reset Reset states of the IQImbalanceCompensator System object

\section*{Common to All System Objects}
\begin{tabular}{|l|ll}
\hline release & Allow System object property value changes
\end{tabular}

\section*{Examples}

\section*{Remove I/Q Imbalance from a QPSK Signal}

Mitigate the impacts of amplitude and phase imbalance on a QPSK modulated signal by using the comm.IQImbalanceCompensator System object?.

Create a constellation diagram object. Specify name-value pairs to ensure that the constellation diagram displays only the last 100 data symbols.
```

constDiagram = comm.ConstellationDiagram(...
'SymbolsToDisplaySource','Property', ...
'SymbolsToDisplay',100);

```

Create an I/Q imbalance compensator.
```

iqImbComp = comm.IQImbalanceCompensator;

```

Generate random data symbols and apply QPSK modulation.
```

data = randi([0 3],1e7,1);
txSig = pskmod(data,4,pi/4);

```

Apply amplitude and phase imbalance to the transmitted signal.
```

ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;

```

Plot the constellation diagram of the received signal. Observe that the received signal experienced an amplitude and phase shift.
```

constDiagram(rxSig)

```

Apply the I/Q compensation algorithm and view the constellation. The compensated signal constellation is nearly aligned with the reference constellation.
compSig = iqImbComp(rxSig);
constDiagram(compSig)

\section*{Remove I/Q Imbalance from an 8-PSK Signal using External Coefficients}

Compensate for an amplitude and phase imbalance on an 8-PSK signal by using the comm. IQImbalanceCompensator System object \({ }^{\mathrm{TM}}\) with external coefficients.

Create 8-PSK modulator and constellation diagram System objects. Use name-value pairs to ensure that the constellation diagram displays only the last 100 data symbols and to provide the reference constellation.
hMod \(=\) comm.PSKModulator(8);
refC = constellation(hMod);
hScope \(=\) comm.ConstellationDiagram(...
'SymbolsToDisplaySource','Property', ...
'SymbolsToDisplay',100, ...
'ReferenceConstellation', refC);

Create an I/Q imbalance compensator object with an input port for the algorithm coefficients.
hIQComp = comm.IQImbalanceCompensator('CoefficientSource','Input port');
Generate random data symbols and apply 8-PSK modulation.
```

data = randi([0 7],1000,1);
txSig = step(hMod,data);

```

Apply amplitude and phase imbalance to the transmitted signal.
```

ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;

```

Plot the constellation diagram of the received signal. Observe that the received signal experienced an amplitude and phase shift.
step(hScope,rxSig);

Use the iqimbal2coef function to determine the compensation coefficient given the amplitude and phase imbalance.
compCoef \(=\) iqimbal2coef(ampImb,phImb);
Apply the compensation coefficient to the received signal using the step function of the comm. IQImbalanceCompensator object and view the resultant constellation. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.
compSig = step(hIQComp,rxSig,compCoef);
step(hScope, compSig)

\section*{Remove I/Q Imbalance from a QAM Signal}

Remove an I/Q imbalance from a 64-QAM signal and to make the estimated coefficients externally available while setting the algorithm step size from an input port.

Create a constellation diagram object. Use name-value pairs to ensure that the constellation diagram displays only the last 256 data symbols, set the axes limits, and specify the reference constellation.
```

M = 64;
refC = qammod(0:M-1,M);
constDiagram = comm.ConstellationDiagram(...
'SymbolsToDisplaySource','Property', ...
'SymbolsToDisplay',256, ...
'XLimits',[-10 10],'YLimits',[-10 10], ...
'ReferenceConstellation',refC);

```

Create an I/Q imbalance compensator System object in which the step size is specified as an input argument and the estimated coefficients are made available through an output port.
```

iqImbComp = comm.IQImbalanceCompensator('StepSizeSource','Input port', ...
'Coefficient0utputPort',true);

```

Generate random data symbols and apply 64-QAM modulation.
```

nSym = 25000;
data = randi([0 M-1],nSym,1);
txSig = qammod(data,M);

```

Apply amplitude and phase imbalance to the transmitted signal.
```

ampImb = 2; % dB
phImb = 10; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(1i*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;

```

Plot the constellation diagram of the received signal.
```

constDiagram(rxSig);

```

Specify the step size parameter for the I/Q imbalance compensator.
stepSize = 1e-5;
Compensate for the I/Q imbalance while setting the step size via an input argument. You can see that the compensated signal constellation is now nearly aligned with the reference constellation.
[compSig,estCoef] = iqImbComp(rxSig,stepSize); constDiagram(compSig)

Plot the real and imaginary values of the estimated coefficients. You can see that they reach a steadystate solution.
plot((1:nSym)'/1000, [real(estCoef),imag(estCoef)])
grid
xlabel('Symbols (thousands)')
ylabel('Coefficient Value')
legend('Real','Imag','location','best')

\section*{Control Adaptation Algorithm for I/Q Imbalance Compensator}

Control the adaptation algorithm of the I/Q imbalance compensator using an external argument.
Apply QPSK modulation to random data symbols.
```

data = randi([0 3],600,1);
txSig = pskmod(data,4,pi/4,'gray');

```

Create an I/Q imbalance compensator in which the adaptation algorithm is controlled through an input port, the step size is specified through the StepSize property, and the estimated coefficients are made available through an output port.
```

iqImbComp = comm.IQImbalanceCompensator('AdaptInputPort',true, ...
'StepSize',0.001,'Coefficient0utputPort',true);

```

Apply amplitude and phase imbalance to the transmitted signal.
```

ampImb = 5; % dB
phImb = 15; % deg
gainI = 10.^(0.5*ampImb/20);
gainQ = 10.^(-0.5*ampImb/20);
imbI = real(txSig)*gainI*exp(-0.5i*phImb*pi/180);
imbQ = imag(txSig)*gainQ*exp(li*(pi/2 + 0.5*phImb*pi/180));
rxSig = imbI + imbQ;

```

Break the compensation operation into three segments in which the compensator is enabled for the first 200 symbols, disabled for the next 200 symbols, and enabled for the last 200 symbols. Save the coefficient data in three vectors.
```

[~,estCoef1] = iqImbComp(rxSig(1:200),true);
[~,estCoef2] = iqImbComp(rxSig(201:400),false);
[~,estCoef3] = iqImbComp(rxSig(401:600),true);

```

Concatenate the complex algorithm coefficients and plot their real and imaginary parts.
```

estCoef = [estCoef1; estCoef2; estCoef3];
plot((1:600)',[real(estCoef) imag(estCoef)])
grid
xlabel('Symbols')
ylabel('Coefficient Value')
legend('Real','Imaginary','location','best')

```

Observe that the coefficients do not adapt during the time in which the compensator is disabled.

\section*{Algorithms}

One of the major impairments affecting direct conversion receivers is the imbalance between the received signal's in-phase and quadrature components. Rather than improving the front-end, analog hardware, it is more cost effective to tolerate a certain level of I/Q imbalance and then implement compensation methods. A circularity-based blind compensation algorithm is used as the basis for the I/Q Imbalance Compensator.

A generalized I/Q imbalance model is shown, where \(g\) is the amplitude imbalance and \(\phi\) is the phase imbalance (ideally, \(g=1\) and \(\phi=0\) ). In the figure, \(H(f)\) is the nominal frequency response of the branches due to, for example, lowpass filters. \(H_{I}(f)\) and \(H_{Q}(f)\) represent the portions of the in-phase and quadrature amplitude and phase responses that differ from the nominal response. With perfect matching, \(H_{I}(f)=H_{Q}(f)=1\).

Let \(z(t)\) be the ideal baseband equivalent signal of the received signal, \(r(t)\), where its Fourier transform is denoted as \(Z(f)\). Given the generalized I/Q imbalance model, the Fourier transform of the imbalanced signal, \(x(t)=x_{I}(t)+x_{Q}(t)\), is
\[
X(f)=G_{1}(f) Z(f)+G_{2}(f) Z^{*}(-f)
\]
where \(G_{1}(f)\) and \(G_{2}(f)\) are the direct and conjugate components of the I/Q imbalance. These components are defined as
\[
\begin{aligned}
& G_{1}(f)=\left[H_{I}(f)+H_{Q}(f) g \exp (-j \phi)\right] / 2 \\
& G_{2}(f)=\left[H_{I}(f)+H_{Q}(f) g \exp (j \phi)\right] / 2
\end{aligned}
\]

Applying the inverse Fourier transform to \(X(f)\), the signal model becomes \(x(t)=g_{1}(t) * z(t)+g_{2}(t) *\) \(z^{*}(t)\).

This suggests the compensator structure as shown in which discrete-time notation is used to express the variables. The compensated signal is expressed as \(\mathrm{y}(\mathrm{n})=x(n)+w x^{*}(n)\).

A simple algorithm of the form
\[
\left\{\begin{array}{l}
y(n)=x(n)+w(n) x^{*}(n) \\
w(n+1)=w(n)-M y^{2}(n)
\end{array}\right.
\]
is used to determine the weights, because it ensures that the output is "proper", that is, \(E\left[y^{2}(n)\right]=0\) [1]. The initial value of \(w\) is determined by the InitialCoefficient property, which has a default value of \(0+0 \mathrm{i} . M\) is the step size, as specified in the StepSize property.

\section*{See Also}

I/Q Imbalance Compensator | iqcoef2imbal | iqimbal2coef

Introduced in R2014b

\section*{step}

System object: comm. IQImbalanceCompensator
Package: comm
Compensate I/Q Imbalance

\section*{Syntax}
```

Y = step(H,X)
Y = step(H,X,COEF)
Y = step(H,X,STEPSIZE)
Y = step(H,...,ADAPT)
[Y,ESTCOEF] = step(H,X)
[Y,ESTCOEF] = step(H,X,STEPSIZE)
[Y,ESTCOEF] = step(H,X,STEPSIZE,ADAPT)
[Y,ESTCOEF] = step(H,X,ADAPT)

```

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(Y=\operatorname{step}(H, X)\) estimates the \(I / Q\) imbalance in the input signal, \(X\), and returns a compensated signal, Y . The input X can take real or complex values and can be either a scalar or a column vector. Double- and single-precision data types are supported. The output \(Y\) has the same properties as \(X\).
\(Y=\) step ( \(H, X, C O E F\) ) accepts input coefficients, COEF, instead of generating them internally. This syntax applies when the CoefficientSource property of H is set to Input port. The input coefficients, COEF, are complex and can be either double or single precision. COEF has the same dimensions as \(X\). At each time instant, COEF is a complex scalar.

Y = step ( \(\mathrm{H}, \mathrm{X}\), STEPSIZE) accepts a step size input, STEPSIZE. This syntax applies when the StepSizeSource property of H is set to Input port. The step size is a real scalar supporting either double or single precision.
\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \ldots\), , ADAPT \()\) accepts a control signal, ADAPT, to enable or disable coefficient updates. This syntax applies when the AdaptInputPort property of H is true. The adaptation control signal is a logical scalar.
[Y,ESTCOEF] = step \((H, X)\) outputs the estimated coefficients, ESTCOEF, when the CoefficientOutputPort property of H is true. ESTCOEF has the same data properties and dimensionality as the input signal, X .
[Y,ESTCOEF] \(=\operatorname{step}(H, X\), STEPSIZE) outputs the estimated coefficients, ESTCOEF, and accepts a step size input, STEPSIZE. This syntax applies when the properties of H are set so that CoefficientOutputPort is true and StepSizeSource is Input port.
[Y,ESTCOEF] = step(H,X,STEPSIZE,ADAPT) outputs the estimated coefficients, ESTCOEF, and accepts a step size input,STEPSIZE, and a control signal input, ADAPT. This syntax applies when the properties of H are set so that CoefficientOutputPort is true, StepSizeSource is Input port, and AdaptInputPort is true.
[ \(\mathrm{Y}, \mathrm{ESTCOEF}]=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{ADAPT})\) outputs the estimated coefficients, ESTCOEF, and accepts a control signal input, ADAPT. This syntax applies when the properties of H are set so that CoefficientOutputPort is true and AdaptInputPort is true.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{reset}

System object: comm. IQImbalanceCompensator
Package: comm
Reset states of the IQImbalanceCompensator System object

\section*{Syntax}
reset (H)

\section*{Description}
reset \((\mathrm{H})\) resets the states of the IQImbalanceCompensator object, H .
This method resets the windowed suffix from the last symbol in the previously processed frame.

\section*{comm.BPSKModulator}

Package: comm
Modulate using BPSK method

\section*{Description}

The BPSKModulator object modulates using the binary phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a binary phase shift signal:
1 Define and set up your BPSK modulator object. See "Construction" on page 3-203.
2 Call step to modulate a signal according to the properties of comm.BPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((o b j, x)\) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
\(\mathrm{H}=\) comm.BPSKModulator creates a modulator System object, H , that modulates the input signal using the binary phase shift keying (BPSK) method.

H = comm.BPSKModulator(Name,Value) creates a BPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.BPSKModulator(PHASE,Name, Value) creates a BPSK modulator object, H. The object's PhaseOffset property is set to PHASE, and the other specified properties are set to the specified values.

\section*{Properties}

\section*{PhaseOffset}

Phase of zeroth point of constellation
Specify the phase offset of the zeroth point of the constellation, in radians, as a finite, real scalar. The default is 0 .

\section*{OutputDataType}

Data type of output
Specify the output data type as one of double | single | Custom. The default is double.

\section*{Fixed-Point Properties}

\section*{CustomOutputDataType}

Fixed-point data type of output
Specify the output fixed-point type as a numerictype object with a Signedness of Auto. The default is numerictype ([],16). This property applies when you set the OutputDataType on page 3-0 property to Custom.

\section*{Methods}
\begin{tabular}{ll} 
constellation & Calculate or plot ideal signal constellation \\
step & Modulate using BPSK method
\end{tabular}
\begin{tabular}{|l|l|}
\hline Common to All System Objects \\
\hline release & Allow System object property value changes \\
\hline
\end{tabular}

\section*{Examples}

\section*{BPSK Data Scatter Plot}

This example creates binary data, modulates it, and then displays the data using a scatter plot.
Create binary data symbols
data \(=\) randi([0 1],100,1);
Create a BPSK modulator System object
bpskModulator = comm.BPSKModulator;
Change the phase offset to pi/16
bpskModulator. PhaseOffset = pi/16;
Modulate and plot the data
```

modData = bpskModulator(data);
scatterplot(modData)

```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the BPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

\section*{Extended Capabilities}

\section*{C/C++ Code Generation}

\section*{constellation}

System object: comm. BPSKModulator
Package: comm
Calculate or plot ideal signal constellation

\section*{Syntax}
\(\mathrm{y}=\) constellation(h)
constellation(h)

\section*{Description}
\(y=\) constellation(h) returns the numerical values of the constellation.
constellation(h) generates a constellation plot for the object.

\section*{Examples}

\section*{Calculate BPSK Modulator Reference Constellation}

Create a BPSK Modulator System object \({ }^{\mathrm{TM}}\) and calculate the reference constellation values.
Create a comm. BPSKModulator System object.
h = comm.BPSKModulator;
Calculate and display the reference constellation values by calling the constellation function.
```

refC = constellation(h)
refC = 2×1 complex
1.0000 + 0.0000i
-1.0000 + 0.0000i

```

\section*{Plot BPSK Modulator Reference Constellation}

Create a BPSK Modulator System object \({ }^{\text {TM }}\) and plot the reference constellation.
Create a comm. BPSKModulator System object.
bpsk = comm.BPSKModulator;
Plot the reference constellation by calling the constellation function.
constellation(bpsk)

\section*{step}

System object: comm.BPSKModulator
Package: comm
Modulate using BPSK method

\section*{Syntax}

Y = step( \(\mathrm{H}, \mathrm{X}\) )

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})\) modulates input data, X , with the BPSK modulator System object, H . It returns the baseband modulated output, Y. The input must be a column vector of bits. The data type of the input can be numeric, logical, or unsigned fixed point of word length 1 (fi object).

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.OFDMModulator}

Package: comm
Modulate signal using OFDM method

\section*{Description}

The OFDMModulator object modulates a signal using the orthogonal frequency division modulation method. The output is a baseband representation of the modulated signal.

To modulate a signal using OFDM:
1 Create the comm.0FDMModulator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
ofdmmod = comm.OFDMModulator
ofdmmod = comm.OFDMModulator(Name, Value)
ofdmmod \(=\) comm.OFDMModulator(ofdmdemod)
Description
ofdmmod \(=\) comm. OFDMModulator creates an OFDM modulator System object.
ofdmmod = comm. OFDMModulator(Name,Value) specifies "Properties" on page 3-209 using one of more name-value pair arguments. Enclose each property name in quotes. For example, comm.OFDMModulator('NumSymbols', 8) specifies eight OFDM symbols in the time-frequency grid.
ofdmmod = comm.OFDMModulator(ofdmdemod) sets the OFDM modulator system object properties based on the specified OFDM demodulator system object comm. OFDMDemodulator.

\section*{Properties}

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

\section*{FFTLength - Number of FFT points}

64 (default) | positive integer
Number of Fast Fourier Transform (FFT) points, specified as a positive integer. The length of the FFT, \(N_{\mathrm{FFT}}\), must be greater than or equal to 8 and is equivalent to the number of subcarriers.
Data Types: double

\section*{NumGuardBandCarriers - Number of subcarriers to the left and right guard bands}
[6;5] (default) | two-element column vector of integers
Number of subcarriers allocated to the left and right guard bands, specified as a two-element column vector of integers. The number of subcarriers must fall within [ \(\left.0,\left[N_{\text {FFT }} / 2\right\rfloor-1\right]\). This vector has the form [ \(\left.N_{\text {leftG }}, N_{\text {rightG }}\right]\), where \(N_{\text {leftG }}\) and \(N_{\text {rightG }}\) specify the left and right guard bands, respectively.
Data Types: double

\section*{InsertDCNull - Option to insert DC null}
false or 0 (default) | true or 1
Option to insert DC null, specified as a numeric or logical 0 (false) or 1 (true). The DC subcarrier is the center of the frequency band and has the index value:
- (FFTLength / 2) +1 when FFTLength is even
- (FFTLength +1 )/ 2 when FFTLength is odd

\section*{PilotInputPort - Option to specify pilot input}
false or 0 (default) | true or 1
Option to specify pilot input, specified as a numeric or logical 0 (false) or 1 (true). If this property is 1 (true), you can assign individual subcarriers for pilot transmission. If this property is 0 (false), pilot information is assumed to be embedded in the input data.

\section*{PilotCarrierIndices - Pilot subcarrier indices}
[12; 26; 40; 54] (default) |column vector
Pilot subcarrier indices, specified as a column vector. If the PilotCarrierIndices property is set to 1 (true), you can specify the indices of the pilot subcarriers. You can assign the indices to the same or different subcarriers for each symbol. Similarly, the pilot carrier indices can differ across multiple transmit antennas. Depending on the desired level of control for index assignments, the dimensions of the property vary. Valid pilot indices fall in the range
\[
\left[N_{\text {leftG }}+1, N_{\mathrm{FFT}} / 2\right] \cup\left[N_{\mathrm{FFT}} / 2+2, N_{\mathrm{FFT}}-N_{\mathrm{rightG}}\right],
\]
where the index value cannot exceed the number of subcarriers. When the pilot indices are the same for every symbol and transmit antenna, the property has dimensions \(N_{\text {pilot }}\)-by- 1 . When the pilot indices vary across symbols, the property has dimensions \(N_{\text {pilot }}\)-by- \(N_{\text {sym }}\). If you transmit only one symbol but multiple transmit antennas, the property has dimensions \(N_{\text {pilot }}\)-by-1-by- \(N_{\mathrm{t}}\)., where \(N_{\mathrm{t}}\). is the number of transmit antennas. If the indices vary across the number of symbols and transmit antennas, the property has dimensions \(N_{\text {pilot }}\)-by- \(N_{\text {sym }}\)-by- \(N_{\mathrm{t}}\). If the number of transmit antennas is greater than one, ensure that the indices per symbol must be mutually distinct across antennas to minimize interference.

To enable this property, set the PilotInputPort property to 1 (true).

\section*{CyclicPrefixLength - Length of cyclic prefix}

16 (default) | positive integer | row vector
Length of cyclic prefix, specified as a positive integer. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length \(N_{\text {sym }}\), the prefix length can vary across symbols but remains the same through all antennas.
Data Types: double

\section*{Windowing - Option to apply raised cosine window between OFDM symbols}
false or 0 (default) | true or 1
Option to apply raised cosine window between OFDM symbols, specified as true or false. Windowing is the process in which the OFDM symbol is multiplied by a raised cosine window before transmission to more quickly reduce the power of out-of-band subcarriers. Windowing reduces spectral regrowth.

\section*{WindowLength - Length of raised cosine window}

1 (default) | positive scalar
Length of raised cosine window, specified as a positive scalar. This value must be less than or equal to the minimum cyclic prefix length. For example, in a configuration of four symbols with cyclic prefix lengths \(12,14,16\), and 18 , the window length must be less than or equal to 12 .

To enable this property, set the Windowing property to 1 (true).

\section*{NumSymbols - Number of OFDM symbols}

1 (default) | positive integer
Number of OFDM symbols in the time-frequency grid, specified as a positive integer.

\section*{NumTransmitAntennnas - Number of transmit antennas}

1 (default) | positive integer
Number of transmit antennas, used to transmit the OFDM modulated signal, specified positive integer.

\section*{Usage}

\section*{Syntax}
```

waveform = ofdmmod(insignal)
waveform = ofdmmod(data,pilot)
Description

```
waveform = ofdmmod(insignal) applies OFDM modulation the specified baseband signal and returns the modulated OFDM baseband signal.
waveform = ofdmmod(data, pilot) assigns the pilot signal, pilot, into the frequency subcarriers specified by the PilotCarrierIndices property value of the ofdmmod system object. To enable this syntax set the PilotCarrierIndices property to true.

\section*{Input Arguments}

\section*{insignal - Input baseband signal}
matrix | 3-D array
Input baseband signal, specified as a matrix or 3-D array of numeric values. The input baseband signal must be of size \(N_{\mathrm{f}}\)-by- \(N_{\text {sym }}\)-by- \(N_{\mathrm{t}}\). where \(N_{\mathrm{f}}\) is the number of frequency subcarriers excluding guard bands and DC null.
Data Types: double
Complex Number Support: Yes

\section*{data - Input data}
matrix | 3-D array
Input data, specified as a matrix or 3-D array. The input must be a numeric of size \(N_{\mathrm{d}}\)-by- \(N_{\mathrm{sym}}\)-by- \(N_{\mathrm{t}}\). where \(N_{\mathrm{d}}\) is the number of data subcarriers in each symbol. For more information on how \(N_{\mathrm{d}}\) is calculated, see the to PilotCarrierIndices property.
Data Types: double
Complex Number Support: Yes

\section*{pilot - Pilot signal}

3-D array
Pilot signal, specified as a 3-D array of numeric values. The pilot signal must be of size \(N_{\text {pilot }}\)-by-1-by\(\mathrm{N}_{\mathrm{t}}\).
Data Types: double
Complex Number Support: Yes

\section*{Output Arguments}

\section*{waveform - OFDM Modulated baseband signal}

3-D array
OFDM Modulated baseband signal, returned as a 3-D array of the same size as the input signal. If the CyclicPrefixLength property is a scalar, the output waveform is of size \(\left(\left(\mathrm{N}_{\mathrm{FFT}}+\mathrm{CP}_{\text {len }}\right) * \mathrm{~N}_{\text {sym }}\right)\)-by- \(\mathrm{N}_{\mathrm{t}}\). Otherwise, the size is \(\left(\mathrm{N}_{\mathrm{FFT}} * \mathrm{~N}_{\text {sym }}+\sum\left(\mathrm{CP}_{\text {len }}\right)\right.\) )-by- \(\mathrm{N}_{\mathrm{t}}\).
Data Types: double
Complex Number Support: Yes

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
release(obj)

\section*{Specific to comm. OFDMModulator}
info
showResourceMapping

Provide dimensioning information for OFDM modulator Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Construct and Modify OFDM Modulator}

An OFDM modulator System object \({ }^{\mathrm{TM}}\) can be constructed using default properties. Once constructed, these properties can be modified.

Construct an OFDM modulator.
ofdmMod = comm.OFDMModulator;
Display the properties of the modulator.
```

disp(ofdmMod)
comm.OFDMModulator with properties:
FFTLength: 64
NumGuardBandCarriers: [2x1 double]
InsertDCNull: false
PilotInputPort: false
CyclicPrefixLength: 16
Windowing: false
NumSymbols: 1
NumTransmitAntennas: 1

```

Modify the number of subcarriers and symbols.
```

ofdmMod.FFTLength = 128;
ofdmMod.NumSymbols = 2;

```

Verify that the number of subcarriers and the number of symbols changed.
```

disp(ofdmMod)
comm.OFDMModulator with properties:
FFTLength: 128
NumGuardBandCarriers: [2x1 double]
InsertDCNull: false
PilotInputPort: false
CyclicPrefixLength: 16
Windowing: false
NumSymbols: 2
NumTransmitAntennas: 1

```

The showResourceMapping method shows the mapping of data, pilot, and null subcarriers in the time-frequency space. Apply the showResourceMapping method.
showResourceMapping(ofdmMod)

\section*{Construct OFDM Modulator from OFDM Demodulator}

An OFDM modulator System object \({ }^{\text {TM }}\) can be constructed from an existing OFDM demodulator System object.

Construct an OFDM demodulator, ofdmDemod and specify pilot indices for a single symbol and two transmit antennas.

Note: You can set the PilotCarrierIndices property in the demodulator object, which then changes the number of transmit antennas in the modulator object. The number of receive antennas in the demodulator is uncorrelated with the number of transmit antennas.
```

ofdmDemod = comm.OFDMDemodulator;
ofdmDemod.PilotOutputPort = true;
ofdmDemod.PilotCarrierIndices = cat(3,[12; 26; 40; 54],...
[13; 27; 41; 55]);

```

Use the demodulator, ofdmDemod, to construct the OFDM modulator.
```

ofdmMod = comm.OFDMModulator(ofdmDemod);

```

Display the properties of the modulator and verify that they match those of the demodulator.
disp(ofdmMod)
```

    comm.OFDMModulator with properties:
                            FFTLength: 64
    NumGuardBandCarriers: [2x1 double]
            InsertDCNull: false
            PilotInputPort: true
        PilotCarrierIndices: [4x1x2 double]
        CyclicPrefixLength: 16
                            Windowing: false
                            NumSymbols: 1
        NumTransmitAntennas: 2
    disp(ofdmDemod)
comm.OFDMDemodulator with properties:
FFTLength: 64
NumGuardBandCarriers: [2x1 double]
RemoveDCCarrier: false
PilotOutputPort: true
PilotCarrierIndices: [4x1x2 double]
CyclicPrefixLength: 16
NumSymbols: 1
NumReceiveAntennas: 1

```

\section*{Visualize Time-Frequency Resource Assignments for OFDM Modulator}

The showResourceMapping method displays the time-frequency resource mapping for each transmit antenna.

Construct an OFDM modulator.
mod \(=\) comm.OFDMModulator;
Apply the showResourceMapping method.
showResourceMapping(mod)

```

Insert a DC null.
mod.InsertDCNull = true;

```

Show the resource mapping after adding the DC null.
showResourceMapping(mod)

\section*{Create Modulator and Specify Pilots}

The OFDM modulator enables you to specify the subcarrier indices for the pilot signals. The indices can be specified for each symbol and transmit antenna. When there is more than one transmit antenna, ensure that the pilot indices for each symbol differ between antennas.

Construct an OFDM modulator that has two symbols and insert a DC null.
```

mod = comm.OFDMModulator('FFTLength',128,'NumSymbols',2,...
'InsertDCNull',true);

```

Turn on the pilot input port so you can specify the pilot indices.
mod.PilotInputPort = true;
Specify the same pilot indices for both symbols.
mod.PilotCarrierIndices \(=\) [12; 56; 89; 100];
Visualize the placement of the pilot signals and nulls in the OFDM time-frequency grid using the showResourceMapping method.
showResourceMapping(mod)

Concatenate a second column of pilot indices to the PilotCarrierIndices property to specify different indices for the second symbol.
mod.PilotCarrierIndices = cat(2, mod.PilotCarrierIndices, ...
[17; 61; 94; 105]);
Verify that the pilot subcarrier indices differ between symbols.
showResourceMapping(mod)

Increase the number of transmit antennas to two.
mod.NumTransmitAntennas = 2;
Specify the pilot indices for each of the two transmit antennas. To provide indices for multiple antennas while minimizing interference among the antennas, populate the PilotCarrierIndices property as a 3-D array such that the indices for each symbol differ among antennas.
```

mod.PilotCarrierIndices = cat(3,[20; 50; 70; 110], ...
[15; 60; 75; 105]);

```

Display the resource mapping for the two transmit antennas. The gray lines denote the insertion of custom nulls. The nulls are created by the object to minimize interference among the pilot symbols from different antennas.
showResourceMapping(mod)

\section*{Create Modulator with Varying Cyclic Prefix Lengths}

Specify the length of the cyclic prefix for each OFDM symbol.
Construct an OFDM modulator having five symbols, four left guard-band subcarriers, and three right guard-band subcarriers. Specify the cyclic prefix length for each OFDM symbol.
mod \(=\) comm.0FDMModulator('NumGuardBandCarriers',[4;3],...
'NumSymbols',5,...
'CyclicPrefixLength',[12 101411 13]);
Display the properties of the modulator and verify that the cyclic prefix length changes across symbols.
```

disp(mod)
comm.OFDMModulator with properties:
FFTLength: 64
NumGuardBandCarriers: [2x1 double]
InsertDCNull: false
PilotInputPort: false
CyclicPrefixLength: [12 10 14 11 13]
Windowing: false

```

NumSymbols: 5
NumTransmitAntennas: 1

\section*{Info Method to Determine OFDM Modulator Data Dimensions}

Determine the OFDM modulator data dimensions by using the info method.
Construct an OFDM modulator System object \({ }^{\text {TM }}\) with user-specified pilot indices, insert a DC null, and specify two transmit antennas.
```

hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
'PilotInputPort',true, ...
'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
[11; 25; 39; 53]), ...
'InsertDCNull',true, ...
'NumTransmitAntennas',2);

```

Use the info method to find the modulator input data, pilot input data, and output data sizes.
```

info(hMod)
ans = struct with fields:
DataInputSize: [48 1 2]
PilotInputSize: [4 1 2]
OutputSize: [80 2]

```

\section*{Create OFDM Modulated Data}

Generate OFDM modulated symbols for use in link-level simulations.
Construct an OFDM modulator with an inserted DC null, seven guard-band subcarriers, and two symbols having different pilot indices for each symbol.
```

mod = comm.OFDMModulator('NumGuardBandCarriers',[4;3],...
'PilotInputPort',true, ...
'PilotCarrierIndices',[12 11; 26 27; 40 39; 54 55], ...
'NumSymbols',2, ...
'InsertDCNull',true);
Determine input data, pilot, and output data dimensions.
modDim $=$ info(mod);

```

Generate random data symbols for the OFDM modulator. The structure variable, modDim, determines the number of data symbols.
```

dataIn = complex(randn(modDim.DataInputSize),randn(modDim.DataInputSize));

```

Create a pilot signal that has the correct dimensions.
```

pilotIn = complex(rand(modDim.PilotInputSize),rand(modDim.PilotInputSize));

```

Apply OFDM modulation to the data and pilot signals.
modData \(=\) step \((\bmod\), dataIn, pilotIn);
Use the OFDM modulator object to create the corresponding OFDM demodulator.
```

demod = comm.OFDMDemodulator(mod);

```

Demodulate the OFDM signal and output the data and pilot signals.
```

[dataOut, pilotOut] = step(demod,modData);

```

Verify that, within a tight tolerance, the input data and pilot symbols match the output data and pilot symbols.
```

isSame = (max(abs([dataIn(:) - dataOut(:); ...
pilotIn(:) - pilotOut(:)])) < 1e-10)
isSame = logical
1

```

\section*{More About}

\section*{Orthogonal Frequency Division Modulation}

Orthogonal frequency division modulation (OFDM) divides a high-rate transmit data stream into \(N\) lower-rate streams, each of which has a symbol duration larger than the channel delay spread and, therefore, mitigates intersymbol interference (ISI). The individual substreams are sent over \(N\) parallel subchannels which are orthogonal to each other. Through the use of an inverse fast Fourier transform (IFFT), OFDM can be transmitted using a single radio. The output is a baseband representation of the modulated signal:
\[
v(t)=\sum_{k=0}^{N-1} X_{k} e^{j 2 \pi k \Delta f t}, \quad 0 \leq t \leq T
\]
where \(\left\{X_{k}\right\}\) are data symbols, \(N\) is the number of subcarriers, and \(T\) is the OFDM symbol time. The subcarrier spacing of \(\Delta f=1 / T\) makes the symbols orthogonal over each symbol period. This orthogonality is expressed as:
\[
\frac{1}{T} \int_{0}^{T}\left(e^{j 2 \pi m \Delta f t}\right) *\left(e^{j 2 \pi n \Delta f t}\right) d t=\frac{1}{T} \int_{0}^{T} e^{j 2 \Pi(m-n) \Delta f t} d t=0 \quad \text { for } m \neq n
\]

The data symbols, \(X_{k}\), are usually complex and can be from any modulation alphabet such as QPSK, 16-QAM, or 64-QAM.

This figure shows an OFDM modulator consisting of a bank of \(N\) complex modulators, where each modulator corresponds to one OFDM subcarrier.

\section*{Guard Bands and Intervals}

OFDM has three types of subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data, and pilot subcarriers are used for channel estimation. Null subcarriers, which provide a DC null and provide buffers between OFDM resource blocks, are not transmitted. These buffers are referred to as guard bands whose purpose is to prevent intersymbol interference. The allocation of nulls and guard bands vary depending on the applicable standard such as 802.11n differs from LTE.

Analogous to the concept of guard bands, the OFDM also supports guard intervals, which to provide temporal separation between OFDM symbols so that the signal does not lose orthogonality due to time-dispersive channels. As long as the guard interval is longer than the delay spread, symbols do not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. Using a cyclic prefix increases overhead.

\section*{Raised Cosine Windowing}

While the cyclic prefix creates a guard period in time domain to preserve orthogonality, an OFDM symbol rarely begins with the same amplitude and phase exhibited at the end of the prior OFDM symbol causing spectral regrowth and therefore, spreading of signal bandwidth due to intermodulation distortion. To limit this spectral regrowth, it is desired to create a smooth transition between the last sample of a symbol and the first sample of the next symbol. This can be done by using a cyclic suffix and raised cosine windowing.

To create the cyclic suffix, the first \(N_{\text {WIN }}\) samples of a given symbol are appended to the end of that symbol. However, in order to comply with the 802.11 g standard, for example, the length of a symbol cannot be arbitrarily lengthened. Instead, the cyclic suffix must overlap in time and is effectively summed with the cyclic prefix of the following symbol. This overlapped segment is where windowing is applied. Two windows are applied, one of which is the mathematical inverse of the other. The first raised cosine window is applied to the cyclic suffix of symbol \(k\) and decreases from 1 to 0 over its duration. The second raised cosine window is applied to the cyclic prefix of symbol \(k+1\) and increases from 0 to 1 over its duration. This process provides a smooth transition from one symbol to the next.

The raised cosine window, \(w(t)\), in the time domain can be expressed as:
\[
w(t)=\left\{\begin{array}{l}
1,0 \leq|t|<\frac{T-T_{W}}{2} \\
\frac{1}{2}\left\{1+\cos \left[\frac{\Pi}{T_{W}}\left(|t|-\frac{T-T_{W}}{2}\right)\right]\right\}, \frac{T-T_{W}}{2} \leq|t| \leq \frac{T+T_{W}}{2} \\
0, \text { otherwise }
\end{array}\right.
\]
where:
- \(T\) is the OFDM symbol duration including the guard interval.
- \(T_{\mathrm{W}}\) is the duration of the window.

Adjust the length of the cyclic suffix via the window length setting property, with suffix lengths set between 1 and the minimum cyclic prefix length. While windowing improves spectral regrowth, it does so at the expense of multipath fading immunity. This occurs because redundancy in the guard band is reduced because the guard band sample values are compromised by the smoothing.

The following figures display the application of raised cosine windowing.

\section*{comm.OFDMDemodulator}

Package: comm
Demodulate using OFDM method

\section*{Description}

The OFDMDemodulator object demodulates using the orthogonal frequency division demodulation method. The output is a baseband representation of the modulated signal, which was input into the OFDMModulator companion object.

To demodulate an OFDM signal:
1 Define and set up the OFDM demodulator object. See "Construction" on page 3-228.
2 Call step to demodulate a signal according to the properties of comm. OFDMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
\(\mathrm{H}=\) comm. OFDMDemodulator creates a demodulator System object, H , that demodulates an input signal by using the orthogonal frequency division demodulation method.

H = comm.OFDMDemodulator(Name,Value) creates an OFDM demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).
\(\mathrm{H}=\) comm. OFDMDemodulator(hMod) creates an OFDM demodulator object, H , whose properties are determined by the corresponding OFDM modulator object, hMod.

\section*{Properties}

\section*{FFTLength}

The length of the FFT, \(N_{\mathrm{FFT}}\), is equivalent to the number of subcarriers used in the modulation process. FFTLength must be \(\geq 8\).

Specify the number of subcarriers. The default is 64 .

\section*{NumGuardBandCarriers}

The number of guard band subcarriers allocated to the left and right guard bands.
Specify the number of left and right subcarriers as nonnegative integers in \(\left[0, N_{\mathrm{FFT}} / 2-1\right]\) where you specify the left, \(N_{\text {leftG }}\), and right, \(N_{\text {rightG }}\), guard bands independently in a 2-by-1 column vector. The default values are [6; 5].

\section*{RemoveDCCarrier}

A logical variable that when true, mandates removal of a DC subcarrier. The default value is false.

\section*{PilotOutputPort}

A logical property that controls whether to separate the pilot signals and make them available at an additional output port. The location of each pilot output symbol is determined by the pilot subcarrier indices specified in the PilotCarrierIndices property. When false, pilot symbols may be present but embedded in the data. The default value is false.

\section*{PilotCarrierIndices}

If the PilotOutputPort property is true, output separate pilot signals located at the indices specified by the PilotCarrierIndices property. If the indices are a 2-D array, the pilot carriers across all the transmit antennas per symbol are the same. If there is more than one transmit antenna (this information is not known by the demodulator), the pilots from different transmit antennas may interfere with each other. To avoid this, specify the pilot carrier indices as a 3-D array with different pilot indices for each symbol across the antennas. This avoids interference between pilots from different transmit antennas, since, on a per-symbol basis, each transmit antenna has different pilot carriers and the OFDM modulator creates custom nulls at the appropriate locations. The size of the third dimension of the PilotCarrierIndices property gives the number of transmit antennas.

\section*{CyclicPrefixLength}

The cyclic prefix length property specifies the length of the OFDM cyclic prefix. If you specify a scalar, the prefix length is the same for all symbols through all antennas. If you specify a row vector of length \(N_{\text {sym }}\), the prefix length can vary across symbols but remains the same length through all antennas. The default value is 16 .

\section*{NumSymbols}

This property specifies the number of symbols, \(N_{\text {sym }}\). Specify \(N_{\text {sym }}\) as a positive integer. The default value is 1 .

\section*{NumReceiveAntennnas}

This property determines the number of antennas, \(N_{R}\), used to receive the OFDM modulated signal. Specify \(N_{\mathrm{R}}\) as a positive integer. The default value is 1 .

modSig = step(mod,dataIn,pilotIn);

```

Use the OFDM modulator object to create the corresponding OFDM demodulator.
```

demod = comm.OFDMDemodulator(mod);

```

Demodulate the OFDM signal and output the data and pilot signals.
```

[dataOut,pilotOut] = step(demod,modSig);

```

Verify that the input data and pilot symbols match the output data and pilot symbols.
```

isSame = (max(abs([dataIn(:) - dataOut(:); ...
pilotIn(:) - pilotOut(:)])) < 1e-10)
isSame = logical
1

```

\section*{Algorithms}

The Orthogonal Frequency Division Modulation (OFDM) Demodulator System object demodulates an OFDM input signal by using an FFT operation that results in \(N\) parallel data streams.

The figure shows an OFDM demodulator. It consists of a bank of \(N\) correlators with one assigned to each OFDM subcarrier followed by a parallel-to-serial conversion.

\section*{Guard Bands and Intervals}

There are three types of OFDM subcarriers: data, pilot, and null. Data subcarriers are used for transmitting data while pilot subcarriers are used for channel estimation. There is no transmission on null subcarriers, which are used to provide a DC null as well as to provide buffers between OFDM resource blocks. These buffers are referred to as guard bands whose purpose is to prevent intersymbol interference. The allocation of nulls and guard bands varies depending upon the standard, e.g., 802.11n differs from LTE. Consequently, the OFDM modulator object allows the user to assign subcarrier indices as required.

Analogous to the concept of guard bands, the OFDM modulator object supports guard intervals that provide temporal separation between OFDM symbols so that the signal does not lose orthogonality
due to time-dispersive channels. As long as the guard interval is longer than the delay spread, each symbol does not interfere with other symbols. Guard intervals are created by using cyclic prefixes in which the last part of an OFDM symbol is copied and inserted as the first part of the OFDM symbol. The benefit of cyclic prefix insertion is maintained as long as the span of the time dispersion does not exceed the duration of the cyclic prefix. The OFDM modulator object enables the cyclic prefix length to be set. The drawback in using a cyclic prefix is increased overhead.

\section*{info}

System object: comm. OFDMDemodulator
Package: comm
Provide dimensioning information for the OFDM method

\section*{Syntax}
\(Y=i n f o(H)\)

\section*{Description}
\(Y=\) info( H ) provides data dimensioning information for the OFDM demodulator System object, H . It returns the expected dimensions for data input into the OFDM demodulator, for the pilot output, and for the data output from the demodulator. The output, Y , is a structure containing three fields: InputSize, DataOutputSize, and PilotOutputSize.
Y.InputSize

Gives the dimensions of the demodulator input data, \(\left[\left(\mathrm{N}_{\mathrm{FFT}}+\mathrm{N}_{\mathrm{CP}}\right) \times \mathrm{N}_{\mathrm{sym}}\right]\)-by- \(\mathrm{N}_{\mathrm{r}}\), where \(\mathrm{N}_{\mathrm{FFT}}\) is the number of subcarriers, \(\mathrm{N}_{\mathrm{CP}}\) is the length of the cyclic prefix, \(\mathrm{N}_{\text {sym }}\) is the number of symbols, and \(N_{r}\) is the number of receive antennas.
Y.DataOutputSize

Shows the dimensions of the demodulator output data, \(\mathrm{N}_{\text {data }}-\mathrm{by}-\mathrm{N}_{\mathrm{sym}}-\mathrm{by}-\mathrm{N}_{\mathrm{r}}\), where \(\mathrm{N}_{\text {data }}\) is the number of data subcarriers such that \(N_{\text {data }}=N_{\text {FFT }}-N_{\text {leftG }}-N_{\text {rightG }}-N_{\text {DCNull }}-N_{\text {pilot }}-N_{\text {custNull }}\). The variables are defined as follows:
\begin{tabular}{ll}
\(\mathrm{N}_{\text {FFT }}\) & Number of subcarriers \\
\(\mathrm{N}_{\text {leftG }}\) & Number of subcarriers in the left guard band \\
\(\mathrm{N}_{\text {rightG }}\) & Number of subcarriers in the right guard \\
\(\mathrm{N}_{\text {DCNull }}\) & \begin{tabular}{l} 
band
\end{tabular} \\
\(\mathrm{N}_{\text {pilot }}\) & \begin{tabular}{l} 
Number of subcarriers in the DC null (either \\
0 or 1)
\end{tabular} \\
\(\mathrm{N}_{\text {custNull }}\) & Number of pilot subcarriers \\
& Number of subcarriers used for custom nulls
\end{tabular}
Y.PilotOutputSize

Provides the dimensions of the pilot signal output array, \(\mathrm{N}_{\text {pilot }}-\mathrm{by}-\mathrm{N}_{\text {sym }}\)-by- \(\mathrm{N}_{\mathrm{r}}\) or \(\mathrm{N}_{\text {pilot }}-\mathrm{by}-\mathrm{N}_{\text {sym }}\)-by- \(\mathrm{N}_{\mathrm{t}}-\) by- \(\mathrm{N}_{\mathrm{r}}\), depending on the number of transmit antennas.

\section*{Description}
reset \((\mathrm{H})\) resets the states of the OFDMDemodulator object, H .
This method resets the windowed suffix from the last symbol in the previously processed frame.

\section*{showResourceMapping}

System object: comm. OFDMDemodulator
Package: comm
Show the subcarrier mapping of the OFDM symbols created by the OFDM demodulator System object

\section*{Syntax}
showResourceMapping(H)
showResourceMapping(H,CI)

\section*{Description}
showResourceMapping (H) shows a visualization of the subcarrier mapping for the OFDM symbols used by the OFDM demodulator System object, H. The subcarrier indices are numbered from 1 to \(N_{\text {FFT }}\).
showResourceMapping ( \(\mathrm{H}, \mathrm{CI}\) ) shows the resource mapping where the optional argument, CI , is used to number the subcarrier indices that will be displayed. CI is a 1 x 2 integer row vector such that \(\operatorname{diff}(C I)=N_{F F T}-1\).

\section*{step}

System object: comm. OFDMDemodulator
Package: comm
Demodulate using OFDM method

\section*{Syntax}

Y = step (H,X)
[Y,PILOT] = step(H,X)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

Y = step ( \(\mathrm{H}, \mathrm{X}\) ) demodulates input data, X , with the OFDM demodulator System object, H, and returns the baseband demodulated output, Y. The input is a double-precision, real or complex, 2-D matrix of symbols whose dimensions are a function of the number of subcarriers, the cyclic prefix length, and the number of receive antennas. You can determine the dimensions by using the info method. The output, Y , is a double-precision, complex, 3-D array.
[ \(\mathrm{Y}, \mathrm{PILOT}]=\operatorname{step}(\mathrm{H}, \mathrm{X})\) separates the PILOT signal on the subcarriers specified by the PilotCarrierIndices property value of H . This syntax applies when the PilotOutputPort property of H is true. PILOT is a double-precision, complex, 3-D array.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.CarrierSynchronizer}

Package: comm
Compensate for carrier frequency offset

\section*{Description}

The comm. CarrierSynchronizer System object compensates for carrier frequency and phase offsets in signals that use single-carrier modulation schemes. The carrier synchronizer algorithm is compatible with BPSK, QPSK, OQPSK, 8-PSK, PAM, and rectangular QAM modulation schemes.

\section*{Note}
- This System object does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:
\begin{tabular}{|l|l|}
\hline Modulation & Phase Ambiguity (degrees) \\
\hline 'BPSK' or 'PAM' & 0,180 \\
\hline ' \(O Q P S K\) ' , 'QPSK ' , or ' QAM' ' & \(0,90,180,270\) \\
\hline ' 8 PSK' & \(0,45,90,135,180,225,270,315\) \\
\hline
\end{tabular}

The "Examples" on page 3-0 demonstrate carrier synchronization and resolution of phase ambiguity.
- For best results, apply carrier synchronization to non-oversampled signals, as demonstrated in "Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization" on page 3-250.

To compensate for frequency and phase offsets in signals that use single-carrier modulation schemes:
1 Create the comm. CarrierSynchronizer object and set its properties.
2 Call the object, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
```

carrSynch = comm.CarrierSynchronizer
carrSynch = comm.CarrierSynchronizer(Name,Value)

```

\section*{Description}
carrSynch = comm. CarrierSynchronizer creates a System object that compensates for carrier frequency offset and phase offset in signals that use single-carrier modulation schemes.
carrSynch = comm. CarrierSynchronizer(Name, Value) sets properties using one or more name-value pairs. Enclose each property name in quotes.

\section*{Properties}

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

\section*{Modulation - Modulation type}
'QAM' (default) | '8PSK' | 'BPSK' | '0QPSK' | 'PAM' | 'QPSK'
Modulation type, specified as 'QAM', '8PSK', 'BPSK', 'OQPSK', 'PAM', or 'QPSK'.
Example: comm. CarrierSynchronizer('Modulation', 'QPSK') creates a carrier synchronizer System object to use with a QPSK modulated signal.

Tunable: No

\section*{ModulationPhaseOffset - Modulation phase offset method}
'Auto ' (default)|'Custom'
Modulation phase offset method, specified as 'Auto' or 'Custom'.
- 'Auto ' - Apply the traditional offset for the specified modulation type.
\begin{tabular}{|l|l|}
\hline Modulation & Phase Offset (radians) \\
\hline 'BPSK', 'QAM', or 'PAM' & 0 \\
\hline ' 0 'PPSK' or 'QPSK' & \(\Pi / 4\) \\
\hline ' 8 PSK' & \(\Pi / 8\) \\
\hline
\end{tabular}
- 'Custom' - Specify a user-defined phase offset with the CustomPhaseOffset property.

Tunable: Yes

\section*{CustomPhaseOffset - Custom phase offset \\ 0 (default) | scalar}

Custom phase offset in radians, specified as a scalar.

\section*{Dependencies}

This property applies when the ModulationPhaseOffset property is set to 'Custom'.
Data Types: double

\section*{SamplesPerSymbol - Number of samples per symbol \\ 2 (default) | positive integer}

Number of samples per symbol, specified as a positive integer.
Tunable: Yes
Data Types: double
DampingFactor - Damping factor of loop
0.707 (default) | positive scalar

Damping factor of the loop, specified as a positive scalar.
Tunable: Yes
Data Types: double

\section*{NormalizedLoopBandwidth - Normalized bandwidth of loop}
0.01 (default) | scalar

Normalized bandwidth of the loop, specified as a scalar in the range ( 0,1 ]. The loop bandwidth is normalized by the sample rate of the synchronizer.

Decreasing the loop bandwidth reduces the synchronizer convergence time but also reduces the pullin range of the synchronizer.

Tunable: Yes
Data Types: double

\section*{Usage}

\section*{Syntax}
[outSig, phErr] = carrSynch(inSig)

\section*{Description}
[outSig, phErr] = carrSynch(inSig) compensates for frequency offset and phase offset in the input signal. This System object returns a compensated output signal and an estimate of the phase error.

\section*{Input Arguments}

\section*{inSig - Input signal}
scalar | column vector
Input signal, specified as a complex scalar or a column vector of complex values.
Data Types: double | single
Complex Number Support: Yes

\section*{Output Arguments \\ outSig - Output signal \\ scalar (default) | column vector}

Output signal, returned as a scalar or column vector with the same data type and length as inSig. The output signal adjusts the input signal compensating for carrier frequency and phase offsets in signals that use single-carrier modulation schemes.

\section*{phErr - Phase error estimate}
scalar (default) | column vector
Phase error estimate in radians, returned as a scalar or column vector with the same length as inSig.

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
```

release(obj)

```

\section*{Specific to comm.CarrierSynchronizer}
info Characteristic information about carrier synchronizer
clone Create duplicate System object
isLocked Determine if System object is in use

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Correct Phase and Frequency Offset in QPSK Link}

Correct phase and frequency offsets of a QPSK signal passed through an AWGN channel. Using preambles, resolve phase ambiguity.

Define the simulation parameters.
```

M = 4; % Modulation order
rng(1993) % For repeatable results
barker = comm.BarkerCode(...
'Length',13,'SamplesPerFrame',13); % For preamble
msgLen = le4;
numFrames = 10;
frameLen = msgLen/numFrames;

```

Add preambles to each frame, which are used later when performing phase ambiguity resolution. Generate random data symbols, and apply QPSK modulation.
```

preamble = (1+barker())/2; % Length 13, unipolar
data = zeros(msgLen,1);
for idx = 1 : numFrames
payload = randi([0 M-1],frameLen-barker.Length,1);
data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end
modSig = pskmod(data,4,pi/4);

```

Create a comm. PhaseFrequencyOffset System object \({ }^{\mathrm{TM}}\) to introduce phase and frequency offsets to the modulated input signal. Set the phase offset to 45 degrees, frequency offset to 1 kHz , and sample rate to 10 kHz . The frequency offset is set to \(1 \%\) of the sample rate.
```

pfo = comm.PhaseFrequency0ffset('Phase0ffset',45, ...
'Frequency0ffset',1e4,'SampleRate',1e6);

```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets with samples per symbol set to 1 .
```

carrierSync = comm.CarrierSynchronizer( ...
'SamplesPerSymbol',1,'Modulation','QPSK');

```

Apply phase and frequency offsets using the pfo System object, and then pass the signal through an AWGN channel to add white Gaussian noise.
```

modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,12);

```

Display the scatter plot of the received signal. The data appear in a circle instead of being grouped around the reference constellation points due to the frequency offset.
```

scatterplot(rxSig)

```

Use the carrierSync System object to correct the phase and frequency offset in the received signal. syncSignal = carrierSync(rxSig);

Use a constellation diagram to display the first and last 1000 symbols of the synchronized signal. Before convergence of the synchronizer loop, the plotted symbols are not grouped around the reference constellation points. After convergence, the plotted symbols are grouped around the reference constellation points.
```

constDiag = comm.ConstellationDiagram( ...
'SymbolsToDisplaySource','Property','SymbolsToDisplay',300, ...
'ChannelNames',{'Before convergence','After convergence'},'ShowLegend',true, ...
'Position',[400 400 400 400]);
constDiag([syncSignal(1:1000) syncSignal(9001:10000)]);

```

Demodulate the synchronized signal. Compute and display the total bit errors and BER.
```

syncData = pskdemod(syncSignal,4,pi/4);
[syncDataTtlErr,syncDataBER] = biterr(data(6000:end),syncData(6000:end))
syncDataTtlErr = 3990
syncDataBER = 0.4986

```

Phase ambiguity in the received signal might cause bit errors. Using the preamble, determine phase ambiguity. Remove this phase ambiguity from the synchronized signal to reduce bit errors.
```

idx = 9000 + (1:barker.Length);
phOffset = angle(modSig(idx) .* conj(syncSignal(idx)));
phOffset = round((2/pi) * phOffset); % -1, 0, 1, +/-2
phOffset(phOffset==-2) = 2; % Prep for mean operation
phOffset = mean((pi/2) * phOffset); % -pi/2, 0, pi/2, or pi
disp(['Estimated mean phase offset = ',num2str(phOffset*180/pi),' degrees'])
Estimated mean phase offset = 180 degrees
resPhzSig = exp(li*phOffset) * syncSignal;

```

Demodulate the signal after resolving the phase ambiguity. Recompute and display the updated total bit errors and BER. Removing the phase ambiguity reduces the BER dramatically.
```

resPhzData = pskdemod(resPhzSig,4,pi/4);
[resPhzTtlErr, resPhzBER] = biterr(data(6000:end),resPhzData(6000:end))
resPhzTtlErr = 403
resPhzBER = 0.0504

```

\section*{Estimate Frequency Offset in an 8-PSK Link}

Estimate the frequency offset introduced into a noisy 8-PSK signal using a carrier synchronizer System object \({ }^{\mathrm{TM}}\).

Define the simulation parameters.
```

M = 8; % Modulation order
fs = le6; % Sample rate (Hz)
foffset = 1000; % Frequency offset (Hz)
phaseoffset = 15; % Phase offset (deg)
snrdb = 20; % Signal-to-noise ratio (dB)

```

Create a comm. PhaseFrequencyOffset System object to introduce phase and frequency offsets to a modulated signal.
```

pfo = comm.PhaseFrequency0ffset('Phase0ffset',phaseoffset, ...
'Frequency0ffset',foffset,'SampleRate',fs);

```

Create a carrier synchronizer System object to use for correcting the phase and frequency offsets. Set the Modulation property to 8PSK.
```

carrierSync = comm.CarrierSynchronizer('Modulation','8PSK');

```

Generate random data and apply 8-PSK modulation.
```

data = randi([0 M-1],5000,1);
modSig = pskmod(data,M, pi/M);

```

Apply phase and frequency offsets using the pfo System object, and pass the signal through an AWGN channel to add Gaussian white noise.
```

modSigOffset = pfo(modSig);
rxSig = awgn(modSigOffset,snrdb);

```

Use the carrier synchronizer to estimate the phase offset of the received signal.
[~, phError] = carrierSync(rxSig);
Determine the frequency offset by using the diff function to compute an approximate derivative of the phase error. The derivative must be scaled by \(2 \pi\) because the phase error is measured in radians.
```

estFreqOffset = diff(phError)*fs/(2*pi);

```

Plot the running mean of the estimated frequency offset. After the synchronizer converges to a solution, the mean value of the estimate is approximately equal to the input frequency offset value of 1000 Hz .
```

rmean = cumsum(estFreq0ffset)./(1:length(estFreq0ffset))';
plot(rmean)
xlabel('Symbols')
ylabel('Estimated Frequency Offset (Hz)')
grid

```

\section*{Correct Phase and Frequency Offset for 16-QAM Using Coarse and Fine Synchronization}

Compensation of significant phase and frequency offsets for a 16-QAM signal in an AWGN channel is accomplished in two steps. First, correct the coarse frequency offset using the estimate provided by the coarse frequency compensator, and then fine-tune the correction using carrier synchronization. Because of the coarse frequency correction, the carrier synchronizer converges quickly even though the normalized bandwidth is set to a low value. Lower normalized bandwidth values enable better correction for small residual carrier offsets. After applying phase and frequency offset corrections to the received signal, resolve phase ambiguity using the preambles.

Define the simulation parameters.
```

fs = 10000; % Sample rate (Hz)
sps = 4; % Samples per symbol

```
```

M = 16; % Modulation order
k = log2(M); % Bits per symbol
rng(1996) % Set seed for repeatable results
barker = comm.BarkerCode(...
'Length',13,'SamplesPerFrame',13); % For preamble
msgLen = le4;
numFrames = 10;
frameLen = msgLen/numFrames;

```

Generate data payloads and add the preamble to each frame. The preamble is later used for phase ambiguity resolution.
```

preamble = (1+barker())/2; % Length 13, unipolar
data = zeros(msgLen, 1);
for idx = 1 : numFrames
payload = randi([0 M-1],frameLen-barker.Length,1);
data((idx-1)*frameLen + (1:frameLen)) = [preamble; payload];
end

```

Create a System object for the transmit pulse shape filtering, the receive pulse shape filtering, the QAM coarse frequency compensation, the carrier synchronization, and a constellation diagram.
```

txFilter = comm.RaisedCosineTransmitFilter( ...
'OutputSamplesPerSymbol',sps);
rxFilter = comm.RaisedCosineReceiveFilter(...
'InputSamplesPerSymbol',sps,'DecimationFactor',sps);
coarse = comm.CoarseFrequencyCompensator('SampleRate',fs, ...
'FrequencyResolution',10);
fine = comm.CarrierSynchronizer( ...
'DampingFactor',0.4,'NormalizedLoopBandwidth',0.001, ...
'SamplesPerSymbol',1,'Modulation','QAM');
axislimits = [-6 6];
constDiagram = comm.ConstellationDiagram('ReferenceConstellation',qammod(0:M-1,M), ...
'ChannelNames',{'Before convergence','After convergence'}, ...
'ShowLegend',true,'XLimits',axislimits,'YLimits',axislimits);

```

Also create a System object for the AWGN channel, and the phase and frequency offset to add impairments to the signal. A phase offset greater than 90 degrees is added to induce a phase ambiguity that results in a constellation quadrant shift.
```

ebn0 = 8;
freqoffset = 110;
phaseoffset = 110;
awgnChannel = comm.AWGNChannel('EbNo',ebn0, ...
'BitsPerSymbol',k,'SamplesPerSymbol',sps);
pfo = comm.PhaseFrequency0ffset('Frequency0ffset',freqoffset, ...
'Phase0ffset',phaseoffset,'SampleRate',fs);

```

Generate random data symbols, apply 16-QAM modulation, and pass the modulated signal through the transmit pulse shaping filter.
```

txMod = qammod(data,M);
txSig = txFilter(txMod);

```

Apply phase and frequency offsets using the pfo System object, and then pass the signal through an AWGN channel to add white Gaussian noise.
```

txSigOffset = pfo(txSig);
rxSig = awgnChannel(txSigOffset);

```

The coarse frequency compensator System object provides a rough correction for the frequency offset. For the conditions in this example, correcting the frequency offset of the received signal correction to within 10 Hz of the transmitted signal is sufficient.
syncCoarse = coarse(rxSig);
Pass the signal through the receive pulse shaping filter, and apply fine frequency correction.
```

rxFiltSig = fine(rxFilter(syncCoarse));

```

Display the constellation diagram of the first and last 1000 symbols in the signal. Before convergence of the synchronization loop, the spiral nature of the diagram indicates that the frequency offset is not corrected. After the carrier synchronizer has converged to a solution, the symbols are aligned with the reference constellation.
```

constDiagram([rxFiltSig(1:1000) rxFiltSig(9001:end)])

```

Demodulate the signal. Account for the signal delay caused by the transmit and receive filters to align the received data with the transmitted data. Compute and display the total bit errors and BER. When checking the bit errors, use the later portion of the received signal to be sure the synchronization loop has converged.
```

rxData = qamdemod(rxFiltSig,M);
delay = (txFilter.FilterSpanInSymbols + rxFilter.FilterSpanInSymbols) / 2;
idxSync = 2000; % Check BER for the received signal after the synchronization loop has converged
[syncDataTtlErr,syncDataBER] = biterr(data(idxSync:end-delay),rxData(idxSync+delay:end))
syncDataTtlErr = 16116
syncDataBER = 0.5042

```

Depending on the random data used, there may be bit errors resulting from phase ambiguity in the received signal after the synchronization loop converges and locks. In this case, you can use the preamble to determine and then remove the phase ambiguity from the synchronized signal to reduce bit errors. If phase ambiguity is minimal, the number of bit errors may be unchanged.
```

idx = 9000 + (1:barker.Length);
phOffset = angle(txMod(idx) .* conj(rxFiltSig(idx+delay)));
phOffsetEst = mean(ph0ffset);
disp(['Phase offset = ',num2str(rad2deg(phOffsetEst)),' degrees'])
Phase offset = -90.1401 degrees
resPhzSig = exp(li*phOffsetEst) * rxFiltSig;

```

Demodulate the signal after resolving the phase ambiguity. Recompute the total bit errors and BER.
```

resPhzData = qamdemod(resPhzSig,M);
[resPhzTtlErr,resPhzBER] = biterr(data(idxSync:end-delay),resPhzData(idxSync+delay:end))
resPhzTtlErr = 5
resPhzBER = 1.5643e-04

```

\section*{MSK Signal Recovery}

Model channel impairments such as timing phase offset, carrier frequency offset, and carrier phase offset for a minimum shift keying (MSK) signal. Use comm.MSKTimingSynchronizer and comm. CarrierSynchronizer System objects to synchronize such signals at the receiver. The MSK timing synchronizer recovers the timing offset, while a carrier synchronizer recovers the carrier frequency and phase offsets.

Initialize system variables by running the MATLAB script configureMSKSignalRecoveryEx. Define the logical control variable recoverTimingPhase to enable timing phase recovery, and recoverCarrier to enable carrier frequency and phase recovery.
```

configureMSKSignalRecoveryEx;
recoverTimingPhase = true;
recoverCarrier = true;

```

\section*{Modeling Channel Impairments}

Specify the sample delay, timingOffset, that the channel model applies. Create a variable fractional delay object to introduce the timing delay to the transmitted signal.
```

timing0ffset = 0.2;
varDelay = dsp.VariableFractionalDelay;

```

Create a comm. PhaseFrequency0ffset System object to introduce carrier phase and frequency offsets to a modulated signal. Because the MSK modulator upsamples the transmitted symbols, set the SampleRate property to the ratio of the samplesPerSymbol and the sample time, Ts.
```

freq0ffset = 50;
phaseOffset = 30;
pfo = comm.PhaseFrequencyOffset(...
'Frequency0ffset',freq0ffset, ...
'Phase0ffset',phase0ffset, ...
'SampleRate',samplesPerSymbol/Ts);

```

Create a comm. AWGNChannel System object to add white Gaussian noise to the modulated signal. The noise power is determined by the EbNo property, that is the bit energy to noise power spectral density ratio. Because the MSK modulator generates symbols with 1 Watt of power, set the signal power property of the AWGN channel System object to 1.
```

EbNo = 20 + 10*log10(samplesPerSymbol);
chAWGN = comm.AWGNChannel(...
'NoiseMethod','Signal to noise ratio (Eb/No)', ...
'EbNo',EbNo,...
'SignalPower',1, ...
'SamplesPerSymbol',samplesPerSymbol);

```

\section*{Timing Phase, Carrier Frequency, and Carrier Phase Synchronization}

Create an MSK timing synchronizer to recover symbol timing phase using a fourth-order nonlinearity method.
```

timeSync = comm.MSKTimingSynchronizer(...
'SamplesPerSymbol',samplesPerSymbol, ...
'ErrorUpdateGain',0.02);

```

Create a carrier synchronizer to recover both carrier frequency and phase. Because the MSK constellation is QPSK with a 0-degree phase offset, set the comm. CarrierSynchronizer accordingly.
```

phaseSync = comm.CarrierSynchronizer(...
'Modulation','QPSK', ...
'ModulationPhaseOffset','Custom', ...
'CustomPhaseOffset',0, ...
'SamplesPerSymbol',1);

```

\section*{Stream Processing Loop}

The simulation modulates data using MSK modulation. The modulated symbols pass through the channel model, which applies timing delay, carrier frequency and phase shift, and additive white Gaussian noise. The receiver performs timing phase and carrier frequency and phase recovery. Finally, the signal symbols are demodulated and the bit error rate is calculated. The plotResultsMSKSignalRecoveryEx script generates scatter plots in this order to show these effects:

1 Channel impairments
2 Timing synchronization
3 Carrier synchronization
At the end of the simulation, the example displays the timing phase, frequency, and phase estimates as a function of simulation time.
```

for p = 1:numFrames
%--------------------------------------------------------------------------
% Generate and modulate data
%----------------------------------------------------------------------------
txBits = randi([0 1],samplesPerFrame,1);
txSym = modem(txBits);
%-----------------------------------------------------------------------------
% Transmit through channel
%
% Add timing offset
rxSigTimingOff = varDelay(txSym,timingOffset*samplesPerSymbol);
%
% Add carrier frequency and phase offset
rxSigCFO = pfo(rxSigTimingOff);
%
% Pass the signal through an AWGN channel
rxSig = chAWGN(rxSigCFO);
%
% Save the transmitted signal for plotting
plot_rx = rxSig;
%
%------------------------------------------------------------------------------
% Timing recovery
%---------------------------------------------------------------------------
if recoverTimingPhase
% Recover symbol timing phase using fourth-order nonlinearity
% method
[rxSym,timEst] = timeSync(rxSig);
% Calculate the timing delay estimate for each sample
timEst = timEst(1)/samplesPerSymbol;
else
% Do not apply timing recovery and simply downsample the received
% signal
rxSym = downsample(rxSig,samplesPerSymbol);
timEst = 0;
end
% Save the timing synchronized received signal for plotting
plot_rxTimeSync = rxSym;
%-----------------------------------------------------------------------------
% Carrier frequency and phase recovery
%---------------------------------------------------------------------------
if recoverCarrier
% The following script applies carrier frequency and phase recovery
% using a second order phase-locked loop (PLL), and removes phase ambiguity
[rxSym,phEst] = phaseSync(rxSym);
removePhaseAmbiguityMSKSignalRecoveryEx;
freqShiftEst = mean(diff(phEst)/(Ts*2*pi));

```
        phEst \(=\bmod (m e a n(p h E s t), 360) ;\) in degrees
    else
        freqShiftEst \(=0\);
        phEst = 0;
    end
    \% Save the phase synchronized received signal for plotting
    plot_rxPhSync = rxSym;
    \% Demodulate the received symbols
    rxBits = demod(rxSym);
    \% Calculate the bit error rate
    errorStats = BERCalc(txBits,rxBits);
    \% Plot results
    \%------------------------------
plotResultsMSKSignalRecoveryEx;
end

Processing
Frame \(=500\)

Display the bit error rate and the total number of symbols processed by the error rate calculator.
```

BitErrorRate = errorStats(1)
TotalNumberOfSymbols = errorStats(3)

```

BitErrorRate =
4.0001e-06

TotalNumberOfSymbols =
499982

\section*{Conclusion and Further Experimentation}

The recovery algorithms are demonstrated by using constellation plots taken after timing, carrier frequency, and carrier phase synchronization.

Open the script to create a writable copy of this example and its supporting files. Then, to show the effects of the recovery algorithms, you can enable and disable the logical control variables recoverTimingPhase and recoverCarrier and rerun the simulation.

\section*{Appendix}

This example uses these scripts:
- configureMSKSignalRecoveryEx
- plotResultsMSKSignalRecoveryEx
- removePhaseAmbiguityMSKSignalRecoveryEx

\section*{Algorithms}

The comm. CarrierSynchronizer System object is a closed-loop compensator that uses the PLLbased algorithm described in [1]. The output of the synchronizer, \(y_{n}\), is a frequency-shifted version of the complex input signal, \(x_{n}\), for the nth sample. The synchronizer output is
\[
y_{\mathrm{n}}=x_{\mathrm{n}} e^{i \lambda_{\mathrm{n}}}
\]
where \(\lambda_{n}\) is the output of the direct digital synthesizer (DDS). The DDS is the discrete-time version of a voltage-controlled oscillator and is a core component of discrete-time phase locked loops. In the context of this System object, the DDS works as an integration filter.

To correct for the frequency offset, first the algorithm determines the phase error, \(e_{\mathrm{n}}\). The value of the phase error depends on the modulation scheme.
\begin{tabular}{|l|l|}
\hline Modulation & Phase Error \\
\hline QAM or QPSK & \begin{tabular}{l}
\(e_{n}=\operatorname{sgn}\left(\operatorname{Re}\left\{x_{n}\right\}\right) \times \operatorname{Im}\left\{x_{n}\right\}-\operatorname{sgn}\left(\operatorname{Im}\left\{x_{n}\right\}\right)\) \\
\(\times \operatorname{Re}\left\{x_{n}\right\}\)
\end{tabular} \\
& \begin{tabular}{l} 
For a detailed description of this equation, see \\
{\([1]\).}
\end{tabular} \\
\hline BPSK or PAM & \(e_{n}=\operatorname{sgn}\left(\operatorname{Re}\left\{x_{n}\right\}\right) \times \operatorname{Im}\left\{x_{n}\right\}\) \\
& \begin{tabular}{l} 
For a detailed description of this equation, see \\
{\([1]\).}
\end{tabular} \\
\hline
\end{tabular}

\hline Modulation & Phase Error \\
\hline 8-PSK & \begin{tabular}{l}
\[
\begin{aligned}
& e_{\mathrm{n}}= \\
& \left\{\begin{array}{l}
\operatorname{sgn}\left(\operatorname{Re}\left\{x_{\mathrm{n}}\right\}\right) \times \operatorname{Im}\left\{x_{n}\right\}-(\sqrt{2}-1) \operatorname{sgn}\left(\operatorname{Im}\left\{x_{n}\right\}\right) \times \operatorname{Re} \\
(\sqrt{2}-1) \operatorname{sgn}\left(\operatorname{Re}\left\{x_{n}\right\}\right) \times \operatorname{Im}\left\{x_{n}\right\}-\operatorname{sgn}\left(\operatorname{Im}\left\{x_{n}\right\}\right) \times \operatorname{Re}
\end{array}\right.
\end{aligned}
\] \\
For a detailed description of this equation, see [2].
\end{tabular} \\
\hline OQPSK & \[
\begin{aligned}
& e_{\mathrm{n}}=\operatorname{sgn}\left(\operatorname{Re}\left\{x_{\mathrm{n} \text {-SamplePerSymbol } / 2}\right\}\right) \\
& \times \operatorname{Im}\left\{x_{\mathrm{n}-\text { SamplePerSymbol } / 2}\right\}-\operatorname{sgn}\left(\operatorname{Im}\left\{x_{\mathrm{n}}\right\}\right) \\
& \times \operatorname{Re}\left\{x_{\mathrm{n}}\right\}
\end{aligned}
\] \\
\hline
\end{tabular}

To ensure system stability, the phase error passes through a biquadratic loop filter governed by
\[
\psi_{\mathrm{n}}=g_{\mathrm{I}} e_{\mathrm{n}}+\psi_{\mathrm{n}-1},
\]
where \(\psi_{\mathrm{n}}\) is the output of the loop filter at sample n , and \(g_{\mathrm{I}}\) is the integrator gain. The integrator gain is determined from the equation
\[
g_{\mathrm{I}}=\frac{4\left(\theta^{2} / d\right)}{K_{\mathrm{p}} K_{0}},
\]
where \(\theta, d, K_{0}\), and \(K_{\mathrm{p}}\) are determined from the System object properties. Specifically,
\[
\theta=\frac{B_{\mathrm{n}}}{\left(\zeta+\frac{1}{4 \zeta}\right)} \text { and } d=1+2 \zeta \theta+\theta^{2},
\]
where \(B_{\mathrm{n}}\) is the normalized loop bandwidth, and \(\zeta\) is the damping factor. The phase recovery gain, \(K_{0}\), is equal to the number of samples per symbol. The modulation type determines the phase error detector gain, \(K_{\mathrm{p}}\).
\begin{tabular}{|l|l|}
\hline Modulation & \(\boldsymbol{K}_{\mathbf{p}}\) \\
\hline BPSK, PAM, QAM, QPSK, or OQPSK & 2 \\
\hline 8-PSK & 1 \\
\hline
\end{tabular}

The output of the loop filter is then passed to the DDS. The DDS is another biquadratic loop filter whose expression is based on the forward Euler integration rule
\[
\lambda_{\mathrm{n}}=\left(g_{\mathrm{P}} e_{\mathrm{n}-1}+\psi_{\mathrm{n}-1}\right)+\lambda_{\mathrm{n}-1},
\]
where \(g_{\mathrm{P}}\) is the proportional gain that is expressed as
\[
g_{\mathrm{P}}=\frac{4 \zeta(\theta / d)}{K_{\mathrm{p}} K_{0}} .
\]

The info object function of this System object returns estimates of the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay. The normalized pull-in range, \((\Delta f)_{\text {pull-in }}\), is expressed in radians and estimated as
\[
(\Delta f)_{\text {pull-in }} \approx \min \left(1,2 \pi \sqrt{2} \zeta B_{\mathrm{n}}\right) .
\]

The expression for \((\Delta f)_{\text {pull-in }}\) becomes less accurate as \(2 \Pi \sqrt{2} \zeta B_{\mathrm{n}}\) approaches 1 .
The maximum frequency lock delay, \(T_{\mathrm{FL}}\), and phase lock delay, \(T_{\mathrm{PL}}\), are expressed in samples and estimated as
\[
T_{\mathrm{FL}} \approx 4 \frac{(\Delta f)_{\mathrm{pull}-\mathrm{in}}^{2}}{B_{\mathrm{n}}^{3}} \text { and } T_{\mathrm{PL}} \approx \frac{1.3}{B_{\mathrm{n}}}
\]

\section*{comm.CCDF}

Package: comm
Measure complementary cumulative distribution function

\section*{Description}

The CCDF object measures the probability of a signal's instantaneous power to be a specified level above its average power.

To measure complementary cumulative distribution of a signal:
1 Define and set up your CCDF object. See "Construction" on page 3-262.
2 Call step to measure complementary cumulative distribution according to the properties of comm. CCDF. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
\(\mathrm{H}=\) comm. CCDF creates a complementary cumulative distribution function measurement (CCDF) System object, H, that measures the probability of a signal's instantaneous power to be a specified level above its average power.

H = comm. CCDF (Name, Value) creates a CCDF object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

\section*{NumPoints}

Number of CCDF points
Specify the number of CCDF points that the object calculates. This property requires a numeric, positive, integer scalar. The default is 1000. Use this property with the MaximumPowerLimit on page 3-0 property to control the size of the histogram bins. The object uses these bins to estimate CCDF curves. This controls the resolution of the curves. All input channels must have the same number of CCDF points.

\section*{MaximumPowerLimit}

Maximum expected input signal power
Specify the maximum expected input signal power limit for each input channel. The default is 50 . Set this property to a numeric scalar or row vector length equal to the number of input channels. When
you set this property to a scalar, the object assumes that the signals in all input channels have the same expected maximum power. When you set this property to a row vector length equal to the number of input channels, the object assumes that the \(i\)-th element of the vector is the maximum expected power for the signal at the \(i\)-th input channel. When you call the step method, the object displays the value of this property is in the units that you specify in the PowerUnits on page 3-0 property. For each input channel, the object obtains CCDF results by integrating a histogram of instantaneous input signal powers. The object sets the bins of the histogram so that the last bin collects all power occurrences that are equal to, or greater than the power that you specify in this property. The object issues a warning if any input signal exceeds its specified maximum power limit. Use this property with the NumPoints on page 3-0 property to control the size of the histogram bins that the object uses to estimate CCDF curves (such as control the resolution of the curves).

\section*{PowerUnits}

Power units
Specify the power measurement units as one of \(d B m|d B W|\) Watts. The default is \(d B m\). The step method outputs power measurements in the units specified in the PowerUnits on page 3-0 property. When you set this property to dBm or dBW, the step method outputs relative power values in a dB scale. When you set this property to Watts, the step method outputs relative power values in a linear scale. When you call the step method, the object assumes that the units of MaximumPowerLimit on page 3-0 have the same value you specified in the PowerUnits property.

\section*{AveragePowerOutputPort}

Enable average power measurement output
When you set this property to true, the step method outputs running average power measurements. The default is false.

\section*{PeakPowerOutputPort}

Enable peak power measurement output
When you set this property to true, the step method outputs running peak power measurements. The default is false.

\section*{PAPROutputPort}

Enable PAPR measurement output
When you set this property to true, the step method outputs running peak-to-average-power measurements. The default is false.

\title{
getPercentileRelativePower
}

System object: comm. CCDF
Package: comm
Get relative power value for a given probability

\section*{Syntax}

R = getPercentileRelativePower( \(\mathrm{H}, \mathrm{P}\) )

\section*{Description}
\(R=\) getPercentileRelativePower( \(H, P\) ) finds the relative power values, \(R\). The power of the signal of interest is above its average power by \(R \mathrm{~dB}\) (if PowerUnits equals ' dBW ', or ' dBm ') or by a factor of R (in linear scale if PowerUnits equals 'Watts') with a probability P.

The method output R , is a column vector with the \(i\)-th element corresponding to the relative power for the \(i\)-th input channel. The method input P can be a double precision scalar, or a vector with a number of elements equal to the number of input channels. If \(P\) is a scalar, then all the relative powers in \(R\) correspond to the same probability value specified in P . If P is a vector, then the \(i\)-th element of R corresponds to a power value that occurs in the \(i\)-th input channel, with a probability specified in the \(i\)-th element of P .

For the \(i\)-th input channel, this method evaluates the inverse CCDF curve at probability value \(P(i)\).

\section*{Examples}

Obtain CCDF curves for a unit variance AWGN signal and a dual- one signal. The AWGN signal is RPW1 dB above its average power one percent of the time, and the dual-tone signal is RPW2 dB above its average power 10 percent of the time. This example finds the values of RPW1 and RPW2.
```

n = [0:5e3-1].';
s1 = randn(5e3,1); % AWGN signal
s2 = sin(0.01*pi*n)+sin(0.03*pi*n); % dual-tone signal
hCCDF = comm.CCDF; % create a CCDF object
step(hCCDF,[s1 s2]); % step the CCDF measurements
plot(hCCDF) % plot CCDF curves
legend('AWGN','Dual-tone')
RPW = getPercentileRelativePower(hCCDF,[1 10]);
RPW1 = RPW(1)
RPW2 = RPW(2)

```

\section*{getProbability}

System object: comm. CCDF
Package: comm
Get the probability for a given relative power value

\section*{Syntax}

P = getProbability ( \(\mathrm{H}, \mathrm{R}\) )

\section*{Description}
\(P=\) getProbability \((H, R)\) finds the probability, \(P\), of the power level of the signal of interest being \(R\) dBs (if PowerUnits equals 'dBW', or 'dBm') or Watts (if PowerUnits equals 'Watts') above its average power. P is a column vector with the \(i\)-th element corresponding to the probability value for the \(i\)-th input channel. Input R can be a double precision scalar or a vector with a number of elements equal to the number of input channels. If R is a scalar, then all the probability values in P correspond to the same relative power specified in \(R\). If \(R\) is a vector, then the ith element of \(P\) contains a probability value for the \(i\)-th channel and for the relative power specified in the \(i\)-th element of R .

For the \(i\)-th input channel, this method evaluates the CCDF curve at relative power value \(\mathrm{R}(i)\)

\section*{Examples}

Obtain CCDF curves for a unit variance AWGN signal and a dual- tone signal. Find the probability that the AWGN signal power is 5 dB above its average power and that the dual-tone signal power is 3 dB above its average power.
```

n = [0:5e3-1].';
s1 = randn(5e3,1); % AWGN signal
s2 = sin(0.01*pi*n)+sin(0.03*pi*n); % dual-tone signal
hCCDF = comm.CCDF;
step(hCCDF,[s1 s2]);
plot(hCCDF) % plot CCDF curves
legend('AWGN','Dual-tone')
P = getProbability(hCCDF,[5 3]) % get probabilities

```

\section*{plot}

System object: comm. CCDF
Package: comm
Plot CCDF curves

\section*{Syntax}

D \(=\) plot(H)

\section*{Description}
\(D=p l o t(H)\) plots CCDF measurements in the CCDF System object, \(H\). The plot method returns the plot handles as an output, D . This method plots the same number of curves as there are input channels. The H input can be followed by parameter-value pairs to specify additional properties of the curves. For example, plot(H,LineWidth,2) will create curves with line widths of 2 points.

The comm. CCDF System object does not support C code generation for this method.

\section*{reset}

System object: comm. CCDF
Package: comm
Reset states of CCDF measurement object

\section*{Syntax}
reset (H)

\section*{Description}
reset \((H)\) resets the states of the CCDF object, H .

\section*{step}

System object: comm. CCDF
Package: comm
Measure complementary cumulative distribution function

\section*{Syntax}
[CCDFY,CCDFX] = step ( \(\mathrm{H}, \mathrm{X}\) )
[CCDFY, CCDFX,AVG] \(=\operatorname{step}(H, X)\)
[CCDFY,CCDFX,PEAK] \(=\operatorname{step}(\mathrm{H}, \mathrm{X})\)
[CCDFY,CCDFX,PAPR] = step \((H, X)\)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((\mathrm{obj}, \mathrm{x})\) and \(\mathrm{y}=\mathrm{obj}(\mathrm{x})\) perform equivalent operations.
[CCDFY, CCDFX] = step \((H, X)\) updates CCDF, average power, and peak power measurements for input \(X\) using the CCDF System object, H . It outputs the y -axis, CCDFY, and x -axis, CCDFX, CCDF points. X must be a double precision, \(M\)-by- \(N\) matrix, where \(M\) is the number of time samples and \(N\) is the number of input channels. The step method outputs CCDFY as a matrix whose \(i\)-th column contains updated probability values measured from the \(i\)-th column of input matrix X. CCDFY contains the \(y\)-axis points of the CCDF curves of each channel. The step method outputs CCDFX as a matrix containing, in its \(i\)-th column, the corresponding updated instantaneous-to-average power ratios for the ith column of input matrix X. CCDFX contains the \(x\)-axis points of the CCDF curves of each channel. The object sets the number of rows in CCDFY and CCDFX equal to NumPoints property +1 . The probability values are percentages in the [0 100] interval. When you set the PowerUnits property to dBW or dBm , the relative powers are in dB scale. When you set the PowerUnits property to Watts, the relative powers are in linear scale. Measurements are updated each time you call the step method until you reset the object. You call the plot method to plot CCDF curves for each channel.
[CCDFY, CCDFX,AVG] = step \((\mathrm{H}, \mathrm{X})\) returns updated average power measurements, AVG, when you set the AveragePowerOutputPort property to true. The step method outputs AVG as a column vector with the ith element corresponding to an updated average power measurement for the signal available in the ith column of input matrix \(X\). You specify the units for AVG in the PowerUnits property.
[CCDFY, CCDFX, PEAK] \(=\) step \((H, X)\) returns updated peak power measurements, PEAK, when you set the PeakPowerOutputPort property to true. The step method outputs PEAK as a column vector with the ith element corresponding to an updated peak power measurement for the signal available in the ith column of input matrix \(X\). You specify the units for PEAK in the PowerUnits property.
[CCDFY, CCDFX, PAPR] = step \((H, X)\) returns updated peak-to-average power ratio measurements, PAPR, when you set the PAPROutputPort property to true. The step methods outputs PAPR as a column vector with the ith element corresponding to an updated peak-to-average power ratio measurement for the signal available in the ith column of input matrix \(X\). When you set the

PowerUnits property to dBW or dBm, the method outputs PAPR in a dB scale. When you set the PowerUnits property to Watts, the method outputs PAPR in a linear scale. You can combine optional output arguments when you set their enabling properties. Optional outputs must be listed in the same order as the order of the enabling properties. For example,

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.CoarseFrequencyCompensator}

Package: comm
Compensate for frequency offset for PAM, PSK, or QAM

\section*{Description}

The CoarseFrequencyCompensator System object compensates for the frequency offset of received signals.

To compensate for the frequency offset of a PAM, PSK, or QAM signal:
1 Define and set up your coarse frequency compensator object. See "Construction" on page 3-272.
2 Call step to compensate for the frequency offset of a PAM, PSK, or QAM signal according to the properties of comm. CoarseFrequencyCompensator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

CFC = comm.CoarseFrequencyCompensator creates a coarse frequency offset compensator object, CFC. This object uses an open-loop technique to estimate and compensate for the carrier frequency offset in a received signal.

CFC = comm. CoarseFrequencyCompensator (Name, Value) creates a coarse frequency offset compensator object, CFC, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as Name1, Value1, ... , NameN, ValueN.

\section*{Properties}

\section*{Modulation}

Modulation type
Specify the signal modulation type as BPSK, QPSK, OQPSK, 8PSK, PAM, or QAM. The default is QAM. This property is nontunable.

\section*{Algorithm}

Algorithm used to estimate frequency offset
Specify the estimation algorithm as one of FFT-based or Correlation-based. The default is FFTbased. This property is nontunable.

The table shows the allowable combinations of the modulation type and the estimation algorithm.
\begin{tabular}{|l|l|l|}
\hline Modulation & FFT-Based Algorithm & Correlation-Based Algorithm \\
\hline BPSK, QPSK, 8PSK, PAM & \(\checkmark\) & \(\checkmark\) \\
\hline OQPSK, QAM & \(\checkmark\) & \\
\hline
\end{tabular}

Use the correlation-based algorithm for HDL implementations and for other situations in which you want to avoid using an FFT.

This property appears when Modulation is 'BPSK', 'QPSK', '8PSK', or 'PAM'.

\section*{FrequencyResolution}

Frequency resolution (Hz)
Specify the frequency resolution for the offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length used to perform spectral analysis and must be less than the sample rate. The default is 0.001 . This property is nontunable.

\section*{MaximumFrequencyOffset}

Maximum measurable frequency offset ( Hz )
Specify the maximum measurable frequency offset as a positive, real scalar of data type double.
The value of this property must be less than \(f_{\text {samp }} / M\), where \(f_{\text {samp }}\) is the sample rate and \(M\) is the modulation order. As a best practice, set MaximumOffset to less than \(r\) / (4M). This property applies only if Algorithm is Correlation-based. The default is 0.05 . This property is nontunable.

\section*{SampleRate}

Sample rate (Hz)
Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1 . This property is nontunable.

\section*{SamplesPerSymbol}

Samples per symbol
Specify the number of samples per symbol, \(s\), as a real positive finite integer scalar, such that \(s \geq 2\). The default value is 4 . This property is nontunable.

This property appears when Modulation is 'OQPSK'.

\section*{Methods}
info Characteristic information about coarse frequency compensator
reset Reset states of the CoarseF requencyCompensator object
step Compensate for frequency offset

\section*{Common to All System Objects}
\begin{tabular}{l|ll}
\hline release & Allow System object property value changes
\end{tabular}

\section*{Examples}

\section*{Compensate for Frequency Offset in a QPSK Signal}

Compensate for a 4 kHz frequency offset imposed on a noisy QPSK signal.
Set the example parameters.
```

nSym = 2048; % Number of input symbols
sps = 4; % Samples per symbol
nSamp = nSym*sps; % Number of samples
fs = 80000; % Sampling frequency (Hz)

```

Create a square root raised cosine transmit filter.
```

txfilter = comm.RaisedCosineTransmitFilter(...
'RolloffFactor',0.2, ...
'FilterSpanInSymbols',8, ...
'OutputSamplesPerSymbol',sps);

```

Create a phase frequency offset object to introduce the 4 kHz frequency offset.
```

freqOffset = comm.PhaseFrequency0ffset(...
'Frequency0ffset',-4000, ...
'SampleRate',fs);

```

Create a coarse frequency compensator object to compensate for the offset.
```

freqComp = comm.CoarseFrequencyCompensator(...
'Modulation','QPSK', ...
'SampleRate',fs, ...
'FrequencyResolution',1) ;

```

Generate QPSK symbols, filter the modulated data, pass the signal through an AWGN channel, and apply the frequency offset.
```

data = randi([[0 3],nSym,1);
modData = pskmod(data,4,pi/4);
txSig = txfilter(modData);
rxSig = awgn(txSig,20,'measured');
offsetData = freqOffset(rxSig);

```

Compensate for the frequency offset using freqComp. When the frequency offset is high, it is beneficial to do coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.
```

[compensatedData,estFreqOffset] = freqComp(offsetData);

```

Display the estimate of the frequency offset.
```

estFreqOffset
estFreqOffset =
-3.9999e+03

```

Return information about the freqComp object. To obtain the FFT length, you must call freqComp prior to calling the info method.
```

freqCompInfo = info(freqComp)
freqCompInfo =
struct with fields:

```
    FFTLength: 131072
    Algorithm: 'FFT-based'

Create a spectrum analyzer object and plot the offset and compensated spectra. Verify that the compensated signal has a center frequency at 0 Hz and that the offset signal has a center frequency at -4 kHz .
specAnal = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true, ...
    'ChannelNames',\{'Offset Signal' 'Compensated Signal'\});
specAnal([offsetData compensatedData])

\section*{Compensate for Frequency Offset Using Coarse and Fine Compensation}

Correct for a phase and frequency offset in a noisy QAM signal using a carrier synchronizer. Then correct for the offsets using both a carrier synchronizer and a coarse frequency compensator.

Set the example parameters.
```

fs = 10000; % Symbol rate (Hz)
sps = 4; % Samples per symbol
M = 16; % Modulation order
k = log2(M); % Bits per symbol

```

Create a QAM modulator and an AWGN channel.
```

channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',k,'SamplesPerSymbol',sps);

```

Create a constellation diagram object to visualize the effects of the offset compensation techniques. Specify the constellation diagram to display only the last 4000 samples.
```

constdiagram = comm.ConstellationDiagram(...
'ReferenceConstellation',qammod(0:M-1,M), ...
'SamplesPerSymbol',sps, ...
'SymbolsToDisplaySource','Property','SymbolsToDisplay',4000, ...
'XLimits',[-5 5],'YLimits',[-5 5]);

```

Introduce a frequency offset of 400 Hz and a phase offset of 30 degrees.
```

phaseFreq0ffset = comm.PhaseFrequency0ffset(...
'Frequency0ffset',400,...
'Phase0ffset',30,...
'SampleRate',fs);

```

Generate random data symbols and apply 16-QAM modulation.
```

data = randi([0 M-1],10000,1);
modSig = qammod(data,M);

```

Create a raised cosine filter object and filter the modulated signal.
```

txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',sps, ...
'Gain',sqrt(sps));
txSig = txfilter(modSig);

```

Apply the phase and frequency offset, and then pass the signal through the AWGN channel.
```

freq0ffsetSig = phaseFreq0ffset(txSig);
rxSig = channel(freqOffsetSig);

```

Apply fine frequency correction to the signal by using the carrier synchronizer.
```

fineSync = comm.CarrierSynchronizer('DampingFactor',0.7, ...
'NormalizedLoopBandwidth',0.005, ...
'SamplesPerSymbol',sps, ...
'Modulation','QAM');
rxData = fineSync(rxSig);

```

Display the constellation diagram of the last 4000 symbols.
```

constdiagram(rxData)

```

Even with time to converge, the spiral nature of the plot shows that the carrier synchronizer has not yet compensated for the large frequency offset. The 400 Hz offset is \(1 \%\) of the sample rate.

Repeat the process with a coarse frequency compensator inserted before the carrier synchronizer.
Create a coarse frequency compensator to reduce the frequency offset to a manageable level.
coarseSync = comm.CoarseFrequencyCompensator('Modulation','QAM','FrequencyResolution',1,'SampleR
Pass the received signal to the coarse frequency compensator and then to the carrier synchronizer.
```

syncCoarse = coarseSync(rxSig);
rxData = fineSync(syncCoarse);

```

Plot the constellation diagram of the signal after coarse and fine frequency compensation.
constdiagram(rxData)

The received data now aligns with the reference constellation.

\section*{Algorithms}

\section*{Correlation-Based}

The correlation-based estimation algorithm, which can be used to estimate the frequency offset for PSK and PAM signals, is described in [1]. To determine the frequency offset, \(\Delta f\), the algorithm performs a maximum likelihood (ML) estimation of the complex-valued oscillation \(\exp (j 2 \pi \Delta f t)\). The observed signal, \(r_{k}\), is represented as
\[
r_{k}=e^{j\left(2 \Pi \Delta f k T_{s}+\theta\right)}, 1 \leq k \leq N,
\]
where \(T_{s}\) is the sampling interval, \(\theta\) is an unknown random phase, and \(N\) is the number of samples. The maximum likelihood estimation of the frequency offset is equivalent to seeking the maximum of the likelihood function, \(\Lambda(\Delta f)\),
\[
\Lambda(\Delta f) \approx\left|\sum_{i=1}^{N} r_{i} e^{-j 2 \pi \Delta f i T_{S}}\right|^{2}=\sum_{k=1}^{N} \sum_{m=1}^{N} r_{k} r_{m}^{*} e^{-j 2 \pi \Delta f T_{S}(k-m)}
\]

After simplifying, the problem is expressed as a discrete Fourier transform, weighted by a parabolic windowing function. It is expressed as
\[
\operatorname{Im}\left\{\sum_{k=1}^{N-1} k(N-k) R(k) e^{j 2 \pi \Delta \widehat{f} T_{S}}\right\}=0,
\]
where \(R(k)\) denotes the estimated autocorrelation of the sequence \(r_{k}\) and is represented as
\[
R(k) \triangleq \frac{1}{N-k} \sum_{i=k+1}^{N} r_{i} r_{i-k}^{*}, 0 \leq k \leq N-1
\]

The term \(k(N-k)\) is the parabolic windowing function. In [1], it is shown that \(R(k)\) is a poor estimate of the autocorrelation of \(r_{k}\) when \(k=0\) or when \(k\) is close to \(N\). Consequently, the windowing function can be expressed as a rectangular sequence of 1 s for \(k=1,2, \ldots, L\), where \(L \leq N-1\). The results is a modified ML estimation strategy in which
\[
\operatorname{Im}\left\{\sum_{k=1}^{L} R(k) e^{-j 2 \pi \Delta \widehat{f} k T_{S}}\right\}=0
\]

This results in an estimate of \(\Delta \widehat{f}\) in which
\[
\Delta \widehat{f} \cong \frac{f_{\text {samp }}}{\Pi(L+1)} \arg \left\{\sum_{k=1}^{L} R(k)\right\}
\]

The sampling frequency, \(f_{\text {samp }}\), is the reciprocal of \(T_{s}\). The number of elements used to compute the autocorrelation sequence, \(L\), are determined as
\[
L=\operatorname{round}\left(\frac{f_{\text {samp }}}{f_{\max }}\right)-1
\]
where \(f_{\max }\) is the maximum expected frequency offset and round is the nearest integer function. The frequency offset estimate improves when \(L \geq 7\) and leads to the recommendation that \(f_{\max } \leq f_{\text {samp }} /\) (4M).

\section*{FFT-Based}

FFT-based algorithms can be used to estimate the frequency offset for all modulation types. Two variations are used in comm.CoarseFrequencyCompensator.
- For BPSK, QPSK, 8PSK, PAM, or QAM modulations the FFT-based algorithm used is described in [2]. The algorithm estimates \(\Delta \widehat{f}\) by using a periodogram of the \(m^{\text {th }}\) power of the received signal and is given as
\[
\Delta \widehat{f}=\frac{f_{\text {samp }}}{N \cdot m} \operatorname{argmax}\left|\sum_{k=0}^{N-1} r^{m}(k) e^{-j 2 \pi k t / N}\right|, \quad\left(-\frac{R_{\text {sym }}}{2} \leq f \leq \frac{R_{\text {sym }}}{2}\right),
\]
where \(m\) is the modulation order, \(r(k)\) is the received sequence, \(R_{\text {sym }}\) is the symbol rate, and \(N\) is the number of samples. The algorithm searches for a frequency that maximizes the time average
of the \(m^{\text {th }}\) power of the received signal multiplied by various frequencies in the range of \(\left[-R_{\text {sym }} / 2\right.\), \(\left.R_{\text {sym }} / 2\right]\). As the form of the algorithm is the definition of the discrete Fourier transform of \(r^{m}(t)\), searching for a frequency that maximizes the time average is equivalent to searching for a peak line in the spectrum of \(r^{m}(t)\). The number of points required by the FFT is
\[
\left.N=\left.2\right|^{\log 2}\left(\frac{f_{\text {samp }}}{f_{r}}\right) \right\rvert\,,
\]
where \(f_{r}\) is the desired frequency resolution.
- For OQPSK modulation the FFT-based algorithm used is described in [4]. The algorithm searches for spectral peaks at \(+/-200 \mathrm{kHz}\) around the symbol rate. This technique locates desired peaks in the presence of interference from spectral content around baseband frequencies due to filtering.

\section*{Introduced in R2015b}

\section*{info}

System object: comm. CoarseFrequencyCompensator
Package: comm
Characteristic information about coarse frequency compensator

\section*{Syntax}

S = info(CFC)

\section*{Description}
\(S=\) info(CFC) returns a structure, \(S\), containing characteristic information for the CoarseFrequencyCompensator System object, CFC. S has fields FFTLength, Algorithm, and MaxLag. Algorithm is the type of algorithm used in estimating the frequency offset. FFTLength is the number of samples used in the FFT and is provided when the algorithm is FFT-based. MaxLag is the number of samples used in estimating the autocorrelation and is provided when the algorithm is Correlation-based.

Note The step method must be run once to determine the FFTLength.

\section*{reset}

System object: comm. CoarseFrequencyCompensator
Package: comm
Reset states of the CoarseFrequencyCompensator object

\section*{Syntax}
reset(CFC)

\section*{Description}
reset (CFC) resets the internal states of the CoarseFrequencyCompensator object, CFC.

\section*{step}

System object: comm. CoarseFrequencyCompensator
Package: comm
Compensate for frequency offset

\section*{Syntax}

Y = step(CFC,X)
[Y,EST] = step(CFC,X)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.
\(\mathrm{Y}=\) step (CFC, X) compensates for the carrier frequency offset of the input X and returns the result in \(Y\). X must be a column vector. The step method outputs the compensated signal Y as a complex column vector having the same dimensions and data type as \(X\).
\([\mathrm{Y}, \mathrm{EST}]=\operatorname{step}(\mathrm{CFC}, \mathrm{X})\) returns a scalar estimate of the frequency offset, EST.

Note CFC specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.ConstellationDiagram}

Package: comm
Display constellation diagram for input signals

\section*{Description}

The comm. ConstellationDiagram System object displays real and complex-valued floating and fixed-point signals in the IQ plane. Use this System object to perform qualitative and quantitative analysis on modulated single-carrier signals.

In the constellation diagram window you can:
- Input and plot multiple signals on a single constellation diagram. You can define one reference constellation for each input signal. For more information, see ReferenceConstellation.
- Choose which channels are displayed by selecting signals in the legend. Use the ShowLegend property to display the legend. For a multichannel signal, specify the input as a matrix with individual signals defined in the columns of the matrix.
- Display the "EVM / MER Measurements" on page 3-297 panel, which displays calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements. When multiple signals are input to a comm. ConstellationDiagram System object, use the Trace Selection pane to choose the signal being measured.

To display constellation diagrams:
1 Create the comm. ConstellationDiagram object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
constdiag \(=\) comm. ConstellationDiagram
constdiag \(=\) comm. ConstellationDiagram(Name, Value)

\section*{Description}
constdiag \(=\) comm. ConstellationDiagram returns a comm. ConstellationDiagram System object that displays real and complex-valued floating and fixed-point signals in the IQ plane.
constdiag = comm.ConstellationDiagram(Name,Value) set the properties of the System object using one or more name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Example: constdiag = comm.ConstellationDiagram('SampleOffset',1e3) specifies that the first 1000 samples received will not be displayed.

\section*{Properties}

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

\section*{Name - Title of Constellation Diagram window}
'Constellation Diagram' (default)| character vector
Title of the Constellation Diagram window, specified as a character vector.

\section*{SamplesPerSymbol - Number of samples used to represent each symbol \\ 1 (default) | positive integer}

Number of samples used to represent each symbol, specified as a positive integer. When the SamplesPerSymbol property is greater than 1, the signal is downsampled before it is plotted.

Tunable: Yes

\section*{SampleOffset - Number of samples to skip before plotting points}

0 (default) | nonnegative integer
Number of samples to skip before plotting points, specified as a nonnegative integer less than SamplesPerSymbol. This property specifies the number of samples to skip when downsampling the input signal.

Tunable: Yes

\section*{SymbolsToDisplaySource - Source of symbols to display \\ 'Input frame length' (default)|'Property'}

Source of symbols to display, specified as:
- 'Input frame length' - The number of symbols to display is equal to the input frame length divided by SamplesPerSymbol.
- 'Property ' - SymbolsToDisplay specifies the maximum number of symbols to display.

Tunable: Yes

\section*{SymbolsToDisplay - Maximum number of symbols to display}

256 (default) | positive integer
Maximum number of symbols to display, specified as a positive integer. Use SymbolsToDisplay to limit the maximum number of symbols displayed when long signals are input. Symbols plotted are the most recent symbols received.

Tunable: Yes

\section*{Dependencies}

This property applies when SymbolsToDisplaySource is set to 'Property'.

\section*{ReferenceConstellation - Reference constellations}
[0.7071+0.7071i -0.7071+0.7071i -0.7071-0.7071i 0.7070-0.7071i] (default)|row vector | cell array

Reference constellations for the input signals, specified as a row vector or cell array of vectors defining the ideal constellation points for each input signal. Input signals can be single channel or multichannel. You can define one reference constellation for each input signal. For multichannel input signals, one reference constellation specification applies to all the individual signals in that input signal. To obtain the "EVM / MER Measurements" on page 3-297, you must set the ReferenceConstellation property.

Tunable: Yes
Data Types: double
Complex Number Support: Yes

\section*{ReferenceMarker - Marker for reference display \\ '+' (default) | string | cell array}

Specify the marker for the reference display as a string or cell array of strings. Select the marker symbol as one of the markers in this table.
\begin{tabular}{|c|c|}
\hline Value & Description \\
\hline '0' & Circle \\
\hline '+' & Plus sign \\
\hline 1*' & Asterisk \\
\hline '.' & Point \\
\hline 'x' & Cross \\
\hline 'square' or 's' & Square \\
\hline 'diamond ' or 'd' & Diamond \\
\hline '^1 & Upward-pointing triangle \\
\hline 'v' & Downward-pointing triangle \\
\hline '>' & Right-pointing triangle \\
\hline '<' & Left-pointing triangle \\
\hline 'pentagram' or 'p \({ }^{\text {' }}\) & Five-pointed star (pentagram) \\
\hline 'hexagram' or 'h' & Six-pointed star (hexagram) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline Value & Description \\
\hline 'none ' & No markers \\
\hline
\end{tabular}

Tunable: Yes
Data Types: string

\section*{ReferenceColor - Color for reference display constellation}
[1 0 0] (red) (default) | row vector | cell array
Color for reference display constellation, specified as a three-element row vector indicating RGB component colors or as a cell array containing RGB component colors for each input signal.
Data Types: double

\section*{ShowReferenceConstellation - Display the reference constellation \\ true (default) | false}

Display the reference constellation, specified as true or false.
Tunable: Yes
Data Types: logical

\section*{ShowTrajectory - Turn on signal trajectory plot}
false (default) | true
Turn on signal trajectory plot, specified as false or true. The signal trajectory is a plot of the inphase component versus the quadrature component of a modulated signal. See the Show Signal Trajectory button on the toolbar in the "Signal Display" on page 3-296.

Tunable: Yes
Data Types: logical

\section*{Position - Scope window position and size}

410-by-300 pixel window at center of screen (default) | four-element vector
Scope window position and size in pixels, specified as a four-element vector of the form [left bottom width height]. The first two elements in the vector indicate the location of the lower left corner and the last two specify the size of the window. The default value for the location depends on the screen resolution. By default, the window is positioned in the center of the screen with a width and height of 410 and 300 pixels, respectively.

Tunable: Yes
Data Types: double

\section*{NumInputPorts - Number of input ports}

1 (default) | integer in the range [1, 20]
Specify the number of input ports, as an integer in the range [1,20]. Each input signal, whether it is a multichannel signal or a single channel signal, becomes a separate input port in the scope.

When multichannel input signals are specified, the maximum number of input ports is limited by the total number of input signals defined. The total number of input signals cannot exceed 20.

\section*{ShowGrid - Turn on grid}
true (default) | false
Turn on the grid, specified as true or false.
Tunable: Yes
Data Types: logical

\section*{ChannelNames - Names for input channels}
empty cell (default) | cell array of strings or character vectors
Names for input channels, specified as a cell array of strings or character vectors. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

The names assigned to input channels appear in the legend and the Measurements > Trace Selection pane.

To show the legend, set ShowLegend to true. The legend displays after you provide an input signal to the comm.ConstellationDiagram System object.

To show the Trace Selection pane, select Measurements > Trace Selection. To enable the Trace Selection pane, you must first provide an input signal to the comm.ConstellationDiagram System object.
Example: constDiag = comm.ConstellationDiagram('ChannelNames', \{'8-QAM', '8PSK' \}) assigns names for two input channels to 8-QAM and 8-PSK.

Tunable: Yes
ShowLegend - Display legend
false (default) | true
Display the legend, specified as false or true. The names listed in the legend are the signal names specified by the ChannelNames property.

From the legend, you can control which signals to plot. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal and hide all other signals, right-click the signal name. To show all signals, press Esc.

Tunable: Yes
Data Types: logical

\section*{ColorFading - Add color fading effect}
false (default) | true
Add color fading effect, specified as false or true. When you set this property to true, the points in the display fade as the interval of time after they are first plotted increases. This animation resembles an oscilloscope display.
Data Types: logical

\section*{Title - Plot title}
blank (default) | character vector | string
Plot title, specified as a character vector or string.

\section*{Tunable: Yes}

\section*{XLimits \(\boldsymbol{x}\)-axis limits}
[-1.375 1.375] (default) |two-element numeric vector
\(x\)-axis limits, specified as a two-element numeric vector of the form [xmin xmax].
Tunable: Yes

\section*{YLimits \(\boldsymbol{-} \boldsymbol{y}\)-axis limits}
[-1.375 1.375] (default) |two-element numeric vector
\(y\)-axis limits, specified as a two-element numeric vector of the form [ymin ymax].
Tunable: Yes

\section*{XLabel - x-axis label}
'In-phase Amplitude' (default)| character vector | string
\(x\)-axis label, specified as a character vector or string.
Tunable: Yes

\section*{YLabel - \(\boldsymbol{y}\)-axis label}
'Quadrature Amplitude' (default) | character vector \| string
\(y\)-axis label, specified as a character vector or string.
Tunable: Yes

\section*{EnableMeasurements - Display measurements pane false (default) | true}

Display measurements pane, specified as false or true. To compute and display EVM or MER measurements, activate this pane.

Tunable: Yes

\section*{Data Types: logical}

\section*{MeasurementInterval - Measurement interval}
'Current Display' (default)|'All displays'|positive integer
Measurement interval, specified as 'Current Display', 'All displays', or a positive integer in the range [2 SymbolsToDisplay]. This property specifies the window length for the EVM and MER measurements.

When the input signal contains one sample per symbol and the reference constellation is provided, the constellation diagram display can measure the signal quality in terms of EVM and MER. The "EVM / MER Measurements" on page 3-297 pane can be displayed by clicking the Signal Quality button. See the toolbar in the "Signal Display" on page 3-296. After the number of input data samples is greater than MeasurementInterval, the EVM and MER measurements are computed.

\section*{Tunable: Yes}

\section*{EVMNormalization - EVM normalization method \\ 'Average constellation power' (default)|'Peak constellation power'}

EVM normalization method, specified as 'Average constellation power' or 'Peak constellation power'. For more information, see "EVM / MER Measurements" on page 3-297.

Tunable: Yes

\section*{Usage}

\section*{Syntax}
constdiag(signal1,signal2,...,signalN)
Description
constdiag(signal1, signal2, ... signalN) displays up to NumInputPorts signals in one constellation diagram.

\section*{Input Arguments}

\section*{signal - Input signal or signals to plot}
column vector | matrix
Specify one or more signals to be plotted in the comm. ConstellationDiagram. Signals can have different data types and dimensions. To create a multichannel signal, specify a matrix with individual signals defined in the columns of the matrix.
Example: constDiag([siganl1_1,signal1_2],signal2) displays the multichannel and multiinput constellation diagram. First input is two concatenated column vectors of length N to make an N -by-2 matrix input signal and the second input is a single channel signal.

Data Types: double
Complex Number Support: Yes

\section*{Object Functions}

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:
```

release(obj)

```

\section*{Specific to Scopes}
show Show scope window
hide Hide scope window
isVisible Determine visibility of scope window

\section*{Common to All System Objects}
step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

\section*{Examples}

\section*{Plot Amplitude-Imbalanced QPSK Constellation}

QPSK modulate random data symbols and apply an amplitude imbalance to the signal. Pass the signal through a noisy channel. Plot the resultant constellation.

Create a constellation diagram object. Because the default reference constellation for the comm. ConstellationDiagram System object is QPSK, it is not necessary to set additional properties.
```

constDiagram = comm.ConstellationDiagram;

```

Generate random data symbols and apply QPSK modulation.
```

data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);

```

Apply an amplitude imbalance to the modulated signal.
txSig \(=\) iqimbal(modData,5);
Pass the transmitted signal through an AWGN channel and display the constellation diagram. Observe that the data points have shifted from their ideal locations.
```

rxSig = awgn(txSig,20);
constDiagram(rxSig)

```

\section*{Plot 16-QAM Constellation}

Apply 16-QAM modulation, transmit data using an AWGN channel, and plot the signal constellation.
Create a 16-QAM reference constellation.
M = 16;
refC \(=\operatorname{qammod}(0: M-1, M)\);
Create a comm. ConstellationDiagram System object. Specify the constellation reference points and axes limits using name-value pairs.
```

constDiagram = comm.ConstellationDiagram('ReferenceConstellation',refC, ...
'XLimits',[-4 4],'YLimits',[-4 4]);

```

Generate random, 16-ary data symbols.
data \(=\) randi([0 M-1],1000,1);
Apply 16-QAM modulation.
sym \(=\) qammod (data, M) ;
Pass the modulated signal through an AWGN channel.
rcv \(=\operatorname{awgn}(s y m, 15)\);
Display the constellation diagram.
constDiagram(rcv)

\section*{View Multi-Input Signals Constellation}

Use the comm. ConstellationDiagram System object to visualize the constellation of multi-input and multichannel modulated signals. Plot a multichannel signal with two 16-QAM signals with SNR 10 and 20 for the first input, and one 8-PSK signal for the second input.

Create a \(16-\mathrm{QAM}\) and a 8 -PSK reference constellation.
```

M = 16;
refQAM = qammod(0:M-1,M);
S = 8;
refPSK = pskmod(0:S-1,S,pi/8);

```

Create a comm.ConstellationDiagram object \({ }^{\mathrm{TM}}\).
```

constDiag = comm.ConstellationDiagram(2,...
'ReferenceConstellation',{refQAM,refPSK},'ShowLegend',true,...
'XLimits',[-6 6],'YLimits',[-6 6], ...
'ChannelNames',{'16-QAM , SNR 10 dB','16-QAM , SNR 20 dB','8-PSK'});

```

Generate random data symbols, modulate the symbols, and add AWGN with two different SNRs to yield two received signals.
```

d = randi([0 M-1],1000,1);
dQAM = qammod(d,M);
rcv1_1 = awgn(dQAM,10);
rcv1_2 = awgn(dQAM,20);
d = randi([0 S-1],1000,1);
dPSK = pskmod(d,S,pi/8);
rcv2 = awgn(dPSK,20);

```

For the first input, create a multichannel signal by concatenating the two received 16-QAM signals. A single reference constellation is applied for all the multichannel signals of one input. Second input uses a single channel 8-PSK signal. This input has a separate reference constellation.

View the multi-input and multichannel signals .
```

constDiag([rcv1_1,rcv1_2],rcv2);

```

\section*{More About}

\section*{Signal Display}

To communicate simulation data that corresponds to the current display, the scope uses the Frames indicator on the scope window. This figure highlights important aspects of the Constellation Diagram window.

To change the Constellation Diagram window settings, select menu options under File, Tools, and View. Changes made via menu options adjust the property settings of the System object accordingly.

\section*{EVM / MER Measurements}

The EVM / MER signal quality pane displays the measurement settings, and error vector magnitude (EVM) and modulation error ratio (MER) measurement calculation results for the specified trace selection.

- EVM - An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The root mean square error vector magnitude, \(E V M_{\text {RMS }}\), is measured for the average and peak constellation power.

On the constellation diagram, you can display the \(E V M_{\text {RMS }}\) measurements normalized by either the Average constellation power or Peak constellation power method as computed using these algorithms.

The EVM / MER pane shows the average and peak EVM \(_{\text {RMS }}\) in both percent and decibels for the selected trace. The EVM reported in decibels is computed as EVM (dB) \(=10-\log 10\left(\mathrm{EVM}_{\mathrm{MS}}\right)=\) \(20-\log 10\left(\mathrm{EVM}_{\mathrm{RMS}}\right)\), where:
- \(e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}\)
- \(I_{k}\) is the in-phase value of the \(k\) th symbol in the input vector.
- \(Q_{k}\) is the quadrature phase value of the \(k\) th symbol in the input vector.
- \(I_{k}\) and \(Q_{k}\) represent ideal (reference) symbol values. \(\tilde{I}_{k}\) and \(\widetilde{Q}_{k}\) represent measured (received) symbol values.
- \(N\) is the input vector length.
- \(P_{\text {avg }}\) is the value for Average constellation power.
- \(P_{\max }\) is the value for Peak constellation power.
- \(\mathrm{EVM}_{\mathrm{RMS}}=\sqrt{\mathrm{EVM}_{\mathrm{MS}}}\)

The maximum EVM value in a vector is \(\mathrm{EVM}_{\max }=\max _{k \in[1, \ldots, N]}\left\{\mathrm{EVM}_{k}\right\}\), where \(k\) is the \(k\) th symbol in a vector of length \(N\).

For more information, see comm. EVM.
- MER - MER is the ratio of the average power of the transmitted signal to the average power of the error vector. The EVM / MER pane indicates average MER measurement result in decibels for the selected trace.

MER is a measure of the SNR in a modulated signal, calculated in dB. The MER over \(N\) symbols is

\section*{\(\operatorname{MER}=10 \cdot \log _{10}\left(\frac{\sum_{n=1}^{N}\left(I_{k}^{2}+Q_{k}^{2}\right)}{\sum_{n=1}^{N}\left(e_{k}\right)}\right) \mathrm{dB}\),}
where:
- \(e_{k}=\left(I_{k}-\tilde{I}_{k}\right)^{2}+\left(Q_{k}-\tilde{Q}_{k}\right)^{2}\)
- \(I_{k}\) is the in-phase value of the \(k\) th symbol in the input vector.
- \(Q_{k}\) is the quadrature phase value of the \(k\) th symbol in the input vector.
- \(I_{k}\) and \(Q_{k}\) represent ideal (reference) values. \(\tilde{I}_{k}\) and \(\widetilde{Q}_{k}\) represent measured (received) symbols.

For more information, see comm.MER.

\section*{Tips}
- If you want any of these features, use a comm. ConstellationDiagram System object.
- Measurements
- Basic reference constellations
- Signal trajectory plots
- Maintaining state between calls
- If you want a simple signal constellation snapshot, use the scatterplot function.

\section*{Extended Capabilities}

\section*{C/C++ Code Generation}

Generate C and C++ code using MATLAB® Coder \(^{\mathrm{TM}}\).
Usage notes and limitations:
- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{See Also}

scatterplot
Introduced in R2013a

\section*{comm.ConvolutionalDeinterleaver}

Package: comm
Restore ordering of symbols using shift registers

\section*{Description}

The ConvolutionalDeinterleaver object recovers a signal that was interleaved using the convolutional Interleaver object. The parameters in the two blocks should have the same values.

To recover convolutionally interleaved binary data:
1 Define and set up your convolutional deinterleaver object. See "Construction" on page 3-302.
2 Call step to convolutionally deinterleave according to the properties of comm. ConvolutionalDeinterleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}
\(\mathrm{H}=\) comm. ConvolutionalDeinterleaver creates a convolutional deinterleaver System object, H . This object restores the original ordering of a sequence that was interleaved using the convolutional interleaver System object.

H = comm.ConvolutionalDeinterleaver(Name, Value) creates a convolutional deinterleaver System object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

\section*{Properties}

\section*{NumRegisters}

Number of internal shift registers
Specify the number of internal shift registers as a scalar, positive integer. The default is 6 .

\section*{RegisterLengthStep}

Symbol capacity difference of each successive shift register
Specify the difference in symbol capacity of each successive shift register, where the last register holds zero symbols as a positive, scalar integer. The default is 2 .

\section*{InitialConditions}

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector, except the last shift register, which has zero delay. If you set this property to a scalar, then all shift registers, except the last one, store the same specified value. You can also set this property to a column vector with length equal to the value of the NumRegisters property. With this setting, the \(i\)-th shift register stores the ( \(\mathrm{N}-\mathrm{i}+1\) )-th element of the specified vector. The value of the first element of this property is unimportant because the last shift register has zero delay. The default is 0 .

\section*{Methods}
reset Reset states of the convolutional deinterleaver object
step Restore ordering of symbols using shift registers

Common to All System Objects
\begin{tabular}{|l|ll}
\hline release & Allow System object property value changes
\end{tabular}

\section*{Examples}

\section*{Convolutional Interleaving and Deinterleaving}

Create convolutional interleaver and deinterleaver objects.
```

interleaver = comm.ConvolutionalInterleaver('NumRegisters',2, ...
'RegisterLengthStep',3);
deinterleaver = comm.ConvolutionalDeinterleaver('NumRegisters',2, ...
'RegisterLengthStep',3);

```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.
```

data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);

```

Display the original sequence, interleaved sequence and restored sequence.
```

\section*{Algorithms}

This object implements the algorithm, inputs, and outputs described on the Convolutional Deinterleaver block reference page. The object properties correspond to the block parameters.

\section*{Extended Capabilities}

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder \(^{\mathrm{TM}}\).
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

\section*{See Also}
comm. ConvolutionalInterleaver|comm.MultiplexedInterleaver
Introduced in R2012a

\section*{reset}

System object: comm. ConvolutionalDeinterleaver
Package: comm
Reset states of the convolutional deinterleaver object

\section*{Syntax}
reset(H)

\section*{Description}
reset \((H)\) resets the states of the ConvolutionalDeinterleaver object, H .

\section*{step}

System object: comm. ConvolutionalDeinterleaver
Package: comm
Restore ordering of symbols using shift registers

\section*{Syntax}

Y = step(H,X)

\section*{Description}

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and \(y=o b j(x)\) perform equivalent operations.
\(Y=\operatorname{step}(H, X)\) restores the original ordering of the sequence, \(X\), that was interleaved using a convolutional interleaver and returns Y . The input X must be a column vector. The data type can be numeric, logical, or fixed-point (fi objects). Y has the same data type as \(X\). The convolutional deinterleaver object uses a set of \(N\) shift registers, where \(N\) is the value specified by the NumRegisters property. The object sets the delay value of the \(k\)-th shift register to the product of ( \(k-1\) ) and RegisterLengthStep property value. With each new input symbol, a commutator switches to a new register and the new symbol shifts in while the oldest symbol in that register shifts out. When the commutator reaches the \(N\)-th register and the next new input occurs, it returns to the first register.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release \(\underline{\text { method to unlock the object. }}\)

\section*{comm.ConvolutionalEncoder}

Package: comm
Convolutionally encode binary data

\section*{Description}

The ConvolutionalEncoder object encodes a sequence of binary input vectors to produce a sequence of binary output vectors.

To convolutionally encode a binary signal:
1 Define and set up your convolutional encoder object. See "Construction" on page 3-307.
2 Call step to encode a sequence of binary input vectors to produce a sequence of binary output vectors according to the properties of comm. ConvolutionalEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step \((o b j, x)\) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. ConvolutionalEncoder creates a System object, H, that convolutionally encodes binary data.

H = comm. ConvolutionalEncoder(Name, Value) creates a convolutional encoder object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.ConvolutionalEncoder(TRELLIS,Name,Value) creates a convolutional encoder object, H This object has the TrellisStructure on page 3-0 property set to TRELLIS, and the other specified properties set to the specified values.

\section*{Properties}

\section*{TrellisStructure}

Trellis structure of convolutional code
Specify the trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the istrellis function to check if a structure is a valid trellis structure. The default is the result of poly2trellis(7, [171 133]).

\section*{TerminationMethod}

Termination method of encoded frame
Specify how the encoded frame is terminated as one of Continuous | Truncated | Terminated. The default is Continuous. When you set this property to Continuous, the object retains the
encoder states at the end of each input vector for use with the next input vector. When you set this property to Truncated, the object treats each input vector independently. The encoder states are reset at the start of each input vector. If you set the InitialStateInputPort on page 3-0 property to false, the object resets its states to the all-zeros state. If you set the InitialStateInputPort property to true, the object resets the states to the values you specify in the initial states step method input. When you set this property to Terminated, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to all-zeros states at the end of the vector. For a rate \(K / N\) code, the step method outputs a vector with length \(N \times(L+S) / K\), where \(S=\) constraintLength-1 (or, in the case of multiple constraint lengths, \(S=\boldsymbol{\operatorname { s u m }}(\) constraintLength(i)-1)). \(L\) is the length of the input to the step method.

\section*{ResetInputPort}

Enable encoder reset input
Set this property to true to enable an additional input to the step method. The default is false. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the TerminationMethod on page 3-0 property to Continuous.

\section*{DelayedResetAction}

Delay output reset
Set this property to true to delay resetting the object output. The default is false. When you set this property to true, the reset of the internal states of the encoder occurs after the object computes the encoded data. When you set this property to false, the reset of the internal states of the encoder occurs before the object computes the encoded data. This property applies when you set the ResetInputPort on page 3-0 property to true.

\section*{InitialStateInputPort}

Enable initial state input
Set this property to true to enable a step method input that allows the specification of the initial state of the encoder for each input vector. The default is false. This property applies when you set the TerminationMethod on page 3-0 property to Truncated.

\section*{FinalStateOutputPort}

Enable final state output
Set this property to true to obtain the final state of the encoder via a step method output. The default is false. This property applies when you set the TerminationMethod on page 3-0 property to Continuous or Truncated.

\section*{PuncturePatternSource}

\section*{Source of puncture pattern}

Specify the source of the puncture pattern as one of None | Property. The default is None. When you set this property to None the object does not apply puncturing. When you set this property to Property, the object punctures the code. This puncturing is based on the puncture pattern vector that you specify in the PuncturePattern on page 3-0 property. This property applies when you set the TerminationMethod on page 3-0 property to Continuous or Truncated.

\section*{PuncturePattern}

Puncture pattern vector
Specify the puncture pattern used to puncture the encoded data as a column vector. The default is [1; 1; \(0 ; 1 ; 0 ; 1]\). The vector contains 1 s and 0 s , where the 0 indicates the punctured, or excluded, bits. This property applies when you set the TerminationMethod on page 3-0 property to Continuous or Truncated and the PuncturePatternSource on page 3-0 property to Property.

\section*{Methods}

Common to All System Objects
release Allow System object property value changes

\section*{Examples}

\section*{Encode and Decode 8-DPSK Modulated Data}

Transmit a convolutionally encoded 8-DPSK modulated bit stream through an AWGN channel. Then, demodulate and decode using a Viterbi decoder.

Create the necessary System objects.
```

hConEnc = comm.ConvolutionalEncoder;
hMod = comm.DPSKModulator('BitInput',true);
hChan = comm.AWGNChannel('NoiseMethod', ...
'Signal to noise ratio (SNR)',...
SNR',10);
hDemod = comm.DPSKDemodulator('Bit0utput',true);
hDec = comm.ViterbiDecoder('InputFormat','Hard');
hError = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay', 34);

```

Process the data using the following steps:
1 Generate random bits
2 Convolutionally encode the data
3 Apply DPSK modulation
4 Pass the modulated signal through AWGN
5 Demodulate the noisy signal
6 Decode the data using a Viterbi algorithm
7 Collect error statistics
```

for counter = 1:20
data = randi([0 1],30,1);
encodedData = step(hConEnc, data);
modSignal = step(hMod, encodedData);

```
```

    receivedSignal = step(hChan, modSignal);
    demodSignal = step(hDemod, receivedSignal);
    receivedBits = step(hDec, demodSignal);
    errors = step(hError, data, receivedBits);
    end
Display the number of errors.

```
```

errors(2)

errors(2)
ans = 3
```

## Convolutional Encoding and Viterbi Decoding with a Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical

Define a puncture pattern matrix and reshape it into vector form for use with the Encoder and Decoder objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by pPatternVec.

```
ENC = comm.ConvolutionalEncoder(...
    'PuncturePatternSource','Property', ...
    'PuncturePattern',pPatternVec);
DEC = comm.ViterbiDecoder('InputFormat','Hard', ...
    'PuncturePatternSource','Property',...
    'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
ERR = comm.ErrorRate('ReceiveDelay',DEC.TracebackDepth);
```

Encode and decode a sequence of random bits.

```
dataIn = randi([0 1],600,1);
dataEncoded = step(ENC,dataIn);
dataOut = step(DEC,dataEncoded);
```

Verify that there are no errors in the output data.

```
errStats = step(ERR,dataIn,dataOut);
errStats(2)
ans = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Encoder block reference page. The object properties correspond to the block parameters, except:
The operation mode Reset on nonzero input via port block parameter corresponds to the
ResetInputPort on page 3-0 property.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder ${ }^{\text {rm }}$.
Usage notes and limitations:

## System object: comm. ConvolutionalEncoder <br> Package: comm

Convolutionally encode binary data

## Syntax

```
Y = step(H,X)
Y = step(H,X,INITSTATE)
Y = step(H,X,R)
[Y,FSTATE] = step(H,X)
```

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step $(H, X)$ encodes the binary data, $X$, using the convolutional encoding that you specify in the TrellisStructure property. It returns the encoded data, $Y$. Both $X$ and $Y$ are column vectors of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate $K / N$ code, the length of the input vector equals $K \times L$, for some positive integer, $L$. The step method sets the length of the output vector, Y , to $L \times N$.
$\mathrm{Y}=\mathrm{step}(\mathrm{H}, \mathrm{X}$, INITSTATE) uses the initial state specified in the INITSTATE input when you set the TerminationMethod property to 'Truncated' and the InitialStateInputPort property to true. INITSTATE must be an integer scalar.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X}, \mathrm{R})$ resets the internal states of the encoder when you input a non-zero reset signal, R. R must be a double precision or logical scalar. This syntax applies when you set the TerminationMethod property to Continuous and the ResetInputPort property to true.
[ $\mathrm{Y}, \mathrm{FSTATE}$ ] = step ( $\mathrm{H}, \mathrm{X}$ ) returns the final state of the encoder in the integer scalar output FSTATE when you set the FinalStateOutputPort property to true. This syntax applies when you set the TerminationMethod property to Continuous or Truncated.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.ConvolutionalInterleaver

Package: comm
Permute input symbols using shift registers with same property values

## Description

The ConvolutionalInterleaver object permutes the symbols in the input signal. Internally, this class uses a set of shift registers.

To convolutionally interleave binary data:
1 Define and set up your convolutional interleaver object. See "Construction" on page 3-314.
2 Call step to convolutionally interleave according to the properties of comm. Convolutional Interleaver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. ConvolutionalInterleaver creates a convolutional interleaver System object, H, that permutes the symbols in the input signal using a set of shift registers.

H = comm. ConvolutionalInterleaver(Name, Value) creates a convolutional interleaver System object, H. This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## NumRegisters

Number of internal shift registers
Specify the number of internal shift registers as a scalar, positive integer. The default is 6 .

## RegisterLengthStep

Number of additional symbols that fit in each successive shift register
Specify the number of additional symbols that fit in each successive shift register as a positive, scalar integer. The default is 2 . The first register holds zero symbols.

## InitialConditions

Initial conditions of shift registers

Specify the values that are initially stored in each shift register as a numeric scalar or vector. You do not need to specify a value for the first shift register, which has zero delay. The default is 0 . The value of the first element of this property is unimportant because the first shift register has zero delay. If you set this property to a scalar, then all shift registers, except the first one, store the same specified value. If you set it to a column vector with length equal to the value of the NumRegisters on page 30 property, then the $i$-th shift register stores the $i$-th element of the specified vector.

## Methods

reset Reset states of the convolutional interleaver object
step Permute input symbols using shift registers

## Common to All System Objects

release Allow System object property value changes

## Examples

## Convolutional Interleaving and Deinterleaving

Create convolutional interleaver and deinterleaver objects.

```
interleaver = comm.ConvolutionalInterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
deinterleaver = comm.ConvolutionalDeinterleaver('NumRegisters',2, ...
    'RegisterLengthStep',3);
```

Generate data, and pass the data through the convolutional interleaver. Pass the interleaved data through the convolutional deinterleaver.

```
data = (0:20)';
intrlvData = interleaver(data);
deintrlvData = deinterleaver(intrlvData);
```

Display the original sequence, interleaved sequence and restored sequence.

```
[data intrlvData deintrlvData]
```

ans $=21 \times 3$

| 0 | 0 | 0 |
| :--- | :--- | :--- |
| 1 | 0 | 0 |
| 2 | 2 | 0 |
| 3 | 0 | 0 |
| 4 | 4 | 0 |
| 5 | 0 | 0 |
| 6 | 6 | 0 |
| 7 | 1 | 1 |
| 8 | 8 | 2 |
| 9 | 3 | 3 |

The delay through the interleaver and deinterleaver pair is equal to the product of the NumRegisters and RegisterLengthStep properties. After accounting for this delay, confirm that the original and deinterleaved data are identical.

```
intrlvDelay = interleaver.NumRegisters * interleaver.RegisterLengthStep
intrlvDelay = 6
numSymErrors = symerr(data(1:end-intrlvDelay),deintrlvData(1+intrlvDelay:end))
numSymErrors = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolutional Interleaver block reference page. The object properties correspond to the block parameters.

## comm.CPFSKDemodulator

Package: comm
Demodulate using CPFSK method and Viterbi algorithm

## Description

The CPFSKDemodulator object demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the continuous phase frequency shift keying method:

1 Define and set up your CPFSK demodulator object. See "Construction" on page 3-319.
2 Call step to demodulate the signal according to the properties of comm.CPFSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.CPFSKDemodulator creates a demodulator System object, H. This object demodulates the input continuous phase frequency shift keying (CPFSK) modulated data using the Viterbi algorithm.

H = comm.CPFSKDemodulator(Name, Value) creates a CPFSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPFSKDemodulator(M,Name,Value) creates a CPFSK demodulator object, H. This object has the ModulationOrder property set to M, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Size of symbol alphabet
Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4 .

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer values. The default is false.

When you set this property to false, the step method outputs a column vector of length equal to $\mathrm{N} /$ SamplesPerSymbol on page 3-0 and with elements that are integers between -
(ModulationOrder on page 3-0 -1 ) and ModulationOrder-1. In this case, $N$, is the length of the input signal, which indicates the number of input baseband modulated symbols.

When you set this property to true, the step method outputs a binary column vector of length equal to $P \times(N /$ SamplesPerSymbol), where $P=\boldsymbol{\operatorname { l o g }} 2$ (ModulationOrder). The output contains length $-P$ bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value, $K$, between -(ModulationOrder-1) and ModulationOrder-1. The object then maps $K$ to the nonnegative integer ( $K+$ ModulationOrder-1)/2. Finally, the object maps each nonnegative integer to a length- $P$ binary word, using the mapping specified in the SymbolMapping on page 3-0 property.

## SymbolMapping

Symbol encoding
Specify the mapping of the modulated symbols as one of Binary | Gray. The default is Binary. This property determines how the object maps each demodulated integer symbol value (in the range 0 and ModulationO rder on page 3-0 -1 ) to a $P$-length bit word, where $P=$ ModulationOrder on page 3-0 (ModulationOrder).

When you set this property to Binary, the object uses a natural binary-coded ordering.
When you set this property to Gray, the object uses a Gray-coded ordering.
This property applies when you set the Bit0utput on page 3-0 property to true.

## ModulationIndex

Modulation index
Specify the modulation index. The default is 0.5 . The value of this property can be a scalar, $h$, or a column vector, $\left[h_{0}, h_{1}, \ldots . h_{\mathrm{H}-1}\right]$
where $\mathrm{H}-1$ represents the length of the column vector.
When $h_{\mathrm{i}}$ varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, $h_{\mathrm{i}}$ must be a rational number.

## InitialPhaseOffset

Initial phase offset
Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is 0 .

## SamplesPerSymbol

Number of samples per input symbol
Specify the expected number of samples per input symbol as a positive, integer scalar. The default is 8.

## TracebackDepth

Traceback depth for Viterbi algorithm
Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is 16 . The value of this property is also the value of the output delay. That value is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

## OutputDataType

Data type of output
Specify the output data type as one of int8 | int16 | int32| double, when you set the Bit0utput on page 3-0 property to false. The default is double.

When you set the BitOutput property to true, specify the output data type as one of logical | double.

## Methods

reset Reset states of CPFSK demodulator object
step Demodulate using CPFSK method and Viterbi algorithm

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## Demodulate a signal using CPFSK modulation with Gray mapping

```
% Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator
    hMod = comm.CPFSKModulator(8, 'BitInput', true, ...
                            'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                            'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPFSKDemodulator(8, 'BitOutput', true, ...
                            'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

Error rate $=0.004006$
Number of errors $=120$

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is $\pi \times h$, where $h$ is the modulation index.

## Extended Capabilities

## comm.CPFSKModulator

Package: comm
Modulate using CPFSK method

## Description

The CPFSKModulator object modulates using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using the continuous phase frequency shift keying method:
1 Define and set up your CPFSK modulator object. See "Construction" on page 3-325.
2 Call step to modulate the signal according to the properties of comm. CPFSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. CPFSKModulator creates a modulator System object, H. This object modulates the input signal using the continuous phase frequency shift keying (CPFSK) modulation method.

H = comm. CPFSKModulator(Name,Value) creates a CPFSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPFSKModulator(M,Name,Value) creates a CPFSK modulator object, H. This object has the ModulationOrder property set to M , and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Size of symbol alphabet
Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4 .

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false. When you set this property to false, the step method input must be a double-precision or signed integer data type column vector.

This vector comprises odd integer values between -(ModulationOrder on page 3-0 -1 ) and ModulationOrder-1.

When you set this property to true, the step method input must be a column vector of $P$-length bit words, where $P=\log 2$ (ModulationOrder). The input data must be double precision or logical data type. The object maps each bit word to an integer K between 0 and ModulationOrder-1, using the mapping specified in the SymbolMapping on page 3-0 property. The object then maps the integer $K$ to the intermediate value $2 K$-(ModulationOrder-1) and proceeds as in the case when you set the BitInput on page 3-0 property to false.

## SymbolMapping

Symbol encoding
Specify the mapping of bit inputs as one of Binary | Gray. The default is Binary. This property determines how the object maps each input $P$-length bit word, where $P=\boldsymbol{\operatorname { l o g }} 2$ (Modulation0rder on page 3-0 ), to an integer between 0 and ModulationOrder-1.

When you set this property to Binary, the object uses a natural binary-coded ordering.
When you set this property to Gray, the object uses a Gray-coded ordering.
This property applies when you set the BitInput on page 3-0 property to true.

## ModulationIndex

Modulation index
Specify the modulation index. The default is 0.5 . The value of this property can be a scalar, $h$, or a column vector, $\left[h_{0}, h_{1}, \ldots . h_{H-1}\right]$
where H-1 represents the length of the column vector. The phase shift over a symbol is $\pi \times h$.
When $h_{\mathrm{i}}$ varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, $h_{\mathrm{i}}$ must be a rational number.

## InitialPhaseOffset

Initial phase offset
Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is 0 .

## SamplesPerSymbol

Number of samples per output symbol
Specify the upsampling factor at the output as a real, positive, integer scalar. The default is 8 . The upsampling factor is the number of output samples that the step method produces for each input sample.

## OutputDataType

Data type of output
Specify output data type as one of double \| single. The default is double.

## Methods

| reset | Reset states of CPFSK modulator object |
| :--- | :--- |
| step | Modulate using CPFSK method |

| Common to All System Objects |  |

| release | Allow System object property value changes |

## Examples

## Demodulate a signal using CPFSK modulation with Gray mapping

```
% Create a CPFSK modulator, an AWGN channel, and a CPFSK demodulator
    hMod = comm.CPFSKModulator(8, 'BitInput', true, ...
                            SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
            'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPFSKDemodulator(8, 'BitOutput', true, ...
                            'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
Error rate = 0.004006
Number of errors = 120
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPFSK Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPFSK the phase shift per symbol is $\Pi \times h$, where $h$ is the modulation index.

## Extended Capabilities

## C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder $^{\text {TM }}$.
Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Introduced in R2012a

## reset

System object: comm. CPFSKModulator
Package: comm
Reset states of CPFSK modulator object

## Syntax

reset(H)

## Description

reset $(\mathrm{H})$ resets the states of the CPFSKModulator object, H .

## step

System object: comm. CPFSKModulator
Package: comm
Modulate using CPFSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

Y = step ( $\mathrm{H}, \mathrm{X}$ ) modulates input data, X , with the CPFSK modulator System object, H . It returns the baseband modulated output, Y. Depending on the value of the BitInput property, input $X$ can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector, Y , is equal to the number of input samples times the number of samples per symbol specified in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

# comm.CPMCarrierPhaseSynchronizer 

Package: comm
(Removed) Recover carrier phase of baseband CPM signal

Note comm.CPMCarrierPhaseSynchronizer has been removed. Use
comm. CarrierSynchronizer instead.

## Description

The CPMCarrierPhaseSynchronizer object recovers the carrier phase of the input signal using the $2 P$-Power method. This feedforward method is clock aided, but not data aided. The method is suitable for systems that use certain types of baseband modulation. These types include: continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), and Gaussian minimum shift keying (GMSK).

To recover the carrier phase of the input signal:
1 Define and set up your CPM carrier phase synchronizer object. See "Construction" on page 3331.

2 Call step to recover the carrier phase of the input signal using the $2 P$-Power method according to the properties of comm. CPMCarrierPhaseSynchronizer. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.CPMCarrierPhaseSynchronizer creates a CPM carrier phase synchronizer System object, H . This object recovers the carrier phase of a baseband continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), or Gaussian minimum shift keying (GMSK) modulated signal using the 2P-power method.

H = comm. CPMCarrierPhaseSynchronizer (Name, Value) creates a CPM carrier phase synchronizer object, H This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPMCarrierPhaseSynchronizer(HALFPOW,Name,Value) creates a CPM carrier phase synchronizer object, H . This object has the P on page 3-0 property set to HALFPOW, and the other specified properties set to the specified values.

## Properties

## P

Denominator of CPM modulation index
Specify the denominator of the CPM modulation index of the input signal as a real positive scalar integer value of data type single or double. The default is 2 . This property is tunable.

## ObservationInterval

Number of symbols where carrier phase assumed constant
Specify the observation interval as a real positive scalar integer value of data type single or double. The default is 100 .

## Methods

reset Reset states of the CPM carrier phase synchronizer object
step (Removed) Recover carrier phase of baseband CPM signal

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

Recover carrier phase of a GMSK signal.

```
% Initialize random seed for repeatability
rng(123)
% Create a GMSK modulator, an AWGN channel, and a GMSK demodulator.
% Use a phase offset of pi/4.
samplesPerSymbol = 4;
modulator = comm.GMSKModulator('BitInput',true,'InitialPhase0ffset',pi/4, ...
    SamplesPerSymbol', samplesPerSymbol);
awgnChannel = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',40) ;
demodulator = comm.GMSKDemodulator('BitOutput',true, ...
    'InitialPhaseOffset',pi/4,'SamplesPerSymbol', samplesPerSymbol);
% Create a System object for frequency offset
frequency0ffset = 1e4;
sampleRate = le6;
pfo = comm.PhaseFrequency0ffset('Frequency0ffset',frequency0ffset, ...
    SampleRate',sampleRate);
% Create a carrier synchronizer
carrierSync = comm.CarrierSynchronizer('SamplesPerSymbol', samplesPerSymbol, ...
    'Modulation','OQPSK');
% Create a preamble for resolving phase ambiguity
preambleLength = 13;
barker = comm.BarkerCode('Length',preambleLength,'SamplesPerFrame', ...
    preambleLength); % For preamble
preamble = (1+barker())/2; % Length 13, unipolar
% Create an error rate calculator, account for the delay caused by
% the Viterbi algorithm used by the GMSK demodulator.
errorCalculator = comm.ErrorRate('ReceiveDelay',demodulator.TracebackDepth);
numFrames = 4000;
symbolsPerFrame = 300;
estimatedPhase0ffset = zeros(symbolsPerFrame*samplesPerSymbol,numFrames);
```

```
errorHistory = zeros(numFrames,1);
for counter = 1:numFrames
    % Transmit 300 bits
    payload = randi([0 1],symbolsPerFrame - preambleLength,1);
    data = [preamble; payload];
    modulatedSignal = modulator(data);
    noisySignal = awgnChannel(modulatedSignal);
    rxSignal = pfo(noisySignal); % with carrier frequency offset
    [syncSignal, phOffset] = carrierSync(rxSignal);
    estimatedPhaseOffset(:, counter) = phOffset;
    phaseCorrection = round((2/pi)*angle(..
        modulatedSignal(1:preambleLength*samplesPerSymbol).* ...
        conj(syncSignal(1:preambleLength*samplesPerSymbol))));
    phaseCorrection(phaseCorrection==-2)=2;
    phaseCorrection = mode(phaseCorrection)*pi/2;
    receivedData = demodulator(exp(1j*phaseCorrection)*syncSignal);
    errorStats = errorCalculator(data,receivedData);
    errorHistory(counter) = errorStats(2);
end
estimatedFreqOffset = estimatedPhaseOffset(:);
% plot((estimatedFreqOffset(2:end)-estimatedFreqOffset(1:end-1))*sampleRate/(2*pi))
% xlabel('Sample')
% ylabel('Estimated Frequency Offset (Hz)');
% Number of bit errors (ignoring those in the first half of the simulation,
% before frequency and phase offset are corrected)
numErrors = errorHistory(end) - errorHistory(0.5*end)
numErrors =
    0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Phase Recovery block reference page. The object properties correspond to the block parameters.

## Compatibility Considerations

## comm. CPMCarrierPhaseSynchronizer has been removed

Errors starting in R2020a
comm. CPMCarrierPhaseSynchronizer has been removed. Use comm. CarrierSynchronizer instead.

reset $(\mathrm{H})$ resets the states of the CPMCarrierPhaseSynchronizer object, $H$.

## step

System object: comm.CPMCarrierPhaseSynchronizer
Package: comm
(Removed) Recover carrier phase of baseband CPM signal

Note comm.CPMCarrierPhaseSynchronizer has been removed. Use comm. CarrierSynchronizer instead.

## Syntax

[Y,PH] = step(H,X)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$[\mathrm{Y}, \mathrm{PH}]=\operatorname{step}(\mathrm{H}, \mathrm{X})$ recovers the carrier phase of the input signal, X , and returns the phase corrected signal, Y , and the carrier phase estimate (in degrees), PH . X must be a complex scalar or column vector input signal of data type single or double.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.CPMDemodulator

Package: comm
Demodulate using CPM method and Viterbi algorithm

## Description

The CPMDemodulator object demodulates a signal that was modulated using continuous phase modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using continuous phase modulation:
1 Define and set up your CPM demodulator object. See "Construction" on page 3-337.
2 Call step to demodulate a signal according to the properties of comm. CPMDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. CPMDemodulator creates a demodulator System object, H. This object demodulates the input continuous phase modulated (CPM) data using the Viterbi algorithm.

H = comm. CPMDemodulator(Name, Value) creates a CPM demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPMDemodulator(M,Name, Value) creates a CPM demodulator object, H, with the ModulationOrder property set to $M$, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Size of symbol alphabet
Specify the size of the symbol alphabet. The value of this property requires a power of two, real, integer scalar. The default is 4 .

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer values. The default is false.
When you set this property to false, the step method outputs a column vector of length equal to $\mathrm{N} /$ SamplesPerSymbol on page 3-0 and with elements that are integers between -
(ModulationOrder on page 3-0 -1) and ModulationOrder-1. Here, $N$, is the length of the input signal which indicates the number of input baseband modulated symbols.

When you set this property to true, the step method outputs a binary column vector of length equal to $P \times(N /$ SamplesPerSymbol), where $P=\boldsymbol{\operatorname { l o g }} 2$ (ModulationOrder). The output contains length $-P$ bit words. In this scenario, the object first maps each demodulated symbol to an odd integer value, $K$, between -(ModulationOrder-1) and Modulation0rder-1. The object then maps $K$ to the nonnegative integer ( $K+$ ModulationOrder-1)/2. Finally, the object maps each nonnegative integer to a length- $P$ binary word, using the mapping specified in the SymbolMapping on page 3-0 property.

## SymbolMapping

Symbol encoding
Specify the mapping of the demodulated symbols as one of Binary | Gray. The default is Binary. This property determines how the object maps each demodulated integer symbol value (in the range 0 and ModulationOrder on page 3-0 -1 ) to a $P$-length bit word, where $P=$ $\boldsymbol{\operatorname { l o g }} 2$ (ModulationOrder).

When you set this property to Binary, the object uses a natural binary-coded ordering.
When you set this property to Gray, the object uses a Gray-coded ordering.
This property applies when you set the BitOutput on page 3-0 property to true.

## ModulationIndex

Modulation index
Specify the modulation index. The default is 0.5 . The value of this property can be a scalar, $h$, or a column vector, $\left[h_{0}, h_{1}, \ldots . h_{\mathrm{H}-1}\right]$
where H-1 represents the length of the column vector.
When $h_{\mathrm{i}}$ varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, $h_{i}$ must be a rational number.

## FrequencyPulse

Frequency pulse shape
Specify the type of pulse shaping that the modulator has used to smooth the phase transitions of the input modulated signal as one of Rectangular|Raised Cosine|Spectral Raised Cosine| Gaussian | Tamed FM. The default is Rectangular.

## MainLobeDuration

Main lobe duration of spectral raised cosine pulse
Specify, in number of symbol intervals, the duration of the largest lobe of the spectral raised cosine pulse. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is 1 . This property requires a real, positive, integer scalar. This property applies when you set the FrequencyPulse on page 3-0 property to Spectral Raised Cosine.

## RolloffFactor

Rolloff factor of spectral raised cosine pulse
Specify the roll off factor of the spectral raised cosine pulse. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is 0.2 . This property requires a real scalar between 0 and 1. This property applies when you set the FrequencyPulse on page 3-
0 property to Spectral Raised Cosine.

## BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse
Specify the product of bandwidth and symbol time for the Gaussian pulse shape. This value is the value that the modulator used to pulse-shape the input modulated signal. The default is 0.3. This property requires a real, positive scalar. This property applies when you set the FrequencyPulse on page 3-0 property to Gaussian.

## PulseLength

Pulse length
Specify the length of the frequency pulse shape in symbol intervals. The value of this property requires a real positive integer. The default is 1 .

## SymbolPrehistory

Symbol prehistory
Specify the data symbols used by the modulator prior to the first call to the step method. The default is 1 . This property requires a scalar or vector with odd integer elements between (Modulation0rder on page 3-0 -1 ) and (Modulation0rder-1). If the value is a vector, then its length must be one less than the value in the PulseLength on page 3-0 property.

## InitialPhase0ffset

Initial phase offset
Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar. The default is 0.

## SamplesPerSymbol

Number of samples per input symbol
Specify the expected number of samples per input symbol as a positive, integer scalar. The default is 8.

## TracebackDepth

Traceback depth for Viterbi algorithm
Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar. The default is 16 . The value of this property is also the output delay, which is the number of zero symbols that precede the first meaningful demodulated symbol in the output.

## OutputDataType

Data type of output
Specify the output data type as one of int8 | int16 | int32 | double, when you set the Bit0utput on page 3-0 property to false. When you set the BitOutput property to true, specify the output data type as one of logical | double. The default is double.

## Methods

reset Reset states of CPM demodulator object
step Demodulate using CPM method and Viterbi algorithm
Common to All System Objects

| :--- | :--- |

## Examples

## Demodulate a CPM signal with Gray mapping and bit inputs

```
% Create a CPM modulator, an AWGN channel, and a CPM demodulator.
    hMod = comm.CPMModulator(8, 'BitInput', true, ...
            'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPMDemodulator(8, 'BitOutput', true, ...
                            'SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
Error rate = 0.004006
Number of errors = 120
```

## Apply GFSK Modulation and Demodulation

Using the comm. CPMModulator and comm. CPMDemodulator System objects apply GFSK modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator object pair.

```
gfskMod = comm.CPMModulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
    'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
```

```
    'BitInput', true);
gfskDemod = comm.CPMDemodulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
    'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
    'BitOutput', true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.
numSym = 100;
x = randi([0 1], numSym*gfskMod.SamplesPerSymbol,1);
$y=$ gfskMod(x);
eyediagram $(y, 16)$

Demodulate the GFSK modulated data. To verify that the demodulated signal data is equal to the original data, you must account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processing.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))
```

```
ans = logical
```

    1
    
## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Demodulator Baseband block reference page. The object properties correspond to the block parameters. For CPM the phase shift per symbol is $\pi \times h$, where $h$ is the modulation index.

Demodulate using CPM method and Viterbi algorithm

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the CPM demodulator System object, H , and returns Y . X must be a double or single precision, column vector with a length equal to an integer multiple of the number of samples per symbol specified in the SamplesPerSymbol property. Depending on the BitOutput property value, output $Y$ can be integer or bit valued.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.CPMModulator

Package: comm
Modulate using CPM method

## Description

The CPMModulator object modulates using continuous phase modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using continuous phase modulation:
1 Define and set up your CPM modulator object. See "Construction" on page 3-345.
2 Call step to modulate a signal according to the properties of comm. CPMModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. CPMModulator creates a modulator System object, H. This object modulates the input signal using the continuous phase modulation (CPM) method.

H = comm.CPMModulator(Name,Value) creates a CPM modulator object, H . This object has each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.CPMModulator(M,Name, Value) creates a CPM modulator object, H, with the ModulationOrder property set to M and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Size of symbol alphabet
Specify the size of the symbol alphabet. The value of this property must be a power of two, real, integer scalar. The default is 4 .

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false.

When you set this property to false, the step method input requires double-precision or signed integer data type column vector. This vector must comprise odd integer values between (ModulationOrder on page 3-0 -1) and ModulationOrder-1.

When you set this property to true, the step method input requires a column vector of $P$-length bit words, where $P=\log 2$ (ModulationOrder). The input data must have a double-precision or logical data type. The object maps each bit word to an integer $K$ between 0 and ModulationOrder-1, using the mapping specified in the SymbolMapping on page 3-0 property. The object then maps the integer $K$ to the intermediate value $2 K$-(ModulationOrder-1) and proceeds as in the case when BitInput is false.

## SymbolMapping

Symbol encoding
Specify the mapping of bit inputs as one of Binary | Gray. The default is Binary. This property determines how the object maps each input $P$-length bit word, where $P=\boldsymbol{\operatorname { l o g }} 2$ (ModulationOrder on page 3-0 ), to an integer between 0 and ModulationOrder-1.

When you set this property to Binary, the object uses a natural binary-coded ordering.
When you set this property to Gray, the object uses a Gray-coded ordering.
This property applies when you set the BitInput on page 3-0 property to true.

## ModulationIndex

Modulation index
Specify the modulation index. The default is 0.5 . The value of this property can be a scalar, $h$, or a column vector, $\left[h_{0}, h_{1}, \ldots . h_{H-1}\right]$
where H-1 represents the length of the column vector. The phase shift over a symbol is $\Pi \times h$.
When $h_{\mathrm{i}}$ varies from interval to interval, the object operates in multi-h. When the object operates in multi-h, $h_{\mathrm{i}}$ must be a rational number.

## FrequencyPulse

Frequency pulse shape
Specify the type of pulse shaping that the modulator uses to smooth the phase transitions of the modulated signal. Choose from Rectangular|Raised Cosine |Spectral Raised Cosine| Gaussian | Tamed FM. The default is Rectangular.

## MainLobeDuration

Main lobe duration of spectral raised cosine pulse
Specify, in number of symbol intervals, the duration of the largest lobe of the spectral raised cosine pulse. The default is 1 . This property requires a real, positive, integer scalar. This property applies when you set the FrequencyPulse on page 3-0 property to Spectral Raised Cosine.

## RolloffFactor

Rolloff factor of spectral raised cosine pulse

Specify the rolloff factor of the spectral raised cosine pulse. The default is 0.2 . This property requires a real scalar between 0 and 1 . This property applies when you set the FrequencyPulse on page 3-
0 property to Spectral Raised Cosine.

## BandwidthTimeProduct

Product of bandwidth and symbol time of Gaussian pulse
Specify the product of bandwidth and symbol time for the Gaussian pulse shape. The default is 0.3 .
This property requires a real, positive scalar. This property applies when you set the
FrequencyPulse on page 3-0 property to Gaussian.

## PulseLength

Pulse length
Specify the length of the frequency pulse shape in symbol intervals. The value of this property requires a real, positive integer. The default is 1 .

## SymbolPrehistory

Symbol prehistory
Specify the data symbols used by the modulator prior to the first call to the step method in reverse chronological order. The default is 1 . This property requires a scalar or vector with odd integer elements between -(ModulationOrder on page 3-0 -1 ) and (ModulationOrder-1). If the value is a vector, then its length must be one less than the value in the PulseLength on page 3-0 property.

## InitialPhaseOffset

Initial phase offset
Specify the initial phase of the modulated waveform in radians as a real, numeric scalar. The default is 0 .

## SamplesPerSymbol

Number of samples per output symbol
Specify the upsampling factor at the output as a real, positive, integer scalar. The default is 8 . The upsampling factor is the number of output samples that the step method produces for each input sample.

## OutputDataType

Data type of output
Specify output data type as one of double | single. The default is double.

## Methods

reset Reset states of CPM modulator object
step Modulate using CPM method

## Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

## Modulate a CPM signal with Gray mapping and bit inputs

```
% Create a CPM modulator, an AWGN channel, and a CPM demodulator.
    hMod = comm.CPMModulator(8, 'BitInput', true, ...
                            'SymbolMapping', 'Gray');
    hAWGN = comm.AWGNChannel('NoiseMethod', ...
                            'Signal to noise ratio (SNR)','SNR',0);
    hDemod = comm.CPMDemodulator(8, 'BitOutput', true, ...
                            SymbolMapping', 'Gray');
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm.
    delay = log2(hDemod.ModulationOrder)*hDemod.TracebackDepth;
    hError = comm.ErrorRate('ReceiveDelay', delay);
    for counter = 1:100
        % Transmit 100 3-bit words
        data = randi([0 1],300,1);
        modSignal = step(hMod, data);
        noisySignal = step(hAWGN, modSignal);
        receivedData = step(hDemod, noisySignal);
        errorStats = step(hError, data, receivedData);
    end
    fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
Error rate = 0.004006
Number of errors = 120
```

## Apply GFSK Modulation and Demodulation

Using the comm. CPMModulator and comm. CPMDemodulator System objects apply GFSK modulation and demodulation to random bit data.

Create a GFSK modulator and demodulator object pair.

```
gfskMod = comm.CPMModulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
    'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
    'BitInput', true);
gfskDemod = comm.CPMDemodulator('ModulationOrder', 2, 'FrequencyPulse', 'Gaussian', ...
    'BandwidthTimeProduct', 0.5, 'ModulationIndex', 1, ...
    'BitOutput', true);
```

Generate random bit data and apply GFSK modulation. Use a scatter plot to view the constellation.
numSym = 100;
$x=\operatorname{randi}([01], n u m S y m * g f s k M o d . S a m p l e s P e r S y m b o l, 1) ;$
$y=$ gfskMod(x);
eyediagram(y,16)

Demodulate the GFSK modulated data. To verify that the demodulated signal data is equal to the original data, you must account for the delay introduced by the Gaussian filtering in the GFSK modulation and demodulation processing.

```
z = gfskDemod(y);
delay = finddelay(x,z);
isequal(x(1:end-delay),z(delay+1:end))
ans = logical
    1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the CPM Modulator Baseband block reference page. The object properties correspond to the block parameters. For CPM the phase shift per symbol is $\Pi \times h$, where $h$ is the modulation index.

## Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® ${ }^{\circledR}$ Coder $^{\text {TM }}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## reset

System object: comm. CPMModulator
Package: comm
Reset states of CPM modulator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the CPMModulator object, H .

## step

System object: comm. CPMModulator
Package: comm
Modulate using CPM method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the CPM modulator System object, H . It returns the baseband modulated output, Y. Depending on the value of the BitInput property, input $X$ can be an integer or bit valued column vector with data types double, signed integer, or logical. The length of output vector, Y , is equal to the number of input samples times the number of samples per symbol specified in the SamplesPerSymbol property.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.CRCDetector

Package: comm
Detect errors in input data using CRC

## Description

The comm. CRCDetector System object computes cyclic redundancy check (CRC) checksums for an entire received codeword. For successful CRC detection in a communications system link, you must align the property settings of the comm. CRCDetector System object with the paired comm. CRCGenerator System object. For more information, see "CRC Syndrome Detector Operation" on page 3-358.

To detect errors in the received codeword containing CRC sequence bits:
1 Create the comm. CRCDetector object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

crcdetector = comm.CRCDetector
crcdetector $=$ comm. CRCDetector (Name, Value)
crcdetector $=$ comm. CRCDetector (poly, Name, Value)

## Description

crcdetector = comm. CRCDetector creates a CRC code detector System object. This object detects errors in the received codewords according to a specified generator polynomial.
crcdetector $=$ comm. CRCDetector(Name, Value) sets properties using one or more name-value pairs. For example, comm. CRCDetector('Polynomial','z^16 + z^14 + z + 1') configures the CRC code detector System object to use the CRC-16 cyclic redundancy check bits when checking for CRC code errors in the received codewords. Enclose each property name in quotes.
crcdetector = comm.CRCDetector(poly, Name, Value) creates a CRC code detector System object. This object has the Polynomial property set to poly, and the other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Polynomial - Generator polynomial

'z^16 + $z^{\wedge 12 ~+~} z^{\wedge} 5+1^{\prime}($ default $) \mid$ polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as ' $z^{\wedge} 3+z^{\wedge} 2+1$.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial. For example, $\left[\begin{array}{lll}1 & 1 & 0\end{array} 1\right]$ represents the polynomial $x^{3}+z^{2}+1$.
- An integer row vector containing the exponents of $z$ for the nonzero terms in the polynomial in descending order. For example, $\left[\begin{array}{lll}3 & 2 & 0\end{array}\right]$ represents the polynomial $z^{3}+z^{2}+1$.

For more information, see "Character Representation of Polynomials".
Some commonly used generator polynomials include:

| CRC <br> method | Generator polynomial |
| :--- | :--- |
| CRC-32 | $\prime z^{\wedge} 32+z^{\wedge} 26+z^{\wedge} 23+z^{\wedge} 22+z^{\wedge} 16+z^{\wedge} 12+z^{\wedge} 11+z^{\wedge} 10+z^{\wedge} 8+z^{\wedge} 7$ <br> $+z^{\wedge} 5+z^{\wedge} 4+z^{\wedge} 2+z+1^{\prime}$ |
| CRC-24 | $' z^{\wedge} 24+z^{\wedge} 23+z^{\wedge} 14+z^{\wedge} 12+z^{\wedge} 8+1^{\prime}$ |
| CRC-16 | $' z^{\wedge} 16+z^{\wedge} 15+z^{\wedge} 2+1^{\prime}$ |
| Reversed <br> CRC-16 | $z^{\wedge} 16+z^{\wedge} 14+z+1^{\prime}$ |
| CRC-8 | $' z^{\wedge} 8+z^{\wedge} 7+z^{\wedge} 6+z^{\wedge} 4+z^{\wedge} 2+1^{\prime}$ |
| CRC-4 | $z^{\wedge} 4+z^{\wedge} 3+z^{\wedge} 2+z+1^{\prime}$ |

Example: ' $z^{\wedge} 7+z^{\wedge} 2+1 ',[10000101]$, and [7 200 ] represent the same polynomial, $p(z)=z^{7}+z^{2}+1$.
Data Types: double | char

## InitialConditions - Initial states of internal shift register

0 (default) | 1 | binary row vector
Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.
Data Types: logical

## DirectMethod - Use direct algorithm for CRC checksum calculations

false (default) |true
Use direct algorithm for CRC checksum calculations, specified as false or true.
When you set this property to true, the object uses the direct algorithm for CRC checksum calculations. When you set this property to false, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see "Error Detection and Correction".
Data Types: logical

## ReflectInputBytes - Reflect input bytes

## false (default)|true

Reflect input bytes, specified as false or true. Set this property to true to flip the received codeword on a bytewise basis before entering the data into the shift register.

When you set this property to true, the received codeword length divided by the value of the ChecksumsPerFrame property must be an integer and a multiple of 8 .

Data Types: logical
ReflectChecksums - Reflect checksums before final XOR
false (default)|true
Reflect checksums before final XOR, specified as false or true. Set this property to true to flip the CRC checksums around their centers after the received codeword is completely through the shift register.

When you set this property to true, the object flips the CRC checksums around their centers before the final XOR.

Data Types: logical

## FinalXOR - Final XOR

0 (default) | binary scalar | binary vector
Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the FinalXOR property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.

Data Types: logical

## ChecksumsPerFrame - Number of checksums calculated

1 (default) | positive integer
Number of checksums calculated for each received codeword frame, specified as a positive integer. for more information, see "CRC Syndrome Detector Operation" on page 3-358.
Data Types: double

## Usage

## Syntax

```
out = crcdetector(codeword)
[msg,err] = crcdetector(codeword)
```

## Description

out $=$ crcdetector (codeword) checks CRC code bits for each received codeword frame, removes the checksums, and then concatenates subframes to the output frame.
[msg,err] = crcdetector(codeword) also returns the checksum error signal computed when checking CRC code bits for each codeword subframe.

## Input Arguments

codeword - Received codeword
binary column vector
Received codeword, specified as a binary column vector.
Data Types: double | logical

## Output Arguments

## out - Output frame

binary column vector
Output frame, returned as a binary column vector that inherits the data type of the input signal. The message word output contains the received codeword with the checksums removed.

The length of the output frame is $n-k * r$ bits, where $n$ is the size of the received codeword, $k$ is the number of checksums per frame, and $r$ is the degree of the generator polynomial.

## err - Checksum error signal

binary column vector
Checksum error signal, returned as a binary column vector that inherits the data type of the input signal. The length of Err equals the value of ChecksumsPerFrame. For each checksum computation, an element value of 0 in err indicates no checksum error, and an element value of 1 in err indicates a checksum error.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.

```
x = randi([0 1],12,1);
```

Encode the input message frame using a CRC generator with the ChecksumsPerFrame property set to 2. This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1],'ChecksumsPerFrame',2);
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1],'ChecksumsPerFrame',2);
[~, err] = crcdetector(codeword)
err = 2\times1
```

0
0

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
err = 2×1
    0
    1
```

## Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.
Create a CRC generator and detector pair using a standard CRC-4 polynomial, $z^{4}+z^{3}+z^{2}+z+1$.

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12-bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);
```

```
for k = 1:numFrames
    data = randi([0 1],12,1); % Generate binary data
    encData = crcgenerator(data); % Append CRC bits
    modData = pskmod(encData,2); % BPSK modulate
    rxSig = awgn(modData,5); %AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2); % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
ans = 6
```

## More About

## Cyclic Redundancy Check Coding

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the checksum or syndrome, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1 , the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see "Cyclic Redundancy Check Codes".

## CRC Syndrome Detector Operation

The CRC syndrome detector outputs the received message frame and a checksum error vector according to the specified generator polynomial and number of checksums per frame.

The checksum bits are removed from each subframe, so that the resulting the output frame length is $n-k \times r$, where $n$ is the size of the received codeword, $k$ is the number of checksums per frame, and $r$ is the degree of the generator polynomial. The input frame must be evenly divisible by $k$.

For a specific initial state of the internal shift register:
1 The received codeword is divided into $k$ equal sized subframes.
2 The CRC is removed from each of the $k$ subframes and compared to the checksum calculated on the received codeword subframes.
3 The output frame is assembled by concatenating the subframe bits of the $k$ subframes and then output as a column vector.

4 The checksum error is output as a binary column vector of length $k$. An element value of 0 indicates an error-free received subframe, and an element value of 1 indicates an error occurred in the received subframe.

For the scenario shown here, a 16-bit codeword is received, a third degree generator polynomial computes the CRC checksum, the initial state is 0 , and the number of checksums per frame is 2 .

Since the number of checksums per frame is 2 and the generator polynomial degree is 3 , the received codeword is split in half and two checksums of size 3 are computed, one for each half of the received codeword. The initial states are not shown, because an initial state of [0] does not affect the output of the CRC algorithm. The output frame contains the concatenation of the two halves of the received codeword as a single vector of size 10 . The checksum error signal output contains a 2 -by- 1 binary frame vector whose entries depend on whether the computed checksums are zero. As shown in the figure, the first checksum is nonzero and the second checksum is zero, indicating an error occurred in reception of the first half of the codeword.

## comm.CRCGenerator

Package: comm
Generate CRC code bits and append to input data

## Description

The comm. CRCGenerator System object generates cyclic redundancy check (CRC) code bits for each input frame and appends them to the frame. For more information, see "CRC Generator Operation" on page 3-369.

To generate CRC code bits for each input frame and append them to the frame:
1 Create the comm. CRCGenerator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

crcgenerator= comm.CRCGenerator
crcgenerator $=$ comm. CRCGenerator(Name, Value)
crcgenerator $=$ comm. CRCGenerator (poly,Name, Value)

## Description

crcgenerator= comm. CRCGenerator creates a CRC code generator System object. This object generates CRC bits according to a specified generator polynomial and appends them to the input frame.
crcgenerator $=$ comm. CRCGenerator (Name, Value) sets properties using one or more namevalue pairs. For example, comm. CRCGenerator('Polynomial','z^16 + $\left.z^{\wedge} 14+z+1 '\right)$ configures the CRC generator System object to append CRC-16 cyclic redundancy check bits to the input frame. Enclose each property name in quotes.
crcgenerator $=$ comm. CRCGenerator (poly, Name, Value) creates a CRC code generator System object. This object has the Polynomial property set to poly, and the other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Polynomial - Generator polynomial

'z^16 + $z^{\wedge 12 ~+~} z^{\wedge} 5+1^{\prime}($ default $) \mid$ polynomial character vector | binary row vector | integer row vector

Generator polynomial for the CRC algorithm, specified as one of the following:

- A polynomial character vector such as ' $z^{\wedge} 3+z^{\wedge} 2+1$.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power. The length of this vector is $(N+1)$, where $N$ is the degree of the generator polynomial. For example, $\left[\begin{array}{lll}1 & 1 & 0\end{array} 1\right]$ represents the polynomial $x^{3}+z^{2}+1$.
- An integer row vector containing the exponents of $z$ for the nonzero terms in the polynomial in descending order. For example, $\left[\begin{array}{lll}3 & 2 & 0\end{array}\right]$ represents the polynomial $z^{3}+z^{2}+1$.

For more information, see "Character Representation of Polynomials".
Some commonly used generator polynomials include:

| CRC <br> method | Generator polynomial |
| :--- | :--- |
| CRC-32 | $\prime z^{\wedge} 32+z^{\wedge} 26+z^{\wedge} 23+z^{\wedge} 22+z^{\wedge} 16+z^{\wedge} 12+z^{\wedge} 11+z^{\wedge} 10+z^{\wedge} 8+z^{\wedge} 7$ <br> $+z^{\wedge} 5+z^{\wedge} 4+z^{\wedge} 2+z+1^{\prime}$ |
| CRC-24 | $' z^{\wedge} 24+z^{\wedge} 23+z^{\wedge} 14+z^{\wedge} 12+z^{\wedge} 8+1^{\prime}$ |
| CRC-16 | $' z^{\wedge} 16+z^{\wedge} 15+z^{\wedge} 2+1^{\prime}$ |
| Reversed <br> CRC-16 | $z^{\wedge} 16+z^{\wedge} 14+z+1^{\prime}$ |
| CRC-8 | $' z^{\wedge} 8+z^{\wedge} 7+z^{\wedge} 6+z^{\wedge} 4+z^{\wedge} 2+1^{\prime}$ |
| CRC-4 | $z^{\wedge} 4+z^{\wedge} 3+z^{\wedge} 2+z+1^{\prime}$ |

Example: ' $z^{\wedge} 7+z^{\wedge} 2+1 ',[10000101]$, and [7 200 ] represent the same polynomial, $p(z)=z^{7}+z^{2}+1$.
Data Types: double | char

## InitialConditions - Initial states of internal shift register

0 (default) | 1 | binary row vector
Initial states of the internal shift register, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial.
Data Types: logical

## DirectMethod - Use direct algorithm for CRC checksum calculations

false (default) |true
Use direct algorithm for CRC checksum calculations, specified as false or true.
When you set this property to true, the object uses the direct algorithm for CRC checksum calculations. When you set this property to false, the object uses the non-direct algorithm for CRC checksum calculations.

For more information on direct and non-direct algorithms, see "Error Detection and Correction".
Data Types: logical

## ReflectInputBytes - Reflect input bytes

false (default) | true
Reflect input bytes, specified as false or true. Set this property to true to flip the input frame on a bytewise basis before entering the data into the shift register.

When you set this property to true, the input frame length divided by the value of the ChecksumsPerFrame property must be an integer and a multiple of 8 .

Data Types: logical
ReflectChecksums - Reflect checksums before final XOR
false (default)|true
Reflect checksums before final XOR, specified as false or true. Set this property to true to flip the CRC checksums around their centers after the input data are completely through the shift register.
Data Types: logical

## FinalXOR - Final XOR

0 (default) | binary scalar | binary vector
Final XOR, specified as a binary scalar or a binary row vector with a length equal to the degree of the generator polynomial. The XOR operation runs using the value of the FinalXOR property and the CRC checksum before comparing with the input checksum. A scalar value is expanded to a row vector of equal length to the degree of the generator polynomial. A setting of 0 is equivalent to no XOR operation.
Data Types: logical

## ChecksumsPerFrame - Number of checksums calculated for each frame

1 (default) | positive integer
Number of checksums calculated for each frame, specified as a positive integer. For more information, see "CRC Generator Operation" on page 3-369.

```
Data Types: double
```

## Usage

## Syntax

codeword = crcgenerator(x)

## Description

codeword $=$ crcgenerator $(x)$ generates CRC code bits for each input frame and appends them to the frame.

## Input Arguments

## x - Input signal

binary column vector
Input signal, specified as a binary column vector. The length of the input frame must be a multiple of the value of the ChecksumsPerFrame property. If the input data type is double, the least significant bit is used as the binary value. For more information, see "CRC Generator Operation" on page 3-369.

## Data Types: double | logical

## Output Arguments

codeword - Output codeword frame
binary column vector
Output codeword frame, returned as a binary column vector that inherits the data type of the input signal. The output contains the input frames with the CRC code sequence bits appended.

The length of the output codeword frame is $m+k * r$, where $m$ is the size of the input message, $k$ is the number of checksums per input frame, and $r$ is the degree of the generator polynomial. For more information, see "CRC Generator Operation" on page 3-369.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Generate CRC-8 Checksum

Generate a CRC-8 checksum for the example shown in $802.11^{\mathrm{Tm}}-2016[1]$ on page $3-0$, section 21.3.10.3 and compare with the expected CRC.

Create a CRC Generator System object ${ }^{\mathrm{TM}}$. To align with the CRC calculation in 802.11-20016, the System object ${ }^{\mathrm{TM}}$ sets the generator polynomial as $z^{8}+z^{2}+z+1$, initial states to 1 , direct method, and final XOR to 1.

```
crc8 = comm.CRCGenerator('Polynomial','z^8 + z^2 + z + 1', ...
    'InitialConditions',1,'DirectMethod',true,'FinalXOR',1)
crc8 =
    comm.CRCGenerator with properties:
```

```
            Polynomial: 'z^8 + z^2 + z + 1'
InitialConditions: 1
        DirectMethod: true
ReflectInputBytes: false
    ReflectChecksums: false
            FinalXOR: 1
ChecksumsPerFrame: 1
```

Process one input frame according to the example from the 802.11-2016 standard in section 21.3.10.3. In the example, the input bit stream $\{\mathrm{m} 0, \ldots \mathrm{~m} 22\}$ is $\{1001100000000000000$ $011\}$ and the expected CRC checksum $\{c 7, \ldots c 0\}$ is $\{00011100\}$.

```
x = [1 0 0 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1]';
expectedChecksum = [0 0 0 1 1 1 0 0]';
checksumLength = length(expectedChecksum);
```

The generated CRC checksum is compared to the expected checksum.

```
codeword = crc8(x);
checksum = codeword(end-checksumLength+1:end);
isequal(checksum,expectedChecksum)
ans = logical
    1
```

## CRC Detection of Errors in a Random Message

Pass binary data through a CRC generator, introduce a bit error, and detect the error using a CRC detector.

Create a random binary vector.
$x=\operatorname{randi}([01], 12,1)$;
Encode the input message frame using a CRC generator with the ChecksumsPerFrame property set to 2 . This subdivides the incoming frame into two equal-length subframes.

```
crcgenerator = comm.CRCGenerator([1 0 0 1],'ChecksumsPerFrame',2);
codeword = crcgenerator(x);
```

Decode the codeword and verify that there are no errors in either subframe.

```
crcdetector = comm.CRCDetector([1 0 0 1],'ChecksumsPerFrame',2);
[~, err] = crcdetector(codeword)
err = 2×1
    0
    0
```

Introduce an error in the second subframe by inverting the last element of subframe 2. Pass the corrupted codeword through the CRC detector and verify that the error is detected in the second subframe.

```
codeword(end) = not(codeword(end));
[~,err] = crcdetector(codeword)
err = 2×1
    0
    1
```

## Cyclic Redundancy Check of Noisy BPSK Data Frames

Use a CRC code to detect frame errors in a noisy BPSK signal.
Create a CRC generator and detector pair using a standard CRC-4 polynomial, $z^{4}+z^{3}+z^{2}+z+1$.

```
poly = 'z4+z3+z2+z+1';
crcgenerator = comm.CRCGenerator(poly);
crcdetector = comm.CRCDetector(poly);
```

Generate 12 -bit frames of binary data and append the CRC bits. Based on the degree of the polynomial, 4 bits are appended to each frame. Apply BPSK modulation and pass the signal through an AWGN channel. Demodulate and use the CRC detector to determine if the frame is in error.

```
numFrames = 20;
frmError = zeros(numFrames,1);
for k = 1:numFrames
    data = randi([0 1],12,1); % Generate binary data
    encData = crcgenerator(data); % Append CRC bits
    modData = pskmod(encData,2); % BPSK modulate
    rxSig = awgn(modData,5); %AWGN channel, SNR = 5 dB
    demodData = pskdemod(rxSig,2); % BPSK demodulate
    [~,frmError(k)] = crcdetector(demodData); % Detect CRC errors
end
```

Identify the frames in which CRC code bit errors are detected.

```
find(frmError)
ans = 6
```

## CRC-16-CCITT Generator for X. 25

Create a CRC-16-CCITT generator as described in Section 2.2.7.4 of ITU-T Recommendation X-25[1] on page 3-0 using the input data and expected frame check sequence (FCS) from Example 2 in Appendix I, I.1.

Create an unnumbered acknowledgement (UA) response frame where address $=\mathrm{B}$ and $\mathrm{F}=1$.

```
Address = [1 0 0 0 0 0 0 0];
UA = [llllllllll
input = [Address UA]';
expectedChecksum = [1 1 0 0 0 0 0 1 1 1 1 0 1 0 1 0]'; % Expected FCS
checksumLength = 16;
crcGen = comm.CRCGenerator(...
    'Polynomial','X^16 + X^12 + X^5 + 1',...
    'InitialConditions',1,...
    'DirectMethod',true,...
    'FinalXOR',1);
crcSeq = crcGen(input);
checkSum = crcSeq(end-checksumLength+1:end);
```

Compare calculated checksum with the expected checksum.

```
isequal(expectedChecksum,checkSum)
```

ans = logical
1

## CRC-32 Generator for Ethernet

Create a CRC-32 code for the frame check sequence (FCS) field for Ethernet as described in Section 3.2.9 of the IEEE Standard for Ethernet[1] on page 3-0 .

```
rng(1865); % Seed the random number generator for repeatable results
```

Initialize a message with random data to represent the protected fields of the MAC frame, specifically the destination address, source address, length or type field, MAC client data, and padding.

```
data = randi([0,1],100,1);
```

Specify the CRC-32 generating polynomial used for encoding Ethernet messages.

```
poly = [32,26,23,22,16,12,11,10,8,7,5,4,2,1,0];
```

Calculate the CRC by following the steps specified in the standard and using the nondirect method to generate the CRC code.

```
dataN = [not(data(1:32));data(33:end)]; % Section 3.2.9 step a) and b)
crcGen1 = comm.CRCGenerator(...
    'Polynomial', poly, ...
    'InitialConditions', 0, ...
    'DirectMethod', false, ...
    'FinalXOR', 1);
seq = crcGen1(dataN); % Section 3.2.9 step c), d) and e)
csNondirect = seq(end-31:end);
```

Calculate the CRC by following the steps specified in the standard and using the direct method to generate the CRC code.

```
crcGen2 = comm.CRCGenerator(...
    'Polynomial', poly, ...
    'InitialConditions', 1, ...
    'DirectMethod', true, ...
    'FinalXOR', 1);
txSeq = crcGen2(data);
csDirect = txSeq(end-31:end);
Compare the generated CRC codes by using the nondirect and direct methods.
```

```
disp([csNondirect';csDirect']);
```

disp([csNondirect';csDirect']);

\section*{More About}

\section*{Cyclic Redundancy Check Coding}

Cyclic redundancy check (CRC) coding is an error-control coding technique for detecting errors that occur when a data frame is transmitted. Unlike block or convolutional codes, CRC codes do not have a built-in error-correction capability. Instead, when a communications system detects an error in a received codeword, the receiver requests the sender to retransmit the codeword.

In CRC coding, the transmitter applies a rule to each data frame to create extra CRC bits, called the checksum or syndrome, and then appends the checksum to the data frame. After receiving a transmitted codeword, the receiver applies the same rule to the received codeword. If the resulting checksum is nonzero, an error has occurred and the transmitter should resend the data frame.

When the number of checksums per frame is greater than 1 , the input data frame is divided into subframes, the rule is applied to each data subframe, and individual checksums are appended to each subframe. The subframe codewords are concatenated to output one frame.

For a discussion of the supported CRC algorithms, see "Cyclic Redundancy Check Codes".

\section*{CRC Generator Operation}

The CRC generator appends CRC checksums to the input frame according to the specified generator polynomial and number of checksums per frame.

For a specific initial state of the internal shift register and \(k\) checksums per input frame:
1 The input signal is divided into \(k\) subframes of equal size.
2 Each of the \(k\) subframes are prefixed with the initial states vector.
3 The CRC algorithm is applied to each subframe.
4 The resulting checksums are appended to the end of each subframe.
5 The subframes are concatenated and output as a column vector.
For the scenario shown here, a 10-bit frame is input, a third degree generator polynomial computes the CRC checksum, the initial state is 0 , and the number of checksums per frame is 2 .

The input frame is divided into two subframes of size 5 and checksums of size 3 are computed and appended to each subframe. The initial states are not shown, because an initial state of [0] does not affect the output of the CRC algorithm. The output transmitted codeword frame has the size \(5+3+\) \(5+3=16\).

\section*{comm.DBPSKDemodulator}

Package: comm
Demodulate using DBPSK method

\section*{Description}

The DBPSKDemodulator object demodulates a signal that was modulated using the differential binary phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential binary phase shift keying:
1 Define and set up your DBPSK demodulator object. See "Construction" on page 3-371.
2 Call step to demodulate a signal according to the properties of comm. DBPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, \(x\) ) and \(y=o b j(x)\) perform equivalent operations.

\section*{Construction}

H = comm. DBPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the differential binary phase shift keying (DBPSK) method.

H = comm. DBPSKDemodulator(Name,Value) creates a DBPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. DBPSKDemodulator(PHASE, Name,Value) creates a DBPSK demodulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

\section*{Properties}

\section*{PhaseRotation}

Additional phase shift
Specify the additional phase difference between previous and current modulated bits in radians as a real scalar. The default is 0 . This value corresponds to the phase difference between previous and current modulated bits when the input is zero.

\section*{OutputDataType}

Data type of output
Specify output data type as one of Full precision | Smallest unsigned integer|double | single | int8 | uint8 | int16|uint16|int32|uint32|logical. The default is Full
precision. When you set this property to Full precision, the output data type has the same data type as the input. In this case, that value must be a double- or single-precision data type.

\(\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})\) modulates input data, X , with the DBPSK modulator System object, H . It returns the baseband modulated output, Y . The input must be a numeric or logical data type column vector of bits.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

\section*{comm.Descrambler}

Package: comm
Descramble input signal

\section*{Description}

The comm.Descrambler object descrambles a scalar or column vector input signal. The comm.Descrambler object is the inverse of the comm. Scrambler object. If you use the comm. Scrambler object in a transmitter, then you use the comm.Descrambler object in the related receiver.

This schematic shows the descrambler operation. The adders and subtracter operate modulo \(N\), where \(N\) is the value specified by the Calculation base property.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the descrambler. To make the comm. Descrambler object reverse the operation of the comm. Scrambler object, use the same property settings in both objects. If there is no signal delay between the scrambler and the descrambler, then the InitialConditions in the two objects must be the same.

To descramble an input signal:
1 Create the comm. Descrambler object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

\section*{Creation}

\section*{Syntax}
```

descrambler = comm.Descrambler
descrambler = comm.Descrambler(base,poly,cond)
descrambler = comm.Descrambler(

```
\(\qquad\)
``` ,Name, Value)
```

## Description

descrambler $=$ comm. Descrambler creates a descrambler System object. This object descrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.
descrambler $=$ comm. Descrambler(base, poly, cond) creates the descrambler object with the CalculationBase property set to base, the Polynomial property set to poly, and the InitialConditions property set to cond.
Example: comm. Descrambler(8,'1 + $z^{\wedge}-2+z^{\wedge}-3+z^{\wedge}-5+z^{\wedge}-7{ }^{\prime},\left[\begin{array}{lllll}0 & 3 & 2 & 2 & 1\end{array}\right]$ ) sets the calculation base to 8 , and the descrambler polynomial and initial conditions as specified.
descrambler = comm.Descrambler( $\qquad$ ,Name, Value) sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.
Example: comm.Descrambler('CalculationBase',2)

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## CalculationBase - Range of input data

4 (default) | nonnegative integer
Range of input data used in the descrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from 0 to CalculationBase - 1 .
Data Types: double

## Polynomial - Connections for linear feedback shift registers

' $1+z^{\wedge}-1+z^{\wedge}-2+z^{\wedge}-4^{\prime}$ (default) $\mid$ character vector $\mid$ integer vector $\mid$ binary vector
Connections for linear feedback shift registers in the descrambler, specified as a character vector, integer vector, or binary vector. The Polynomial property defines if each switch in the descrambler is on or off. Specify the polynomial as:

- A character vector, such as ' $1+z^{\wedge}-6+z^{\wedge}-8$ '. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0-6 -8], listing the descrambler coefficients in order of descending powers of $z^{-1}$, where $p\left(z^{-1}\right)=1+p_{1} z^{-1}+p_{2} z^{-2}+\ldots$
- A binary vector, such as [1000000101], listing the powers of $z$ that appear in the polynomial that have a coefficient of 1 . In this case, the order of the descramble polynomial is one less than the binary vector length.

Example: '1 + $z^{\wedge}-6+z^{\wedge}-8 '$, $[0-6-8]$, and $[100000101]$ all represent this polynomial:
$p\left(z^{-1}\right)=1+z^{-6}+z^{-8}$

## Data Types: double | char

InitialConditionsSource - Initial conditions source
'Property' (default)|'Input port'

- 'Property' - Specify descrambler initial conditions by using the InitialConditions property.
- 'Input port' - Specify descrambler initial conditions by using an additional input argument, initcond, when calling the object.

Data Types: char
InitialConditions - Initial conditions of descrambler registers
[0 $\left.\begin{array}{llll}0 & 1 & 2 & 3\end{array}\right]$ (default)|nonnegative integer vector
Initial conditions of descrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of InitialConditions must equal the order of the Polynomial property. The vector element values must be integers from 0 to CalculationBase - 1 .

## Dependencies

This property is available when InitialConditionsSource is set to 'Property '.

## ResetInputPort - Descrambler state reset port

false (default) | true
Descrambler state reset port, specified as false or true. If ResetInputPort is true, you can reset the descrambler object by using an additional input argument, reset, when calling the object.

## Dependencies

This property is available when InitialConditionsSource is set to 'Property'.

## Usage

## Syntax

```
descrambledOut = descrambler(signal)
descrambledOut = descrambler(signal,initcond)
descrambledOut = descrambler(signal,reset)
```

## Description

descrambledOut $=$ descrambler(signal) descrambles the input signal. The output is the same data type and length as the input vector.
descrambledOut = descrambler(signal, initcond) provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to 'Input port'.
descrambledOut $=$ descrambler(signal, reset) provides an additional input indicating whether to reset the state of the descrambler.

This syntax applies when you set the InitialConditionsSource property of the object to 'Property ' and the ResetInputPort to true.

## Input Arguments

## signal - Input signal

column vector
Input signal, specified as a column vector.
Example: descrambled0ut $=$ descrambler([[0 $118 c c c c])$
Data Types: double | logical

## initcond - Initial register condition

nonnegative integer column vector
Initial descrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of initcond must equal the order of the Polynomial property. The vector element values must be integers from 0 to CalculationBase - 1 .
Example: descrambledOut = descrambler(signal, $\left.\left[\begin{array}{llll}0 & 1 & 1 & 0\end{array}\right]\right)$ corresponds to possible initial register states for a descrambler with a polynomial order of 4 and a calculation base of 2 or higher.
Data Types: double
reset - Reset initial state of descrambler
scalar
Reset initial state of the descrambler when the simulation starts, specified as a scalar. When the value of reset is nonzero, the object is reset before it is called.
Example: descrambled0ut = descrambler(signal, 0) descrambles the input signal without resetting the descrambler states.
Data Types: double

## Output Arguments

## out - Descrambled output

column vector
Descrambled output, returned as a column vector with the same data type and length as signal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

| step | Run System object algorithm <br> release |
| :--- | :--- |
| Release resources and allow changes to System object property values and input <br> characteristics |  |
| reset | Reset internal states of System object |

## Examples

## Scramble and Descramble Data

Scramble and descramble 8-ary data using comm. Scrambler and comm.Descrambler System objects $^{\mathrm{TM}}$ having a calculation base of 8 .

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N,'1 + z^-2 + z^-3 + z^-5 + z^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
ans = 5 3 3
\begin{tabular}{lll}
6 & 7 & 6 \\
7 & 5 & 7 \\
1 & 7 & 1 \\
7 & 0 & 7 \\
5 & 3 & 5
\end{tabular}
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
ans = logical
    1
```

## Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the InitialConditionsSource property to 'Input port' so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
descrambler = comm.Descrambler(N,'1 + z^-3','InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the symerr function.
errVec $=$ zeros(10,1);
Scramble and descramble random integers while changing the initial conditions, initCond, each time the loop executes. Use the symerr function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine errVec to verify that the output from the descrambler matches the original data.

## Introduced in R2012a

## comm.DifferentialDecoder

Package: comm
Decode binary signal using differential decoding

## Description

The DifferentialDecoder object decodes the binary input signal. The output is the logical difference between the consecutive input element within a channel.

To decode a binary signal using differential decoding:
1 Define and set up your differential decoder object. See "Construction" on page 3-387.
2 Call step to decode a binary signal according to the properties of comm.DifferentialDecoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = $\underline{\text { step }(o b j, x) \text { and } y=o b j(x) \text { perform equivalent operations. }}$

## Construction

H = comm.DifferentialDecoder creates a differential decoder System object, H. This object decodes a binary input signal that was previously encoded using a differential encoder.

H = comm.DifferentialDecoder(Name,Value) creates object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## InitialCondition

Initial value used to generate initial output
Specify the initial condition as a real scalar. This property can have a logical, numeric, or fixed-point (embedded.fi object) data type. The default is 0 . The object treats nonbinary values as binary signals.

## Methods

## reset Reset states of differential decoder object

step Decode binary signal using differential decoding

## Common to All System Objects

```
release Allow System object property value changes
```

## Examples

## Decode Differentially Encoded Signal

Create a differential encoder and decoder pair.

```
diffEnc = comm.DifferentialEncoder;
```

diffDec = comm.DifferentialDecoder;

Generate random binary data. Differentially encode and decode the data.

```
data = randi([0 1],100,1);
encData = diffEnc(data);
decData = diffDec(encData);
```

Determine the number of errors between the original data and the decoded data.

```
numErrors = biterr(data,decData)
numErrors = 0
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Differential Decoder block reference page. The object properties correspond to the block parameters, except: The object only supports single channel, column vector inputs.

## step

System object: comm.DifferentialDecoder Package: comm

Decode binary signal using differential decoding

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=\operatorname{step}(H, X)$ decodes the differentially encoded input data, $X$, and returns the decoded data, $Y$. The input $X$ must be a column vector of data type logical, numeric, or fixed-point (embedded.fi objects). Y has the same data type as X . The object treats non-binary inputs as binary signals. The object computes the initial output value by performing an Xor operation of the value in the InitialCondition property and the first element of the vector you input the first time you call the step method.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.DifferentialEncoder

Package: comm
Encode binary signal using differential coding

## Description

The DifferentialEncoder object encodes the binary input signal within a channel. The output is the logical difference between the current input element and the previous output element.

To encode a binary signal using differential coding:
1 Define and set up your differential encoder object. See "Construction" on page 3-391.
2 Call step to encode a binary signal according to the properties of comm.DifferentialEncoder. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = $\underline{\text { step }(o b j, x) \text { and } y=o b j(x) \text { perform equivalent operations. }}$

## Construction

H = comm.DifferentialEncoder creates a differential encoder System object, H. This object encodes a binary input signal by calculating its logical difference with the previously encoded data.

H = comm.DifferentialEncoder(Name,Value) creates object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## InitialCondition

If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.DiscreteTimeVCO

Package: comm
Generate variable frequency sinusoid

## Description

The DiscreteTimeVC0 (voltage-controlled oscillator) object generates a signal whose frequency shift from the quiescent frequency property is proportional to the input signal. The input signal is interpreted as a voltage.

To generate a variable frequency sinusoid:
1 Define and set up your discrete time voltage-controlled oscillator object. See "Construction" on page 3-395.
2 Call step to generate a variable frequency sinusoid according to the properties of comm. DiscreteTimeVCO. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.DiscreteTimeVCO creates a discrete-time voltage-controlled oscillator (VCO) System object, H. This object generates a sinusoidal signal with the frequency shifted from the specified quiescent frequency to a value proportional to the input signal.

H = comm.DiscreteTimeVCO(Name, Value) creates a discrete-time VCO object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## OutputAmplitude

Amplitude of output signal
Specify the amplitude of the output signal as a double- or single-precision, scalar value. The default is 1 . This property is tunable.

## QuiescentFrequency

Frequency of output signal when input is zero
Specify the quiescent frequency of the output signal in Hertz, as a double- or single-precision, real, scalar value. The default is 10 . This property is tunable.

## Sensitivity

Sensitivity of frequency shift of output signal
Specify the sensitivity of the output signal frequency shift to the input as a double- or singleprecision, real, scalar value. The default is 1 . This value scales the input voltage and, consequently, the shift from the quiescent frequency value. The property measures Sensitivity in Hertz per volt. This property is tunable.

## InitialPhase

Initial phase of output signal
Specify the initial phase of the output signal, in radians, as a double or single precision, real, scalar value. The default is 0 .

## SampleRate

Sample rate of input
Specify the sample rate of the input, in Hertz, as a double- or single-precision, positive, scalar value. The default is 100.

## Methods

reset Reset states of discrete-time VCO object
step Generate variable frequency sinusoid
Common to All System Objects

## Examples

## Generate FSK Signal Using Discrete Time VCO

Create a signal source System object ${ }^{\text {tm }}$.
reader $=$ dsp.SignalSource;
Generate random data and apply rectangular pulse shaping.

```
reader.Signal = randi([0 7],10,1);
reader.Signal = rectpulse(reader.Signal,100);
```

Create a signal logger and discrete time VCO System objects.

```
logger = dsp.SignalSink;
discreteVC0 = comm.DiscreteTimeVC0('OutputAmplitude',8,'QuiescentFrequency',1);
```

Generate an FSK signal.

```
while(~isDone(reader))
    sig = reader();
```

```
    y = discreteVCO(sig);
    logger(y);
end
oscsig = logger.Buffer;
```

Plot the generated FSK signal.
$\mathrm{t}=(0:$ length(oscsig)-1)'/discreteVCO. SampleRate;
plot(t,reader.Signal,'--r', 'LineWidth',3)
hold on
plot(t,oscsig,'-b');
hold off
xlabel('Time (s)')
ylabel('Amplitude (V)')
legend('Input Signal','FSK Signal','location','se')

## Algorithms

This object implements the algorithm, inputs, and outputs as described on the Discrete-Time VCO block reference page. However, this object and the corresponding block may not generate the exact same outputs for single-precision inputs or property values due to the following differences in casting strategies and arithmetic precision issues:

- The block always casts the result of intermediate mathematical operations to the input data type. The object does not cast intermediate results and MATLAB decides the data type. The object casts the final output to the input data type.
- You can specify the SampleRate object property in single-precision or double-precision. The block does not allow this.
- In arithmetic operations with more than two operands with mixed data types, the result may differ depending on the order of operation. Thus, the following calculation may also contribute to the difference in the output of the block and the object:
input * sensitivity * sampleTime
- The block performs this calculation from left to right. However, since sensitivity * sampleTime is a one-time calculation, the object calculates this in the following manner:
input * (sensitivity * sampleTime)

## Extended Capabilities

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ generates a sinusoidal signal, Y , with frequency shifted, from the value you specify in the QuiescentFrequency property, to a value proportional to the input signal, X . The input, X , must be a double or single precision, real, scalar value. The output, $Y$, has the same data type and size as the input, X .

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.DPD

Package: comm
Digital predistorter

## Description

The comm. DPD System object applies digital predistortion (DPD) to a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier. For more information, see "Digital Predistortion" on page 3-405.

To predistort signals:
1 Create the comm. DPD object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
dpd = comm.DPD
dpd = comm.DPD(Name,Value)
Description
```

dpd $=$ comm.DPD creates a digital predistorter System object to predistort a signal.
dpd = comm.DPD(Name, Value) sets properties using one or more name-value pairs. For example, comm.DPD('PolynomialType','Cross-term memory polynomial') configures the predistorter System object to predistort the input signal by using a memory polynomial with cross terms. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## PolynomialType - Polynomial type

'Memory polynomial' (default)|'Cross-term memory polynomial'
Polynomial type used for predistortion, specified as one of these values:

- 'Memory polynomial ' - Predistorts the input signal by using a memory polynomial without cross terms.
- 'Cross-term memory polynomial' - Predistorts the input signal by using a memory polynomial with cross terms.

For more information, see "Digital Predistortion" on page 3-405.

## Coefficients - Memory-polynomial coefficients

complex([1 0 0 0 0; 0 0 0 0 0; 0 0 0 0 0]) (default)|matrix
Memory-polynomial coefficients, specified as a matrix. The number of rows in the matrix must equal the memory depth of the memory polynomial.

- If PolynomialType is 'Memory polynomial', the number of columns in the matrix is the degree of the memory polynomial.
- If PolynomialType is 'Cross-term memory polynomial', the number of columns in the matrix must equal $m(n-1)+1 . m$ is the memory depth of the polynomial, and $n$ is the degree of the memory polynomial.

For more information, see "Digital Predistortion" on page 3-405.

```
Data Types: double
Complex Number Support: Yes
```

## Usage

## Syntax

```
out \(=\operatorname{dpd}(i n)\)
```

## Description

out $=\mathrm{dpd}(\mathrm{in})$ predistorts a complex baseband signal by using a memory polynomial to compensate for nonlinearities in a power amplifier.

## Input Arguments

## in - Input baseband signal

column vector
Input baseband signal, specified as a column vector.
Data Types: double
Complex Number Support: Yes

## Output Arguments

## out - Predistorted baseband signal

column vector
Predistorted baseband signal, returned as a column vector of the same length as the input signal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

| step | Run System object algorithm <br> release |
| :--- | :--- |
| Release resources and allow changes to System object property values and input <br> characteristics |  |
| reset | Reset internal states of System object |

## Examples

## Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');
rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using coef, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);
u = qammod(s,16);
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.

```
y = dpd(x);
```

## Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistortion System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the memory-polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3 -by-5 coefficient matrix of zeros and setting the coef $(1,1)$ element to 1 . Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn (3,5)+1j*randn (3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, coef.

```
dpd = comm.DPD('PolynomialType','Memory polynomial',''Coefficients',coef);
```

Generate an input signal and predistort it using the dpd System object.

```
x = randn(20,1) + lj*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element $y(18)$ to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u.*abs(u) u.*(abs(u).^2) u.*(abs(u).^3) u.*(abs(u).^4)])))
ans = logical
    1
```

## Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the cross-term memory polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3-by-5 coefficient matrix of zeros and setting the coef (1,1) element to 1 . Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,3*(5-1)+1);
coef(1,1) = 1;
coef = coef + 0.01*(randn (3,13) + 1j*randn (3,13));
```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, coef.

```
dpd = comm.DPD('PolynomialType','Cross-term memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the dpd System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element y (18) to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u*abs(u.') u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4)])))
ans = logical
    1
```

## More About

## Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where $G$ is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} c_{m} \times u(n-m)+\sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{m j k} \times u(n-m) \times|u(n-j)|^{k} .
$$

The memory polynomial with cross terms has ( $M+M \times M \times(K-1)$ ) coefficients for $c_{m}$ and $a_{\mathrm{mjk}}$.

- The memory polynomial without cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{m k} \times u(n-m) \times|u(n-m)|^{k}
$$

The polynomial without cross terms has $M \times K$ coefficients for $a_{m k}$.

## Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n) / G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memorypolynomial coefficients:

- $\quad c_{m}$ and $a_{m j k}$ for a memory polynomial with cross terms
- $a_{m k}$ for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n) / G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see "Power Amplifier Characterization with DPD for Reduced Signal Distortion".

For background reference material, see the works listed in [1] and [2].

## comm.DPDCoefficientEstimator

Package: comm
Estimate memory-polynomial coefficients for digital predistortion

## Description

The comm. DPDCoefficientEstimator System object estimates the coefficients of a memory polynomial for digital pre-distortion (DPD) of a nonlinear power amplifier, given the baseband equivalent input and baseband equivalent output of the power amplifier. For more information, see "Digital Predistortion" on page 3-414.

To compute predistortion coefficients:
1 Create the comm.DPDCoefficientEstimator object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

```
estimator = comm.DPDCoefficientEstimator
estimator = comm.DPDCoefficientEstimator(Name,Value)
```

## Description

estimator $=$ comm.DPDCoefficientEstimator creates a digital predistortion coefficient estimator System object to estimate the coefficients of a memory polynomial for digital predistortion (DPD) of a nonlinear power amplifier.
estimator $=$ comm. DPDCoefficientEstimator(Name, Value) sets properties using one or more name-value pairs. For example,
comm. DPDCoefficientEstimator('PolynomialType','Cross-term memory polynomial') configures the predistortion coefficient estimator System object to estimate the coefficients for a memory-polynomial with cross terms. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## DesiredAmplitudeGaindB - Desired amplitude gain

10 (default) | scalar
Desired amplitude gain in dB , specified as a scalar. This property value expresses the desired signal gain at the compensated amplifier output.

Tunable: Yes
Data Types: double

## PolynomialType - Polynomial type

'Memory polynomial' (default)|'Cross-term memory polynomial'
Polynomial type used for predistortion, specified as one of these values:

- 'Memory polynomial ' - Computes predistortion coefficients by using a memory polynomial without cross terms
- 'Cross-term memory polynomial' - Computes predistortion coefficients by using a memory polynomial with cross terms

For more information, see "Digital Predistortion" on page 3-414.

## Degree - Memory-polynomial degree

5 (default) | positive integer
Memory-polynomial degree, specified as a positive integer.

## Data Types: double

## MemoryDepth - Memory-polynomial depth

3 (default) | positive integer
Memory-polynomial depth in samples, specified as a positive integer.

## Data Types: double

## Algorithm - Estimation algorithm

```
'Least squares'(default)|'Recursive least squares'
```

Adaptive algorithm used for equalization, specified as one of these values:

- 'Least squares ' - Estimate the memory polynomial coefficients by using a least squares algorithm
- 'Recursive least squares' - Estimate the memory polynomial coefficients by using a recursive least squares algorithm

For algorithm reference material, see the works listed in [1] and [2].
Data Types: char \| string

## ForgettingFactor - Forgetting factor

0.99 (default) | scalar in the range ( 0,1 ]

Forgetting factor used by the recursive least squares algorithm, specified as a scalar in the range ( 0 , 1]. Decreasing the forgetting factor reduces the convergence time but causes the output estimates to be less stable.

Tunable: Yes

## Dependencies

To enable this property, set Algorithm to 'Recursive least squares'.
Data Types: double

## InitialCoefficientEstimate - Initial coefficient estimate

[] (default) | matrix
Initial coefficient estimate for the recursive least squares algorithm, specified as a matrix.

- If InitialCoefficientEstimate is an empty matrix, the initial coefficient estimate for the recursive least squares algorithm is chosen automatically to correspond to a memory polynomial that is an identity function, so that the output is equal to input.
- If InitialCoefficientEstimate is a nonempty matrix, the number of rows must be equal to MemoryDepth.
- If PolynomialType is 'Memory polynomial', the number of columns is the degree of the memory polynomial.
- If PolynomialType is 'Cross-term memory polynomial', the number of columns must equal $m(n-1)+1$. $m$ is the memory depth of the polynomial, and $n$ is the degree of the memory polynomial.

For more information, see "Digital Predistortion" on page 3-414.

## Dependencies

To enable this property, set Algorithm to 'Recursive least squares'.
Data Types: double
Complex Number Support: Yes

## Usage

## Syntax

```
coef = estimator(paIn,pa0ut)
```

## Description

coef = estimator(paIn, pa0ut) estimates the coefficients of a memory polynomial for use by the comm. DPD System object to predistort a complex baseband signal by using a memory-polynomial to compensate for nonlinearities in a power amplifier.

## Input Arguments

## paIn - Power amplifier baseband equivalent input

column vector
Power amplifier baseband equivalent input, specified as a column vector.
Data Types: double
Complex Number Support: Yes

## pa0ut - Power amplifier baseband equivalent output <br> column vector

Power amplifier baseband equivalent output, specified as a column vector of the same length as paIn.
Data Types: double
Complex Number Support: Yes

## Output Arguments

coef - Memory-polynomial coefficients
matrix
Memory-polynomial coefficients, returned as a matrix. For more information, see "Digital Predistortion" on page 3-414.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Predistort Power Amplifier Input Signal

Apply digital predistortion (DPD) to a power amplifier input signal. The DPD coefficient estimator System object uses a captured signal containing power amplifier input and output signals to determine the predistortion coefficient matrix.

Load a file containing the input and output signals for the power amplifier.

```
load('commpowamp_dpd_data.mat','PA_input','PA_output')
```

Generate a DPD coefficient estimator System object and a raised cosine transmit filter System object.

```
estimator = comm.DPDCoefficientEstimator( ...
    'DesiredAmplitudeGaindB',10, ...
    'PolynomialType','Memory polynomial', ...
    'Degree',5,'MemoryDepth',3,'Algorithm','Least squares');
rctFilt = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',2);
```

Estimate the digital predistortion memory-polynomial coefficients.

```
coef = estimator(PA_input,PA_output);
```

Generate a DPD System object using coef, the estimated coefficients output from the DPD coefficient estimator, as for the coefficient matrix.

```
dpd = comm.DPD('PolynomialType','Memory polynomial', ...
    'Coefficients',coef);
```

Generate 2000 random symbols and apply 16-QAM modulation to the signal. Apply raised cosine transmit filtering to the modulated signal.

```
s = randi([0,15],2000,1);
u = qammod(s,16);
x = rctFilt(u);
```

Apply digital predistortion to the data. The DPD System object returns a predistorted signal to provide as input to the power amplifier.
$y=d p d(x) ;$

## Format of Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistortion System object configured using a memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the memory-polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the memory-polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3 -by-5 coefficient matrix of zeros and setting the coef $(1,1)$ element to 1 . Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,5);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,5)+1j*randn(3,5));
```

Create a DPD System object using the memory polynomial coefficient matrix, coef.

```
dpd = comm.DPD('PolynomialType','Memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the dpd System object.

```
x = randn(20,1) + 1j*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element $y(18)$ to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u.*abs(u) u.*(abs(u).^2) u.*(abs(u).^3) u.*(abs(u).^4)])))
```

```
ans = logical
```

    1
    
## Format of Cross-Term Coefficient Matrix for Digital Predistortion Memory Polynomial

This examples shows the format of the coefficient matrix for the DPD memory polynomial by using a randomly generated coefficient matrix. The example:

- Creates a digital predistorter System object configured using a cross-term memory polynomial coefficient matrix with the memory depth set to 3 and the polynomial degree set to 5 consisting of random values.
- Predistorts a signal using the cross-term memory polynomial coefficient matrix.
- Compares one predistorted output element to the corresponding input element that has been manually computed using the cross-term memory polynomial coefficient matrix.

Create a coefficient matrix representing a predistorter with the output equal to the input by generating a 3 -by-5 coefficient matrix of zeros and setting the coef $(1,1)$ element to 1 . Add small random complex nonlinear terms to the coefficient matrix.

```
coef = zeros(3,3*(5-1)+1);
coef(1,1) = 1;
coef = coef + 0.01*(randn(3,13) + 1j*randn(3,13));
```

Create a DPD System object using the cross-term memory polynomial coefficient matrix, coef.

```
dpd = comm.DPD('PolynomialType','Cross-term memory polynomial','Coefficients',coef);
```

Generate an input signal and predistort it using the dpd System object.

```
x = randn(20,1) + lj*randn(20,1);
y = dpd(x);
```

Compare the manually distorted output for an input corresponding output element $y(18)$ to show how the coefficient matrix is used to calculate that particular output value.

```
u = x(18:-1:(18-3+1));
isequal(y(18),sum(sum(coef.*[u u*abs(u.') u*(abs(u.').^2) u*(abs(u.').^3) u*(abs(u.').^4)])))
ans = logical
    1
```

## More About

## Digital Predistortion

Wireless communication transmissions commonly require wide bandwidth signal transmission over a wide signal dynamic range. To transmit signals over a wide dynamic range and achieve high efficiency, RF power amplifiers (PAs) commonly operate in their nonlinear region. As this constellation diagram shows, the nonlinear behavior of a PA causes signal constellation distortions that pinch the
amplitude (AM-AM distortion) and twist phase (AM-PM distortion) of constellation points proportional to the amplitude of the constellation point.

The goal of digital predistortion is to find a nonlinear function that linearizes the net effect of the PA nonlinear behavior at the PA output across the PA operating range. When the PA input is $x(n)$, and the predistortion function is $f(u(n))$, where $u(n)$ is the true signal to be amplified, the PA output is approximately equal to $G \times u(n)$, where $G$ is the desired amplitude gain of the PA.

The digital predistorter can be configured to use a memory polynomial with or without cross terms.

- The memory polynomial with cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} c_{m} \times u(n-m)+\sum_{m=0}^{M-1} \sum_{j=0}^{M-1} \sum_{k=0}^{K-1} a_{m j k} \times u(n-m) \times|u(n-j)|^{k} .
$$

The memory polynomial with cross terms has ( $M+M \times M \times(K-1)$ ) coefficients for $c_{m}$ and $a_{\text {mjk }}$.

- The memory polynomial without cross terms predistorts the input signal as

$$
x(n)=f(u(n)) \triangleq \sum_{m=0}^{M-1} \sum_{k=0}^{K-1} a_{m k} \times u(n-m) \times|u(n-m)|^{k} .
$$

The polynomial without cross terms has $M \times K$ coefficients for $a_{m k}$.

## Estimating Predistortion Function and Coefficients

The DPD coefficient estimation uses an indirect learning architecture to find function $f(u(n))$ to predistort input signal $u(n)$ which precedes the PA input.

The DPD coefficient estimation algorithm models nonlinear PA memory effects based on the work in reference papers by Morgan, et al [1], and by Schetzen [2], using the theoretical foundation developed for Volterra systems.

Specifically, the inverse mapping from the PA output normalized by the PA gain, $\{y(n) / G\}$, to the PA input, $\{x(n)\}$, provides a good approximation to the function $f(u(n))$, needed to predistort $\{u(n)\}$ to produce $\{x(n)\}$.

Referring to the memory polynomial equations above, estimates are computed for the memorypolynomial coefficients:

- $c_{m}$ and $a_{m j k}$ for a memory polynomial with cross terms
- $a_{m k}$ for a memory polynomial without cross terms

The memory-polynomial coefficients are estimated by using a least squares fit algorithm or a recursive least squares algorithm. The least squares fit algorithm or a recursive least squares algorithms use the memory polynomial equations above for a memory polynomial with or without cross terms, by replacing $\{u(n)\}$ with $\{y(n) / G\}$. The function order and dimension of the coefficient matrix are defined by the degree and depth of the memory polynomial.

For an example that details the process of accurately estimating memory-polynomial coefficients and predistorting a PA input signal, see "Power Amplifier Characterization with DPD for Reduced Signal Distortion".

For background reference material, see the works listed in [1] and [2].

## comm.DPSKDemodulator

Package: comm
Demodulate using M-ary DPSK method

## Description

The DPSKDemodulator object demodulates a signal that was modulated using the M-ary differential phase shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

To demodulate a signal that was modulated using differential phase shift keying:
1 Define and set up your DPSK modulator object. See "Construction" on page 3-418.
2 Call step to demodulate a signal according to the properties of DPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. DPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the $M$-ary differential phase shift keying (M-DPSK) method.

H = comm.DPSKDemodulator(Name, Value) creates an M-DPSK demodulator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DPSKDemodulator(M,PHASE,Name, Value) creates an M-DPSK demodulator object, H. This object has the ModulationOrder property set to M, the PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8 .

## PhaseRotation

Additional phase shift

Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is pi/8. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

## Bit0utput

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values. The default is false. When you set this property to true the step method outputs a column vector of bit values. The length of this column vector is equal to $\log 2$ (Modulation0rder on page 3-0 ) times the number of demodulated symbols.

When you set this property to false, the step method outputs a column vector. The length of this column vector is equal to that of the input data vector. The output contains integer symbol values between 0 and Modulation0rder-1.

## SymbolMapping

## Constellation encoding

Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) bits to the corresponding symbol as one of Binary | Gray. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the input integer $m$, between ( $0 \leq m \leq$ Modulation0rder-1) maps to the current symbol. This mapping uses $\exp (j \times$ PhaseRotation $+j \times 2 \times \pi \times m /$ ModulationOrder $) \times$ (previously modulated symbol).

## OutputDataType

Data type of output
Specify the output data type as one of Full precision $\mid$ Smallest unsigned integer | double | single | int8|uint8|int16|uint16| int32|uint32. The default is Full precision. When you set this property to Full precision, the input data type is single or double precision, the output data is the same as that of the input. When you set the BitOutput on page 3-0 property to true, logical data type becomes a valid option.

## Methods

## Examples

## 8-DPSK Signal in AWGN

Create a DPSK modulator and demodulator pair. Create an AWGN channel object having three bits per symbol.

```
dpskmod = comm.DPSKModulator(8,pi/8,'BitInput',true);
dpskdemod = comm.DPSKDemodulator(8,pi/8,'BitOutput',true);
channel = comm.AWGNChannel('EbNo',10,'BitsPerSymbol',3);
```

Create an error rate calculator. Set the ComputationDelay property to 1 to account for the one bit transient caused by the differential modulation

```
errorRate = comm.ErrorRate('ComputationDelay',1);
```

Main processing loop steps:

- Generate 50 3-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],150,1);
    modSig = dpskmod(txData);
    rxSig = channel(modSig);
    rxData = dpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 0.0098
numErrors = errorStats(2)
numErrors = 147
numBits = errorStats(3)
numBits = 14999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-DPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® ${ }^{\circledR}$ Coder $^{\mathrm{TM}}$.
Usage notes and limitations:

## Description

reset $(\mathrm{H})$ resets the states of the DPSKDemodulator object, H .

## step

System object: comm.DPSKDemodulator
Package: comm
Demodulate using M-ary DPSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the DPSK demodulator System object, H , and returns Y . Input X must be a double or single precision data type scalar or column vector. Depending on the BitOutput property value, output Y can be integer or bit valued.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.DPSKModulator

Package: comm
Modulate using M-ary DPSK method

## Description

The DPSKModulator object modulates using the M-ary differential phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential phase shift keying:
1 Define and set up your DPSK modulator object. See "Construction" on page 3-424.
2 Call step to modulate a signal according to the properties of comm.DPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. DPSKModulator creates a modulator System object, H. This object modulates the input signal using the M-ary differential phase shift keying (M-DPSK) method.

H = comm.DPSKModulator(Name, Value) creates an M-DPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm. DPSKModulator(M, PHASE,Name, Value) creates an M-DPSK modulator object, H. This object has the ModulationOrder property set to M, the PhaseRotation property set to PHASE, and the other specified properties set to the specified values.

## Properties

## ModulationOrder

Number of points in signal constellation
Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 8 .

## PhaseRotation

Additional phase shift
Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is $\mathrm{pi} / 8$. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input must be a column vector of bit values whose length is an integer multiple of $\log 2$ (ModulationOrder on page 3-0 ). This vector contains bit representations of integers between 0 and ModulationOrder-1. When you set this property to false, the step method input requires a column vector of integer symbol values between 0 and Modulation0rder1.

## SymbolMapping

## Constellation encoding

Specify how the object maps an integer or group of $\log 2$ (ModulationOrder on page 3-0 ) input bits to the corresponding symbol as one of Binary | Gray. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the input integer $m$, between ( $0 \leq m \leq$ ModulationOrder-1) shifts the output phase. This shift is (PhaseRotation on page 3-0 $+2 \times \pi \times m /$ ModulationOrder) radians from the previous output phase. The output symbol uses $\exp (j \times$ PhaseRotation $+j \times 2 \times \pi \times m /$ ModulationOrder $) \times$ (previously modulated symbol).

## OutputDataType

Data type of output
Specify output data type as one of double | single. The default is double.

$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the DPSK modulator System object, H . It returns the baseband modulated output, $Y$. Depending on the value of the BitInput property, input $X$ can be an integer or bit valued column vector with numeric or logical data types.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.DQPSKDemodulator

Package: comm
Demodulate using DQPSK method

## Description

The DQPSKDemodulator object demodulates a signal that was modulated using the differential quadrature phase shift keying method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using differential quadrature phase shift keying:
1 Define and set up your DQPSK modulator object. See "Construction" on page 3-429.
2 Call step to demodulate a signal according to the properties of DQPSKDemodulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $\mathrm{y}=$ step $(o b j, x)$ and $y=o b j(x)$ perform equivalent operations.

## Construction

$H=$ comm. DQPSKDemodulator creates a demodulator System object, H. This object demodulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

H = comm. DQPSKDemodulator(Name, Value) creates a DQPSK demodulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Namel,Value1,...,NameN,ValueN).

H = comm. DQPSKDemodulator(PHASE, Name, Value) creates a DQPSK demodulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

## Properties

## PhaseRotation

Additional phase shift
Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar. The default is $\mathrm{pi} / 4$. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

## BitOutput

Output data as bits
Specify whether the output consists of groups of bits or integer symbol values. The default is false. When you set this property to true the step method outputs a column vector of bit values with
length equal to twice the number of demodulated symbols. When you set this property to false, the step method outputs a column vector, of length equal to the input data vector, that contains integer symbol values between 0 and 3 .

## SymbolMapping

Constellation encoding
Specify how the object maps an integer or group of 2 bits to the corresponding symbol as one of Binary | Gray. The default is Gray. When you set this property to Gray, the object uses a Grayencoded signal constellation. When you set this property to Binary, the integer $m$, between $0 \leq m \leq 3$ maps to the current symbol as $\exp (j \times$ PhaseRotation on page 3-0 $+j \times 2 \times \pi \times m / 4) \times$ (previously modulated symbol).

## OutputDataType

Data type of output
Specify the output data type as one of Full precision | Smallest unsigned integer|double | single | int8|uint8|int16|uint16| int32|uint32. The default is Full precision. When you set this property to Full precision the output has the same data type as that of the input. In this case, the input data type is single- or double-precision value. When you set the BitOutput on page 3-0 property to true, logical data type becomes a valid option.

## Methods

reset Reset states of DQPSK demodulator object
step Demodulate using DQPSK method

## Common to All System Objects

release Allow System object property value changes

## Examples

## DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the ComputationDelay property to 1 to account for the one bit transient caused by the differential modulation
errorRate = comm.ErrorRate('ComputationDelay',1);
Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 0.0170
numErrors = errorStats(2)
numErrors = 170
numBits = errorStats(3)
numBits = 9999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the DQPSK Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## C/C++ Code Generation

Generate C and $\mathrm{C}++$ code using MATLAB® $\mathrm{Coder}^{\mathrm{TM}}$.
Usage notes and limitations:
See "System Objects in MATLAB Code Generation" (MATLAB Coder).

## reset

System object: comm.DQPSKDemodulator
Package: comm
Reset states of DQPSK demodulator object

## Syntax

reset (H)

## Description

reset $(\mathrm{H})$ resets the states of the DQPSKDemodulator object, H .

## step

System object: comm.DQPSKDemodulator
Package: comm
Demodulate using DQPSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=\operatorname{step}(\mathrm{H}, \mathrm{X})$ demodulates input data, X , with the DQPSK demodulator System object, H , and returns Y . Input X must be a single or double precision data type scalar or column vector. Depending on the BitOutput property value, output Y can be integer or bit valued.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.DQPSKModulator

Package: comm
Modulate using DQPSK method

## Description

The DQPSKModulator object modulates using the differential quadrature phase shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using differential quadrature phase shift keying:
1 Define and set up your DQPSK modulator object. See "Construction" on page 3-434.
2 Call step to modulate a signal according to the properties of comm. DQPSKModulator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y=$ step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm. DQPSKModulator creates a modulator System object, H. This object modulates the input signal using the differential quadrature phase shift keying (DQPSK) method.

H = comm. DQPSKModulator(Name, Value) creates a DQPSK modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

H = comm.DQPSKModulator(PHASE,Name, Value) creates a DQPSK modulator object, H. This object has the PhaseRotation property set to PHASE and the other specified properties set to the specified values.

## Properties

## PhaseRotation

Additional phase shift
Specify the additional phase difference between previous and current modulated symbols in radians as a real scalar value. The default is $\mathrm{pi} / 4$. This value corresponds to the phase difference between previous and current modulated symbols when the input is zero.

## BitInput

Assume bit inputs
Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input must be a column vector of bit values. The length of this vector is an
integer multiple of two. This vector contains bit representations of integers between 0 and 3 . When you set this property to false, the step method input must be a column vector of integer symbol values between 0 and 3 .

## SymbolMapping

Constellation encoding
Specify how the object maps an integer or group of two input bits to the corresponding symbol as one of Binary | Gray. The default is Gray. When you set this property to Gray, the object uses a Grayencoded signal constellation. When you set this property to Binary, the input integer $m$, between $0 \leq m \leq 3$ shifts the output phase. This shift is (PhaseRotation on page 3-0 $+2 \times \pi \times m / 4$ ) radians from the previous output phase. The output symbol is $\exp (j \times$ PhaseRotation $+j \times$ $2 \times \pi \times m / 4) \times($ previously modulated symbol).

## OutputDataType

Data type of output
Specify output data type as one of double \| single. The default is double.

## Methods

reset Reset states of DQPSK modulator object
step Modulate using DQPSK method

## Common to All System Objects

release $\quad$ Allow System object property value changes

## Examples

## DQPSK Signal in AWGN

Create a DQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
dqpskmod = comm.DQPSKModulator('BitInput',true);
dqpskdemod = comm.DQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',6,'BitsPerSymbol',2);
```

Create an error rate calculator. Set the ComputationDelay property to 1 to account for the one bit transient caused by the differential modulation
errorRate $=$ comm.ErrorRate('ComputationDelay',1);
Main processing loop steps:

- Generate 50 2-bit frames
- 8-DPSK modulate
- Pass through AWGN channel
- 8-DPSK demodulate
- Collect error statistics

```
for counter = 1:100
    txData = randi([0 1],100,1);
    modSig = dqpskmod(txData);
    rxSig = channel(modSig);
    rxData = dqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 0.0170
numErrors = errorStats(2)
numErrors = 170
numBits = errorStats(3)
numBits = 9999
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the DQPSK Modulator Baseband block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

## Description

reset $(\mathrm{H})$ resets the states of the DQPSKModulator object, H .

## step

System object: comm.DQPSKModulator
Package: comm
Modulate using DQPSK method

## Syntax

Y = step( $\mathrm{H}, \mathrm{X}$ )

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$\mathrm{Y}=$ step $(\mathrm{H}, \mathrm{X})$ modulates input data, X , with the DQPSK modulator System object, H . It returns the baseband modulated output, Y. Depending on the value of the BitInput property, input X can be an integer or bit valued column vector with numeric or logical data types.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

## comm.ErrorRate

Package: comm
Compute bit or symbol error rate of input data

## Description

The ErrorRate object compares input data from a transmitter with input data from a receiver and calculates the error rate as a running statistic. To obtain the error rate, the object divides the total number of unequal pairs of data elements by the total number of input data elements from one source.

To obtain the error rate:
1 Define and set up your error rate object. See "Construction" on page 3-439.
2 Call step to compare input data from a transmitter with input data from a receiver and calculate the error rate according to the properties of comm. ErrorRate. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.

## Construction

H = comm.ErrorRate creates an error rate calculator System object, H. This object computes the error rate of the received data by comparing it to the transmitted data.

H = comm.ErrorRate(Name, Value) creates an error rate calculator object, H , with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

## Properties

## ReceiveDelay

Number of samples to delay transmitted signal
Specify the number of samples by which the received data lags behind the transmitted data. This value must be a real, nonnegative, double-precision, integer scalar. Use this property to align the samples for comparison in the transmitted and received input data vectors. Specify the delay in number of samples, regardless of whether the input is a scalar or a vector. The default is 0 .

## ComputationDelay

Computation delay

Specify the number of data samples that the object should ignore at the beginning of the comparison. This value must be a real, nonnegative, double-precision, integer scalar. Use this property to ignore the transient behavior of both input signals. The default is 0 .

## Samples

Samples to consider
Specify samples to consider as one of Entire frame|Custom| Input port. The property defines whether the object should consider all or only part of the input frames when computing error statistics. The default is Entire frame. Select Entire frame to compare all the samples of the RX frame to those of the TX frame. Select Custom or Input port to list the indices of the RX frame elements that the object should consider when making comparisons. When you set this property to Custom, you can list the indices as a scalar or a column vector of double-precision integers through the CustomSamples on page 3-0 property. When you set this property to Input port, you can list the indices as an input to the step method.

## CustomSamples

Selected samples from frame
Specify a scalar or a column vector of double-precision, real, positive integers. This value lists the indices of the elements of the RX frame vector that the object uses when making comparisons. This property applies when you set the Samples on page 3-0 property to Custom. The default is an empty vector, which specifies that all samples are used.

## ResetInputPort

Enable error rate reset input
Set this property to true to reset the error statistics via an input to the step method. The default is false.

## Methods

reset Reset states of error rate calculator object
step Compute bit or symbol error rate of input data
Common to All System Objects

| release | Allow System object property value changes |
| :--- | :--- | :--- |

## Examples

## Calculate Error Statistics

Create two binary vectors and determine the error statistics.
Create a bit error rate counter object.

```
errorRate = comm.ErrorRate;
```

Create an arbitrary binary data vector.
$x=[100101010210] ' ;$
Introduce errors to the first and last bits.
$y=x$;
$y(1)=\sim y(1)$;
$y($ end $)=\sim y(e n d) ;$
Calculate the error statistics.
z = errorRate(x,y);
The first element of the vector $z$ is the bit error rate.
z(1)
ans $=0.2000$
The second element of $z$ is the total error count.
z(2)
ans $=2$
The third element of $z$ is the total number of bits.
z(3)

```
ans = 10
```

## Calculate BER between Transmitted and Received Signal

Create an 8-DPSK modulator and demodulator pair that work with binary data.

```
dpskModulator = comm.DPSKModulator('ModulationOrder',8,'BitInput',true);
dpskDemodulator = comm.DPSKDemodulator('ModulationOrder',8,'BitOutput',true);
```

Create an error rate calculator, accounting for the three bit (one symbol) transient caused by the differential modulation.

```
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Calculate the BER for 10 frames.

```
BER = zeros(10,1);
for i= 1:10
    txData = randi([0 1],96,1); % Generate binary data
    modData = dpskModulator(txData); %Modulate
    rxSig = awgn(modData,7); % Pass through AWGN channel
    rxData = dpskDemodulator(rxSig); % Demodulate
    errors = errorRate(txData,rxData); % Compute error statistics
    BER(i) = errors(1); % Save BER data
end
```

Display the BER.

```
BER
BER = 10×1
    0.1613
    0.1640
    0.1614
    0.1496
    0.1488
    0.1309
    0.1405
    0.1399
    0.1370
    0.1411
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Error Rate Calculation block reference page. The object properties correspond to the block parameters, except:

- The Output data and Variable name block parameters do not have a corresponding properties. The object always returns the result as an output.
- The Stop simulation block parameter does not have a corresponding property. To implement similar behavior, use the output of the step method in a while loop, to programmatically stop the simulation. .
- The Computation mode parameter corresponds to the Samples on page 3-0 and CustomSamples on page 3-0 properties.

## Extended Capabilities

C/C++ Code Generation
Generate C and $\mathrm{C}++$ code using MATLAB® Coder $^{\mathrm{TM}}$.
Usage notes and limitations:

reset $(\mathrm{H})$ resets the states of the ErrorRate object, H .

## step

## System object: comm. ErrorRate <br> Package: comm

Compute bit or symbol error rate of input data

## Syntax

Y = step(H,TX,RX)
Y = step(H,TX,RX,SEL)
Y = step(H,TX,RX,RST)

## Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step (obj, $x$ ) and $y=o b j(x)$ perform equivalent operations.
$Y=$ step (H,TX,RX) counts the number of differences between the transmitted data vector, TX, and received data vector, RX. The step method outputs a three-element vector consisting of the error rate, followed by the number of errors detected and the total number of samples compared. TX and RX inputs can be either scalars or column vectors of the same data type. Valid data types are single, double, integer or logical. If TX is a scalar and RX is a vector, or vice-versa, then the block compares the scalar with each element of the vector.
$Y=\operatorname{step}(H, T X, R X, S E L)$ calculates the errors based on selected samples from the input frame specified by the SEL input. SEL must be a real, double-precision integer-valued scalar or a column vector. The vector lists the indices of the elements of the RX input vector that the object should consider when making comparisons. This syntax applies when you set the Samples property to 'Input Port'.
$\mathrm{Y}=$ step ( $\mathrm{H}, \mathrm{TX}, \mathrm{RX}, \mathrm{RST}$ ) resets the error count whenever the input RST is non-zero. RST must be a real, double, or logical scalar. When you set the RST input to a nonzero value, the object clears its error statistics and then recomputes them based on the current TX and RX inputs. This syntax applies when you set the ResetInputPort property to true. You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of the enabling properties.

Note obj specifies the System object on which to run this step method.
The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release $\underline{\text { method to unlock the object. }}$

## comm.LinearEqualizer

Package: comm
Equalize modulated signals using linear filtering

## Description

The comm. LinearEqualizer System object uses a linear filter tap delay line with a weighted sum to equalize modulated signals transmitted through a dispersive channel. The equalizer object adaptively adjusts tap weights based on the selected algorithm. For more information, see "Algorithms" on page 3-479.

To equalize modulated signals using a linear filter:
1 Create the comm. LinearEqualizer object and set its properties.
2 Call the object with arguments, as if it were a function.
To learn more about how System objects work, see What Are System Objects? (MATLAB).

## Creation

## Syntax

lineq = comm.LinearEqualizer
lineq = comm.LinearEqualizer(Name,Value)

## Description

lineq $=$ comm.LinearEqualizer creates a linear equalizer System object to adaptively equalize a signal.
lineq = comm.LinearEqualizer(Name, Value) sets properties using one or more name-value pairs. For example, comm. LinearEqualizer('Algorithm', 'RLS') configures the equalizer object to update tap weights using the recursive least squares (RLS) algorithm. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are nontunable, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is tunable, you can change its value at any time.
For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

## Algorithm - Adaptive algorithm

'LMS' (default) |'RLS' | 'CMA'

Adaptive algorithm used for equalization, specified as one of these values:

- 'LMS ' - Update the equalizer tap weights using the "Least Mean Square (LMS) Algorithm" on page 3-480.
- 'RLS' - Update the equalizer tap weights using the "Recursive Least Square (RLS) Algorithm" on page 3-481.
- ' CMA ' - Update the equalizer tap weights using the "Constant Modulus Algorithm (CMA)" on page 3-481.

Data Types: char | string

## NumTaps - Number of equalizer taps

5 (default) | positive integer
Number of equalizer taps, specified as a positive integer.
Data Types: double

## StepSize - Step size

0.01 (default) | positive scalar

Step size used by the adaptive algorithm, specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tip To determine the maximum step size allowed, use the maxstep object function.

Tunable: Yes
Dependencies
To enable this property, set Algorithm to 'LMS ' or 'CMA '.

## Data Types: double

## ForgettingFactor - Forgetting factor

0.99 (default) | scalar in the range ( 0,1 ]

Forgetting factor used by the adaptive algorithm, specified as a scalar in the range ( 0,1 ]. Decreasing the forgetting factor reduces the equalizer convergence time but causes the equalizer output estimates to be less stable.

Tunable: Yes
Dependencies
To enable this property, set Algorithm to 'RLS '.
Data Types: double
InitialInverseCorrelationMatrix - Initial inverse correlation matrix
0.1 (default) | scalar | matrix

Initial inverse correlation matrix, specified as a scalar or an $N_{\text {Taps }}$-by- $N_{\text {Taps }}$ matrix. $N_{\text {Taps }}$ is equal to the NumTaps property value. If you specify InitialInverseCorrelationMatrix as a scalar, $a$, the equalizer sets the initial inverse correlation matrix to $a$ times the identity matrix: $a\left(\operatorname{eye}\left(N_{\text {Taps }}\right)\right.$ ).

Tunable: Yes

## Dependencies

To enable this property, set Algorithm to 'RLS '.
Data Types: double
Constellation - Signal constellation
pskmod(0:3,4,pi/4) (default)| vector
Signal constellation, specified as a vector. The default value is a QPSK constellation generated using this code: pskmod (0:3,4, pi/4).

Tunable: Yes
Data Types: double

## ReferenceTap - Reference tap

3 (default) | positive integer
Reference tap, specified as a positive integer less than or equal to the NumTaps property value. The equalizer uses the reference tap location to track the main energy of the channel.
Data Types: double

## InputDelay - Input signal delay

0 (default) | nonnegative integer
Input signal delay in samples relative to the reset time of the equalizer, specified as a nonnegative integer. If the input signal is a vector of length greater than 1 , then the input delay is relative to the start of the input vector. If the input signal is a scalar, then the input delay is relative to the first call of the System object and to the first call of the System object after calling the release or reset object function.

## Data Types: double

## InputSamplesPerSymbol - Number of input samples per symbol

1 (default) | positive integer
Number of input samples per symbol, specified as a positive integer. Setting this property to any number greater than one effectively creates a fractionally spaced equalizer. For more information, see "Symbol Tap Spacing" on page 3-479.
Data Types: double

## TrainingFlagInputPort - Enable training control input <br> false (default)|true

Enable training control input, specified as false or true. Setting this property to true enables the equalizer training flag input tf.

Tunable: Yes
Data Types: logical
AdaptAfterTraining - Update tap weights when not training true (default) | false

Update tap weights when not training, specified as true or false. If this property is set to true, the System object uses decision directed mode to update equalizer tap weights. If this property is set to false, the System object keeps the equalizer tap weights unchanged after training.

Tunable: Yes
Data Types: logical
AdaptWeightsSource - Source of adapt tap weights request
'Property' (default)|'Input port'
Source of adapt tap weights request, specified as one of these values:

- 'Property ' - Specify this value to use the AdaptWeights property to control when the System object adapts tap weights.
- 'Input port ' - Specify this value to use the aw input to control when the System object adapts tap weights.

## Dependencies

To enable this property, set Algorithm to 'CMA ' .
Data Types: char | string

## AdaptWeights - Adapt tap weights <br> true (default) | false

Adapt tap weights, specified as true or false. If this property is set to true, the System object updates the equalizer tap weights. If this property is set to false, the System object keeps the equalizer tap weights unchanged.

Tunable: Yes

## Dependencies

To enable this property, set AdaptWeightsSource to 'Property ' and set AdaptAfterTraining to true.
Data Types: logical

## InitialWeightsSource - Source for initial tap weights

'Auto' (default)|'Property'
Source for initial tap weights, specified as

- 'Auto ' - Initialize the tap weights to the algorithm-specific default values, as described in the InitialWeights property.
- 'Property ' - Initialize the tap weights using the InitialWeights property value.

Data Types: char \| string
InitialWeights - Initial tap weights
0 or $[0 ; 0 ; 1 ; 0 ; 0]$ (default) | scalar | column vector
Initial tap weights used by the adaptive algorithm, specified as a scalar or vector. The default is 0 when the Algorithm property is set to 'LMS' or 'RLS'. The default is $[0 ; 0 ; 1 ; 0 ; 0]$ when the Algorithm property is set to 'CMA'.

If you specify InitialWeights as a vector, the vector length must be equal to the NumTaps property value. If you specify InitialWeights as a scalar, the equalizer uses scalar expansion to create a vector of length NumTaps with all values set to InitialWeights.

Tunable: Yes
Dependencies
To enable this property, set InitialWeightsSource to 'Property '.
Data Types: double

## WeightUpdatePeriod - Tap weight update period

1 (default) | positive integer
Tap weight update period in symbols, specified as a positive integer. The equalizer updates the tap weights after processing this number of symbols.
Data Types: double

## Usage

## Syntax

```
\(y=\operatorname{lineq}(x, t s y m)\)
\(y=\operatorname{lineq}(x, t s y m, t f)\)
\(y=\) lineq( \(x\) )
\(y=\) lineq( \(x\), aw)
Description
```

$y=$ lineq ( $x, t s y m$ ) equalizes input signal $x$ by using training symbols tsym. The output is the equalized symbols. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS'.
$y=$ lineq $(x, t s y m, t f)$ also specifies training flag $t f$. The System object starts training when $t f$ changes from false to true (at the rising edge). The System object trains until all symbols in tsym are processed. The input tsym is ignored when tf is false. To enable this syntax, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to true.
$y=$ lineq $(x)$ equalizes input signal $x$. To enable this syntax, set the Algorithm property to 'CMA'.
$y$ = lineq( $x, a w)$ also specifies adapts weights flag aw. The System object adapts the equalizer tap weights when aw is true. If aw is false, the System object keeps the weights unchanged. To enable this syntax, set the Algorithm property to 'CMA' and AdaptWeightsSource property to 'Input port'.
[y,err] = lineq (__ ) also returns error signal err using input arguments from any of the previous syntaxes.
[y,err, weights] = lineq (__ ) also returns weights, the tap weights from the last tap weight update, using input arguments from any of the previous syntaxes.

## Input Arguments

## x - Input signal

column vector
Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the InputSamplesPerSymbol property value. For more information, see "Symbol Tap Spacing" on page 3-479.
Data Types: double
Complex Number Support: Yes

## tsym - Training symbols

column vector
Training symbols, specified as a column vector of length less than or equal to the length of input $x$. The input tsym is ignored when tf is false.

## Dependencies

To enable this argument, set the Algorithm property to 'LMS ' or 'RLS'.
Data Types: double
Complex Number Support: Yes

## tf - Training flag

true | false
Training flag, specified as true or false. The System object starts training when tf changes from false to true (at the rising edge). The System object trains until all symbols in tsym are processed. The input tsym is ignored when $t f$ is false.

## Dependencies

To enable this argument, set the Algorithm property to 'LMS' or 'RLS' and TrainingFlagInputPort property to true.
Data Types: logical
aw - Adapt weights flag
true | false
Adapt weights flag, specified as true or false. If aw is true, the System object adapts weights. If aw is false, the System object keeps the weights unchanged.

## Dependencies

To enable this argument, set the Algorithm property to ' CMA ' and AdaptWeightsSource property to 'Input port'.

## Data Types: logical

## Output Arguments

## y - Equalized symbols

column vector
Equalized symbols, returned as a column vector that has the same length as input signal x .

## err - Error signal

column vector
Error signal, returned as a column vector that has the same length as input signal x .

```
weights - Tap weights
```

column vector
Tap weights, returned as a column vector that has NumTaps elements. weights contains the tap weights from the last tap weight update.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Specific to comm. LinearEqualizer

| isLocked | Determine if System object is in use |
| :--- | :--- |
| clone | Create duplicate System object |
| info | Characteristic information about the equalizer object |
| maxstep | Maximum step size for LMS equalizer convergence |
| mmseweights | Linear equalizer MMSE tap weights |

## Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

## Examples

## Linearly Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object ${ }^{\mathrm{TM}}$, specifying a linear LMS equalizer having eight taps and a step size of 0.03 .

```
bpsk = comm.BPSKModulator;
eqlms = comm.LinearEqualizer('Algorithm','LMS','NumTaps',8,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqlms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use maxstep to find the maximum permitted step size.

```
mxStep = maxstep(eqlms,rxsig)
```

```
mxStep = 0.1384
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqlms(rxsig,x(1:200));
```

## Linearly Equalize QPSK-Modulated Signal

Apply linear equalization using the least mean squares (LMS) algorithm to recover QPSK symbols passed through a multipath AWGN channel.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
```

Generate QPSK-modulated symbols. Apply multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object and display the default configuration. Adjust the reference tap to 1 . Check the maximum permitted step size. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer
eq =
    comm.LinearEqualizer with properties:
            Algorithm: 'LMS'
                NumTaps: 5
                    StepSize: 0.0100
                Constellation: [1x4 double]
                    ReferenceTap: 3
                    InputDelay: 0
        InputSamplesPerSymbol: 1
        TrainingFlagInputPort: false
            AdaptAfterTraining: true
            InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
eq.ReferenceTap = 1;
mxStep = maxstep(eq,rx)
mxStep = 0.3154
[y,err,weights] = eq(rx,tx(1:numTrainingSymbols));
```

Plot the constellation of the impaired and equalized symbols.
constell = comm. ConstellationDiagram('NumInputPorts', 2 ); constell(rx,y)

Plot the equalizer error signal and compute the error vector magnitude (EVM) of the equalized symbols.
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|');title('Equalizer Error Signal')

Equalizer Error Signal

```
errevm = comm.EVM;
evm = errevm(tx,y)
evm = 11.7710
```

Plot the equalizer tap weights.

```
subplot(3,1,1);
stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
title('Equalizer Tap Weights')
subplot(3,1,2);
stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
subplot(3,1,3);
stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([0 6 -0.5 1])
```

## Linearly Equalize System By Using Different Training Schemes

Demonstrate linear equalization by using the least mean squares (LMS) algorithm to recover QPSK symbols passed through an AWGN channel. Apply different equalizer training schemes and show the symbol error magnitude.

## System Setup

Simulate a QPSK-modulated system subject to AWGN. Transmit packets composed of 200 training symbols and 1800 random data symbols. Configure a linear LMS equalizer to recover the packet data.

```
M = 4;
numTrainSymbols = 200;
numDataSymbols = 1800;
SNR = 20;
trainingSymbols = pskmod(randi([0 M-1],numTrainSymbols,1),M,pi/4);
numPkts = 10;
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',5,'ReferenceTap',3,'StepSize',0.01);
```

## Train the Equalizer at the Beginning of Each Packet With Reset

Use prepended training symbols when processing each packet. After processing each packet, reset the equalizer. This reset forces the equalizer to train the taps with no previous knowledge. Equalizer
error signal plots for the first, second, and last packet show higher symbol errors at the start of each packet.
jj = 1;
figure
for ii = 1:numPkts
$\mathrm{b}=$ randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M, pi/4);
packet = [trainingSymbols; dataSym];
rx = awgn(packet,SNR);
[~,err] = lineq(rx,trainingSymbols);
reset(lineq)
if (ii ==1 || ii == 2 ||ii == numPkts) subplot ( $3,1, \mathrm{j}$ ) plot(abs(err)) title(['Packet \# ',num2str(ii)]) xlabel('Symbols') ylabel('Error Magnitude') axis([0,length(packet), 0,1]) grid on; jj = jj+1;
end
end

## Train the Equalizer at the Beginning of Each Packet Without Reset

Process each packet using prepended training symbols. Do not reset the equalizer after each packet is processed. By not resetting after each packet, the equalizer retains tap weights from training prior packets. Equalizer error signal plots for the first, second, and last packet show that after the initial training on the first packet, subsequent packets have fewer symbol errors at the start of each packet.

```
release(lineq)
jj = 1;
figure
for ii = 1:numPkts
    b = randi([0 M-1],numDataSymbols,1);
    dataSym = pskmod(b,M,pi/4);
    packet = [trainingSymbols;dataSym];
    channel = 1;
    rx = awgn(packet*channel,SNR);
    [~,err] = lineq(rx,trainingSymbols);
    if (ii ==1 || ii == 2 ||ii == numPkts)
        subplot(3,1,jj)
        plot(abs(err))
        title(['Packet # ',num2str(ii)])
        xlabel('Symbols')
        ylabel('Error Magnitude')
        axis([0,length(packet),0,1])
        grid on;
        jj = jj+1;
    end
end
```

## Train the Equalizer Periodically

Systems with signals subject to time-varying channels require periodic equalizer training to maintain lock on the channel variations. Specify a system that has 200 symbols of training for every 1800 data symbols. Between training, the equalizer does not update tap weights. The equalizer processes 200 symbols per packet.

```
Rs = 1e6;
fd = 20;
spp = 200; % Symbols per packet
b = randi([0 M-1],numDataSymbols,1);
dataSym = pskmod(b,M,pi/4);
packet = [trainingSymbols; dataSym];
stream = repmat(packet,10,1);
tx = (0:length(stream)-1)'/Rs;
channel = exp(li*2*pi*fd*tx);
rx = awgn(stream.*channel,SNR);
```

Set the AdaptAfterTraining property to false to stop the equalizer tap weight updates after the training phase.

```
release(lineq)
lineq.AdaptAfterTraining = false
lineq =
    comm.LinearEqualizer with properties:
```

```
            Algorithm: 'LMS'
            NumTaps: 5
            StepSize: 0.0100
                Constellation: [1x4 double]
                        ReferenceTap: 3
            InputDelay: 0
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
        AdaptAfterTraining: false
InitialWeightsSource: 'Auto'
    WeightUpdatePeriod: 1
```

Equalize the impaired data. Plot the angular error from the channel, the equalizer error signal, and signal constellation. As the channel varies, the equalizer output does not remove the channel effects. The output constellation rotates out of sync, resulting in bit errors.

```
[y,err] = lineq(rx,trainingSymbols);
figure
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('Time (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(err))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel Without Retraining')
```

scatterplot(y)

Set the TrainingInputPort property to true to configure the equalizer to retrain the taps when signaled by the trainFlag input. The equalizer trains only when trainFlag is true. After every 2000 symbols, the equalizer retrains the taps and keeps lock on variations of the channel. Plot the angular error from the channel, equalizer error signal, and signal constellation. As the channel varies, the equalizer output removes the channel effects. The output constellation does not rotate out of sync and bit errors are reduced.

```
release(lineq)
lineq.TrainingFlagInputPort = true;
symbolCnt = 0;
numPackets = length(rx)/spp;
trainFlag = true;
trainingPeriod = 2000;
eVec = zeros(size(rx));
yVec = zeros(size(rx));
for p=1:numPackets
    [yVec((p-1)*spp+1:p*spp,1),eVec((p-1)*spp+1:p*spp,1)] = ...
        lineq(rx((p-1)*spp+1:p*spp,1),trainingSymbols,trainFlag);
    symbolCnt = symbolCnt + spp;
    if symbolCnt >= trainingPeriod
        trainFlag = true;
        symbolCnt = 0;
    else
        trainFlag = false;
    end
end
figure
```

```
subplot(2,1,1)
plot(tx, unwrap(angle(channel)))
xlabel('t (sec)')
ylabel('Channel Angle (rad)')
title('Angular Error Over Time')
subplot(2,1,2)
plot(abs(eVec))
xlabel('Symbols')
ylabel('Error Magnitude')
grid on
title('Time-Varying Channel With Retraining')
```

Time-Varying Channel With Retraining

scatterplot(yVec)

## Linearly Equalize Delayed Signal

Simulate a system with delay between the transmitted symbols and received samples. Typical systems have transmitter and receiver filters that result in a delay. This delay must be accounted for to synchronize the system. In this example, the system delay is introduced without transmit and receive filters. Linear equalization, using the least mean squares (LMS) algorithm, recovers QPSK symbols.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
mpChan = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
systemDelay = dsp.Delay(20);
snr = 24;
```

Generate QPSK-modulated symbols. Apply multipath channel filtering, a system delay, and AWGN to the transmitted symbols.

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4); % OQPSK
delayedSym = systemDelay(filter(mpChan,1,tx));
rx = awgn(delayedSym,snr,'measured');
```

Create equalizer and EVM System objects. The equalizer System object specifies a linear equalizer that uses the LMS algorithm.

```
lineq = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',5);
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
```

## Equalize Without Adjusting Input Delay

Equalize the received symbols.

```
[y1,err1,wts1] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Find the delay between the received symbols and the transmitted symbols by using the finddelay function.

```
rxDelay = finddelay(tx,rx)
rxDelay = 20
```

Display the equalizer information. The latency value indicates the delay introduced by the equalizer. Calculate the total delay as the sum of rxDelay and the equalizer latency.

```
eqInfo = info(lineq)
eqInfo = struct with fields:
    Latency: 4
totalDelay = rxDelay + eqInfo.Latency;
```

Until the equalizer output converges, the symbol error rate is high. Plot the error output, err1, to determine when the equalized output converges.

```
plot(abs(err1))
xlabel('Symbols')
ylabel('Error Magnitude')
title('Equalizer Error Signal')
```

Equalizer Error Signal

The plot shows excessive errors beyond the 1000 symbols training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 2000 symbols.

```
dataRecl = pskdemod(y1(2000+totalDelay:end),M,pi/4);
symErrWithDelay = symerr(data(2000:end-totalDelay),dataRec1)
symErrWithDelay = 5999
evmWithDelay = evm(y1)
evmWithDelay = 29.5795
```

The error rate and EVM are high because the receive delay was not accounted for in the equalizer System object.

## Adjust Input Delay in Equalizer

Equalize the received data by using the delay value to set the InputDelay property. Because InputDelay is a nontunable property, you must release the lineq System object to reconfigure the InputDelay property. Equalize the received symbols.

```
release(lineq)
lineq.InputDelay = rxDelay
lineq =
    comm.LinearEqualizer with properties:
```

```
            Algorithm: 'LMS'
            NumTaps: 9
            StepSize: 0.0100
                Constellation: [1x4 double]
                        ReferenceTap: 5
            InputDelay: 20
InputSamplesPerSymbol: 1
TrainingFlagInputPort: false
        AdaptAfterTraining: true
    InitialWeightsSource: 'Auto'
        WeightUpdatePeriod: 1
[y2,err2,wts2] = lineq(rx,tx(1:numTrainingSymbols,1));
```

Plot the tap weights and equalized error magnitude. A stem plot shows the equalizer tap weights before and after the system delay is removed. A 2-D line plot shows the slower equalizer convergence for the delayed signal as compared to the signal with the delay removed.

```
subplot(2,1,1)
stem([real(wts1), real(wts2)])
xlabel('Taps')
ylabel('Tap Weight Real')
legend('rxDelayed','rxDelayRemoved')
grid on
subplot(2,1,2)
stem([imag(wts1),imag(wts2)])
xlabel('Taps')
ylabel('Tap Weight Imaginary')
legend('rxDelayed','rxDelayRemoved')
grid on
```

figure
plot([abs(err1), abs(err2)])
xlabel('Symbols')
ylabel('Error Magnitude')
legend('rxDelayed','rxDelayRemoved')
grid on

Plot error output of the equalized signals, rxDelayed and rxDelayRemoved. For the signal that has the delay removed, the equalizer converges during the 1000 symbol training period. When demodulating symbols and computing symbol errors, to account for the unconverged output and the system delay between the equalizer output and transmitted symbols, skip the first 500 symbols.
Reconfiguring the equalizer to account for the system delay enables better equalization of the signal, and reduces symbol errors and the EVM.

```
eqInfo = info(lineq)
eqInfo = struct with fields:
    Latency: 4
totalDelay = rxDelay + eqInfo.Latency;
dataRec2 = pskdemod(y2(500+totalDelay:end),M,pi/4);
symErrDelayRemoved = symerr(data(500:end-totalDelay),dataRec2)
symErrDelayRemoved = 0
evmDelayRemoved = evm(y2(500+totalDelay:end))
evmDelayRemoved = 9.4435
```

## Linearly Equalize Symbols By Using EVM-Based Training

Recover QPSK symbols with a linear equalizer by using the constant modulus algorithm (CMA) and EVM-based taps training. When using blind equalizer algorithms, such as CMA, train the equalizer
taps by using the AdaptWeights property to start and stop training. Helper functions are used to generate plots and apply phase correction.

Initialize system variables.

```
rng(123456);
M = 4; % QPSK
numSymbols = 100;
numPackets = 5000;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -12],'MaximumDopplerShift',1e-5);
SNR = 50;
adaptWeights = true;
```

Create the equalizer and EVM System objects. The equalizer System object specifies a linear equalizer by using the CMA adaptive algorithm. Call the helper function to initialize figure plots.

```
lineq = comm.LinearEqualizer('Algorithm','CMA', ...
    'NumTaps',5,'ReferenceTap',3, ...
    'StepSize',0.03,'AdaptWeightsSource','Input port')
lineq =
    comm.LinearEqualizer with properties:
                                    Algorithm: 'CMA'
                                    NumTaps: 5
                            StepSize: 0.0300
                Constellation: [1x4 double]
                ReferenceTap: 3
    InputSamplesPerSymbol: 1
                AdaptWeightsSource: 'Input port'
            InitialWeightsSource: 'Auto'
                WeightUpdatePeriod: 1
info(lineq)
ans = struct with fields:
    Latency: 2
evm = comm.EVM('ReferenceSignalSource', ...
    'Estimated from reference constellation');
[errPlot,evmPlot,scatSym,adaptState] = initFigures(numPackets,lineq);
```

## Equalization Loop

To implement the equalization loop:
1 Generate PSK data packets.
2 Apply Rayleigh fading and AWGN to the transmission data.
3 Apply equalization to the received data and phase correction to the equalizer output.
4 Estimate the EVM and toggle the adaptWeights flag to true or false based on the EVM level.
5 Update the figure plots.

```
for p=1:numPackets
```

```
data = randi([0 M-1],numSymbols,1);
tx = pskmod(data,M,pi/4);
rx = awgn(raylChan(tx),SNR);
rxDelay = finddelay(rx,tx);
[y,err,wts] = lineq(rx,adaptWeights);
y = phaseCorrection(y);
evmEst = evm(y);
adaptWeights = (evmEst > 20);
updateFigures(errPlot,evmPlot,scatSym,adaptState, ...
    wts,y(end),evmEst, adaptWeights,p,numPackets)
```

end

rxDelay
rxDelay $=0$
The figure plots show that, as the EVM varies, the equalizer toggles in and out of decision-directed weight adaptation mode.

## Helper Functions

This helper function initializes figures that show a quad plot of simulation results.

```
function [errPlot,evmPlot,scatter,adaptState] = initFigures(numPkts,lineq)
yVec = nan(numPkts,1);
evmVec = nan(numPkts,1);
wVec = zeros(lineq.NumTaps,1);
```

```
adaptVec = nan(numPkts,1);
figure
subplot(2,2,1)
evmPlot = stem(wVec);
grid on; axis([1 lineq.NumTaps 0 1.8])
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2)
scatter = plot(yVec, '.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on
xlabel('In-phase'); ylabel('Quadrature'); title('Scatter Plot');
subplot(2,2,3)
adaptState = plot(adaptVec);
grid on; axis([0 numPkts -0.2 1.2])
ylabel('Training'); xlabel('Symbols'); title('Adapt Weights Signal')
subplot(2,2,4)
errPlot = plot(evmVec);
grid on; axis([1 numPkts 0 100])
xlabel('Symbols'); ylabel('EVM (%)'); title('EVM')
end
```

This helper function updates figures.

```
function updateFigures(errPlot,evmPlot,scatSym, ...
    adaptState,w,y,evmEst,adaptWts,p,numFrames)
persistent yVec evmVec adaptVec
if p == 1
    yVec = nan(numFrames,1);
    evmVec = nan(numFrames,1);
    adaptVec = nan(numFrames,1);
end
yVec(p) = y;
evmVec(p) = evmEst;
adaptVec(p) = adaptWts;
errPlot.YData = abs(evmVec);
evmPlot.YData = abs(w);
scatSym.XData = real(yVec);
scatSym.YData = imag(yVec);
adaptState.YData = adaptVec;
drawnow limitrate
end
```

This helper function applies phase correction.

```
function y = phaseCorrection(y)
a = angle(y((real(y) > 0) & (imag(y) > 0)));
a(a< 0.1) = a(a< 0.1) + pi/2;
theta = mean(a) - pi/4;
y = y * exp(-1i*theta);
end
```

## Linearly Equalize Packetized Signals in Fading Environments

Recover QPSK symbols in fading environments with a linear equalizer, using the least mean squares (LMS) algorithm. Use the reset object function to equalize independent packets. Use helper functions to generate plots. This example also shows symbol-based processing and frame-based processing.

## Setup

Initialize system variables, create an equalizer System object, and initialize the plot figures.

```
M = 4; % QPSK
numSym = 1000;
numTrainingSym = 100;
numPackets = 5;
numTaps = 9;
ttlNumSym = numSym + numTrainingSym;
raylChan = comm.RayleighChannel('PathDelays',[0 1], ...
    'AveragePathGains',[0 -9], ...
    'MaximumDopplerShift',0, ...
    'PathGains0utputPort',true);
SNR = 35;
rxVec = zeros(ttlNumSym,numPackets);
txVec = zeros(ttlNumSym,numPackets);
yVec = zeros(ttlNumSym,1);
eVec = zeros(ttlNumSym,1);
lineq1 = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',numTaps,'ReferenceTap',5, ...
    'StepSize',0.01,'TrainingFlagInputPort',true);
[errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq1, ...
    raylChan.AveragePathGains);
```

## Symbol-Based Processing

For symbol-based processing, provide one symbol at the input of the equalizer. Reset the equalizer state and channel after processing each packet.

```
for p = 1:numPackets
    trainingFlag = true;
    for q=1:ttlNumSym
        data = randi([0 M-1],1,1);
        tx = pskmod(data,M,pi/4);
        [xc,pg] = raylChan(tx);
        rx = awgn(xc,25);
        [y,err,wts] = lineql(rx,tx,trainingFlag);
```

Disable training after processing numTrainingSym training symbols.

```
    if q == numTrainingSym
    trainingFlag = false;
    end
    updateFigures(errPlot,wStem,hStem,scatPlot,err,wts,y,pg,q,ttlNumSym);
    txVec(q,p) = tx;
    rxVec(q,p) = rx;
```

    end
    After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default set of tap weights.

```
reset(raylChan)
reset(lineq1)
```

end

## Packet-Based Processing

For packet-based processing, provide one packet at the input of the equalizer. Each packet contains ttlNumSym symbols. Because the training duration is less than the packet length, you do not need to specify the start-training input.

```
yVecPkt = zeros(ttlNumSym,numPackets);
errVecPkt = zeros(ttlNumSym,numPackets);
wgtVecPkt = zeros(numTaps,numPackets);
lineq2 = comm.LinearEqualizer('Algorithm','LMS', ...
    'NumTaps',9,'ReferenceTap',6,'StepSize',0.01);
for p = 1:numPackets
    [yVecPkt(:,p),errVecPkt(:,p),wgtVecPkt(:,p)] = ...
        lineq2(rxVec(:,p),txVec(1:numTrainingSym,p));
    for q=1:ttlNumSym
        updateFigures(errPlot,wStem,hStem,scatPlot, ...
            errVecPkt(q,p),wgtVecPkt(:,p),yVecPkt(q,p),pg,q,ttlNumSym);
    end
```

After processing each packet, reset the channel System object to get a new realization of channel taps and the equalizer System object to restore the default set of tap weights.

```
    reset(raylChan)
    reset(lineq2)
end
```

## Helper Functions

The helper function initializes the figures.

```
function [errPlot,wStem,hStem,scatPlot] = initFigures(ttlNumSym,lineq,pg)
yVec = nan(ttlNumSym,1);
eVec = nan(ttlNumSym,1);
wVec = zeros(lineq.NumTaps,1);
figure;
subplot(2,2,1);
wStem = stem(wVec);
axis([1 lineq.NumTaps 0 1.8]); grid on
xlabel('Taps'); ylabel('|Weights|'); title('Tap Weight Magnitude')
subplot(2,2,2);
hStem = stem([0 abs(pg) 0]);
grid on;
xlabel('Taps'); ylabel('|Path Gain|'); title('Channel Path Gain Magnitude')
subplot(2,2,3);
errPlot = plot(eVec);
axis([1 ttlNumSym 0 1.2]); grid on
xlabel('Symbols'); ylabel('|Error Magnitude|'); title('Error Magnitude')
subplot(2,2,4);
scatPlot = plot(yVec,'.');
axis square; axis([-1.2 1.2 -1.2 1.2]); grid on;
```

```
xlabel('In-phase'); ylabel('Quadrature'); title(sprintf('Scatter Plot'));
end
```

This helper function updates the figures.

```
function updateFigures(errPlot,wStem,hStem,scatPlot, ...
    err,wts,y,pg,p,ttlNumSym)
persistent yVec eVec
if p == 1

## Nonadaptive Linear Equalization

Use the linear equalizer in nonadaptive mode. Use the mmseweights object function to calculate the minimum mean squared error (MMSE) solution and use the weights returned as the set of tap weights for the linear equalizer.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps,1,tx),25,'measured');
```

Create a linear equalizer System object configured to use CMA algorithm, set the AdaptWeights property to false, and the InitialWeightsSource property to Property. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm','CMA','AdaptWeights',false,'InitialWeightsSource','Propert)
eq =
    comm.LinearEqualizer with properties:
    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0100
        Constellation: [1x4 double]
```

```
    InputSamplesPerSymbol: 1
        AdaptWeightsSource: 'Property'
            AdaptWeights: false
    InitialWeightsSource: 'Property'
            InitialWeights: [5x1 double]
        WeightUpdatePeriod: 1
wgts = mmseweights(eq,chtaps,EbN0)
wgts = 5x1 complex
    0.0005 - 0.0068i
    0.0103 + 0.0117i
    0.9694 - 0.0019i
    -0.3987 + 0.2186i
    0.0389 - 0.1756i
eq.InitialWeights = wgts;
[y,err,weights] = eq(rx);
```

Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.
plot(abs(err))
grid on; xlabel('Symbols'); ylabel('|e|')

errevm = comm.EVM;
evm $=$ errevm(tx,y)
evm $=140.6177$
Plot equalizer tap weights.
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8 line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1) title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8 line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1) subplot (3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 - 0 line([eq. NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)

## More About

## Symbol Tap Spacing

You can configure the equalizer to operate as a symbol-spaced equalizer or as a fractional symbolspaced equalizer.

- To operate the equalizer at a symbol-spaced rate, specify the number of samples per symbol as 1 . Symbol-rate equalizers have taps spaced at the symbol duration. Symbol-rate equalizers are sensitive to timing phase.
- To operate the equalizer at a fractional symbol-spaced rate, specify the number of input samples per symbol as an integer greater than 1 and provide an input signal oversampled at that sampling rate. Fractional symbol-spaced equalizers have taps spaced at an integer fraction of the input symbol duration. Fractional symbol-spaced equalizers are not sensitive to timing phase.

## Algorithms

## Linear Equalizers

Linear equalizers can remove intersymbol interference (ISI) when the frequency response of a channel has no null. If a null exists in the frequency response of a channel, linear equalizers tend to enhance the noise. In this case, use decision feedback equalizers to avoid enhancing the noise.

A linear equalizer consists of a tapped delay line that stores samples from the input signal. Once per symbol period, the equalizer outputs a weighted sum of the values in the delay line and updates the weights to prepare for the next symbol period.

Linear equalizers can be symbol-spaced or fractional symbol-spaced.

- For a symbol-spaced equalizer, the number of samples per symbol, $K$, is 1 . The output sample rate equals the input sample rate.
- For a fractional symbol-spaced equalizer, the number of samples per symbol, $K$, is an integer greater than 1. Typically, $K$ is 4 for fractionally spaced equalizers. The output sample rate is $1 / T$ and the input sample rate is $K / T$, where $T$ is the symbol period. Tap-weight updating occurs at the output rate.

This schematic shows a linear equalizer with $L$ weights, a symbol period of $T$, and $K$ samples per symbol. If $K$ is 1 , the result is a symbol-spaced linear equalizer instead of a fractional symbol-spaced linear equalizer.

In each symbol period, the equalizer receives $K$ input samples at the tapped delay line. The equalizer then outputs a weighted sum of the values in the tapped delay line and updates the weights to prepare for the next symbol period.

For more information, see "Equalization".

## Least Mean Square (LMS) Algorithm

For the LMS algorithm, in the previous schematic, $w$ is a vector of all weights $w_{i}$, and $u$ is a vector of all inputs $u_{i}$. Based on the current set of weights, the LMS algorithm creates the new set of weights as

$$
w_{\text {new }}=w_{\text {current }}+(\text { StepSize }) u^{*} e
$$

The step size used by the adaptive algorithm is specified as a positive scalar. Increasing the step size reduces the equalizer convergence time but causes the equalized output signal to be less stable. To determine the maximum step size allowed when using the LMS adaptive algorithm, use the maxstep object function. The * operator denotes the complex conjugate and the error calculation $e=d-y$.

## Recursive Least Square (RLS) Algorithm

For the RLS algorithm, in the previous schematic, $w$ is the vector of all weights $w_{i}$, and $u$ is the vector of all inputs $u_{i}$. Based on the current set of inputs, $u$, and the inverse correlation matrix, $P$, the RLS algorithm first computes the Kalman gain vector, $K$, as

$$
K=\frac{P u}{(\text { ForgettingFactor })+u^{H} P u} .
$$
